Vol. XXXV. No. 1687.—*January* 2, 1891.

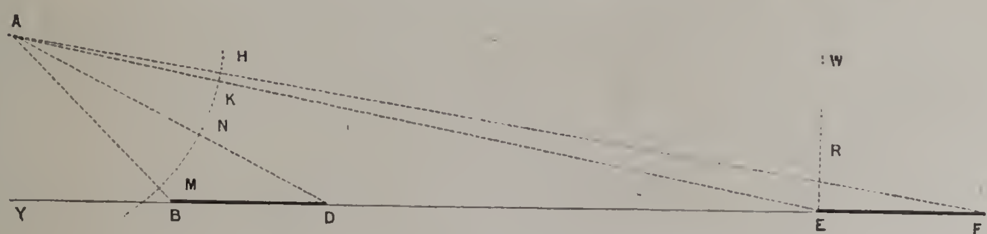
CONTENTS.

## SAFE DEVELOPMENT IN GOOD LIGHT.

In the Photographic News Year-Book just issued, we gave full details in relation to the principles governing developing room illumination, and how to make a lamp which will give a practically uniform light from one year's end to another, so that one element of uncertainty in developing is removed, and whatever may occur with the plates, the operator never has occasion to doubt the constancy of his light. Another and greater advantage of the plan is that, under a scientific system of developing room illumination, the photographer has the power of working in the maximum amount of coloured light which any particular brand of plates will bear, greatly to his comfort day by day, and to the benefit of his eyesight after the lapse of years.

Another step towards the abolition of empiricism in developing operations is to make proper use of the uniformly steady and trustworthy coloured glow when it is employed. Acquaintance with a few leading principles in this matter will enable a photographer to develop his plates safely in the same light in which another photographer using the same plates might get pronounced fog.

Fig. 1 helps to explain two principles, namely, the influence of the distance of the horizontal plate in the developing dish from the source of light, and the influence of keeping the plate as much as possible in a horizontal rather than a vertical position during developing operations. Let YF be a table six feet long, and A the source of light; with transparent coloured glass in the lantern, A is the flame itself; with a translucent coloured screen, it is a point on the surface of that screen, such screens becoming themselves, for argumentative purposes, virtually the source of



light. A photographic plate, BD, a foot square, is represented with its edge B at a distance of one foot from the point Y, which is directly below the luminous point A, and EF is another plate a foot square, with its edge E five feet from Y. The diagram shows that the latter plate has far less light acting upon it than has the first one; the plate EF receives only the cone of rays represented by the angle AKH, whilst BD receives the cone of rays included by the angle AMN. Rapid plates, which would fog, say, if developed in the position BD, might, perhaps, be developed with absolute safety at EF, at the end of the table. With the same source of light, it might be unwise to develop slow landscape plates in the dim illumination at EF, when they might bear the brighter illumination of the position BD. By far the best way to develop plates of different rapidities with safety is to suitably vary the distance of the developing dish from the source of light, and not to alter the light itself.

Whether the plate, in handling, be held much in a vertical or in a horizontal position, has an influence upon the amount of light it receives, consequently upon its tendency to get fogged. For instance, tilt the horizontal plate EF into the vertical position EW; the diagram, by the additional length RW, shows that it then receives about four times more light.

The powerful influence of developing at different distances from the lamp may be illustrated by fig. 2, a cut which we used for another purpose in the Year-Book, and which cut is reproduced from the standard work on "Chemistry," written by the late Professor W. Allen Miller. Let the candle in this cut represent the source of light, and 2 represent a sensitive plate one foot square, placed at two feet from the flame; now move the vertical plate to a distance of six feet, and it will be seen that it receives one-ninth the previous amount of light, so that the chance of fogging is greatly reduced by working with the plate at that distance.

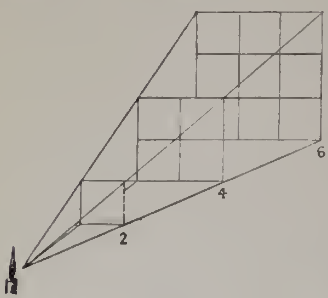


*Fig.* 2.

By careful attention to such principles as these, it is possible to develop plates without fog, by the aid of a naked candle, without any dark room lamp at all, a plan which, if our memory be not at fault, was first published by Captain Abney; at all events, we read it somewhere, and have on rare occasions employed the method in the bedrooms of mountain hotels, with the actual plates of the late Dr. Van Monckhoven, which were slow. The plan is to put a candle down on the floor in one corner of a large bedroom, and to hang a towel over a clothes-horse placed immediately in front of the light; then go to the farther corner of the bedroom, and with the back to the lighted corner, and the developing dish immediately in front of the body, take out the plate, and pour on the developing solution, preferably a yellow one or one which quickly turns yellow. This will bring out the image, and by care not to infringe various principles herein laid down, an unfogged image can be brought out, and then washed and fixed. In this instance the candle illuminates its own corner of the room and the ceiling close to that corner, whence some is reflected to the opposite corner, but not to the plate, because of the interposition of the body of the operator; next some of the residual light is reflected to the developing dish.

In telegraphy certain excellent instruments cannot be used, because their working needs intelligent knowledge of electricity on the part of the operator, who is thus made virtually a part of the apparatus; such a worker, however, can command more salary, hence it in some cases is more profitable to use an inferior machine, worked by a less educated man, such, perhaps, as a railway policeman, who is usually helpless directly the instrument gets out of order; he cannot put it right. So is it in developing. The brightest light can only be used constantly with safety when the intelligence of the operator virtually forms a part of the developing room lantern.

Another influence should be borne in mind in developing room work. The plate is much safer than before when covered by the developer, even when the developer itself is colourless, for the surface of liquid reflects a portion of the light which falls upon it, and that reflected light cannot reach the plate. Of every 100 rays of light falling at an angle of 50 degrees, water reflects 72, glass 54, marble 60, mercury and speculum metal 70. Dark coloured substances reflect little light. At a small or grazing angle, much light is reflected, so much so that even a sheet of white paper can be made to act as a mirror. If a sheet of white paper be held horizontally between the eye and a candle-flame, and almost at the level of the eye, the observer will see an image of the flame reflected by the paper.

When the total effect of all the influences mentioned is considered, it becomes evident what a vast gain in safety there is by developing at the position EF, fig. 1, instead of at the position BD.

That any plate should be developed at one particular distance from the lantern to get the best results with the maximum of light, is neither necessary nor desirable. The operator can have illumination enough to comfortably take a very sensitive plate out of the slide at a distance of six or ten feet from the lantern, to put it in the developing dish, and to cover it with the solution, after which, in accordance with the principles just enunciated, it will bear moving much nearer to a bright yellow light than would otherwise have been the case. As development goes on, it will bear bringing still nearer to a bright light, and towards the close —in those instances in which the plate has been underexposed—it is actually advantageous to open the coloured window of the lantern, and to allow the white light from the flame to shine upon the plate in the developer. This may produce a slight veil, but it will bring up some detail which otherwise would have been lost, as Mr. Cowan has recently proved by sensitometer experiments, and in practical photography it is scarcely possible to have a safer guide than Mr. Alexander Cowan, who is the manager of the works of Messrs. Marion and Co. at Southgate. It is well for a photographer to get into the regular habit of taking the plate out of the slide, and covering it with the developer at a good distance from the lantern.

As to the advantages set forth in the last Year-Book, of yellow over red light in the developing room, when orthochromatic plates are not employed, Mr. Debenham deserves the thanks of photographers for his letter in another column for the correction of an historical error as to the date and origin of the first publication of the explanation of the cardinal mistake about the proper colour of the light to use with gelatine plates, which had previously existed in all text-books. We were not aware of the existence of that paragraph when drawing attention to an article from another source, in which diagrammatic and tabular evidence was given of the truth of the principle enunciated. Since then, more accurate measurements than Fraunhöfer's of the relative luminous intensities of the different parts of the spectrum have become available; for instance, the following more modern table on the subject has been published in Amédée Guillemin's "Forces of Nature," translated from the French by Mrs. Norman Lockyer:

| Colours. | Luminous Intensities. | Lines |
|---|---|---|
| Extreme Red ... | ... Imperceptible ... | ... A |
| Red ... | 32 | ... B |
| Red ... | 94 | ... C |
| Orange | 640 | ... D |
| Yellow | 1,000 | ... |
| Green ... | 480 | ... E |
| Blue ... | 170 | ... F |
| Indigo... | 31 | ... G |
| Extreme Violet | 6 | ... H |

This table shows the relative luminosity of the spectrum where cut by the eight principal lines of Fraunhöfer. The maximum brightness is between D and E, nearer D, and distant from it about one-tenth of the total interval DE. Thus the eye, according to Guillemin, is more than ten times more sensitive to yellow than to red light, and this physiological peculiarity of the eye, which of course is not represented in spectrum photographs, has to be considered when selecting the best light for developing room operations with plates which are not orthochromatic.

This matter is a serious one for professional photographers, because of the injury to eyesight brought about by constant work in the red light of the developing room. Mr. William Ackland, an experienced oculist, stated at a meeting of the Photographic Society, held November 30th, 1883, that he had noticed that a larger proportion of photographers than other people had found it necessary to have the glasses of their spectacles changed for others of higher power; he attributed the circumstance to the general use of red light in the developing room. Mr. Valentine Blanchard attributed a weakening of his eyesight to the red light, and Mr. J. J. Briginshaw once stated that, by substituting yellow for red light, his eyes had found great relief, and that, by the former light, he could work a longer time in the developing room, with less inconvenience, than when he operated therein for a shorter time by red light.

## SUPPLEMENT TO THE PHOTOGRAPHIC NEWS.

To-day is issued, as a supplement to the Photographic News, a photogravure print from Mr. Lyonel Clark's photograph of Dedham Bridge, which won a medal at the last exhibition of the Photographic Society. Mr. Clark is an energetic member of the Camera Club, and the son of Mr. Latimer Clark, the well-known electrician, who has been connected with submarine and other telegraphy from the earliest times.

Lantern Plates.—Messrs. B. J. Edwards and Co. have sent us some specimen gelatino-chloride lantern plates, accompanied by a ready-prepared iron developing solution. We found them to give nice, warm brown tones, and to work in a clean manner, without veil. The magnesium light was used for printing by contact. Messrs. Edwards and Co. also enclosed some gelatino-bromide lantern plates; they were found to work well in the copying camera, also in contact printing. The quinol developer which the firm recommends gave clear, black images; the pyrogallol developer it recommends we found to give rather warmer tones.

## THE PHOTOGRAPHIC REPRODUCTION OF LITERARY MATTER.

Many tastily executed volumes owe their principal adornments either directly or indirectly to photography, which art is as useful a handmaid to book-writing as it is to many other branches of art. And a few books depend altogether upon photographic processes for their existence. As a case in point, we may mention the excellent reproduction of John Burnet's art essays, which was issued by an American publisher a short time ago. In this case it was, of course, imperative that the illustrations should be exact copies of the originals, or they would have been valueless; and it was, no doubt, cheaper to reproduce the printed matter in the same way than to set up the type anew. The ease with which type can be reproduced by photography was also instanced a year or two back, on the completion of the last edition of the *Encyclopædia Britannica*. Hardly had the last volume been issued before an American publisher, with that utter disregard for copyright which is a characteristic of the class, announced the whole work for sale at a greatly reduced price. The volumes had been copied page by page by means of the camera, and reproduced in block form by the zinc etching process.

But where photography is seen at its best in book work is in the reproduction of old black letter type, or in manuscript volumes. One of these latter now lies before us, and a very remarkable volume it is. The original is in various handwritings, for the book was contributed to by different persons who lived in the sixteenth, seventeenth, and eighteenth centuries. The work—which is entitled, "Arcana Fairfaxiana, or ye Apothecarie, his booke," in *fac simile*—is a literary curiosity of great interest, particularly to those who, like photographers, have anything to do with matters chemical.

The history of this reprint is curious. During alterations of some business premises in Pilgrim Street, Newcastle-on-Tyne, which had been in the occupation of a firm of chemists for more than a hundred years, a number of books was turned out from a lumber room, and among them was one that attracted the attention of Mr. George Weddell. With infinite care, this gentleman examined the volume and found it to consist of a number of domestic and medical recipes written in different handwritings. By the exercise of unusual sagacity, he succeeded in tracing the work to the Fairfax family, hence the title which he has conferred upon it. Several of the leaves were so discoloured that it was almost impossible to reproduce them by photography, so they were traced and transferred to stone; but, where possible, photography has been employed, so that we have before us the identical handwriting of those who, some of them, "went down into silence" three hundred years ago. The book is not only most interesting as containing specimens of the different styles of writing which prevailed at various periods, but is a delightful peep into the domestic economy and medical superstitions of a bygone age. In some cases the M.S. is not readily decipherable, not through any fault in reproduction, which is excellent throughout, but more on account of archaic abbreviations and old-fashioned modes of writing particular letters which are strange to the modern eye. But, taking the MS. as a whole, we may say that we frequently receive letters from worthy correspondents who do not write half so plainly as some of the persons who contributed to this volume. But, although the caligraphy leaves little to be desired, we should not recommend our correspondents to copy the method adopted in this volume for writing formulæ; for there is a little too much of the careless, go-as-you-please, rule-of-thumb business about them. For instance, a formula for development would not be of much use if written in the following vague manner:—

"To Make Puffe Paste.

"Take a quantety of fine flower, 4 whits of Eggs, a little rose water or other cold water; mold your paste together, and beat it with your rollin-pin, for ye stiffer yu make it, ye better."

Here, again, is a curious relic of the superstitious medical knowledge of a long past period, an attempt at diagnosis which was no doubt, at one time, commonly put into practice.

"How to Know ye K[ing's] Evill.

"Take a ground worme alive and lay him upon ye swelling or sore and cover him with a leafe. Yf it be ye disease, ye worme will change, and turn into earth. Yf it be not, he will remain whole and sound."

This comical idea that a worm would not only turn, but would actually turn into earth, probably had its origin in the observation of worm-casts on the grass, which, taking so closely the form of the creature which made them, might give rise to the suggestion of actual transformation. But earth worms were apparently a favourite remedy for different complaints, for in this book they form one of the component parts in various mixtures of extreme nastiness. For example, there is a remedy "for ache, stitch, or swelling," which begins thus:—

"Take half a peck of earth-worms and putt them into hay to skowre themselves."

The unfortunate worms, after sufficient scouring in the hay, are stamped small—and the effect of stamping small half a peck of earth-worms is a thing which the imagination does not care to dwell upon—and are then transferred to a quantity of wine, and the mixture is boiled until it is evaporated down to one half. The redeeming point in this precious concoction is that it is intended for external application only. But there aro nastier remedies in this book which our forefathers used to sip, if not with relish, with the firm conviction that good would accrue; and there is little doubt that in many cases their hopes would be realised, for faith in a remedy is half tho battle, as every doctor knows. We must congratulate Mr. Weddell iu giving us a literary treat which is of interest from so many points of view.

## NOTES ON PORTRAITURE.

BY H. P. ROBINSON.

No. 1.

Of all the applications to which many branches of art have been put, that of portraiture is the most ancient, the most universal, and always has been the most popular. Indeed, it may be justly said that for portraiture art was invented. The persistence of its types is wonderful. According to tradition it began with a silhouette, and the same simple art is being revived by American photographers.

What was the origin of portraiture? The time-worn tradition tells us that its simple rudiments were due to the Greek maiden who traced the outlines of the shadow of her lover on the wall, that she might be reminded of him when he had gone to the wars—a pretty myth that ought to be true. This is said to have happened about 800 B.C.; yet this must have been a late date in the history of art, for Aristotle ascribes the invention to Euchir, who flourished about 400 years earlier. Other authors give the honour to other names, but all agree that its first appearance was among the Greeks, and that the earlier portraits represented the bare shadow, which was produced by circumscribing the figure with a single line only, and was the art they called *Sciagraphia*. Afterwards shading was added to give the appearance of roundness, but, as a quaint old writer puts it, "The advantages it brought to its inventors were so inconsiderable that they still found it necessary to write under every individual piece the name of whatever it was designed to represent, lest otherwise the spectators should never be able of themselves to make the discovery."

The date I have mentioned as the time of the beginning of art, a little over three thousand years ago, seems a far-off time, yet art, and probably portraiture, was practised, it is calculated, quite two hundred thousand years earlier. We have direct evidence of the portraiture of pre-historic man in the outlines of extinct animals engraved on mammoth ivory, and discovered in the drift.

We will skip a few thousand years, and come down to comparatively modern times.

Portraiture has always been the chief purpose of art, at least numerically. In England scarcely any other form of pictorial art was practised until the last century, if we exclude the art of miniature painting, of which we have such splendid examples in Missals and similar books. The English school can boast of the two greatest portraitists that ever lived, Holbein in the reign of Henry VIII., and Van Dyck in the time of Charles I. During the seventeenth and eighteenth centuries the number of portrait painters must have been enormous, yet the names of very few of them have come down to us. We can scarcely go into an old country house without finding a collection of portraits, usually all very bad, and so much alike according to date that you would suppose they represented the ideal of the painter rather than the individual. The conventionality of pose was, it is said, once carried to such an extent that when, in the time of heavy perukes, it was the fashion to carry the hat under the arm, if a sitter insisted on being represented with his hat on his head, he was painted with *two* hats, one on his head, the other under the arm: the painter would not give up his favourite pose. I have, however, never met with one of these double-hatted portraits. These family portraits are generally nameless as regards the painter, and, indeed, often doubtful as to the name of the person. There must have been a great number of itinerant portraitists going about the country in those days.

I happen to know one or two of these old country mansions or halls. As is often the case in these days of agricultural depression, the occupiers are not the owners, and take their ancestors on lease with the house and furniture, which is, perhaps, better than buying them in Wardour Street. It affords more variety; you can get a fresh set of ancestors every time you change house. In the one I have now in my mind's eye the portraits are very good, beginning with the dark and sensual face of Charles II., who visited the place. There are many Lely's and Kneller's (what immense portrait manufactories these popular painters must have had), after which, as usual, they become anonymous. There is the usual handsome captain, time of Queen Anne, attitudinising before the spectator; the dean in gown and bands, without whom no gentleman's family could be complete; the county squire; and the co-heiress twins.

In another house the portraits are nearly all of the last century, as though the family began and ended in that period. This, however, is not the case, for there are still successors in existence. Can it be that the portraiture of the first half of the present century was too bad to encourage or to keep? There were a few good portraitists, as we all know, seventy or eighty years ago—the successors of Gainsborough and Reynolds; but from examples one sometimes meets with, the ordinary oil portrait must have been very bad. We are told that when things come to their worst they mend. It is a fact that middle-class portraiture of the time was sometimes so bad that ordinary people, who could not afford to employ the fashionable painters, Lawrence, Raeburn, Romney, Opie, or Shee, had, in despair, to have recourse to the humble silhouette. The popularity of this precursor of the photographic portrait for many years was marvellous. It was to be found in every home, both high and low, just as the photograph is now, but not, of course, to so great an extent. They began to be popular in the early years of the last century, and lasted up to the introduction of photography, and were never more popular than between 1830 and 1850. It is darkest before the dawn. I believe it would be now still easier to find a silhouetter than a Daguerreotypist.

It is a curious satire on fads, crazes, and fashions in art that even these black sticking-plaster portraits have been held up, if not as the highest art, as preferable to the work of the legitimate portrait painter, just as the "impression" of the present-time naturalistic is preached up by some latter-day enthusiasts as being superior to great art.

In 1780, a German follower of Lavater, as quoted by Mr. Tuer in the *English Illustrated Magazine*, wrote a volume in which he claimed the shadow portrait as a specimen of true art when compared with the "daub of the day" (the day of Reynolds, of Romney, and of Raeburn!) "This art," he says, "is older than any other. In Arcadia itself silhouettes were drawn. The shepherds of that golden age, in their happy simplicity, traced shadows of their beloved on the sand—to worship in absence. From silhouettes came cartoons, then monochrome, and, finally, painting. The most perfect in the order of things displaces the less perfect. But now, again, since this new culture of physiognomy, silhouettes are asked for, since these give a truer idea than the daubs of the ignorant. The taste of man has revolted against affectation and returned to the simple." Silhouettes gave rise to the invention of the profile machine, a rod working on a pivot or universal joint. The long arm was passed over the profile while the pencil in the short arm marked the likeness. Photographers are not, then, the first to take portraits by machinery, and the profile-machinists were patronized by Royalty—or said they were—like some photographers.

We are in the habit of considering and talking of the enormous number of photographic portraits produced each year, and photographers have a right to boast of their output, if not of their quality; but the portrait painters, also, must have been most productive, in some cases, indeed, beyond belief.

Michael Jansen Mirevelt, a contemporary of Rembrandt, is credited with having painted the largest number of portraits. Besides a number of altar-pieces, he is estimated by Descamps to have painted 10,000 portraits; this prodigious number is, however, limited by Houbraken to 5,000. Taking the lesser number, and giving him forty years' work, he must have averaged over two heads a day, which, as Euclid says, is absurd. As he seldom painted a portrait of a less size than 30 by 20, his hands must have been full. Lely and Kneller had wholesale businesses, but the great painters of the latter half of the last century—Reynolds and Gainsborough—numerous as their productions appear to us, could have counted their pictures by hundreds only.

I remember several itinerant painters who visited country towns before the advent of photography—or, rather, before it became available for portraiture. They usually began by taking a portrait of the beadle in his gorgeous livery; everybody knew the beadle, and this was a capital advertisement, which never failed to bring in sitters. Photography has altered all that. The itinerant has vanished, and English portrait painting has resumed its former glories. Who shall say that this revival is not due, in some measure, to the impetus given by our more humble art?

## SOME OF THE TENDENCIES IN PHOTOGRAPHIC ART.*

BY PHILIP H. NEWMAN.

Now it may be asked, why is it, then, that rough papers are used? Surely the photographers know something of this rule of scale, if amateurs do not! They, many of them, do know, but they are on the horns of a dilemma, and this is the real crux of the matter. Much as the old albumen silver print is despised, none of the new processes of printing quite supply its place in range of tones; the reason being that lack of transparency in platinum and bromide papers, and, necessarily, incident in all matt surfaces. Photographers, feeling this, have endeavoured to mitigate the evil by breaking up their printing surfaces, and letting light into them by using rough papers, and that regardless of the scale which I have pointed out. We are all charmed by a chalk or charcoal drawing, because of this transparency in the shadows given equally by diagonal lines as by roughness of surface, and it is, of course, wished to realise this charm in photography if possible. Since the introduction of the carbon process especially, photographers have been further stimulated by the reproduction of drawings, etchings, and engravings,

* Concluded from p. 1003, vol. xxxiv.

and they wish to obtain similar artistic results directly from nature. We must, however, be content to wait for this until a satisfactory process is invented, for it must be allowed, I think, we have not quite got it yet. Another reason for our anxiety shows a little human weakness. We are disgusted when we hear that paralysing phrase, "a mere photograph!" Let us admit at once that this is weakness. Should we not rather be proud of our mere photographs? Is not the exhibition, after all, but an exhibition of mere photographs? At least no exhibit can be the grander by affecting to imitate some other form of art; the art of making a photograph is none the higher for making it imitate a second-rate sepia drawing.

But there are other photographs at the exhibition which are calling loudly for our attention.—Van der Weyde's capital Japanese costume group, Mr. Sawyer's artistic effects on the Tyne, and the excellent works of Mr. Gale and Mr. Edgar Lee. Mr. F. H. Evans gives some excellent and well-chosen pictures from Canterbury Cathedral. No one who has not photographed in a cathedral knows quite what it means. The temper and patience necessary in keeping the authorities—from Dean to verger—in good humour during the long exposures in the dark interior, is a diplomatic exercise of no mean order. Vergers particularly have a rabid, if pious, horror of a tripod stand. Visitors to the cathedral also get in front of the camera, and, although they do not always spoil a long exposure, cause considerable nervous anxiety to the photographer. Mr. Evans told me how long he had to expose a rapid plate in the crypt of Gloucester. I will not hazard a recollection, however, in case I might exaggerate. It is pleasant to note that in photographing architectural objects, the custom of placing the camera directly in front, so as to get a symmetrical picture, is giving way to a more artistic insight, and, consequently, a more desirable result. In mentioning the very artistic results observable in landscape by Mr. Sawyer and others, it should be noticed that these are obtained apparently by perfectly legitimate means. A selection of time and subject, atmospheric effect occurs in its proper place and planes, the choice of the stops used has been judicious, and no sacrifice of sharpness—or, rather, clear definition—is made unnecessarily. That there should be perfectly successful work in landscape, with atmospheric effect, and aerial perspective in the receding planes, at the same time that an agreeable and reasonable amount of definition is given in the foreground, is in itself an emphatic protest against a school of photographers who endeavour to persuade us that an inartistic subject may be rendered acceptable by fuzziness, and by the artists deliberately stultifying themselves in the use of the lens—I mean in putting the subject entirely out of focus. It is, of course, a pity that such a false view of art should obtain at all in the face of the customs and traditions of past centuries, but that men whose tastes and abilities have been shown to be superior to many of their compeers should be induced to stoop to such trifling devices is almost incredible, and greatly to be deplored, in the interest of that art they might do so much to advance.

I revert now to the subject of lantern exhibits on the screen, a custom on Monday evenings at Pall Mall, and which will be more honoured in the breach than in the observance if some judicious, not to say ruthless, weeding-out does not take place, both in the interest of art and the patience of the visitors. Moreover, to say nothing of artistic proclivities, I look upon it as a downright absurdity to continually exhibit such monstrous pictures. It is bad enough in Pall Mall, but it is worse in some places, where one is made to look upon—say, a man and woman—a pair of lovers perhaps ten feet high on a donkey fourteen feet long. I cannot admit I enjoy this sort of thing, or find the sentiment of the subject magnified proportionately. I have never seen an artistic lantern slide yet that would bear enlarging beyond eight feet diameter, and would not have been better much less. Perhaps I feel this the more that I have a weakness for lantern slides. Some people think that it is inartistic; on the contrary, it is because there is a chance of their being artistic that I like them. At the exhibition in Pall Mall they show some very good ones (especially on the Field Club nights), but I have also seen some execrably bad ones, and it is for that reason I suggest judicious weeding. It, no doubt, interests some amateurs to photograph an ugly building from every conceivable point of view, and perhaps they may take a diabolical pleasure in presenting them successively on the screen, but no purpose is served by it in the interests of art, or of the spectators. Mr. Pecksniff had many diverse views in his office of Salisbury Cathedral, but then it was Salisbury Cathedral.

There are many figure compositions in the exhibition that call for notice. Some of these are medalled, I presume for some technical excellence that is beyond my ken, as, in an artistic sense, I fail to see their merits. They certainly often show a striving and effort to obtain an artistic result, but this very want of spontaneity is fatal to the success of this ambitious class of work. It would take too long to examine all these individually, and a mere catalogue would serve no useful purpose; doubtless, however, many of these photographs live in your recollection, especially those that obtained an award. Some works in the exhibition that are not medalled are very excellent indeed. Some of these—notably one silver print—can only have been passed over, I should say, because it was a silver print. If I remember rightly, it was a group of children on a cliff, treated with great delicacy and force, and called "Idle Hours," by Mr. Robert Slingsby. When I look back to the old collodion days, and remember under what difficulties excellent work was done in all parts of the world, it is a matter of surprise and great dissatisfaction to me that the present facilities of operation have not allowed a much greater advance artistically than I find. Now you know when a man has to paint a picture or design, a cartoon, or take a photograph by the collodion process, his spontaneity is necessarily handicapped by the continuity and difficulties of the absolute physical work to be done; and the long breath —*le longue haleine*, as the French say—may be exhausted before he comes to the close of his performance, and we may naturally pardon him something if the attempt surpassed the execution. But in photography—*i.e.*, modern photography—surely this is unpardonable, and one has seriously to reflect whether, after all, this is not our most important lesson—viz., the small advance in genuine art in modern times. Perhaps the fact that photographs being more numerous emphasises the case of pictures being so few.

I shall now bring my paper to a close by briefly summarising my observations, the more desirable because of their necessarily discussive character. Firstly, we have seen, I think, that the best negative may be done ill justice to by injudicious printing. Secondly, that obscurity and negation of sharp focus, or reasonable definition, does not necessarily imply fine art. Thirdly, that the grain of the paper used in printing should not be a matter of fad, but is seriously and actually a matter of absolute scale. Fourthly, that exaggeration and affectation is an affront to æstheticism and pure taste. Also let me add that, however a society may deem it expedient, and even honest, to medal works tendered to them for exhibition on the sole principle of encouraging worthy effort by such means, the amateur must use his own discretion, not being scared into blind worship of such work, but sift the matter for himself, and learn to discriminate between laudable effort and entire success. If the amateur does not do this, he will be unquestionably one of those who, following blind guides, fall by the way. Now one word to this Society in particular, who have honoured me by their kind and patient attention so far. I take it that most of you, by your very presence here to-night, if I may be allowed to say so, listening to my dry but really earnest talk, have an equally earnest desire to do some really good work, and will take not a little pains for the mere love of art to do something more than pour ounces of developer over glass plates, and mess your fingers *pour passer le temps* in the interest of the dry plate maker, or for the production of fog, as each of you has a desire to do something really worth looking at.

Of course in a Society like this there are many who have done so already, but I am not speaking to them, but to those, if there be any who have not been so fortunate, who are the real amateurs—I say to these: Don't fritter yourself away in formulas—the snare of all beginners; master one process, and, being assured that under most circumstances you can obtain a technically good negative, don't bother yourself about the chemicals any more, but devote yourself to your art, your greatest art, the art of photographing nothing, unless you see some reasonable chance of getting a pleasant composition, an interesting subject with agreeable and harmonious lines in it; something that shall not hereafter pall upon you, something that you can endure to live with, and that your friends shall say very nice to, and really mean it when they say it; then when you have done this you may conscientiously lay the flattering unction to your soul that you have been working on the right road, and are far nearer ultimate success than some of the exhibitors in Pall Mall who, "troubled about many things," are, it seems to me, giving far more attention just now to processes and chemicals—to say nothing of blurred focusses—than they are to art. Art is art. Your art, Amateur Photographers of West Kent, is the art of photography, which again is the art of expressing your feelings and sympathies, something of your own *ego*, something of your own souls, if you will, by photography, "mere photography;" never be ashamed of it. Let every tub stand on its own bottom. The photographic tub, if only true to itself, shall hold a dignified position; it can never be a reproach to a photograph that it is a mere photograph if an artist has selected the subject and photographed it earnestly, and with this axiom ever in his mind, viz., that though "art fulfils itself in many ways," the highest purposes of any art are not fulfilled in imitating, however well, the technical qualities of another.

---

It is requested that all books and papers which are intended for presentation to the Photographic Society, towards the foundation of its library, may be addressed to the Secretary, at the Society's Rooms, 50, Great Russell Street, London.

### MISS MARR AND HER DETECTIVE CAMERA.

Miss Marr is a young lady rather under than above twenty years of age, and of a most light and blithesome nature. Indeed, her vivacity and playfulness are her prominent characteristics. We may mention also in passing that she is an enthusiastic amateur photographer. Now this interesting young lady has for some time been receiving the earnest attentions of two young men of Carpentersville, Edwin R. Cole and Alonzo Doubleday. Each is an excellent young man, a member of the Young Men's Christian Association, and a teacher in the Sunday school. There was really little choice between them, and Miss Eunice has found it impossible to decide which one to select. Under ordinary circumstances she would, of course, have taken the one to whom her parents objected, but, unfortunately, these worthy people, for some unknown reason, did not look with any great favour on either. She did not, however, allow her anxiety in deciding to interfere with her buoyancy of spirits. In her extremity she hit upon this ingenious plan: she determined to insist on an elopement, arranging with each of them for the same night, and then go with the one who arrived first. She accordingly instructed Edwin R. Cole to put a ladder up to the north window of her room at two o'clock Tuesday morning, and told Alonzo Doubleday to do the same at the west widow at the same time. One must almost certainly come a little before the other, and the other could scarcely blame her for not waiting. Having thus settled the perplexing question, she went about for the next few days with even a lighter heart than usual.

Monday night, when Miss Marr retired she set the alarm on her clock for half-past one. Arising at that time, she was ready in fifteen minutes. Then she got out her detective camera and put it in readiness, her idea being to take a snap shot at the minister during the ceremony. This attended to, she sat down, and waited the arrival of the man who was to be her husband with her young heart in a pardonable flutter, something which was doubtless increased by the pleasing uncertainty as to whether it would be Edwin R. Cole or Alonzo Doubleday. At one minute before two she heard a slight noise outside the north window, as she thought. She listened, and it seemed at the west window. A horrible thought flashed upon her. She rushed to the north window; Edwin R. Cole was wrestling with a heavy ladder below. She rushed to the west window; Alonzo Doubleday had a ladder about half-way up. She stepped back and paused one moment. Simultaneously through the darkness she made out the upper end of a ladder rise at both the north and west windows. She saw that the time had come to act, and she did not hesitate. Going to the north window, she spoke to the ardent Cole, and told him to take his ladder around the corner to the west window. Quickly passing to the west window, she instructed the fervid Doubleday to carry his ladder around to the north window. Each impetuous young Romeo seized his ladder and started with it in an upright position. They met at the corner in the darkness. One ladder fell against the house with a loud report—the other crashed into a tree. Then these two young men fought. There, amid the wreck of the ladders, they clinched in almost a death struggle, and shouted and used language which startled and shocked the lonely night watchman on his beat, hardened and profane man though he was. In the thickest of it, while they were belabouring each other over the head with rungs torn from the ladders, there was a bright glare of light from above. The coy young girl that each had thought to make his bride had taken a flash-light photograph of them. The night watchman then came up, and, after clubbing them judiciously, arrested them. They were fined ten dollars apiece in the morning, and each used the money to pay it which he had intended for the minister.

Nor was this the end of it, sad as it is. It is now announced that Miss Eunice Marr will not marry either of these young men, but a pale youth who sings in the choir named Foster; while the Y.M.C.A. is taking steps to expel both Cole and Doubleday on the strength of the watchman's report of their language; and the playful Miss Eunice is printing off her flash picture at the rate of fifty a day, and selling them, the proceeds to go to the foreign mission society.—*The Photographic Globe.*

## Notes.

The amyl-acetate lamp is not alone useful for the purpose of testing photographic plates, and for employment as the unit of light in photographic research, but it can be made of value as the source of illumination in the developing room lantern. The only alteration necessary would be to slip off the removable spring clip which carries the standard screen with its small aperture, and to slip on another spring clip carrying an opaque tube with the bottom of which to cut off the light from the top of the flame, so as to minimise variations due to flickering. Light paraffin spirit, commonly called benzoline, will practically do well enough to burn it when it is used for developing room purposes. If the parts of lamp were to be made by special machinery, so that the retail cost should bear a moderate relation to the cost of the metal plus the labour, possibly it might have a world-wide sale among the general public for household purposes. The present little benzoline lamps sold in the shops in such large numbers at a few pence each, have a wretched arrangement for raising the wick, which arrangement soon gets out of order. We know of a case in which some individuals made diligent inquiry in lamp shops over an area of about two square miles in London, in the attempt to get better benzoline lamps with good double screws for raising the wicks, but were unsuccessful in the search; in fact, such lamps do not seem to be in the market. The general public, of course, would care nothing whether such lamps did or did not give a standard light of use in photometry, but any manufacturer who produced them might as well give the standard dimensions settled by the Paris Congress, as any other dimensions.

Some weeks ago we put the question why glass studios should not be jacketed, on the principle of the double-windows so extensively used in houses in Continental Europe, in order that the interior may keep comfortably warm with a small expenditure of fuel. One friend at once ridiculed the idea as "impracticable," but a week or two later came the letter from our St. Petersburgh correspondent, setting forth that in that city nearly all the glass photographic studios *are* jacketed; the outer glass "skin" is usually about eight inches everywhere from the inner skin. The arctic weather in London during the past three weeks may cause photographers to think a little about the merits of such studios, and also to think whether there would not be some wisdom in the introduction of the double-window system into all English houses. In Iceland the very cattle have double doors to their homes, as represented in one of the photographs taken by a member of the party of amateurs which recently visited that bleak and desolate country. The photographs were such as to send a cold chill through those observers whose tastes lead them to prefer the sunny south, the regions of the myrtle and the vine, of the palm tree and the orange blossom.

Another subject on which the professional photographer may well brood in this dark, inclement season is, why the smoky air of British towns should be allowed to come between him and the solar source of his more immediate means of subsistence, as distinguished from the term potential energy when employed in a scientific sense. The Londoner pays so much a ton for coal, then burns it in such ignorantly constructed grates that about three-quarters of the heat for which he has paid escapes up the chimney, accompanied by myriads of "blacks" to do injury to the poor photographer. The jerry-builders are answerable for much household waste and misery. With the intensely conservative nature of uneducated men who follow small mechanical trades, they imitate the methods of their fathers before them, and turn out pie-crust houses with bad drains, bad ventilation, ignorantly devised grates, ugly architecture, and so on, their only excuse being that the house is constructed to fall down at the end of the lease. The average Briton has to put up with these rotten homes, because he is practically divorced from the possession of any of the soil of his own country—except, perhaps, the six feet or thereabouts of which he may be the possessor in the end.

St. Peter at last has become a subject of joking in the photographic world, or rather in the *Photographic Globe* in italics, for in that journal appeareth the offence:—

*St. Peter*: "Who are you?" *New Arrival*: "An amateur photographer." *St. Peter*: "You will find the dark room down below."

Why St. Peter should be dragged into the photographic world is not clear, for there is no record that he had anything to do with photography; but those jokists who deal with him in comic papers are in danger, as evidenced by the following narrative from last week's *Pick-Me-Up*:—

Not a few stories, of more or less doubtful origin, have been told of St. Peter; but the following can be vouched for:—The janitor was enjoying a cool siesta, when he was aroused by the dismal strains of the "Dead March" rising from beneath. Thinking, however, it could hardly mean business coming his way—it very seldom does of late—he was again composing himself to sleep, when lo! the usual tap at the door. "What do you want?" asked Peter, peering through a chink, for he has to be very circumspect nowadays. "Who are you?" "I was the champion jokist of a leading comic paper. So sorry I had to come away just now; I had just excelled myself. The funniest thing I ever did. They are bringing it out in this week's ——." "Yes, I know," said the doorkeeper, gently, as the last melancholy note of the "Dead March" was wafted to his ear, "I hear them at it!" And as he drew the bolt of the trap-door on which the jokist stood, the latter slode gracefully down the pneumatic tube.

The photographer deals with not a few solutions and salts which deteriorate from exposure to air, and various are the dodges which he will adopt to prevent atmospheric oxygen from playing its accustomed pranks. There is now in the market a form of bottle which will be prized by many, for by a simple movement the stopper fitted to it makes the closure comparatively airtight. We trust that this form of stopper may be adapted to bottles of different sizes for the use of photographers and chemists generally, but at present it seems to be relegated to a far more lowly employment. It is as a receptacle for pickles, standing on a dinner table at a restaurant, that we saw it. The stopper consists of two discs, connected at their edges by a band of red rubber. When a lever on the top is depressed, the two discs are brought nearer together, and the india-rubber band is bulged out, thus pressing against the neck of the bottle. The oxygen of air exceedingly slowly passes through india-rubber, but more quickly than the nitrogen.

---

Photographers who are interested in geology, and who wish to find in a small compass ready to their hand different examples of rock formation, and geological phenomena, cannot do better than pay a visit to the Isle of Man. The journey is not a very tempting one at this time of year, for only one boat crosses daily from Liverpool, and it starts at such an hour that he who would be a passenger by it must leave Eustou by the newspaper train at 5.15 a.m. There is, too, an uncertainty about the duration of the voyage. Nominally it is five hours, but when a fog comes over the estuary of the Mersey that period can be drawn out indefinitely, as it was one day lately, when the voyage from coast to coast occupied twenty-eight hours.

---

But in the summertime things are different. Swift boats are employed, which cover the distance in less than four hours, and the journey is worth a little inconvenience, for the island is full of beauties. But what we particularly wish to call attention to are the wondrous rock formations which girt its coasts. In one spot in the south, covering a distance of only two or three hundred yards, we lately came upon several typical forms of rock, and one which we believe to be unique. Here, for instance, was a splendid example of a "fault." Close by was a trap-dyke jutting out like a wall from the stratified limestone on either side. Within a stone's-throw was a stack of black basalt, with the typical hexagonal plates crowning the mass, while masses of lava also pointed to violent volcanic disturbance in the long-forgotten past.

---

The unique appearance is found in a bay in which the rocks have been violently upheaved, so that their natural "bedding" stands vertically instead of horizontally, as they were originally deposited. To-day they stand up like so many fingers pointing to the sky, and in their midst is a clearly defined crater, the edges of which are formed of this same limestone, more or less crystallised and metamorphosed by the intense heat to which it has been subjected. A weird spot is this, which might inspire painter or poet if bent on depicting the infernal regions. One painter, at least, was so inspired by the rocks which girdle the Isle of Man; this was Martin, who studied here, and produced those three vast pictures, one of which is called "The Great Day of His Wrath."

In the present dull weather—for in London we have been something like thirty-six days without a gleam of sunshine—the illustrated papers, especially those which depend upon reproduction of pictures in foreign and American journals, would have been seriously inconvenienced but for the electric light. All photo-mechanical engravers in a large way of business find the electric light indispensable. How to get out the blocks with only the murky grey light of the past six weeks to work by would have been almost an impossible task. For this reason, if for no other, the reading public should be grateful to electricity.

---

It is a curious thing that the hairless-faced man is the one whom artists find most difficult to portray. The subtle play of the features which the beard and moustache conceal is here shown to an extent which drives the artist to exasperation, because of the rapid changes of expression. There are certain faces which are perfectly inert and expressionless when in repose, but, when animated, the countenance lights up, and quite another man is presented to the spectator. Mr. John Morley has one of these tantalising faces, and is not only the despair of cartoonists, but is considered by artists who have to draw him for illustrated papers as a most difficult subject. Most photographers are familiar with faces of this type; whether taken full face, three-quarter view, or profile, they are equally unsatisfactory, and the worst of it is, so far as the artist is concerned, when he draws from a photograph, that this is the kind of face upon which the retoucher exhausts himself, and, in so doing, succeeds in destroying all individuality.

---

The difference which the beard makes is well seen in the altered appearance of Mr. Herkomer, R.A. Mr. Herkomer's bearded face was not a difficult one to draw, but as he was seen at the *Graphic* dinner, with every vestige of hair removed, we should fancy that most artists would like to have time to study the new lines thus presented, before attempting his portrait.

---

Photography is continually adding to our knowledge of astral phenomena. Admiral Mouchez has recently had the pleasure of minutely examining the magnificent photograph of the annular nebula in Lyra, which has been made for him at the Observatory of Algiers, by Messrs. Trépied and Rabourdin. Hitherto observations of this nebula have appeared to indicate that the bright central nucleus and the brilliant nebulous ring surrounding it are distinct and separate. Admiral Mouchez has found, in examining the new photograph, that this is not so. The two bodies are not entirely separated, but the intervening space is faintly illuminated with nebulous matter. To the unscientific mind this discovery may not be of any importance, but in astronomical study it is impossible to say to what a new discovery may lead.

## IMPRESSIONISM IN PHOTOGRAPHY.*

BY GEORGE DAVISON.

I see no reason, then, why photography should not be used to express our impressions of natural scenes as well as any other black and white method. (I have, of course, all along intended that colour should be kept out of any comparison. The waut of colour places a method altogether upon an inferior level.) Worked under the same conditions as the eye, or under conditions as nearly approximate as possible, nothing gives so truthful a record in drawing as photography, and nothing, in my opinion, when the proper means are used and the requisite knowledge is possessed by the photographer, gives so delicately correct a relation of tones. It is to the proper use of the proper means at their disposal that photographers still need stimulating. The most important of these means are such as are directed to securing the proper light effect and relations of light values, and those which give the focussing and relative interests of the subject. In photography, the subject of focus has altogether overshadowed the more important matter of tone, for no one, except Captain Abney, has given this latter any scientific atteution. It is impossible now to go into the subject of means and methods, but it is worth while noting that some of the simplest facts of light are overlooked by photographers, who have been governed by untrue and misleadiug conventions and dogmas concerning gradation and brilliancy. For instauce, the necessity for points of the deepest black is insisted on, in order to give scope for as long as possible a series of steps up to points of white, regardless of the fact that this black is generally much too black for the purpose in hand. A little experiment would show how light out-door shadows should be as a rule. For iustance, the darkest shadow out of doors seen at a little distance is *lighter* than the shadow side of a *white* curtain *in* a room. Consequently, it is of first-rate importance in landscape pictures to keep the shadows light. To repeat the impression of out-door light the whole picture must be luminous, and not heavy and dark, as is the effect of the ordinary style of developiug, and the use of albumenised silver paper. Further, the shadows when the sun shines are lighter than when he is obscured. Or, again, there is the elementary observation that many objects seen against the blue sky come light on dark. The photographer has beeu so accustomed to obtaining a blank white sky on a blue day in his prints that he arrives at a conviction that this is correct. So much so, indeed, that it is related in the journals that the early photographers prided themselves upon their beautiful white skies, and would have no others.

In regard to focussing, again, there are, similarly, misleading conventions which prevent the free and general use of the full powers of photography. We still hear repeated the doctrine that miuute definition is the distinctive quality of photography, and that, therefore, this should be made the most of in artistic work. Even if it were, it would be sufficient answer to this that such definition is uot the distinctive characteristic of *seeing*. But definition is no more the distinguishing feature of photography than is exaggerated perspective, or, indeed, want of definition that is diffusion or softness. This depends upon the instruments used. We are told that in any broad treatment by focus we are imitating the natural characteristics of a certain school of painting. It might, with equal force or no force, be alleged that those in favour of minute definition are, in their sharpest tendencies, apeing the characteristics of the old miniature workers. Whether in painting or photography, it is purely a matter of the instrument used and the use made of it. In the one, either a fine point or a broad brush may be used. In the other, the optician's idea (a scientific aspect) of perfection in a lens is surely not expected to sway those bent on giving æsthetic pleasure. Everyone has seen that so-called mathematical accuracy is not necessarily artistic truth. Nothing but what observation or science can establish can be adopted as a principle by a naturalistic photographer. That the eye with one point of sight sees in different focus near and distant objects everyone admits; within what limits and with what differentiation is not so clear. If mere observation and feeling are of any weight, I should say that in some subjects the relative interests are given best with considerable differentiation, and in others the effect on the mind is best gained by general diffusion. I am aware that this is somewhat opposed to the very forcible argument in favour of one point of sight for focus as for perspective in any picture; but in many instances the difference of effect in the two treatments does not appear important, and is by no means easy to distinguish, even by expert observers.

A not unimportant consideration, bearing in some measure both upon the matter of values and definition, is the printing medium employed. I find, in the newest extra rough-surfaced papers, very excellent and distiuctive qualities, in respect, particularly, of breadth and luminousness. Some extraordinary objections have been taken to the results on these papers as not being photography because they bear resemblance to wash-drawings; and one gentleman finds in this, and the character of diffraction photographs, an opening of the door to any and every kind of brush-work upon the print. But the answer is, first, that there is no aim to get wash-drawing appearance; and secondly, all the process is pure photography. Both the photographer and the painter have the same aim, and it is not surprising if printing upou the same papers produce similar results, for photographic deposit more resembles painted surfaces than any other method. Both work in tones, or shades of monochrome, and both may be worked upon any medium which promises to give more truly and more effectively our impressions of nature. It is certainly very refreshing in its audacity to be told that, because photographers have consented to smirch the fair name of their art by the general use of albumenised paper and small stops, therefore this is to be its character for ever. In some respects the use of these rough papers, which are only now likely to become general for artistic work, constitute one of the greatest advances yet made. It need hardly be said that rough paper will not make a bad picture good or great, but it will do this: It will make all the difference to the majority of educated spectators between interested observation and contempt. It is difficult to overestimate the importance of the printing medium, as far as the credit of artistic photography with the critical public is concerned. There is almost as great a superiority for most subjects in the new platinotype paper over the ordinary platinum surfaces, as there is betweeu these latter aud silver printing. This quality of the printing has more effect upon the casual tasteful observer than any other quality of the production. The defective printing medium has obscured the qualities of photography. The effect of prints upon such papers as I allude to at once shakes the superstition of honest critics, who have hated photography for its hardness, vulgarity, and untruth. These extra rough surfaces I consider the best printing medium that has been introduced, not excepting reproduction of the negative upon a copper-plate or photo-etching. Unfortunately, the difficulties in the way of quick production must probably leave the field of commercial publication to the photo-etching process.

This leads me to say a word in comparison of photography with other black and white processes. It is admitted to have very justly been the death of line engraving. We have heard much about the interpretation of a painting by the engraver in black and white; but both painter and public who wish to see retained the original quality of the work must prefer a photogravure to the hard, formal, and unnatural character of the line engraving. Photography has pre-eminently more of painting qualities than any other monochrome process. Take etching, for example. Which is the better adapted for reproducing natural effect, photography or etching by line? Mr. P. G. Hamerton, in his standard work, "Etching and Etchers," compares etching with other arts, and finds the superiority of etching in its power to express form, and in its freedom, precision, and power. He admits that "perfect tonality is very difficult in etching," and that other arts are better in the representation of clouds. He recognises that the brush is better than the point, because lines do not exist in nature; but he contends that painting is not quite so well adapted to the expression of transient thoughts. How does etching com-

* Concluded from page 1010, vol. xxxiv.

pare with photography in these respects? I venture to think even less favourably than with monochrome painting. Photography is not specially limited to, nor compelled to emphasise, facts of form. It gives form by means of tone against tone, and that is the best means of rendering it, and its truth of form is unequalled. In regard to tone, it is equal to any other black and white process, not excepting mezzotint, to which, indeed, it is often superior in respect of delicacy of gradation. This, of course, only refers to photography used at its best. We are considering its powers, not the average of its productions. The crude, ignorant workmanship that is so common is no fair test of its capabilities. For instance, let it be admitted there are great difficulties in a large range of subjects in respect of rendering their relative light values, and the ordinary practitioner very rarely takes any trouble to overcome them.

Further, then, every observer knows the perfection of photography under suitable conditions of light as regards transient action and effects, and in nothing more than cloud forms is the delicacy of its tonal discrimination shown. But Mr. Hamerton would say that all this technical perfection—even if he admitted it—is useless, inasmuch as the camera is incapable of what he calls "idealisation of natural form, emphasis in lines, and concentration of natural light and shade." These very vague qualities are, to him, the artist's especial and peculiar work. As I have already treated this matter to some extent, I will here only refer to the etchings in Mr. Hamerton's book for an example in illustration of my argument.

Some of the finest etchings in the work are photographic in character—using photographic in the best sense of giving true tone, drawing, and simple naturalness, without any playing with facts—such, for instance, as that by Rembrandt ("Rembrandt drawing"), those by Lalanne, and in part that by Whistler. Referring to the Whistler etching of "Billingsgate," Mr. Hamerton notices, with just appreciation, the observant work in the buildings on the quay, and he refers to the harmony in the festoons of the converging cables of the boats as approaching poetical synthesis. I should prefer to call the rendering of these festooned cables a bit of most natural analysis. It is the result of close observation, with a marvellous power of expressing the leading facts exactly as we know them, and as Whistler saw them. The exquisite pleasure that this bit of the drawing gives is due to the natural way in which the impression of ropes forming long curves away from the eye and dipping in the stream is reproduced with a simple touch. In short, it is artistic truth—the truth that the artist wanted, unencumbered with local facts of which he would not be conscious save by scientific examination. This is true imitation, an exact hitting off of the leading fact, a power thought to be easy and mechanical, but one as rare in graphic as in literary art. Photography may never have yielded such subtle and exquisite analysis as this, and as the suggestion of heaving water, but photography has yet to get its Whistlers, and it works in a manner very different from etching. In the same etching it is strange that there should be such evidence of slovenliness and want of observation in the character and the form of the boats, which are egregiously unlike any vessel ever found at Billingsgate or elsewhere. Perhaps this would pass for exaltation of the natural images with Mr. Hamerton, but it would be painful to those educated by observation of the character of the objects.

Mr. Hamerton would have conferred lasting credit upon his insight had he, against the rigid prejudices of the time, been able to recognise the just claims of photography, and had he included for comparison in his book, "The Graphic Arts," an example of photography at its best. Others, at any rate, are now able to see its power for expression of artistic feeling, a power budding under naturalistic influences and a more severe scholarship in the *technique* of the art. If the power of expressing artistic impressions by photography is impossible, then must all the work of the naturalistic school of painters be excluded from the pale of graphic art, for theirs is confessedly "an honest attempt to paint what they see," and photography, artistically employed, has the same aim.

Concerning photographs bearing somewhat the naturalistic character, that is, with truth of tone and suppression of unnatural detail, it is no uncommon thing to hear it said, "Oh yes, they are artistic enough, but they are not photographs." Such is the domination of conventional views. I believe, indeed, that some of our friends are prepared to accept this view, and we have an ingenious suggestion that as there are painter-etchers so there should be painter-photographers, a name to be accepted, I presume, either on the *lucus a non lucendo* principle that all painting is rigidly excluded from their plates and prints, or to proclaim that they gladly admit the soft impeachment that their photographs are guilty of looking like sepia drawings.

Be that as it may, I will now only say in conclusion that it is such work that has been most instrumental in breaking down the wide-spread prejudice against photography as an essentially mechanical, harsh, and vulgar medium for anything like artistic expression, and that it is in that direction we shall have to look for its elevation to its proper place amongst foremost black and white processes. It is from no mere formula of fuzziness or definition that the best work derives, or can derive, its quality; but from the acquisition of artistic facts by observation and experience—facts of light, the limitations in black and white work, the relation of light surfaces, orthochromatics, relation of objects in respect of focus or mental interest, study of form, action, and typical character, the use and application of lenses, knowledge of the subtleties of development with the relation of exposure thereto, and the study of the qualities of printing processes. This is no question of months, but a matter of years before a man can hope to see clearly what it is he wishes to express, and move freely in expressing his impression. We need not be discouraged that unnatural "exaltations and combinations are impossible to us. The quality of naturalness will tell in the long run. Men will weary of emphasis, and graphic artists will leave past history, archæology, and fiction to literature or scientific drawing. The keenest æsthetic pleasure is to be derived from the spirited, truthful rendering of character, whether in face, figure, or landscape. The things of to-day will be of deeper interest to-morrow. As Emerson says "It is in vain that we look for genius to reiterate its miracles in the old arts; it is its instinct to find beauty and holiness in new and necessary facts, in the field and roadside, in the shop and mill." The scope of photography is extended. Nature will never go out of fashion. Prejudice will fade, and even one generation ahead will find the value of photographic portraiture, if it be natural and permanent, as it may be. The prospect is worthy of work, devotion, and sacrifice, and, in our enthusiasm, we may be forgiven for indulging visions of a time when, with Truth and Nature as its watchword still, photography shall have taken to itself such glorious attributes that, with fewer limiting conditions, our every impression of the visible world, light, colour, action, and form will come within its scope to express.

---

The Photographic Society.—The next meeting of this Society will be held on January 13th in the Society's new premises. A paper, which was unavoidably postponed from the December meeting, will be read by Mr. E. W. Maunder, F.R.A.S., on "Photography Applied to Astronomy," and Mr. W. England will give a flash-light demonstration. Mr. Cocking having resigned the position of assistant secretary, the Council have appointed Mr. H. A. Lawrance to the vacant position. Mr. Lawrance will take up the duties of the appointment on January 1st, 1891, and from that date members' subscriptions are to be paid to Mr. H. A. Lawrance, 50, Great Russell Street, London, the Society's new premises. These are opposite the British Museum, and will be open from January 1st, 1891, between the hours of 2 p.m. and 9.30 p.m. each week-day. After that date all meetings will take place in these premises, unless otherwise notified. The dark room will be prepared for use and the library put in order as soon as possible. No paper will be read at the anniversary meeting on February 10th, 1891, which will be devoted to the consideration of the report of the council, the election of a new council, and other general business. Members who wish to raise any question as to the management of the Society are requested to bring the matter forward at the anniversary meeting.

## THE PICTURES AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.—IV.

### CLASS V.—PORTRAITS ABOVE 10 BY 12 INCHES, IN SETS OF SIX DIRECT PRINTS.

IN this class are some of the most prominent pictures in the Exhibition; many are on 20 inch and larger plates. They comprise large groups, and single figures from full-length to life-size busts. Of the fifty-four exhibits, all are in platinum save six, and two of the latter are on plain paper platinum toned.

William Crooke's works are quite a feature of the Exhibition. They have fortunately been almost all grouped together, and, as they are quaintly framed in old-fashioned black moulding with antique gilt slip, and only a narrow white border with a thread line is seen outside the platinum print, they closely resemble in effect a number of old-fashioned engravings. These are most characteristic portraits of notables in the legal world, in wig and gown. In many cases Mr. Crooke has been most happy in securing a pose that specially individualises the subject. Besides these, Mr. Crooke exhibits a life-size bust of M. Paderewski, from a plate that must have measured at least twenty-six inches. Some might think this under-exposed, but it is bold and striking.

Marshall Wane shows good work. No. 460A is an effective twenty-inch bust, well lighted and posed, brilliant yet soft; No. 462 is a three-quarter length of a child in a rakish hat, rich in colour; No. 465, on a plate not less than twenty-four inches, is a soft and delicate bust; No. 604 is a three-quarter length of a lady, somewhat low in tone, but quite in keeping with the subject, natural and unconventional in treatment.

Messrs. Wane and Allan exhibit several full-length subjects noticeable for their rendering of flesh-tint; No. 401 is a pleasantly posed child, rich in colour; others by the same firm with similar qualities are somewhat formal in pose.

Alexander Ayton, jun., sends a number of finely-lighted figures. No. 398, representing two children coming down some steps, is specially bright, happy, and natural. No. 414 is a bust of an elderly gentleman, showing fine flesh texture.

Wm. Warneuke shows a remarkable set of character studies of large size, among which "Portia" is notable for its simplicity of pose, "Herman Vezin" particularly striking for its strength, and "Desdemona" for softness and delicacy. In all his work there is a fine harmony between the lighting, pose, and expression.

John Moffat, in No. 595, exhibits a good profile bust very tenderly treated; No. 621 is also a capital bust full of flesh-tone, and No. 451 is a beautiful boy natural in pose.

Wm. J. Kilpatrick has a very pleasing picture of a child in its night-dress going upstairs with a candle, entitled "Good Night."

R. R. Russell shows a natural and well-composed group of two young ladies at a piano.

R. Slingsby again exhibits some of his remarkable flash-light work, notable for breadth of illumination.

J. Martin shows a brilliant print of a young lady in white drapery. Other exhibitors in this class do not call for particular comment. X. Y. Z.

## THE AWARDS AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.

Annexed is note of Awards by the Jurors at the Edinburgh Photographic Exhibition, forwarded by Mr. J. Barclay, hon. secretary.

| CLASS. | SILVER MEDAL. | BRONZE MEDAL. | HONOURABLE MENTION. |
|---|---|---|---|
| 1.—Landscape ... ... | Richard Keene, Derby (681)... ... ... | C. Digby Jones, Edinburgh (529) .. ... | J. P. Gibson, Hexham (226, 230) |
| 2.— Do. ... ... | F. Boissonnas, Geneva (708) ... ...<br>H. P. Robinson, Tunbridge Wells (631) ... | J. P. Gibson, Hexham (179) ... ... | G. Bruce, Duns. (532) |
| 3.—Portraits ... ... ... | J. Moffat, Edinburgh (479) ... ... ... | Marshall Wane, Edinburgh (458) .. ...<br>Alexr. Ayton, jun., Edinburgh (386, 387) | |
| 4.— Do. ... ... ... | Window & Grove, London (241, 288) ... | J. G. Tunny & Co., Edinburgh (699, 713) | |
| 5.— Do. ... ... ... | William Crooke, Edinburgh (368, 379, 380) | Marshall Wane, Edinburgh (410, 440, 460A, 462, 465, 604) ... ... ...<br>Alexr. Ayton, jun., Edinburgh ... ... | |
| 6.—Figures ... ... ... | J. H. Hogg, Kendal (376) ... ... ... | R. S. Webster, Edinburgh (659) ... ...<br>Ralph W. Robinson, Redhill (789) ... | |
| 7.—Combination Printing ... | No Awards. (None considered of sufficient merit.) | | |
| 8.—Genre ... ... ... | Lyd. Sawyer, Newcastle (335) ... ... | J. Terras, Markinch (288) ... ... ... | A. Diston, Leven (909) |
| 9.—Instantaneous ... ... | Charles Reid, Wishaw (598) ... ... ... | Lyd. Sawyer, Newcastle (325) ... ... | |

| 13.— Do. ... ... ... | J. H. Forbes, Edinburgh (260) ... ... | J. K. Taylor, Buxton (1031) ... ... | J. E. Austin, Detling (579)<br>R. Kidston, Stirling (394) |
| 14.— Do. ... ... ... | J. G Patterson, Eskbank (185) ... ... | W. Mitchell, Dalkeith (165) ... ...<br>Major Redon, Glencarse (192) ... ... | |
| 15.—Prize Pictures ... ... | No Awards. (The Jurors unable to select one as distinctly outstanding.) | | |
| 16.—Lantern Slides ... ... | Geo. W. Wilson & Co., Aberdeen (1076) ... | James Dore, Sandown (1075) ... ... | |
| 17.—Reproductions ... ... | Autotype Co., London (899, &c.) ... ... | James Patrick, Edinburgh (804) ... ...<br>William Crooke, Edinburgh (390) ... ... | |
| 18.—Vitreous Enamels ... | H. P. Robinson, Tunbridge Wells (64) ... | J. G. Tunny & Co., Edinburgh (55) ... | |
| 19.—Photo-mechan. Prints... | Autotype Co., London (883) ... ... ...<br>Walter L. Colls, London (833) ... ...<br>James C. H. Balmain, Edinburgh (874) ...<br>W. J. Annan & Son, Glasgow (886) ... | | |
| 20.—Enlargements ... ... | F. H. Worsley-Benison (189) ... ... | T. G. Whaite (491) ... ... ... ... | |
| 21.—Apparatus ... ... | G Mason & Co., Glasgow (Studio Camera-stand) ... ... ... ... ...<br>W. Wray, London (Lenses) ... ... ...<br>J. M. Turnbull, Edinburgh (Hand-camera and Film Carriers) ... ... ... | Wm. Hume, Edinburgh ... ... ... | |

The Jurors have not been able to select any one picture of such prominent merit as to justify their recommending it for the Society's Gold Medal.

## ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

Commencing, then, with the first application of the telescope to the investigation of the heavenly bodies by Galileo in 1609, we find that the largest telescope he could make gave only a magnifying power of about 30.

The first improvement made in the telescope, as left by Galileo, was due to a suggestion—by some attributed to Kepler, but certainly used by Gascoigne—to replace the concave eye-lens that Galileo used by a convex one. Simple as this change looks, it makes an important, indeed vital improvement. The telescope could now be used, by placing a system of lines or a scale in the common focus of the two lenses, to measure the size of the image produced by the large lens; the axis or line of collimation could be found, and so the telescope could be used on graduated instruments to measure the angular distance of various objects; in fact, we have now, in every essential principle, the true astronomical telescope. It is useless as an ordinary telescope, as it inverts the objects looked at, while the Galilean retains them in their natural position. The addition, however, of another lens, or pair of lenses, re-inverts the image, and we then have the ordinary telescope. It was soon found that the single lens surrounds all bright objects with a fringe of colour, always of a width of about one-fiftieth of the diameter of the object-glass, as we must now call the large lens; and, as this width of fringe was the same whatever the focal length of the object-glass, the advantage of increasing this focal length, and so getting a larger image without increasing the size of the coloured fringe, became apparent, and the telescope therefore was made longer and longer, till a length of over one hundred feet was reached; in fact, they were made so long that they could not be used. A picture of one of these is shown, from which it can be easily imagined the difficulties of using it must have been very great, yet some most important measurements have been made with these long telescopes. Beyond the suggestions of Gregory and Cassegrain for improvements in the reflecting telescope, little was done with this instrument.

During the eighteenth century immense advances were made in both kinds of telescopes. With the invention of the achromatic telescope by Hall and Dollond, the long-focus telescopes disappeared.

Newton had turned to the reflecting telescopes, believing from his investigations that the dispersion and refraction were constant for all substances; this was found not to be so, and hence a means was possible to render the coloured fringe that surrounds bright objects when a single lens is used less prominent, by using two kinds of glass for the lens, one giving more refraction with somewhat similar dispersion, so that while the dispersion of one lens is almost corrected or neutralised by the other, there is still a refraction that enables the combination to be used as a lens giving an image almost free from colour.

In 1733, Hall had made telescopes having double object-glasses on this plan, but never published the fact. Dollond, who had worked independently at the subject, came to the conclusion that the thing could be done, and succeeded in doing it; the invention of the achromatic telescope is with justice, therefore, connected with his name.

* Continued from page 1013, vol. xxxiv.

Although this invention was a most important one, full advantage could not be taken of it, owing to the difficulty of getting discs of glass large enough to make into the compound object-glass, discs of about four inches being the largest diameter it was possible to obtain. With the reflecting telescope, unhampered as it always has been by any except mechanical difficulties, advance was possible, and astronomers turned to it as the only means of getting larger instruments. Many most excellent instruments were made on the Newtonian plan. The plan proposed by Gregory was largely used, as in this instrument objects are seen in their natural position, so that the telescope could be employed for ordinary purposes.

Many were also made on the plan proposed by Cassegrain. The diagrams on the wall enable you to at once see the essential points of these different forms of reflectors.

About 1776 Herschel commenced his astronomical work; beginning with reflecting telescopes of six or seven inches, he ultimately succeeded in making one of four feet aperture. With these instruments, as everyone knows, most brilliant discoveries were effected, and the first real survey of the heavens made.

Herschel's larger telescopes were mounted by swinging them in a surrounding framed scaffolding that could itself be rotated. The smaller ones were mostly mounted on the plan of the one now before us, which the Council of the Royal Astronomical Society have kindly allowed me to bring here. The plan nearly always used by Sir William Herschel was the Newtonian, though for the larger instruments he used the plan proposed years before by Le Maire, but better known as the Herschelian, when the observer looks directly at the large mirror, which is slightly tilted, so that his body does not hinder the light reaching the telescope. In all cases the substance used for the mirrors was what is called speculum metal.

*(To be continued.)*

## Patent Intelligence.

### Applications for Letters Patent.

20,438. R. W. Thomas, 70, Chancery Lane, London, "Flash-Light Apparatus for Photography."—December 15th.

20,452. A. Edington and A. Daniell, 3, Great King Street, Edinburgh, "Cameras."

20,501. S. H. Fry, Minerva Road, Kingston-on-Thames, "Holding and Exposing Sensitive Photographic Surfaces."—December 16th.

20,563. Sarah Tucker and W. J. Spurrier, Cotton Lane, Moseley, near Birmingham, "Magazine Hand Camera."—December 18th.

20,774. J. Pitt and W. Hudson, 118, Gooch Street, Birmingham, "Photographic Dark Slides."—December 20th.

### Specifications Published.

18,689. *November 21st*, 1889.—"Washing Photographic Prints." Birt Acres, 131, Richmond Road, Hackney, London.

My invention relates to the washing of photographic silver and other prints; the object of my invention is that the prints may be kept in an upright position in a tank or other suitable vessel of water, in such a manner that they could not stick together, double up, become crumpled, or in any other way damaged.

To secure this object I construct two light frames of wire or any other suitable material (if of metal, protected by a coating of water-proof enamel, paint, or varnish), a little larger than the size of the print intended to be washed, the top of one of the frames having a shoulder projecting at each end to allow of its being suspended in a tank or other suitable vessel; each of these frames is covered with a network of wire or other suitable material; the two frames are hinged together at the base so as to open aud shut in book form. Wheu closed a simple clasp or any other suitable fastening keeps the two frames closed in position; the netwcrks being adjusted to the frame in such a manner that they (the two networks) cannot touch each other, but leave a space of about one-eighth of an iuch between their eutire surfaees, in which space the print to be washed is kept in position, the coutacts of the two frames, when the apparatus is closed, preventing the print slippiug out of the apparatus,

151. *January 4th*, 1890.—"A Developing Dish Rocker." JOHN BOULTBEE BROOKS, Great Charles Street, Birmingham, Manufaeturer.

This specification describes the mechanical details of dish-rocking clockwork, actuated by a spring.

511. *January 11th*, 1890.—"Adaptiug Shutters to Lens Hoods." JOHN EDWARD THORNTON and EDGAR PICKARD, St. Mary's Street, Deansgate, Manchester, Manufacturers.

This invention provides improved means for adapting photographic shutters to lens mounts or hoods, so that shutters having openings of suitable standard sizes may be readily fitted to lenses of intermediate sizes.

In carryiug out our invention, we provide rubber bands or packing of suitable sectional form, as hereinafter described, for insertiou in the aperture iu the back of the photographic shutter.

Through the side of the shutter case we fit a screw so that the end thereof may press behind the rubber band. By turning the screw inwards or outwards respectively, the diameter of the aperture can be diminished or increased. By making the bands of various thicknesses—for instance, $\frac{1}{16}''$ $\frac{1}{8}''$ $\frac{3}{16}''$ $\frac{1}{4}''$—an ample range of sizes is obtained, whilst the screw permits of any intermediate adjustment.

The rubber band is formed with one edge rounded or bevelled, and the other with a projeeting rib thereon. When the band is inserted in the shutter aperture the bevelled or rounded edge of the rubber makes the aperture of "bell-mouth" shape, so that the lens-hood or mount may be easily pushed in, whilst the rib forms a stop which prevents it from going in too far. In order that the band may fit tightly within the aperture, we find it necessary that the thin or rounded edge shall be longer than the thick or ribbed edge, so that the thin edge may have a greater tendency to spring outwards when inserted iu the aperture. This we obtain by forming the band in circular or semi-circular flat strips, having the rib on the inner or shorter edge. Such a band, when made of moderately hard rubber, and sprung edgewise into the aperture, serves the purpose required.

By another method we dispense with the rib, aud simply use a plain flat band, in which case the requisite stop is formed by using a flat ring or washer of the required size, which is inserted in the aperture before the band. We do not confine ourselves to the use of rubber exclusively, as leather, paper, or any other suitable material may be used.

The advantages of the hereiubefore described method of adapting photographic shutters to lenses are that a smaller stock of shutters may be kept on hand, as the various sized lenses may be readily fitted to the standard apertures, instead of having to fit each shutter to a particular size of lens in the usual way; the user can also adjust the opening to fit his lens tightly.

15,789. *October 6th*, 1890.—"Photographic Stands or Holders." ARNOLD ROCHOLL, 68, Skalitzer Strasse, Berlin, Manufacturer.

This iuveution relates to photographic stands which contain a fixed number of photographs, and iu which said photographs are made to ehange their places one after the other by meaus of a slide.

Iu using this stand, the foremost photograph is pressed out, and glides down into a lower eompartment. Upou lowering the slide and lifting it again, another photograph (always the hindmost) is gripped and also transported to the upper compartment, causing the foremost photograph of said upper compartment to slide down into the lower compartment upon its predecessor. Thus the photographs are caused to perform a eircuit from the upper to the under compartment aud back, until the first photograph is to be seen again.

## Correspondence.

### YELLOW LIGHT IN DEVELOPING ROOMS.

SIR,—In the editorial article on page 44 of the YEAR-BOOK it is stated that the explauation—based upon the superior illuminating power of the yellow rays—of the popular error iu favour of red light for dark room work was first published in photographic journalism on Nov. 28th, 1884.

On that date will be found an article by Mr. W.H. Harrison, in which the argumeut is indeed used, but that this was by no means the first time that it was brough; forward is evidenced by the followiug extraets from articles of mine that had previously appeared in the same journal.

Jan. 25th, 1884: "Ruby glass will certainly cut off more of the chemical actiou of light than yellow glass; but then, it will cut off at the same time very much moie of the luminosity to the eye by means of which we perform the operations of the dark room. To make the comparison usefully, we should, either by repeated sereens of yellow, by lowering the souree of light, or by some means, at all events, reduce the inteusity and the quantity of the yellow light uutil it reaches the same amouut of brightness of illumination to the eye that we have with the ruby light, and then see which has the most ehemical effect upon the plate."

May 31st, 1884 (See article on "Coloured *v.* Non-actinic Light," iu reply to Mr. Lewis Wright): "Suppose it to be found that the lower down the spectrum, the less is the photographic action, it would follow as a matter of course that deep crimson, red, or magenta is the proper colour to use in the laboratory. As a fact, however, the red possesses much less illumiuating power than the yellow, yellow green, aud yellow orange, and the question should rather be, Which part of the spectrum possesses the least effect upon the photographic film in proportion to its illuminating power?"

As meutioned in one of those articles, I recognised the value of Mr. Harrison's support in the positiou to which I was led when seeking for a working light less injurious to the sight than the ruby theu insisted upou, but that geutleman would surely not be pleased to find the editor crediting him with what does not beloug to him. W. E. DEBENHAM.

### THE QUAGGA.

SIR,—In your issue of October 31st, received here to-day, you meution the photographiug of some quaggas at the Zoological Gardens in 1872. Iu April, May, and June of that year I was engaged to take a series of uegatives of the animals, reptiles, and birds then in the Gardens for Mr. Fred York; I believed then, as I do uow, that they were some of the finest negatives ever taken in the Gardeus. I ran mauy risks, and one especially with the rhinoceros. I was inside the paddock—to get rid of the railings—when he charged me; I managed to get clear away with my camera—a very heavy one—without a seratch. For this I was sketched in the *Police News*. I learnt a great deal eoncerniug this kiud of work while I was in the Zoo, aud Mr. York gave me great credit for my work. I left England in June, 1872, and have uot returned to it since; I am coming home next year. Mr. York promised me that he would credit me with any honour the pictures received at the Exhibition, but this I never got. I think this must have slipped his memory, as I know he could not, if he tried, be ungrateful; I may say I have a very high opinion of him. I have seen in this country many of my pictures shown on the screen, which seut me back to days gone by. Could I have stayed longer I was going to Palestine, but fate sent me here. I have uot corresponded with Mr. York for some years; I hope to see him in the flesh soon.

You are mistaken about the quagga. They run wild here yet down in the colony, and a few hours from here they are seen. Query: Is it a hybrid? Very often bucks of all kinds will run with a farmer's flocks and cattle for months together. They are slightly marked a very dull colour, not so distinct as Burchell's zebra. A colonial—or anyone else, for the matter of that—could never mistake them if they had once seen them. I shall recognise the animal in your YEAR-BOOK. I will give you the *modus operandi* next mail. I am writing against time, so excuse this disjointed letter.

If you see Mr. York, he will verify this letter. Messrs. Marion, my London agents, send me your journal every week.

I would like to hear from you your own and the public opinion of those pictures I took in the months of May and June of 1872. Mr. York promised this, but I never got it. It must be Mr. Harvey and the dodo, not Mr. York. B. HARVEY.

*The Kimberley Photographic Studio, December 1st*, 1890.

[Mr. Bartlett, the manager of the Zoological Gardens says that the colonials in South Africa commonly mistake Burchell's zebra for the quagga. He is not aware that a quagga has been seen for many years —ED.]

THE WORKS OF THE LATE O. G. REJLANDER.

SIR,—We have pleasure in informing you that we have acquired from the widow of this celebrated artist the whole collection of original negatives, numbering nearly 400, of the finest examples of photography.

It is our intention to shortly hold an exhibition of these works at our show rooms, and to publish them in the form of prints, enlargements, and lantern slides. The photographic public will thus have an opportunity of obtaining at popular prices high-class reproductions of the works of this photographer, who was, as you are aware, one of the finest exponents—if not the finest—of the art side of photography the world has yet seen. A. E. HAYMAN.

*The Fry Manufacturing Company, 5, Chandos Street, Charing Cross, W.C., December 24th*, 1890.

INTENSIFYING WEAK NEGATIVES.

SIR,—The process you describe of Dr. Liesegang for intensifying weak negatives by means of a varnish containing an evanescent aniline dye was suggested by me to Mr. W. J. Wilson about nine years ago, but there are objections to it as a practical process. I know of no aniline dye that will fade by the action of winter light with sufficient rapidity to be of any use; if there be one, then the objection you point out would quickly assert itself, viz., the bleaching over the whole negative, especially if it were left carelessly about face uppermost in the light. Films tinted with the dye and inserted between the negative and the printing paper would be a better way of carrying out this method. A useful plan for intensifying a finished negative (before varnishing) is one I used occasionally some eighteen or twenty years ago, viz., the powder process. This is an immense power in the hands of an intelligent and skilful operator, as by its use a negative can be either generally or locally intensified, according to the exposure of the bichromatized gum coating through the negative; an entirely new negative can be superimposed on the original, or merely the very highest lights strengthened to any amount. GEORGE C. WHITFIELD.

*Watford, December 29th*, 1890.

THE PHOTOGRAPHIC CLUB.—The subject for discussion on January 7th will be "Photomicrography"; January 14th, "Dark Room Illuminants."

IN the course of a discussion at the Photographic Society of Chicago about the best method of making good lantern slides, Mr. Douglass remarked, "It depends more upon the man than upon the process."

IT is said that as the workmen were beginning their daily duty on a fine house which Mr. Herkomer is having built at Bushey, there was a frieze to be carved, and Mr. Herkomer seized the implements and worked away with such a will that before sunset the frieze was finished. The men were bidden to copy it, and had hard work to do so.

# Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society, held on Tuesday evening, the 23rd of December, the chair was occupied by Mr. T. SEBASTIAN DAVIS.

A discussion on the use or omission of the eye-piece of the microscope when photographing microscopic objects for lantern slides was opened by the CHAIRMAN, who said that in his experience there was a certain amount of halation when the eye-piece was used. The eye-piece certainly gave a larger image, but that could be managed by putting the focussing screen farther from the objective. He wanted to know whether any of the members present had had any special experience of photographing microscopic objects with and without the eye-piece. He also mentioned that he had found it necessary to use a very fine ground glass for the focussing screen for this class of work, and he recommended that the transparency of the screen should be increased by rubbing with grease when photographing objects of very minute character. There was also the question as to which kind of plate should be used when photographing subjects that were both of a ruby character as to colour, and that possessed great opacity from the thickness of the body, such, for instance, as the common flea.

Mr. T. E. FRESHWATER had done a large amount of photographing of microscopic objects recently, and if he could possibly help it he never used the eye-piece. He found that there was a tendency to reversal of the image when the plate was at all over-exposed. Only when he could not get a sufficient degree of enlargement without it, did he use the eye-piece.

Mr. W. E. DEBENHAM enquired what were the circumstances which, in Mr. Freshwater's experience, necessitated the use of the eye-piece instead of simply removing the screen to a greater distance for obtaining the required degree of enlargement?

Mr. FRESHWATER said that only when the camera would not extend sufficiently to get the image large enough did he use the eye-piece.

Mr. A. MACKIE said that he had seen a statement by Mr. A. Pringle that nobody now took photo-micrographs without the eye-piece.

The CHAIRMAN hoped that further investigation would be given to the subject.

Mr. H. CHAPMAN JONES asked whether Mr. Freshwater, in condemning the use of eye-pieces, referred to those made expressly for photographic use, or to the ordinary microscopic eye-pieces.

Mr. FRESHWATER said that he was speaking of the eye-pieces made for photographic work. He would not attempt to work with an ordinary eye-piece. He used a 4-inch condenser, and then condensed the light again with a smaller one. The exposure was sometimes very short. Last evening he had photographed the palate of a water snail, merely opening the objective and closing it again.

The CHAIRMAN used paraffin as the illuminating agent, and of course gave comparatively very long exposures. When using the tube of the microscope, without the eye-piece being inserted, he found that there was apt to be a peculiar central flare, which arose from reflections from the inner surface of the tube. He found that a black velvet lining was best for reducing this reflection to a minimum.

Mr. MACKIE said that with a narrow tube even a velvet lining would not suffice to prevent reflection entirely.

Mr. FRESHWATER said that a tube was quite unnecessary when there was no eye-piece. He brought the objective and the front of the camera close together.

Mr. DEBENHAM asked whether any of the members had made comparative experiments as to the advantages of a microscopic objective and that of a photographic lens of an aplanatic character, such as the Petzval portrait lens, for photographing objects up to a certain degree of enlargement.

The CHAIRMAN said that for enlargement up to four diameters he preferred photographic lenses.

Mr. E. W. FOXLEE, as the result of his experience, preferred photographic lenses to microscopic objectives, for enlargement up to twelve diameters.

Mr. H. A. LAWRENCE referred to a formula for developing transparencies that had been quoted by Dr. Kiss, which, he thought, somewhat strange. There was citric acid as well as carbonates of magnesium and ammonia.

Mr. A. COWAN said that citrate of magnesium gave a very good colour, and it was more convenient to make it up by adding citric acid to carbonate of magnesia than to have to weigh out such a deliquescent substance, even if it were generally obtainable commercially.

### THE LANTERN SOCIETY.

*December 22nd.*—Lieut. C. E. GLADSTONE, R.N., read a paper on "Some Architectural Features of Normandy and Brittany." The slides shown were made by the lecturer from his own 12 by 10 negatives on stripping films taken during the past summer. The paper was principally intended to illustrate the characteristic marks of the ecclesiastical and domestic architecture of the country, and the differences between the contemporary styles in England and France were pointed out.

### THE ENFIELD CAMERA CLUB.

AT a meeting held on the 17th ult., Mr. PINKNEY (chairman) read a paper by Mr. H. V. CLEMENTS on "Development."

The writer expressed his opinion that it was important that all development should be carried on by artificial light of a standard illuminating power, by which means it is infinitely easier to judge the exact density acquired than it is possible to do by the ever varying daylight. He advised beginners to select a developing formula—either one recommended by the maker of the plates they purpose using, or one they know some friend is using, and from which they see he gets good results—and then stick to it until they have mastered it. Mr. Clements confines himself to two developers, viz., the pyro-ammonia, and the hydrokinone, prepared according to Mawson and Swan's formula; when developing, he starts off with a weak solution, and gradually increases it until it gets the desired result. He considers that if the plate is flooded with the normal developer at first, unless the plate is correctly exposed, the result must necessarily be faulty, and it is a very difficult task to make it presentable; if much over-exposed it cannot be saved. He would impress upon beginners the importance of having a safe ruby light, and of keeping the plate as much in shadow as possible to prevent fog, for which many developers are blamed, and to see that the plate is covered with the solution free from air-bells, which are easily removed with a camel-hair brush or the finger; he uses the latter, as he always knows where to find one in the dark. Mr. Clements contended that over-exposure is preferable to under-exposure, for when one knows how to use the chemicals, the former can be counteracted, but neither chemicals nor knowledge will compensate for the absence of light. Slow development, he said, is the right thing, for in a quickly developed plate the surface of the film is attacked too energetically at the commencement of the development, and the surface rendered hard and somewhat insoluble or non-porous, preventing to some extent the equable action of the developer at the back of the film, and causing the plate when in the fixing bath to lose much of its pluck and gradations though apparently fully developed. In conclusion, he wished to impress on all beginners the fact that cleanliness is absolutely essential in every branch of photography.

RECEIVED.—We have received from Kimberley the photographic portrait of a South African celebrity, whose white, short pipe stands out in the picture in brilliant contrast to his black face. It is inscribed: "With Umjala's compliments to the White Man who photographs across the sea." Remarking, in passing, that such a feat requires a lens of long focus, we thank the donor, and hope that the fire-water, which he is pictured as pouring from a bottle to a tumbler, was distilled and flavoured to his satisfaction.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

T. DALY (Tralee).—*Art Instruction.* Since writing to you last week, further enquiries have only served to confirm the recommendation then given. Find out the nearest centre of art classes held in your district, and if that should happen to be too far away to make it convenient to attend, write to the Art Master there asking his advice.

M. F.—*Printing by Development.* Messrs. Farmer and Tompkins's process of silver-gold printing ought to be useful during this dull weather, but the details given at the technical meeting were very meagre, and insufficient to enable you to put it to a practical trial. All that is known about it is printed in the NEWS of April 6th, 1888, page 217, and it does not appear that any patent was applied for.

F. J. THORNTON.—*An Old Relic.* The camera which you happened to pick up is evidently Thomas Skaife's patent "Pistolgraph," which was brought out in the year 1858; described and figured in the *Photographic Journal*, Vol V. p. 98, with further explanations in Vol. VI. p. 231, and Vol. VII. p. 189. It was one of the earliest forms of camera worked with an instantaneous shutter released by a trigger, and originally the whole apparatus bore some resemblance to a pistol, but this was soon discarded in favour of a square camera working flat plates, instead of the one-inch watch glasses with which Mr. Skaife started.

DARKNESS.—*Question of Copyright.* If the photogravure is an actual copy of your original portrait you could probably restrain the publication, and get damages, by applying to the High Court of Chancery, but the process might be costly. We should advise you to register at once, and then you could prevent any further piracy. Your case is so clearly stated, in its legal aspects, by Mr. C. Fleetwood Pritchard, barrister-at-law, in the YEAR-BOOK, p. 87, that we may confidently refer you to that article for specific guidance. You do not say whether your own photograph was ever published, or only taken in the way of ordinary business? The death of an eminent local official, or celebrity, often leads to an immediate demand for his portrait; this you should have anticipated by prompt registration.

J. M.—*Slow Printing.* The only consolation must be that we have passed the shortest day, but that will not help you in the execution of your order. Now is the time to stimulate your efforts in the direction of photo-mechanical printing.

R. E.—*Pigeon Post Photographs.* You might, by chance, still be able to obtain them of the London Stereoscopic and Photographic Company, who had them on sale twenty years ago. Failing in this quarter, you must seek out MM. Dagron et Cie, or the publisher, M. Lahure, 9, Rue Fleurus, Paris.

E. N.—*Warm Water Washing.* This practice has been repeatedly advocated of late, and Professor W. K. Burton has specially urged its general adoption. By squeegeeing the prints at each change of water the time of washing may be still further reduced.

C. S.—*Erratum.* In the third line, for "professed" read *preferred.*

WOBURN.—*Standard Portfolios.* Enquire of Messrs. Slade Bros., Great Portland Street; or Messrs. Marion and Co., Soho Square, W.

PRINTER.—*Photo-Engraving and Collotype.* Mr. Wilkinson's book can be had of Messrs. England Brothers, 12, Charles Street, Notting Hill, W. (price 5s.). Ernst Lietze's work is published in New York, and the price is unknown to us; try Messrs. Kegan Paul, Trübner, and Co.

R. PARR (Barnsley).—*Salcombe Views.* You might enquire of Messrs. John Hawke and Sons, 8, George Street, Plymouth, or any other local photographer.

CONTENTS.

## YELLOW *VERSUS* ORANGE LIGHT IN THE DEVELOPING ROOM.

As the use of red light in the developing room with plates which are not orthochromatic may now be considered to be a mistake on the part of those who wish, for the benefit of their eyesight, to work in as bright a light as possible, the relative merits of yellow and orange light remain to be considered. The following table by Amédée Guillemin, which we published last week, at once throws much light on the question:—

| Colours. | Luminous Intensities. | Lines. |
|---|---|---|
| Extreme Red ... | Imperceptible ... | A |
| Red ... | 32 | B |
| Red ... | 94 | C |
| Orange | 640 | D |
| Yellow | 1,000 | |
| Green ... | 480 | E |
| Blue ... | 170 | F |
| Indigo... | 31 | G |
| Extreme Violet | 6 | H |

This table shows the relative luminosity of the spectrum where cut by the eight principal lines of Fraunhöfer. The maximum brightness is between D and E, nearer D, and distant from it about one-tenth of the total interval DE. The yellow, it will be seen, appears to the eye to be not very far from double as bright as the orange of the same spectrum, therefore orange is a colour to be avoided in developing room operations; but it is a far better colour to use than red.

In farther illustration of this principle, we reprint the diagram from the YEAR-BOOK showing the luminous intensity to the eye of the different parts of a diffraction spectrum, and it will be seen that the brightest rays are the yellow, between D and E, fig. 1. Guillemin probably used a spectrum produced by a prism or prisms. Anyhow, the falling off in luminous intensity is so great in the orange as compared with the yellow, that the former ought not to be used. We prefer a full sunflower yellow, not deep enough to be mistaken for orange, and to use a translucent screen.

Still, under certain conditions, light lemon yellow can be used with safety. One reason why what is called "canary medium" answers well in some hands is that the fabric is thick, and, in addition, may be used in more than one layer, so that the good translucency of the material adds to such safety as is given by the colour. By avoiding the use of too strong a light, by developing at a suitable distance from the screen, and by attending to the conditions we published last week, there is no difficulty in employing the canary fabric with safety; indeed, many photographers have for years used it with satisfaction.

A fundamental error running through much of the literature of the past, is the recommendation to put an unexposed plate in a slide with the shutter half drawn, then hold it in front of the developing lamp window, expose thereto for five minutes, and afterwards pour on the developer to see if it gives fog on

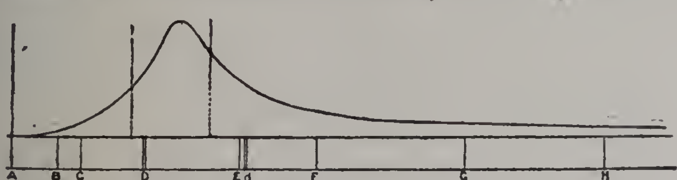

*Fig.* 1.

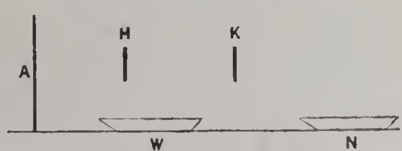

*Fig.* 2.

the exposed half. In actual work a plate is practically never so exposed, and should it thus give fog may yet do well for developing operations when the conditions are applied which we published last week.

For instance, let A, fig. 2, be the translucent front of the developing room lantern, and H a plate held vertically before it for five minutes, at a distance of nine inches, and suppose the plate to be then slightly fogged. Had it been held eighteen inches off, at K, probably it would not have been fogged, because the intensity of the light there is four times less. Again, it probably would not have been fogged had it been placed in the dish W, and covered with the developer, because the light falling on the horizontal plate would be less, and directly the developer was poured on, most of that light would not reach the plate at all, but be reflected from the surface of the liquid. A good way of working is to get the plate under the developer at the position N, and when the image is half out, bring the dish to the position W.

A light which slightly fogs the plate when the dish is close to the translucent screen is not necessarily objectionable, because the operator can then develop a little farther off, and has the satisfaction of knowing that he is using so nearly the strongest light possible, that working a few inches nearer to the coloured screen will give fog. The method of working of the old school leaves the operator in doubt whether some useful light, good for his eyes, has not been cut off by the screen.

Fogging of plates is commonly enough produced by the operator lifting the plate much too soon from the developing dish, and holding it close to the screen to try to see how the image looks by transmitted light. The full power of the light then acts directly upon unaltered bromide through the back of the plate. Care should be taken not to do this, and it is well that one of the windows of the lamp, not the one facing the developing dish, should be of two thicknesses of transparent, highly non-actinic glass, through which the naked flame can be seen; for it is easier to detect certain faults in sensitive films by looking through them at a flame rather than at an illuminated translucent screen.

## BACKGROUNDS AND ACCESSORIES.

The great attention which has, of late years, been paid to the artistic possibilities of photography has had the effect, among other good results, of revolutionising the furniture and general equipment of the photographic studio. What was considered correct in past days, and what well enough contented a not too critical public, can be seen by studying the pages of any old family portrait album, an exercise most beneficial to all workers in photography, chiefly, perhaps, as an object lesson in "what to avoid." A similar lesson can often be learnt by examining the contents of the show-cases of photographers in the unfashionable neighbourhoods of our large cities and towns, to which, like fashions in dress, the relics of past fashions in accessories and backgrounds have drifted. These are generally of the most preposterous nature, and it is as well that they are still extant, in order that they may serve as fearful warnings to the rising generation of photographers. The gorgeous columns and balustrades, the vases and fountains, may still be seen here, and are, no doubt, attractive enough to those who, if they do not dream of dwelling "in marble halls," like their friends to see their counterfeit presentments depicted amid the semblance of such surroundings. For the average 'Arry, when he wants his portrait taken, dons his Sunday best, and, "looking quite the gentleman," as he would express it, he must be "took" with genteel surroundings. These surroundings usually take the form of a table with a single *papier maché* curved leg, a Corinthian pillar cut in half, upon which he can carelessly lean, and over the edge of which he hangs a substantial hand, and a curtain which half hides a park-like landscape in the distance, which is separated from the model's boots by the aforesaid balustrade. But if we confine our enquiries to a higher rung of the social ladder, we still have ample evidence that early workers in photography paid very little attention to suitable surroundings to their portraits. In looking through any old album, we find that incongruities are the rule rather than the exception. Here, for instance, is the portrait of a buxom matron, her form enveloped in a rich silk dress studded with an enormous brooch containing a portrait, with a long chain, which has been picked out in gold paint by the artist so as to make it as aggressive as possible. She is as common-place in appearance as any mortal is possible to be, but she sits in a chair which, apparently, is a bad copy of a sixteenth century Italian model. Why such a chair in such company? one naturally asks. But this is not all, for by her side there is a kind of cabinet or pedestal—it is difficult to say which—with an ornamentally carved fluted panel, which is clearly English, and of a period which dates a century earlier than the chair. The pedestal, or whatever it is, has, at first glance, no kind of *raison d'etre*, until closer inspection shows us that it holds up the bulging fold of a curtain hung from nothing. ... ..

The idea in introducing these monstrosities into a picture was evidently born of ignorance, and the custom need not excite surprise when it is remembered how, in the early days of collodion, all sorts and conditions of men were attracted to photography as to a gold mine. So long as they could learn how to coat a plate with the viscid fluid and dip it into a bath, they were qualified, so they thought, to undertake portraiture. The public whom they had to deal with in those days was as ignorant as themselves, and between them art and photography were kept as far apart as the poles. So it became the custom to combine as many things as possible in the picture. It did not matter whether they were incongruous or not; it was looked upon as the right thing to do, and it was done. Besides, the demand quickly caused small factories to be established, where photographic accessories of fearful shapes were turned out by the gross, and were quickly sold to those who were reaping a golden harvest from their silver baths. The philosopher's stone had at last been discovered, and everyone was happy.

With the foundation of schools of art all over the country, and the appearance of many books which deal with the necessity of art education, a better state of things has arisen. Photographers now know better than to fill in their pictures with gimcrack imitations of gorgeous pieces of furniture, and aim at simple effects of light and shade rather than elaborate detail. Backgrounds and accessories are still used, and when rightly used are most effective, but they are of a far finer type than those of which we have been speaking. Many of our readers must have seen, at recent exhibitions of photographic apparatus, the beautifully modelled cabinets, old iron and stone work, and fireplaces which, compounded of canvas and plaster, and touched up in monochrome by an artistic hand, are so effective when photographed. There is nothing staringly offensive or aggressive about these things—no hard high lights or deep shadows—so that they retire, as it were, from competition with the living figure which is placed in front. So it is with the modern well-painted backgrounds which are now purchasable. The designs have nothing staring about them, and are rather suggestive of the presence of things than assertive of their existence. In this way a door, a window, or a mass of trees may give attraction to a picture which, without them, would be cold and bare. In backgrounds and accessories the art of portraiture has certainly progressed, and good workers now well understand that it is a part of their business which must not be neglected.

## OUR BROTHER THE CRAB.

### [A Photographic Revelation.]

BY JAMES MEW.

Years ago, when the lines dividing the wrong and the right use of a detective camera were somewhat blurred and indistinct, a suggestion was made touching the possible publication of a volume of incidents in court, political, and social life, compiled by the agency of this ingenious instrument for the delectation of the fashionable world. It was urged—and so far, indeed, with truth—that the most interesting records of contemporary events, such as those well known of Pepys and Hutchinson, of Clarendon and Bishop Burnet, of the Duc de Saint Simon and Philippe de Comines, which have appeared in letterpress only, would pale their lambent and comparatively ineffectual fires before the rising day-star of a book illustrated by photographic aid, with the exact attitudes and appearances of the important personages it describes.

If you will take at random a page of "Greville's Memoirs," the value of this suggestion may be rendered more clear. "I went," he says, April 8th, 1832, "the other night to see Sheridan Knowles' new play, *The Hunchback*. Very good, and a great success. Miss Fanny Kemble acted really well; for the first time, in my opinion, great acting. I have not seen anything since Mrs. Siddons (and perhaps Miss O'Neill) so good." How much of life could be put into this simple statement by a photographic accompaniment, showing to our eyes Miss O'Neill, Mrs. Siddons, and Fanny Kemble as they appeared to his, may be safely left to the estimate of any intelligent reader. The enterprising amateur photographer who will trouble himself to keep a diary, political or social, religious or scientific, and to illustrate it with judgment, and taste, and skill by the aid of his camera, will have no reason hereafter to regret, in this respect, a waste of labour, of money, or of time. A photographic Greville would, unless unequal fates opposed his way, be equally sure of fame and fortune.

But it is with a photographer of animal portraits that the present article is immediately concerned, and for him the time is now ripe. A knot has been tied worthy the intervention of such a god, and all appliances are his to boot. Stupendous chemical compounds await his beck and call.

There was an old woman, so runs a tale, of which, since we cannot all know all things, some of the readers of the Photographic News may be yet wholly unacquainted, who, on being asked her opinion of a new preacher, expressed her dissatisfaction with the clean shaven youth who had, with due dignity of deliberate movement, ascended for the first time the steps leading to the pulpit of her small village church, and expounded therein the way of salvation to the patient congregation below. Being asked for what reason she held the young man in little esteem, and why she preferred her late pastor to her present, she replied that the latter had never once, in the whole course of his sermon, mentioned that blessed word "Mesopotamia," which was so familiarly frequent in the sermons of his predecessor, and had on so many occasions given her spiritual consolation of no little strength in her hour of trouble. As this blessed word acted upon that old woman in the production of ghostly satisfaction and internal peace, so may some other words lately begotten of him who was the father of eikonogen compel reverence in the bird-witted folk who sit in the seat of the scorners to deliver judgments on photography all day long. Hardy, indeed, and fortified by a shield of triple brass, must be the soul of that person who would dare to speak lightly—or indeed, to speak at all, in public—of those new compounds by which a negative may be developed quickly or slowly, as the operator wills; of dioxynaphtalindisulphite, and its twin brother naphtohydrochinonmonosulphite. If the use of these agents is at all proportionate to the greatness of their names, our photographer of animal portraits may commence the business which will be suggested to him further on with supreme confidence in a successful result.

Mr. Ruskin and others seem to think—it is difficult to speak precisely in this matter—that a landscape, however fair, ceases to be so when photographed, unless figures of humanity are introduced. "Where humanity is not, and was not, the best natural beauty is more than vain." Such is the dictum of the great master. A critic gives as an instance of opposition to this sentence the celebrated Taj Mahal, at Agra. This instance hardly complies with Mr. Ruskin's conditions. Humanity certainly was where this building is; and the chief feature in the picture of the Taj would not be natural in the ordinary sense of that word, but artificial. Neither the instance of a mountain peak, nor of a rolling sea, comes necessarily under Mr. Ruskin's rule, for humanity may have been on the top of both. Probably the idea of the artistic philosopher is, when simply expressed, little more than this, that photographs of wild nature are idle without human figures. But to assert this is to assert a great deal. The position may in some measure claim Milton's support. More, we know from that poet, than the sight of vernal bloom or summer's rose, and more than any vision of flocks or herds, is the sight of the human face divine. To behold this in storm or sunshine, lurid with the scowl of envy, hatred, malice, and all uncharitableness, or brightly beaming with good humour, amiability, generosity, and love, is that after which the world of humanity mostly hankers.

Many of our noted novelists have given in words a vivid portrait of the darker passions of mankind. It remains for the photographer to give a precise pictorial facsimile of the effect of these evil passions on the face. Unfortunately, it is difficult to find a man, and still more difficult to find a woman, who would consent to have a likeness taken of features contorted by the rude action of these harpies of the mind. Fortunately, on the other hand, a substitute is to be found displaying a remarkable resemblance of the ugliness they produce. Dr. Emerson has introduced to us the crab.

He has also introduced the octopus. Both these beasts remind him much of his fellow-men. They are, he tells us, fit company, these terrible monsters—the octopus and the crab to wit—and it is their "human-like actions that make them so loathsome." Speaking of a crab which had, by a ruse of successful cunning and Machiavellian sagacity, obtained a portion of a bloater's head, he says that after beating a hasty retreat to the water's edge, he—the crab, not the doctor—"crouched down and began to tear and eat it in his repulsive and even human manner." Another crab, occupied with a shrimp, clutched it, we are told, with greed—the greed of the miser. A full-grown ghoul came and sat down on the ooze by Dr. Emerson's side, just like the big spider, to compare small things with great, by the side of Miss Muffet. But the doctor, far from being frightened away by his assessor, was "fascinated by his bestial actions, so human were they in movement and sentiment."

It is clear, then, that by the humble example of the crab we may hold up a mirror to human nature, and, without the necessity of wounding any feelings of delicacy or self-love in our sitters or squatters, may compose a gallery of faces animated by the various demons of passion, esthetically entertaining, if not morally useful. We have already seen that the attitude of the crab may express greed. The "cold, cruel, chinless, triangular face, with wide-parted eyes and hairy mandibles, without one ray of light to illumine the dreadful countenance," may also convey to an attentive observer the expression of "brutal lust." This power of reproducing human passion is probably an exclusive endowment of the crab. Dr. Emerson has, indeed, also mentioned cursorily the octopus; but, in his illustrations, the crustacean reigns supreme.

No other animal, from the tiger to the titmouse, participates in this remarkable gift with the crab. No horse—whatever may be said of an ass—has, in all probability, ever reminded Edward Muybridge of a human creature by any similarity in the expression of evil. Nor, in a case where we might well look for it, has Ottomar Anschütz, it is confidently believed, ever yet confided to the public his detection of any resemblance in facial wickedness in the monkey and in the man. Therefore, let the photographer of animals confine himself to the portraiture of the crab. He will learn to detect, with unerring constancy, that dreadful ugliness of likeness which, by its very likeness, is made more ugly—as it adds deformity, according to Bacon, to an ape to be so like a man—an ugliness which is not noticed by the casual observer. He will become an artist in the highest and best sense of that much-abused appellation. He will by degrees attain that subtle feeling of diversities of aspect—born in some few highly-favoured men, but in the vast majority the slow result of culture and refinement—which enables the operator to produce what are commonly known as portrait effects. Every crab must constitute for him an all-important study. He must cultivate the acquaintance of every genus, of every species, of every family, of every individual of the *brachyura*, or short tailed-division of decapod crustaceans.

The *Carcinus Mœnas*, or common shore crab, must be his familiar friend; but the *Cancer Pagurus*, or edible crab, which is probably—though the matter is darkened by much doubt—the crab of which the physiognomy is in Dr. Emerson's eyes so full of human interest, must be to our photographer, in no secondary sense, a brother. With him there must be nothing of that restraint which usually exists between strangers in the first dawning of social intercourse; nor must too great familiarity, on the other hand, breed in either contempt. To say that the photographer must be extremely careful about the pose of his client; that, if aught is wrong, he must take means to secure another sitting; that it is his duty to see the sitter's good and bad points, to make the most of the latter, and, by adroit retouchings, to smooth away the former, are pieces of advice so trite that it almost demands an apology to repeat them.

After some time, and by means of much patient study, our photographer may open a museum of portraits representing, in their most repulsive forms, the seven cardinal sins. The passions of lust and avarice, as they are reflected in these hard-shelled mirrors, have been already shown to us in words by Dr. Emerson in the case, probably, of the *Cancer Pagurus*. In other invertebrates of the same genus other human failings may be found. Pride may appear in a carefully executed cabinet of the *Stenorhynchus tenuirostris;* envy in a carte of the devil-crab or *Portunus puber*. The hermit crab might furnish an interesting picture of sloth; the *Cardisoma Carnifex*, who in the West Indies enjoys his grave and gruesome banquet in a burial ground, of gluttony; and the *Porcellana platychelys*—who, moved by his passion, voluntarily resigns his limbs in instalments sooner than quit the field of combat—of anger.

Photographs of this kind, if exposed in the shop windows of our streets, would counterbalance, in some degree, the present disconcerting and vexatious preponderance of the good and the excellent, the brave, the bountiful, and the beauteous, which appears in the portraits of our boxers, bishops, and ballet-girls, and from the mixture of opposites the mind of the spectator might attain neutral tranquility. The equable state of soul arising from a contemplation of photographic pictures of moral extremes is as desirable as that state which was the object of the wise prayer of Agur, the son of Jakeh: "Give me neither poverty nor riches; feed me with food convenient for me."

---

London and Provincial Photographic Association.—New quarters, the Champion Hotel, Aldersgate Street. Thursday, January 15th, adjourned discussion on "Developers."

Photography in Newcastle.—The following advertisement appears in *The Newcastle Daily Chronicle* of January 5th last:—"Central Exchange Art Gallery, Newcastle-on-Tyne. Now on view for a short period only, the Loudon Camera Club collection of Mr. Lyddell Sawyer's principal photographic studies. Old Newcastle places aud faces, river scenes, marine subjects, instantaneous effects, genre studies, &c. Pronounced to be photographic *chef d'œuvres* by all the London press. Awarded thirty-two medals aud diplomas at all the promiuent exhibitions of the day."

Clubs, societies, and newspapers whose subscribers are iu arrears with their payments, might adopt the following American specimen of gentle reminder: "Lives of poor men oft remiud us, houest toil don't stand a chance; more we work we leave behind us bigger patches on our pants. On our pants, once new and glossy, now are marks of different hue; *all because subscribers linger, and won't pay up what is due.* Then let all be up and doing; send in your mite be it so small, or when the snows of winter strike us, we shall have uo pants at all."

## NOTES ON PORTRAITURE.

### No. II.

BY H. P. ROBINSON.

I hope I shall not get angry in this paper. There are certain things I feel strongly, and may perhaps state with too much force.

In photographic portraiture we are running in a groove, and little effort is made to get out of it. This is, after all, perhaps not to be wondered at when we consider the influence that fashion exercises in almost every detail of our lives. It is therefore of little use to abuse professional photographers for not striking out into a fresh path; they have to get a living, and must supply the demand of their customers. At present fashion demands that every face shall be made to look like polished marble, regardless of life, likeness, expression, texture, or Nature, "the same with intent to deceive." But such deception deceives nobody, for nobody now believes in photographic portraits as likenesses. Such attempt at deception is not far removed from painting the natural face and dyeing the hair, and it does not want an expert to detect the fraud at once. Deception of this kind, therefore, does not answer the end which it had in view; it deceives nobody but the vain victim who thinks that the marble gloss substitute for the bloom of youth is natural to her. Education in art has not advanced far enough to enable these silly people to see that the unnatural retouching of to-day destroys photographs as works of art, and renders them valueless as documentary facts. This excessive polishing is acting an untruth, and should be held in the same detestation as falsehood with the tongue. Even if it were successful, it is well to remember the wise aphorism that tells us that "those who conceal their age do not conceal their folly." Not that I would abolish retouching; for in judicious hands it is a valuable aid to a better representation of nature; but I would have no mercy on the retoucher until he had educated himself into a frame of mind that made him look aghast at his present productions. Of course I speak only of the ignorant retouchers, not more, perhaps, than nine out of every ten, for I know there are some who understand the anatomy of the face—how to respect it, what to do with it, how far to go, and when to let it alone.

Then, notwithstanding what I have said about photographers having to obey their patrons, I cannot but think that some effort after improvement, or if not improvement at least some alteration tending towards improvement, might be made in the styles of portraits. For instance, the ordinary cabinet vignette head is undoubtedly a good style of portrait, very easy to do, though not always well done; very effective; a very good means of eliminating difficulties that may arise from the possible awkwardness of the figure, and for shirking unmanageable composition. But we have had thirty years of it; we have produced them by the million, and they are beginning to be a trifle monotonous. Cannot we add a background? It is true we are very bad at backgrounds, but cannot we improve? We usually make our portraits upright: cannot we make them horizontal, for a change? We usually make our sitters, in a full length, appear to stand on their feet, or, more often and awkwardly, on their toes: cannot we make them stand on their heads? This latter suggestion is not, perhaps, "within the limits of civilization," but it partly suggests what I mean. In short, cannot we get up a revolution? Photographers ought, by this time, to be sufficiently exasperated with the monotony of their work to be ready for anything—even to the extreme extent of putting their portraits out of focus.

It is now time, perhaps, to be a little more serious. I recognise that my reader has every excuse here for asking the question, "What do you recommend? Suggest something, or for ever hold your peace." I cannot say that I can comply with the request. The something new must be evolved by the photographer himself.

He must try to be individual, and not rely on imitation. I know there is great difficulty; I know that the mass of humanity will not make pictures as well as portraits. As I write I receive a bundle of photographs from a photographer whose business is in a smoky town in the north of England. He thinks his lighting is in fault, or his manipulation. Well, they are. But I sorrowfully confess that very little could be done to improve his portraits of such sitters. It is as well to let them have their half-a-crown's worth and go away satisfied, which, perhaps, they would not do with anything more delicate or better, anything they were not accustomed to. There were some heads among them that would have made good pictures if properly managed, but not portraits. Even on these cheap cartes the retouching demon had left his scratches; the old coal miner had lost his wrinkles, and the hallilujah lass smirked under the added grace of puffiness.

I have urged the photographer to be individual and strike out lines for himself, yet there is something to be said for the other side—combination; or rather, they should be individual, and yet combine. They may have their own styles and sizes in their general work, and yet combine to push one kind of picture; to make a certain class of picture so fashionable—I am sorry to have to use the dreadful word—that it must be had regardless of trouble to the sitter, or expense.

Nothing ever increased the business of the photographer as the carte-de-visite mania. Men who were in the depths of despair suddenly found themselves in the height of prosperity. This continued for some years, until the existence of a good thing induced competition, brought down prices, and vulgarised the style. Perhaps nothing did so much to spoil the business as the attempt to give too much for the money; not so much the giving of a large number for the price charged, as the cramming of the largest possible figure into the small space. The original carte represented a full-length figure justly proportioned to the space; then half-lengths and head vignettes were introduced for the purpose of giving a more visible head, and the style got confused. It went on till the heads were made so large that, when put in an album, the end of the nose of a profile and the back of the head were hidden by the opening, and in full-lengths the head touched the top of the mount, and the feet the bottom, so that all proportion was lost, and the sitters looked like a race of giants. If anything as popular should ever be introduced to the fortunate photographer, it will certainly be something very simple. When it comes, it would be well to let well alone, and not improve it off the face of the earth.

I cannot help thinking that for general purposes something more sketchy than the ordinary heavy looking portrait would find favour with the public. For this the platinum processes seem to offer great advantages. A light-figured background may be so vignetted in a platinum print as to suggest clever sketching with a lead pencil, and yet be truly photographic. It only requires to mix a few platinum prints with the ordinary pink albumenized paper horrors to show how refined the former are, and how utterly vulgar the latter. Why is this pink paper so universally used for business purposes, and so seldom for exhibition? In the last Pall Mall Exhibition the hangers had, in mercy, to remove the pink prints as far as possible from the platinums. There was reason in the light greyish blue tint first applied to albumenised paper; it neutralised the tendency to a sickly yellow to which this paper was rather prone; but it succumbed to the law of decadence which seems to insist that all good things shall degenerate, either by adulteration, or a pandering to vulgar taste. And so the pearly beauty of the first tinted papers has degenerated down to pink and mauve, which colours are gradually becoming stronger, and are the ugliest in the spectrum—no, not in the spectrum (all colours are pure there), but that ever came out of an aniline dye manufactory.

## INTERIOR PHOTOGRAPHY.

BY LIEUTENANT C. E. GLADSTONE, R.N.

I trust that I may not be thought too egotistical in the remarks I propose to make to-night on the subject of interior photography, but it is difficult to know what to say on such a subject beyond giving the results of one's own experience, and if a good deal of practice qualifies one to speak on any subject, perhaps I may claim to be so qualified, as I have worked at most of the English cathedrals, spending several days at each, besides a good many foreign ones, and many churches and other interiors.

Whether interior photography is an agreeable pursuit or not is mainly a question, I imagine, firstly, of the temperament of the individual, and secondly, of whether he be acquainted with architecture.

Some photographers find their greatest happiness in introducing human figures into their pictures, but, for my own part, if there is one thing more than another I hate whilst photographing, it is my fellow man and brother. I greatly admire these workers for the trouble and pains they take in thinking out and arranging their compositions —one must admire good men struggling with adversity— but I have no desire to imitate them, and I cannot help thinking that their results might be more agreeable, and possibly more artistic, if they substituted for the human form some accomplished lay figures.

To one with these possibly abnormal ideas interior photography has a natural charm. I know that the human animal can cause me no inconvenience. He may walk where he will, plant himself in front of the camera, or do just what he pleases, and, given a good long exposure, the plate remains profoundly indifferent to his presence.

On the other hand, I do not suppose that one who was not interested in architectural matters would find much pleasure in making a practice of interior photography. The exposures are necessarily long in most cases, and if one has nothing to do in the meantime, the inclination is irresistible to cut the exposure short, with the almost certain result of spoiling the negative.

If, however, one is interested in architecture—interested in trying to solve the problems that meet one at every turn in an old building—then the time passes all too quickly, and there is no desire to reduce the exposure, the negative benefiting greatly thereby, for, as a general rule, it may be taken that it is a matter of difficulty to over-expose an interior, and in the rare cases where it does occur the error may usually be corrected in development, whereas with under-exposure, no subsequent operations can remedy the defect.

I say that the exposures are generally long, and perhaps I ought to preface my remarks by saying that they refer to work done with a 12 by 10 camera, and therefore with lenses of some focal length. With small cameras, and lenses of shorter focal length, the exposures become considerably shorter. A month or two ago there appeared in the photographic journals a paper by Mr. Debenham, wherein he showed that the definition of out-of-focus planes did not depend on the relation between the diameter of the stop and the focal length of the lens, *i.e.*, on the intensity ratio, but that it depended on the absolute diameter of the stop itself, and on that alone. From this it follows that if we have two lenses, one double the focal length of the other, and if we find that, in order to obtain the necessary amount of definition with the short focus lens we have to use a stop of a quarter of an inch in diameter, then we shall also have to use a stop of a quarter of an inch diameter with the long-focus lens in order to obtain the same amount of definition, the result being that the exposure with the long-focus lens will be four times that of the other. Another reason for long exposure is that it is nearly always necessary to use the rising front and swing back, the effect of the latter being to throw the top and bottom of the picture completely out of focus. Their use cannot be avoided, as otherwise the picture is spoilt by too much foreground, and their effect on the definition of the picture can only be neutralised by the use of a small stop. I very soon found out that the amount of rising front and swing back, as supplied by the maker, were quite insufficient for interior work. Fortunately, it was an easy matter to alter the fittings so as to largely increase the amount of each obtainable, and occasions not unfrequently arise when it is necessary to use this increased amount to its full extent.

It is necessary, when using the rising front with W. A. lenses, to make sure that the bottom corners of the picture are not cut off, and as it is a difficult matter in many cases to see whether these lower corners are cut off or not, owing to the darkness of the image on the ground glass, it is advisable to try beforehand and see how much the rising front can be raised with safety with different lenses. By pointing the camera to the sky, the ground glass is well illuminated, and on raising the front it can be seen in a moment when the corners begin to get dark; the position of the front should then be noted. Providence has fortunately arranged matters so that the more one tilts the camera, the more one can raise the front, so that in extreme cases it will be found, with the great majority of cameras, that the rising front can be used to its full extent without cutting off the corners.

As regards the actual exposures that are necessary for interior work, I do not propose to say anything; the variations in exposure being so enormous that it is simply useless attempting to lay down any rules on the subject. I have here two prints which happen to be the longest and shortest exposures I ever gave for interiors. The actual exposure for the long one was four hours, but reducing both exposures, for the purposes of comparison, to what would have been given if an intensity ratio of $f/9$ had been used, the exposures then become thirty minutes and ten seconds, *i.e.*, one plate received an exposure of 180 times the other.

I may mention one point in connection with long exposures that I have occasionally noticed, but which may possibly be more common than I imagine. It is that the images of bright windows are sometimes visible on the film before development, the image appearing as a grey patch on a white ground.

As a general rule, sunlight shining direct on the subject is bad, though occasionally excellent effects may be obtained this way. These effects, however, in my experience are not under the photographer's control, and the more usual result is that patches of abnormal density appear on the negative which produce on the print white patches devoid of detail. Of sunlight, provided it be not directly on the subject, one cannot have too much. It increases the amount of reflected light, and consequently reduces the blackness of the shadows, and tends to prevent those violent contrasts which are so common in interiors.

At one time I was troubled by occasional patches of fog on the negative, which always appeared in the vicinity of a window and close to the edge of the plate, and the cause of which was not discoverable for some time. I eventually traced it to the image of a bright window, half of which was included in the picture, and half of which was outside the picture, being reflected from the square edge of the woodwork of the camera surrounding the plate on to the plate itself. The square edge being bevelled off so as to prevent reflected light from it falling on to the place, effectually disposed of the difficulty.

With reference to the use of wide-angle lenses for interior work, two things, I take it, are certain; firstly, that they should be absolutely avoided for general work, and secondly, that they are absolutely necessary on occasion. Many amateurs have only two lenses, one of which may be regarded as a "general purposes" lens of moderately long focal length, the other being probably a wide angle of very pronounced type. If an amateur so equipped commence interior work, he will very speedily find that, in many cases, his long-focus lens will not take in enough, and, having only one other lens, he is compelled to use that, with the result that he gets most unpleasing and exaggerated perspective in his pictures. For this reason, a series of lenses of different focal lengths is invaluable, and enables one to avoid using the most W.A. ones, except on very special occasions. A series of lenses is also a necessity if any large amount of work is to be done. Everyone knows how the composition of any subject changes by simply moving the point of view a few yards, and in interior photography, owing to the confined positions, and the fact that the different planes of the subject are at such varying distances from the point of view, this fact becomes of the greatest importance. A foot or two either way will so alter the composition of a picture as practically to make it an entirely different one. It is, therefore, necessary to be able to select the exact spot where you wish to place your camera, and then to have a lens which will, from that spot, include just as much as you want to get in your picture. The widest angle lens I use is a nine-inch one, which gives an angle of sixty-seven degrees on a twelve-inch plate. This angle, though a very moderate one compared to that included by many wide-angle lenses in common use, undoubtedly gives, under certain circumstances, unpleasing perspective, and it is one that I only use on exceptional occasions. The angle that it includes is, I think, the extreme limit that should be employed, and a view that could not be taken, except by using a still wider angle lens, would give such violent perspective that it would be better not to take it at all.

There is a difference in the effect on the eye of the perspective when using a wide-angle lens, according to whether the picture is an oblong or an upright one. In the former case, especially in such cases as a nave or choir, where a row of arches is to be found on either side of the picture, the tendency of the lens to cause unpleasant perspective is greatly increased, whilst, in the latter case, the exaggeration, though produced by precisely the same lens, does not appear to be so noticeable to the eye. This would appear to be recognised by artists, as, from an inspection of etchings or engravings of interiors, it will be seen that care is always taken with an oblong picture to avoid anything approaching to exaggerated perspective, whilst with upright ones the angle of view included is frequently so great that it could only be obtained in photography by the use of an abnormally wide-angle lens.

I have brought here to show you a levelling tripod top, which I have found for interior work to be quite the most useful piece of apparatus in my possession. Everyone knows the trouble and loss of time caused by the necessity of accurately levelling the camera for interiors, and the shifts that have to be gone to in certain cases where it is difficult to find a firm footing for the tripod legs. With this top levelling becomes a matter of a few seconds, and the legs, having been once fixed in convenient resting places, need not be touched again. On smooth-tiled floors, and in confined situations where it is a matter of considerable difficulty to find any place at all for the tripod legs, this is a point of considerable importance. For getting the ground glass vertical and horizontal, I have found nothing to equal a circular spirit level. The method of ruling lines on the ground glass, and then getting the subject vertical by means of these, is one that does not commend itself to me. It is a method that can only be used with comfort when the subject is very well lit, and the lens is one of large aperture. With dark subjects, and with lenses working at $f/16$ or $f/20$ at their full aperture, the image on the ground glass becomes so dark as to make the method a most tedious one, and, on occasion, the subject is shrouded in such obscurity that it simply becomes a physical impossibility to see the lines on the glass at all; lastly, in all old buildings, the pillars, more frequently than not, are not vertical themselves, and are, consequently, most unsafe guides to go by.

I have also here a view meter which has the advantage of enabling you to see your picture with all the surrounding objects cut off, thereby enabling you to get a much better idea of the composition; and it also enables you, by altering the position of the draw-tube, to ascertain exactly what lens you will want to use to include any given view. The most practical advantage of this is that, whilst your camera is taking one view, you are able, at your leisure, to study the composition of the next one you intend to take, and select with the greatest care the exact spot from which to take it.

Development is a subject which I propose to treat like exposures, and say nothing about. It is just as necessary to vary the proportions of your developer for interiors as for anything else. This much I may say, though, that I suppose everyone has what he regards as his normal developer for ordinary out-door work, and which he varies as occasion requires. If, then, you take this normal developer, halve the pyro, and double the water, you will have what you may regard as a very fair normal developer for interiors; not a developer which will develop every interior you take equally well, but one which will require to be constantly varied to suit the subject, and which may, nevertheless, be looked upon as your normal developer. It is some years since I used plates for any kind of work, but to those who do use them I would say, never take an interior without backing the plate. There are many methods of backing, and it will be enough if I mention that, for my part, I prefer black varnish. This, when dry, is always hard and clean, and, before development, can be removed with the greatest ease with cotton-wool and turpentine. It is only necessary to clear away the central portion on the plate, leaving that round the edges to wait until after fixing.

One word more as to the time of year for interior work. Some time ago I did a good deal of work late in October, and, although the weather was exceptionally bright, I found, on development, that most of the films were under-exposed, more especially those taken early in the morning and late in the afternoon. The explanation is, I think, that the light, though bright enough to the eye, is nevertheless weak, the reflected light inside the the buildings is feeble, and, as a consequence, the shadows are always black, and the contrast between them and the high-lights much greater than in summer, when a flood of light is reflected from every part of the interior. Anyway, the practical result of my failures was that I decided that, when the sun set at six o'clock, it was time to stop taking interiors.—*Camera Club Journal.*

## A BURST PRESSURE GAUGE.

The other day an action was tried which is of great interest to all lanternists, for it arose out of the bursting of a pressure gauge whilst *in situ* on an oxygen gas cylinder. The accident unfortunately resulted in the operator losing the sight of one eye, and the sight of the other has since been endangered through what doctors term "sympathetic action." The bursting was not due to any explosive mixture of gases, but simply and solely to the pressure exerted upon the inner tube of the gauge by the compressed gas. The gauge had been tested three or four times previously to being sent out, and the defendants, Brin's Oxygen Company, pleaded that this was the case. They further pleaded that they were not the makers of the gauge, but that it was an article generally sold as a pressure gauge, and also that the contract between them and the plaintiff was for the supply of a guage in general, and not for a gauge for a specific purpose. In the end the plaintiff gained the action, and, by previous arrangement, received from the defendants £325 damages.

There is always, unfortunately, a suspicion, when any vessel constructed to bear a great pressure is said to have been tested to an extent far beyond that which it will normally be called upon to bear, that the test itself may possibly have weakened its walls, and caused a strain which may at some future time bring about disaster. This may have been the case in the present instance, or the accident may, perhaps, be accounted for by some flaw in the metal tube which forms the main part of a pressure gauge. But it is difficult to trace the exact cause of the disaster, and we can only surmise that it may have been due to one of the circumstances suggested. We can, however, offer a hint to the makers or owners of these gauges, whereby danger from a ruptured tube would be obviated.

It is assumed that we are writing of the common pressure gauge made with a strong brass casing, and containing a *Berdun* tube. Should this tube burst, the brass case immediately becomes filled with gas, and the glass front, being the weakest part of the structure, is forced out, and its fragments deal destruction around, as in the unfortunate case already cited. We have before heard of a glass being smashed in this way, but luckily with no evil results to the manipulator, and whatever be the actual cause, it is evidently an accident that may happen to any one using a gauge of this description. We suggest, as a preventive of injury from such an occurrence, that each gauge should be provided with a safety valve. This might take the form of an opening in the metal case, or the said case might be made of brass perforated in an ornamental style. The gas would then, in case of accident, find a ready means of escape on every side, and the glass front would remain intact. Until such a plan be adopted it would be as well if all users of such gauges were to pursue the course which we have always followed, of turning the face of the gauge away from us when turning on the gas valve. The turning of the valve should, moreover, be quite gradual, so as not to put any sudden strain upon the gauge.

The same pressure gauge may be used for both hydrogen and oxygen bottles; but as it is now the custom—a custom, by the way, which is much to be commended—to furnish the former with a left-hand thread to its screw nozzle, a left-hand threaded adapter will be necessary before the gauge can be attached to that bottle. The section of the Berdun tube is so small that there is really no danger from explosion if the two gases should get mixed within it; but, practically, the time occupied in moving the gauge from one cylinder to the other will give ample opportunity for it to get clear from any residue. The junction points between gauge and cylinders should never be oiled. A case of ignition of gas is on record which was traced to the heat caused by working a metal flange against an oily leather washer.

South London Photographic Society.—At the meeting on January 2nd, at Hanover Hall, Peckham, Mr. Howson gave a demonstration of lantern plates. The next meeting will be on January 16th, when Mr. Warnerke will give a demonstration on "Mechanical Printing as Applied to Photography."

Society of Arts.—The following are the papers to be read at the meetings of the Society of Arts after the Christmas recess:—J. F. Green, "Steam Lifeboats"; A. G. Green, C. F. Cross, and E. J. Bevan, "Photography in Aniline Colours"; Carmichael Thomas, "Illustrated Journalism"; T. Emmerson Dowson, "Decimal Coinage, Weights, and Measures"; Sir Roper Lethbridge, M.P., "The Proposed Irish Channel Tunnel"; Wm. Topley, F.R.S., "The Sources of Petroleum"; Colonel Sir Charles Wilson, K.C.B., K.C.M.G., F.R.S., "Methods and Processes of the Ordnance Survey"; E. J. Ravenstein, "Lands available for Colonisation"; Prof. J. J. Hummell, "Fast and Fugitive Dyes"; William Robinson, "The Use of Petroleum in Prime Motors"; H. Newman Lawrence and Arthur Harries, M.D., "Electricity in relation to the Human Body"; J. Harrison Carter, "Milling Machinery"; F. H. Cheeswright, "Breakwaters." The next series of Cantor Lectures will be by Mr. A. J. Hipkins, F.S.A., on "The Construction and Capabilities of Musical Instruments." The course of three lectures will commence January 26th.

## THE CAMERA AND ITS VARIOUS MOTIONS.

BY PROFESSOR W. K. BURTON, C.E.

CHAPTER IV.—THE TRIPOD-STAND, TURNTABLES, ETC.

In spite of the great amount of ingenuity that has been spent on camera stands, I think it is generally felt that the ideal stand has yet to be invented, or perhaps that it is impossible to fulfil all the qualities demanded. A few of these are strength, rigidity, lightness, portability, great height, accompanied with the capacity to shorten each of the *three* legs independently, capability of being instantly erected, and durability—a nice little list for the enterprising inventor!

It would be out of the question to attempt to enumerate, much less to describe, all the various tripods that have been designed with a view to fulfilling as many of the conditions as possible, and all succeeding more *or less*. Only a few words on the several conditions can be allowed.

As regards strength and rigidity, it should always be remembered that they are not, by any means, the same thing. To take a definite example: There has probably never been a stand invented that combined so much rigidity with lightness as the "Alpen Stock" stand, invented some years ago by Mr. George Smith. So stiff was this that, although intended only for a small camera, I used the stand for a somewhat heavy 12 by 10. The stand was rigid enough; in fact, it was more rigid than any stand that I have used since, and did very well till an attempt was made to lift about the camera with it, when it simply collapsed! It is fair here to remind the reader that the stand was not intended for a heavy camera. Lightness is compatible with stiffness, but not, apparently, with strength. If one has a heavy camera he must submit to a heavy stand; at least, if he wants to be able to pull about the camera, already erected, with any degree of ease.

It is *almost* impossible to have a really stiff stand with a very small top; and, moreover, it is an advantage, in every case, to have a comparatively large top, as this increases greatly the stiffness of the base-board, a thing of great importance in the case of some of the lighter makes of modern cameras.

Lack of rigidity in the stand itself should not be confused with "shakiness" of the camera itself on the top of the stand. This latter fault is a very general one, and especially in the case of stands with wooden tops or triangles. It arises, of course, from either convexness or springing of either the top of the stand or the base-board of the camera. It may be useful to know that it may always be cured by fixing the leather pads on the camera top, so that the camera will actually rest on three points. I illustrate the way in which this may be done in the case of a wooden triangle and a metal tripod top. In each case A A A are small pads of leather.

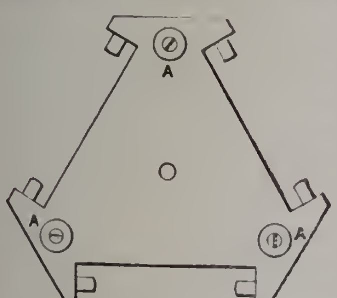

*Fig.* 10.

It should be understood that more rigidity is given by *three* pads than by four or any other number, and much more than by covering the tripod top altogether with leather. The pads may be fixed with screws, screwed down till the heads have sunk into the leather.

One word in connection with the use of a tripod-head with the three pads just described. Caution must be used in tightening the screw, otherwise the base-board may be split.

*Turntables.*—The turntable, as applied to cameras, was one of the improvements first popularised by McKellen. The arrangement is illustrated here. It may be said to consist of a turned circular top revolving in a bored ring. It gives great steadiness, and the camera may be clamped tightly in any position by a screw.

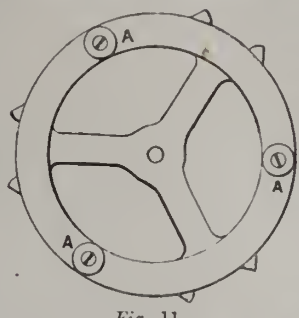

*Fig.* 11.

*Telescopic Metal Stands, Walking-Stick Stands, &c.*—I have not had much experience of these, but I know that there are several forms of them that are light and convenient, and that are stiff enough for very small cameras.

---

THE SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.—The Society of Amateur Photographers of New York is incorporated under the laws of the State of New York for the cultivation and promotion of the science and art of photography. In carrying out these objects, the Society has provided itself with convenient quarters, consisting of a club room, well supplied with photographic literature, and all the leading periodicals of this country and Europe; commodious dark rooms fully supplied with all necessary utensils and chemicals, and convenient lockers for the storing of personal effects; and a large hall for meetings, exhibitions, etc. It also possesses complete sets of apparatus for printing, making enlargements and lantern slides by electric light, with all facilities for operating the same.

DISTINGUISHED AMATEUR PHOTOGRAPHERS.—To the already long list of distinguished amateur photographers, says an evening paper, may be added the Princesses Maud and Victoria of Wales, who are thus able to return the compliment so constantly paid to them at public ceremonies. The Prince of Wales sometimes seems to be determined to avert his gaze from the camera of the ever-present photographer at a railway station or a stone-laying function. Four members of Parliament are well known as energetic and successful amateur photographers. Sir Richard Webster, Q.C., M.P., indulges in the art as a relief to the duties of an Attorney-General; Mr. Cyril Flower, the handsome representative of Luton in Parliament, has many negatives of Mr. Gladstone—the result of a visit paid by the right hon. gentlemen to Ashton Clinton; Sir A. K. Rollit, M.P., has dabbled in photography to a modest extent; while Mr. Patrick O'Brien, M.P., is, of course, famous for his doings at Tipperary and elsewhere. Mr. George Wyndham, M.P., tried his hand at rivalling Mr. O'Brien on his recent visit to some of the distressed portions of Ireland. Gustave Eiffel, who, like the Balbus of our Latin grammars, "built a tower," is an amateur photographer as well as an engineer. Mr. H. H. Johnston, the explorer, knows the dark room as well as the dark places of Africa. Another explorer, Nanssen, whose book so many are reading, is also a photographer of high ability. Miss Alice Longfellow, the daughter of the poet, practises the "gentle art;" and Mr. W. T. Stead did not disdain a detective camera at Oberammergau, although he was soon compelled to refrain from taking "snap shots" of the Passion play. The late Archbishop of York was an ardent photographer. For a long while before the present craze for this pleasing hobby, his Grace had taken a deep interest in the Dry Plate Club. Of the Amateur Photographic Association Dr. Thomson was a vice-president for many years. The various publications relating to photography—so numerous at the present day—were read by the Archbishop with keen enjoyment.

## Notes.

The second meeting of the International Photographic Congress will be held this year in Brussels, at some period not yet fixed, during the holding of the International Photographic Exhibition in that city. The Exhibition will open on the 10th of July, and close on the 5th of September. It will take place in the New Museum, a magnificent and comparatively new building on one side of the road leading from the King's Palace to the Palace of Justice. The latter the Belgians claim to be the finest secular building in the world; photographs of it on sale in London and elsewhere ordinarily do not do it justice, in consequence of the use—or rather misuse—of wide-angle lenses. All who wish to exhibit should write as soon as possible, or before May 1st at latest, to the secretary of the Belgian Association of Photographers, M. Ch. Puttemans, Industrial School, Boulevard du Hainaut, Brussels. If the exhibits are also intended for sale, they should let him know the price. In any case, the photographs will be submitted to a jury, who will decide as to their admission or otherwise to the Exhibition.

The Association will select the best of the accepted exhibits, and award to them diplomas of honour—gold medals, silver-gilt medals, bronze medals, and honourable mentions—in accordance with the decisions of a jury specially appointed to decide upon their merits. In the list of objects which may be exhibited, everything connected with photography seems to be included. The classification and terminology thereof are in accordance with the decisions last year at the Paris Conference, which seems to us to be reasonable, and to evolve order out of chaos. Why they have not been publicly discussed by any influential English photographic organisation is a mystery. One medal-in-chief will be given to the most meritorious of the exhibitors, no matter in what class he exhibits.

The jury will be composed of the president of the Belgian Photographic Association, of the general secretary of the Exhibition, of two persons to be elected by Belgians from among the members of the Association, of two members outside the Association to be nominated by the committee of the Association, and of five persons who are not exhibitors to be elected by foreign exhibitors; the latter will receive voting papers with their admission tickets.

At the close of the Exhibition there will be a lottery, the prizes in which will be some of the exposed objects. Exhibitors of photographs will have to pay five francs for every square metre, or fraction of a square metre, occupied by their pictures. All goods must be removed within eight days after the close of the Exhibition.

Each exhibitor must send his carte-de-visite before the 10th of June, with his signature thereupon, and with the number of his exhibit, to the general secretary, that it may be stamped, countersigned, and otherwise be turned into a non-transferable season ticket, in accordance with Belgian custom on railways and elsewhere. Those who wish full information should write to the secretary.

The new home of the Camera Club is in an unfinished state. The wintry wind whistleth through its vaulted aisles, and the owl hooteth on the battlements thereof:—

> "Here winter holds his unrejoicing court,
> And through his airy hall the loud misrule
> Of driving tempest is for ever heard;
> Here the grim tyrant meditates his wrath,
> Here arms his winds with all-subduing frost,
> Moulds his fierce hail, and treasures up the snows,
> With which he now oppresses half the globe."

At the last meeting of the Committee of the Camera Club fifty new members were elected. It is said that many more candidates are applying for admission, so that it is fair to assume that, on an early day, the Club will be pronounced "full," and future elections will therefore necessarily be slow. In consequence of the unfinished state of its new home, and another tenant being in possession of the old one, the Thursday evening meetings of the Camera Club will not be resumed until February.

From Melbourne has been sent to us a copy of the illustrated newspaper, *The Australasian*, setting forth how Mr. Farquhar, photographer, has succeeded in obtaining negatives of all the principal events at the Flemington Spring Races. A large engraving of the finish for the Melbourne Cup represents a number of horses with their legs in the ungainly positions previously revealed by the photographs of Mr. Muybridge. Mr. Farquhar used whole-plates in the work, and it is said that the time of exposure was 1-230th of a second, but no information is given as to how the speed of the shutter was ascertained. Perhaps more interesting than the attitudes of the horses are the expressions upon the faces of the winners and losers amongst the betting people in the crowd. Mr. Farquhar did not photograph the finish "broadside on," so that his task was easier than otherwise would have been the case; he intends to attempt the greater feat next year.

A few weeks ago, we commented in these columns upon the utilisation on shipboard of the optical lantern as a means of relieving the tedium of long voyages, and expressed a hope that the new departure would presently lead to wide adoption on ocean going steam ships. It would seem, however, that the lantern is destined to fulfil another service at sea, and one which is not for the mere amusement of passengers, but is put forward as a means of communicating with the shore or with neighbouring vessels in case of need. The system is described in the *Scientific American*, and is, we are told, "adapted for use by the mercantile marine, by lighthouses, signal, coast-guard, telegraph, and other stations, and for the use of lightships." The idea is simple, and, we should say, most effective if properly carried out. Briefly described, it comprises a sail rigged up at any required angle above the deck to act as a screen or sheet, and an optical lantern, by which the images of certain letters—cut out stencil fashion from thin metal, and acting as lantern slides—can be projected.

---

It is obvious that in this way the operator, if possessed of a complete alphabet of stencilled letters and numerals, can quickly cause their enlarged images to spell out any message which may be required. A lime-light or electric arc lamp would be the best form of luminant to employ, but on dark nights an oil lamp would answer the purpose; for the cut out letters transmit a far larger amount of light than any device upon glass, as anyone accustomed to lantern experiments well knows. The weak part of the system seems to lie in the ready way in which anyone can decipher signals which are meant for others. In this respect it falls behind the older method of signalling by means of long and short flashes which at present is in use in our navy. Still, the system is an ingenious one, and reflects credit upon its inventor, Mr. John W. Hayward, of Astor House, New York City.

---

The brightness of a stencilled figure as opposed to one prepared in the usual way on glass, was well shown in Mr. Beale's choreutoscope, which, we may remind our readers, is an instrument for projecting upon a screen a series of figures so rapidly following one another as to give the idea of movement, as in the case of the better-known zoetrope. One of the designs used in the instrument was a dancing skeleton, a device which admitted of being prepared as a stencil in thin brass. By use of such a stencil, a friend of ours—who was fond of practical jokes—cast the image of a skeleton upon the white side of a house near his own, much to the consternation of passers-by. The apparently dancing figure was about forty feet high, and it required a comparatively feeble light to project it that size. His little joke was only carried on for a few minutes, for the crowd which quickly assembled proved to be inconvenient, and very difficult to disperse.

---

A matter has been lately commented upon which will interest those who believe in the great future which lies before the optical lantern as an educational instrument. Of course, we all know that for some years it has been more or less used in colleges and schools, but that a recently appointed professor at Queen's College, Manchester, should announce his intention of illustrating a series of lectures on the British poets in the same popular manner is indeed a new departure. For our part we hail the news with delight, for we have long held that whatever be the subject of a lecture, it should be made as attractive as possible by the help of illustrations, experimental or pictorial. The difficulty in the case of such a subject as poetry will be to find pictures of a sufficiently good type for the purpose; copies from living models might certainly be arranged, but both models and those who group them must be selected with care, for the ridiculous is always within dangerous proximity of the sublime.

---

Whatever advantages "process" work has over wood engraving, there is in it one distinct inconvenience resulting from want of care which, when seen in the finished print, makes the artist feel inclined to tear his hair, and retire from public gaze for at least a month. The inconvenience in question is caused by the carelessness of the workman who mounts the block, and is generally in evidence in the place where it is most objectionable. We allude to the "printing up" of the nails which secure the plate to the block. When this happens, the nail almost invariably comes in the centre of the forehead, making the person look as if he had been crucified; or by the side of his nose, suggesting that nature had blessed him with an enormous wart. Why these nails persist in making themselves thus prominent is one of those things which no artist can understand. He can only put it down to pure "cussedness" on the part of the nail.

---

The death of Mr. Charles Keene, the well-known *Punch* artist, is announced. One of the features of Mr. Keene's drawings was what might be called a photographic quality. Unlike most comic draughtsmen, who are quite contented with two or three types upon which they ring the changes, Mr. Keene was laboriously exact in his sketches of character. He was continually going to nature for his bits of life; but we fancy that, unlike the photographic camera, he had not the power of seizing rapidly an expression; hence his range was somewhat limited. His work had not appeared in the pages of *Punch* for some months before his death, owing to the lingering illness which terminated fatally. *Punch* has been fortunate to secure a draughtsman of considerable original power to follow him in the person of Mr. Reed, the son of Sir Edward Reed, the late chief constructor of the Navy.

---

When Father Damien died, a whole host of newspapers which published his portrait was very neatly trapped. The only picture of Damien in existence was a photograph, not from life, but, as it turned out to be, from a drawing. When the philanthropist died, photographs were bought, copied, and published in the usual way. Directly after publication, however, the man who made the drawing came down heavily upon the proprietor of each newspaper who had infringed his copyright. He imposed his own terms —which in one case amounted to as much as £50— and the money was paid, because it was cheaper to pay even £50 than go to law with the certainty of being defeated.

## "OLD MASTERS" AT THE ACADEMY.

BY REV. F. C. LAMBERT, M.A.

THE twenty-second winter exhibition (now open) contains rather fewer "oils" than usual, but by way of compensation is offered an unusually interesting collection of water-colour work, which illustrates fairly well the history of art in that medium from about the middle of the last century up to recent times.

The first fifty-nine water-colours will be found in the little "black-and-white room," commencing with seven works by Paul Sandby, R.A. (1725-1809), lent by H.M. the Queen, representing various views in and about Windsor and Hyde Park—all characteristic of the artist. Then come two architectural works by Michael Angelo Rooker, A.R.A.

Nos. 16-29 form an interesting series of works by J. R. Cozens; Nos. 16 and 17 are both good examples; Nos. 18 and 19 are severely formal in composition; No. 25 is very cold in tone, but of skilful form; No. 23 being, perhaps, the most attractive, by reason of the able rendering of distance and atmosphere.

Two pictures (Nos. 30 and 31), the latter signed and dated 1813, by François L. T. Francia, are well worth notice for their broad and simple treatment. The "Pool of London," by J. C. Barrow, representing the great frost of 1789, which was of European fame, comes before us just at a time when the old-fashioned winters are better in art than in fact. Close by is another old Thames view, under more agreeable climatic conditions, from the brush of Thomas Girtin. Nine other works by this master are shown, none of which present him at his best; perhaps Durham (No. 38) and Lichfield Cathedral (No. 44) are the most noteworthy; while the rainbow in No. 42 is a failure; and No. 40 (Peterborough Cathedral) certainly gives one the feeling of a wide-angle lens used "not wisely . . . &c." Two of Henry Edridge's (Nos. 48 and 49) are of his average quality. The remaining ten works in this room are by John Varley, of which Nos. 54 and 55 will well repay examination.

Passing now into the Water Colour Room, we find ten examples of J. S. Cotman. Note the *flow* of the water in No. 60. In No. 62 we have a splendid piece of cloud drawing, and at once say, "this man would have appreciated a good cloud photograph." [Cotman is also known by his two-volume work on the "Architectural Antiquities of Normandy," and also for a volume on "Sepulchral Brasses of Norfolk."] The "Sea Piece" (No. 66) indicates possibly some influence of Turner, to whom Cotman was junior (1780-1820). Next, we have no less than twelve examples of David Cox; of these Nos. 70, 71 are very fine; No. 74 will delight the advocates of rough paper; No. 76 is interesting as showing the masters' method of treating water. For two years in succession the authorities have shown us some Turners, and once again we have a baker's dozen. The first example (No. 82, sea piece) is interesting as showing his method of working with body colour on tinted paper, with indications of the lead pencil being used with fine effect. No. 85 is very sweet and tender, painted in one of his brightest moods. No. 87, York, is more after his early method, and No. 91 again shows his power of dealing with bright sunlight; the sun in his lens, as *we* should say. It is here well worth noting that Nos. 82, 83, 86, 93, 94, show Turner's mastery in depicting rough water, while Nos. 84, 87, 91, 92 give his other method in dealing with a placid, calm surface.

Peter de Wint (1783-1849), practically a contemporary with Turner, is represented by nine pictures. He also appears to have had two modes, which are represented by Nos. 96, 98, and by 99, 102. No. 103 is exceedingly interesting, as showing his highly successful rendering of a primary and secondary rainbow, an effect seldom seen, and, perhaps, never before attempted in painting. Next come twelve frames containing fairly representative work of William Hunt (1790-1864). Of these, No. 108, "The Cricketer," is a splendid example of vigour and "go," giving one an idea of what an *ideal* snap-shot with the camera might be. In No. 112 the boys' faces are not sufficiently typical in form or colour; otherwise the picture is very fine in artistic quality. George Barret is represented by seven works, Nos. 116-122. Of these Nos. 117, 121, and especially 122, may be taken as representing his power in depicting scenes bathed in warm light. Prout is only represented by two very un-Prout-like works, while G. F. Robson is well seen in No. 131, "Durham." R. P. Bonnington also is well represented by Nos. 135 and 136. Samuel Palmer's vivid colouring is adequately presented in Nos. 139 and 140. Of the six pictures by J. F. Lewis, No. 142 is conspicuous, and, in a truly wonderful manner, indicates the outside bright sunlight by showing its effect diffused in and throughout the interior of a harem, with here and there patches of stronger light finding their way through the lattice. The lesson this picture conveys to interior photographers as regards transparency and luminosity of shadow is most valuable. The water-colour section closes with fourteen examples, Nos. 147-160, by a modern master whose life was cut short in his prime. If F. Walker (1840-1875) had only painted these fourteen pictures, they would entitle him to rank as a painter of the first order. Space does not permit notes upon each picture at length; but No. 150, "The Old Farm Garden," No. 152, "Girl driving Geese," No. 154, "Vale of Rest," No. 158, "The Ferry," No. 156, "Philip in Church"—in fact, every one of these splendid works, must be seen. Note how, in nearly every one, he catches a figure at a point of graceful rest, and yet with all the swing and go of full motion. Note, too, how the light bathes the whole scene, especially in Nos. 154 and 158. Here was a man who, we are told, only would put brush to paper when the fit was on him, but "a little and good" was perhaps his motto.

Of the oils of those painters whom we more generally designate as old masters, the first room contains many good examples by Gainsborough, Reynolds, &c. In No. 1 we see Gainsborough as a landscapist, followed by several of his portraits. In Nos. 9 and 39 John Crome shows his regular "crome-esque" trees, &c. George Romney gives a lady's portrait, nor does the pigment seem to have been as much affected by time as most of the other paintings in this room; the colouring of this (No. 10) is very fine; the shadows are grandly luminous. A scene from "Comus" by Etty (No. 13) is in his usual graceful form. Turner is seen to disadvantage in No. 18, and to advantage in a sea piece, No. 21. Two snow pieces by Sir E. Landseer seem to throw the whole room out of harmony. When it is remembered that this room contains seven Gainsboroughs, five Sir Joshuas, five Romneys, two Hogarths, three Zoffanys, two Turners, two Hoppners, and many others, it will be seen at once that any incongruous element is a matter for regret. On taking a last look, it will be noticed that all the ladies are presented in big hats, and one wonders how they managed to keep them "fixed" at such a high angle, especially in windy weather.

As we enter Room II., we find it is now the turn for the gentlemen to take the big hat. This room, as usual, is a Dutchman's gallery, containing many fine and seldom seen examples. On no account must the visitor fail to notice several magnificent portaits by Frans Hals, Nos. 69, 71, 72, 73; two typical river pieces (Nos. 49 and 54) by Jan van Goyen; two interiors (Nos. 53 and 78) by David Teniers; a very characteristic waterfall (No. 58) by Jacob van Ruysdael; an equally typical Hobbema landscape (No. 60); two regular Cuyp cattle pieces (Nos. 81 and 87); and No. 76, a Wouverman *without* his white horse trade mark.

In Rooms III. and IV. there are also many fine and typical works, which are for the first time put before the public. From among the many, one may mention a few which certainly should be seen, viz., No. 99, Palma Vecchio; No. 106, Spagnoletto; No. 107, Canaletto; No. 108, Claude; Nos. 112, 113, 116, Velasquez; No. 114, Murillo; No. 118, Tintoretto; No. 121, Hals; Nos. 123, 125, Van Dyck; No. 130, Romney; No. 146, Pinturicchio; &c., &c.

The early examples are of great interest to the historic student of art, and also to the archæologist; but, quite apart from either of these two particular ways of examining this year's gathering, all genuine and earnest students of painting will find themselves well repaid by a quiet and thoughtful examination of the works now brought together in Burlington House.

To photographers, the water-colour drawings should be of special interest, as they are, for the most part, typical of English painters at a time just before the advent of camera work.

---

The Photographic Club.—The subject for discussion on January 14th will be "Dark-Room Illuminants;" January 21st, "American Slides."

The Proposed Photographic Institute.—At a recent meeting of the Photographic Society, Mr. W. S. Bird said that they would all have read the report of the committee which had been deputed to consider the subject of the proposed Photographic Institute. Their labours had resulted in the drawing up of a large scheme and of a smaller scheme. The larger scheme was a project of the future, but the smaller one was of a more practicable nature, and the committee had had the advantage of conferring with the Lord Mayor on the subject, who thought that it might be possible to collect a sum which had for its limit £10,000, provided that the project was shown to be of public utility. If this was so, he thought that the photographic community generally should take some steps towards defining practical methods of carrying the scheme forward, and then they could approach the Lord Mayor with this project, and with some promises of financial support. In foreign countries the Government provided the means by which such institutions were founded, and in Berlin it took a very practical character, but in England this was not the case; he (Mr. Bird) felt that if this movement was to be a success, it must begin at home, and the Photographic Society ought to use what influence it possesses to assist in the work. Mr. W. Bedford thought that substantial assistance might be derived from the city companies if they thought the scheme would be likely to redound to their credit. The city companies were looking for praiseworthy objects on which to expend their funds, and photography was certainly a science and an art which might justly claim a portion of the wealth which had been accumulated. He did not think that very much assistance was to be expected from the various photographic societies, but at least they could do good by bringing the matter before the notice of their members.

## PHOTOGRAPHY IN GERMANY.

BY DR. H. W. VOGEL.

Stripping the Negative with Fluoric Acid—Eggenweiler's Gallery—Ruget's New Zircon Light—Schirm's New Flash-Lamp.

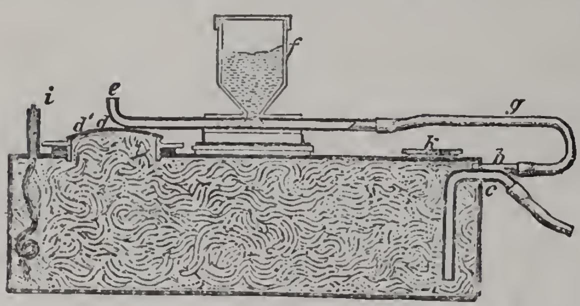
*Stripping the Negative with Fluoric Acid.*—It is now an easy matter to strip and reverse gelatine negatives. The process is old and used by only a few. Fluoric acid is used; this is kept in gutta-percha bottles. Glass and the hands have to be protected. The acid should be measured in a silver thimble with a wooden handle, and must be diluted with a hundred times its volume of water. Asphaltum dishes should alone be used. The acid is harmless in a diluted condition. In this diluted acid the gelatine negative is placed, and after about two minutes it will strip completely from the glass; the film may then be placed in water. Here it stretches about one-third of its length and width, so that a picture $6\frac{2}{3}$ by $10\frac{2}{3}$ will appear in place of the 5 by 8. A larger size is thus obtained, to the advantage of the photographer. The film is left under water until the desired extension has been reached, and the skin is caught again under water upon a glass, and left to drain in a horizontal position. The facility and rapidity with which the work proceeds are generally astonishing. If carbon prints or collotypes are desired they are reversed.

*Eggenweiler's Gallery.*—For the last two years the gallery construction of Eggenweiler has been recommended, and I believe that it is of particular interest for America, with its brighter sunlights and less dark days. The most peculiar feature of the gallery is that it has no skylight. It is a high room situated on the north side, with a northern glass side twenty feet high, but without glass roof. The roof, which admits no light, does not incline towards the front, but falls pretty sharply towards the rear, and is painted with a light colour on the inside. At a certain height, about ten feet from the floor, a semi-transparent white covering of gauze has been spread horizontally. This receives a strong light from the extensive glass side and the reflecting roof, and serves as a substitute for the top light. I, for my part, do not consider this screen necessary. The Court photographer, Mr. Kuntze, deems it worthy of our consideration. It cannot suffer from rain or snow, and has the advantage of excluding the sunlight completely, besides being much cheaper than an ordinary studio.

*Ruget's New Zircon Light.*—Mr. Richard Hugel, as representative of Setten and Company, exhibits a new incandescent gas lamp of the latest construction after Dr. Auer's system, for enlargement. The principle of the same is based upon the essential heating power of the gas brought to combustion in a Bunsen burner by application of the lighter hydrocarbons (petroleum gas) and repeated suction of air containing oxygen, so that the illuminating power of the glowing zircon body hanging in the flame is thus considerably increased. The apparatus necessary for this consists of a tin dish with two projecting short pipes, to which is attached some rubber tubing. Through one of these tubes air is introduced into the dish pneumatically by pressing the rubber bulb, while the air, impregnated with petroleum gases, passes from the other tube and reaches the Bunsen burner. The illuminating power of the Auer burner is thus brought to a strength of from sixty to eighty candles. The price of this light, including the gradual consumption of the zircon body, is from 4 to $4\frac{1}{2}$ pfennigs per hour. The effect of the flame and its whiteness are brilliant.

*Schirm's New Flash-Lamp.*—Upon a very similar principle the benzine flash-lamp of Schirm has been constructed. The apparatus consists of a tin vessel, *a*, filled with spongy matter, which is soaked with benzine. All free liquid is poured off. A small tube, *c*, which empties into the vessel, is connected with a pneumatic apparatus. This apparatus (rubber bulb) must be provided with two valves which carry the air only in one direction, and prevent a back-suction from the flame. In the upper part of the lamp is a cover, *d*, that can be screwed off, with fine openings around a circular line. Above the middle of this circle with the opening for the gas passage, the magnesium blow-pipe, *e*, with the magnesium carrier, *f*, can be inserted. This blow-pipe is connected by a thin rubber tube, *g*, with a pipe-end, *h*, near the pipe *c*. Close to the above-described burner is a small tube, *i*, filled with a wick, at whose end the flame is burning, which serves to ignite the emitted gas.

The action of the apparatus is the following: By pressure upon the bulb air is forced through the vessel and is fed with benzine gases, passes partly through the ring of fine openings *d*, ignites at the flame *i*, and forms a long, extremely intense flame. Another part of the air, saturated with combustible gas, passes through the magnesium



conducting-pipe *e*, receives here the magnesium powder, and conducts it to the above-mentioned flame for combustion. In this way an extremely intense and complete combustion is obtained, and the illuminating power of the burning magnesium powder is considerably increased.

This new lamp combines the advantage of the Bunsen burner (with great heating power) with the easy transporting facility of the former spirit lamp, harmless manipulation, great economy in burning material, and increased illuminating power. While the spirit lamp, when frequently used, had always to be refilled again, and a considerable consumption of burning material took place, one filling will now be sufficient for 1,000 flashes, and the lamp, containing no free liquid, can be transported without inconvenience. Every danger is also excluded, as in case of an upsetting of the lamp no combustible matter will run out, and the small flame will be at once extinguished. The magnesium supply for this lamp is so arranged that as soon as the magnesium reservoir stands upright the magnesium powder will fill the blow-pipe of its own accord, and a slight tap on the lamp is sufficient, after each flash, to effect a new fill with the powder. If the magnesium reservoir is turned over the magnesium supply is shut off. To fill the lamp the screw, *k*, is opened, a quantity of benzine is poured in, and the opening is closed again. After unscrewing the cover, which protects the ring of fine gas passages, *d*, during transportation, insertion of the blow-pipe into the middle of this opening, ignition of the flame, and opening of the magnesium reservoir, the apparatus is ready for use. To keep the apparatus in order, the small opening, *d*, should be cleaned sometimes with a needle, and it should not be neglected to turn the reservoir over before the last flash, to prevent the magnesium powder from reaching the lamp part during transportation. As soon as the flame becomes weak and is not very perceptible, a new filling is required. If a continued light-stream (by blowing, for instance) is driven through the lamp, and the magnesium reservoir is slightly tapped with the fingers, a lasting light can be produced.—*Anthony's Photographic Bulletin.*

## PHOTOGRAPHY IN VIENNA.

The History of Photography—Orthochromatic Photography—A Correction—Cristallos.

*The History of Photography.*—The only history of photography at present in existence is written in English. But the materials have increased so much, and the subject is so interesting, that several German authors are busy meeting this want in literature. In the first place, J. M. Eder, in his great "Handbuch," has devoted much space to the historical department with rare thoroughness, collecting all information about light and its effects from the times of the Greeks and Romans down to Daguerre. But from there he rapidly passes in review the development of photography. A second work, of which a preliminary notice has already appeared, is being prepared by an author named Charles Schiendl. It is likely to form a portly 8vo. volume. This book passes rapidly over the beginning of photo-chemistry, but becomes more detailed from that point on when the first pictures were produced by camera. Doubtless it will be interesting reading, as the author has the advantage of the valuable help of Davanne, Carey Lea, and other leading men.

*Orthochromatic Photography.* — Recently the learned Berlin investigators, Dr. H. W. Vogel and Dr. Neuhauss, have been engaged in an interesting enquiry concerning the priority of the discovery of orthochromatic photography. This controversy is likely to throw a light not only on the chronological succession of the theoretical speculations which preceded the practical success, but also on the real nature of the thing itself. In a technical journal here, Dr. Neuhauss has described the matter very objectively, it would seem, as follows:—

"In practical photography it has long been known as a fact that the addition of silver iodide to silver chloride or silver bromide greatly increases the sensitiveness of the silver salts for those spectral colours which are near the red end of the spectrum. To explain this phenomenon, Schultz-Sellack made several experiments, guided by the thought of the connection between the absorption and the chemical action of the rays. Such a connection had been made probable by Herschel's experiments concerning the fading of vegetable colouring matters, and by Draper's experiments on the decomposition of oxalate of iron.

"According to the method described by him, Schultz-Sellack melted the silver salts to masses clear as glass, which are particularly adapted for investigating optic absorption, and which change but slowly under the action of light. In this condition silver chloride is colourless; iodide light yellow and transparent; silver bromide is a somewhat darker yellow, but the mixture obtained by melting the last two is orange. Tested by photography, silver chloride showed itself sensitive only for the outside violet to about half way between Fraunhofer's lines H and G, iodide sensitive beyond G, silver bromide nearly to line F, a mixture of iodide and silver bromide to line E. Therefore the weak absorption of light by silver chloride comes together with weak photographic action, which is confined to the violet end of the spectrum. On the other hand, the increasing yellow and yellow-red colouring of the silver salts brings with it an increased sensibility for the blue-green and green division of the spectrum, that is, for those colours which are absorbed by the silver salts. In spectral examination the optic absorption of transparent plates of these substances shows itself to be strictly confined to the limits of chemicals already given."

Schultz-Sellack sums up his discovery in these words:—"I have found that optical and chemical absorption of light exactly correspond. All colours which are noticeably optically absorbed by the silver haloid-salts—in a thickness of some millimetres—produce chemical decomposition; the absorption of light with these materials is always united to chemical action." Again: "The haloid combinations of the silver are chemically changed by all the rays that they absorbed in any appreciable degree."

This last sentence is the foundation-pillar of all orthochromatic photography. There is but a single step from Schultz-Sellack's discovery to producing plates sensitive for green, yellow, red, with the help of the addition of colouring stuffs to the light-sensitive silver salts. To H. Vogel belongs the credit of having taken that step. A fortunate accident made it easier for him. Vogel found, namely, that English Wortley plates examined by him were unusually sensitive in the green at line E. He surmised that these plates contained some substance which absorbs green in a high degree, and found this surmise fully confirmed. The Wortley plates contained nitrate of uranium, gum, gallic acid, and a yellow colouring material as a coating. Vogel removed the colouring by washing with alcohol and water, and then had a plate which no longer showed signs of increased sensibility in green. Encouraged by this observation, he added a colouring agent to the silver bromide, which absorbs particularly the yellow rays, in the hope of thereby increasing the sensitiveness for yellow. For this purpose he chose an alcoholic solution of coralline, which, very much thinned in the spectroscope shows an absorption-stripe between D and E (yellow-green). As a matter of fact, such plates showed great sensibility for yellow-green rays.

The relation of Vogel's discovery to Schultz-Sellack's is best characterised by the former's own words: "The experiments to the fullest extent confirm the connection between absorption and chemical force (first surmised by Draper and Herschel, and confirmed by Schultz-Sellack), or they extend the views hitherto entertained. Schultz-Sellack supposes that silver haloid salts are chemically changed only by the rays which they absorb to a perceptible extent. My experiments show that not only the optic absorbing capacity of the sensitive silver salts themselves, but also the optic absorbing capacity of added substances, plays a part in the sensibility to light of photographic plates. Also Schultz-Sellack expressly emphasises the fact that Vogel's discovery only confirms the facts found out by him (Schultz-Sellack)."

Most objection has been taken to the expression "optical sensitizers" chosen by Dr. Vogel, for, as a fact, the fading of colours or their sensitiveness to light is a chemical process, not a physical one. Without this sensitiveness to light, these colours added to the emulsion are hardly adapted to play a part as sensitizers. But well-informed persons have adopted Vogel's doctrine, and assert that the *chemical* sensitizers produce an increase of general sensibility all over the plate, whereas *optical* sensitizers shift the conditions of sensibility of single parts of a plate; they limit the sensitiveness to certain optical regions, *e.g.*, green, red, namely, for those coloured rays which they absorb, by which means they themselves are decomposed. From this point of view, say they, the name of optical sensitizers is fully justified.

This view might be upset if one found completely colourless sensitizers which act sensitisingly for single parts of the spectrum. But it has not been proved that such exist, although for a time "salicine" was believed to do so. But as these are *colours* which absorb certain rays without, however, being changed by those rays, therefore their changes cannot be transferred to bromide of silver or iodide of silver, and this party concludes therefrom that such stuffs lack the capacity of sensitizing —that they are not sensitizers. The limitation of chemical action on certain optic areas is obtained by interposing coloured glasses which do not allow certain colours of the spectrum to pass, which is certainly a physical process, and from this they derive the justification of the expression "optical sensitizers" for those which localise effect of light.

Having here given the views of the opposing parties, I must leave it to the future and further experience which view finally wins the day.

*A Correction.*—I must make two small corrections in my former letters. Mr. Victor Angerer (see p. 1684), as I have since learnt, is a passionate angler, and the accident happened to him while crossing a weir in the Danube. Again, among the periodicals appearing in Vienna, for a short time now there has been a small monthly one called *Photographie* (see p. 1684).

*Cristallos.*—This developer, mentioned by Mr. Putz, consists, according to an analysis made by an able chemist, of the following composition:—

| | | |
|---|---|---|
| Hydroquinone... ... ... ... | 9 | grammes |
| Sulphite of sodium ... ... ... | 30 | ,, |
| Ferrocyanide of potassium ... ... | 5 | ,, |
| Caustic soda ... ... ... ... | 20 | ,, |
| Water ... ... ... ... ... | 200 | ,, |

A developer made according to this receipt produced exactly the same effects as the French cristallos. Hitherto it has not been possible to find out what the colouring substance is, but it is only an ornament, and not an essential component.

Photographers' Benevolent Association.—At the meeting held on the 2nd inst. (Mr. Benham chairman), three applications for assistance were considered and granted.

Newcastle-on-Tyne and Northern Counties Photographic Association.—The annual meeting will be held on Tuesday, January 13th, 1891, in the Morley Street Café, Newcastle-on-Tyne, at 7.30 p.m.

The *Photo-Gazette* (Paris), in its number for December 25th, 1890, just to hand, contains an illustration of M. Balagny's collographic process on flexible bichromatised plates, together with an explanation by the inventor.

In the *Photographisches Archiv*, also, M. Balagny is quoted in connection with a new instruction for development with hydrochinon.

## Literary Notices.

Photographischer Almanach und Kalender fuer das Jahr 1891. (*Dusseldorf: Ed. Liesegang.*)

The photographic almanac annually issued by Dr. Liesegang is less bulky than most of the contemporary publications of a similar kind, but contains much useful matter. The calendar is full of references to events of a photographic character, the observation of which, when it is referred to for the customary purpose of ascertaining current dates, is calculated to instil a certain amount of historical knowledge of photography, an element which we have found to be very deficient amongst photographers, both professional and amateur, especially, as a matter of course, amongst the newer devotees of the science.

The almanac is illustrated by three photo-ink reproductions; the first is a collotype portrait of Franz Veress, whose labours in the field of colour photography created so much stir a short time since. The very intelligent head of Herr Veress is seen to advantage in this collotype, of the quality of which it may be enough to say that it looks like a fine platinotype. A short biographical notice and description accompanies the portrait. Of the importance of Herr Veress' improvements we are hardly as yet in a position to judge, but it is scarcely probable that Dr. Eder would have spoken of them in the high terms he did if they were of the insignificance that in some quarters has been attributed to them.

A print from a half-tone zinc etching by Tuercke, whose process has been described in our Year-Book, is a good example of a river view with buildings, as rendered by a method of typographic printing; but the most charming illustration, to our mind, is that of a scene at Grönenbach reproduced in collotype by, as we are told, a pupil in Crowenberg's institute of instruction. There is a beautiful range of tone that gives life and reality to the whole. This is shown particularly in the deeper parts, where what would be a general heaviness in some processes is rendered luminous by the clear brightness of small portions of decidedly greater depth.

The subject of the colour of the light best suited for dark-room illumination, and the objectionable character of red light as affecting the eyesight, appears to be attracting attention in Germany just now, for besides a paragraph by Herr Liesegang, in which he mentions that the injurious character of red light is now generally accepted as a fact, we find an article by Arno Kersten, in which he says that we cannot caution too much against the use of red light, which is so very injurious to the eyes. He recommends, in place of red, to paste upon one or both sides of ordinary glass several thicknesses of a paper which is in common commercial use in Germany, and is known as "Rehbraunen Seidenpapier." This is a paper of a fawn or sienna colour. When dry, the paper is rendered translucent by imbuing it with vaseline or paraffin, and a pleasant light is obtained that is not trying to the eyes. As a source of light, he advises petroleum or gas, on account of the varying character of daylight. He adds that he has now used this yellowish light for some years, after having seriously impaired his sight by the use of red light.

As the result of a canvass amongst professional photographers in Germany to ascertain the developer most in use, we are told that more than half employ the ferrous oxalate, 25 per cent. eikonogen, 15 per cent. hydrokinone, and 10 per cent. the pyrogallic developer. This is, we should say, a very different result from that which would represent the practice of photographers in this country, where the relative proportions of the users of pyro and ferrous oxalate would be probably found to be about in a reverse ratio. Amongst amateurs we are given a different proportion, hydrokinone being the favourite with 30 per cent., eikonogen next with 26 per cent.; then follows ferrous oxalate with 20 per cent., and last again pyro with 16 per cent. It would be interesting to have some explanation of this curious diversity of practice.

Amongst information useful to tourist photographers is a list of dark rooms available for travellers' use, and we are pleased to notice that the list for England occupies more space than is taken by those of all the other countries mentioned.

There are, of course, a number of articles which our space will not permit us to go into, but many of which will well repay perusal, and a compact summary of formulæ completes a work which will doubtless command a large circulation wherever there are photographers to whom a work in the German language is intelligible.

---

The American Annual of Photography for 1891. (*The Scovil and Adams Company, New York; Hamilton, Judd, and Company, London.*)

This annual is about double the size of those published in England; it is also double the price. The most interesting article in it is that by Mr. C. W. Canfield, illustrated by twelve authentic portraits of Daguerre, reproduced by photo-mechanical processes. The other articles contain more or less useful practical information, and there are plenty of photo-mechanical illustrations, varying much in quality. Mr. S. F. H. Hewitt gives the following reducing formula, which he says is better than Mr. Farmer's when an acid fixing bath has been used:—

Belitski's Acid Reducer.

| | |
|---|---|
| Water ... ... ... ... ... | 7 ounces |
| Potassium ferric oxalate ... ... ... | 2½ drams |
| Crystallised neutral sulphite of soda ... | 2 ,, |
| Powdered oxalic acid ... ... | 30 to 45 grains |
| Hyposulphite of soda ... ... ... | 1½ ounces |

The solution must be made in the order given; filtered, and kept in tightly closed bottles in subdued light. This reducer can be used over and over again, and keeps well for months. With repeated use its activity is not diminished, because the oxygen that had parted from the ferric salt in favour of the silver is replaced by absorption from the atmospheric air. The acid reducing fluid tans gelatine films.

---

Pyro-Stained Hands.—*L'Amateur Photographic* advises the following solution for ridding the fingers and hands of pyrogallic stains:—Hydrochloric acid 93 grammes, oxalic acid 22 grammes, phosphoric acid 25 grammes, and water 500. For our part, we have found a strong solution of citric acid sufficient in almost every case. It is remarkable that some people's fingers become more deeply stained than others under similar conditions. Hydrochloric acid diluted in proportion of about 1 to 5 is with many manipulators sufficiently effective. We should, however, recommend the following method: Whilst developing, have by one a beaker filled with water, in which a few crystals of citric acid have been dissolved, and from time to time, as the fingers come in contact with the developer, dip them in the solution, and rinse them under the tap. When the work is completed, scrub the fingers and nails with a *clean* nailbrush, using the citric acid solution, and in all cases, of course, avoid the use of soap or soapy water, the alkaline nature of which will undo all the good services of the acid.—*The Photographic Art Journal*,

## HIGH RELIEF BLOCKS.

In no department of photography has there been more striking progress in the last few years than in the production of high relief blocks for printing along with letterpress matter. We have numerous instances of this improvement in the commercial use of such blocks for illustrating current periodical literature, but it is probably more thoroughly and extensively carried out in Germany than elsewhere. We have before us the current number of the *Radfahr Chronik*, a journal devoted to cycling, published at Munich, which is plentifully illustrated in this way. On the front page is a Meissenbach reproduction from a negative of a cyclists' congress held at Liege, in the course of last year. The picture is about nine inches in length, and contains representations of about eighty cyclists with their machines grouped in front of a handsome building, and enlivened by trees. Not only is the foliage well defined and free from heaviness, but the faces, although each but little larger than the head of an ordinary pin, come out with so much distinctness that as portraits they must be easily recognised by persons acquainted with the originals.

## FIRE AT MESSRS. STONE & CO.'S.

A MOST disastrous fire broke out on the night of the 5th inst. on the premises of Messrs. Stone and Co., photographic mount makers, of 7 and 8, Fulwood's Rents, W.C. The flames were first noticed at about 12·30 shooting through the roof of No. 8, and the firemen at once received a call. It was some time before an adequate supply of water could be used, on account of the difficulty in approaching the building, and meantime the fire had spread to No. 7. The contents of the building were mostly papers, and these, especially in the upper floors, were very inflammable, as this portion of the premises is heated by steam, and the large sheets of paper are separated there for drying. It was not till four o'clock in the morning that the fire, after the united efforts of some sixty or seventy firemen and twelve steam engines, directed by Captain Shaw in person, was got under, and meantime it had spread to the adjoining premises, No. 6, Fulwood's Rents, occupied by Sir Joseph Causton and Co., wholesale stationers, and also at the back to Waldack's private hotel, of which the whole of the back portion was completely gutted. The wind was from the north and took the flames in a southerly direction; had it been otherwise the adjoining premises on the north side, a large factory, occupying the space of three houses, Nos. 9, 10, 11, in the occupation of Messrs. Watson and Sons, as a photographic cabinet shop, and in which are stored immense piles of dry wood used by them for their cameras, would have caught fire, and in this case nothing could have prevented an enormous conflagration; but, excepting a few charred beams, which were extinguished almost as soon as they lighted, the breakage of all the back windows and the skylights, and the flooding of the basement with water, Messrs. Watson and Sons have escaped. Messrs. Stone's premises were reduced to a shell; the mass of burning material in the basement was so hot that it was practically impossible to enter the building during the 6th inst., and the hose was kept playing on the ruins all day; late in the evening this was discontinued. About three o'clock in the morning, however, flames again broke out, and at four o'clock the fire was almost as bad as on the previous night. The hose was kept playing till a late hour on Wednesday, 7th. Messrs. Stone and Co. are well known to photographers for their mounts; they have occupied these premises for twenty-six years, and this is their first experience of such a disaster. They were insured.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN. — An ordinary meeting will be held at 50, Great Russell Street, Bloomsbury, W.C., on Tuesday, 13th inst., at 8 p.m. A paper will be read by Mr. E. W. Maunder, F.R.A.S., on "Photography Applied to Astronomy."

### Specifications Published.

1,715. *February 1st*, 1890.—"Exposing a Succession of Photographic Films." MARSHALL ARTHUR WIER, 3, Palace Grove, Upper Norwood, Surrey, Engineer.

My invention relates to that class of photographic camera where a number of sensitised films are exposed one after the other without the use of dark slides. It consists of a rectangular receptacle or film-box for the purpose of holding the films. To change the films after exposure, I cause the exposed film to travel from the front of the receptacle to the rear thereof, and in order to cause this action to take place I employ rollers, which are suitably placed on the film-box or receptacle. The rollers may be placed thus: One on the front, one on the top, and one at the rear sides of the film-box. The front roller is a spring roller, on to which a band or ribbon of suitable material is wound a few times, the other end of the band being attached to the rear roller. On the front of the film-box is placed a movable or sliding frame, against which the edges of the films are caused to press by any suitable means.

When the film, after exposure, is to be removed to the rear of the film-box, the front frame is first pushed up; this action brings one edge of the film into position between the front roller, the band, and the middle or top roller, and, upon turning the rear roller by means of a suitable handle, the band is wound upon it and the film is drawn up, over the top roller, and down into the rear part of the film-box, the spring roller rewinding the band back again upon releasing the hold upon the handle. Instead of the top roller, a half round fixed piece may be employed. By means of the roller and band arrangement, the exposed films may be drawn to any other place or position in the box by suitably adjusting their relative positions.

The above arrangement may be fitted into a box to form a hand or detective camera, or it may be formed into a separate narrow box so that it may be used in a similar manner to the well known roller slide.

2,023. *February 7th*, 1890.—"Improvements in Enlarging Cameras." WALTER GRIFFITHS, Highgate Square, Birmingham, Manufacturer.

My invention has for its object improvements in enlarging cameras, by means of which I am enabled to enlarge to any extent upon either glass or paper from an ordinary negative in a simple, quick, and effective manner by daylight, or with an ordinary lamp, and without the necessity of working the camera in a dark room.

In carrying my invention into effect, I form the enlarging camera with an oblong body or box, preferably square and open at the ends, and formed of any such suitable material as wood, metal, stout mill-board, or straw-board; but I prefer to form it of either of the two latter, the ends being in that case strengthened with wood bands. At the one end I fix the carrier in which the negative is placed, the lens being placed in the centre of the body, and is so constructed and framed in a sliding partition that it may be moved backwards and forwards within the body at the will of the operator. At the other end I provide au end which telescopes within the body, in which a dark slide, cousisting of a frame with back and shutter, aud having a plain glass fixed therein, which is provided so that either sensitive paper or glass can be used as required, and which at the same time registers a position for correctly focussing the plate by the use of a smaller piece of ground glass which is held against the clear glass in the dark slide until the proper focus has been obtained by the telescope movement, after which the sensitive glass or paper is inserted in the place of the ground glass, in which position, it will be understood, it is exactly the same focus as the ground glass used for the purpose of focussing.

The action of using my enlarging camera is as follows :—

I insert the negative in the carrier with the film towards the lens. Draw the shutter, take out the back of the dark slide, and adjust the lens partition, and slide part until the required focus is seen upon the glass in the dark slide. To move the lens partition I remove the cap from negative end, which then admits the hands, after which I focus accurately by placing the square of fine ground glass against the large piece of clear glass about midway between centre and edge in any direction. I then charge the slide with the sensitive paper or plate iu the dark room with its face uext the glass, replace the back, and see that the shutter is closed, afterwards inserting the slide in the camera, and exposiug according to circumstances.

My improvements, therefore, consist in the particular arrangemeut and constructiou of the various parts, as well as the use of the clear glass iu the dark slide, the whole forming a compact, portable, and cheap enlarging camera, easy of focus, and capable of beiug worked in the light aud with an ordinary lamp.

2,626. *February 18th*, 1890. "Opalescent Glass." Charles Huelser, of Huelser and Co., 142, Fleet Street, Loudon, Solicitors of Patents. (A communicatian from abroad by Joseph Kempner, of Berliner Strasse No. 60, Goerlitz, Germany, Merchant.)

The object of this inventiou is a new process, derived from melting experiments, for producing opalescent glass. Said experiments have demonstrated that fluorides of alkalies alone do not produce opalescent glass—which fact is also established by other tests (*vide Dingler's Polytechnisches Journal*, vol. 256, p. 361, 1885)—that even cryolite produces opalescent glass only if added iu a large proportion ; that, however, silicofluorides of alkalies (silicofluoride of sodium or silicofluoride of potassium) or compounds thereof, when added in a relatively small quantity to a glass batch of auy suitable composition, produce au intensely opalescent glass. The communicator, for instance, ascertained that when adding to three equal batches of the same compositiou respectively ten grammes of fluoride of sodium, cryolite, and silicofluoride of sodium, the first two mixtures resulted in a perfectly clear white glass, but the third mixture, containing silicofluoride of sodium, in a completely milky, opalescent glass.

When making batches for opalescent glass in glass works, the proportion of silicofluoride of alkali to be incorporated will naturally depend on the nature of the substances constituting the glass batch, on the temperature of the furnace, and on the degree of dullness desired to be produced.

If, for instauce, in an ordinary cryolite opalescent glass batch consisting of 30 uuits of cryolite, 46 units of carbonate of soda, 12 units of chalk, and 165 units of sand, the cryolite is replaced by 25 units of silicofluoride of sodium, and eventually 20 units of kaolin, a glass perfectly equal to cryolite opalescent glass is obtained ; the kaolin, however, is not absolutely necessary, but any other aluminiferous mineral may be substituted therefor, as it merely serves to produce a glass similar to cryolite.

Silicofluorides of alkalies may also be advantageously employed for enrichiug any opalescent glass batches. In the batch above referred to, for instance, 15 uuits of the cryolite contained therein may be replaced by silicofluoride of alkalies. The batch, which would then be composed of 15 units of cryolite, 46 units of carbonate of soda, 12 units of chalk, 165 units of saud, and 12½ units of silicofluoride of sodium, results in an opalescent glass, which is at least as good as if only cryolite had been employed.

9,715. *June 23rd*, 1890.—"Photographic Cameras." Alfred Julius Boult, 323, High Holborn, Middlesex. (A communication from Hugo Thumler, 82, Potsdamerstrasse, Berlin, Manufacturer.)

The object sought to be attained in devising this improved photographic camera is to combine the greatest possible economy with the advantages of a camera capable of being folded together in a compact form, so as to occupy a minimum of space wheu stored up for subsequent use or transport. To obtain this result the camera is preferably made solely of paper and cardboard. A bellows of cylindrical shape, made of preferably black paper impervious to light, is folded in the same manner as is usual iu the manufacture of Japanese lanterns. Into one of the folds a cardboard disc is inserted and suitably fixed by means of paste, &c. In the centre of this disc is fitted an ordinary landscape lens. A few folds of the bellows remain free in front of the disc, and the front end of the bellows is pasted on to a square plate or sheet of cardboard in such a manner as to prevent the admission of light at the joint, and in the centre of which sheet of cardboard is provided a circular aperture for the admission of light. This wall fulfils the purpose of a blind or shutter for the object glass. The opposite end of the bellows is also closed by means of a square sheet of cardboard, pasted or otherwise, attached thereto, so as to shut out all light at the joiut. This sheet or plate is externally provided with a cardboard frame, the thickness of which should be somewhat in excess of the usual thickness of the glass plates used for emulsions, and to the outer surface of this frame another plate or sheet is secured. Both the cardboard sheets at the inside and outside of the before-mentioned frame are provided with corresponding central openings, preferably of circular shape, whose size is proportioned according to the space the image is to occupy upon the negative plates. A square dry plate is inserted through the upper opening in the before-mentioned frame into a dark space provided for the purpose between the two last-mentioned sheets. The upper end of the outer sheet is extended so as to form a cover or lid, which carries on its inner side a piece correspoudiug to the portion which is wanting in the side of the frame, which side piece, when the said cover or lid is lifted, grasps the upper edge of the dry plate, so as to hold the latter in position.

To prevent access of light to the dry plate when the camera is exposed to daylight, a narrow lid of a suitable fabric or strong paper is placed upon the front edges of the cardboard sheets, while a piece or cover suspended from the said narrow lid is placed against the rearmost sheet, which is made smaller on the sides and its lower edge than the frame and the sheet at the inner side of said frame. This deficiency is supplied by strips provided on the sides and the lower edge of the cover, which strips thus effectively shut out the light around the sheet. Two india-rubber bands attached to the rear of the cardboard sheet are passed over the cover at its top and bottom parts respectively, whereby the dry plate is securely locked in position.

The bellows has a tendency to remaiu in its central compressed position, so that when it is extended beyond this normal limit it exercises a spring action upon two stops diagonally fixed by means of flexible ties, preferably of fabric, each to one side of the front of the camera, and compresses the same between the sheets, front and back of the camera. These two stops consist of cardboard strips, and are of such length that, when it is desired to obtain sharply defined photographic impressions, they extend the camera exactly to the required extent.

When upon opening the lids, and at the back of the camera a ground glass plate is inserted in lieu of a dry plate, the photographic impression received by the camera may be inspected through the wide opening in the rearmost sheet. For the purpose of throwing light upon the emulsion plate, a lid or door is arranged in front of the opening in the front plate, and adapted to be raised and lowered as desired. To enable the camera to be readily moved from place to place, all the lids are closed, and the before-mentioued stops are disconnected and swung about their flexible hinges and laid flat against the front plate. The bellows is then compressed and attached to the rear of the door which is at the back of the camera by meaus of an india-rubber band, the whole being thus made to assume a compact form. The rubber band passed over the front sheet or plate across the stops aud across the door or lid at the front of the camera, also serves to secure the latter in position, and the whole camera being by such means reduced to a portable size, may be easily carried about in the pocket or otherwise.

16,037. *October 9th*, 1890.—"Printing on Glass and Porcelain." Hermann Grauel, Paulstr., Berlin, Merchant.

This invention has for object the rapid and easy printing chiefly of label-like and ornamental designs on objects of glass, porcelain, and like materials in one or more colours. This is accomplished by means of an apparatus in which, by the turniug of a lever or frame, colour is carried by rollers from a pad to a rigid printing plate, from which the matter to be printed or impressed is transferred to au elastic plate in readiness for the printing operation.

The inventor claims :—

1. The process for printing ou flat or curved surfaces of glass, porcelain, and like materials, label-like and ornamental matter in one or more colours, consisting in so operating backwards and forwards a lever or frame carrying a plate of elastic material, that this latter is alternately moved against a printing plate containing the design, and turned over with its elastic and impressed surface ready for printing from, or consisting in so operating backwards aud forwards a lever or frame, carrying a rigid printing plate, that this latter is moved against a plate of elastic material, and away from the same, leaving the elastic plate impressed, and ready for printing from.

2. In carrying out the process referred to in the preceding claim, an arrangement for obtaining the negative picture on an elastic plate, comprising a lever or frame carrying the elastic plate, operated backwards and forwards, the elastic plate being brought in contact with a printing plate containing the matter to be printed, and a colouring roller or rollers in connection with the lever or frame, and operated by it, so as to supply colour to the printing plate after the taking of each impression therefrom.

---

The *Deutsche Photographen Zeitung* opens its New Year greeting to its readers with the announcement that the number of copies printed will be raised to three thousand.

Liverpool Amateur Photographic Association.—Applications for space in the International Photographic Exhibition must be made before the 20th inst. Full particulars will be sent on application to Mr. T. S. Mayne, Fenwick Court, Liverpool.

Boxes for Lantern Slides.—At a recent meeting of the New York Society of Amateur Photographers Mr. Beach said :— "I would like to call your attention to a new method of packing lantern slides which I have just devised. It is a method which has for its object the safe transit of slides when shipped by express. Heretofore the trouble has been that the thiu wooden grooves of the boxes would sometimes crack off aud break, and the slides iu transit would cousequently push against each other or strike each other and become cracked. Now, to avoid that, it occurred to me to make these divisions of very thin rubber, and by doing so we are able to get a thinner division, and are able to get a great many more slides in a given amount of space, and I estimate that you can pack fifty slides in eleven inches of space, whereas, ordinarily, it takes about fifteen or eighteen inches. The way this is made is simply by taking two boards that are grooved with a saw, and then these strips of rubber—rubber belting—are glued in. Another and a better way is to have a mould made and cast the rubber the same as you would a rubber mat, and I will say that I am about to have these made ; when that is done all you have to do is to tack them or glue them on to the side of the box ; then you will have it all complete, and you can throw this package around wherever you want to, aud it will not break."

# Correspondence.

## ZOOLOGICAL PHOTOGRAPHS.

Sir,—I have just read your article, page 218 in the Year-Book, and am rather surprised to learn that the list of animals I photographed nearly twenty-seven years ago contained so many, as you put it, "geuerally more uusuccessful." The photographs of many of the animals mentioned by you as failures were shown by me in the lantern at a receut meeting of the Photographic Club, and I do not think they were considered failures by those present.

You do not seem to be aware that the clouded tiger is an animal easily tamed and often kept as a pet in the East ; there my reason for not entering his cage was the true one. Considering that I did go into the enclosures or cages of many of the animals, the insinuation is uncalled for. That better work than mine ought to be done now with all the improvements in cameras, lenses, plates, and chemistry, is only natural, but I believe I may claim to have been the pioneer. I shall be much obliged by your inserting this in the Photographic News, and I think it ought also to appear in your next Almauac.

Frank Haes.

28, *Bassett Road, London, January 5th*, 1891.

## THE FIRE IN HOLBORN.

Sir,—With reference to the disastrous fire, on the evening of 5th inst., at Messrs. Stone and Co's. warehouse, adjoining our factory, 9, 10, 11, Fulwood's Rents, would you kindly allow us to state in your columns, in consequence of the numerous enquiries we are receiving, that our premises have sustained but slight damage, and not sufficient to inconvenience us materially in the conduct of our business. W. Watson and Sons.

313, *High Holborn, London, W.C., January 6th.*

---

# Proceedings of Societies.

The London and Provincial Photographic Association.

*January 1st.*—Mr. A. Cowan iu the chair. This was the first meeting held at the new quarters, the Champion Hotel, 15, Aldersgate Street, London.

The Hon. Secretary announced that Dr. P. H. Emerson had presented his new work, "Wild Life ou a Tidal Water," to the Association.

Referring to the subject down for discussion—viz., "Developers"—Mr. F. P. Cembrano said his standard developer was

| | |
|---|---|
| Pyro ... ... ... ... ... | 2 grains |
| Ammonia ... ... ... ... ... | 2 ,, |
| Bromide ... ... ... ... ... | 1 grain |

to each ounce of water. For instantaneous work, he preferred carb. soda to liq. ammonia. A useful formula he had found to be three parts of eikonogen and one part of hydrokinoue used with carbonate of potash.

Mr. A. Mackie, for studio work, would use much less pyro and bromide.

Mr. W. E. Debenham had some years ago used a very good studio developer, the formula for which was—

| | |
|---|---|
| Pyro ... ... ... ... ... | 1 graiu |
| Ammonia ... ... ... ... ... | 3 graius |
| Bromide ... ... ... ... ... | 1 grain |

to each ouuce of water. This was also a good landscape developer for suitable plates correctly exposed. On the question which was the best solution to keep the bromide mixed with, he preferred to keep the three solutions separate.

Mr. A. Mackie, for indoor work, mixed the bromide with the ammonia, but for landscape work he preferred separate solutions.

Mr. J. S. Teape, in cases of great contrast, used no bromide at all, and started development with the full amount of ammouia. Soaking the plate in plain water decreased the coutrast.

Mr. Cembrano said that he had frequently found that gelatine lantern plates increased in density during washing, after the developer had been thrown off; he used a carbonate of ammonia developer.

Mr. H. M. Hastings remarked that this developer was very rapid, and its action would probably continue until the subsequent washing had quite cleared the film.

Mr. P. Everitt had recently used acid sulphite, and had found development very slow. Was this due to the cold weather or the acid?

The Chairman was inclined to think tardy development would more likely be attributable to the weather.

A question was raised whether sulphite was used principally as a preservative for pyro, or to improve the colour of the negative. The majority of the members present used it as a preservative.

Mr. E. Clifton had kept pyro several years preserved with citric acid only.

Mr. C. H. Cooke did not believe in bromide as a restrainer; in cases of over-exposure he increased the quantity of pyro.

The Chairman said that Mr. Warnerke had recommended, in cases of plates hopelessly over-exposed, to soak them in a sixty-grain solution of bromide of ammonium for some time previous to development.

Mr. A. Haddon preferred sulphurous acid as a preservative.

---

West London Photographic Society.

*January 2nd.*—Technical meeting, W. A. Brown, president, in the chair.

The first part of the evening was spent in examining an exhibition of apparatus, the work of members.

Mr. Rogers shewed an apparatus for making lantern slides by reduction; the whole of which, including the dark slide, was constructed of pine. He also exhibited a tourists' half-plate camera and slides; both the reducing and tourists' camera were constructed by himself.

Mr. Winter explained a novel form of walking-stick tripod for hand-cameras constructed entirely of metal.

Mr. C. Whiting exhibited some prints from wet plate negatives which had been orthochromatised with erythrosine, also a very convenient revolving cutting knife for cutting out lantern masks, and a useful developing brush made of a piece of felt fixed in a wooden handle.

The annual exhibitiou of members' work, and conversazione, will take place this evening at the Broadway Lecture Hall, Hammersmith. On Saturday, the 10th., there will be an exhibition of the prize slides at 7.30.

---

The Great Yarmouth and Eastern Counties Photographic Society.

At the monthly meeting of this Society, held at the Friendly Societies' Hall, Great Yarmouth, on the 6th inst., Mr. Smith, of the Eastman Company, exhibited and explained the method of working the kodak transparent films, bromide paper, and enlarging and contact priuting.

The next monthly meeting will be held on Tuesday, 3rd February, when Mr. A. Price will read a paper entitled "Practical Photographic Notes."

---

A large number of pictures by Mr. J. P. Gibson, of Hexham, who is an excellent landscape photographer, is now on view in the rooms of the Liverpool Amateur Photographic Association.

Grained Margin on Mounts.—A grained effect may be produced on the margin of mounts, as a substitute for embossing, by the following method. Take a sheet of coarse sandpaper and cut out from the centre the size of the print which is to be mounted, allowing for an extra eighth of an inch or so between the picture and the grained surface. The sandpaper is then laid face down on the mount, which must be marked to show where the aperture falls. The marking may be done with a paper knife round the edge of a glass cutting plate. The two sheets are then placed between two pieces of stout card-board, and placed under a copying press and screwed down firmly. A few minutes' pressure will suffice.—*The Photographic Record.*

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

A. de la B. (Marcoussis).—*Petzval's Optics, &c.* 1. Professor Petzval's "Researches on Optics" were originally published by the Imperial Academy of Sciences in Vienna about the year 1858. You will find an epitome of them, occupying five pages, in the *Journal of the Photographic Society* for December, 1857. There was also an explanatory letter, signed by Joseph Petzval, in the same Journal for April, 1858, which, two months later, was answered by Herr Voigtlander. The "lens controversy," as it came to be called, engaged much attention in England at that time, and you may find frequent references to it, throughout this and the following year, printed in the above-named Journal. 2. Sir George Airy's papers all appear in the *Transactions of the Royal Society*, of which he was for many years the distinguished president. 3. Later discussions can be followed with more profit than by turning back to the old treatises of Ganot, Watts, and Balfour Stewart.

William Adcock.—A correspondent would be glad to find some one acquainted with the late William Adcock, of Melton Mowbray, who was for several years an exhibitor and member of the Photographic Society of Great Britain.

L. J.—*Photo-Mechanical Details.* See answer to "Printer" last week.

M. I. C. E.—*Theoretical Instruction.* We should recommend you to make a point of attending the Cantor Lectures on "Photographic Chemistry," which are announced for delivery, by Professor Meldola, on the 9th, 16th, and 23rd of March at the Society of Arts. In the meantime you might read up the author's previous course, entitled the "Chemistry of Photography," and published by Messrs. Macmillan and Co.

C. S.—*Mounting Enamelled Photographs.* This is always a difficult and uncertain process, on account of the stiff nature of both cardboard and photograph. We should advise you to apply the glue all over the back, and not at the edges only, and then to dry under pressure as you have been doing. A light coating of encaustic paste rubbed on the face of the print might enable you to cope with accidents such as happened to your specimen, and permit of the spot of glue being washed off without injury to the photographs. In many cases a good effect is got by mounting first and finishing off with collodion.

Luton.—*Snow as a Test of Atmospheric Purity.* Your observation is a true one, and now that the snow has been lying on the ground so long, one can see at a glance the indication of purity or otherwise of the air in different localities, by noticing the relative discolouration due to smuts and blacks which distinguishes the metropolitan from the purer deposits of snow in a rural district. The same remark applies to rain water collected in towns and open country.

Artist.—*Dedham Bridge.* The illustration of last week is a reduction of Mr. Lyonel Clark's medal picture, which was said to have been toned with palladium and intensified with silver. The sepia tone has been closely imitated in the small reproduction sent out with the News.

W. T. (Leeds).—*The Bust Portrait.* There are some American specimens, and we have seen a good result produced by Mr. Medrington, of 29, Bold Street, Liverpool. It was the head of a lady with fine neck and shoulders, loosely attired in classic drapery, and set on a short pedestal after the manner of a sculptured bust.

W. M.—We will enquire of the Editor, and let you know by post.

"Nitrate Bath" and another correspondent received as we were going to press.

Vol. XXXV. No. 1689.—*January* 16, 1891.

CONTENTS.

## ASTRONOMICAL PHOTOGRAPHY AT THE PHOTOGRAPHIC SOCIETY.

At the first meeting of the Photographic Society in its new rooms last Tuesday, Mr. Maunders read one of the most interesting papers which has been brought before the members for some time past; its subject was "Astronomical Photography." Lantern photographs in large numbers were used to illustrate the remarks of the speaker.

Among the more curious facts brought under the notice of the meeting, was the aid which photography has given in determining the velocity of some of the so-called fixed stars. Assume a star to be motionless, and to be emitting waves of light, a certain number of those waves will enter the eye in a second; suppose that star next to be approaching the spectator at high velocity, it is plain that more waves will enter the eye in a second, and if the star were to recede at high velocity, fewer waves would enter the eye in a second. This approaching or receding causes a slight shifting of the position of lines in the spectrum of the light of the star, which shifting can be both measured and photographed, and slides showing the results thus obtained by photography by the German astronomer, Vogel, had their images projected upon the screen at last Tuesday's meeting.

Vogel has given much attention to the variable star Algol, in the Head of Medusa. For a consecutive period of eight hours during about every three days, this star diminishes in brilliancy, and many have been the speculations as to the cause thereof. One of them was that possibly a planet revolving around Algol passed between the observer and that sun. Another was that dark spots of large size on Algol faced our earth at regular intervals as the star revolved upon its axis. A third was that some of the variable stars might be moving in an orbit of great elongation, so that when in one position less light reached the eye of the spectator. In regard to Algol, it is now clear that the falling off of the light is due to some dark body coming between the star and the earth, and recent researches on the lines we have already stated have proved Algol to have a relative orbitual motion of its own. The result of Vogel's researches is, that he has been able to give the size and the weight of the planet revolving around Algol, although the planet has never been seen, and probably never will be visible to the human eye.

The stars are suns more or less like our own sun, but appear small because of their immense distance, a distance so great that it takes some years for the light to travel from even the nearest of them to the earth; consequently, when we gaze at the heavens by night, we see the stars, not as they are now, but as they were some years ago. As our own sun has a few large planets revolving around it, the natural assumption is that the other suns possibly also have planets revolving around them, but that these dark little bodies should become visible to us at the vast distance of the fixed stars seems to the scientific world to be for ever impossible.

Photographs of the sun and of various solar phenomena were exhibited, including some magnificent representations of sun spots, and of the general mottling of the solar surface. In this, as in most other cases, the speaker did not stop to explain the supposed causes of the facts pictured, or his paper would have been of increased interest; time was short, and his lantern slides were many. A popular scientific theory of the cause of the spots on the sun is, that they are due to the down-rush of a comparatively cool absorbing atmosphere. The heat of the sun is so great that even metals are raised into the gaseous state, and these gases, when somewhat cooled, are supposed to shower down towards the centre of the sun as luminous molten rain.

Various photographs of the great nebula in Orion—some taken by Mr. Common, and others by Mr. Roberts—were also projected upon the screen; the best photograph obtained by Mr. Common was not among them, but the set included one not far short of it in quality. The distance of this nebula is so great, that one astronomer has calculated that, if there be no absorption of light in space, the light from the nebula cannot travel to our earth in less than sixty thousand years.* When such circumstances as these are considered, and when it is remembered what myriads of suns can be seen lavishly scattered like luminous dust in space, man feels his own insignificance, and is raised, for the time, above thought of the mean aims and low ambitions of earth; he can somewhat realize how, before the gaze of the Eternal, "ages likes flies in summer heats pass by," and can feel in sympathy with the dream of the poet:—

"God called up from dreams a man into the vestibule of Heaven, saying, 'Come thou hither, and see the glory of my house.' And to the servants that stood around his throne he said, 'Take him, and undress him from his robes of flesh: cleanse his vision, and put a new breath into his nostrils; only touch not with any change his human heart—the heart that weeps and trembles.' It was done; and, with a mighty angel for his guide, the man stood ready for his infinite voyage; and from the terraces of Heaven, without sound or farewell, at once they wheeled away into endless space. Sometimes with the solemn flight of angel wing they fled through Zaarahs of darkness, through wildernesses of death, that divided the worlds of life; sometimes they swept over frontiers that were quickening under prophetic motions from God. Then, from a distance that is counted only in Heaven, light dawned for a time through a sleepy film; by unutterable pace, the light swept to *them*; they, by unutterable pace, to the light. In a moment the rushing of planets was upon them; in a moment the blazing of suns was around them.

"Then came eternities of twilight, that revealed, but were not revealed. On the right hand and on the left, towered mighty constellations, that, by self repetitions and answers from afar, that, by counter-positions, built up triumphal gates, whose architraves, whose archways rested, rose at altitude by spans that seemed ghostly from infinitude. Without measure were the architraves, past number were the archways, beyond memory the gates. Within were stairs that scaled the eternities below; above was below, below was above, to the man stripped of gravitating body: depth was swallowed up in height insurmountable—height was swallowed up in depth unfathomable. Suddenly, as thus they rode from infinite to infinite—suddenly, as thus they tilted over abysmal worlds, a mighty cry arose, that systems more mysterious, that worlds more billowy, other heights and other depths, were coming, were nearing, were at hand.

"Then the man sighed, and stopped, shuddered, and wept. His overladen heart uttered itself in tears; and he said, 'Angel, I will go no farther; for the spirit of man acheth with this infinity. Insufferable is the glory of God. Let me lie down in the grave, and hide me from the persecution of the infinite; for end, I see, there is none.' And from all the listening stars that shone around issued a choral voice, 'The man speaks truly: end there is none, that ever yet we heard of!' 'End is there none?' the angel solemnly demanded: 'Is there indeed no end? and is this the sorrow that kills you?' But no voice answered, that he might answer himself. Then the angel threw up his glorious hands to the Heaven of Heavens, saying, 'End is there none to the universe of God. Lo! also there is no beginning.'"

---

Torquay Photographic Association.—The monthly meeting was held at St. Winifred's on Tuesday evening, 13th, when a paper on "Platinotype" was read by Mr. Geo. Edwards. Afterwards some successful experiments in development were made.

Mr. Crookes:—Mr. William Crookes, who was the editor of this journal at the time of its foundation, and an active worker in photographic research, has been elected president of the Institution of Electrical Engineers, and last night delivered an able and interesting presidential address to the members. Its subject was "Electricity *in transitu*: from plenum to Vacuum."

* *The Orbs of Heaven.* O. M. Mitchell, A.M., Director of the Cincinnati Observatory.

## ON PAINTING A PLAIN BACKGROUND.

In an article last week on "Backgrounds and Accessories," we remarked upon the notable improvement which has taken place in the choice and use of such aids to photographic art, and traced that improvement to the culture which has been acquired by workers owing to the rapid progress in artistic knowledge generally in this country. The educated photographer of to-day knows well enough that he can produce with a plain background a far more artistic effect than he can by hanging behind his sitter a meritricious landscape or palatial interior, and that, by shading portions of such a plain background, and by illuminating other portions, as can easily be done by a few simply arranged curtains and reflectors, he can produce all those effects of light and shade which are attained by the best artists in oil colours. The simplest kind of plain background can now be purchased in the form of fabric of convenient width and in any tone of colour which the photographer may desire. A woven material has also been introduced, in which a gradual shade from light to dark is brought about in the operation of weaving. In another form of shaded background the base is of paper, while the shading is produced by lithographic printing. So that it will be seen that the worker has his choice of several kinds of backgrounds.

But there are many photographers who hardly believe in anything unless it be their own handiwork and home-made, and for such workers we have a great respect, for from them come the little inventions and clever notions which are so valuable to the fraternity at large. Such a man will take a delight in making for himself that which often it would cost him less to buy, even when he does not take his own labour into account. Still he is happier for having done the work himself, is proud of his achievement, and sleeps the sleep of the just with that feeling of "something attempted, something done" which, according to Longfellow, makes the lot of a village blacksmith such a happy one.

But although a man can do many things in the way of simple and ordinary carpentry—such as fitting up shelves, making boxes, picture frames, and the like—he generally experiences an utter failure in his first attempts at making and painting a background. And the reason of this is not far to seek. The work is of an unusual character, and embraces certain technicalities which an amateur cannot very well get a mastery of, unless he have an opportunity of getting behind the scenes; and we use the term in its most literal sense, for the operation of painting a background for photographic purposes is akin to that of painting a scene for a theatre. If, then, we can learn a little regarding the materials employed in theatrical work to produce such wonderful illusions on the stage, we shall soon conquer the difficulties involved in painting a background.

The best course for the tyro to pursue is to attempt at first nothing but a plain background in one even tint of monochrome. Seven feet by six is a serviceable size, and he will require a strong wooden frame of these dimensions to serve as a temporary support for the material upon which he works. Good, strong, unbleached calico two yards wide must be tacked on to this frame, so that it presents an even flat surface free from ruck or wrinkle. A little art is necessary here: first, the four corners must be secured, taking care to stretch the material well from the centre as each tack is driven home; the tacking down of the edges is then a mere matter of detail. The cloth must next be *primed* with very thin glue, and allowed to dry, after which comes the colouring process. It is in the mixing and application of this distemper colour where the amateur worker is apt to fail. As a rule, he is in such a hurry to see the effect of his work that he will not take sufficient time for his colour to get cold. The drying of the priming coat will, however, take several hours even in a warm and dry atmosphere, and he should mix his colour immediately after the priming has been laid in.

Take a couple of balls of ordinary household whiting, place them in a basin or clean pail, and pour upon them enough water to reduce them to a viscid mud. Stir with a wooden spoon until this white mud is perfectly free from lumps, and then add colour until the required tint is attained. Lamp black, or drop black, and burnt umber, both ground in water, can be obtained of most artists' colourmen, and small pieces of the soft pasty tints must be added at a time, and well incorporated with the whiting by the aid of the spoon. But a word of caution is necessary here as to testing the colour from time to time, in case it should be made too light or too dark in tone. A little of the wet mass must be brushed on a card, and dried before the fire, before the tyro can judge of the tint, for all distemper colours are several shades darker when they are wet than when they are dry. When the right tone is reached, add to the contents of the vessel half a pound of patent size, which has been previously melted on the fire, in a pint of hot water, and stir up the colour most thoroughly. When this has been done, put the vessel away in a cold place.

At the end of some hours, when the colour has become perfectly cold, it will assume the form of a thin jelly, and it is now in a fit state to be laid on the primed cloth. A broad, flat white-wash brush, known as a *two-tie*, is the tool to use in applying the colour to the cloth. The colour must be laid in firmly, first in vertical, and then in horizontal strokes of the brush, the latter crossing the former. The work should be done expeditiously, a couple of square feet at a time, until the whole surface is covered. The result will be, if these directions are closely followed, a smooth, even surface of monochrome, which, when removed from its temporary supporting frame, can be attached to a roller, and thus preserved from injury when not in use. When the beginner has succeeded in this elementary lesson in distemper painting, he will, no doubt, be wishful to do something of an artistic kind; but he will do well to learn to walk before he attempts to run.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Two Quinol Developers—Brown and Reddish Tones on Bromide Prints by Eikonogen Development.

*Two Excellent Quinol Developers.*—The following developer, which is recommended by Mr. F. Wilde, in the *Photographisches Wochenblatt*, is said to bring out all the details in the weakly exposed parts of the plate, and to act very energetically, giving at the same time sufficient density.

*Solution* No. 1.

| | |
|---|---|
| Water ... ... ... ... ... | 250 c.c. |
| Sodium sulphite ... ... ... ... | 60 grammes |
| Cryst. citric acid ... ... ... ... | 5 ,, |
| Pyrogallic acid ... ... ... ... | 20 ,, |

*Solution* No. 2.

| | |
|---|---|
| Quinol ... ... ... ... ... | 10 grammes |
| Alcohol ... ... ... ... ... | 200 c.c. |

*Solution* No. 3.

| | |
|---|---|
| Water ... ... ... ... | 1,200 c.c. |
| Sodium sulphite ... ... ... | 100 grammes |
| Soda ... ... ... ... | 300 ,, |

Just before use are mixed—

| | |
|---|---|
| Solution No. 1 ... ... ... ... | 8 c.c. |
| Solution No. 2 ... ... ... ... | 8 ,, |
| Solution No. 3 ... ... ... ... | 34 ,, |

The action of the developer may be still increased, and the time of exposure shortened for one-third of the otherwise required time, if to the above quantity of the mixture about twenty drops of the following solution are added:—

| | |
|---|---|
| Hyposulphite of soda ... ... ... | 5 grammes |
| Potassium bromide ... ... ... | 20 ,, |
| Water ... ... ... ... ... | 1,000 c.c. |

In cases where it is admissible to allow to the negative a somewhat longer time for development, the above mixture may be diluted with an equal quantity (50 c.c.) of water.

Another hydroquinone developer, very well suited for instantaneous exposures, has been recommended of late, according to the *Photographisches Archiv*, by M. Balagny.

The following two solutions are prepared:—

*Solution* No. 1.

| | |
|---|---|
| Boiling water ... ... ... ... | 1,000 c.c. |
| Sodium sulphite ... ... ... ... | 250 grammes |

When dissolved, add—

| | |
|---|---|
| Quinol ... ... ... ... ... | 20 grammes |

The solution is stirred until the quinol has completely dissolved. After cooling down the solution is poured into a glass bottle, which is then stoppered.

*Solution* No. 2.

| | |
|---|---|
| Water ... ... ... ... ... | 900 c.c. |
| Caustic soda ... ... ... ... | 100 grammes |

When dissolved, the following solution is added:—

| | |
|---|---|
| Water (warm) ... ... ... ... | 100 c.c. |
| Ferrocyanide of potassium ... ... | 10 grammes |

The latter gives to the negatives softness, and preserves the whites. Besides, a third solution should be kept in stock, consisting of—

*Solution* No. 3.

| | |
|---|---|
| Water ... ... ... ... ... | 100 c.c. |
| Potassium bromide ... ... ... | 10 grammes |

This is only required in the case of a freshly prepared bath. To develop an instantaneously exposed plate of half-plate size, mix—

| | |
|---|---|
| Solution No. 1 ... ... ... ... | 80 c.c. |
| Water ... ... ... ... ... | 40 ,, |
| Solution No. 3 ... ... ... ... | 1 ,, |

The plate is placed on the bottom of a glass dish, and the above mixture poured over it. It is allowed to act for about half a minute. Then, in a glass measure, 2 c.c. of solution No. 2 are poured, which are mixed with the bath in the dish, and in which the plate is again placed. After a few seconds again 2 c.c. of solution No. 2 are added, and so on, until the image begins to appear. As soon as it is faintly perceived, the addition of the alkaline solution should be interrupted; only, if it is noted that the plate has been under-exposed, the solution No. 2 should be added also after the high-lights have appeared, but always only 2 c.c. of it at one time. After development the plate is well washed, and then placed for half a minute in a solution of

| | |
|---|---|
| Tartaric acid ... ... ... ... | 25 grammes |
| Water ... ... ... ... | 1,000 c.c. |

which prevents the negative turning yellow in the fixing bath. The plate is again well washed, and then fixed in a 20 per cent. solution of hypo. To develop a time exposure, the bath is prepared as follows:—

| | |
|---|---|
| Water ... ... ... ... ... | 80 c.c. |
| Solution No. 1 ... ... ... ... | 40 ,, |
| Solution No. 3 ... ... ... ... | 4 ,, |

The further treatment is the same as with instantaneous exposures. If the bath becomes weak, after a larger number of plates have been developed in it, it may, notwithstanding, be used if prepared as follows:—

| | |
|---|---|
| Old solution ... ... ... ... | 100 c.c. |
| Solution No. 1 ... ... ... ... | 25 ,, |

and if, as described above, 2 c.c. of the alkaline solution are added at one time.

*Brown and Reddish Tones on Bromide Prints by Eikonogen Development.*—Dr. F. Stolze, editor of the *Photographie Nachrichten*, publishes in the columns of that journal a very practical and useful process of producing warm tones on bromide prints by the use of the eikonogen developer, combined with a modification of the tone of the deposit in the finished print. For the first development he uses an eikonogen developer of the following composition:—

*Solution* No. 1.

| | |
|---|---|
| Sodium sulphite ... ... ... ... | 20 parts |
| Eikonogen ... ... ... ... | 4 ,, |
| Dist. water ... ... ... ... | 300 ,, |

*Solution* No. 2.

| | |
|---|---|
| Carbonate of potash ... ... ... | 50 parts |
| Dist. water ... ... ... ... | 300 ,, |

In the case of normal negatives, 50 parts of solution No. 1 are mixed with 20 parts of solution No. 2, and with 150 to 180 parts of dist. water. In the case of soft negatives more of solution No. 1 is taken, whilst in the case of hard negatives, the bulk of solution No. 2 and of the water should be increased. The temperature of the solution should be at least 59° to 60° F. In the case of over-exposure from soft negatives, 10 to 25 drops of a solution of potassium bromide 1:10 should be added to 100 c.c. of the above mixture. By this means very agreeable, slightly yellowish-brown tones are obtained. In order to produce brown or reddish tones, it is, however, necessary to modify the tone of the finished print, which is done by transforming the silver image into bromide of silver, and by re-developing it with eikonogen. For this purpose the following two solutions are prepared:—

| | | |
|---|---|---|
| A.—Sulphate of copper ... ... ... | | 1 part |
| | Dist. water ... ... ... ... | 100 parts |
| B.—Potassium bromide ... ... ... | | 1 part |
| | Dist. water ... ... ... ... | 100 parts |

The two solutions are mixed, and the prints are bleached in the mixture. They are then washed five to six times, to remove the copper bromide as completely as possible. The prints are then, in daylight, treated with the above eikonogen developer, which for this purpose is composed as follows:—

| | |
|---|---|
| Solution No. 1. ... ... ... | 50 parts |
| Solution No, 2. ... ... ... | 20 ,, |
| Dist. water ... ... ... ... | 4,930 ,, |

The action is, of course, very slow, but entirely uniform. The tone is passing from a very vivid red-chalk tone through all shades of reddish-brown and blackish-red to a dark violet black. To prevent the toning process continuing in the washing water, the prints are placed in a bath of—

| | |
|---|---|
| Citric acid ... ... ... ... | 1 part |
| Water ... ... ... ... ... | 100 parts |

They are then again washed, and dried. According to the degree of the second development, the character of the original picture must be a different one. In order to obtain a red-chalk tone, the picture should be a little over-developed, so that all the tender half-tones are too dark without the shadows being, however, too heavy. For darker tones the original picture should always be of a greyer tone, and the high-lights should appear entirely white, even slightly devoid of details. During the second development all these apparently wanting tones will make their appearance. This method may, therefore, be used in the case of quite flat original pictures in order to intensify them successfully. It is necessary to free the prints completely from the developing solutions by washing, to prevent their turning yellow afterwards. This process is at the same time an excellent means for intensifying flat negatives.

## THE RESTORATION OF DARKENED EIKONOGEN.

An evil complained of a great deal in the development with eikonogen is the circumstance that the eikonogen will change soon if proper care is not taken; that is, it will become brown and be useless for developing solutions. We have been asked the question repeatedly: Can eikonogen, after it has become brown, be restored again so as to be fit for use? and in view of this really favourite developer, it will certainly be of general interest to discuss this question a little closer.

It may be remarked beforehand that it is possible to make the changed eikonogen useful again, and in different ways. For instance, by the following process: Prepare a not very concentrated solution of sulphite of soda, and add to the same one-half the weight of eikonogen to be so treated. If the solution is alkaline, it is neutralised and made to boil in a glass flask. After this the rest of the eikonogen is added, and the cooking is continued until the eikonogen is completely dissolved, or nearly so. In the beginning only enough liquid should be taken to make the solution saturated; it is also good if a little of the eikonogen remains undissolved. The proportion may, for instance, be 500 c.c. sulphite solution to 90 to 100 grams of eikonogen. The solution is then cooled off quickly by stirring it with a glass rod to accelerate crystallisation. A powdery deposit will form, from which the coloured liquid can be separated by decanting. This deposit is finally washed with cold alcohol, and dried at a moderate heat.

In this manner an almost colourless product is obtained, which is applicable again for developing solutions. For the practical photographer this process is somewhat complicated. We recommend, therefore, a trial of the following method by A. Pétry, which is much simpler :—

Dissolve the brown eikonogen cold or with application of heat in the proportion of 20 grams to 500 c.c. of ordinary water. If warm water is used the solution should cool off. On the other hand, dissolve 50 grams tartaric acid in 1 litre of ordinary water. Of this solution take 150 c.c., and pour the same gradually (4 to 5 c.c. at once) into the eikonogen solution under continual stirring with a glass rod. The solution, which in the beginning is of a dirty dark-red colour, assumes gradually a garnet-red colour. It thickens very quickly, and has then the appearance of a slightly light pink-coloured paste. This is put into a glass funnel with a sufficiently large paper filter. The discharged water is of a more or less intensely red colour, according to whether the eikonogen was more or less changed. If a few cubic centimetres of the above tartaric acid solution are added to this liquid, it will darken and form a new precipitate, which is filtered. The precipitate is then washed several times with the rest of the tartaric acid solution, and left to drain. Finally, the filter paper is removed from the funnel, spread upon two or three sheets of blotting paper, and left to dry in an airy place, which should not be too light.

The whole operation is finished in thirty minutes, and all the apparatus necessary is generally in the possession of every photographer.

The dry deposit can be easily removed from the filter paper, and has the shape of fine scales of a pinkish colour, does not change in the open air, cannot be dissolved in water, but is easily soluble if sulphite of soda is added to the water. The crystallised scales are easily reduced to powder by a light pressure. To save time in making the developer the powder may be changed to pellets, each pill containing 1 grain powder.

Mr. Pétry calls this product oxidised eikonogen. The question whether it pays to change the original eikonogen with another product, he answers decidedly in the affirmative. It is not only, in case of need, practical, he says, but the oxidised eikonogen has also always the advantage of dissolving cold completely in water containing sulphite of soda, and that there is no weighing and no heating required by application of the same in the shape of pellets of a definite weight.

Pétry gives also the following developing solution :—

| | |
|---|---|
| Sulphite of soda (pure) ... ... ... | 30 grams |
| Oxide of eikonogen ... ... ... | 5 ,, |
| Carbonate of soda ... ... ... | 50 ,, |
| Water ... ... ... ... ... | 500 c.c. |

The sulphite of soda is first dissolved in water, the oxidised eikonogen is then added, and after it has dissolved, the carbonate of soda, reduced to a powder, is added. The bath, even in an open tray, should keep well for several days, and give well coloured negatives with good details. In case of necessity, a few drops of a 10 per cent. bromide of potassium solution may be added.

We remark, finally, that the above-mentioned precipitate can also be obtained with muriatic acid, sulphuric acid, and nitric acid, in place of the tartaric acid.—*Photographisches Archiv.*

---

The Photographic Club.—Wednesday, January 21st, "Photography" (American Slides); January 28th will be Annual Lantern and Musical Entertainment.

## THE CAMERA AND ITS VARIOUS MOTIONS.

BY PROFESSOR W. K. BURTON, C.E.

### Chapter V.—Hand Cameras, Stereoscopic Cameras.

One thing in which I find it possible to agree with Dr. Emerson is that the expression "detective camera" is an objectionable one, as applied to cameras intended to be put to the use that is made of cameras sold under that name. The idea that amateur photographers—or any photographer, for the matter of that—should go about taking photographs of people when these object to the operation—the idea distinctly conveyed in the term "detective photography"—is most offensive; but it should be borne in mind that, when the term "detective camera" was first applied, the idea was that cameras of the kind so described would actually be used by the detective force, and that this was the origin of the term.

As I have already said, there are such multitudes of hand-cameras at the present day—scarcely a week, apparently, passing but a new design is put on the market—that it would be impossible to describe them all. I, therefore, only say a word or two on general principles.

The hand-camera being a "one lens camera," it is scarcely possible to consider the camera entirely apart from the lens.

So much has recently been written of the advantages of long-focus lenses—long in relation to the size of the plate, that is—that it is not necessary to say more on the subject, but that the advantage holds good *at least* as much in the case of a hand-camera as in the case of others. The lens should also be capable of working at a large aperture; if possible, No. 2 of the U.S.

Of the various advantages of different details of construction of hand-cameras, the purchaser must be his own judge. There is scarcely any structural advantage that does not bring with it at least some little drawback, and it is often difficult to decide whether the advantage is gained at too great a price or not. To take an example or two. It is certainly an advantage to have a fairly large size of camera; but, with increase of size, there comes, besides increase in bulk and weight, very great increase in the optical difficulties met with, especially in the matter of reduced depth of focus, and the number of possible subjects is thus greatly diminished. The advantage of having the plates—a supply of, say, a dozen—within the body of the apparatus, instead of in separate dark slides, cannot be denied; but the weight, bulkiness, and complication of the apparatus are thereby of necessity increased. Finders are of undoubted use—in some cases, at least—but they add to the expense of the camera, if not to the weight and bulk.

One arrangement that will, I think, be quite generally admitted as peculiarly adapted to use with hand-cameras is the roll-holder, especially when filled with continuous rolls of the new celluloid films.

Such motions as vertical or horizontal swing-backs, sliding fronts, &c., are not, I think, at all necessary or desirable in the case of hand-cameras.

*Lenses of "Fixed Focus."*—This is a matter that has been considerably discussed of late, and that deserves a word or two. The term "fixed focus," as applied to a lens, in as far as it has any meaning at all, means that all planes of any subject likely to be photographed with it will be in focus without adjusting the distance between the lens and ground glass, or, in other words, without focussing; and farther, to all intents and purposes, in connection with hand-camera work, it means that the lens should display these properties whilst working with a large angular aperture—say $f/8$ at least.

Strictly speaking, this property does not exist at all; but, in the case of some lenses, so near an approach to it exists that none of the planes in any subject likely to be photographed will be perceptibly, or at least offensively, out of focus. A mistake, however, that seems sometimes to be made, is to suppose that the qualified "fixed focus" that I now describe can be got by the adoption of some particular *form* of lens, whereas it depends *solely* on the focal length and the aperture.

In a communication on "Depth of Focus" that I sent to the PHOTOGRAPHIC NEWS some time ago, the optical part of this question was fully discussed. Here I shall only give a short description of the way in which a hand-camera should be adjusted so as to get the best effect with a fixed focus.

A distant object should be focussed for, and the camera should then be extended till it is seen that this distant object is just out of focus, or, if the full aperture of the lens be $f/8$, as it most commonly is, the camera should be extended $\frac{1}{50}$th to $\frac{1}{32}$th of an inch beyond the position of best focus.

To give an idea of the practical result of adjusting a camera in this way, I may give the following figures; taking a set of lenses such as are likely to be used for hand-cameras, the assumption being that all are used at $f/8$.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| With a focus of | 4 ins., | the object | in best focus | will be | about | 17 | ft. dist. |
| ,, | 5 | ,, | ,, | ,, | ,, | 26 | ,, |
| ,, | 6 | ,, | ,, | ,, | ,, | 38 | ,, |
| ,, | 7 | ,, | ,, | ,, | ,, | 52 | ,, |
| ,, | 8 | ,, | ,, | ,, | ,, | 67 | ,, |
| ,, | 10 | ,, | ,, | ,, | ,, | 100 | ,, |

Whilst objects at *half* these distances will be only just perceptibly out of focus from being too near the camera. It may be said, roughly, that no adjustment is needed for quarter-plate cameras; that adjustment is not needed in the case of 5 by 4 cameras, for the majority of work; and that a very considerable deal of work might be done, even with half-plate cameras, without adjustment.

It is to be noted that there is no necessity for achromatisation in the case of lenses used with fixed focus, if an adjustment of the camera be made corresponding with the difference of the visual focus, and of the focus of the chemical rays.

A deal of ingenuity has been spent in so designing hand-cameras that the fact that they *are* photographic gear is concealed. They are made in the form of boxes, hand-bags, parcels; like watches, to go within the waistcoat, the lens protruding through a button-hole; and in a multitude of other forms besides. There can be no doubt that this concealment may be useful for some kinds of work, although it always gives rise to suspicion of that kind of *detective* work that was condemned at the beginning of this chapter; but it is surprising how much the greater part of the work commonly done by hand-cameras, specially made, can be done with an ordinary small camera of the best make, with a good lens and instantaneous shutter. All that is necessary is to know that everything is *absolutely* light-tight. In exposing, the camera is held in the hand, and "aiming" may be done by any simple sighting arrangement fixed to the camera, or even by looking along one of the edges of the baseboard. As an example of the way in which a common camera may be used for hand work, I may be allowed to describe the arrangement I use myself. This is simply a quarter-plate camera of what I consider the best English make, with a rectilinear lens working at a maximum aperture of No. 2 U. S. (a little more than $f/6$). The camera was first of all adjusted in the following way: A distant object was focussed with the greatest sharpness under an eye-piece. and from the position of the camera thus fixed, the lens was racked out $\frac{1}{16}$ inch. A peg was fixed so that, without removing it, this was the farthest that the camera could be racked in. The camera is now so adjusted that, used with the full aperture of the lens, the distance will be just perceptibly out of focus—an object at a distance of about fifty feet will be in the sharpest focus (the focal length of the lens being about six inches), and everything up to within a little more than twenty feet off will be in at least fairly good focus.

A set of marks have also been made so that, with smaller stops, by adjusting to the different marks, the condition of always having the distance just a little out of focus shall be fulfilled. The marks are made so that the lens is racked out from the position of sharpest focus for a distant object, the following distances for the following stops. The list includes the full aperture, No. 2, already mentioned:—

| | | | | | | |
|---|---|---|---|---|---|---|
| For No. 2, $\frac{1}{16}$ inch | when an object about | 50 ft. off | will be in best focus and one | 25 ft. off | will still be in fair focus. |
| ,, No. 4, $\frac{1}{25}$ ,, | ,, | 38 ,, | ,, | 19 ,, | ,, |
| ,, No. 8, $\frac{1}{8}$ ,, | ,, | 25 ,, | ,, | 13 ,, | ,, |
| ,, No. 16, $\frac{1}{8}$ ,, | ,, | 19 ,, | ,, | 10 ,, | ,, |
| ,, No. 32, $\frac{1}{4}$ ,, | ,, | 13 ,, | ,, | 7 ,, | ,, |

*Stereoscopic Cameras.*—I entered—if not fully, at least sufficiently to give a general idea of the subject—into stereoscopy generally in the series of articles on optics that I communicated to the PHOTOGRAPHIC NEWS some time ago, and almost anything that I could say here would be little more than repetition of what I said before.

The greatest distance commonly met with between the human eyes is about $2\frac{3}{4}$ ins., and theoretically there should be no greater distance than this between the lenses of a stereoscopic camera, and the length of the plate should be limited to $5\frac{1}{2}$ inches. In practice, however, a larger size than this is always used, the lenses being correspondingly separated. The largest size of plate, so far as I know, ever used with the common stereoscopic camera is 8 by 5, involving a distance of four inches between the lenses. I think, however, that such a distance should be avoided, as, at least in the case of any near objects being included, an effect of exaggerated stereoscopy is liable to be produced; 7 by 5 inches is a better size, and $6\frac{1}{2}$ by $4\frac{3}{4}$, or $6\frac{1}{2}$ by $4\frac{1}{4}$, probably better still.

Many stereoscopic cameras are so made that, removing a central division, and substituting a front with one lens flange for that with two, the camera can be used for ordinary photography on the whole size of the plate.

In doing stereoscopic work with modern dry plates, a shutter for giving an exposure simultaneously with both lenses is almost an essential, and this shutter should be capable of giving a "time" as well as an instantaneous exposure, otherwise, in addition, a flap uncovering and covering both lenses simultaneously will be needed for giving exposures of from, say, half a second upwards.

---

WHITE mackintosh with a matt surface is proposed as a screen for the lantern; its chief advantages are its opacity, thinness, and freedom from liability to crack when rolled,

## A NEW HAND CAMERA.

Messrs. Mawson & Swan have exhibited to us a new hand-camera of Dutch origin, manufactured by Messrs. Loman & Co., of Amsterdam, and which possesses two leading features, one of which is that the theoretically excellent roller blind shutter next the plate is employed, and the other is that the image to be photographed is seen of full size and in sharp focus the instant before making the exposure. Variations of focus can be made by the aid of the ground glass screen.

The camera is made in different forms, the simplest of which is pictured in fig. 1. A plane mirror, not shown in the cut, normally rests at an angle of 45°, and reflects on to the ground glass at the top in the old camera-obscura fashion. It has also one of the old-fashioned shades which, when not in use, lies flatly on the top of the ground glass.

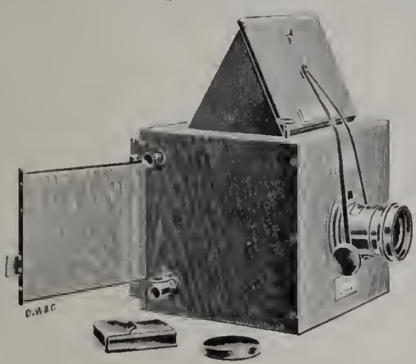

*Fig.* 1.

When the image is in true focus upon the screen, it is in equally true focus on the plate when the mirror is removed. The roller-shutter behind the mirror can be set to any speed. The lens, in the camera of this pattern, is a rapid rectilinear, fitted with rack-and-pinion.

Fig. 2 represents a camera of the same class, but more expensively finished. The lens is inside, and works at *f* 5·6, and we are told that it gives good definition even at this aperture, and, as it has an iris diaphragm, smaller apertures can be used if required. The instruments are worth examination by those who are selecting a hand-camera, and they present some features which are theoretically good, and should be of practical value.

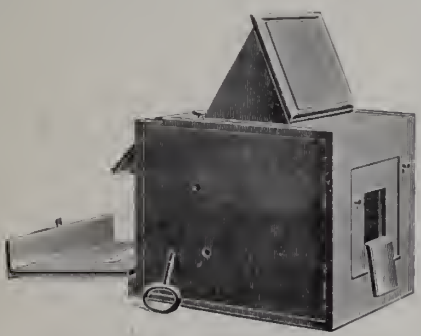

*Fig.* 2.

Reproduction of Positives in Original Size.—When the bellows of the camera which we have at our disposal does not give us the required size, one may proceed as follows: Place in the pressure-frame an ordinary gelatino-bromide dry plate, then immediately the original on top, so that the image be in direct contact with the sensitive film. It goes without saying that if the print has been stuck on a mount it must be removed from it. Place over the whole another glass plate, then expose in such a manner that the light only reaches the sensitive plate after having passed through the glass and the print. The exposure lasts in diffused light from one-half second to five seconds. The negative is developed as usual, and we obtain a perfectly sharp reproduction without a shadow of granulation, as might be feared, on account of the interposition of the paper.—*Der Amateur Photograph.*

## MOULDING PHOTOGRAPHIC LENSES.

A communication from the Glastechnisches Laboratorium, Schott and Gen., in Jena, published in the *American Journal of Photography*, deals with the influence of the process of cooling upon the optical properties of glass, and the production of pressed lenses in a thoroughly annealed state, and says that the very imperfect state of annealing generally met with in the glass-discs for larger telescopes formed for years a constant source of complaint from opticians who, in the manufacture of large-sized lenses, are working strictly spherical surfaces. For this and other reasons, it has been our aim ever since the erection of our works to improve the process of annealing. The method hitherto in use, viz., that of allowing the temperature of the red-hot glass to fall in a kiln completely enclosed by brick-work, which gradually transmits the heat stored up in it to the surrounding atmosphere, has been discontinued by us in all cases where high optical properties are aimed at, and in its place we adopted the plan of storing the glass in a vessel the temperature of which may be accurately measured, and subjected to a very slow and strictly uniform decrease, the duration of which may be adjusted to suit special requirements.

The experimental researches which formed the necessary predecessors of our new process of annealing, offered ample opportunity for minutely studying the influence of internal strains and pressures upon the optical properties of the glass. We intend to treat *in extenso* on this subject at a later date; here it may suffice to mention the most important of those results which will interest practical opticians:

1. Any kind of glass becomes strained—*i.e.*, the molecules of the glass are subjected to tension—unless the process of solidification be extended over a very long period.

2. The refractive index of one and the same piece of the glass varies according to the duration of the process of annealing; this diversity may extend to several units of the third decimal place.

3. If a lens or circular disc, on being carefully examined by means of polarised light, be found to yield a regular black cross, which remains perfectly free from any distortion during a complete rotation of the disc about the optic axis, it may be inferred that the tension is strictly regular throughout the entire piece of glass under examination. The presence of a moderate tension of this kind has no other effect as if there were a slight gradual diminution of the refractive index in the direction of of the axis. Owing to the symmetrical arrangement of the tensions round the axis, they do not exercise any detrimental influence on the image.

4. If, however, a lens or circular disc, while being turned round its axis under examination in polarised light, show in any one or several positions a displaced black cross or any other irregular figure, the tensions must be considered to be irregular. The influence of such tensions dissymmetrically grouped round the axis is identical to that of a difference of the refractive power in different parts of the lens. Glasses of this kind should never be employed for the manufacture of large-sized objectives. With telescopic lenses made of glass where this defect existed in a moderate degree, many opticians attempt to compensate this differentiation of refraction by introducing at random deviations from strictly

spherical surfaces through polishing, with the result of thus obtaining pretty satisfactory images.

By means of our method of annealing, we have succeeded in producing discs for object-lenses having a diameter up to 35cm. nearly perfectly free from tension ; the entire surface of the disc being made to become efficient under the polaroscope. All that is necessary during the test is to exclude any differences of temperature of the discs, as these are apt to give rise to temporary tensions. Nearly all discs annealed according to the older system show the distinct black crosses characterizing the presence of strain and pressure, even in those cases where the diameter of the discs does not exceed 2 cm.

Though it must be admitted that many opticians, before grinding large-sized lenses for telescopes, will ascertain the properties of the glass with respect to annealing, yet we know from experience that there is considerable inclination to underrate the serious effects of tension, and that many go so far as to consider examination before or after making a lens hardly worth the trouble.

We append to these lines a sketch of an apparatus, the principle of which is due to Prof. Mach, of Prag, which may be readily put up, and by means of which plane plates (fig. 2) or positive lenses (fig 1) may be tested. The apparatus must be adjusted in such a manner that with parallel nicol prisms the eye at $E$ sees the lens or disc to be tested fully illuminated ; if now the nicol prisms be crossed, total extinction will take place with glasses having no internal tensions, whereas with imperfectly annealed glasses the well-known figures indicative of tension will present themselves.

In order to examine the figures due to strain or pressure in all positions of the prism with respect of the disc of glass, it will be found advantageous to turn both prisms synchronically rather than to turn the discs themselves, as these, owing to the touch of the warm hand, may become locally heated.

In order to better distinguish the present new method of annealing from that hitherto in use—raw annealing—we have introduced the term "fine annealing" when referring to the former.

Our experiments and improvements made with regard to the process of glass-annealing, have induced us to adopt for our fabrication the well-known plan, worked in Paris for many years, of moulding the glass by means of pressing it while in a semi-liquid state between metal cups having as nearly as possible the same curvatures as the lens. Lenses produced in this manner are utterly useless for application in better class instruments if the ordinary quick process of annealing be employed, as the internal strain in the glass will generally be very great, and sometimes may become so excessive as to cause the rough lens to fly into small pieces as soon as an attempt is made to grind it. However, with our new method of annealing, which permits of annealing at such low temperatures as to put deformations out of the question, ready means are furnished to produce lenses of this kind entirely free from internal strains by subjecting them, after having allowed them to cool down, to a second process of annealing in the above mentioned apparatus.

Wishing to remove a prejudice held by many opticians, we will not omit to distinctly state that the pressure exerted on the glass while in a semi-liquid state is by no means the cause of internal strain or pressure ; on the contrary, the only source of these must be looked for in the accelerated process of chilling which has to be made use of in order to prevent deformation.

The favourable practical results obtained by many opticians with glass prepared in this manner encourage us to recommend its application for all such cases where large numbers of lenses of the same kind have to be made with various curvatures and diameters within the limits between 12 to 120 mm. The increased costs of glass prepared in this manner are amply compensated for by the saving of material and work. Lenses having the exact form of the desired lenses suffice as patterns. On account of the prolonged period of annealing, we require, as a rule, a term for delivery from six to eight weeks. We are prepared to submit sample lenses to our customers.

*Fig.* 2.

$A$ Illuminating source (bright-burning petroleum flame).
$B$ Polarising nicol prism.
$C$ Lens or disc to be tested.
$D$ Analysing prism.
$E$ The observer's eye.
$S$ Concave mirror.

In fig. 1 $A$ and $B$ are conjugative points with respect to the lens $C$ ; in fig. 2 both points are situated in the plane of the centre of curvature of the mirror $S$.

---

EIKONOGEN DEVELOPMENT.—According to a recent communication of M. L. Jullien, photographer, of Geneva, the best process for development is the following : Place for a minute the exposed plate in the carbonate of soda bath or the carbonate of potash bath, withdraw it and plunge it in a bath containing the eikonogen and the sulphite. The carbonate of soda enters into the pores of the gelatine, and the quantity contained in them on coming from the first bath is more than sufficient to facilitate the reduction. This method gives good results, it seems—better than any hitherto obtained.—*Revue Suisse de Phot.*

AMERICAN PHOTOGRAPHERS AND TARIFFS.—Photographers have all learned of the new "Tariff Bill," and the majority have become informed by their enterprising stock-dealers of the increase of price of some of the principal staples used in the production of photographs. At first sight—"in these times when the prices for photographs are so ruinously low"—all this appears rather dismaying to the average photographer. It need *not* dismay him, however, unless he wills that it should do so. There is a bright side to it all, and he can gradually and surely work over to it if he wants to. For a long time there has been a continuous howl about "rough competition" and "cut rates." Now, the first step over to the bright side, after you begin to believe there is one, is to ignore the competition and raise the rates. Two good advances are thus made. We do not advocate a large advance in prices. If fifty cents per dozen were added all over the country, it would secure more than double enough to pay the "extra tariff" on albumen paper, nitrate of silver, eikonogen, and so on. Then you could stop "howling," for there would be nothing left to howl about. It is true your patrons would howl a little, but—let 'em. They will soon stop, provided you keep a neat establishment, work alongside of the growth of your art, pay for your *Magazine* promptly for 1891, and make the best of work.—*Wilson's Photographic Magazine.*

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

FRENCH PHOTOGRAPHIC SOCIETY—DEVELOPING PASTILLES—CLOTH BACKGROUND—LENSES BY ZEISS—EXPOSURE SHUTTERS—IRIS DIAPHRAGMS—PRINTS BY THE ARTIGUES PROCESS—LANTERN IMAGES—SYNDICATE OF PHOTOGRAPHY—PROPERTY IN PHOTOGRAPHIC PRODUCTIONS—PHOTOGRAPHIC INSTRUCTION—EXPOSURE METER—CHLORIDE OF SILVER PAPER AND CELLOIDINE—BIBLIOGRAPHY.

*Developing Pastilles.*—M. Pétry, of Bar-sur-Seine (Aube), has sent to the Society some developing pastilles, the composition of which has not been disclosed. This is the fourth or fifth time that a photographic medicament of this kind has been produced. Many persons have remarked that products which are of a dangerous nature ought not to be presented in this form. They resemble bon-bons, which might tempt the appetite of children who stray into the laboratory. Care must, therefore, be taken to keep in safety pastilles which are destined for quite other purposes than that of medicine or of satisfying the palate.

*Cloth Background.*—A manufacturer sends a sample of cloth for photographic backgrounds, shaded from black to white in the fabric itself. It may be good, but I prefer the natural shading produced by a plain ground arranged on a curved frame.

*Lenses by Zeiss.*—M. Fabre has written a paper in favour of the new lenses by Zeiss, made with the Jena glass of a highly refractive kind. The lenses tried by him possess exceptional properties, which, he says, have not been shown by any lenses of other makers. There are notably two wide-angle objectives of great rapidity, the one embracing an angle of 100°, and the other of 110°. The facts stated are extremely curious, and merit attention; but as the conclusions arrived at have alone been given, I defer farther remark until the complete experiments are made known.

*Various Exposure Shutters.*—M. Balagny showed a triplex exposure shutter of American origin, of which he speaks very highly on account of its ingenious mechanism, which allows one to expose at will, by the simple pressure of the rubber ball, without having to reset the spring. We can, at will, give either an instantaneous or a timed exposure. Messrs. Marilier and Robelet also showed a new model shutter of Parisian creation, the working of which appeared to be very smooth. The system is that of Levêque and Harlé. The number of instantaneous shutters is already considerable, but the imaginations of inventors in this direction are far from having come to an end.

*Iris Diaphragm.*—M. Gravier, in the names of Messrs. Clement and Gilmer, showed a circular plate with iris diaphragm ready to be mounted in a photographic tube. It is well combined, and capable of realising any diameter of diaphragm that may be required.

*Prints by the Artigues Process.*—The same member exhibited prints obtained by the carbon process of M. Artigues, which was mentioned in the letter published in the PHOTOGRAPHIC NEWS of 1889, p. 517. This very interesting process has since remained *in statu quo.* It has been in vain to apply to M. Artigues for samples of the paper with which to try it. We ought, however, to be able to derive benefit from a method which gives such remarkable results as those which were placed before the meeting. M. Gravier's only object in bringing up again the work of M. Artigues has been to rouse him, if possible, from torpor. We have already expressed our view of the proceedings necessary for trying M. Artigues' method. A thin film of gelatine is coated upon paper, and, as soon as set, it is sprinkled with black powder. It is allowed to dry, and then bichromated. Development is effected, as M. Artigues informed us, by mixing sawdust with the hot water used for the purpose, and by pouring this mixture on to the sheet placed in a vertical position. The possible applications of this process to photogravure appear to me particularly interesting.

*Lantern Slides.*—M. Balagny has made a journey in Switzerland, during which he has executed a number of pellicular negatives of large size, reductions from which, admirably prepared, were shown in the lantern. The charming journey from Lucerne to the Engadine was made without any fatigue: nothing but the gratification of the eyes. This fine series of lantern projections is certainly one of the most remarkable that has ever been shown to the Society.

*General Syndicate of Photography.*—The question of property in photographic productions crops up afresh. The projected law only endows owners with a proprietary right for twenty-five years—a considerable difference from that of fifty years after the death of the author accorded to drawings, engravings, and lithographs. This inequality may cause much confusion and great injury; the general syndicate, therefore, is endeavouring to obtain a legal assimilation of photography to the other graphic arts. Active steps in this direction have been taken by means of representations to the deputies.

*Photographic Instruction.*—There being, in France, an almost complete absence of photographic instruction, the syndicate is occupied with the subject, and watches closely the efforts made in England towards the creation of a photographic institute. It is seeking a way to stimulate a movement of a similar character in Paris, but that will be a difficult matter.

*Watkins' Exposure Meter.*—The president presented to the syndicate the exposure meter of Watkins. It was described, and the advantages offered by this ingenious instrument were explained. It constitutes a sure guide as to the length of exposure in difficult cases, where the appreciation by the eye puts the most experienced judgment at fault. This photometer, so complete in its form and in its combinations, was examined with interest.

*Chloride of Silver Paper and Celloidine.*—Another interesting presentation was that of paper and celloidine by M. Engel Feitknecht, of Douanne, Switzerland. The paper, prepared with collodio-chloride of silver, is rapid, and gives fine impressions. Toning and fixing are carried on simultaneously in a bath the formula for which is given by the maker. Eight to ten minutes suffice for the operation. Prints thus obtained should have greater permanency than those on albumenised paper.

*Bibliography.*—Amongst the recent photographic publications, we may mention "Photographic Recreations," by Messrs. Bergeret and Drouin. This work is an interesting collection of a host of *tours de main*, revealing the manner of achieving certain results, of which examples have been seen or heard, without its being known how they were accomplished. Thanks to "Photographic Recreations," we may amuse ourselves considerably, and get out of the monotony which is offered by work alone. There is a host of descriptions for the production of an infinity of pleasant surprises.

## Notes.

*Nature*, a journal which has considerable influence in the world of science, is now rendering good service to the general public by calling attention to the filthy air of London, the dirt in which consists chiefly of unburnt and wasted fuel. One correspondent suggests that the different scientific societies of London should take up the subject, and bring their influence to bear either upon the Government or the County Council, in the endeavour to get them to take steps to abolish the nuisance. Photographers are more affected than others by the dirt in the air, because of the large amount of daylight it cuts off. The inert masses of the public are slow to move in the abolition of old-established nuisances, which, by force of long familiarity, almost come to be looked upon as valuable property, so initiatory steps in the direction of improvement are more likely to come from above than from below. Probably commercial profit could be made by a public company which would supply and fix rational household grates in place of the ignorantly devised grates put into houses by jerry-builders, and would arrange with the householder that they shall be paid for gradually out of the money they will save in the consumption of coal. At present about three-quarters of the heat produced in common household grates escapes up the chimney, and it is probably safe to assume that in London more than twice as much coal is burnt for house-warming purposes than would be necessary with an intelligent system of consumption.

This month the Swiss *Revue de Photographie* has entered upon the third year of its existence; it is an excellent periodical. The January number contains some good illustrations, one of them a photo-mechanical print by Messrs. Thevoz & Co., of Geneva, a comparatively young firm, but one which has made rapid progress in the quality of its productions. A chromophototype by Mr. J. Brunner, of Winterthur, is pretty, representing a little girl playing with a bird; some grass in the picture is of rather too gaudy a green to appear quite natural. From the *Revue* we learn that the Geneva Photographic Society has seventy-eight members, and that, during the past year, a rule was altered in order to admit ladies. The same journal quotes some particulars about the diazotype processes from our pages; it also suggests that a general meeting of Swiss photographers shall take place in Lausanne in March or April next.

Photographic exhibitions are multiplying abroad as well as at home. One under the auspices of the Photographic Society of Nantes will open at the Préaubert Gallery, rue Le Kain, in that city, on the 25th of this month, and will close on the 25th February; it will be devoted chiefly, if not entirely, to the artistic side of photography. A French exhibition will open in Moscow on the 15th of October next, and in it Class VI. will be devoted to photography. An International Exhibition will be open in Bordeaux from May 1st next to November 5th. The first group, Class III., includes photographs and photographic apparatus.

Those aggressively healthy persons who despise great coats, who break the ice before entering their morning bath, and who for years have been complaining that we never have an "old-fashioned Christmas now," have had, this year, we think, enough and to spare of discomforting weather. For many weeks Jack Frost has now had undisputed sway, and, in London at least, has been helped to make things generally disagreeable by the smoke-fog fiend. Photographers especially have suffered in their business from this dreadful partnership, and complaints are heard from all sides of the utter impossibility of doing any kind of work. One large firm of carbon printers, who depend upon solar light, tell us that for fifteen days their hands were idle. Others are stopped for want of clients, for even the electric light will not charm sitters out of doors in this dreadful weather. Burst water-pipes represent another minor inconvenience that affects photographers more than other folk, and make them fancy that January is certainly not "the happiest month of all the glad new year."

While most persons have been abusing the snow, and the vestries for not carting it away from our thoroughfares, one lady of scientific proclivities writes to the *Times*, and calls attention to its beauty. She sings of snow falling "in stellar forms of infinite and indescribable beauty," and quotes Tyndall as follows: "In the polar regions these exquisite forms were observed by Dr. Scoresby, who gave numerous drawings of them. I have observed them in mid-winter filling the air, and loading the slopes of the Alps; but in England they are also to be seen, and no words of mine could convey so vivid an impression of their beauty as the annexed drawings of a few of them executed at Greenwich by Mr. Glaisher."

This mention of a well-known phenomenon will doubtless excite the energy of some enthusiastic photographer, who will endeavour to fix with his camera these beauteous forms. We must own that we have tried to do so, but have failed. We employed a half-inch microscopic objective attached to the camera front, and a bed of black velvet to catch the falling snow flakes. It is true that we caught several, but they all seemed determined to stick up edgeways, and it was impossible to get any one of them to lie flat enough for our purpose. They also insisted upon partially melting before we had done with them. We shall be glad to hear from any of our readers who have had better success than we have. So far as we are aware, the beautiful six-rayed stars of which snowflakes are made up have never yet been successfully photographed.

The French paper *l'Illustration* publishes some pictures descriptive of a scheme which has been revived for journeying towards the North Pole by means of a balloon. Of these pictures, one shows the balloon serenely sailing away over the ice hummocks with a heavy trailing rope to keep it at a fixed altitude, while another depicts the interior of the car. This is a kind of Noah's ark, for two compartments contain sundry animals, another forms the living room of the aëronauts, while the the third is a photographic dark room, with a hole in the floor, down which points a camera. There certainly would not be much to photograph with this vertical position of the camera, for one hummock is much like another, and there is not much variety in the character of ice floes. But everything looks very nice and snug in the pictures, and a journey to the North Pole, on paper, in this form, is evidently a thing to hanker after. The enterprise is, however, fraught with a few difficulties. The polar regions are, travellers tell us, almost without wind, and thus the motive power upon which the travellers depend would be absent. Ballooning schemes have always had a fascination for the French, possibly because the balloon is of French origin. A word is wanted to describe those enthusiasts who believe in the possibility of controlling them. How would *balloonatics* do?

---

It is a pity that journalists, when writing on photography, do not take the trouble to make inquiries before putting their opinions on paper. For want of this precaution, we get such a statement as the following:—"The preposterous charges which photographers have been wont to make for reproductions of still-life objects—including such articles as statuary, medals, book-plates, &c.—seem likely to be on the verge of breaking down. There is now such an army of amateur workers who know what the actual cost out of pocket of photography is, that everybody's eyes have been opened to the excessiveness of the charges." The reason why the writer has arrived at the above conclusion, is simply because the University Press at Oxford announces that it is prepared to hand over one hundred collotypes—prints from a whole-plate negative—for 12s., the original cost of the negative being 3s. What connection there is between a trading concern which goes in for photography on a large scale, and a private photographer who is engaged to photograph "still-life objects," it is difficult to see. The two transactions are conducted on a totally different basis.

---

It is surely no novelty to be told that collotype prints can be produced at a cheap rate. This is a matter of common knowledge and common experience. As for the amateurs opening the eyes of everybody to the excessiveness of the charges of professional photographers, this is a question which, in order to deal with adequately, demands more space than can be afforded here. The proposition that a dry plate costs so much, developers so much, fixing solution so much, that, therefore, the photograph should be such-and-such a sum, is equivalent to saying of one of Sir John Millais' pictures, that the paint-brushes cost this sum, the paints that sum, the canvas so many shillings, the frame possibly so many pounds, and that, consequently, Sir John Millais should be contented with a modest profit—say a certain amount for his time, and, possibly, 15 per cent. on his outlay for materials. The question of brains appears to have been left out of consideration altogether.

---

The writer winds up with this conclusion:—"At present hundreds of collectors, with thousands of objects, only await the time when photographers will condescend to recognize the fact that inanimate and animate objects do not present the same difficulties, and so should not be charged upon the same scale, to put an enormous amount of business into their hands." In answer to this, one has only to reply that if there is a sufficient amount of work to keep a photographer fully employed, there is not the slightest difficulty in obtaining scores of capable men who will do the work at a price which will enable the public to obtain reproductions of works of art at a moderate rate. But, as everybody who is at all acquainted with the subject knows, the photographer is not the man who is responsible for these vast undertakings. He is simply the man who does the work; somebody else engineers the business, and somebody else performs the office of middleman in supplying the public with the prints. It is not the photographer who gets the lion's share of the profit. In many cases, considering the uncertainties which the most experienced photographer cannot guard against, the result to the responsible man has been a loss rather than a gain.

---

Mr. Henry N. Stevens, the son of the famous book-collector, Mr. Henry Stevens, of Vermont, points out an interesting use of photography. He says that his father was in the habit of photographing the titles of rare books, and by this means he frequently became aware of the existence of unknown editions. It is a matter of common knowledge that the slightest variation in the printing of an early edition of rarities gives the particular volume an enhanced value in the eyes of bibliophiles. Mr. Stevens used to find that, by photographing one particular edition (for he not only photographed titles, but sometimes whole pages of the book, and even the book itself), that he was able to detect minute differences in the type, and to unearth all manner of curiosities dear to the heart of the book-collector. Mr. H. N. Stevens says that one of his own finds, on which he sets great store, was due entirely to his possessing a photograph of a rarity, which, on comparing with the copy of a book offered for sale at an auction, disclosed to him the fact that the latter was of an unknown edition, and he was, therefore, enabled to carry it off unsuspected under the eyes and noses of a *cognoscenti*, to his own considerable profit. From this it would be seen that troublesome and costly though the process of photographing a volume may be, still, looking at it practically, and in a pecuniary light, it pays.

## ERYTHROSIN SILVER.

BY J. GAEDICKE.

THE extended application of erythrosin silver for the production of orthochromatic plates justifies the practical importance of an investigation concerning the conditions under which erythrosin will precipitate nitrate of silver. The investigation of these conditions has shown that it is by no means indifferent whether the nitrate of silver is poured into the erythrosin solution, or the erythrosin solution into the nitrate of silver solution. To determine the conditions under which these two bodies precipitate, two filtered solutions were produced, namely :—

1st. An aqueous tenth-normal nitrate of silver solution, which in 1 c.c. contained 0·017 grm. nitrate of silver.

2nd. An erythrosin solution in 1 part of water and 3 parts alcohol, which in 1 c.c. contained 0·002 grm. erythrosin.

With these solutions the following two tests, A and B, were made :

A.—1 c.c. tenth-normal nitrate of silver solution was diluted a little with alcohol and gradually mixed with the above erythrosin solution until precipitation ceased and the erythrosin was slightly in excess. The limit of reaction was discovered by placing a drop of the liquid upon white blotting-paper. The red precipitate of erythrosin and silver remains as a red circle, surrounded by a moist halo. As long as the erythrosin is not in excess this halo will be colourless, but the least excess will give it a reddish tint. This appearance took place when 10 c.c. erythrosin solution had been added. Therefore 20 parts erythrosin had precipitated 17 parts nitrate of silver. But the precipitate thus formed was found able to precipitate still more nitrate of silver. To determine the limit of this reaction, the precipitate was mixed with a tenth-normal nitrate of silver solution, shaken, left standing for a little while, and then tested. This was continued until a weak excess of nitrate of silver could be proven. The test was made in such a way that a drop of the liquid put upon white blotting-paper, and the halo forming around the red circle were touched with a solution of ammonium chromate. As long as the halo coloured yellow no excess of silver was present, and the first indication of such was when the halo became brownish-red by the reaction. This took place after 1 c.c. nitrate of silver solution had been used. The erythrosin silver had therefore subsequently absorbed just as much silver as it contained already. The precipitate had therefore united 2 by 17 = 34 parts of nitrate of silver and 20 parts of erythrosin.

B.—Reversing the test, other figures were the result. 10 c.c. of erythrosin solution were mixed drop by drop with tenth-normal nitrate of silver solution, and the test made upon blotting paper until the halo was no longer pink, but colourless. The requirement for this was not 1 c.c. nitrate of silver solution as with A, but only 0·5 c.c. Here 20 parts erythrosin have therefore been precipitated completely by only 8·5 parts nitrate of silver. The erythrosin silver has therefore carried along just as much erythrosin as it contained thereof. The colourless liquid on top of the precipitate had a fluorescing green colour. The red precipitate absorbed still nitrate of silver, but much slower.

To produce the brown halo of chromate of silver, 1 c.c. nitrate of silver solution was required. In this arrangement of the test 20 parts erythrosin had therefore bound 25·5 nitrate of silver against 34 parts as with test A.

For the production of the richest erythrosin silver the following prescription results, therefore, from above tests. Dissolve 17 parts nitrate of silver, and pour into this liquid a solution of 20 parts erythrosin ; add after this another solution of 17 parts nitrate of silver, and let stand for several hours under frequent stirring; finally add a few drops of erythrosin solution.—*Photographisches Wochenblatt.*

## THE YELLOW SCREEN IN ORTHOCHROMATIC WORK.

BY LEON VIDAL.

MANY times and oft we have read or heard said that the use of a yellow screen greatly prolongs the time of exposure, and that it is necessary this screen should be but slightly coloured in order to render its use possible. We are desirous of assailing this error, which is caused by using ordinary plates. It is evident that, in this case, the exposure is greatly increased, and it is necessary, if recourse is had to a yellow screen, to diminish the activity of the blue and violet rays, to give a longer exposure. But this is not the case with orthoscopic plates sensitive to the yellow rays, such as eosine or erythrosine plates. These films, possessing great sensitiveness to the yellow rays, lose but little of their general sensitiveness on account of the interposition of a yellow screen between the subject to be reproduced and the plate. It is not necessary, therefore, to expose more than from two to four or six times, according as the coloured screen is more or less rich in colour. Now, if we consider that the times of exposure are, in normal white light, of a few fractions of a second, or of some seconds at most, we find but little objection to an increase of exposure which will require, instead of a half second, for example, one, four, or twelve seconds.

We have been enabled to make instantaneous prints on orthoscopic plates, correcting the too short exposure by a larger diaphragm, and we are convinced that, owing to the greater sensitiveness of plates treated by colouring substances, it will be possible to operate through coloured mediums just as well as with the ordinary plates. The use of smoked glass has been recommended to moderate the brilliancy of the sky and of the high whites. We see here simply a means of reducing the total activity, but not the partial activity, of any particular part of the view. Against the high whites the remedy is easy ; it will be found in an excess of exposure, and if a yellow screen be used, we will get at the same time a sufficient wiping-out of the blues.—*Le Moniteur de la Photographie.*

THE CHICAGO EXHIBITION, 1893.—A Reuter's telegram announces that President Harrison has issued a proclamation declaring that satisfactory proof has been presented to him that adequate grounds, buildings, and funds have been provided at Chicago for the Columbian Exhibition ; and he therefore declares that it will be opened on May 1st, 1893, and will not close before the last Thursday in the October following. The President, in the name of the Government and people of the United States, invites all the nations of the earth to take part in the commemoration of an event pre-eminent in human history, and of lasting interest to mankind, by appointing representatives at the Exhibition, and by sending such exhibits as may most fitly and fully illustrate their resources and industries, and the progress of civilisation.

## SOME HINTS ON PHOTO-MICROGRAPHY.*

BY T. CHARTERS WHITE.

It is not my intention to inflict on you a long dissertation on the subject of this evening's discussion, but merely to put my remarks in a more coherent form than I should by simply stating them in a conversational way; and in opening these I wish to direct your attention to one point in which I am personally interested, nor do I wish to claim for myself more than my fair share in the revival of the science of photo-micrography. Those who, like myself, are familiar with the progress of microscopical investigations, and have watched and followed their elucidations, have been familiar with the splendid work of Drs. Woodward and Draper in America, and Drs. Beale and Maddox in this country, done in former times. I am speaking now of between thirty and forty years ago, when work was accomplished which, for clearness of definition and amplification, cannot in our days of elaborate apparatus be surpassed, and that in the face of those physical difficulties which optical science has done little to overcome. These difficulties are with us to-day, and in the nature of things must ever continue. I fear it was the appearance of these difficulties which discouraged many in the practice of photo-micrography; nevertheless, others continued in the practice of what must be always a fascinating branch of photography, but whatever was done by different workers in it was not published during the last twenty years—at least, to my knowledge—and it seemed to have reached its ultimatum, and was well nigh dropped out of sight.

All who study histology must have felt, as I did, that the diagramatic engravings illustrating books on minute anatomy and of physiology very inadequately, if not incorrectly, represented the organs and tissues of which they treated, and from this dissatisfaction on my part I resolved to see if a more correct delineation could not be accomplished by photo-micrography. I therefore set to work, and, having only limited means—or if I had had the means, no suitable apparatus was, at that time, forthcoming—I made a very primitive, homely "rig up," for I can designate it by no other name, and succeeded so far that I showed my results to others whom I thought might be interested microscopically, who at first endeavoured to show me that it would never work; others had tried it and given it up as hopeless, but I did not coincide with their views, and, determined not to be deterred in my convictions, I persevered and produced more correct representations of tissues than found in any text books on histology extant at that time. My example and my results stimulated others to try what they could do, and by demonstrations and exhibition of my poor prints at different scientific societies, others were induced to take up the practice, infected by my example, and soon the revival was in full swing, till now the medical journals contain, in almost every issue, photographic representations of pathological specimens. So far, I am greatly satisfied with the progress made since my first paper on this subject appeared in the *British Journal of Photography* in 1883.

Photo-micrographs will henceforth give a more definite view of tissues than was ever the case before; they will, however, never supersede the microscope and microscopical observation, for however highly magnified, however clearly defined they may appear, none of them will stand examination with an ordinary magnifying glass; they can but indicate to the student the general appearances to be looked for, and will be fairly accurate representations drawn by the pencil of light, and free from any bias on the part of the draughtsman. They will also be accomplished in a much shorter time than can be done by the camera-lucida, besides containing also all the elaborations of the most complicated tissue, which fairly defies the capabilities of the most painstaking and careful draughtsman. To produce these results certain conditions must be observed, which experience on my part, as well as on that of others, has fully confirmed. Perhaps the most important is that the photo-micrographic apparatus must be absolutely steady, and free from the very slightest vibration.

There are very few houses in London or any other great town which are sufficiently stable not to be influenced by persons moving about in them, or that are not slightly shaken by tremors arising from the passing traffic, and therefore this tendency to vibration must be neutralised by selecting an operating room in the basement, on as solid a foundation as it is possible to procure. Next, the apparatus itself must be strongly constructed, that no unsteadiness exists in its constituent parts. It must be fixed on a firm base-board, so that whatever slight vibration may arise will be communicated uniformly throughout the whole system of light, microscope, and plate. The base-board must also be placed on some elastic support. Various devices have been adopted to accomplish this by different workers with whom I am familiar. One hangs his apparatus on strong india-rubber rings, suspended from strong iron supports let into the wall of his operating room. Another places blocks of india-rubber as feet under his base-board; others have put bags of cotton-wool under. I find that a bundle of journals placed under each end of the base-board, while firmly and steadily supporting it, serves to break any vibration that may arise, and, notwithstanding many sources of local disturbances, my results show very little, if any, evidence of vibration.

Having overcome this difficulty, the next disturbance may arise from another source. Light your lamp, and accurately focus your object, and let things remain for ten minutes; then look at your object. It will now appear blurred, and considerably out of focus. This arises from the expansion of all the metal parts of the apparatus from the heat of the lamp. Now focus your object again, and in another ten minutes examine it, when probably it may remain as sharp as when you first arranged it, and no further expansion will take place the rest of the evening.

The next precaution to be observed is that the light is accurately centred. This is most important, as upon this depends that freedom from diffraction without which it is hopeless to look for sharp definition. The plan to be adopted is simply to put on the microscope a low power objective—say a 1-inch or $1\frac{1}{4}$-inch focus—and if a diaphragm with a very small stop is attached to the condenser in the sub-stage, rack the microscope out till the image of the stop occupies the centre of the focussing screen. This may be done by altering the relative position of the lamp to the condenser, but is more perfectly done if the condenser has adjusting screws attached to it. I find that having done this with a low power, if that is superseded by one of a higher grade, such as a $\frac{1}{3}$ or $\frac{1}{5}$, the first centreing is only approximate, and a further adjustment is required, but this is more easily done, having had the previous rough adjustment. Too much attention cannot be

* Read at the Photographic Club, January 7th, 1891.

paid to this point, especially with the use of the higher powers, as any errors in illumination existing with the lower power would be exceedingly exaggerated when employing anything higher than a $\frac{1}{3}$ of an inch focus. In photographing with the lower power objectives, *i.e.*, from $1\frac{1}{2}$-inch down to 4-inch focus, a great evenness of illumination will be derived from the use of a ground-glass screen interposed between the lamp and the sub-stage condenser, the ground surface of the glass being placed next to subject to be photographed. This glass acts as a radiant, and serves to diffuse a soft, even light all over the field of view, without perceptibly increasing the length of the exposure. It is well to mention this, as many who may feel inclined to take up photo-micrography would do well to begin with low powers before proceeding to high power work.

Having attended to these three primary considerations, there remains one other which can only be overcome in two ways. I allude to the difference between the visual and actinic foci of the lenses. This difference exists to a greater extent in the lower powers, but also is found in those above $\frac{1}{6}$, but not in so marked a degree. I seldom use any objective lower than a $\frac{1}{3}$, but with this and upward I always find it advisable to withdraw the objective to a slight, *but very slight*, appearance of fuzziness after I have obtained the maximum of sharpness. Even then I cannot be always sure of my success; but, in the majority of cases, this will be found sufficient. The makers of some objectives for this work have corrected them for the actinic foci; this is especially remarkable in the apochromatic lenses constructed at the present day, and which, but for their high price, would be most invaluable to many in the practice of this art; and it makes one regret that the necessity for economy prevents the acquisition of such important appliances. Having, therefore, a steady apparatus free from vibration, a due regard for the expansion of the microscope by heat, a correctly centred beam of illumination, and a corrected objective, the practice of photo-micrography may be said to be reduced to the easiest conditions.

A few words might be said upon such subsidiary subjects as the proper preparation of the subjects to be submitted to this process, such as the flatness of the object and its proper staining; but as some specimens are to be passed through the lantern by way of illustration, the consideration of these subjects might be reserved for some future occasion. I will explain the slides as they are passed through, only asking you not to be hypercritical in your judgment, for I can truly say with Martial, "You cannot say harder things of my trifles than I have said myself of them."

A NEW APPLICATION OF THE MAGIC LANTERN.—A correspondent of the *Optical Lantern Journal* says:—"We are in the habit of utilizing the lime-light lantern in connection with advertising our numerous classes and entertainments, and hitherto written or printed slides have been used; the thought occurred to me that if I could write on a transparent gelatine paper by the typewriter it would look much neater and bolder on the sheet, which is fixed on the opposite side of the roadway to the lantern. The experiment was tried. I found the gelatine would not hold sufficient of the ordinary ribbon-ink, so that it was necessary to dust it over with powdered chalk before writing; the gelatine sheet was then mounted between glass in the ordinary manner, and the result was extremely satisfactory in every respect. The display required a little ingenuity to get it in the limited space, but it was, as expected, much bolder and clearer than the old method."

## ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

DURING the present century the aperture of the refracting telescope has increased enormously; the manufacture of the glass discs has been brought to a high state of perfection, particularly in France, where more attention is given to this manufacture than in any other country. Early in the century the great difficulty was in making the disc of flint glass. M. Guinand, a Swiss, beginning in 1784, succeeded in 1805 in getting discs of glass larger and finer than had been made before, and refractors grew larger and larger as the glass was made. In 1823 we have the Dorpat glass of 9·6 inches, the first large equatorial mounted with clock-work; in 1837 the 12-inch Munich glass; in 1839 the 15-inch at Harvard, and in 1847 another at Pulkowa; in 1863 Cooke finished the 25-inch refractor which Mr. Newall gave, shortly before his death last year, to the Cambridge University.

This telescope the University has accepted, and it is about to be removed to the Observatory at Cambridge, where it will be in charge of the Director, Dr. Adams. In accordance with the expressed wish of the late Mr. Newall, it will be devoted to a study of stellar and astronomical physics. There is every prospect that this will be properly done, as Mr. Frank Newall, one of the sons of the late Mr. Newall, has offered his personal services for five years in carrying on this work. Succeeding this we have the 26-inch telescope at Washington, the 26-inch at the University of Virginia, the 30-inch at Pulkowa, and the 36-inch lately erected at Mount Hamilton, California—all these latter by Alvan Clark and his sons. By Sir Howard Grubb we have many telescopes, including the 28-inch at Vienna. Most of these telescopes have been produced during the last twenty years, as well as quite a host of others of smaller sizes, including nearly a score of telescopes of about 13 inches diameter by various makers, to be employed in the construction of the photographic chart of the heavens, which it has been decided to do by international co-operation.

The first of these photographic instruments was made by the Brothers Henry, of the Paris Observatory, who have also made many very fine object glasses and specula, and, more important than all, have shown that plane mirrors of perfect flatness can be made of almost any size; the success of M. Lœwy's new telescope, the equatorial *coudé*, is entirely due to the marvellous perfection of the plane mirrors made by them. The reflecting telescope has quite kept pace with its elder brother.

Lassell, in 1820, began the grinding of mirrors; he, like Sir William Herschel, working through various sizes, finally completing one of 4 feet aperture, which was mounted equatorially. Lord Rosse also took up this work in 1840; he made two 3-foot specula, and in 1845 finished what yet remains the largest telescope, one of 6 feet aperture. All these were of speculum metal, and all on the Newtonian form. In 1870 Grubb completed for the Melbourne Observatory a telescope of 4 feet aperture, on the Cassegrain plan, the only large example. The mirror of this is of speculum metal. In 1856 it was proposed by Steinheil, and in 1857 by Foucault, to use glass as the material for the concave mirror, covering the surface with a fine deposit of metallic silver in the manner that had then just been perfected. In 1858 Draper, in America,

* Continued from page 13.

completed one on this plan of 15 inches aperture, soon after making another of 28 inches. In France several large ones have been made, including one of 4 feet at the Paris Observatory. In England this form of telescope is largely used, and mirrors up to 5 feet in diameter have been made and mounted equatorially.

Optically the astronomical telescope, particularly the refractor, has arrived at a splendid state of excellence; the purity of the glass discs and the perfection of the surfaces is proved at once by the performances of the various large telescopes. No limit has yet been set to the increase of size by the impossibility of getting discs of glass or working them, nor is it probable that the limit will be set by either of these considerations. We must rather look for our limiting conditions to the immense cost of mounting large glasses, and the absorption of light by the glass of which the lenses are made, coming injuriously into play to reduce the light-gathering power, though it will be probably a long time before this latter evil will be much felt.

With the reflecting telescope the greater attention given to the working and testing of the optical surface has enabled the concave mirror to be made with a certainty that the earlier workers never dreamed of. The examination of the surface can be made optically at the centre of curvature of the mirror in the manner that was used by Hadley in the beginning of the last century, and revived some years ago by Foucault, who brought this method of testing specula to a high degree of perfection; in fact, with the addition of certain methods of measuring the longitudinal aberrations, we have now a means of readily testing mirrors with a degree of accuracy that far exceeds the skill of the worker. It enables every change that is made in the surface during the progress of the figuring, as the parabolisation of the surface is called, to be watched and recorded, and the exact departure of any part from the theoretical form measured and corrected. Mirrors can be made of very much greater ratio of aperture to focal length; I have one here where the focal length is only 2¼ times the aperture; such a mirror in the days of speculum metal mirrors with the methods then in use, would have necessarily had a focal length of about 20 feet. The difference in curvature between the centre and edge of this mirror is so great that it can be easily measured by an ordinary spherometer, amounting, as it does, with one of six inches diameter, to $\frac{3}{10000}$ of an inch, an amount sufficient to make the focus of the outer portion about one inch longer than the inner when it is tested at the centre of curvature. The diagram on the wall, copied roughly from one of the records I keep of the progress of the work on a mirror during the figuring, shows how this system of measurements enables one to follow closely the whole operation.

The use of silver on glass as the reflecting surface is as important an improvement in the astronomical telescope as the invention of the achromatic telescope. It gives a permanency to a good figure once obtained that did not exist with the mirrors of speculum metal. To restore the surface of silver to the glass speculum is only a small matter now. How readily this is done may be seen by the practical illustration of the method I will give. I have here two liquids—one a solution of the oxide of silver, and another a reducing agent, the chief material in solution being sugar. I pour the two together in this vessel, the surface of which has been cleaned and kept wet by distilled water, which I shall partly empty, leaving the rest to mix with the two solutions; you will see in the course of about five minutes the silver begin to form, eventually covering the whole surface with a brilliant coating that can be polished on the outer surface as bright as that you will see through the glass.

Reflecting telescopes have advantages over the refracting telescopes in many ways, but in some respects they are not so good. They give images that are absolutely achromatic, while the other form always has some uncorrected colour. They can be made shorter, and, as the light-grasping power is not reduced by the absorption of the glass of which the lenses are made, it is in direct proportion to the surface or area of the mirror. They have not had in many cases the same care bestowed upon either their manufacture or upon their mounting as has been given in nearly every case to the refracting telescope. Speaking generally, the mounting of the reflecting telescope has nearly always been of a very imperfect kind—a matter of great consequence, for upon the mounting of the astronomical telescope so much depends. To direct the tube to any object is not difficult, but to keep it steadily moving, so that the object remains on the field of view, requires that the tube should be carried by an equatorial mounting of an efficient character. The first essential of such a mounting is an axis parallel to the axis of rotation of the earth. The tube, being supported on this, will follow any celestial object, such as a star, by simply turning the polar axis in a contrary motion to that of the earth, and at the same rate as the earth rotates on its axis. If we make the telescope to swing in a plane parallel to the polar axis, we can then direct the telescope to any part of the sky, and we have the complete equatorial movement. There are several ways in which this is practically done; we can have a long open-work polar axis supported at top and bottom, and swing the telescope in this, or we can have short, strong axes. As examples of the first, I will show you pictures of the mountings designed for Cambridge and Greenwich Observatories some forty years ago by Sir G. Airey, lately and for so long our eminent Astronomer-Royal; and as examples of the other form, amongst others, the large telescope lately erected at Nice, and also the larger one at Mount Hamilton, California, now under the direction of Prof. Holden.

The plan of bringing all the various handles and wheels that control the movement of the telescope and the various accessories down to the eye end, so as to be within reach of the observer, is carried to the highest possible degree of perfection here, as we can see by an inspection of the picture of the eye end of this telescope. The observer with the reflecting telescope is, with moderate-size instruments, never very far from the floor, but in the case of the Lick telescope he might have to ascend some thirty feet for objects low down in the sky. Thanks to the ingenuity of Sir Howard Grubb, to whom the idea is due, the whole of the floor of the Observatory is made to rise and fall by hydraulic machinery at the will of the observer—a charming but expensive way of solving the difficulty, as far as safety goes, but not meeting the constant need of a change in position as the telescope swings round in keeping up with the motion of the object to which it is directed. The great length of the tube of large refractors is well seen in this picture of the Lick telescope; it suggests flexure as the change is made in the direction in which it points, and the consequent change of stress in the different parts of the tube.

### Applications for Letters Patent.

283. W. FIDDES, 1, Berkeley Crescent, Clifton, Bristol, "Photometrical Apparatus."—January 6th.

352. J. B. KING and J. BICKLE, Great Western Docks, Plymouth, "Cameras."—January 8th.

402. J. E. THORNTON, 3, New Lorne Street, Manchester, "Changing Photographic Plates."—January 9th.

443. R. FOWLER, 6, Lord Street, Liverpool, "Improvements in Cameras Carrying their own Plates."—January 9th.

### Specifications Published.

3,979. *March 13th*, 1890.—"Picture-frame Fasteners." MARIE ROSALIE KROOK, 1, Rosary Gardens, South Kensington, Married Woman.

My invention is designed to supply a long felt want of keeping pictures, especially small ones, in their exact position when hanging on walls, and preventing them from being pushed away when being dusted or from moving when doors are closed.

For this purpose I use a special pin, which will somewhat vary according to the size and material of the picture frame for which it is intended.

For ordinary small wooden frames, I use a pin somewhat like two drawing pins joined together, having either a round or square collar and a sharp-pointed steel pin at either end, one end of which, of a length sufficient to hold firmly, is driven into the back of the picture frame, while the other is driven into the wall, and, having a fine point, and being small in size, it makes a scarcely perceptible hole in the wall, and does no damage, yet holds the picture securely in its position.

For larger pictures, I make the collar with a hole for a small screw or nails to fasten it to the picture frame, or the end which is inserted in the frame may be made as a screw.

For plush, composition, or other small frames, where a needlepoint or screw cannot be inserted, I make the collar of wood, which may be glued or attached by cement to the picture frame.

The collar may also be made thicker at the top than at the bottom, and bevelled, or triangular in shape, so as to hold securely in their position pictures which may be hung sloping forward, and which, therefore, only touch the wall at the edge of the bottom of the frame.

6,918. *May 5th*, 1890.—"Strips or Bars for Glazing." GEORGE DEACON, 103, Lower Thrift Street, Northampton, Horticultural Builder.

My invention relates to improvements in strips or bars for glazing, applicable to rafters, frames, sashes, and the like, and consists of a core or strip of wood (or metal) covered with sheet lead on the top and the two sides, and partly on each side at the bottom, and bent outwards to form the lapping strips to cover or secure the edges of the glass. These said strips or bars are intended to be screwed or nailed on to the top of rafters or the like. The aforesaid strips or bars are about one-third the size of the rafter it is intended to be fixed to, in order that the glass shall have a bearing on the rafter similar to the ordinary rebate, and the lead strips pressed down to secure the glass.

The bars or rafters to which the strips are attached may be of any suitable section and of any material.

The strips are fastened with nails or screws, but preferably with copper or brass screws to prevent rust.

The object of my invention is, that by taking out the screws the strips may be removed from the rafters, to permit the glass to be taken off the rafters without damage; temporary buildings can be erected and removed by this system more readily than by the ordinary glazing process now in common use.

### Patents Granted in America.

441,831. (United States Patent Office.) "Photographic Film." GEORGE EASTMAN, Rochester, N.Y. Filed November 6th, 1890. Serial No. 370,435. (No model.)

*Claim.*—1. As a new article of manufacture, a flexible film-support containing when dried a volatile substance, combined with a sealing-coating on each of its sides.

2. As a new article of manufacture, a photographic film consisting of a flexible film-support containing a volatile substance, combined with a sealing-coating on one side, and with a sealing-coating which is photographically sensitive on the other side.

3. As a new article of manufacture, a photographic film consisting of a flexible film-support containing a volatile substance, combined with a sealing-coating on one side, and with a sealing-coating of sensitive gelatino-argentic emulsion on the other side.

4. As a new article of manufacture, a photographic film consisting of a flexible film-support containing a volatile substance, combined with a sealing-coating of insoluble gelatine on one side, and with a sealing-coating of sensitive gelatino-argentic emulsion on the other side.

5. As a new article of manufacture, a photographic film consisting of a flexible film-support containing a volatile substance, combined with a sealing-coating on each side, one of said coatings carrying photographically-sensitive material.

6. As a new article of manufacture, a flexible film-support composed of a nitro-cellulose compound containing a volatile substance, as camphor, combined with a sealing-coating on each of its sides.

7. As a new article of manufacture, a photographic film consisting of a flexible film-support composed of a nitro-cellulose compound containing a volatile substance, as camphor, combined with a sealing-coating on one side, and with a sealing-coating which is photographically sensitive on the other side.

8. As a new article of manufacture, a photographic film consisting of a flexible film-support composed of a nitro-cellulose compound containing a volatile substance, as camphor, with a sealing-coating on one side, and with a sealing-coating of sensitive gelatino-argentic emulsion on the other side.

9. As a new article of manufacture, a photographic film consisting of a flexible film support composed of a nitro-cellulose compound containing a volatile substance, as camphor, combined with a sealing-coating of insoluble gelatine on one side, and with a sealing coating of sensitive gelatino-argentic emulsion on the other side.

10. As a new article of manufacture, a photographic film consisting of a flexible film-support composed of a nitro-cellulose compound containing a volatile substance, as camphor, combined with a sealing-coating on each side, one of which carries photographically-sensitive material.

---

M. LEON VIDAL has been appointed a professor in the National School of Decorative Arts at Paris.

ENFIELD CAMERA CLUB.—The first annual exhibition will be held in the Lecture Hall, Chase Side, Enfield, on Saturday, January 31st, from 3 to 6 p.m., and from 7.30 to 10 p.m. The exhibition will be opened by Captain H. F. Bowles, M.P. There will be on each occasion an optical lantern entertainment, and a selection of vocal and instrumental music.

NEXT Thursday night, at eight o'clock, Dr. J. Reynolds will give a lecture, with lantern illustrations, at the Gresham Hall, Gresham Road, Brixton, under the auspices of the Brixton and Clapham Camera Club. His subject will be "Iceland." He apparently does not wish to be thought one of those peculiar people who rejoice in regions of ice and snow, for it is announced that the lecture will be descriptive of "scenes in the volcanic and hot-spring regions of the south-west."

A DYNAMITE BLAST PHOTOGRAPHED.—A daring feat in photography was performed last week by Dr. George H. Bailey, of Boston. He succeeded in getting a fine negative of a blast of a ledge near Savin Hill, one of the largest on record, in which two hundred and fifty pounds of dynamite were used. He did it at the risk of being crushed by some huge rock, and moved himself and camera out of the way just as a boulder several tons in weight was about to land dangerously near him. The picture was taken just as the dust and stones had reached their highest elevation, and is as interesting as it is rare.—*Photographic Times.*

# Correspondence.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Sir,—Will you kindly allow me to inform our numerous members and friends, through the medium of your journal, that we have just been presented with a handsome book-case by one of our members (Mr. E. W. Parfitt). We now desire to fill it with photographic literature as speedily as possible, and I am requested by the council to state that all gifts of books, &c., for that purpose will be most cordially acknowledged if addressed to us at the Champion Hotel, 15, Aldersgate Street.

R. P. Drage, *Hon. Sec.*

*The "Champion" Hotel, Aldersgate Street, January 12th.*

## ZOOLOGICAL PHOTOGRAPHS.

Sir,—In the first page and a-half of Mr. Frank Haes' article in the Photographic News of February 16th, 1866, eight animals are mentioned of which that gentleman attempted to take the portraits—to wit, a horse, a chimpanzee, a monkey, a lemur, an aye-aye, a bat, a clouded tiger, and a binturong.

In the case of the horse Motley, the "result was an absolute failure." With the monkey, "I never was more baffled in my life; in fact, I had to give it up." Of the aye-aye, "I only obtained one negative; all the others were useless." The bat "I was obliged to relinquish, as the animal was constantly clambering over the wires." "Of the clouded tiger, "the photograph is much spoilt." Of the binturong, "the photograph is a failure." In the commencement of his article Mr. Frank Haes speaks of a record of his "mishaps and misadventures." It is useless to continue. We have quoted Mr. Frank Haes' own words, and wonder—though a failing memory may account for it—that he is now "rather surprised to learn that his list of animals contained so many, generally more unsuccessful."

In the matter of the clouded tiger, our apology is ignorance. Though aware that this animal is occasionally tamed in the East, we knew not—Mr. Frank Haes himself has omitted to mention it—that there was a tame and pet tiger in the Zoological Gardens in the summer of 1865. This fact certainly renders our compliment to Mr. Frank Haes on his discretion—which is the better part of valour—unnecessary. In his own language, the "insinuation is uncalled for."

The Writer of the Article in the "Year-Book."

# Proceedings of Societies.

## The Photographic Society of Great Britain.

At the first ordinary meeting of this Society held in its new rooms, 50, Great Russell Street, on the 13th inst., the chair was occupied by Captain W. de W. Abney, C.B., F.R.A.S., vice-president.

Auditors of the Society's accounts were nominated, and Messrs. G. Scamell and F. Ince accepted the office.

Messrs. F. Ince, Chas. Sawyer, J. Desiré England, E. Clifton, and J. R. Gotz were appointed scrutineers of the balloting papers at the ensuing election of members of council.

A presentation of Dr. Emerson's "Wild Life on a Tidal Water" was received, and a vote of thanks recorded.

Mr. E. W. Maunder, F.R.A.S., of the Greenwich Observatory, then commenced the display ot a large number of lantern slides illustratiug "Photography Applied to Astronomy," accompanied by copious explanations and remarks. He commenced with a statement that he should not deal with such questions as the composition of developers or sensitive plates, concerning which he should rather come to the Society for instruction than presume to give any. He proposed to give an account of what photography had done for astronomy, and as its first important work in that direction was photography of the sun, he should begin with some illustrations of that kind of work. He showed drawings of the Dallmeyer photoheliograph used at Greenwich, and that of Mr. De la Rue. The first slide shown was that of a sun spot taken on November 18th, 1882. This was by far the largest spot ever photographed at Greenwich; its area extended over 3,500,000,000 square miles. When this spot first appeared, a magnetic disturbance began which became very violent as the spot approached the centre of the suu's disc. Signalling was interrupted at many telegraphic stations, and an aurora was visible at the same time. A photograph exhibitiug very much better definition, taken by Janssen, of Meudon, of a spot in June, 1885, was next put on the screen. An American slide showing the granulations of the surface, and the faculæ near the edge of the sun, followed; several composition photographs of the corona taken in 1878, 1882, and 1886 were showu, and it was explained that any single photograph would not have included detail both in the highest lights and in the weakly illuminated portions. An actual photograph of the corona of January, 1889, was exhibited in proof of this. Up to 1881 there had been no success in photographing comets, but a slide of one taken by Janssen in June 30th of that year was shown. In 1882 a series of photographs of a comet was taken by a photographer at the Cape of Good Hope, with the telescope belouging to the observatory there, slides from which were exhibited. The Brothers Henry, of Paris, were at about that time engaged in astronomical photography, and a series of photographs of double stars taken by them was shown. A photograph from a chart of a portion of the Pleiades which had occupied about three years in making, and contained nearly a thousand stars, was shown in comparison with a slide of the same portion photographed direct by the Brothers Henry with three hours' exposure. The latter was more accurate, and contained many more stars. Photography of nebulæ was next taken up, and a slide shown of a nebula which was discovered by photography. Photographs by Mr. Isaac Roberts, in which various exposures had been given to a nebula, showed the effect of this variation by the great differences in the size and form of the image. Photographs by the Brothers Henry of the planets Jupiter and Saturn, as well as some of the same subjects taken at the Lick Observatory, were followed by a series of photographs of the lunar surface from the latter place. Mr. Roberts' splendid photographs of the Nebula of Orion, and the very instructive series of the same subject by Mr. Common, were then shown. A photograph of the best drawing of the Nebula of Andromeda was placed on the screen, and certain rifts in the nebula were pointed out, the meaning of which was not at all understood until, in the photograph next shown, taken by Mr. Roberts, it was seen that these rifts were part of a spiral formation. Another slide of a portion of Cygnus, by Mr. Roberts, containing 32,000 stars, was next exhibited. Spectroscopic photography was then introduced, and slides showing the apparatus for compariug the spectra of various metals with that of the sun were put on the screen. The apparatus of Professor Vogel, of Potsdam, was described, as well as the observation for showing the advance or retreat of stars. The most beautiful photograph of the spectrum itself had been taken by Higgs, of Liverpool, and slides of portions of it showed lines of extraordinary clearness. Dr. Common's photographs had been taken with a reflecting telescope; latterly with a 5-foot speculum of 27-foot focus.

Mr. W. E. Debenham asked whether accessory exposure had been employed in astronomical photography. Objects of such faint illumination that they could not otherwise be developed with a given exposure might be made to show themselves by this means. The possibility of getting more stars out by subsidiary exposure was shown by one of the comet photographs taken at the Cape. Where there was faint light from the comet over the sky the stars were most numerous.

Mr. Maunder thought that for the most part astronomers had been satisfied to give longer exposures.

Mr. J. Spiller suggested the use of orthochromatic plates in astronomical photography.

It was stated that Mr. Common is now experimenting in this direction, using orthochromatic and ordinary plates on the same subject.

The Chairman thought that unless a yellow screen were used there would be very little difference between them except in the case of photographing nebulæ. As to what Mr. Debenham had said with regard to preliminary exposure, a plate so treated could not properly be compared with another not thus exposed. He was very pleased to notice the excellent work done with Mr. Common's reflecting telescope.

It was announced that the progress medal had been awarded to Colonel J. Waterhouse, B.S.C., and that an exhibition of photographs and apparatus would be opened at St. Petersburgh on March 29th.

Messrs. W. Barry, John Collier, Capt. J. H. Cowan, H. Dixon, Rev. H. B. Hare, G. Strickland, S. C. Weston, W. Window, and Charles Winter were balloted for and elected members.

---

The Photographic Society of Ireland.

A meeting of this Society was held at 15, Dawson Street, Dublin, on the 9th inst., Prof. J. A. Scott, M.B., in the chair. The Boston Camera Club set of lantern slides entitled "In and round Columbus" was exhibited, and was highly appreciated. The lantern was worked by Mr. Jas. Carson and Mr. M. Hedley, while the descriptive matter accompanying the slides was read by Mr. Greenwood Pim.

A vote of thanks was passed to the Boston Camera Club for the loan of the slides.

---

The London and Provincial Photographic Association.

*January 8th.*—Mr. W. E. Debenham in the chair.

The presentation of a handsome book-case was made to the Society by Mr. E. W. Parfitt, for which a warm vote of thanks was accorded by the members.

Mr. A. Cowan, with a view of testing sulphite of soda as a preservative, which had formed the subject of discussion at the previous meeting, mixed a solution of eikonogen containing 5 grains to the ounce; this was put into five open vessels. To No. 1 was added 5 grains of bisulphite to the ounce; an addition was made to No. 2 of 1 grain sulphite; No. 3, 2 grains; No. 4, 4 grains; and No. 5, 8 grains to each ounce. The solutions were allowed to stand all night, with the result that No. 5 only was colourless in the morning.

Mr. F. C. Kellow asked the best way of making transparencies by reduction in the camera by artificial light; he had tried with an oil lamp of about 60-candle power, but was unsuccessful in obtaining an image after several hours' exposure.

Mr. A. Cowan suggested burning a piece of magnesium wire in the focus of a condenser.

Mr. F. A. Bridge said that in making enlargements with artificial light, the colour of the negative was very deceptive in judging exposure. He had enlarged from a ¼-plate to 20 by 25, using a fairly rapid paper, in from fifteen to twenty seconds.

This being the usual monthly lantern night, a large collection of members' slides was projected on the screen, contributed by Messrs. Everitt, Teape, Freshwater, Cooke, and Briginshaw.

A number of slides was then shown, lent by Mr. Sturmey, sent by the "American Lantern Slide Interchange" for the use of English photographic societies. These slides were the work of members of various American photographic societies, and consisted of views of Washington, New York, Virginia, Florida, Philadelphia, Kentucky, Boston, and other American cities. Particularly interesting was a series of views taken of the wreckage at Johnstown. This disaster happened on May 31st, 1889, and was caused by the overflow of an artificial lake, three miles long, and from half to three-quarters of a mile wide, situated two-hundred and fifty feet above the head of the valley. In consequence of heavy rains, the earth at the sides of the lake gave way, and the water poured through the city, carrying everything before it. The slides, as sent from America, were ranged in boxes furnished with india-rubber grooves, as recommended by Mr. Beach. The plan was much admired, but the question was raised whether the sulphur in the grooving would attack the images after the lapse of time.

The North Middlesex Photographic Society.

At the annual general meeting, with Mr. Humphries, F.S.A., in the chair, Mr. G. R. Martin resigned the secretaryship, and Mr. E. S. Paul the treasurership.

Alterations in the rules were made, by which the title was changed from the North Middlesex Photographic Club to the North Middlesex Photographic Society, and the membership of the council was enlarged from eight to twelve. The retiring officers and members of the council received a vote of thanks for their services.

The following officers and members of the council were elected:—*President*—J. Humphries, F.S.A.; *Vice-Presidents*—W. T. Goodhew, H. Walker; *Curator*—F. Piper; *Council*—C. Beadle, H. Beckett, J. Cherry, T. W. Cox, C. Gill, T. C. Lathbridge, W. A. Lowanchy, G. R. Martin, J. C. S. Mummery, F. L. Pither, J. Saville, H. Smith; *Treasurer*—J. W. Marchant; *Hon. Sec.* — J. McIntosh, 14, Lowman Road, Holloway, London.

---

The West London Photographic Society.

The annual exhibition and conversazione of the West London Photographic Society was held at the Broadway, Lecture Hall, Hammersmith, on the 9th and 10th of January. The president, Mr. W. A. Brown, occupied the chair.

The exhibition presented an attractive appearance, the entire wall space available being covered with pictures, and the frames set off by a background of rich, dark blue cloth. Upwards of 200 frames were hung, and there was a marked general improvement over the work shown at the last exhibition. The room was tastefully decorated with various coloured draperies and choice specimens of dried grasses. Light refreshments, provided by the president, were served each evening, and this department was under the management of Miss Annette Brown, Mrs. Blackmore, and Mrs. Hodges. An excellent musical progamme was provided, which contributed in no small degree to the success of the evening.

The President, after formally opening the proceedings, said that upon the occasion of the last exhibition they were favoured with the attendance of the judges, who, in a few kindly remarks by way of criticism, gave the members much useful information. Unfortunately, the judges could not make it convenient to be present that evening; therefore he regretted that the members would not have the opportunity of being benefited by their comments. He congratulated the Society on the number of pictures, and hoped one result of the exhibition would be to induce others to join the Society.

The Hon. Secretary (Mr. J. A. Hodges) then read the judges' report, which is as follows:—"We, the undersigned, having examined the photographs exhibited at the West London Photographic Society, award as follows:—Silver medal — No. 48, 'Crypt, Canterbury Cathedral,' C. Whiting. Bronze medal — No. 5, 'A Nocturne,' L. C. Bennett. Bronze medal — No. 7, 'Where Duty Calls,' G. F. Blackmore. Bronze medal—No. 24, 'Near Rockford, N. Devon,' J. A. Hodges. Bronze medal—No. 31, Dr. F. H. Low. Bronze medal—No. 41, 'The Distant Sea,' Harry Selby. Bronze medal—No. 49, 'A Snow Scene,' C. Winter. Bronze medal — No. 50, 'Drying the Nests, Whitby,' J. Wilson.

"We have also examined the lantern slides sent in for competition by projection on the screen, and award as follows:—First bronze medal—'Hoar-frost Study,' J. E. Kellow. Second bronze medal—'Waiting to Embark,' J. A. Hodges. We have much pleasure in expressing our gratification at the more than usual merit of the exhibits generally; at the same time, we should like to have seen more figure studies, the photographs sent in being to a large extent topographical. Speaking of the exhibits generally, the selection of the point of view in the landscapes is exceedingly good. We further consider that it is gratifying to see that albumenised silver printing is becoming a thing of the past with the West London Photographic Society. (*Signed*) J. Gale, J. B. B. Wellington, Thomas Clark."

Dr. Low, in proposing a vote of thanks to the judges, said that the following of precedents in a young society appeared no doubt a very desirable thing in the minds of those who had asked him to undertake the duty, for it had been his good fortune to have been placed in a similar position last year. That the thanks of the members were due to the judges for performing what was agreed to be a difficult and invidious task no one would doubt, especially when it was remembered that in the report they referred to the unusual merit of the exhibits. Their praise was, however, a little discounted by speaking of the landscapes as being of a "topographical nature." The word no doubt was a good one, and had been much used of late by certain critics, but in this instance, he (Dr. Low) thought it was not quite the word which was intended.

Mr. G. F. BLACKMORE, in seconding the motion, said that the judges must have had a difficult task in deciding upon the prize pictures, the average merits of the exhibits being higher than it had ever been before, and he could not help feeling that it was extremely creditable to the West London Photographic Society to bring such a fine collection of pictures together. The motion was carried unanimously.

Mr. CHAS. WHITING wished to thank the Hon. Secretary and the Exhibition Committee for the excellent way in which they had performed their work. A glance round the walls must convince anyone that the pictures could not well have been hung to better advantage. He confessed that at one time he did not think the room quite suitable for an exhibition, but he was agreeably surprised to see the transformation which had taken place. The motion having been seconded by Mr. Geo. Lamley, was carried. Mr. Chas. Bilton then proposed a vote of thanks to the ladies and gentlemen who had contributed so much to the success of the evening by providing a musical programme, which was carried unanimously.

On Saturday the proceedings were brought to a close by the exhibition in the optical lantern of the competition slides. The two prize slides were first shown, Mr. J. E. Kellow taking first bronze medal with a beautiful rendering of hoar-frost; the second medal was awarded to Mr. J. A. Hodges, hon. secretary, for a pretty figure study, "Waiting to Embark." Among other sets sent in, those of Messrs. Whiting, Scanlan, Rogers, and Wilson were of a high order of merit. A loan collection of prize slides made from Mawson's plates was then exhibited. Some views in Norway by Paul Lange, and other views by prominent slide makers in the Liverpool Society, were then shown, and the entertainment was brought to a close by the exhibition of Mr. Chas. Whiting's fine series of lantern slide views of Canterbury Cathedral and Stratford-on-Avon.

---

THE TUNBRIDGE WELLS AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE fourth annual meeting of the above Association was held at the Mechanics' Institute on Wednesday, January the 7th, at eight o'clock; the President, Mr. F. G. SMART, occupied the chair. Messrs. Lauder, Wilson, and Penn were elected members.

The HON. SECRETARY, in presenting his report for the past year, congratulated the members upon the increased average attendance at the meetings. This annual report set forth, amongst other items, that the Association has lost one member and has been recruited with seven, which brings the total up to thirty, with three now to be elected. There have been four excursions, with an average of nine attending; one of these was by special invitation to Broomhill, the seat of Sir David Salomons, Bart., where the members were hospitably received.

Mr. Cornell gave a demonstration with his oxy-hydrogen microscope, which was interesting and much appreciated. The members also invited their friends to view the Boston lantern slides upon several evenings. Apparatus was shown, as also were the results of the excursions.

The exhibition, which took place at the end of November, was the best one which the Association has held, and it was favourably commented on by the judges—Sir David Salomons, Mr. H. P. Robinson, and Mr. Hastings for that purpose. Sir David Salomons opened the exhibition, and kindly gave the opening entertainment with his specially made lantern. Twenty members competed with 326 pictures; three sent in pictures "not for competition," including some paper negatives, by Dr. Prince, taken as long ago as 1851; twenty-seven amateurs sent in 178 for the open classes, and ten professionals entered with 71. Mr. H. P. Robinson kindly sent his pictures, which had been at the Pall Mall Exhibition, as also did Mr. R. W. Robinson. Unfortunately, the weather was so severe that it was impossible for the public to attend, in consequence of the heavy fall of snow, which was the cause of the exhibition not being a financial success. This is much to be regretted, as this year the work is of a much higher standard, and the first year a change was made, which, it was hoped, would clear expenses.

Dr. Abbott will read his paper on "Optics" at the beginning of March, and Dr. Prince will follow in April with one on his "Experiences and Difficulties in Photography Forty Years Ago;" The Hon. Sec. added that he hoped that Mr. Howard would be able to read his paper on the "Chemical Action of Light." Arrangements will also be made for lantern evenings at informal meetings of the members, of which notice will be given.

The Association has been presented during the year with a plate-rocker, copies of "Photographic Notes," photographic journals, slide rule, and exposure books, by Sir David Salomons, Bart.; Dr. Emerson's "East Anglian Life," by the author; "Naturalistic Photography," by Mr. Lewis.

Exhibits were sent by members to the Kidderminster and Crystal Palace Exhibitions, the latter in competition with other societies for a challenge cup.

It was agreed that members of recognised Clubs and Societies shall be at liberty to attend the ordinary meetings as visitors upon giving notice in writing to the Hon. Secretary.

The following officers were re-elected:—*President*—Mr. F. G. Smart; *Vice-Presidents*—Mr. J. G. Calway, Rev. A. T. Scott, Rev. J. E. Rogers, Mr. G. Percival Smith; *Hon. Treasurer*—B. Whitrow; *Hon. Secretary*—Joseph Chamberlain; *Hon. Auditor*—W. E. Brampton; *Committee*—Messrs. J. W. Morgan, A. W. Pierson, G. W. Howard.

The HON. SECRETARY intimated that he had received a ticket from Mr. H. Harvey-George (secretary of the Great Yarmouth and Eastern Counties Photographic Society) constituting him an honorary member of that Society for the year.

The arrangements were discussed for the entertainment to be held on the 27th inst., which will consist of lantern slides, vocal and instrumental music during the interval between the sets, full particulars of which will be announced.

---

THE HACKNEY PHOTOGRAPHIC SOCIETY.

AT the meeting on Thursday last Dr. GERARD SMITH was in the chair.

In the course of some remarks by members on Shew's adapter, Mr. BECKETT said he thought a large stand would be necessary.

Mr. A. MACKIE then gave his demonstration of the collodio-bromide process, prefacing his demonstration with a short history of the process and its discovery; he made the working of it clear to the non-workers. After coating a plate, he proceeded to expose it for about one second by magnesium ribbon, and develop it with a modified alkaline developer, and fix by ordinary fixing bath. He farther illustrated the process by explaining the composition of the emulsion method of preparing it. Lantern slides made by this process, and shown on the screen, before being put through the lantern were warmed to prevent being broken by the heat.

Mr. F. Gregg was nominated as a member.

---

THE ENFIELD CAMERA CLUB.

A MEETING was held on January 7th, with the president, Mr. D. G. PINKNEY, in the chair.

After transaction of the ordinary business, including the proposal of a new member, the PRESIDENT read a paper on "Eikonogen," and afterwards gave a practical demonstration with this developer as compared with hydrokinone. In the course of his remarks, Mr. Pinkney said that he had found with an under-exposed plate eikonogen certainly brought to view some details which hydrokinone was apparently unable to do, and he produced for inspection two Thomas' extra rapid half-plates which had received identical exposures, namely, two-thirds of a second at 2.50 p.m. on the 20th December under a dull sky.

At first sight it would appear that the hydrokinone developed plate was superior, because it has such a vigorous black in the high light, and almost clear glass in the shadows. The eikonogen developed plate, however, was of a grey colour, and while the sky was quite dark enough for printing purposes, there was undoubtedly more detail in the shadows than in the other negative. At the same time, the reader remarked, the exposures having been purposely cut short in order to test the pretensions of eikonogen as *the* developer for a really under-exposed plate, it must not be inferred that hydrokinone was the inferior of the two; indeed, his opinion was decidedly the reverse. Mr. Pinkney then proceeded to develop before the members two Thomas' lantern plates, two Ilford special lantern plates, and two pieces of Eastman bromide paper, with eikonogen and hydrokinone, the conditions being precisely the same as regards exposure of the plates and papers. It was clearly shown, 1st, that eikonogen was much slower than hydrokinone, and 2nd, that eikonogen produced a thin veil on lantern plates (which clearing would not remove) which was entirely absent with hydrokinone. The black tone on the bromide papers produced by hydrokinone was much preferred by the members to the cold grey by eikonogen.

A number of slides by members was then exhibited in Mr. James' lantern, kindly lent by him, and a flash-light picture of those present was taken by another member, Mr. R. B. Lodge.

The Sheffield Photographic Society.

The monthly meeting was held at the Masonic Hall, Surrey Street, on January 8th, Mr. B. J. Taylor in the chair.

It was announced that the winners of the President's prizes were as follows:—1st. Mr. E. Beck, with a picture entitled "With the Morning Tide;" 2nd. Mr. Thomas Hibbert, with "Cloud Effects."

It was arranged that an exhibition of prize lantern slides should be given at the next monthly meeting to members and friends. The Secretary reported that vice-president Mr. A. Davy had offered £2 2s., and Mr. Draper a bronze shield, to be given in prizes.

Messrs. Hibbert and Furniss gave a two-man lantern exhibition of their own work.

The Lewes Photographic Society.

A meeting was held on the 6th inst., at the Fitzroy Library, High Street, Lewes (where the future meetings of the Society will be held); the President in the chair. Mr. A. E. Venn was elected a member.

The evening was devoted to an exhibition of slides, over 200 being passed through the lantern.

An exhibition of members' work, with lantern entertainments and concerts, will be held on the 28th inst. Next meeting February 3rd, when a paper will be read by Mr. A. H. C. Corder on "Printing Processes."

The Croydon Microscopical Society (Photographic Section).

*Friday, January 9th.*—President (Mr. E. Lovett) in the chair.

Mr. A. W. Clayden, M.A., F.C.S., F.G.S., gave an interesting paper on the method of taking photographs of clouds for meteorological purposes. He also exhibited a camera constructed by himself especially for the purpose. The top of the stand carrying the camera is so small that any desired angle can be got without shifting the legs, and in the front of the lens, set at an angle of 33°, is a dark piece of highly polished glass; the photograph of the cloud being taken from the reflecting surface of the glass. By this means the actinic rays from the blue sky were polarized, or, so to speak, toned down, and facilitated the taking of fine cirrus clouds, which were impossible to get by the old method of pointing the lens straight at the sky. Solar halos can be taken with it, and, in fact, the ease with which fine, fleecy clouds within a little distance of the sun can be taken is very curious.

Many slides taken by this method were exhibited on the screen, consisting of fine forms of cirrus and cumuli clouds, and were notable for their brilliancy and depth.

The President, Messrs. Boyard, I. Weir-Brown, K. Mc.Kean, and W. Low Sarjeant, took part in a discussion that followed.

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Pharm.—*List of Members, Photographic Society.* It has been the custom to print once in three years, and the current list bears date February, 1889. For members elected subsequently you must consult the reports and proceedings *seriatim.*

S. Barnard.—*Focussing on Dark Days.* Use a candle flame held in a position corresponding to the plane of the object to be photographed; and, if necessary, move it over the field to ascertain whether you have secured the best all-round focus. Stoppages of water and gas in towns are frequent accompaniments of frost and fog.

Subscriber.—*Photographers' Benevolent Association.* 1. By the rules you are at liberty to nominate any other member for election into the committee at the forthcoming annual meeting in February. It would certainly be desirable to give notice of such intention to the honorary secretary, Mr. H. J. Beasley, 66, Chancery Lane, W.C. 2. Now all the offices are honorary, so that the only expenses are for printing and postage, beyond the payment of grants, as authorised by the committee. The claims this year have been exceedingly heavy, and timely assistance has been given to those applicants whose cases have stood the test of enquiry. On this account the funds of the Association require to be liberally supplemented if the good work is to be continued.

Nitrate Bath.—*Purification of Same.* With an old printing bath having a degree of concentration equal to 120 grains to the ounce, probably the best way would be to evaporate it down to dryness and heat the residue just to the point of fusion in a good porcelain dish. This would destroy organic impurities and get rid of free acid; but before doing this, however, we should be inclined to test a portion of the silver bath by diluting with an equal bulk of water, and shaking it up with kaolin. If paper sensitised with it prints well, be content to use it up in this way.

W. M.—Your manuscript will probably be accepted and utilised later on. The subject is one which does not urgently demand consideration at the present time.

G. L.—*The Oxford Photo-Prints.* The prices demanded for reproductions from the Bodleian manuscripts are certainly very moderate:—Three shillings for a 10 by 8 negative, and four pence for a silver print taken therefrom. Platinotypes and carbon prints of the same size are charged ten pence each. One hundred collotype prints, with clean margins, can be had for twelve shillings in addition to the price of the negative. Application to be made to the Controller of the University Press, Oxford, who is prepared to give estimates for larger sizes.

B. & S.—*Photo-Enamels.* You might enquire, in the first instance, of Mr. A. L. Henderson or Mr. C. A. Rudowsky. If neither of them will undertake your commission, apply to MM. Benque & Cie, of Paris.

J. T.—*Parent Society.* The premises are already open daily from 2 p.m. at 50, Great Russell Street. Nominations for new council must be sent in by Wednesday next, 21st inst., addressed to the assistant-secretary.

H. F. Smith.—*Developers.* Want of intensity in your case is due probably to the use of a weak developer, especially during this cold weather. The remedy is obvious. Both plates have recently given us excellent results.

M. P.—You are mistaken; the rainfall of last year was *below* the average, although July was so wet.

CONTENTS.

## NEW DISCOVERIES IN PHOTO-ELECTRICITY.

An article by Professor Minchin will be found upon another page, setting forth some of his new discoveries relating to photo-electricity laid before the Physical Society last Friday, as well as some information about their relation to photography. Last Monday we had the pleasure of inspecting his apparatus, and receiving from him information as to his earlier and later methods of preparing the sensitive plates.

He uses two kinds of cells. One of them consists of a glass tube three or four inches long, as represented in fig. 1 of his article, in which tube is some pure methyl alcohol from oil of wintergreen, covering the two plates; platinum wires, sealed into the tube by heat, pass through the glass to the plates. The smaller plate is of absolutely clean, pure tin, a quarter of an inch long, a sixteenth of an inch broad. The larger and sensitive plate is one inch long and one-eighth of an inch broad. This one also is of perfectly pure tin, for any impurity, especially any trace of copper, promotes failure in the results. The plate is first cleaned with sodic hydrate, and afterwards with dilute hydrochloric or hydrofluoric acid; then it is laid upon a horizontal arm of porcelain so bent at the other end that, on raising from below a dish containing liquid, the said liquid covers the plate. By this method the second plate, or the one which has to be covered with a sensitive film, is immersed in the following solution:—

| | |
|---|---|
| Distilled water... | 500 c.c. |
| Nitric acid | 3 ,, |
| Nitrate of ammonia | 15 grammes |

The exact nature of the surface thus given to the tin plate is not known, but from the composition of the liquid it is probable that the effect is one of oxidation of some kind. The plate is left in the liquid about four minutes, and becomes covered uniformly with a whitish deposit. The solution is then removed by lowering the dish, and the under surface of the horizontal porcelain support is dried with blotting-paper. This dried under surface is then uniformly heated with a spirit flame moved about underneath until the liquid above has evaporated; the surface of the tin plate will then present a dirty slate colour. As the heating is continued, a point is reached at which a dark shadow passes over the whole surface of the plate; if the heating be now stopped, a sensitive plate is produced, but not one of the maximum sensitiveness. Upon continuing the heat the surface will change into a perfectly white one, and the heating should be continued until the thin vapour or smoke which is given off ceases to appear, and until the smell of nitrous acid entirely disappears. Care must be taken not to melt the tin in this process, and when the treatment is complete, the plate should be plunged into methyl alcohol from pure oil of wintergreen. A fine platinum wire has first to be fixed to the top of the plate, either by means of a solder with a low melting point, or by passing the wire through a little hole at the top of the plate and then bending the end of the wire back over the top edge; the latter plan is found to give sufficiently good contact for practical purposes. The clean, plain tin plate is sealed to the bottom of the tube by means of its platinum wire; after the methyl alcohol and the other plate are inserted, the upper part of the tube, with the wire from the second plate passing through it, is sealed by heat. All this may be done in daylight. The complete cell has to be left from two to five hours in the dark before it will exhibit its maximum powers.

In much which has just been stated, it may be noticed what a strong analogy exists between this method of preparing a sensitive plate, and one of the methods which Becquerel employed to produce a surface on a silver plate to adapt it to the taking of a photograph in natural colours.

The tin plate thus rendered sensitive, and mounted in a cell as described, when exposed to good diffused daylight, will exert an electromotive force—E.M.F. in electricians' language—of half a volt or more, as exhibited by means of the quadrant electrometer, and it will yield a steady stream of electricity for three or four hours, after which the E.M.F. falls off.

Supposing an exposure not to have been too long, the cell will gradually recover itself in the dark; if it be not exposed for more than ten minutes or so at a time, it will recover itself in the dark; one of the cells which has been used only in the latter manner has been so employed by Professor Minchin for four years.

According to the dynamic hypothesis of the invisible photographic image, the phenomena just stated may be explained on the principle that the shorter exposures do not result in the decomposition of the molecule, which decomposition the longer exposures effect.

Some of these cells are found to be "impulsion cells," that is to say, that they do not act until the support of the apparatus is tapped; a slight touch with a lucifer match is enough. The working of small frictional electrical machines will give an impulsion from a distance. If the alcohol in the cell be changed four or five times, the necessity for impulsion disappears.

More recently Professor Minchin has been working with selenium sensitive films. The plates are sealed in very thin little glass tubes, one-eighth of an inch in diameter, and about four inches long. At the lower end is a plate of pure aluminium cleaned by scraping. The plate above it, but not touching it, is of pure aluminium coated with a thin layer of selenium. Platinum leading wires pass through the sealed ends of the tube to the plates. The liquid used in this cell is pure acetone.

To prepare the sensitive plate, the zig-zag porcelain arm already mentioned has the aluminium plate held by a forceps upon its horizontal projecting end, and the arm and plate are heated from below by means of a Bunsen flame. A melted blob of aluminium is placed upon a hot glass rod, and while one hand holds one end of the plate by means of the forceps, the other hand, by means of the rod, smears the selenium over the plate in one uniform, black, viscous layer; at the same instant the gas flame is removed, and the aluminium plate taken rapidly off the porcelain arm, and waved rapidly three or four times in the air; then it is placed upon a comparatively cool part of the flat porcelain arm to anneal it, and any tendency to remelt is checked by blowing over the plate.

Next, the gas flame is worked uniformly under the porcelain arm bearing the plate. The selenium surface will then exhibit a series of changes: first of all, the black surface becomes slatey white, and, as the heating and blowing are continued, the slatey white will turn to a grey, which may be of several shades. Should it be a light grey marked by any glossy streaks or spots, the plate is to be rejected as not one of maximum sensitiveness; the melting and smearing process then has to be repeated all through until the surface finally obtained is uniform, and half way between a grey and a brown in colour, but decidedly brownish. Hitherto it has not been supposed that this is the colour for the most sensitive selenium.

The cell made with the two plates just described acts with great rapidity when exposed to light, and the E.M.F. disappears almost instantly when the cell is screened, but this quickness of action does not characterise the cell some days after it has been formed, although its sensitiveness is unimpaired. These selenium cells do not permanently deteriorate by any amount of continuous exposure to daylight, so far as is yet known; they have been made only about six months; they recover their powers always during the night.

Their maximum sensitiveness is in the yellow, but the whole of the rays of the spectrum give results not much inferior. The E.M.F. they yield under the action of good diffused daylight is from one-half to two-thirds of a volt. They will stand any amount of exposure to light while in open circuit, as when their E.M.F. is tested by means of the quadrant electrometer; but if the two wires from the cell be joined up so as to complete the circuit, the cell will then somewhat slowly deteriorate under the continuous action of daylight. Professor Minchin has joined up a battery of fifty of these cells, and with ordinary diffused daylight it gives an E.M.F. of twenty-five volts. One end of a strong local battery may be connected with the movable part of the electrometer, so the circuit shall be completed when the part is deflected. By means of this relay, the strong current resulting from the effects of the weak one may be made to do practical work, such as the ringing of electrical bells, or the automatic turning up of the gas when the daylight grows weak.

A favourite remark of Professor Tyndall is, that discoveries in one branch of science often throw light upon problems connected with another branch of science. These discoveries in photo-electricity, and the discoveries of Mr. Croft in relation to breath images, seem to give the power of attacking the mystery of the nature of the invisible photographic image from fresh standpoints.

## ABOUT INSTANTANEOUS SHUTTERS.

One of the most curious results of the introduction of rapid dry plates has been the amount of ingenuity and inventive ability which has been expended in designing and constructing shutters for instantaneous exposures. If the shade of Daguerre should haply have the opportunity of revisiting the earth, he would marvel that such things could be necessary, seeing that the time of exposure under his system entailed minutes rather than seconds, and although after Goddard's introduction of bromide in aid of the iodide of silver this exposure was very much lessened in duration, yet it was far too long to need the employment of any mechanical appliance to uncover the lens. But some form of instantaneous shutter soon became necessary when the collodion method superseded the Daguerreotype.

It is the fashion for modern photographers, and especially those who are recent aspirants for fame, to talk glibly of the shortcomings of collodion in the way of rapidity, and to imagine that it was as slow as the old Daguerreotype process. The truth is that they take very little pains to make themselves acquainted with the history of the art, and, after reading in a very cursory manner of the labours of Daguerre, Fox

Talbot, and other pioneers, they get rather mixed in their notions of the different processes which have, from time to time, been introduced, and jumble them all up together as things which were slow, and, generally, of little use. They are encouraged in their error, to some extent, by the ridiculous and mischievous method which has been adopted in some quarters of comparing the rapidity of a modern gelatine plate with the celerity of a wet plate, while anyone who has worked both processes will know that it is possible, by adjusting certain formulæ, to make a wet plate actually quicker than a modern dry one. Expert workers with collodion knew well that they could so compound their chemicals that a very quick plate was the result, and the instantaneous shutter was the natural outcome of their labours in this direction.

The simple drop shutter was no doubt the first thing of the kind which was thought of. Another form was that of a blind which travelled over a small roller, and so arranged that when one end was pulled downwards the other was raised. This form of shutter, although not very quick in action, had several advantages, the chief of which was that the operator, string in hand, could make the length of exposure suit the subject in hand, and could give a longer exposure to the foreground than to the sky. We have in our possession a shutter of this kind made about thirty years ago by the late Mr. Dallmeyer, and a good testimonial to its efficiency is seen in the circumstance that the idea has been patented, and brought out as a new thing within recent times.

It was about thirty years ago that Breeze produced his wonderfully effective studies of sky and sea for the stereoscope, and anyone looking at these beautiful pictures must acknowledge that some sort of shutter must have been used in their production. Of course, a very quick shutter was not used in those times, but it is a fact that the old, and in some quarters despised, wet collodion process would yield a picture of such a bright subject as sky and sea in a fraction of a second.

In our humble opinion, many of the shutters now made are far too elaborate in construction to bear the wear and tear of ordinary work. Some are almost as complicated as watch movements, and, although they are most ingenious in design, they will not bear rough treatment, and apparatus which is intended for out-door employment must be prepared, in our English climate, to rough it a little. One shutter was shown to us lately which, its owner told us, refused, at a critical moment, to do the work expected of it. We examined it, and found that its working parts were choked with woolly dust. Its proprietor had carried it in his pocket, and it had quickly picked up the *fluff* which invariably gathers in such a receptacle. How many shutters there are which would, after such treatment, also refuse to move. Some, indeed, have to be kept in special dust-tight cases to preserve their delicate constitutions.

Of course, in the taking of certain subjects, such as a trotting horse, a jumping dog, a lawn tennis player, or a diver, the shutter must work at a high speed, and somewhat complicated arrangements may be necessary to secure this end. But we believe that for ordinary purposes the more simple in design that a shutter can be made the better. Another important consideration is that these complicated arrangements require a great deal of attention in the way of previous calculation and setting, and thus the operator's brain is busy upon a tiresome detail of his work, instead of being devoted to the main business of watching his picture.

## PHOTO-ELECTRICITY.

BY PROFESSOR GEORGE M. MINCHIN.

The generation of electromotive forces and currents by the action of light on various metallic plates whose surfaces are prepared by special processes has been the subject of very numerous experiments by me since the beginning of the year 1877. The investigations treated of in the paper which I read before the Physical Society last Friday may be briefly summarised under the following four heads:—

1. The electric currents obtained by the action of light on silver plates coated with emulsions of various salts of silver, such as chloride, iodide, nitrate, and bromide (Liverpool emulsion). These, when powdered and emulsified with collodion or gelatine, were spread over clean strips of silver foil fixed on glass plates; two such plates were immersed in a glass vessel containing water in which were dissolved a few grains of chloride of sodium, iodide of potassium, nitrate of barium, or bromide of potassium; one plate was screened from light and the other exposed, both were connected with the poles of a sensitive galvanometer, and then currents were produced the directions of which depended on the nature of the emulsion on the plates. The electromotive forces developed thus depend, of course, on the intensity of the light, but with diffused daylight they are not high; they may amount to about $\frac{1}{20}$ of a volt.

The plates were also coated with emulsions of various aniline dyes, such as eosine, iodine green, and naphthaline red; the currents produced by the first were comparatively large.

The most important observation under this head was the *photographic action of the current*. It was found that if a current from a bichromate cell were passed for a few seconds through a cell containing two silver plates, each coated with a layer of Liverpool emulsion, and each about half immersed in water holding in solution a few grains of bromide of potassium, on removing the silver plates from the cell, that which was connected with the carbon pole was visibly blackened on its immersed part, while no visible effect was produced on the other; but, on developing this plate with pyrogallic acid and ammonia, its immersed part also became dark, exactly as if it had been exposed to light for a few seconds. This photographic effect was also produced by replacing the bichromate cell by a photo-electric cell, whose plates were coated with an eosine emulsion, one of these being screened, while the other was exposed to light. The photo-current generated by the latter cell passed for an hour or so through the former silver bromide cell, which was kept in a dark room, and when the plates of this latter were removed and developed, the photographic darkening took place, as before, on the immersed parts of the layer of Liverpool emulsion. This action could have been accelerated by first exposing the plates of this cell for a few seconds to gaslight.

Another important observation in this connection is the *localisation of the photographic effect* on the parts of a sensitised plate through which a current passes. For this observation several narrow strips of silver (1, 2, 3, 4, . . . .) were cemented close together on a glass plate, and the whole plate was coated with a layer of Liverpool emulsion; this plate was immersed in the presence of a clean silver plate in a cell containing water and bromide of potassium; the strips (1, 3, 5, . . . .) were all connected together, and with one pole of a voltaic cell; the strips (2, 4. 6, . . . .) were left out of the circuit; the clean silver plate was connected with the other pole of the voltaic cell, and both plates were about half immersed. The current having passed for a few seconds, the sensitised plate was removed and developed, and it was found that the darkening took place only on the immersed parts of the strips (1, 3, 5, . . . .) through which the current had passed.

The object of this experiment was to prove the fundamental possibility of the solution of the problem of seeing at a distance by means of an electric current. Various other metallic plates besides silver, such as copper, bismuth, and iron, were also tried, but the results are of minor importance.

2. Plates of tinfoil fixed on glass have been the subject of long investigation. As the tinfoil comes from the manufacturer, with its surface not specially treated in any way, if a glass cell containing two such plates is filled with water, and the plates (one of them screened) are connected with the poles of a sensitive galvanometer, it will, in nearly all cases, be found that rather strong currents are produced when the other plate is exposed to light. The exposed plate may be either positive or negative towards the unexposed. If the former, the action of strong light continued for a few minutes will often change the sign of the E.M.F.

A tinfoil plate which is negative towards a clean plate in a cell can be obtained by cleaning its surface with sodic hydrate, and then with dilute HCl, and exposing it to the action of $SH_2$, or rubbing a little mosaic gold on its surface. A plate which is positive is obtained by a special process involving some trouble. Its surface having been thoroughly cleaned, it is laid on a fixed glass or porcelain plate, which is immersed in a solution composed of 500 c.c. of distilled water, 3 c.c. of pure nitric acid, and 15 grammes of nitrate of ammonia. After about four minutes' immersion the surface is covered with a uniform white deposit, and the vessel containing the solution is withdrawn. Then the under surface of the glass or porcelain plate is dried with blotting-paper, and the heat of a spirit lamp is uniformly applied to this under surface. The liquid having been then quite evaporated, the surface of the tin undergoes a series of visible changes, resulting finally in a very white layer resembling the white oxide of tin. The plate is then suspended from a fine platinum wire, and sealed into a small glass tube containing methyl alcohol in presence of a clean tin plate similarly sealed into the tube. For the successful production of this surface the tinfoil must be pure; the thin German tinfoil which purports to be pure is not suitable. The strip of foil usually taken is about 1 inch long and about $\frac{1}{8}$ inch wide, its thickness being about that of stiff note paper. On connecting these plates with the poles of a sensitive quadrant electrometer, and exposing the cell to diffused daylight, an E.M.F. of as much as $\frac{2}{3}$ of a volt can be obtained. Its maximum sensitiveness will usually be developed in a few hours after the cell is sealed up and kept in the dark.

Cells formed thus—the alcohol not being, of course, renewed—almost invariably develop a most curious property, from which they are called *impulsion cells*. A day or so after they have been set up, on exposure to light they indicate no E.M.F. whatever, or in some cases a negative E.M.F.; but a slight tap given to the base or support of the cell at once restores their original sensitiveness to light, and another tap destroys it, and so on. The change from the insensitive state to the sensitive can also be effected by the inductive action of the spark of a frictional machine, such as the ordinary gas-lighter, or by the spark of a Hertz oscillator at a great distance from the cell; in the case of one such cell this effect was observed to take place, when the Hertz was eighty-one feet from the cell. In some cells (owing, no doubt, to some want of uniformity in the layer on its surface, or in the heating) a portion of the plate may be found to possess, on exposure, the impulsion property, while the remaining portion remains unaffected by impulses, and always positive. It has been observed that if a cell is not sealed up, but closed by a removable cap, the impulsion effects are made to disappear by simply replacing the alcohol by fresh alcohol as often as these effects repeat themselves. Thus, in one such cell made four years ago, the alcohol was renewed on six successive days, and then the impulsion results ceased, the cell having ever since remained sensitive and the plate positive.

A curious result with a sensitive cell was obtained by connecting it through a very high resistance—about 10 megohms—with a Daniell cell. When connected in such a way that the action of light on the cell was opposed to that of the Daniell—*i.e.*, the Cu pole of the latter with the sensitised plate—the action of light was about five times as great as when the connections were reversed.

These cells are deteriorated by continuous exposure to strong light for several hours, and when the light is withdrawn the E.M.F. generated by it disappears very slowly; but this residual effect can be rapidly, and without injury, pumped out of the cell by connecting the cell in the first of the above ways with a Daniell by means of a make-and-break key; a few seconds' connection, followed by short circuiting, leaves the cell as it was originally. The following figure gives a view of the cell—without its support,

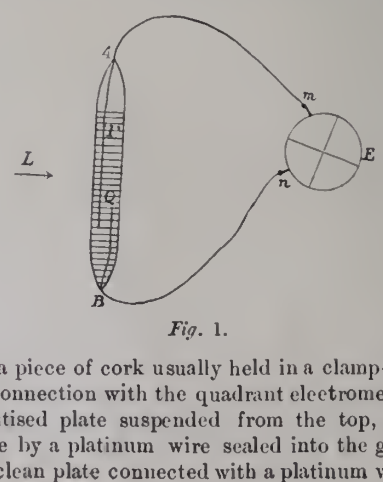

*Fig.* 1.

which is a piece of cork usually held in a clamp—together with its connection with the quadrant electrometer. P is the sensitised plate suspended from the top, A of the glass tube by a platinum wire sealed into the glass at A; Q is the clean plate connected with a platinum wire sealed to the tube at B; $m$, $n$, the poles of the electrometer E: L, the direction of incident light.

3. A new cell in which selenium plays a part was recently discovered. The selenium "cells" hitherto known are copies of that made by Professor A. Graham Bell, and used in the photophone. They are not properly "cells" at all, since they are not used to generate E.M.F. They are merely portions of the circuit of a voltaic battery, and it is their variability as resistances under the action of light which has been employed.

After many experiments with various metals and liquids, I found, last summer, that by smearing a uniform thin layer of melted selenium on a small plate of aluminium, about half an inch long and about $\frac{1}{16}$ inch broad, and then gradually heating and cooling the plate on a porcelain plate, the selenium surface passes through a series of visible changes—exactly as the tin plate does—the final surface aimed at being a uniform brownish one, not exactly a grey, as is generally supposed to be the best, the most sensitive plate is produced. In the heating and cooling process there are various shades of grey, marked by glossy spots or streaks, which most readily present themselves as the final surfaces; but they are all to be rejected. On the average, a sensitive plate takes ten minutes to make. It is sealed into a glass tube, as in fig. 1, in presence of a very small clean plate of aluminium—this latter may be of the size of the head of a pin—the tube contains acetone, which is found to be the best liquid. The cell is called a *seleno-aluminium cell.*

Such a cell develops a large E.M.F. in all parts of the spectrum, the maximum being in the yellow. Diffused daylight will give more than half a volt. The cell, if not short circuited, does not appreciably deteriorate by continuous exposure during the day; recovery takes place at night.

By means of the E.M.F. developed by a battery of twelve

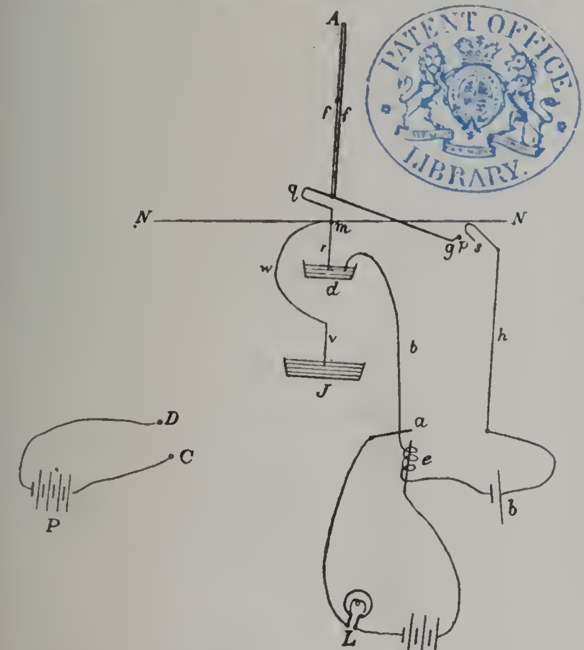

*Fig.* 2.

of these little cells, an electric bell can be rung by the light of a taper or a match. The sensitised plate is always negative. The above (fig. 2) represents the arrangement for lighting an electric lamp, ringing a bell, &c., by means of the E.M.F. of a photo battery P, connected with the poles C D of a quadrant electrometer whose needle is N N, the quadrants not being represented. A very fine glass tube, $g\ q\ m$, passes through the middle, $m$, of the needle, and a platinum wire, $p\ g\ q\ m\ r$, runs through this tube, dipping at $r$ into a flat mercury dish $d$, into which also dips a platinum wire $t$, connected with one end of the coil of a small electro-magnet $e$, the other end of the coil being connected with one pole of a weak voltaic cell $b$, whose other pole is connected with a small platinum plate $s$, inside the case of the electrometer, and held close above the quadrants, and also close to the position of rest of the end $p$ of the platinum wire $p\ g\ q\ m\ r$. The needle is charged from the sulphuric acid jar J, by a fine platinum wire $w\ v$, of which the part $w$ is bent into a semi-circle round the outside of the dish $d$ (so as not to touch $d$ in the motion of the needle), and the part $v$ is vertical, and under the centre $m$. When, by means of the E.M.F. of the photo-battery P, the point $p$ touches the plate $s$, the circuit of $b$ is complete, and, at the same time, the motion of the armature $a$, of the electro-magnet $e$, completes the circuit of a strong battery B, in whose circuit is a lamp. The needle is suspended by fine silk fibres $f\ f$, passing round the glass arm $g\ q$. The portion $g\ q$ of this glass tube is at right-angles to the long diameter of the needle N N.

The possibility of the solution of three problems in photo-electricity was touched on. Firstly, it was pointed out that some scientific comparison of the relative values of two different lights might be effected by some such cell as the seleno-aluminium, owing to its giving such large results in all parts of the spectrum. Secondly, the problem of telephotography, or seeing at a distance, was mentioned. It does not, at present, seem to be very near solution by any satisfactory process; but, doubtless, it will yet be effected. Thirdly, the question of utilising the energy of the solar rays for performing useful work by means of photo-electric batteries, which would act merely as transformers of energy without consumption of their own materials, was discussed; and I ventured to dispute the inference usually made from the pyrheliometer experiments of Pouillet and Violle, viz., that the solar rays at the distance of the earth have not enough power for the object in view. It was shown that, according to Pouillet, we receive from the sun about sixty-three foot-pounds' weight per second falling normally on a square foot of surface, and about ninety-one, according to Violle. Neither amount is large, but it may possibly be that, by catching a solar beam on a blackened surface, we do *not* succeed in transforming *every kind* of energy in the beam into heat. In the solar rays there may be forms of energy which take no notice of blackened surfaces, and, if so, it may be possible to discover some receiving surface which, employed in a photo-electric battery, will transform more energy than is accounted for by black bulb experiments. This was put forth as an encouraging possibility to the experimenter in opposition to the commonly received dogma of the necessary transformation of all kinds of energy into heat, and the consequent death of the whole "visible" universe, as portrayed by Tait and Stewart.

---

OF the one-man and one-woman exhibitions of photographic work yet held at the Camera Club, we take it that an overwhelming majority of the members of the Club would vote in favour of Mrs. Cameron having produced the finest artistic results in portraiture. Probably portraits of the type she executed would take well with the cultured section of the public at this time.

## DR. EMERSON'S RENUNCIATION OF NATURALISTIC PHOTOGRAPHY.

DR. P. H. EMERSON has just issued a pamphlet with a black-edged border on the cover; the title of the essay is "The Death of Naturalistic Photography," and he writes as follows:—

DEAR SIR,—Will you reprint this *in full* in the next issue of the PHOTOGRAPHIC NEWS. It is copyright, but I hereby give you full permission to reprint it.—P. H. EMERSON.

The pamphlet is preceded by the following motto:—

"If offence come out of truth, it were better the offence come than the truth be concealed."—FRANCIS BACON.

Then comes the utterance itself:—

A RENUNCIATION.

*To all Photographers.*

LOVING Brethren that were, I salute you. I owe you one apology, oh! my friends, for in the earnestness of my heart I *partly* misled you. You, who stuck by me in storm and stress I shall never forget—if any of you, after this renunciation, seek advice, ask and you shall receive of my best. You, enemies, who will now rub your hands with small-souled glee, rub on, till it all ends in imaginary soft-soap. You, whom I have in mistaken zeal attacked, pray forgive and forget.

And now list. I, saner than ever, renounce and abjure all theories, teachings, and views on art written, and first promulgated by me in sundry works, articles, &c., and finally collected in a volume, entitled "Naturalistic Photography." I cast them upon the dust-heap.

I am for the present and future neither idealist, realist, naturalist, nor impressionist—*photographic impressionist** indeed!—as though ALL graphic artists were not impressionists, and as if the photographic process could give aught but transcripts more or less literal. Shall I, forsooth, explain this burning of books?

List, you who have ears to hear and eyes to see.

In the fulness of my heart I dreamed a dream. I thought art might be taught by writing. I was wrong, I confess. I, even I, "the lover of nature"—everyone is that now—preached that all art that did not conform to "truth to nature" principle was bad—that was a fatal sermon to many. From this followed again the idea—mistaken, alas!—that photography *pure*—not impure, on rough papers, touched up by clumsy hands—was an art surpassing all black and white methods. *Eheu!* That this was ever believed! However, I was sincere, enthusiastic, but mistaken, and I was and am no amateur. I have by the sweat of my brow learned, under a master, something of this thing they call art. Being no amateur, I have therefore left the Camera Club, the home of the "amateur." But ye reasonable ones in photography—some of you *are that*, true and worthy sons of the goddess Science, who has little to do with the goddess Art—you will ask, and with right, why this thusness? I respect you true workers in science—ye Abneys, Dallmeyers, Hurters, Driffields, Vogels, Jones, Harrisons, Bolas, Waterhouses, Eders, and others. I will tell you, for the vulgar mob of pseudo-scientists have done naught but prove their ignorance and show signs of the itch—the itch for publicity and venom.

To you, then, who seek an explanation for my conduct, Art—as Whistler said—*is not* nature—is not necessarily the reproduction or translation of it—much, so very much, that is good art, some of the very best—is not nature at all, nor even based upon it—*vide* Donatello and Hokusai.

* "A term consecrate to charlatans," and especially to photographic impostors, pickpockets, parasites, and vanityi-ntoxicated amateurs.

The limitations of photography are so great that, though the results may and sometimes do give a certain æsthetic pleasure, the medium must always rank the lowest of all arts, *lower than* any graphic art, for the individuality of the artist is cramped; in short, it can scarcely show itself. Control of the picture is possible to a *slight* degree, by varied focussing, by varying the exposure (but this is working in the dark), by development, I doubt (I agree with Hurter and Driffield, after three and a-half months' careful study of the subject); and, lastly, by a certain choice in printing methods.

But the all-vital powers of selection and rejection are *fatally* limited, bound in by fixed and narrow barriers. No differential analysis can be made, no subduing of parts, save by dodging; no emphasis, save by dodging; and that is not pure photography; impure photography is merely a confession of limitations. A friend once said to me, "I feel like taking nearly every photograph and analyzing it." Compare a pen and ink drawing by Rico or Vierge, in Pennell's book. I thought once—Hurter and Driffield have taught me differently—that true values could be obtained, and that values could be *altered at will* by *development*. They cannot; therefore, to talk of getting the values in any subject whatever as you wish, and of getting them true to nature, is to talk nonsense.

It is impossible in most subjects to alter your values *as you wish*, and to talk of such things now is mere emptiness and puffed-up humbug.

Some amateurs, following Colonel Noverre's REVIVAL of rough printing-papers LAST YEAR (1889), have thought that salvation lay in rough surfaces. Colonel Noverre's dust-heap was ransacked, and we have heard of a "new departure," a new "school," and all the bleat of the overweeningly vain "amateur."

If there can be no scientific basis for an art, as some have asserted, Meissonier can claim to be as artistic as Monet, and Monet as Meissonier. The sharp photographer can assert his artistic rights alongside of the veriest "blottist." So all opinions and writings upon art are as the crackling of thorns beneath the pot. In short, I throw my lot in with those who say that photography is a very limited art. I regret deeply that I have to come to this conclusion. Photography is first of all the *handmaiden of art and science*. It has and will register new facts of light, form, and texture. Pure photography is a scientific method of drawing, and scientists should work on until a true and literal scientific transcript of nature can be made—this by orthochromatics, &c.

It will interest some to hear what I think of some points that have been vexed questions in a war I have, I regret to say, stirred up. Composition, as understood by Burnet and others, I hold to be futility itself, though I can appreciate the attempts to meet the difficulties in this matter. The eternal principles of art I have heard so much of are mere catchwords.

*Sharpness v. Diffusion.*—If the work is for scientific purposes, work sharply; if for amusement, please yourself; if for business, do what will pay.

I have—I regret it deeply—compared photographs to great works of art, and photographers to great artists. It was rash and thoughtless, and my punishment is in having to acknowledge this now. Think of the marvellous dexterity of the man who with pencil, pen and ink, or paint and brush, produces a masterpiece, the drawing equal to that of the lens, the tones in harmony, the colour delicate and marvellously beautiful. Read Rood's "Chromatics" for a hint of the manifold difficulties surrounding this subject. Then think of the amateur photographer who, if clever, can *in a few weeks* turn out good, technical work.

It may be asked, then, what theories on art I have. I answer, at present, *none*. What artists I admire? I answer, all good artists and all good art. To what school do I now belong? None. What do I think of writings upon art and art criticisms? Mistakes.

A final word. Suggestions have been made that I get some of my ideas from a book called "Naturalistic Painting." I have a letter in my possession from an artist, wherein is stated clearly and exactly that Mr. Bate* had read a paper of mine on "Naturalistic Photography" *before* his first article appeared in the "Artist." At the Society of Arts the other day, a paper was read by Mr. Davison—an amateur without training, and with superficial knowledge—in which my *old* ideas were freely and impudently handed about, and no credit given me. It was whispered about by my enemies that this person had originated some of the ideas of Naturalistic Photography. To enlighten the public, I append a quotation from his letter to me on this point. There are plenty more confessions of "his lack of knowledge"; that his articles were "drivel"—it is his own word—and other confessions of incompetence and proofs of plagiarism, if necessary. He is now welcome to my cast-off clothes if he likes—he or anybody else. It is with deep regret I do this thing, and it is only as a duty to myself. I justify myself by stating that I wrote privately to Mr. Davison, expostulating with him for freely appropriating my ideas, and telling him that if he did not give me full credit at the Society of Arts, I should publish a history of the matter. He never replied. He can publish my letter in full if he likes. This was Mr. Davison's reply to a letter I wrote to him and others asking them if they minded me thanking them in public for their support. His reply is dated from the Camera Club, Dec. 16th, 1889, ONLY A YEAR AGO. It is, "I AM GLAD AND PROUD TO BE IDENTIFIED IN ANY WAY WITH NATURALISTIC PHOTOGRAPHY, BECAUSE I BELIEVE IN WHAT I UNDERSTAND IT MORE AND MORE CLEARLY TO BE, BUT I DOUBT VERY MUCH WHETHER ANYTHING I HAVE DONE DESERVES RECOGNITION."

I sent a copy of "Naturalistic Photography" some time ago for review to the editor of the *Journal of the Society of Arts*, and it got a bad notice. All the ideas offered the other night were thus offered to the Society *previously*. Lastly, a special speech, read from a paper by a friend of mine, especially pointing out how I had originated these ideas, was not reported as it was read, the printed report giving altogether a different impression from what the speaker said. Those who heard the original can refer to the speech, as reported in the *Journal of the Society of Arts*—not Artists, as Mr. J. Pennell has aptly described it. This sort of treatment, which is nothing new to me, may excuse some of my bitterly written invectives.

Finally. Some of my friends to whom I have recently privately communicated my renunciation, have wished to know how it came about. Misgivings seized me after conversations with a great artist after the Paris Exhibition; these were strengthened by the appearance of certain recent researches in psychology, and Hurter and Driffield's papers; and, finally, the exhibition of Hokusai's work and a study of the National Gallery pictures after three and a half months' solitary study of nature in my house-boat did for me.

*P.S.—Will every secretary of every photographic society take four wafers and a sheet of black paper, and hide for ever the words "To the Student" in pictures of East Anglian life.*

L'ENVOI.

Having taken some earnest photographers a little way into the art world, I feel it my duty to say that, when I have *fully* reconsidered the limited art possibilities of photography and the general philosophy of art, I will write another book; in the meantime, let students avoid all spurious imitations.

Lastly, Dr. Emerson gives the accompanying epitaph on the cover of his pamphlet:—

EPITAPH.

In Memory of
NATURALISTIC PHOTOGRAPHY,
WHICH RAN A SHORT BUT ACTIVE LIFE,
UPSET MANY CONVENTIONS,
HELPED TO FURTHER MONOCHROME PHOTOGRAPHY TO THE UTMOST OF ITS LIMITED ART BOUNDARIES,
STIRRED MEN TO THINK AND ACT FOR THEMSELVES,
PRODUCED MANY PRIGS AND BUBBLE REPUTATIONS,
EXPOSED THE IGNORANCE OF THE MULTITUDE,
BROUGHT OUT THE LOW MORALITY OF CERTAIN PERSONS IN THE PHOTOGRAPHIC WORLD,
BROKE DOWN THE PREJUDICE OF THE OUTSIDE PUBLIC AGAINST PHOTOGRAPHY'S VERY SLENDER ART CLAIMS,
ENCOURAGED MANY AMATEURS TO BABBLE AND MAKE THE WORDS "ART," "TRUTH," AND "NATURE" STINK IN THE NOSTRILS OF SERIOUS ARTISTS,
ENDING BY GIVING A FEW A BRUTAL SORT OF APPREHENSION OF ART, AND DYING WHEN ITS ALLOTTED TASK WAS DONE WITH A GIBE ON ITS LIPS,
FOR THE "AMATEUR," THE "PLAGIARIST,"
THE "PRATING TRUE-TO-NATURE MAN,"
THE "IMPRESSIONIST," THE "NATURALIST," THE "IDEALIST,"
AND THE HUMBUG.

---

THE Fourteenth Annual Stanley Cycle Show, open at the Crystal Palace from the 23rd to the 31st inst., is far more interesting than any of its predecessors, several novel features being introduced. Mr. E. R. Shipton, secretary to the Cyclists' Tourist Club, will, on Monday evening next, read a paper on improvements in the manufacture of tyres, and sections of the various tyres will be shown on the screen by means of lantern slides.

SOLUTIONS OF CELLULOID.—Dr. Charles Ehrmann writes:—"Alcoholic solution of celluloid has been said to be an exceedingly fine retouching varnish. But celluloid is in reality not more soluble in alcohol than ordinary gun-cotton or xyloidine. When small and tiny shreds of celluloid are macerated in alcohol of nine-five per cent., the substance swells up like gelatine does in water; the alcohol permeates its pores and dissolves the camphor contained, so that the final result is a solution of camphor, nothing else. We do not deny that a thin stratum of camphor upon the gelatine film will assist materially retouching with a graphite pencil, but the medium is by no means celluloid, which has proved to be so excellent to retouch upon. After macerating the celluloid in alcohol, and a thorough dissolution of camphor, washing it in water and drying, it will burn with detonation, exactly like gun-cotton does—proof enough that the alcohol had no other effect upon it than that above stated."

* This does not imply that Mr. Bate took any ideas from my paper; on the contrary, I feel sure his ideas were his own, as were mine.

## Literary Notices.

Optical Projection. By Lewis Wright. (*London: Longmans, Green, and Co.*, 1891.)

This book, issued last Monday, is a first-class one in relation to some of the principles of construction and use of the lantern, also in relation to the application of the instrument to demonstration purposes at scientific lectures. Much of it is the result of original and previously unpublished research relating to the construction of lanterns, and the optical and mechanical details relating thereto, in which the author was aided by Mr. Herbert C. Newton.

The first chapter lays down elementary principles and conditions of optical projection, such as are well known to many photographers who use the lantern, but are not so well known to the general public. Farther on, Mr. Wright deals with practical details, and we soon come upon the following useful little suggestion about the value of two side doors to the lantern:—

> Where exhibitions may have to be made in various places, it is of some importance to have a door on *both* sides of the lantern. Most people work from the right side (as the lantern faces the screen), but this is not always possible, especially with experiments. In all lanterns used with the lime-light, each door should be furnished with a sight-hole glazed with dark *blue* glass, through which the state of the lime can be examined without dazzling the eye. For a lantern used only with paraffin oil, sight-holes are useless, the flame being examined through a sight-hole at the back of the lamp.

The contradiction in terms in the last sentence of the above quotation is evidently a slip.

The subject of the best form of condenser is one in which the photographic public, at present, take more interest than in any other connected with the lantern; this problem is dealt with at some length, aided by numerous illustrations. For ordinary use, with lantern slides of the common size, the author recommends the condenser now in ordinary use, consisting of two plano-convex lenses with their convex surfaces nearly in contact, and says that, with an oil light, it is better than the double convex and meniscus combination devised by Sir John Herschel. About the merits of double *versus* triple condensers, he says:—

> Condensers of three and even four lenses have been used, especially in America. Theoretically, they admit of more perfect corrections for aberrations, and a larger angle of light; but this is complicated by the number of extra reflecting surfaces. I have perfectly satisfied myself that for exhibition lanterns they afford no gain whatever. For large condensers, as five inches and over, and where the light is to be condensed upon a *small* surface, as for the projection microscope, they are of advantage, and allow us to use a pencil of 90°.

In the above paragraph we have the elements of strong contention among authorities in relation to the lantern. Many of the improvements in the optical lantern during the present generation have had their origin in America, and that class of condenser which is largely in use among experienced lanternists in that country is thus condemned by Mr. Wright. Mr. Traill Taylor, who is known among photographers as an authority upon this subject, has published that, with a triple condenser, the gain in illumination of the disc is great, and has illustrated his remarks by a diagram, from which it would appear that the amount of light passing through is nearly doubled by the use of the third lens. Sir R. Ball, Astronomer-Royal for Ireland, once brought his own lantern to the Royal Institution, to use in projecting diagrams and pictures during his lectures, and it had a third lens fitted up inside, to throw more light upon an ordinary condenser. Was this done because of a mistake in practical optics? In some condensers of good design it is necessary to have them a little larger in diameter than the common one, to well cover a slide of the same dimensions, but this is no practical objection, for it merely means a little extra first cost with no subsequent extra expenses. The triple-condenser men, of course, admit the slight deteriorating influence of two extra reflecting surfaces, but assert it to be of practically no importance as compared with the extra amount of light transmitted.

Mr. Wright, in his just-quoted paragraph, admits the triple condenser to be right theoretically, and, instead of authoritatively saying that it is of no use practically, he should have given a demonstration of the truth of the assertion, for in these turbulent times, and in this scientific age, a stiff-necked generation demands proof, and pays little deference to the voice of authority, the accumulated experience of mankind having taught men the folly of doing otherwise. The best results are always obtained by true theory and true practical application going hand in hand, but Mr. Wright demands that, in this matter, they shall be divorced. This problem is one of the most vital importance connected with the lantern, for it involves the question of how to obtain the maximum of illumination with the minimum of light and heat.

That the third lens may sometimes give a condenser more liable to be cracked by heat seems no valid objection; the third lens should be thin, and so mounted as to be easily and quickly replaced by another should it get cracked, and, from its smaller diameter, it need not cost much; it may, moreover, decrease the liability of the other two and more expensive lenses to crack. Moreover, a skilful worker is not likely to crack a properly made condenser; he will take care not to heat the lantern too rapidly. A private individual has difficulty in thoroughly investigating this matter for himself, because to do so requires a number of lenses differing in curvatures and focal lengths, which there might be difficulty in obtaining in the market, and he would require special appliances for the relative centreing and otherwise adjusting.

The public will not allow the flat contradiction in statements by authorities upon lantern condensers to rest where it is, now that the instrument is in use in the home of nearly every photographer, and is everywhere growing in popularity. The users of the lantern are sure to take steps to get the maximum of illumination of the screen with the lowest possible amount of light in the lamp. The trade will respond to the demand, but, perhaps, will not initiate any change, for trade is slow in quitting its established channels. Meanwhile, Mr. Taylor's recent utterances at the Camera Club on English and American condensers laid down true principles, and we think it likely that he will in the end come out of this contention by proving himself to be right, and Mr. Wright wrong. Mr. Wright uses a triple condenser himself in his own oxy-hydrogen microscope; why not, then, in the ordinary lantern? One can quite understand that by taking any common double condenser, and any smaller lens that may be handy, the three together may not give an improved result, from unsuitability of the focal lengths and curves of the three elements; but any such method of testing a principle is unscientific, and likely to lead to false conclusions.

The author expresses the following opinions about condensers:—

Condensers are usually made of crown glass, density about 1·516. This answers perfectly for ordinary purposes; but for the highest glass of modern exhibitions, which have to cover large screens of twenty to thirty feet diameter, sometimes at great distances, it is objectionable, as the green colour absorbs light which can ill be spared in such circumstances. Chance's "optical" flints, of course, leave nothing to be desired in this respect, but condensers so made are very expensive; in some cases, however, they are worth while, as the glass is both more colourless, and the lenses are *thinner* for the same focus. A more common flint would answer practical purposes, and it is desirable that some colourless glass should be introduced if possible, rather than green crown. This need not make them so very much more expensive; for while "optical" flint must be homogeneous, and is usually wanted dense for a condenser, a perceptible amount of *striæ* is of little practical importance, and density is not required, only colourlessness. It is utterly useless to pay the cost of optical perfection in a condenser for any ordinary purposes. A perceptible bubble in the lens next the slide, however, would be a defect of importance, probably showing as a black spot. It is very likely that many purchasers would reject a colourless lens with perceptible striæ, rather than a crown lens which showed none; nevertheless there can be no question that the first would be the better condenser, unless the striæ were excessive.

The point most commercial condensers chiefly fail in, however, is that the lenses are not ground *thin at the edges*; nearly all lantern makers being far too careless in this respect. Not only is a needlessly thick lens much more likely to crack, and more absorbent of light, but it is distinctly worse in optical performance. The lenses should be ground to as nearly knife-edges as possible, being only just edged down for fixing into their cells.

Both lenses should be mounted so *loosely* in their brass cells that they can be turned round with the fingers, else they may crack merely from expansion when heated, and they often become hotter than the hand can bear. Holes must be pierced in the margin of the cell, to allow of the escape of the aqueous vapour which always forms when the lantern is first lit. Only the back lens ever cracks from heat alone. If the crack be irregular, the lens must be replaced; but it often happens that the crack is quite straight across a diameter, in which case the cracked lens will answer perfectly well if the crack is arranged perpendicularly, and the operator may feel certain that his lens will never crack again.

In speaking of single lenses as compared with photographic portrait lenses—or modifications thereof—for projections, Mr. Wright gives useful information about a French single combination, consisting of a concave lens of flint cemented between two double convex crown glass lenses, the whole then assuming a double convex form. Mr. Wright says:—

Some of these lenses perform exceedingly well. They were used a great deal by Mr. Dancer for his lanterns, and I possess a pair of them, 6-inches focus, whose performance can hardly be distinguished from that of the best of the construction next to be described. They appear to me to combine flatness of field, evenness and sharpness of definition, and ortho-symmetry of image, in a greater degree than any other single lenses, and I think it is to be desired that more attention should be directed to this construction for long focus work. My pair of 6-inch lenses have a clear diameter of $1\frac{3}{4}$ inch, and require a 1-inch stop placed about $2\frac{1}{2}$ inches in front to produce their best effect. In this position the stop cuts off scarcely any rays of serious importance, and the image of a slide of printed matter is exceedingly good. For lenses of 9 inches focus and upwards no stop whatever would be required, and such lenses would be much cheaper, and pass more light than double combinations.

The chief points to be attended to in projection lenses are to see that they are of sufficiently large diameter to take in all the cone of rays coming from the condensers, and that they give a flat field combined with good definition.

About the petroleum oil for use in lamps, Mr. Wright says that the "common trash" often sold as "paraffin oil" should not be used, and that much of it "is not safe to use in any lamp, and none of it gives a good light;" only the best refined paraffins should be used. If such dangerous oils are in market, and in weather, too, when there is a run upon them for household purposes, the Government should be made aware of the infringement of the law as regards the flashing-point of the said oils. Notwithstanding the hundreds of tons of such oils burnt in London for heating purposes during the recent severe weather, we are not aware of a single accident therefrom having been recorded in the newspapers.

In relation to oil lamps, a word of warning might have been uttered in the book, about those of faulty construction, so made that the light cannot, in certain cases, be brought so near to the condenser as when the limelight is employed. Information also might, with advantage, have been given about the merits of circular wick lights, such as yielded by Trinity House two-ring burners, as compared with the ordinary three-wick lamps, and the slight unevenness of illumination of the screen given by the latter.

The fact that oxygen gas passes through india-rubber, but less rapidly than the nitrogen, does not seem to be generally known. Attempts have been made to obtain, by this method, air rich in oxygen available for practical purposes, but as yet it has not been done to commercial advantage. In relation to this passage of oxygen through india-rubber, Mr. Wright states:—

Gas should never be kept in a bag any length of time. Oxygen acts rapidly upon the material; but independently of this, no gas can remain pure, owing to that wonderful process of diffusion through the material which physicists call *osmosis*. A bag filled with perfectly pure oxygen will contain a portion of air in some hours' time, and any bag tight in the morning is perceptibly slackened by night. Supposing gas to be left over one night, to any amount, there is no reason, if convenient, why it should not be kept, and merely filled up for *the next* night; but beyond this gas should never be kept, or the light will be perceptibly affected.

If in photographic research the experimenter could get coloured glasses to give all the more pronounced colours of the spectrum quite pure, such a set of glasses would be extremely useful, and the author of the book under notice says that Mr. Madan has discovered that, by superposing Chance's signal green on a rich cobalt blue glass, the two only transmit rays between F and G. This, therefore, is the way to obtain a true blue by means of flat glass plates, and is an interesting fact worth notice.

The work contains useful practical information about lime-light jets, photo-micrographic instruments, and the application of the magic lantern to purposes of scientific demonstration. The book contains practically nothing about the history of the magic lantern. Those interested in the latter branch of the subject will find much about it scattered up and down in pages of this journal during the last five or six years.

Taking Mr. Wright's book altogether, it is about the best we have seen on the subject, but is defective in not going into sufficient detail about the optical system of the lantern, the relative merits of various condensers, and the focal lengths and other points about the lenses of which they are composed. It also is too meagre in information about oil lamps.

## Notes.

In a partly serious and partly ironical pamphlet, Dr. Emerson has renounced what has, unfortunately, been called "naturalistic" photography, and most of the outcome and adherents thereof. At all events, the general result of his efforts has been to stir up much thought on the artistic aspects of photography, and to initiate the production of a new class of pictures, some of which were exceedingly beautiful, as acknowledged by those photographers who do not care to have their names pinned to any particular "school." Widespread public attention was early drawn to the merits for special purposes of rough-surfaced papers and broad photographic treatment by the picture of Penzance Harbour, exhibited by Col. W. L. Noverre at one of the exhibitions of the Photographic Society, and reproduced as a supplement by this journal. In Mr. Lyonel Clark's photograph of Dedham Bridge, which we reproduced at the beginning of this month, there was not a sharp line in the picture; yet the result was generally regarded by the public as pleasing.

Photography is to the front in the pantomime at the "Elephant and Castle" Theatre. The clown produces a tripod stand of special construction, and which may well be inspected by manufacturers of photographic apparatus. On this stand he places a camera, and in front thereof a policeman, seated on a chair in the street. At the moment of uncapping the lens, the clown, to rivet the attention of the sitter, points upwards and says, "See the little dickey-bird fly," when, behold, the photograph is taken by the primuline process, and drawn out at the back of the camera as the head of a jackass or nondescript animal printed upon a pocket-handkerchief. The sitter being dissatisfied, a gun camera is substituted and fired, whereupon the sitter takes to his heels smothered with flour. The unfortunate policeman, being an emblem of authority, gains no sympathy from most of the observers when he is ill-treated in a pantomime.

The General Syndicate of Photography in Paris is an organisation which deals with the commercial and other interests of photography; it has already adopted the principle of arbitration in trade disputes, in place of going to law, and has framed some rules as to the conditions under which the Syndicate will arbitrate. The Syndicate gives attention to the dealing of Custom Houses with photographic plates and goods of all kinds; it keeps a watchful eye on all legislation affecting the interests of photographers, and seeks to make itself generally useful.

Composite heliochromy, or the plan of taking three negatives of a scene through three glasses of suitable colours, and then obtaining therefrom superimposed images in suitable pigments, so as to build up mechanically a coloured representation of the original views, is said by Mr. F. E. Ives to be capable of giving fine effects in tho optical lantern. In a paper read last month before the Franklin Institute, he stated that the effects can be brought before the public in the form of optical lantern lecture illustrations, not with the triple lantern, but with transparent colour-print heliochromes mounted as lantern slides. If the colour-prints are made by the Woodburytype process, such heliochromic lantern slides, infinitely superior to hand-painted ones, can be made in quantity, he said, at a cost not exceeding one dollar each.

It is an inexorable law in matters photographic, as in other fields of work, that demand must stimulate supply, and manufacturers of photographic apparatus are so watchful of what is going forward that a suggestion is no sooner made than it seems to be acted upon. Printing on smooth paper has, to some extent, had its day, and there is just now a demand for rough-textured material. The demand has operated in the customary manner, and, after a few energetic workers had experimented with different processes for sensitising the roughest drawing-paper which they could obtain, it is now to be bought ready prepared by the Fry Manufacturing Company for photographic purposes.

The experiments in this direction have usually followed the old process of salting and sensitising by means of a nitrate bath, or perhaps a nitrate *brush.* But this new paper is prepared with gelatine emulsion, and so it comes under the head of bromide paper, a paper, however, which is far rougher than any before to be obtained. There is little doubt that photographers, by the adoption of this (Whatman's) paper, have taken a very useful leaf out of the water colour artist's book, for it is greatly due to the texture of the paper that the painter is able to get those pearly tones and effects of atmosphere upon which he so much prides himself. The photographer certainly has a much harder task before him in securing the same result, for he cannot work in colour; still, he makes a step in the right direction by borrowing a hint from the painter in water colours.

A curious problem crops up in connection with this use of sensitised rough paper, and one which it is not very easy to solve. It is this: Although rough and smooth paper may be coated from the same bottle of bromide emulsion, the former will require more than double the exposure of the latter. Why should this be so? Certainly not because of any chemical impurity or difference in the paper, for the material for water-colour work is made—generally by hand—with the most scrupulous care, so that there shall be no possible chemical reaction with the colours laid upon it. We should be rather inclined to fancy that the lowered sensitiveness in the case of rough paper must be partly due to the absorbent nature of the material —which would cause many of tho molecules to be buried—and partly to the rugose nature of the surface, which would hide many more in its crevices from the access of light.

Another application of our ubiquitous art! We learn that a firm of Nottingham curtain manufacturers employ a photographer whose business—happy man—is to seek out secluded nooks and glens, where ferns and underwood flourish, where streamlets murmur, and where the kingfisher and dragon-fly glide. He takes photographic notes of these natural pictures, and from his photographs artists work out designs for lace curtains. Up to within quite recent times, English manufacturers were dependent upon French designs for their lacework, but the camera has been introduced into the service, and Waterloo, in this case, has not yet been avenged.

---

It is satisfactory to see that the British Museum authorities are alive to the advantages of photography. Simultaneously with the announcement of the discovery of the Aristotle papyrus comes the statement that the latter is to be photographed. It is very clear that photography places a considerable power in the hands of scholars and antiquarians. By means of facsimiles, comparison can be made with specimens in foreign libraries, and thus the possibility of deception and forgery effectually guarded against.

---

It would be interesting to know how a phrenologist can give an analysis of a person's character from a photograph. It is clear that he cannot feel the bumps, though perhaps it may be argued that, by intently studying the conformation of the skull and the various elevations thereon, he may evolve something out of his inner consciousness. Anyway, Dr. Koch has been phrenologised by the *Phrenological Magazine* simply from study of his picture. As a contemporary remarks, "photographs are dangerous things from which to describe a person's phrenological properties." The writer, it seems, has overcome the difficulty by granting to Dr. Koch almost every gift and capacity extant.

---

We are not aware that photographers are addicted to photographing themselves, but possibly this may be due to the mechanical difficulties in the way. Artists have not the same trouble, and it is not surprising that most well-known artists have painted their own portraits. Indeed, a collection of portraits of painters by their own hands has been suggested as a means of elevating art, and there is already a most interesting gallery of the kind in the *Uffizzi* at Florence. Sir Frederick Leighton does not, however, favour the proposition, as he says that to paint one's own face is distasteful to the artist. We do not know why this should be so, as an artist paints from his reflection in the glass, and such a reflection, the student of human nature will say, is always one that is agreeable to the person reflected. When we look in the glass we see the image we want to see. This is why a photograph which takes us with an unfamiliar look upon our faces comes at times as such a painful surprise. We do not think that Sir Frederick Leighton is altogether correct in his opinion. Experience points to the opposite.

It may not be long before the ingenious pantomime mask-makers, in want of a new monstrosity, will go to photography for it. The photographs of insect life, exhibited by Mr. Poulton in his lecture to children at the Society of Arts, are said to show such grotesqueness and unexpected forms, that nothing so curious has ever been seen at the opening of a pantomime. This certainly gives a new field for the Dynwinkyn—whose name used to be a household word in the mask world—of the future.

---

Panama is about the worst place in the whole world for photography. We are informed by a traveller who has recently visited the Isthmus that it is absolutely impossible to buy any moderately decent photographs either of the canal works or anything else. Photographers give up the task in "despair." This is on account of the extreme humidity of the atmosphere. Some idea of this may be imagined when we say that the contents of a trunk which formed a portion of our informant's luggage, and which trunk was never opened while at Panama, were found to be incrusted with a green mould. Only those who have travelled on the Isthmus can form any idea of the hygroscopic conditions. Naturally the climate is as fatal to life as it is to photography.

---

It is sad to have to confess that photography lends itself easily to bad ends, but such is the fact. The old dodge of inviting ladies to send stamps, and in return they would have unlimited work in the way of colouring photographs, for which "no previous experience" was required, is, it is true, exploded, but a new artifice has taken its place, and would appear to be even still more remunerative. This plan consists of advertising that a generous firm will supply you with a pastel portrait on the sole condition that you have the picture nicely framed, and recommend the work of the firm to your friends. When you send your photograph, you get back an intimation that nothing can show off the "pastel portrait" so well as one of the "firm's" frames, a pattern sheet of which is enclosed. If you decline to purchase a frame, the pastel portrait never comes, nor is your photograph returned. A Shoreham solicitor who had been done in this way, bringing an action this week in the Worthing County Court, obtained judgment for two guineas—the amount demanded for the failure of the contract. As the defendants did not put in an appearance, it is more than likely the two guineas will be as invisible as themselves. The lucrative nature of this advertising dodge may be imagined from the statement by the plaintiff's solicitor that as much as £800 had been traced through the post office representing remittances sent in in one day to the firm in question.

---

A storekeeper at Barberton has a queer advertisement in the *Barberton Herald*. After going through the list of his goods, he says, "Photographers wanted to take display for next Transvaal Exhibition. No amateurs need apply." Why this contempt for amateurs?

## PHOTOGRAPHY IN ANILINE COLOURS.*

BY A. G. GREEN, C. F. CROSS, AND E. J. BEVAN.

In the diazotype process, which is the main subject of this paper, we have as the actual photographic agent not only a highly-sensitive compound—highly sensitive, that is, to the action of light—but one which can be readily converted into a variety of colouring matters. The process consists of three stages :—(1) Drying or coating the surface upon which it is required to photograph with a particular compound, which is theu (2) converted into a photo-sensitive derivative ; and (3) exposed to the light under the usual conditions for giving the picture ; (4) converting the seusitive compound, wherever it survives, through having been protected by the shadows of the object photographed, into colouring matters, and thus the picture is developed from the weakly coloured sensitive compound into well-marked shades of red, orange, brown, purple, or blue ; and these shades being formed in stable colouring matters, the picture is at the same time fixed.

For the better understanding of the process, it is necessary that we should acquaint ourselves with the properties of these substances, apart from any reference to photographic action.

The compound we start with is a yellow-coloured body, to which the " trivial " name of primuline has been giveu. This compouud is obtained by the actiou of sulphur upon toluidiue, a coal-tar base closely allied to aniline. In this action uot only is there combinatiou with sulphur, but several molecules of the toluidine are built up into one complex molecule.

Then, to express the matter in our modern formulæ, we start with $C_6H_5\ Cu_8\ NH_2$ toluidine, and obtain—

$$CH_3.C_5H_3<{}^{S}_{N}>C.\quad C_6H_3<{}^{S}_{N}>C.\quad C_6H_3<{}^{S}_{N}>C.\quad C_6H_4Nu_2$$

primuliue base—a very formidable looking compound. Now, the important part of this formula to us is uot the uuwieldy body, but the head, the small group $NH_2$. We can consider primuline in its simplified form $X.NH_2$, and we see that this differs from ammonia, $H.NH_2$, in having one H replaced by a complete group. Correspouding to this general resemblance, there is a similarity in their distinguishing property ; both are basic or alkaline substances, and combine with all acids to form salts. One only of these we have to consider, that very combination with which the stable primuline—highly resistant to all agencies which destroy the more fugitive colouring matters—is converted iuto a photo-sensitive derivative. This acid is nitrous acid, $HNO_2$. Nitrous acid and ammonia combine to form ammouium tritrite. Wheu this tritrite is heated, it is resolved spontaueously into nitrogen gas—the inert constituent of atmospheric air - and water.

Primuline, in common with all coal-tar bases, combines with nitrous acid to form a species of nitrite, which is termed a diazo compound. All that we need note abont these diazo compounds is that they correspond to the intermediate stage in the transition of the ammonium nitrate to the condition of nitrogen (and water) thus :—

| | | |
|---|---|---|
| $NH_3.\ HNO_2$ | $H.\ N\ N\ OH$ | $N_2$ |
| Ammoniuu nitrite. | $(-H_2O)$ | $(-2H_2O)$ |
| | $X.\ N = N.OH$ | |
| | Diazo-primuliue. | |

These diazo derivatives are, as a class, sensitive to light undergoing decomposition with evolution of nitrogen gas. But what concerns us, for the moment, is their avidity for construction or syuthetic reaction with two large groups of coal for compounds—the bases and phenols. With these they combine very much as the original bases combiue with nitrous acid, to form these active diazo compounds, and the products are the azo-colouring matters. We cite the more importaut of these, obtained from primuline. In the case of the several phenols, their alkaline solutious are employed, while in the case of the bases aud solutions are used—

*Primuline* and nitrous acid gives *Diazo-primuline.*

| | | | | | |
|---|---|---|---|---|---|
| β Naphthol. | Pheuol. | Resorcin. | Pyrogallol. | α Naphthylamine. Hydrochlorinde. | Amido. β Naphthol. Sulphuric Acid. |
| *Red.* | *Yellow.* | *Orange.* | *Brown.* | *Purple.* | *Blue.* |

These relations we demoustrate with diazo-primuline and the several reagents above-mentioned.

We now come to the photographic applicatiou of these reactions. The essential conditiou of primuline photography is—(1) that these reactions take place with primuline after its applicatiou to any surface or material, such as wool or silk, as a dye, without in the least affectiug its union with the material ; and (2) that the diazo-derivative produced, in combination with these materials, by treatiug the primuline-dyed surface with nitrous acid, is photo-sensitive in the highest degree, far more so, in fact, than the derivative itself, when free or uncombined.

Having thus prepared the way, we proceed to a complete experimental demonstration of the process. We first show the building up of the colouring matters upou the cotton and silk fabrics, showing that the reactions take place in silk without disturbing the union between the colouring matter aud fabric ; and that the azo colouring matters so built up withstand the action of boiling soap.

We have now to demonstrate the sensitiveness to light of a surface dyed with primuline, and sensitised by treatment with nitrous acid, and we shall show that the actiou of the light is to destroy the diazo-derivative, that this destruction is due to the splitting off of its two characteristic nitrogen atoms in the gaseous form. We are enabled to show this to au audieuce owing to the curious fact that, iu a gelatine medium, the nitrogen, though liberated from combination, is not evolved until the gelatine is softened by contact with water. We expose a primuline-gelatine plate to photographic action, and on plunging into a transparent bath of water, an image of which is thrown on the screen, we see the form of the print instantly developed in minute bubbles of gas. On then treating the plate with one of our developers, we see that when the gas has formed—the evidence, *i.e.*, of the destruction of the diazo-primuline—then no development of colour takes place.

We now develop a number of prints which have been exposed in the daylight, and brought here in the conditiou in which they left the priuting frame. In these developed pictures the high lights are represented by the ueutral tint—varying from buff to cream—of the product of destruction of the diazo derivative, the absence of development in these portions being due to the chemical mixtures of this product.

The development of colours correspondiug to the shadows and half tones of the object is exactly proportionate to their depth, to the degree of protective action which they have exerted on the sensitive surface beneath—iu other words, to the quantity of diazo-primuliue which survives.

Revertiug to the considerations which we advanced in the earlier portion of this paper, we should explain the action of the light on an addition of euergy or atomic motion to the molecule of the diazo-primuline, whereby the split or cleavage of the molecule at the point occupied by the two nitrogeu atoms is determined, just as by adding heat to ammonium nitrite its molecule is resolved into nitrogen, and a residue, which iu this case is not a complex compouud, but water.

We have already alluded to the fact that the rays which attack the diazo-primuline are by no means confiued to the blue and violet constituents of the spectrum, but extend well through the yellow to the orange red. In other words, a primuline print is more nearly a measure of the visual intensity of the sun's rays than the sensitive substances used in the ordinary methods of photography, in relation to which it is well known that the photographic intensity of sunlight is a very different thing from visual intensity, owing to the enor-

* A paper read last Wednesday night before the Society of Arts, with Capt. W. de W. Abney in the chair. We omit the preamble.

mously greater activity of the blue and violet rays—*i.e.*, those of least visual intensity—in decomposing the compounds which they employ.

It will be convenient here to point out another contrast of this method with those more commonly employed. The prints obtained with it are positives, the light and shadow in the object being exactly produced in the coloured picture. Natural objects, therefore, of convenient form, such as leaves, may be photographed directly; reproductions from camera pictures require glass positives, or positive paper prints made transparent in the usual way with vaseline.

In view, perhaps, of the chemistry of the method, it would perhaps be more correctly termed a negative method, since the action of the light is destructive, and when it acts, the construction or development of the colour is rendered impossible. In the ordinary methods, on the other hand, the light is an agent, as it were, in the synthesis of colour—when there is most action the deepest tones are developed—and the photographic action would, in this case, perhaps, be more correctly termed positive. The point, however, is not a very important one.

There now remains to be noticed a second photographic process, based upon the peculiar properties of the diazo-derivatives of the coal-tar bases; a method which, to use the ordinary term, is a negative one, *i.e.*, the light plays a constructive part in the development of a coloured picture.

When the diazo compounds are treated with an alkaline bisulphite, they are converted into the diazo sulphonates. These compounds are sensitive to light, the action of which is to set free the diazo group from its combination, but they do not react with phenols and amines, as do the diazo compounds. The mixture of a diazo sulphonate with the latter is unattended by any colour reaction, but, on exposure to light, the diazo group being set free in presence of a phenol, the development of an azo-colour takes place *pari passu*. This reaction is the basis of the process invented and patented by A. Feer. The photographic surface is a mixture of a diazo sulphonate with the alkali compound of a phenol applied to any suitable material. On exposure to light under a transparency, development of colour takes place in proportion to the quantity of light transmitted, giving, therefore, a reversed reproduction, or negative picture. When printed, the unattacked mixture is dissolved away by copious washing, leaving the picture, already developed in the azo-colour, permanently fixed upon the fabric or material.

This process is not rapid enough to admit of being conveniently demonstrated by means of the artificial light at our disposal. We must, therefore, content ourselves with this brief description, referring those who wish for further information to the specification of the original German patent, No. 53,455/ga.

In concluding our brief sketch of this new departure in the application of the coal-tar colours, we need not, perhaps, apologise for its brevity. We learn that our friend, Professor Meldola, is to give a course of Cantor Lectures on "Photographic Methods;" and his survey of the field will be wide and complete. We have not attempted to give a general account of photographic methods partly on this account, and partly, also, because these diazotype processes are entirely typical of all printing processes, and, as subjects of lecture or educational demonstration, have the great advantage of involving the very simplest reaction possible; whereas, the changes which take place in silver compounds are very complicated, and as yet but imperfectly understood.

The primuline process is simplicity itself. It can be practised with the minimum of apparatus, and requires no technical training. The results are striking and pleasing, as we hope we have been able to show.

At the close of the reading of the foregoing paper a few questions were asked.

Mr. T. R. Dallmeyer asked if the authors knew the spectral qualities of the colours obtained by the process with a gelatine vehicle, and whether the qualities were equal to those obtainable by means of manufactured glass.

Mr. Leon Warnerke wished to know whether the authors had, so far, been able to get rid of the yellow ground to the prints.

Mr. Cross, in reply to these and other questions, said that he would leave the question of the spectral values of the colours obtained to Captain Abney. When primuline is used the yellow ground cannot at present be avoided, but the whole subject is new; with other dyes of the class the authors have obtained a nearly colourless ground. The applications of the primuline process are general, and the results obtained will resist the action of hot soap and water; they are also exceedingly fast to light.

Captain Abney, the Chairman, stated that Mr. Bevan had been at his laboratory experimenting upon the absorption spectrum of the sensitive compound, and could give all the particulars. The absorption extends over nearly the whole spectrum, but fades off between the yellow and the red. He (the speaker) had worked the process to a limited degree, and had become quite fascinated by it; he thought that it would become a perpetual source of amusement in the decoration of houses. Everyone knew how ladies bought pictures to stick them to glass, spending much time over such work; but by means of the process just demonstrated they could decorate their furniture and their homes, and go to nature for their subjects. The materials were simple, and he thought that he was right in saying that they were harmless; they also can be contained in a few beakers; the only other adjunct required was a common photographic printing frame; obtaining natural objects from the garden to photograph was then all that was necessary. He had to thank the authors for their interesting process. Not every day is it that we get a thoroughly new photographic process, and this was thoroughly novel; at least, he had never heard of anything of the kind until about six months ago. Unfortunately, the sensitiveness of the compound is not great enough for the camera, but there is no knowing what may happen in such matters.

---

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Subject for January 29th, "Photo-Micrography."

LORD RAYLEIGH will lecture to-night at the Royal Institution on "Some Applications of Photography," and in the library some objects of photographic interest will be exhibited, including some "pigeon-post films."

PROCESS FOR DETECTING WOOD-PAPER.—M. Wurster.—The following reagents serve to distinguish wood-paper from pure cellulose:—

| Reagent. | Wood-paper. | Cellulose. |
|---|---|---|
| Orcine... | Dark red ... | Nothing |
| Resorcine ... | Deep green... | Violet |
| Pyrogallic acid | Blue-green... | " |
| Phenol ... | Yellow-green | " |
| Phloroglucine | Blue-Violet | Nothing |

The presence of wood in paper can be detected, and the quantity even estimated, by means of dimethyl paraphenylendiamine.—*Journal de Pharmacie et de Chimie.*

RECOVERY OF URANIUM RESIDUES.—For the recovery of uranium residues, Lambe (according to the *Zeit Angewandte Chemie*) recommends the following modification of the Reichardt process:—"The residues from titrations are collected together, and the clear liquid is decanted off from time to time. When a sufficient quantity has been collected, the pasty mass is either heated in the pot by introducing steam, or in an iron pan over an open fire. Soda crystals are then added until the precipitate appears chiefly dissolved. It is let cool, mixed with a sufficiency of ammonia, and the phosphoric acid is precipitated with magnesia mixture. After standing for twelve hours the supernatant liquid is syphoned off, and the precipitate is washed with ammoniacal water. The alkalide liquids are neutralised either with hydrochloric or sulphuric acid, heated to expel carbonic acid, and the uranium is precipitated at a boiling heat with ammonia as uranium oxide ammonium. The precipitate is washed by decantation. A small quantity of some ammonium salt must be added to the last washing waters, as the precipitate otherwise does not settle well. For obtaining uranium nitrate, the precipate is dissolved in excess of nitric acid and concentrated by evaporation."

## DEVELOPMENT.*

BY J. K. TULLOCH, M.B.

THE question of development is a very wide one, and, in fact, the compounding of a developer is the very simplest part of the whole. It is not to be denied that even in the purely chemical part there is a wide field for interesting experiment, and I have whiled away many an hour contrasting soda with potash, and this, again, with ammonia. There is room and need for such work; but I say it is not enough to confine one's attention solely to this aspect of the question, and it is my intention to-night, while not neglecting this side, to dwell also upon other considerations that are, unfortunately, too often lost sight of. In this way the subject comes naturally to be divided into two heads: first, what do we wish to develop? and, secondly, how and by what special means are we to attain development?

First, then, what do we wish to develop? This seems almost a nonsensical question; we wish to develop a picture, of course. This is undoubtedly so, but all pictures are not alike, and here steps in a very common error. It is assumed by almost everyone that perfect development means getting the last particle of detail out with pluck and roundness of image. This is not always the object of the true photographic artist. Scarcely in two pictures does he aim at the same amount of light and shade or of detail. If he has thought out the effect he wishes to produce, he must be prepared to sacrifice detail sometimes, or pluck, or even roundness. Every effect should not be the same, or his results, however perfect from a photographic point of view, will be tame and often inartistic. In looking over the works of a friend not long ago, he whipped a picture from my hand, saying that he had taken the plate from the developer before the detail was out on a distant hill, but that he had taken it again; here it was. On comparing the two, there could be no doubt that the first effect was immeasurably the better, but you must all have seen in your own experience how sometimes absolutely *bad* photography (from one point of view) gave, accidentally, effects you might have striven in vain for intentionally, unless you recognise upon what the artistic success of a picture depends. I saw in the hands of a beginner the other day a splendid view of the river with a dark, lowering outline of the Tay Bridge. He was in great grief over his failure, having, as he thought, either under-exposed or under-developed, or played havoc otherwise with it. I make bold to say he will not make a picture like it again for years. But not to lose sight of the point, I wish to insist upon it that grand effects may be produced, showing the utmost variety of light and shade, detail, and every other photographic quality, which is (according to some) always a fixed amount—namely, as much as you can get into every plate. Suppose, for instance, that the painter was to get such an absurd notion into his head; he would be obliged often to put in detail into his shadows, when, in point of fact, his eye had seen none. Yet this is just what a great many photographic men do. They pick up a photographic picture, and, after generously allowing its great artistic merit, will sagely add: "Pity there had not been a little more detail in the shadows," oblivious of the fact that this may be the very reason of its artistic excellence. There is no standard quality of detail—or light and shade either, for that matter—and it certainly is very absurd to count the success of a photograph by reference to such quality as the amount of detail in the shadows, or any other part of the picture.

If a picture is an artistic success, this is enough, without a moment's consideration of it from either an optical or chemical point of view. Yet almost the one point spoken of in relation to developers is this power of giving detail in the shadows, as if this were a *sine qua non* in every photographic experiment. I quite grant that a man may desire to produce a picture free of detail in the shadows, or all over even; but this is a very different thing from insisting that every successful photograph shall be crowded with detail, and that successful development always means this and nothing else. This is a huge point in my estimation—to grasp the fact that successful development *may* mean anything, from almost clear glass to very near opacity, and that whatever method be adopted, results as widely different as these shall be within the power of the operator.

I think it almost a necessity to adopt artificial light in the dark room. How is it possible to hit the thing to a nicety when the sun may be streaming in upon your dark room window the one moment, and scarcely light enough to see the dish the next? If it is not an utter impossibility, it is at least a needless difficulty. I have a small gas lamp enclosed in white glass, covered with yellow paper. I have the same light every time, for I have what they call a rat-tail flame, which I turn up till it touches a wire exactly two and a-half inches above the burner. This is a very constant power of light, and adds much to the ease and certainty of judging the density. But I have another aid, and as this introduces other considerations, I must seem for the moment to go off at a tangent.

It must have occurred to you that it is an unfortunate thing that the production of detail and the acquiring of density are processes going on at the same time, but not much dependent the one upon the other. Sometimes, when the exact amount of detail desired is just there, the plate will be too thin, and to get it thicker one has to develop on with a certainty of losing the effect he had aimed at. At other times the plate will be quite opaque in parts before enough detail has had time to come up. In order to be master of the situation, and have an easy mind, one must be able to say he will have more detail but no more density, or *vice versa*, just as he thinks fit. And so he can, but not by the ordinary method; he must separate the two processes. He must first develop a thin image with just that detail he wants, and secondly, he must add to its density afterwards.

Of course this is nothing new; it has been proposed often, but somehow people seem to prefer to stumble on in the bad old way rather than be troubled to learn a newer and better method. Since I have adopted this plan, photography has new charms for me. I am not now a creature of circumstances, but feel that if a picture is not up to the mark, it is my ideal that is at fault, not a mere accident of manipulation. This is an immense gain. And now to revert a moment to where we were. Do you see that, while developing this *thin* image, the plate is always beautifully transparent, and by looking through it to a light of constant strength, one soon learns enough to make the process a certainty as to the amount of detail.

I may say that I do not attach any very great importance to the compounding of a developer. When soda was first introduced I tried it very critically, and got it

* Abridgment of a paper read before the Dundee and East of Scotland Photographic Association.

into my head that there was something very particularly fine in the working of it. I imagined that a soda-developed negative gave a better range of tones and all what not. The lapse of time, however, brought calm reflection, and then I had to admit that, however pleasant to work, my ammonia-developed pictures were every whit as good. The same thing happened with potash. I read all I could about this alkali, and had potash on the brain for a certain time. The negatives which I got with potash and sulphite of soda were some of them exquisitely beautiful, but as printers they turned out failures.

*(To be continued.)*

## NOTES ON PORTRAITURE.

BY H. P. ROBINSON.

No. III.

Photography has been called every man's business. In the past the art has been a too facile refuge for those who have failed in other walks in life. The brewer, and baker, and candlestick maker have found it an easier means of a narrow existence than the practice of the mechanical trades to which they had been brought up, and filled the spaces which would have been better occupied—for the credit of the art—by those who were properly educated for it. It may be said of photographers as Byron said of critics :—

> "A man must serve his time to ev'ry trade
> Save censure—critics all are ready-made."

But this state of things is improving, and the best places in the business of photography are being gradually filled up by those who have been properly educated and trained to it, just as other businesses are led up to by apprenticeship or articled pupilage ; and to attempt to open a studio now without some such training would be to undertake a great responsibility.

What, then, should be the qualification of a first-rate portrait photographer? Is it a knowledge of chemistry, optics, carpentry? Certainly not. The first consideration is that he should be an educated gentleman. Not that he need be educated according to the much-abused conventional or scholastic meaning of the word, which can only see education at the Universities. What is wanted is correct language, easy manners, quick perception and insight into human nature.

To this must be added the ordinary knowledge which every educated person should possess, added to what might be called newspaper information, for daily use. He should be all things to all men, and ready to discourse with at least plausible knowledge on all ordinary subjects, and if he could make himself acquainted with a few erudite studies, or have a hobby of some scientific, naturalistic, or archæological character, it would be to his advantage. General education, then, should be the foundation on which our future superstructure should rest. Without it, or with only a little of it, our photographer may be a good photographer, and able to take a portrait technically excellent, but it would be by a rare chance if it were the best that could be done of the sitter, and in all arts and sciences—and, indeed, in all relations of life—it is better to eliminate chance, yet at the same time being ready to take advantage of any happy opportunity that may occur. The Duke of Wellington said it was the general who made the fewest mistakes who won the battle. Of course there are positions in photography where the best is not called for, or expected, but I am now speaking of the aspirant to the highest position.

The next qualification is a knowledge of art. Not merely the shallow acquaintance with it that is to be got from a few lessons in a drawing class or an art school—which, however, would be the best beginning—but the wider knowledge that embraces the history of art and a study of all the schools, from Cimabue down to the many varieties of the present time. Some of these latter are at least remarkable for their enthusiasm.

But this as a digression. Art should grow up with other knowledge ; the first dawn of it cannot come too early. It is difficult for a man who has not cared for it the first half of his life to say, "Now I will begin to study art, to be enthusiastic about it, to teach it." I only know of one instance in which great art came to a man in his mature years without previous study, and that man was Claude Gelleé, of Lorraine. To take an exception from our own art, Mrs. Cameron did not take up photography until late in life, and this she did without any training for art of any kind. Her portraits were full of artistic feeling, but as works of art and photography they were very immature. They were full of promise, but lacked fulfilment, although of late they have been lauded to the skies. Before her death she saw the defects of her earlier work, and was advancing to more photographic completeness.

The photographic press of the time has been recently ignorantly accused of a "vulgar outcry" against Mrs. Cameron's pictures. To say that her pictures were full of faults did not imply that there was no merit in them. The *artistic* merit was always recognised ; it was the *photographic* defects that were condemned by the photographic press, not more so, however, than they would be at the present time, even by those who now virtuously profess to wonder "how critics should have existed to shower abuse" on these photographs. It was the ignorance of those outside critics who professed to admire these very unequal productions, *because of their faults*, that was chiefly ridiculed. There is an effect of superior knowledge and cleverness in finding beauties where they do not exist, or are not visible to others, that is irresistible to some critics, and it is not a new discovery. Sir Joshua Reynolds noticed it in his time, if we may judge from the following passage in his discourses: "So far, indeed, is the presence of genius from implying an absence of faults, that they are considered by many as its inseparable companions. Some go such lengths as to take indication from them, and not only excuse faults on account of genius, but presume genius from the existence of certain faults."

To return more directly to our subject, the future photographer, prepared as I have indicated, is now ready to study photography for professional purposes.

There can be no doubt that a course of elementary chemistry would be of the greatest use to the budding portraitist, but it should be confined to the elements. I remain convinced, as I always have been convinced, that too much science is inimical to art.

There are, of course, some minds great enough to hold the two, but the hard fact of science is apt to clash with the only half-understood feeling of art. There is a good deal that an artist does that he knows is right but cannot easily explain, and any attempt to put it under the microscope and analyse it scientifically soon makes prose of the poetry, and an exhaustive study of exact science is apt to engender a turn for that analysis which is opposed to feeling. There is a good deal of fine poetry which the world enjoys that would not stand the test of the grammarian's scrutiny, and much artistic romance that would not bear the touch of the Ithuriel's spear of a scientific Mark Twain. I must not carry this argument too far, or it would be made into an excuse for not learning anything —there is always danger in extremes—and I may lay myself open to be misunderstood. I have a great reverence for science, but think that the artist should take just as much as would be good for him, and no more.*

I know that this is not the opinion of those who usually decide upon what a photographer must learn, and that a student can get a certificate that he knows all about photography when he knows the complete chemistry of the operation short of the composition of the image; and, indeed, in strict technical truth, so he does, but he has only learned the technical application of his materials, and has yet to know how to put them to artistic use in the making of pictures, and the mischief is that when students go for the advanced science of photography they sometimes get lost in it, and the result is that it often happens that learned chemical papers are read against each other by great scientists at photographic societies to prove or disprove a simple fact that a mere tyro could easily settle by a couple of experiments.

It is pleasant to see that there is at last to be some addition made to the usual chemical course at at least one great teaching centre, and that the managers of the Polytechnic Institution are about to add lectures on art as applied to photography to their programme. It is to be hoped that if a great photographic institute should ever be founded, that it should not be a mere chemical laboratory, but that students should be taught to put the art to use. Abstract science must be held in all respect, but the average photographer is a practical man, and wants to know how to make pictures.

The Photographic Club.—On Jan. 28th the annual lantern and musical entertainment will take place; subject for Feb. 4th, "The Tone of Lantern Slides."

The Croydon Microscopical Society (Photographic Section)—January 16th was a lantern night, when a good selection of over 200 slides, by members, were passed through the lantern during the evening. The next ordinary meeting will take place on the 6th, and lantern night on February 20th.

Last Saturday the employés and friends of Messrs. Percy Lund and Co. met in the Teetotal Hall, Bower Street, Bradford, Yorkshire, for their annual winter social evening. Proceedings commenced with a tea, to which over seventy persons sat down, and after the tables had been cleared, an excellent variety programme was gone through. As a number of the employés are young people in their "teens," a departure from the usual rule at such gatherings was made by introducing a few old-fashioned games, such as blind man's buff. The platform items of the programme included a couple of dramatic sketches, a short comedietta, and a variety of vocal and instrumental music, and recitations.

* This paragraph was written some weeks ago, and I cannot help referring to a singular illustration of its truth which has just occurred, and will probably be announced to-day. A study of Messrs. Hurter and Driffield's scientific papers, aided by a few minor considerations, has so convinced Dr. Emerson that true values cannot be obtained by photography that, with a courage worthy of all praise, and which I, his old opponent, respect, he has renounced "Naturalistic Photography," proclaimed its death, and written its epitaph. The throwing up of a cherished belief which has occupied the thoughts of many of the best years of a studious life, through scientific conviction, is a heroic proceeding, which, while it commands our admiration, makes one almost thankful for ignorance, and for freedom from the nightmares of science.

## PHOTO-ELECTRICITY AT THE PHYSICAL SOCIETY.

At the Physical Society on December 12th, 1890, with Professor W. E. Ayrton, president, in the chair—

Mr. Shelford Bidwell, F.R.S., showed some experiments with selenium cells. The crystalline variety of selenium was, he said, most interesting to physicists, owing to its electrical resistance being greatly diminished by light. This property was shown experimentally with different forms of cells, the construction of which was explained. The form recommended was that in which two copper wires are wound near each other round a slip of mica, and the spaces between the wires filled with selenium. The wires form the terminals of the so-called "cell," which, before being used, is annealed for several hours at a temperature above 200° C. Many such cells were made in 1880, 1881, and their sensitiveness to light remained unimpaired during 1882. In 1885, however, several were found less sensitive, and others totally useless; only one out of thirteen retained its sensibility till September, 1890. The loss of sensitiveness Mr. Bidwell believes due to an excessive amount of selenide of copper being formed, for, although some selenide is essential to the satisfactory working of the cell, too much is fatal to its action. The selenide of one defective cell was electrolyzed, red tufts of amorphous selenium appearing on the anodes. A white substance, resembling moist calcium chloride, was also present: this he believed to be oxide or hydroxide of selenium. Small polarisation currents had been obtained from selenium cells. A lecture apparatus illustrating the properties of selenium cells was exhibited. It consisted of a cell connected in series with a relay and a battery. The relay was arranged so that it might either ring a bell, or light an incandescent lamp. When the bell was joined up, it remained silent as long as the selenium cell was illuminated, but on screening the cell the bell rang. By using various coloured glasses as screens, the effect was shown to be due to the red and yellow rays. A similar experiment with the glow lamp was very striking, for on turning down the gas-lamp illuminating the cell, the electric lamp lighted, and was extinguished on turning up the gas. This demonstrated the possibility of an automatic lamp-lighter, which would light or put out lamps according as they are required or superfluous. Amongst the other practical applications suggested were, announcing the accidental extinction of railway-signal lamps or ships' lights, and the protection of safes and strong rooms.

Prof. Minchin said that he had lately constructed cells of a different kind from those shown by Mr. Bidwell, and found that they gave an E.M.F. when exposed to light. For his purposes the long annealings were quite unnecessary, and a complete cell could be made in ten minutes. One of his cells gave an E.M.F. of over 0·25 volt as measured by an electrometer, by the light of a fog. Their promptness of action falls off in a day or two, but if they are kept on open circuit, a week has no effect on the final E.M.F. On closed circuit, however, they deteriorate.

Prof. S. U. Pickering said that both oxides of selenium were deliquescent, and the author's conclusion as to the white substance formed by electrolysis was probably correct.

Prof. S. P. Thompson believed Prof. Graham Bell had tried platinum instead of copper, and found that the selenium cracked off in annealing. He had also found that it was only necessary to carry on the annealing until the characteristic slate colour appeared. Mr. Bidwell's experiments, he said, showed the possibility of seeing at a distance, and had also suggested to him that the effect of screening might be utilised for driving a completely detached pendulum electrically.

Prof. Forbes said that silver sulphide, when electrolyzed, presented appearances resembling those noticed by Mr. Bidwell in copper selenide.

In reply to questions from the President and Prof. Perry, as to whether the low resistance and unsensitiveness of old cells was due to moisture, Mr. Bidwell said that drying them had no effect; baking restored the resistance but not their sensitiveness. Speaking of the effect of annealing cells, he said this reduced their resistance considerably. Prof. Graham Bell, he believed, gave up using platinum because the resistances of such cells were very high.—*Nature.*

## THE VENTNOR AND BONCHURCH PHOTOGRAPHIC EXHIBITION, ISLE-OF-WIGHT.

This event takes place during this week, and is under the presidency of Sir Monier Monier Williams, and a local committee of seven members, with Col. R. V. Malden—an experienced amateur photographer—as their chairman, and Mr. Wm. Hoskin secretary. The three judges are Messrs. T. M. Brownrigg, of Guildford, J. Fielder (Messrs. Russell and Sons, Chichester), and Dr. Lord, of Wilton Street, Southsea. It is held in the reading room of the Literary and Scientific Institution, and though the room is not very large, it is by no means overcrowded with the two hundred and eighty-seven frames of exhibits upon the walls and screens. As might have been expected, the space is largely occupied with the performances of the local artists, for whom, however, the judges have no partiality, as the awards plainly show, and in the opinion of many, three at least of the Isle-of-Wight exhibitors should have had some distinction granted.

As usual, Messrs. Byrne, of Richmond, make an extensive display, and take a bronze medal for 20 by 16 direct studies. Mr. Shapoor N. Bhedwar, a Hindoo of Redhill, Surrey, has taken a silver medal for portraits, Nos. 87, 88, and 89, studies of heads very nicely posed, and quiet in tone, and it is noticeable that low tones and grey colours in matt surfaces seem to gain the preference over silver prints and brilliant effects and sharpness anywhere, which latter seem to be held in abhorrence by the modern exhibition judge on principle.

Messrs. Window & Grove, for four excellent portrait studies in carbon, take the silver medal for the set No. 11.

Mr. J. P. Gibson, of Hexham, sends a set of three views (Nos. 44, 45, and 46) very nice, well-composed pieces of scenery printed in platinum; silver medal.

Messrs. G. West & Sons, of Southsea, take the silver medal for an enlargement of the yacht *Mohawk*, apparently in bromide, and untouched. Also the bronze medal for a set of three direct yacht studies (Nos. 65, 66, and 67), "Outward Bound," and yachts *Tarana* and *Melissa*, in their usual brilliant style, full of energy and life, making you almost hear the wind and smell the sea. They also take a silver medal for a set of six transparencies of marine studies.

Mr. Cecil V. Shadbolt also takes a silver medal for a set of six transparencies (No. 252), views in the Holy Land, and representing scenes full of scriptural interest, and familiar to most Sunday school children.

For his set of "The Tor Bay Regatta," Mr. W. D. Welford takes a bronze medal; Mr. C. V. Shadbolt one also for six views in Spain. The cold tones produced by hydrokinone development have prevailed in these transparencies, but for the lantern many subjects are better suited by the warm, rich, purple brown to be obtained with Brookes' or other chloride emulsions.

We were much pleased with No. 257, a set of twenty-five views in the Engadine by Mr. P. H. Fincham, very well chosen points of view, and showing remarkably fine detail in the distances; a point of importance where Alpine scenery is concerned, and no less valuable than difficult to secure consistently with full detail in the shadows of near objects.

A handkerchief sachel and some wall pockets were embellished with prints on white silk by Mrs. S. F. Clarke, but the subjects were not very striking, and the prints rather disappointing.

Mr. Karl Greger, of Islington, takes a silver medal for three exhibits on Obernetter paper, Nos. 196, 197, and 198, all pretty rural scenes—of which "Gathering in the Homestead" is perhaps the best—and bronze medal for set of three views. Mr. A. R. Dresser takes two silver medals, one for Nos. 130, 131, 132, pictures of stormy weather at Bognor, and in the "Zuyder Zee." His instantaneous exhibits are good; he claims to use the very great speed of the 250th of a second; if a shutter to work actually at such a speed is upon the market, probably it will meet with a large sale.

Mr. J. E. Austen, of Maidstone, sends a good set of varied landscape work and marine pieces, for which he scores a bronze medal.

Mr. A. Hendry, of Huntingdon, bronze medal for a set of nine views. "A Day in the Fog;" snow scenes, in which there is so much atmospheric effect that a brilliant one or two would be a relief. They are, however, artistic, and possess much charm.

Dr. T. H. Morton, for three interiors of Lincoln and Durham Cathedrals, bronze medal.

Mr. John Catto (Nos. 188 and 190), "Three Studies of Dogs," bronze medal.

Miss S. Ballard (Nos. 203-5) for subjects entitled "Contemplation," "The Milkmaid," and "Roses," bronze medal.

Mr. H. Everitt, for three sets of landscapes, silver medal; and Miss Ada Scott, set of nine landscapes, bronze medal. Meritorious work.

Mrs. Clarke, prize for her "Queen of Hearts."

Mr. Alfred Stieglitz (Nos. 79, 80, and 81), bronze medal.

Mr. Stanley Hurst, bronze medal for a bromide enlargement of a child, untouched, in which we saw nothing but technical qualities to recommend it.

Mr. J. W. Evans, bronze medal for an enlargement (No. 159).

Mr. E. Court Cole, of Oxford, silver medal for his interiors—Reredos, New College Chapel, Oxford, and Queen's College Library—in Blanchard's platinum process.

Mr. W. D. Groundsell (No. 118), second prize, for seven views of Shanklin; nicely chosen subjects.

Space fails us to tell of those which are really good, and which have failed to obtain awards; but among them we must mention the beautiful lantern slide transparencies by Mr. James Dore, the sets of views by Mr. F. N. Broderick, the sylvan bits of landscape by Mr. J. Milman Brown; and, amongst the amateurs, the splendid sets of Indian scenes by Col. Malden (not for competition), the many pieces of Isle-of-Wight scenery by Mr. H. L. Painter, a young amateur from Bristol College, exhibits by Mr. J. G. Livesay, of Bonchurch, and many others. The catalogue is rather unsatisfactory, as it does not indicate which subjects have gained prizes, neither does it classify them distinctly, nor distinguish between the professionals and amateurs. A word to the wise is said to be sufficient, and we hope future committees will take heed to this, and make their catalogues thoroughly intelligible, and more useful for reference.

## Patent Intelligence.

## Correspondence.

### THE CAMERA CLUB CONFERENCE.

Sir,—I am requested by the Camera Club Confercuce Committee to send you the enclosed preliminary notice of the 1891 Photographic Conference, and to ask you if you would kindly draw the attention of your readers to it.

G. Davison, *Hon. Sec.*

*Camera Club, Charing Cross Road, W.C., January 19th.*

The Camera Club Photographic Conference, 1891.

The 1891 Conference will be held in the Theatre of the Society of Arts (by kind permission of the Council) on Tuesday and Wednesday, April 7th and 8th, under the presidency of Capt. W. de W. Abney, C.B., R.E., D.C.L., F.R.S.

On Monday, April 6th, at 8.30 p.m., there will be a special smoking concert at the new Club House, Charing Cross Road, and the members' annual exhibition of photographs will be opened.

On Tuesday, April 7th, at 2 p.m., the President will open the Conference at the Society of Arts, and papers will be read from 2 to 5.30 p.m. In the evening a lantern slide exhibition will be given in the Theatre of the Society of Arts, for which special tickets may be obtained.

On Wednesday, April 8th, at 2 p.m., the Conference will be renewed. At 7.30 the annual dinner for members and friends will be held.

A complete programme will be issued later and distributed. All photographers are cordially invited to attend and take part in the discussions at the Society of Arts.

### PROCESS BLOCKS.

Sir,—The question is frequently asked, "How many impressions can be printed from half-tone blocks?" We think it will interest many of your readers to learn that 155,000 good copies have been printed from the Meisenbach blocks supplied for the Christmas number of the *Lady's Pictorial*, still leaving the blocks in a perfectly satisfactory coudition, as will be seen from the sheet of specimens which we have the pleasure of enclosing herewith for your inspection. We think you will agree with us that the result is creditable alike to the engravers, printers, paper and ink makers, and shows what can be done with process blocks under fair conditions.

W. T. Dilworth, for Meisenbach Co., Limited.

*Wolfington Road, West Norwood, London, January 15th.*

[Fine specimens of work from Meisenbach blocks were enclosed with this letter; the machining of them is excellent.—Ed.]

## Proceedings of Societies.

The London and Provincial Photographic Association.

The usual weekly meeting was held on Thursday, Jan. 15th, Mr. Leon Warnerke in the chair.

The Chairman made remarks upon the forthcoming Photographic Congress to be held at Brussels in the latter part of August, and said he had been requested to call the attention of the English photographic societies to it, and to invite their co-operation. He suggested that a committee shonld be formed, and delegates appointed to represent the Association at the Congress. He then exhibited an acetate of amyl lamp, of which only three had as yet been produced. He said it was the standard unit of light fixed by the French Photographic Society, and ought to be in every photographer's possession.

Mr. W. E. Debenham suggested that a suitable oil should be used instead of acetate of amyl.

The Chairman agreed that oil might be used, and referred to Mr. Bothamley's recent article on the subject. He also said that the lamp, to prevent oxidation, should be made of pure silver.

Mr. A. Haddon, to prove his statement at a recent meeting, that sulphurous acid was sufficient to preserve pyro in solution, took 1 ounce of sulphurous acid, and made it up to 9 ounces 1 dram with distilled water, which he added to 1 ounce of pyro, thus making an exact 10 per cent. solution. The colour of the solution was a pale yellow, which, he asserted, would not change; half of it was then put in a stoppered bottle, and labelled with description and date, and placed in the cupboard of the Association, together with two solutions made up by Mr. Freshwater in the following proportions:—

| | |
|---|---|
| Sulphite of soda... ... ... ... | 4 ounces |
| Pyro ... ... ... ... ... | 1 ounce |
| Water ... ... ... ... ... | 32 ounces |

The three solutions were to be kept intact for twelve months to see what change took place.

Mr. J. B. B. Wellington had observed that in mixing pyro and sulphite in ordinary water, and then adding ammonia, it became pinkish.

Mr. A. Haddon considered that due to the use of plain water.

The Chairman said that eikonogen was a favourite developer with him; he used it in a very concentrated solution, together with caustic potash, which he believed the best alkali to use with it. Eikonogen he considered far superior to any other developer for rapid exposures, and no matter how black it became, it still had full developing power. If he wanted a very dense negative he used more eikonogen; for soft effects he diluted it with water. Bromide he used to a very little extent, and only when dealing with over-exposures.

Mr. W. E. Debenham referred to a statement in a German paper that the caustic alkalies gave more density and a brighter image.

The Chairman asked if any one had tried intensifying with eikonogen and silver.

Mr. Wellington had used silver dissolved in alkaline pyro with sulphocyanide added, and found it to work best with plates containing little gelatine in the film.

Mr. Haddon observed that he had found hydrokinone and acetic acid to develop wet plates in a satisfactory manner.

Mr. W. E. Debenham made the first preseutation of photographic literature for the new library for the use of members.

The South London Photographic Society.

*Friday, January 16th.*—Mr. F. W. Edwards in the chair.

Mr. Leon Warnerke gave a demonstration of collotype printing. Having shown how to sensitise the support, and given formulæ and instructious for drying, printing, and making ready for the press, he initiated the members into the mysteries of inking-up, and finally produced a number of capital prints. Mr. Warnerke used, and drew particular attention to, an apparatus made by the Autocopyist Co., of London Wall, E.C., specially for use by collotypists; it was an ingeniously constructed printing frame for use in an ordinary copying press, and fully equal to the work required of it.

On February 6th, the subject for consideration will be "Enlarging," to be opened by Mr S. Wiles. On February 20th will be a lantern night, when admission to non-members will be by ticket obtainable free of charge from any of the Society's officers.

### The Putney Amateur Photographic Society.

At the last meeting of this Society (January 10th) the following were elected upon the Council for 1891 :—*President*—The Hon. Baron Pollock ; *Vice-Presidents*—Mr. T. Gilbert, Rev. L. Macdona ; *Council*—Mr. Chas. Ballard (Hon. Sec.), Mr. E. V. Barrett, Mr. W. H. Congreve, Dr. J. F. Farrar, Mr. W. F. Gorin, Mr. J. C. Leman, Mr. M. S. E. Manifold.

The meetings are held fortnightly, on the second Wednesday and last Saturday in each month. Those desirous of joining should communicate with the Hon. Secretary, 46, Erpingham Road, Putney.

### The Lantern Society.

On January 12th, Mr. E. M. Nelson, F.R.M.S., dealt with the subject of "The Lantern in its Relation to Photography and the Microscope." Speaking of the fittings of a lantern, the lecturer observed that no matter what kind of jet is used, at a certain pressure it will always hiss, and this cannot possibly be avoided. As regards limes, the conventional ones with a hole through them appeared specially constructed with the view of making them easy to crack, and he advocated the use of a disc of lime, the jet playing on a point near the circumference, and the disc being revolved as it got pitted. He strongly objected to the use of many taps, as being likely to lead to confusion, and explained a simple arrangement of taps of his own. Speaking of condensers, he described various forms, pointing out that for oil lamps having a large luminant a condenser of long focus was required, also explaining that the effective diameter of the back lens was very much less than the diameter of the lens itself.

Some interesting experiments were carried out with condensers of various forms ; the best shown was a triple one which showed a remarkable superiority in the brilliancy of the picture over all the others. Speaking of the lantern in its relation to the microscope, Mr. Nelson referred to Abbe's researches with apochromatic lenses, and pointed out the superiority of the photographic lantern slide of microscopic objects over the projection microscope for exhibiting results to an audience. The lecture was illustrated with microscopic and other slides.

The discussion afterwards turned mainly on the experiments which had been shown with condensers, which appeared to have excited general interest.

### The Birkenhead Photographic Association.

Mr. George E. Thompson, on Thursday evening last, signalised his election to the presidency of the Birkenhead Photographic Association by holding a reception of members and friends in the Y.M.C.A. Institute, Grange Road. The guests invited numbered about 250 ; the greater portion of these attended, and on arrival were received in the library by Mr. and Miss Thompson. In this room the medals of the Association —gained in December last by various members—were exhibited, also a large number of effective transparencies taken by several members, and showing different views of scenery in and about Liverpool and Wirral.

Mr. Frank N. Eaton's exhibits proved him a thorough connoisseur of Wirral scenery ; some fine clouds studies, taken from the Mersey, were shown by A. F. Stanistreet ; and Mr. Paul Lange was to the fore with several wood scenes which excited general admiration. Other exhibitors were Messrs. G. E. Thompson, W. Tomkinson, Charles B. Reader, and T. W. Briggs.

Several photographic volumes were also in the room, and were inspected.

In the lecture room adjoining, two capital concerts, arranged by Dr. W. H. Hunt, were given. Lime-light demonstrations were also given concurrently in the upper and lower rooms, and were presided over respectively by Mr. G. A. Carruthers and Mr. A. F. Stanistreet. The lanternists were Mr. F. Hope Jones and Mr. J. H. Phillips, and the views exhibited showed much artistic treatment.

### The Leicester and Leicestershire Photographic Society.

*Thursday, January 15th.*—At the meeting held in the Mayor's parlour, Old Town Hall, Mr. S. S. Partridge presided. The election of officers for the ensuing year was then proceeded with, and the following was the result :—*President* —Mr. J. T. Cook ; *Vice-President* – Mr. F. G. Pierpoint ; *Committee*—Messrs. Porritt, Joliffe, Bankart, Partridge, and Weatherhead : *Treasurer*—Mr. Wilson ; *Secretary*—Mr. H. Pickering.

Mr. Wilson (Treasurer) then presented his account for the past year, showing a substantial balance.

On the proposition of Mr. S. S. Partridge, seconded by the Hon. Secretary, and carried unanimously, it was decided that the members of this Society offer their cordial sympathy to Mr. John Traill Taylor, on the loss of his wife.

*Friday, January 16th.*—An interesting and instructive evening was passed at the large room of the Co-operative Hall, under the auspices of the above Society, when Mr. E. Howard Jaques, of the Birmingham Photographic Society, came at the invitation of Mr. George Bankart to lecture before the Society on "A Trip through Western Norway." Between 300 and 400 persons were present on the occasion. Mr. Jaques gave a description of the various slides passed through the lantern, which numbered over 200, and for the greater part were accompanied with suitable and descriptive music by Mr. C. E. Birch.

### The Derby Photographic Society.

The monthly meeting of this Society was held at Smith's Restaurant on Tuesday last, when Mr. Keene occupied the chair.

Mr. Pickering, the hon. secretary of the Leicester Society, gave an interesting and instructive paper on "The Art of Emulsion-making and the Preparing of Dry Plates." He first showed by practical demonstration how the sensitive silver compounds were formed in a solution of gelatine by double decomposition, and afterwards purified and rendered of various degrees of sensibility to light by a process of ripening. Instruction for coating plates was given, and afterwards the emulsion prepared in the room was distributed amongst the members (with the formula for same) for private trial. Some excellent lantern slides made on plates coated with this emulsion were exhibited. He strongly advised amateurs to coat their own plates on account of the additional interest and pleasure it would give, also on economical grounds.

### Newcastle-on-Tyne and Northern Counties Photographic Association.

The annual meeting was held on Tuesday, the 13th, Mr. J. P. Gibson in the chair, and there was a large attendance of members. The secretary's and treasurer's reports were deferred till next month's meeting, but it is stated that the past year has been a prosperous one for the Association.

The officers elected for the current year are as follows :— *President*—A. S. Stevenson, J.P. ; *Vice-Presidents*—J. P. Gibson, H. R. Proctor ; *Treasurer*—John W. Robson ; *Secretary* —Edgar G. Lee; *Council*—M. Auty, J. Brown, J. E. Goold, T. O. Mawson, F. Park, W. Parry, H. G. Ridgway, J. H. Robinson, H. Shand, L. Williamson.

Mr. Edgar G. Lee then read a paper on "Lantern Slide Making" (in our next), in which he spoke upon the manipulation of gelatino-bromide plates, and recommended vigorous negatives and full exposures for the production of good slides.

Messrs. Lee and Brown then demonstrated the development of lantern plates, the former using Thomas' hydroquinone formula, and the latter Warnerke's eikonogen formula, diluted and restrained with bromide of potassium, two grains to the ounce. Successful slides resulted in each case.

The lantern was afterwards brought into requisition, and about 150 slides put through.

NOTTS AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE first meeting of the year of this Society was held at the new rooms in Market Street. The business of the meeting consisted of a motion by Mr. R. S. ARMITAGE, seconded by Mr. J. ANDERSON, "That this Association having secured suitable rooms with a suitable approach, by which the objection entertained to the admittance of lady amateurs is removed, lady amateurs be admitted members of this Society;" and a second proposition, "That a cordial invitation be given to the Nottingham Camera Club to join the Association." Both were carried unanimously. In committee, on the motion of Mr. BURROWS, it was decided to set apart a whole week for the production of lantern slides of local views, for exchange with kindred societies. Mr. Henry Cooper was unanimously elected a member. Mrs. Richardson, St. Mary's Vicarage, and the Rev. H. Wynne Ffoulkes, were proposed as members. The official meeting having closed, Mr S. WELLS, president, took the chair at the smoking concert with which the members inaugurate the New Year.

THE GLASGOW PHOTOGRAPHIC ASSOCIATION.

*January 15th.*—Mr. WM. LANG, jun., F.C.S. in the chair.

Professor J. G. M'Kendrick, M.D., F.R.S., Arthur Robinson, David Johnston, and Matthew Edwards were elected members. A resolution expressing regret at the death of Mr. A. Schulze, F.R.M.S., and the loss the Society had sustained, was unanimously agreed to.

Mr. J. ADAMSON, jun., Rothesay, gave a practical demonstration of a method for taking instantaneous pictures indoors by means of Slingsby's magnesium flash-lamp. Two plates were successfully exposed and developed during the meeting.

A letter of Sir David Brewster's referring to the albumen process, and written in 1850, was shown to the members, and prints on Fry's naturalistic bromide paper were handed round.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

*General Meeting, 15th January.*—Dr. J. K. TULLOCH read a paper on "Development," and Mr. ANDREW STEWART one entitled "Hypnotism *versus* the Camera."*

Mr. BERRY exhibited a two-wick sciopticon which illuminated a small screen very fairly. The lantern was placed in front of and facing the audience, the screen used being a sheet of ground glass; the pictures appeared through the screen soft and bright.

THE PHOTOGRAPHIC SOCIETY.—The next monthly technical meeting will be held at the Society's rooms, 50, Great Russell Street, Bloomsbury, London, on Tuesday, January 27th, at 8 p.m.

MR. J. F. SNAPPSCHOTTE has, by request, resigned his membership of the Leopardsville Camera Club, and complains that he therefore cannot now borrow chemicals or apparatus from his former colleagues.

RECEIVED:—From Messrs. Marion and Company, Tomlinson's spotting medium, consisting of a piece of opal glass coated with the medium, so that a little can be taken off with a damp brush when required to spot prints. From the same firm a white powder, called "Berkeley's theonine," to dissolve with hypo to keep it from discolouration.——From Messrs. Fry and Company, some sheets of their new bromide paper for enlargements.——From the Publishers, 55, Chancery Lane, London, "The Photographer's Diary and Desk-Book for 1891," with a likeness of Mr. C. H. Bothamley as the frontispiece.

* These and other papers we are compelled, by pressure on our space, to hold over till our next.

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and or the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5 Furnival Street, London.

M. L. S.—*Binding of Volume XXXIV.* Not counting Mr. Lyonel Clark's "Dedham Bridge," which appeared on the 2nd inst., there were six pictorial supplements issued with the NEWS last year, viz.:—"Penzance Harbour," by Col. Noverre (February 14th); the first magic lanterns (March 14th); Portrait of Thomas Wedgwood (April 11th); Specimen of Ancient Bookbinding, reproduced in chromo-collotype by Messrs. Waterlow and Sons (July 11th); Charles Kingsley's House and Church, Eversley (August 15th); and Mr. Cembrano's "Richmond Bridge" (September 26th). As you say, many of these are worth framing; but, if you bind them, we would suggest that they be put in together at the beginning or end of the book, so as to avoid putting the plates between the leaves of printed type, for fear of a possible set-off and consequent injury to them.

B. T. (Aberdare).—*Faulty Albumen Prints.* From inspection of your samples, the albumen surface seems to have fleeced off by reason of too weak a silver bath having been employed for sensitising the paper; try the use of a stronger bath for the purpose of more effectually coagulating the albumen.

J. M. (Colchester.)—*Freezing of Developers.* The addition of alcohol, where permissible, will retard the freezing of developers and other solutions during these cold nights, but it would certainly be advisable to set up a little gas stove.

M. I. C. E.—*Electrical Engineers.* Continuing the announcement made at the foot of page 38, it may be of interest to know that a fine portrait (steel plate engraving) of the newly elected President of the above Institution, Mr. William Crookes, F.R.S., has been issued with the current number of *The Electrician.* It is an admirable likeness of our friend, the founder and first Editor of the NEWS.

J. T.—*Nominations, Phot. Soc.* Wednesday, 21st inst., was the last day for sending in nominations for council and officers. Your letter does not make it clear whether you have already taken steps, or now desire to do so. Upon this point we answered you in good time last week.

A MEMBER.—*Blistering of Lantern Slides.* The cracking of the varnish and blistering of the picture representing a group of astronomers during the exhibition of this slide in the oxy-hydrogen lantern last week, was an unfortunate occurrence. We cannot tell whether it had been recently prepared or varnished, but imagine that another transparency could be easily procured.

L. P.—*Brown Tones on Bromide Prints.* You were asking some time ago how these brown and reddish brown tones on bromide paper could be obtained? By reading Dr. Hermann Gunther's letter in last week's NEWS, page 40, you will get some useful practical hints, and a formula fully stated for working out your requirements.

PROF. G. S. B.—*Cyanotypes of Sea Weeds.* Putting together all that Mr. William Lang, junr., has written on the subject, it seems probable that the two volumes of "British Algae," by Mrs. Atkins, were obtained at the sale of Mr. Robert Hunt's library on the 7th of November, 1888. If so, the handwork of this lady was never published, but produced only for private circulation. There is another copy in the British Museum Library. See Mr. Lang's article in the YEAR-BOOK, page 83.

C. L.—*The Scarf Pin Camera.* You will find details, with working sketches and reproductions of the miniature portraits, in the *Bulletin Belge* of November last. M. Edmond Bloch is the inventor of what is there called "la cravate photographique." It is not very different in principle to Stirn's camera, which also is intended to be worn beneath the vest, but the idea of bringing up the lens to form a scarf pin is ingenious and on occasion may be an improvement.

# THE PHOTOGRAPHIC NEWS.

VOL. XXXV. No. 1691.—*January* 30, 1891.

CONTENTS.

## PHOTOGRAPHIC LIBRARIES AND MUSEUMS.

Now that the Photographic Society has premises of its own, it has begun the work which should have been performed years ago, of establishing a lending library of books upon photographic, chemical, and artistic subjects. When the work is in an advanced state, it will probably tend to highly benefit the Society, for people —especially residents in the provinces—often become members of organisations, when the subscription is moderate, with no other object than that of getting access to a first-class library relating to a special subject.

The Photographic Society is also about to establish a museum, and has some funds promised to make a beginning. Other societies have been before it in this field of operations, for the Photographic Society of France has a valuable collection of historical objects and photographs, including some pleasing coloured landscapes taken by the curious process of Ducos du Hauron.

Not long ago, Mr. William England informed us that a valuable collection of ancient photographs was on view in a museum at Lille. Accordingly we went to Lille, and to the great art gallery and museum at the Hotel de Ville, but there they knew nothing about the photographic curiosities, and suggested that the Museum of Commerce should be tried. At the latter place, also, the officials knew nothing of any collection of historical photographs in the city, but two black-robed Catholic priests who chanced to be present opined that it might be in the Industrial Museum in the Halls of the Sugars, to which place they then guided and accompanied the inquirer, through many tortuous and narrow ways, for the Halls of the Sugars are in an out-of-the-way place, at the other end of Lille. The two French priests were kindly and jovial men, and had a merry eye.

In an upper hall was the collection of photographs, and it included a photographic proof taken direct upon paper in 1819 by M. H. Bayard, of Paris; Daguerreotypes taken upon plates sensitised by bromine, iodine, and chlorine, in 1842, by Blanquart-Evrard; a Daguerreotype of "Mother and Child," by Blanquart-Evrard, in the production of which chloride of gold and "accelerators" were employed; a Daguerreotype taken in 1841 by M. Vincent Chevalier, over which chlorine was first employed as a sensitiser, as indicated by Fizeau and Claudet; a specimen of the result of the first employment of chloride of gold to render Daguerreotypes more stable, 1839, by M. Bonofans, of Loos; a positive proof on paper by M. H. Bayard, 1839; a positive paper proof by Fox Talbot, 1839; an architectural view on a Daguerreotype plate by M. Lerebours, 1839.

An interesting item in the collection is a photo-mechanical print by Nicephore Niepce, 1824. He took a tin plate, covered it with bitumen of Judea dissolved in oil of lavender, dried it, and exposed to light in contact with an engraving under glass; afterwards he dissolved away the parts unacted upon by light by means of oil of lavender and turpentine, th n etched the plate with an acid to get an image in relief for printing purposes.

The collection also contains paper proofs, deeply printed and toned, by Blanquart-Evrard in 1846-47, likewise prints upon albumen from albumen negatives, produced about 1848. Old albumen negatives and early collodion negatives are exhibited, also photographic prints produced at Lille in 1851. Some among our readers may remember the curious photo-sculpture process and appliances connected therewith; one case in the Museum contains a set of the prints used in the manipulations. There are some beautiful prints in colours of flowers and leaves, taken by Ducos du Hauron; they are better, indeed, than the specimens in the Paris collection; various negatives by Ducos du Hauron are on view. Some photographs in natural colours by Edmond Becquerel, in 1848, are enclosed at Lille in three cases to protect them from the action of light; and near at hand is a protected photograph in natural colours upon paper, taken by Poitevin in 1865. Next is a stereoscopic view taken by Niepce de St. Victor in 1868. Early ceramic photographs by Geymet and Alker, Lafon de Camarsac, and M. C. Cousin, are on view; also some photographs on metallic leaves, by

Geymet and Alker, and by Cousin. Early astronomical photographs are in the collection, including one of the eclipse of the sun, taken in India, Aug. 18th, 1868, and a photograph of the spectrum of the solar protuberances. The various phases of the moon are represented in old transparencies by the albumen process on glass. A transparency upon mica is also to be seen.

A large burnt-in photograph, measuring about 8 in. by 8 in., is in the museum; it was produced by MM. Tessie du Motay, and Marechal, of Metz.

The photographic curiosities in this remarkable collection number about 120 altogether; they are not catalogued, nor is there anyone on the premises who can give detailed information concerning them; those particulars which are given above we gleaned from the tickets alongside the objects. They were presented to the public by the late Blanquart Evrard, who was a citizen of Lille, and a member of the Lille Society of Sciences.

From what has been said, it may be gathered that within a few hours' ride from London is a most interesting collection of historical photographs, which well deserve inspection. Many a busy photographer, who now and then, perhaps, has but from Saturday to Monday to spare, might do worse than to go to Dover by the London, Chatham, and Dover Railway, thence re-book and cross to Ostend by one of the Belgian boats, of which there are three a day, then in twenty minutes reach Bruges, the finest city in all Belgium for old ecclesiastical and secular edifices. Thence he might go to the Lille, and return by Calais and the South Eastern Railway. The circuit is a short one, but it includes much well worth seeing.

Considering the interest of the collection, it seems strange that so little seems to be known about its existence, even in the very city in which it is situated. "Full many a flower is born to blush unseen, and waste its sweetness on the desert air." Mr. Ruskin's little museum at Sheffield, some years ago, was outside the town in a little cottage, and was entered through a small door in the garden wall. In the museum was not so very much to be seen, but, if the visitor displayed real interest, the attendant would open wooden drawers and reveal the choicest articles in the collection, which the merely idle sight-seer would have missed. Mr. Ruskin is not one of those shallow individuals who exhibits all his best goods in his shop window.

---

For two or three months past a plan has been under consideration for the holding of a kind of "Photographeries" in the West End of London this year. The plan seems to be somewhat on the same lines as the Crystal Palace photographic exhibitions.

In Russia, says a daily paper, the use of the balloon as an aid to an army is continually being made the subject of experiment, and there can be little doubt that in the extensive plains which form so large a proportion of the surface of Russia the balloon must prove of utility. Experiments are presently to be carried out at St. Petersburg with the view of shooting from the cars of balloons, and also of taking photographic views of the surrounding country.

## PHOTOGRAPHIC IMPOSTURES.

Impostors are plentiful enough in every condition of life, and will flourish so long as "some people has branes and no money, and others has money and no branes," as a certain nobleman who a few years ago was "lanquishing at Dartmoor" was kind enough to remark for the benefit of an amused public. Imposters are sure to appear in shoals in connection with any branch of science or art which is capable of startling or apparently miraculous results. The art of medicine has, perhaps, produced as many of these gentry as any other occupation, and many fortunes have been made by ignorant adventurers with quack nostrums, which only required to be advertised with sufficient persistency to be patronised by eager buyers. The so-called science of phrenology has also produced many impostors, with whom may be classed the fortune-tellers, who are the modern representatives of the old astrologers.

Photography, being an art which produces pictures in a manner which, to ignorant minds, is akin to magic, has naturally attracted, from time to time, a number of those cunning individuals who hold the doctrine with regard to the wedding of brains with impecuniosity which we have quoted above. With just such a smattering of the art as will prevent them making any palpable exhibition of ignorance, they are able to play upon the fancies of those who know nothing whatever about it, and who are only too ready to swallow any statement which may be made to them, and to part with their money, provided that the tempter is sufficiently plausible in his address and unblushing in his impudence.

The recent exposure of the methods pursued by one or two firms who advertise largely that they will make a crayon portrait without payment, and then afterwards entice their victim into paying an extravagant price for a frame to put it in, reminds us that this is by no means the first shady transaction which has been started on a photographic basis. Photography in natural colours is, of course, advertised every few years as a thing which has at last been actually accomplished, and many hundred pounds have changed hands as the price of the valuable secret. The secret process-monger is, indeed, a creation of the art of photography, and has not confined his talents to the discovery of pictures in colour. At one time he has a patent enamelling fluid; at another a new developer. Next he will produce some marvellous method of toning a quire of paper with one grain of gold, or a magic liquid which will develop every plate into a perfect negative, whatever may have happened to it in the way of under or over-exposure. For a couple of pounds or so he will sell the secret to you, and if you are so foolish as to buy it, you will soon find out that you have been "had," and, for shame's sake, will hold your tongue. It is this reticence on the part of the victims to publish their own folly that enables these cunning fellows to make a good living.

In the Daguerreotype days, when people were not so well informed as they are now, and when the photographic amateur was as yet unborn, swindles were common. The general public did not even know that a good light was necessary for the successful production of a portrait, and they would often present themselves at the studio long after the afternoon sun had begun to approach the horizon. But a likely customer was not to be spurned away on this trivial account. His money was taken, the order was booked, and the innocent model was placed before the camera for a sitting of long duration. There was no sensitive plate in that camera, and the operation was only gone through in order that the sitter should have an idea that he was getting something for his money. He was told later on that the picture had unfortunately been unsuccessful, that it was too late in the day to take another, and would he call the following day, when &c., &c. Perhaps it is hardly fair to call the transaction a swindle, because there was no intent to defraud, and no doubt the portrait was duly executed the next day.

But under another category must come the dodge which has been exposed more than once, to which we next refer. This was practised by the wet plate process, and usually by two men, one of whom acted as tout, and the other as operator. Their stock in trade consisted of a perambulator fitted as a dark tent by means of a superstructure of the usual Hampstead Heath or Epping Forest pattern, and which contained the necessary chemicals, and *one* glass plate to fit the camera which they also carried. Their *modus operandi* was to call at a surburban house, and offer to take it for a certain sum. The idea was perhaps a novel one to the inmates, and they accepted the suggestion, grouping themselves on the doorstep, or perhaps at the windows, after paying the half-crown or other sum demanded by the enterprising artists. The negative was taken, and was shown to the clients, with the explanation that positive copies on card would be prepared, and sent to them in a few days' time. Then that deceitful operator would, as soon as he was round the corner, wipe off every trace of that negative image from his one plate of glass, and would polish up its surface for a fresh coat of collodion, in readiness for the next order for a house that the tout would manage to get for him.

Such are a few of the nefarious methods of getting a living which unscrupulous men have been able to elaborate out of a little photographic knowledge. But their field of labour is bound to suffer contraction now that a camera is such a common adjunct to a private household. It is a matter of surprise that, considering how ubiquitous the modern amateur certainly is, enough pigeons should have been found by the latest detected form of swindling to pay for the plucking. But then, of course, the grand formula with regard to "branes" already quoted is a factor which must not be neglected.

Photographers' Benevolent Association.—At the meeting held on 23rd of January (Mr. W. Bedford in the chair), three applications for assistance were considered and granted; and Messrs. Gray and Davies were elected as subscribers.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Development and Temperature—Warm Brown Tones with Bromide Prints—Transfers upon Stones without Grinding off the Previous Engraving—Rapid Hydroquinone Developer.

*Development and Temperature.*—An interesting paper was read of late before the Berlin Association of Professional Photographers, on temperature in development, by Dr. Miethe. It is well-known that, in general, cold developers act less energetically than warm ones; also, that cold developers give harder negatives than warm developing solutions. As regards the influence of heat on the reducing power of the developing substances, Dr. Miethe stated that this influence varied in different developers. With regard to the sensitiveness to temperature, the chief developers may be arranged in the following descending order:—Hydroquinone, pyrogallic acid, ferrous oxalate, eikonogen. Eikonogen, as regards reducing power, seems not at all to be influenced by temperature; hydroquinone, however, is subject to the influence of temperature to such a degree that, at 41° F., it was practically without any action on the exposed plate. Pyro-soda, as also ferrous oxalate, showed but slight action, even if cooled down below 32° F. Eikonogen, however, maintained a separate position; at low temperature the negatives turned out flat instead of hard, as in the case of the other developers. Dr. Miethe stated that, in his opinion, this was the cause of failures which many operators had met with in using this developing agent.

*Warm Brown Tones with Bromide Paper.*—In a previous letter I gave a description of Dr. Stolze's method of imparting to bromide prints beautiful reddish-brown tones; that description may now be completed by reproducing two formulæ given by Mr. Robert Talbot in the *Photographische Neuheiten*, which, as the author states, have proved to be very successful in his hands:—

1. With uranium nitrate. This method is very well suited for Eastman positive paper, as well as for transferrotype paper. After the prints have been fixed, washed, and eventually transferred, the following two solutions are prepared:—

*Solution A.*

| | |
|---|---|
| Ferricyanide of potassium ... ... | 5 grammes |
| Water ... ... ... ... ... | 500 c.c. |

*Solution B.*

| | |
|---|---|
| Uranium nitrate ... ... ... | 5 grammes |
| Water ... ... ... ... ... | 500 c.c. |

Just before use, equal parts of solutions A and B are mixed. The print is immersed in the solution until the desired tone has been obtained, then washed thoroughly, and placed once more in the fixing bath—

| | |
|---|---|
| Water ... ... ... ... ... | 100 c.c. |
| Hyposulphite of soda ... ... ... | 20 grammes |

After five minutes it is removed and well washed. The above gives warm red tones. Warm brown tones are obtained if the print is allowed to remain in the above bath until it begins to acquire a brown colour; it is then immersed in a weak alum solution, when it is rinsed, fixed as above, and again thoroughly washed.

2. With potassium chloride. Three solutions are prepared:—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... | 1000 c.c. |
| Potassium oxalate ... ... ... | 330 grammes |

*Solution B.*

| | |
|---|---|
| Water ... ... ... ... | 1000 c.c. |
| Potassium chloride ... ... ... | 130 grammes |

*Solution C.*

| | |
|---|---|
| Water ... ... ... ... | 500 c.c. |
| Sulphate of iron ... ... ... | 24 grammes |
| Citric acid ... ... ... ... | 2 ,, |
| Potassium bromide ... ... ... | 2 ,, |

The paper should be fully exposed, and then soaked in clean water. Then mix—

| | |
|---|---|
| Solution A ... ... ... ... ... | 20 c.c. |
| Solution B ... ... ... ... ... | 5 ,, |
| Solution C ... ... ... ... ... | 5 ,, |

The more of B is taken, the browner will be the tone. The print is cleared, fixed, and washed as usual.

*Transfers upon Stones without Grinding off the Previous Engraving.*—A recent invention by the firm of Hyle and Klein, of Bannen, which will be of use to photo-lithographers, consists of making new and perfect transfers upon stones which have been used a few minutes before for printing, without grinding off the previous engraving. Turpentine is applied with a painter's brush in the case of recently used stones, while for old stones a dilute solution of nitric acid is used. The stone is then again covered with a stronger solution of nitric acid, washed off, and put aside until it is dry. After this, it is treated with a solution which is a secret of the inventors. Within about five minutes the stone will be ready for the new transfer. The same stone may be treated in the same way over again without being ground. The process has been patented in this country.

*Rapid Hydroquinone Developer.*—In the *Photographisches Correspondenz*, Mr. A. Lainer publishes the following hydroquinone developer, which is said to act quickly, so that the exposure may be materially shortened, giving at the same time very intense half tones:—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... ... | 900 c.c. |
| Sodium sulphite ... ... ... | 40 grammes |
| Ferrocyanide of potassium ... ... | 120 ,, |
| Hydroquinone ... ... ... ... | 10 ,, |

*Solution B.*

| | |
|---|---|
| Caustic potash ... ... ... ... | 50 grammes |
| Water ... ... ... ... ... | 100 c.c. |

For use are mixed—

| | |
|---|---|
| Solution A ... ... ... ... | 60 c.c. |
| Solution B ... ... ... ... | 2 ,, |

The following formula acts as quickly as the previous one, but gives softer negatives:—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... ... | 950 c.c. |
| Sulphite of soda... ... ... ... | 30 grammes |
| Ferrocyanide of potassium ... ... | 90 ,, |
| Hydroquinone ... ... ... ... | 10 ,, |

*Solution B.*

| | |
|---|---|
| Caustic soda ... ... ... ... | 30 grammes |
| Water ... ... ... ... ... | 90 c.c. |

For use, mix—

| | |
|---|---|
| Solution A ... ... ... ... | 60 c.c. |
| Solution B ... ... ... ... | 12 ,, |

---

The Photographic Society of Great Britain.—The annual dinner will take place at the Café Royal, Regent Street, February 9th, at 6.30. Tickets (6s. each) may be obtained of Mr. W. England, 7, St. James's Square, Notting Hill, W.; or the Secretary of the Society, 50, Great Russell Street, Bloomsbury, London.

## DEVELOPMENT.*

BY J. K. TULLOCH, M.B.

I have many good negatives developed with all the usual alkalis, alone and in combination; yet I cannot say that after all my labour to discover the best, I yet know which is best. I have abandoned everything but ammonia and pyro, and am getting on certainly as well, if not better, than when I used the others. By way of justifying my present position, I will give a few conclusions which in the meantime, at least, seem to me to be warranted. Using in every case pyro, I find that potash gives a beautifully delicate image, full of detail and of exquisite gradation, but not sufficiently obstructive of light to make a good printer. Even when made very dense, much of the half-tone is lost by being not opaque enough to impress its strength on paper. For this reason there is to my eye a peculiar oily softness (so to speak) about a potash-developed picture, fascinating to begin with, but soon getting distasteful. Soda gives a different effect; it gives an image with more pluck and obstructiveness to light, but in the process it buries detail. I am quite convinced of this; I have examined microscopically the image produced by soda as against that produced by ammonia, and find this to be the case. Rule a number of fine lines upon a sheet of white paper, photograph this, cut the plate into two pieces, and develop *to the same density*, one in soda and one in ammonia. My experience is—and I have tried this several times—that the ammonia-developed plate will show the lines much clearer and sharper than the soda. I cannot explain why this should be. There is less risk of fog with soda than with ammonia, and yet somehow the deposit seems not to be confined by the same keen edge. Many of my best pictures have been produced by a soda developer, and I dare say that, for large work, it is probably the most reliable alkali; still, it has that drawback where the picture must be delicate and fine, as for lantern slides.

One very good point about soda is its great power of giving density with over-exposure. Indeed, there is great latitude of exposure using soda. To come now to the ammonia pyro developer, which, in spite of many rivals, has no superior: Perhaps the first point to consider is the question, Why should the various formulæ differ so completely the one from the other? Without taking into account extraneous ingredients such as soda, sulphite, citric acid, you will find that the three *necessary* ingredients differ very widely in their proportions. To begin with, there are many different makes of plates in the market, each one working better with one composition of developer than any other. In the second place, one man works chiefly landscape, another portraiture. A developer safe enough for studio work would be eternally getting the landscape man into trouble from over-exposure, therefore he gradually alters his developer to suit the risk of over-exposure rather than under-exposure.

The real difficulty in development is not got over by getting a so-called *grand* developer. The difficulty is first to know when your picture is there before you, neither more nor less, and the only other item—and this only a small matter—to hit upon a good working plan suiting your plates, and over which you have the necessary control. Having said so much, you will be prepared to hear that I have no developer in particular to recommend. I think, however, I can say something to the point, especially to beginners. First analyse any formula you may

* Concluded from page 71.

want to try, and see that it is not just your own proportions differently stated. Secondly, do not imagine that, by changing the proportion of bromide some minute fraction of a grain, you are to notice a sudden and wonderful improvement in your work. A little longer exposure or a little longer in the developer will bring you just where you were again, perhaps quite unintentionally on your part. And, thirdly, recognise that if you know precisely *when* the picture which you are aiming at is before you, there is not much difficulty in bringing it there.

As I stated in the early part of my paper, my plan is to develop a thin image by means of a weak developer of no special formula; and after this is well out I pour it off, rinse the plate, and apply a more concentrated solution. Whether under-exposed or over-exposed, this is equally the best treatment, and leaves the operation thoroughly under control.

I have only two other points which I should like to mention. The first is that, after hundreds of experiments, I find none of the substitutes better than pyro. The second is, that in cases of under-exposure, if, after soaking the plate in developers, it be taken out before the solution begins to get brown, and washed gently under water, put into an empty dish and covered over with a sheet of glass to prevent evaporation, you will find as a rule a beautiful though thin image in a few hours, which will thicken up to any amount by a stronger developer applied then.

## TESTING THE SENSITIVENESS OF PHOTOGRAPHIC PLATES.

A long article appeared recently in the *Chemical News* from the pen of Professor Victor Schumann on "Determining the Sensitiveness of Photographic Plates by means of the Spectrograph." The author begins by speaking of Warnerke's sensitometer as an instrument of limited efficacy, but not entirely useless. In the case of orthochromatic plates, however, its advantages have, he says, become "seriously sceptical," even for practical working, apart from abstract scientific purposes, for no other light but blue is emitted by the phosphorescent plate.

All sensitometers, says the author, have been superseded by the trustworthy spectrograph, by the aid of which more distinct information on the sensitiveness of photographic plates is obtained. Whoever desires to learn of their relations to the action of light rays of different colours should resort to the spectrograph. Heavy flint glass, like that of the Amici prisms, should, however, be entirely excluded from the instrument; these glasses are impenetrable to ultra-violet. Violet even, and not less so indigo and blue, are held back with much energy, while the luminous rays, yellow and red, are allowed to pass through them without any hindrance almost. Such prisms must naturally lead to erroneous sensitometer numbers. On account of partial absorption, yellow is reproduced with excessive force, and plates found to be highly sensitive for yellow and red in the spectroscope will fail to show the same properties with objective exposures.

Lenses and prisms made of crown glass, or of light flint with less dispersive power, are preferable for ordinary purposes. With any camera, and without much trouble, a suitable spectrograph may be easily constructed. To obtain faultless spectrum photographs, a scrupulously correct instrument is not necessary. I have made the sharpest pictures with precision instruments as well as with apparatus but roughly built, and even professional spectroscopists have made the most astounding discoveries with improvised instruments.

To find the behaviour of plates towards any light source, a series of spectra, with regularly increasing time of exposure, should be photographed, the plates dried, and be examined in regard to the time required to produce a developable impression by different colours. The different sensitiveness will then be found to be reversely proportioned to the time of exposure. Were we, for example, to inquire how the sensitiveness of a Vogel eoside of silver plate (manufactured by Prentz, of Munich) is proportioned to our own instrument, the first spectrum of the series to be photographed should be exposed for such a short time as not to produce a developable impression. Subsequent and longer exposure will then generally produce an image of extremely feeble character—a mere breath upon the plate. The thinner the picture of the spectrum, and the clearer ground of the plates, the more reliable is the sensitometer number derived from the series of spectrograms made by increasing time of exposure. As long as sensitiveness alone is the object of inquiry, the intensity of the plate is of no importance whatever. It is totally wrong to determine numerical value of light-sensitive films by the density of the negative.

Sensitiveness and intensity are two entirely different things, as every photographer knows who understands the use of the sensitometer. How little hold is offered by the intensity of the plate, when inquiring into its sensitiveness, is proved by the fact that the two never go hand in hand. Some plates resist strenuously the action of certain rays before decomposition of the light-sensitive components takes place; but when their stability has yielded at all to the force of the developer, the intensity of the negative increases with much rapidity. Density builds up easily when the exposure has been longer than required for the production of the breath-like picture; not proportionately, however, but progressively. This phenomenon occurs with Vogel's eosine plates to an unusual extent. A hundred times have I had opportunity to observe these properties when associated with Dr. Zettnow, of Berlin, and to whom we are indebted for the most important researches on erythrosine plates, to examine extensive series of orthochromatic plates. Other phenomena occurring and observed by studious investigators may be well explained by this progressive increase of density, pre-eminently among them two peculiarities—the very changeable intensity of the maximum in yellow, and different yellow action even under strictly normal conditions.

Whoever wishes, with the foregoing explanation on hand, to determine the yellow and blue sensitiveness of erythrosine plates, will find that the former never reaches the height, numerically, stated by Dr. Vogel when the exposure is made at high altitude of the sun. Far from mid-day, or in winter time, the proportions of brightness in the sun spectrum are entirely changed. The general sensitiveness of the plate advances then more and more towards the red end of spectrum. When the sun stands low, at its rise and set, the erythrosine silver plate may triumph to a still greater extent, for then it is nearly exclusively sensitive to yellow and red, but to no other rays.

There will be a photographic exhibition at the Crystal Palace in the course of this year.

## PHOTOGRAPHIC TOURISTS IN ICELAND.*

BY J. REYNOLDS, M.D., F.R.G.S.

Mr. President, ladies, and gentlemen, I purpose, as you already know, to give you a short description of a tour in Icelaud which I, together with seveu other gentlemen, made in July of last year. But before I proceed to describe the tour, and places visited, it may not be amiss to give you first of all some idea of the situation of this strange land of fire and frost in the far north.

*Slide* 1 (showing map).—Iceland, then, is situated in the North Atlantic, between the 64th and 66th degrees of north latitude, about 650 miles west of Norway, and some 410 miles from the east coast of Greeuland. One of the headlands projects just one mile north of the arctic circle. In area it is one-third larger than Ireland—*i.e.*, about 38,000 square miles; of this area about 7,500 square miles are lava deserts, and sandy, stouy wastes. The lava tract around Heckla alone is about 240 square miles, aud iu the south-western portion of the island, with which chiefly I am concerned to-night, there are about 500 square miles of couutry covered with lava.

The total area of pasture land does not probably exceed 14,000 square miles. The glaciers, lava, and sand deseits, moorlands, and pasture cover about 28,000 square miles, and the remaiuiug 10,000 consists chiefly of mountain masses, varying in height from 2,000 to 3,500 feet, snow-covered for nine months out of the year. No doubt the inclemeut character of the climate for three-quarters of the year, together with the isolated position of this interesting land, accounts somewhat for the general ignorance respecting nearly everything conuected with the country.

I will first glance over the map and point out to you the relative position of the various important points in the island. Vatna Jokull, Askja, Skaptar Jokull; here in 1783 was the greatest lava flow ever known in Iceland or elsewhere, when lava welled forth beneath the sea and built up the island of Eldey, one hundred and fifty miles distant.

Here we have the world-famed Heckla, and here the Geysers; here is Gullfoss, Iceland's largest and grandest waterfall; and here is the classic Thingvellir. I want you to bear these positions in mind, as I shall this evening show you some scenes photographed by me iu the actual spots indicated.

You can get to Iceland by two routes; one is by the Iceland and Leith Steamship Co.'s boat *Magnetic*, starting from Leith and going direct to Reykjavik in about four days; and the other is by the Danish steamboats, which run between Copenhagen and Iceland, and call at Granton for mails and passengers *en route*. The quickest route is undoubtedly by the Scotch boat, but the most comfortable passage is certaiuly that by the Danish steamer. We started from Leith iu the Scotch boat on June 30th, arrived at Reykjavik early on the morning of July 4th—*i.e.*, in about three aud a-half days—and at ten o'clock on the same morning we landed; we went to the "Hotel Island," in the main street.

*Slide* 2.—Here all was strange and new, and we hardly knew which way to turu first, so in order to collect our scattered thoughts we sat down to breakfast, and this is what we had: black bread, raw salted herrings dressed with raw onion, raw salmon, rolled cooked mutton, hard boiled eggs cut in quarters, raw ham, anchovies, white bread and very good Danish butter, lobsters, splendid coffee and cream, and schnapps. Well, I ate all I came iu contact with, and asked no questions—the best way when you are in doubt, especially in Iceland. Several Icelandic gentlemen were present, and welcomed us most cordially to their shores, and at once anuounced our arrival and inteuded route in their newspapers. Breakfast being over, we went out to see the town, and to photograph some of the chief places. Now I will show you something of what we saw.

*Slide* 3.—Here you see farther up the main streeet the very picturesque wiudmill on the top of the hill; this is the main road and exit from the town wherever you want to go, and whichever route you desire ultimately to take.

*Slide* 4.—The next view is one of a side street leading down to the shore of the Faxa Fjord. Here you see oue of the modes of drying the fish; it is first split open, aud then laid on the lava blocks forming the walls of the garden to dry in the sun until it is as hard as boot-leather; this article is now collected iuto bundles aud tied together, and either sent to the interior or exported.

*Slide* 5.—This view shows you some of the genuine old Icelandic houses called "boes." You will see that the walls are built of blocks of lava with slabs of turf interposed, and they are made four or five feet thick to keep out the cold of the long and extreme Arctic winter of nine months' duration. Resting ou these walls is a timber roof covered over with large living turfs. Each of these houses has, usually, a square space of grouud enclosed with a low wall made of the same kind of lava blocks, aud this is called a tun. The floor of these houses is the bare earth. In one of the roouis there is a peat fire, and the smoke, in some of the houses in the interior, is allowed to find its way out as it best can, not a very bad arrangement in Iceland, as it possesses certain disiufecting and deodorising properties. The lava walls, which are quite clean, are, as you see, also used for drying clothes.

*Slide* 6.—I will now show you a view illustrating the mode of shippiug ponies. These sure-footed, amiable little beasts are one of Icelaud's chief exports, the others being sheep, eider-down, and dried fish. You will observe that the little creature is in no humour to quit his native shore, and no wonder, when I tell you that his most probable destiny is a coal mine in England, and that, when once let down the shaft, he will never see daylight again.

*Slide* 7.—This is simply another view of same kind of industry.

*Slide* 8.—A still farther illustration, showing also a portion of the shore view of the town.

*Slide* 9.—Here we have a scene showing how goods are taken from the landing stage for shipment.

*Slide* 10.—Here we have a view of the Faxa Fjord from the shore, showing in the foreground a fisherman's hut, and a woman engaged in splitting open the fish, numbers of which, ready-prepared, are drying on the beach in the sun; in the distance you see the shipping, and the steamer *Magnetic* lying at anchor.

*Slide* 11.—Yet one more shore view; this time at the east end of the harbour.

*Slide* 12.—Now we will take a view of the part of the town supposed to be aristocratic. This square shows the statue of Bertel Thorwaldsen iu the centre.

*Slide* 13 shows the cathedral aud part of the Althing House; the former is a very plain building covered with plaster, and washed over with pale orange, which is a wretched colour to photograph; hence the result.

*Slide* 14.—Here we see the interior of the cathedral, which, although Lutheran, looks at first glance like the interior of a Roman Catholic church.

*Slide* 15.—This shows the interior of the chief room in the parliament house (called Althing House), with a portrait of Sugurdssou, the liberator of Iceland, whose memory is revered by every true Icelander.

*Slide* 16.—This is a nearer view of the statue of Bertel Thorwaldsen in the Square. Having taken these views duriug Friday aud Saturday, we finished up by having four of our party arrested for furious riding. Reykjavik possesses *one* policeman, a most gorgeous official resplendent with gold lace, and I suppose he thought such an opportunity of running in four Englishmen should on no account be lost, so he brought our four companions before the Governor-General, and these were fined two krone apiece; I need hardly say this policeman's life was no siuecure during the remainder of our stay in Reykjavik. We decided to start for our first resting place on the tour on Sunday morning at teu o'clock, but this wretched limb of the law again stood in our way, and threatened to arrest and fine us if we started for Krisuvick before three p.m., so we sent our baggage aud apparatus on first, and waited until the appointed time, then off we started, four guides and eight of ourselves, making twelve in all, and about forty pouies, at a good sharp trot.

*(To be continued.)*

* A lecture delivered last week before the Brixton and Clapham Camera Club.

## A REPLY TO DR. EMERSON'S RENUNCIATION.

BY GEORGE DAVISON.

There are one or two matters of public interest in Dr. Emerson's eccentric "Renunciation," and one or two requiring personal reply, which I should like to refer to briefly. It would be waste of time to take this undignified production too seriously, for it is evidently only the outcome of violent egotism and offended vanity.

First, do not let photographers suppose that Dr. Emerson has the right to claim any originality in regard to naturalistic art. He has merely adapted to photographic methods ideas current among certain artists. He is, therefore, neither entitled to claim further recognition than this, nor has he the slightest right or power to order the funeral of naturalism in photography. Secondly, the limitations of photography are not so great as he now . . . . wishes to make out, for the individuality of the worker is freer than he asserts, and he has allowed himself to be misled by an absurd confusion about Messrs. Hurter and Driffield's experimental results. The power to alter relative values by exposure, development, and other purely photographic means is infinite. Thirdly, if "all writings and opinions upon art are as the crackling of thorns," why does Dr. Emerson return to his vomit in this pamphlet, and re-discuss certain art matters; and why, in the name of all that is consistent, does he threaten photographers with another book on art later on? Fourthly, what on earth has "the dexterity" of the man with paint and brush to do with the matter? The photographer's dexterity as an artist is *not* a matter of a few weeks. It takes as long as the artist's to cultivate. It is a mental training, and the handicraft follows the brain. Fifthly, Dr. Emerson is wise to give up every "school" title, and to take to admiring "all good artists and all good art." It is what every sensible person has always wished to do, and after passing from one violent extreme to another we may hope he will in time reach a reasonable medium. Sixthly, I believe it to be false that anyone has claimed novelty in the use of rough papers. All the same, these pictures have spoken and will speak for themselves to those who are less amateurs than Dr. Emerson, who has, "by the sweat of his brow, learned under a master!" Long before Col. Noverre's excellent specimens were exhibited, I, and probably many besides, had spoken to Mr. Willis and others about the necessity for such rough-surfaced papers. . . . . Eighthly, Dr. Emerson's repudiation of the claims of photography as a means of capable artistic expression is perhaps only natural. In my opinion there is something sadly wanting in most of his photographs, and he himself is probably now finding this out. I trust he is devoting himself to some other pursuit more suited to his abilities—a humorous friend of mine suggests fretwork.

In regard to the personal matter, and what Dr. Emerson calls my "superficial knowledge," I shall be well pleased to let my photographic pictures speak for themselves, and stand side by side with his before any competent and unbiassed judge. The quotation used from my private letter seems to me to read in refreshing contrast to the rest of the pamphlet. Dr. Emerson was anxious *at that time* to recognise what I had done for naturalistic photography. I was not, however, particularly anxious to be very closely identified with Dr. Emerson and his violent aggressiveness. A little of the same appearance of modesty would not injure him. The whole of this business appears to have arisen first in that I dared in a very appreciative criticism to point out Dr. Emerson's weakness in respect to treating figures in photographic pictures. In reply to that he wrote: "You are wrong about my figures; they are as yet alone"—a sweet bit of Emersonian modesty. From that time, although treating with me to write for a journal he proposed to start which was to knock everything else endways, he seems to have begun to say hard things about me to others. That I should have ventured to differ from him in respect of the qualities of diffractive photographs caused him further attacks of spleen; and, finally, the fact of my being invited to read a paper at the Society of Arts appears to have upset the whole of his years of study on naturalistic photography, and wrought him up to the pitch of fulminating this . . . pamphlet. The letter which he calls an "expostulation," and to which I sent no reply, was one long, violent insult, alternating between threats and wheedling. . . . .

As to the unfairness he complains of at the Society of Arts, he does not mention the name of the friend whose speech was misreported. It can hardly have been Mr. Maskell or Mr. Newman, and they were the only speakers who *read* their speeches. All the reports seem to me to be fairly accurate so far as they go.

Finally, I do not wish it to be supposed that I do not sympathise with Dr. Emerson in his affliction. There are some grains of sense in the pamphlet—more, indeed, than could be expected from anyone even with a good liver after three and a-half months' solitary study in a house-boat during the recent weather. But every reader ought to be cautioned against paying much heed to the outbursts of one who is blown about by every wind of doctrine—now a well-expressed word of a "great painter," now the influence of a common every-day artist, and now a misunderstanding of a scientific experiment. Give such an one three and a half months' further confinement in a house-boat and a fresh quarrel, and a new crop of theories or burning thereof may be expected. It is certainly to be hoped that no photographer who is working out his own salvation by serious study and practice will be deluded by such cheap trash as this pamphlet contains. Let Dr. Emerson cast all the copies of "Naturalistic Photography" upon the dust-heap; let him—as I think wisely—succeed in covering up the crude and absurd directions "To the Student" in every one of the volumes of "East Anglian Life," which, with his genius for advertising himself expensively, Dr. Emerson sowed broadcast over the country—let him do all this and go on "renouncing" to the crack of doom, and he will only publish his own vanity, and will not be able to stem the tide of advancing culture amongst photographers.

[Owing to the provocation given in the pamphlet of Dr. Emerson's which we reprinted last week, to our valued contributor, Mr. Davison, it is only right that we should insert his reply; but as warm discussions of this kind scarcely answer any useful purpose, we shall let the matter drop after this, unless the disputants confine themselves to non-personal artistic and scientific arguments of interest to the public. We have omitted a sentence or two from Mr. Davison's article at places marked by dots.—Ed.]

Photographic Conference.—The Camera Club will hold its Photographic Conference for 1891 on Tuesday and Wednesday, April 7th and 8th, in the rooms of the Society of Arts. The chairman will be Captain Abney, R.E. On April 7th there will be a lantern slide exhibition.

## PHOTOGRAPHY AND ILLUSTRATED JOURNALISM.*

BY CARMICHAEL THOMAS.

FOR many reasons I am sorry to see the good old-fashioned wood-engraving being superseded by the many mechanical processes which are being perfected; but I am quite sure that, in time, the really good wood-engravers, instead of finding their work leaving them, will find they are more and more sought after. The fourth-rate engraver no longer exists—he is ousted by process; then the third-rate engraver disappeared. The second-rate men are now having a fairly good time of it; but they must look out, for we do not know what further developments are coming on in mechanical process.

In the future, I believe, the first-rate engravers will be able to command almost any price for their work. For the last few years there has been a mania for etchings; high prices have been paid and are being paid for etchings, simply because they are etchings, no matter whether good or indifferent; but the etchers will be—no doubt are—feeling the change; photographic processes in the shape of photogravures are gradually pushing the second-rate etchings out of the market, just in the same way as the poorer class of wood-engravings are being superseded. I should not be at all surprised if, in a few years' time, a good wood-engraving is as much sought after as an etching is in the present day. The first-rate wood-engraver will make his fortune, while his second-rate fellow-worker will starve.

In America there is another startling change in illustrated journalism, for some of the papers there are not only giving up the wood engravers, but they are giving up the artists as well. The illustrations are composed of photographs taken from nature or life, and reproduced direct by process without a touch from either artist or engraver. The manager of the paper, instead of asking an artist to illustrate a story, puts the manuscript in the hands of a photographer. Here, on the screen, is a story illustration prepared in that way. In another case, the manager wishes to illustrate the work being done by the Salvation Army in New York, and sends the photographer round with the reporter, instead of the artist. The result is most terribly monotonous and devoid of artistic treatment, but I think it is interesting here, as showing the latest development of illustrated journalism.

There is the advantage, though, that an illustration produced in this way cannot well have doubt thrown on its genuineness. If I were to show you a sketch in which the old lady who keeps the cows in St. James's Park was seen putting water into the milk, you might say it was made up; but when I place before you a photograph of such a proceeding, you must then admit, although all your better feelings are rudely shocked by the revelation, that it is true.

One more subject I will put on the screen before I leave this part of my paper, and that is the one you now see. In this case there is no artist's work; the photo from life was taken on board a P. and O. boat, sent to the *Graphic* office, where it was photographed direct on to the wood, and engraved.

Where photography is so very useful is, not as a means of doing away with the work of artist and engraver, but of assisting them to get the details of their subject correct. Twenty years ago, during the Franco-German War and the Commune, the camera was a most important and valuable friend to the newspapers. When Paris was at the mercy of the lowest ruffians that the slums could produce, at the time when they were playing havoc with the buildings, monuments, and streets, the photographers were hard at work, and the negatives they took give a true but dreadful picture of those terrible days. On the screen will be shown one or two specimens of what I refer to.

This shows the Rue Royale deserted and partly in ruins, taken during the last days of the Commune. The next is a scene on the Boulevards. The next shows the Rue de Rivoli; the damage to the houses is caused by shot and shell, not by fire. One can hardly believe that this bright and cheerful street could ever have been a scene of such utter desolation and misery as you see here. The next one depicts a barricade in the Rue Castiglione, taken from the Place Vendome.

All these subjects appeared in the *Graphic* at the time, and show how important a part photography played even as far back as twenty years ago. The next slide is a photograph of one of the meat tickets which was supplied to the *Graphic* agent (among others) during the siege. The ticket itself was far too valuable to be sent, so a photograph of it was taken and forwarded by balloon post. It was necessary to send two or three photographs by different balloons, or if sketches were used, to send tracings of them, for as likely as not the balloons would be captured by the Prussians, and whether they came down within reach ot the enemy or not, the *Graphic* had to give its readers illustrations of all that was going on in the beleaguered city. Many manœuvres had to be executed to get the sketches and photographs outside Paris, and through the Prussian lines to London.

Any sort of meat was ruinously dear at that time, and even a good sized dog could not be bought under £8 or £10. This slide represents a cat and dog butcher's, prepared from one of the sketches received at the *Graphic* by balloon post. The day's dinner was not the only trouble; anxiety of every sort was there as well.

When the *Daily Graphic* first started, some of the illustrations were drawn on wood and engraved, but the result was not satisfactory; and now they are produced by a photographic process from drawings made on smooth white card with a very black ink. There have been published some very good illustrations done by people who have had no experience whatever in such rapid journalistic work as is necessary in the case of the *Daily Graphic*. Lady Butler has sent sketches from Egypt, done with such a bold, vigorous touch that they can be used as model drawings for the kind of work required. There is just enough work in her drawings, not too much to obscure the clearness, and yet quite enough everywhere to show exactly what she wishes to portray.

When the drawings are finished, they are handed to the manager of the photo-etching department, who prepares the plates for the printer. The camera by means of which the negative is taken is slung from the roof, so that the vibration of machinery or passing traffic may not spoil the result. The negative, when taken, is placed over a sheet of zinc which has been made sensitive to light, and this light (from an arc lamp) shining through the clear lines of the negative, acts upon the sensitive surface in such a way as to leave a record upon the zinc. In short, by this operation the drawing is reproduced upon the zinc plate. Its lines are then made to resist the attack of the acid, and the plate put into an acid bath, where the non-protected parts are eaten away, leaving the drawing in relief—a surface which can be printed from.

These plates are then sent to the printing office, and, having been mounted on wood in order to make them the same level as the type, they are, with the type, arranged as required into complete pages.

Mr. Luke Fildes, R.A., presided at the meeting at which the foregoing paper was read for the author by Mr. T. C. Hepworth. The attendance was large. In the course of the discussion Mr. Henry Blackburn said that it was about the year 1875 when it became possible to turn out by photography type-high blocks in a practically available way for newspaper printing. Mr. Russell Scott described a newly invented method of producing pictures of various colours at a rapid rate with one impression from a single lithographic stone or block.

* A portion of a paper on "Illustrated Journalism," read last Wednesday night before the Society of Arts.

---

MAKING PAPER TRANSPARENT.—The following method of making paper transparent for copying drawings is adopted by the Austrian Hydrographic Bureau:—The sheet of paper, having been placed over the drawing to be copied, is lightly rubbed with a ball of cotton saturated with pure benzine. The tracing can then be readily made, owing to the transparency produced, and the benzine on evaporating, leaves the paper opaque, as before, and perfectly odourless. To secure satisfactory results, however, absolutely pure benzine must be used.—*Illustrations.*

## LANTERN SLIDE MAKING.*

BY EDGAR G. LEE.

CONFINING my work almost entirely to the production of lantern slides, I have thought it expedient to take up a portion of your time to-night by contributing a few rough notes on this interesting and important branch of the photographic art.

At the present day, by far the most popular process is the gelatino-bromide, although the collodion, both wet and dry, and other processes, give more latitude as regards the production of a good slide from an indifferent negative. First of all, it is necessary to consider what constitutes a good slide: one in which the highest lights are represented by clear glass, and the deepest shadows are of such a density as to be easily penetrated by a fair average light in the lantern. A good slide need not be composed of, say, equal proportions of clear glass and opaque deposit, like more than one make of commercial slides in the market. So long as we have a trace of clear glass to add brilliancy to the picture on the screen, it may with advantage, as seen *out of the lantern*, appear a trifle thin.

To produce this *good* slide, having the characteristics which I have mentioned above, a negative is required showing considerable contrast. Personally, I prefer one of the type which yields a brilliant or plucky silver print. Whilst, on the one hand, a negative of the most extreme density will make a passable slide, thinness and want of contrast of the character which is suitable for bromide printing is, for slide work, absolutely hopeless.

Coming to the actual working, we have two methods: we may reduce in the camera, or print by contact from small negatives. To the latter method I confine myself almost entirely, as nearly all my negatives are quarter-plates. The first point to be considered is naturally exposure, which may be made to a paraffin light, gas flame, or magnesium light—daylight, of course, being too strong and uncertain. Gaslight is, generally speaking, most useful, and exposures with the printing frame two feet from an average burner may run from thirty seconds to ten minutes, varying according to the density of the negative. For very dense negatives, exposure to magnesium light is to be decidedly recommended. With a negative verging on thinness, the exposure must be fairly exact, but with a dense negative and certain brands of lantern plates the latitude is simply enormous, and much greater than is usually supposed. With such a negative the exposure may be ten times the normal, and a perfect slide result from it—of course, varying in tone according to the extent of exposure. I have observed that the general tendency of beginners is to under-expose, which is fatal, as the image either develops up patchy, or veils over before density is obtained. A lantern plate can *not* be forced in development.

As to development, we have the choice of four reducing agents: ferrous oxalate, pyro, hydroquinone, and eikonogen. Each and all of these are capable of producing equally good results in the hands of careful workers. The easiest, by reason of the latitude it permits, is hydroquinone, the tone being dependent partly upon the negative, partly upon the exposure, and in no small degree upon whether the development is rapid or gradual, a remark which will be found to apply to any developing agent. It is not my intention to recommend any one formula, believing as I do that there is nothing magical in any prescribed combination of chemicals. My advice would therefore be to choose a well-tried and reliable formula, and stand by it.

For warmth of tone pyro is, without doubt, the best developer, and as the tendency is now in that direction, it merits our attention. There is no difficulty in its use if we remember its staining properties, to counteract which it is always employed with a much larger proportion of preservative.

The image, when fully developed, has an over-done, sunk-in appearance, and unless this point is arrived at, the slide, when taken from the fixing bath, will be found much too thin.

After fixing in a perfectly clean hypo bath, and a thorough washing, the slide will in all cases be the better for a short immersion in an alum and citric acid bath, which clears up the picture and improves its brilliancy. If too dense, or fogged beyond the capacity of the acid bath to reduce, the ferricyanide of potash and hypo reducer (made distinctly alkaline with ammonia) should be resorted to.

Intensification at its best (which best may be represented by mercury and cyanide of silver) is but an unsatisfactory proceeding, and much the better alternative is to make another slide. Intensifying by mercury, followed by various alkalies, yields warm tones, varying with the agent used, many of them very fine, but all of doubtful permanency.

After fixing and washing, slides may be toned in a gold and sulphocyanide bath through a long range of bluish tones, useful for moonlight effects.

Mounting calls for no particular mention, but I cannot refrain from adding a vigorous protest against the continued use of masks of circular and other eccentric shapes. Broadly speaking, the oblong form suits most subjects, and produces the best effect. A safe rule for guidance is to fit the subject to the mask when taking the negative, and not to fit the mask to the subject at the last moment before binding the slide.

* A communication to the Newcastle-on-Tyne and Northern Counties Photographic Association.

INCREASING THE SENSITIVENESS OF PHOTOGRAPHIC FILMS.—The following process is by York Schwartz, of Hanover, Germany. It consists in mixing the materials for making the film with, or coating the photographic films with formaldehyde or a compound of formaldehyde with bisulphite salts. The process is based on the discovery that the sensitiveness of silver compounds to light is materially increased, or that the effect of light on the same is continued by the presence of formaldehyde, or a compound of formaldehyde with a bisulphite of an alkali metal, or of ammonia, or of substituted ammonia (capable of forming bisulphite), in the sensitive silver compounds. For photographic purposes these discoveries may be utilised as follows:—First, by adding one or more of the specified compounds, either alone or in mixture with other substances, to the substances for making the films at the time of the production of the sensitive film; second, by bathing the finished photographic film in a solution of the said compounds or mixtures before the film is exposed to light; and third, by treating the photographic film after exposure with a solution of the said compounds or mixtures. In this case the changes produced in the film by the action of the light are continued, so as to obtain in this manner the same result as by a correspondingly longer exposure to light. The application of the said compounds constitutes an important improvement in the manufacture of photographic films, because they possess in an increased measure all advantages of the substances hitherto employed for similar purposes, without sharing their faults—for instance, the tendency to form clouds or specks, or of imparting a yellowish tint to the film. —*Scientific American.*

## Notes.

Photography is still making headway in India. The Photographic Society of India now has 270 members, and the increase has long been at a steady rate, so some additions have been made to the body of managers. Those recently elected to serve are Colonel Rogers, Messrs. J. H. Lane, A. L. H. Palmer, W. H. Jobbins, and Captain Hayes. The new honourary secretary is Mr. T. A. Pope; the new president of the Society is the Hon. Sir Comer Petheram, Chief Justice of Bengal. The new committee of the Society does not like the proceeding of the old one in abandoning the International Photographic Exhibition, and has passed the following resolutions:—1st. That this committee regrets the decision arrived at by the late committee to abandon the holding of au International Exhibition. 2nd. That this committee believes the postponement of the Exhibition would have been sufficient to meet the case. 3rd. That this committee decides to cancel the previous committee's decision, and to hold an International Exhibition on the 15th March next and following days, and empowers the Hon. Secretary to notify the same in the press. 4th. That a sub-committee be formed to make all the necessary arrangements to secure the return of the foreign exhibits now lying in Calcutta awaiting despatch to the senders, and to arrange for the return of such exhibits as have been already sent back by post.

---

A pretty contention has now been launched upon the photographic world in relation to the best form of condenser for the magic lantern. Mr. Lewis Wright has issued in this country a book upon the lantern, and Mr. Andrew Pringle has launched one in America. In both triple condensers are spoken of as if no more practical use than one of the ordinary double form. Mr. Traill Taylor, however, who is an authority upon this subject, stated at the Camera Club that triple condensers transmit much more light, also that all the best lanterns in the United States have triple condensers. Last Tuesday, at the Photographic Society, Mr. W. E. Debenham made some remarks in favour of the triple form. One of the most essential points in a good lantern is, that it shall have the best possible condenser, and it is remarkable to see two books on the subject in error, as we believe, about a vital element in the construction of an optical system of the better form, such a system as will, according to a diagram by Mr. Taylor, nearly double the amount of light thrown upon the screen. Mr. E. J. Wall, in his new "Dictionary of Photography," adopts Mr. Taylor's views. The triple condenser being right in theory, the two authors display bravery in flying in the face of strong authority, including that of the screaming bird once described in Court by an American lawyer, whose client had stolen a pig, as "The glorious eagle of our country, which stands with one foot on the Atlantic Ocean, and the other on the Rocky Mountain, waving aloft the star-spangled banner, amid the wreck of matter and the crash of worlds!"

---

The Photographic Society is now domiciled in its new rooms, and before long will, no doubt, begin to feel comfortable therein; but at present everything looks newly finished. The entrance is directly opposite to the entrance to the British Museum, and in the library of the latter is a wealth of literature relating to photography. There is no name or plate on the door of the new establishment, and the first flight of stairs is scarcely lighted at all at night, so that some people have entered and left the doorway under the impression that it was the wrong house. The Autotype Company has lent some fine photographs to decorate the walls of the room. Among them are some Alpine peaks photographed by the late W. F. Donkin, a sea-view by Mr. Mayland, a lion by Mr. Gambier Bolton, and a view of Palmyra. The proximity of the offices to the British Museum will prove highly convenient to those photographers who are likewise literary men.

---

The refreshing novelty of the primuline process, and its excessive cheapness, ought to present attractions to the general public if brought under their notice. One way of doing so, when a professional photographer has a transparency of a sitter, is to offer to mark his pocket-handkerchief with the sitter's likeness; on a sunshiny day the whole operation can be gone through and finished in about fifteen minutes, and the sitter sent away rejoicing with a portrait upon cambric of himself in gorgeous colours, which will resist the action of hot soap and water. Recently, at a photographic conference in Lyons, the primuline process was spoken of by M. Léon Vidal as one of peculiar interest to that city, so celebrated for the excellence of its silk manufactures.

---

The other day we were at a lantern lecture where a somewhat unusual episode occurred. The top of the lantern front, just above the upper condenser—the instrument was a biunial—took fire. We also noticed that the top lantern, previous to this mishap, had, compared with the bottom one, been giving a very poor light. The instrument, we may add, was of first-rate construction by an eminent maker, but the operator had not used it previously, although it had been in constant and successful use in the hands of others. The flame was speedily suppressed, and the lecture was continued without the use of the top lantern, the cause of the mishap remaining for the time a mystery.

---

After the lecture was over, we had an opportunity of enquiring into the cause of the *contretemps*, but could obtain no clue until we examined the lime cylinder which had been in use. This we found to be indented with a deep pit where the full force of the blow-pipe flame of the mixed jet had impinged upon it. The cause of the fire now became obvious. The operator had either neglected to turn the lime, or the turning apparatus had failed to act. A cavity had gradually formed in the cylinder, and had reflected the flame on to the upper part of the woodwork, which had taken fire in spite of its metal lining. Had the flame been reflected to a lower point the condensing lens would have been broken, for many have been fractured from a similar cause. The operator would do well to remember the advice which the bells of London seemed to whisper to a celebrated personage on Highgate Hill: "Turn again, Whittington." We need hardly add that the paucity of light was due to the same cause as the ignition of the lantern.

---

Messrs. Marion are about to place on the market a new form of hand or detective camera, which is very novel in design, and which we hope to notice at length in a future number. But there is one novel point connected with its manufacture which we think is of extreme interest, and which will most probably point the way to doing work of a similar character. The most notable feature of the apparatus is a fan-shaped arrangement of metal grooves, in which the plates are stored. These grooves must be most carefully made in metal, and must each be correct in form to a hair's breadth. They could not easily be stamped, and it was out of the question to make each one by hand, so the device was hit upon of producing them by the electrotype process in copper. From a suitable mould, these pieces of metal are now produced at a comparatively rapid rate by use of the copper bath and a dynamo machine. We know of no other similar application of the electrotype process to the production of mechanical apparatus.

---

A gentleman who was caught lately by the enlargement-for-nothing dodge, which has recently met with such ruthless exposure, and who forwarded a sovereign for the handsome frame required for the work of art, recounts his experiences in a provincial journal. He plaintively says that he submitted both portrait and frame to the unbiassed opinion of one or two artistic friends, and that, after mature consideration, and after turning the portrait upside down, right-way-up, and sideways, so as to give it full advantage of varied positions, these judges came to the conclusion that there was nothing for it but to burn the dreadful thing to ashes, and it was then and there put behind the fire.

---

It would seem that, occasionally, photography throws too much light upon astronomical observations; that is to say, it discloses the apparent existence of phenomena which might be misleading. Fortunately, there are so many astronomers working with photography in different parts of the world, that any mechanical error which has been set down as referring to some variation in the celestial body observed is readily detected. A case in point was brought before the notice of the Royal Astronomical Society at its last meeting. Some time ago Mr. Fowler, of the Observatory of the Royal College of Science, South Kensington, thought he had discovered spectroscropic evidence of the duplicity of *a* Lyræ, and a paper was read on the subject at the Society by Prof. Lockyer. It now turns out that, whatever may have been the cause of the doubling of this particular star, the cause is not to be found in the star itself. Prof. F. C. Vogel, of Potsdam Observatory, has taken eleven photographs of the spectrum of *a* Lyræ since 1888, and in all these photographs the lines were perfectly sharp. Some of these photographs had been exposed during a period of forty minutes or more, and, if the observations at South Kensington had been correct, the changing separation of the lines during the period of the exposures ought to have caused them to appear blurred and confused, whereas they were perfectly sharp.

---

Mr. Ranyard also brought forward evidence derived from an examination of photographs of the spectrum of *a* Lyræ taken by the Bros. Henry, and had found the lines single and perfectly sharp. Mr. Ranyard suggested that the duplicity in the lines of the South Kensington photographs might be caused by the pinching of the prism in front of the object glass by a screw, which, if the strain were sufficient, would give rise to very sensible double refraction. Mr. Fowler, while admitting that, in the face of the facts brought forward, *a* Lyræ could not be a double star, thought it was impossible that there could be sufficient strain ever put upon the prism at South Kensington to give rise to the double refraction Mr. Ranyard had suggested. It now remains for the South Kensington astronomers to find out the reason of the apparent doubling in the photographs.

---

The ordinary journalist, in writing upon photographic subjects, is, for want of knowledge, not very exact in terms, and hence unintentionally falls into blunders. For instance, we read in a contemporary that "the January number of *The Chase* contains another experiment in photographing in colours." If this were really so, the wished for perfecting of a most important problem might have been reached. Of course, what the journalist meant to say was that the picture in question was a reproduction in colours from a photograph.

---

The National Portrait Gallery is to be utilised at last, but in a way which will surprise most photographers. Green's "Short History of the English People" is to be issued in monthly parts, and a well-known engraver has been commissioned to make woodcuts of the National Portrait Gallery pictures, a task which will take three years at the least. How is it that these pictures cannot be photographed? The time of photographing and preparing blocks, would be at least half that required by the engraver, the cost would be less, and of the accuracy there could be no doubt. Are there any regulations which prohibit these pictures being photographed?

## FERROUS OXALATE DEVELOPMENT AND SOME MODIFICATIONS.

In our notice of Dr. Liesegang's annual on page 32 we remarked upon a statement calculated to create some surprise amongst English readers, to the effect that the result of a canvas amongst German professional photographers showed the users of ferrous oxalate as a developer to be as five to one in proportion to those who employ pyrogallic acid for that purpose. The work of the Germans is by no means behind, and, with a view of placing before our readers the most recent review of the subject, we subjoin the following, taken from an article by E. Kiewning on "The Ferrous Oxalate Developer and its Variations," in Dr. Liesegang's Almanac.

"The very valuable enquiry set on foot by the editor of the *Photographisches Archiv*, 'Which kind of development is employed in the most important photographic establishments?' has resulted in the surprising information that, for the most part, practical photographers still give the preference to the oxalate developer.

"Other developers, of which hydrokinone stands in the first rank, are, on account of their peculiar adaptibility for certain cases, not to be condemned. Hydrokinone, particularly for instantaneous exposures, and for landscape purposes, renders most important services, concerning which I shall have something to say on another occasion; but none of the known developers permits of such manifold applications as the ferrous oxalate, and this on account of the variations that may be made in it, variations that with other developers are simply impossible.

"It is not only that with the accustomed and well-known formula of normal proportions it works brilliantly, but we have at hand a modification by adding more or less of the iron solution, either in the first instance, or in the course of development.

"Another variation is the preliminary bath. It is well-known what can be accomplished by the use of a preliminary bath, especially with plates of certain make, and having regard to certain conditions, conditions which I have indicated in a previous article in the *Photographisches Archiv*, 1889, p. 197.

"A further variation is a bath with oxalate of potash, and a small addition of hyposulphite of soda, followed by an addition of iron solution, which, under certain circumstances, yields a very brilliant result.

"For subjects of very great contrast, in which very bright lights as well as deep, heavy shadows have to be photographed, the oxalate developer is capable of rendering most valuable service, as I have mentioned in a communication to the Berlin Society of Photographic Operators, and particularly when used in the following manner, as I have often experienced.

"The plate is first immersed in a solution of iron and hyposulphite of soda, and then, this solution being poured off, it is followed by one of simple oxalate of potash, and the development thus effected. It is astonishing what this variation of the developer permits us to accomplish in the cases mentioned, whether, say, in landscape photography, we take the case where light buildings in a dazzling illumination have to be photographed along with large masses of deep green foliage; or in portraiture, where a lady in white dress is photographed with a gentleman clothed in black. Another case is that of what is called artistic lighting effect, when, for instance, a person at a window in direct sunlight is photographed from within the apartment. Here the apparatus, contrary to all the customary proceedings, is directed almost to the light itself. The method of development just described may be employed with the happiest results.

"To go more into detail. Prepare a solution of hyposulphite of soda of 2 per cent., and of this add according to the requirements of the case—say, for a plate of cabinet size—5, 6, or up to 10 drops to each 50 c.cm. (about $1\frac{3}{4}$ ounces) of iron solution. The proportion of hypo in this preliminary bath is about 1 in 2,000 to 2,500. The plate is immersed in this solution for from one to two minutes, and the solution is then poured off and preserved for further use, and the oxalate solution is poured on. If with this treatment the contrasts appear too weak, a small quantity of fresh iron solution may be added, and a very considerable amount of vigour be thereby gained.

"Another important advantage of the oxalate developer is that the gelatine film becomes tanned, so that, for the purpose of obtaining the utmost sensitiveness, and of work of which the plate is susceptible, it will bear to be warmed to a considerable degree without danger of losing the film during development. This is an advantage of less consequence in summer-time, but in winter is of great importance, for the sensitiveness and softness of the negative are enhanced to a great extent thereby. I have, in this way, taken instantaneous flash-light pictures on plates that were by no means particularly sensitive, using the hypo preliminary bath at a temperature of 18° to 20° Reaumur (72° to 77° Fahrenheit), and an oxalate developer warmed to 30°, 35°, and even 40° Reaumur (100° to 122° Fahrenheit) with the most gratifying results.

"With alkaline developers, whether pyrogallic, hydrokinone, or eikonogen, the temperature of 18°, or at the highest 20° Reaumur, can be exceeded only with the greatest caution, if the danger of frilling or losing the film is not to be incurred.

"The oxalate developer has the advantage, seen especially in portrait photography, over all alkaline developers, of giving greater harmony in the gradation of tone. Whoever is sensitive in this regard will, on comparison, soon find the difference. In this, as in all other matters, Prove all things, and hold fast to that which is best."

Leeds Photographic Society.—*Syllabus of meetings for February.* February 5th, "A Good and Bad Photograph," with lantern and other illustrations, Mr. C. H. Bothamley, F.I.C.; February 16th, "Development," Mr. S. A. Warburton; February 26th, Exhibition of Lantern Slides.

A Dangerous Flash-Light.—"Run! the building is falling!" This cry came from the throats of a thousand people standing near the City Hall at 9.45 last evening. There had just been a heavy explosion, and a great stone had fallen from the roof. Both were the result of an effort to photograph the new Pulitzer building. On the roof had gathered six young men, preparing to take an instantaneous picture. One of the men dropped a spark from a blazing match into a box of magnesium or flash-light powder. The report that followed exceeded anything they had dreamed of. It could be heard a long distance, and the big building was rocked to its base by the explosion. The six men on the roof were thrown flat on their backs, and a three hundred pound coping stone went crashing down to the pavement below. When the people had calmed down they went round to learn what damage had been done. They discovered that about every window pane on the east side of the hall had been broken, but otherwise no damage had been done, so far as could be learned. A lot of small stones were also thrown from the roof, and these struck a good many people, but no one was seriously hurt.—*The Brooklyn Journal.*

## Literary Notices.

Fotografisk Tidskrifts Arsbok, 1890. Edited by Albin Roosval. (*Stockholm: R. Blaedel & Co.*)

A year-book for 1890 of the *Photographic Journal*, published at Stockholm, has lately appeared under the able direction of Albin Roosval, illustrated by nine artistic supplements. The editor confesses in his preface his indebtedness for this idea of a photographic annual, in which his readers are presented with a practical book of photographic reference, to a foreign example and an alien lead. He trusts—he tells us—that his little volume will touch some responsive chord of interest in both amateur and professional, and that when his next yearly issue appears, it will be looked upon already as an old and familiar friend.

The year-book contains some forty or fifty articles of original contribution by authors of distinguished merit. Among the principal of these are "Photographic Discoveries of Unseen Stars," by the Professor of Astronomy in the Upsala University, N. C. Duner; "The Lighting of the Studio," by J. Petersen, the editor of the leading photographic journal in Copenhagen; "The Methods of Photographic Reproduction," by A. Börtzell; "Photographic Economy," by Im. Mohr; "Micro-photography," by A. Smitt; "Stereoscopic Pictures," by Peter Knudsen; and "A New Technical Principle in Lithography," by Lars Ostlin.

The year-book contains also a list of amateur photographers and of amateur photographic clubs in Helsingfors, in Finland; a notice of the photographic societies in Christiania, Copenhagen, Stockholm, Upsala, and Göteborg; tables of English weights and measures, a droptable after Eder, a list of abbreviations commonly employed in photographic chemistry, original receipts, and much other varied information likely to be useful to the photographic student.

Among the illustrations of the year-book are autotypes from the studios of W. Silfversparre, of Norrlandsgatan, and J. Cederquist, of Barnhusgatan, Stockholm, of C. Angerer and Göschl, in Vienna, and of W. Cronenberg, in Grönenbach; phototypes from V. Wolfenstein, of Stockholm, and Sinsel Dorn and Co., of Leipzig, and pictures on aristotype paper from Christensen and Lörensen, of Silkeborg.

The frontispiece, from the lithographic establishment of Stockholm, is a phototype from a negative after nature by Gösta Florman on magneta paper. Silfversparre's autotype of a girl, nude to the waist, bearing a pitcher, is taken from a photograph of the Photographic Society of Berlin, and is a reproduction of M. Nonnenbruch's picture, "The Greek Water Carrier." M. Sinsel Dorn & Co's. illustration of a group of poor children is, perhaps, the most characteristic picture in the annual; the negative was taken on kodak film by G. Kallstenius. V. Wolfenstein has contributed a so-called duplex portrait of himself and Hr. Knut Ahnlöf in a *tête à tête* conversation, taken by handpress from a negative after nature. A scene from Sachs-Meiningen is contributed by the pupils of W. Cronenberg. Photographs of oil paintings have supplied J. Cederquist with two excellent autotypes, one from J. v. Holst's well-known picture entitled "Det Nappar," or "The Nibble," in which the expression of eager curiosity of the two dogs in the fishing boat has been ably reproduced; the other a contribution from the Lurlei motive of C. v. Bodenhausen.

Angerer and Goschl's autotype, which modestly occupies the last place among the illustrations of the year-book, is a reproduction after a negative of an amateur, Prof. Carl Curman, one of the members of the Swedish Photographic Union. The gentleman who holds a paper in his hand, and contemplates the observer with a benevolent smile, situated in a seemingly well-ventilated conservatory, is, we are informed, the political poet, Björnsterne Björnson. We have no space to notice the literary merits of some of the articles. We trust we have said enough to show that this new Swedish year-book is an useful and entertaining contribution to photographic literature.

---

Photography as a Business. By H. P. Robinson. (*London*, 1890: *Percy Lund & Co.*)

This book is upon a subject with which Mr. H. P. Robinson is highly competent to deal, and it contains plenty of useful practical information for those in the trade.

About the "amateur question" Mr. Robinson says:—

The amateur may surreptitiously sell a few prints; he may even commit the enormity of giving some away; he may help the cause of charity by photographing the curate for a bazaar; and the profits of the patronage he bestows on the professional may not be so colossal as he supposes, but none of these errors are criminal. The real mistake he makes and mischief he commits is in becoming a professional, and, with few qualifications for the business, increasing the crowd. He begins by buying a cheap set, and after a few months' practice produces a few prints, which too partial friends unduly praise, and thinks he is fitted to become a full-blown professional photographer. He has probably a little capital, and—to find an easy and agreeable solution to the ever-pressing question of a career—buys a business or builds a studio, and then, and not till then, he finds that the ability to take a portrait—I will go further, and say a good portrait—is but a minor part of a business for the proper prosecution of which he should have had years of training. If there is something exceptional in him he struggles through, but if he is less than exceptional he waits until his capital is exhausted, and then subsides into another line in life, or becomes an assistant, when, probably, his real education begins.

I may be answered that I am exaggerating the failures; that the *Gazette* shows very few bankruptcies which would happen if so great a number failed. One easy reply is that photographers, not keeping stock, are seldom sufficiently in debt to make bankruptcy worth while; another is that, as a body, they are so seldom trusted as to have little chance of getting into debt.

---

Received.—J. H. Steward's catalogue of magic lanterns, dissolving views and effects. It is handsomely bound, well illustrated, and most conveniently arranged for reference.——From R. Morgan, Norwood, "The British Weather Chart, 1891," by B. J. Jenkins, F.R.A.S. The chart is stated to be based on the author's paper on "Forecasting the Weather," in the Bulletin of the Royal Academy of Sciences of Belgium. The chart is accompanied with letter-press explanation and predictions of probable weather during the twelve months of the year.——From E. L. Wilson, New York, *Photographic Mosaics for* 1891, "its twenty-seventh appearance, swollen to twice its former girth," says the preface. It contains several full-page engravings, the frontispiece being a portrait of the veteran actor and artist, Joseph Jefferson. The price of this annual is just double that of the Year-Book.——From Taylor, Taylor, and Hobson (London office, 6, Southampton Street, High Holborn), Price List of Photographic Lenses. It contains, in addition to commercial announcements, advice on "Choosing a Lens," and an essay on "The Principles of a Lens' Action."——From Sampson Low, Marston, and Co., "Bibliotheca Polytechnica"; a directory of technical literature, in which the catch-words are given in English, French, and German. An enumeration of the technical journals in these three languages is also given. It is edited by Fritz von Szczepanski.

## PHOTOGRAPHING THE DEAD.

THE following particulars are from a recent number of *The New York Sun*:—

For many years the city has had photographs taken of most of the dead bodies which have been brought to the Morgue and not identified by friends or relatives within two or three days after reception. The object of this is evident. A record of the appearance of the unknown dead is thus preserved on a single sheet of paper, which is infinitely more serviceable than verbal descriptions, which might fill a volume. These records in silver and sunlight have, in hundreds of instances, led to the identification of the dead long after burial—in some cases months and years afterwards. Besides, when a photograph of an unidentified body has been secured, the body can be buried in the Potter's Field on Hart's Island without delay. The system is rendered practically perfect by New York's method of burial in the Potter's Field. A body buried there any time within the past twenty years can be recovered with certainty and without trouble.

A few months ago a man called at the office of the Department of Charities and Correction at Third Avenue and Eleventh Street, and asked to see President Porter. He exhibited several photographs of persons taken after death. The workmanship was excellent. The man explained that he was a photographer, and had frequently been called upon by families to make pictures of their dead. His success with the work had suggested to him that he make it a specialty. He has done so, and now, after several years of experimenting, he considered himself an expert. Mr. Porter examined the portraits, and pronounced them first-class. The man then made a formal application for the work of photographing the dead of the city Morgue.

"Do you know what we pay for that work?" asked Mr. Porter.

"Yes," said the photographer, "you pay five dollars for each photograph."

"That is so," said Mr. Porter, "but do you know how much it all amounts to in the course of the year?"

"I do not," replied the photographer; "but I do know that your present photographer, Oscar G. Mason, manages to live in pretty good style, and does not have to do outside work."

"Would it surprise you to know," asked Mr. Porter pointedly, "that Mr. Mason's work costs the city between $400 and $600 a year?"

The photographer whistled softly, and was silent. Then he said that the business was very much smaller than he had supposed, but that still, at the rate of five dollars a photograph, it was well worth the doing. He said he was disappointed in the prospect, but that, nevertheless, he would press his application, and, if successful in getting the work, he would run the Morgue work in along with his outside business, and in that way make it profitable.

"Very well," said Mr. Porter, "but before you commit yourself, I will give you a few facts about Mr. Mason and his work. You evidently do not know that photographing occasional dead bodies at five dollars each is not a tithe of the work that Mr. Mason does for us, yet it is the only work for which he gets any pay whatever. The great bulk of his time is devoted to photographing cases of disease and deformity in the hospital, surgical operations of an exceptional nature, and miscellaneous operations in various stages intended to serve as pictorial histories of the advance of surgery, and as models for the instruction of students, young physicians, and inexperienced surgeons. This high-class scientific work he throws in for nothing, contenting himself with the scanty income which comes from the occasional jobs in the Morgue, and ——."

"But," interrupted the photographer, reaching for his hat, "why on earth does he do all that for nothing? That is high-class work. Is not the city willing to pay him for it?"

"We have frequently offered to pay him for his very valuable medical and surgical photography," said Mr. Porter, "but he positively refuses any compensation except for the unpleasant work of photographing eighty or a hundred Morgue cases a year. He persists in this course, notwithstanding that he devotes almost his entire time to department work, and is always ready and willing to sacrifice any outside interests to do us a service. But, to come down to the question before us, if you seriously want to undertake all of Mr. Mason's work upon his terms, you may leave your application with the Commissioners, and we will consider whether it is to the interests of the city and of Bellevue Hospital to substitute you for Mr. Mason as the department photographer."

The photographer arose. He said simply that he withdrew his application. Then he put on his hat and left the building. He is not the only one who has applied for Mr. Mason's job. Within the last two or three years, particularly, there have been many applications for the work of photographing the city's unknown dead; but every applicant has heard the same story about the city's photographer, and, upon hearing it, has reached for his hat and abruptly left the room.

## ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

THE mounting of the reflector has been treated, if not so successfully, with more variety than in the case of the refractor, as we shall see from the pictures I will show you, especially where the Newtonian form is used. The 4-foot reflector at Melbourne is mounted on the German plan, in a similar way to a refractor, and an almost identical plan has been followed by the makers of the 4-foot at the Paris Observatory. Lassell, who was the first to mount a large reflector equatorially, used a mounting that may be called the forked mounting, the polar axis being forked at its upper end, and the tube of the telescope swinging between the forks; a very excellent plan, dispensing with all counterpoising. Wishing to obtain certain conditions that I thought—and think now—favourable to the performance of the reflector, I devised a mounting where the whole tube was supported at one end on a bent arm; a 3-foot mirror was mounted on this plan in 1879, and worked admirably. The Newtonian form demands the presence of the observer near the high end of the telescope, and the trouble of getting him there and keeping him safely close to the eye-piece is very great. As we see from the various photographs, several means have been employed to do this, none of them quite satisfactory.

All the refracting telescopes of note in the world are covered by domes that effectually protect them from the weather; these domes are in some cases comparable in cost with the instruments they cover. It is not surprising, therefore, that efforts have been made to devise a means of getting rid of this costly dome and the long movable tube.

It was suggested many years ago that a combination of plane mirrors could be used to direct light from any object into a fixed telescope. This idea in a modified form has often been used for special work, one plane mirror being used, as we see in the picture on the screen, to throw a beam of light into a telescope fixed horizontally; for certain kinds of work this does admirably, but the range is restricted, as can be easily seen, and the object rotates in the field of view as the earth goes round. The next step would be to place the telescope pointing parallel to the axis of the earth, and send the beam of light into it from the mirror, which could now be carried by the tube, so that by simply rotating the tube on its own

* Continued from p. 51.

axis the object would be kept in the field of view. Sir Howard Grubb makes a small telescope on this plan, and some years ago proposed a somewhat similar plan. A sketch of this plan I will show you. You will see, however, that here again the range is restricted, and to use the telescope, means would be required to constantly vary the inclination of the small mirror at one-half the rate of inclination of the short tube carrying the object-glass.

By the use of two plane mirrors, however, the solution of the problem of a rotating telescope tube placed as a polar axis is solved. By having such a telescope with a plane mirror at an angle of 45° to the axis of the telescope in front of the object-glass, we can, by simply rotating the telescope, see every object lying on the equator; and by adding another similar plane mirror at an angle of 45° to the axis of the telescope, *as bent out at right angles by the first plane mirror*, and giving the mirror a rotation perpendicular to this axis, we obtain the same power of pointing the telescope as we have in the equatorial. The idea of doing this was published many years ago, but it was left to the skill and perseverance of M. Lœwy, of the Paris Observatory, to put it into practical use. He devised, and had made, a telescope on this principle, of 10½ inches aperture, which was completed in 1882. It has proved itself an unqualified success, and many other larger ones are now being made in Paris, including one of twenty-three inches aperture, now nearly completed, for the Paris Observatory.

A lantern copy of a drawing of this latter telescope will be thrown on the screen, in order that you may see what manifest advantages exist in this form of telescope. There is but one objection that can be urged—that is, the possible damage to the definition by the plane mirrors; but this seems, from what I have seen of the wonderful perfection of the plane mirrors made by the Brothers Henry, to be an unreasonable one—at any rate, not an insurmountable one. In every other respect, except perhaps, a slight loss of light, this form of telescope is so manifestly superior to the ordinary form, that it must supersede it in time, not only for general work, but for such work as photography and spectroscopy.

*(To be continued.)*

THE MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.—A photographic exhibition in connection with this Society will be held at the Manchester Athenæum (George Street entrance), on Monday, Tuesday, and Wednesday, February 9th, 10th, and 11th, 1891. Open Monday, 6 to 10 p.m.; Tuesday and Wednesday, 10 a.m. to 10 p.m.

POPULAR AFTERNOON LECTURES.—The Council of the Society of Arts have arranged for a course of five popular lectures to be given by Captain W. de W. Abney, on the following afternoons, at half-past four o'clock—February 13th, 20th, 27th, March 6th, 13th. The subject will be "The Science of Colour." The lectures will be of a popular and elementary character, and will be fully illustrated by experiments. The regulations for admission will be the same as for the Cantor Lectures, each member having the privilege of admitting one friend.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.—The first annual general meeting of this Association will be held, as announced elsewhere, at the Colonnade Hotel, Birmingham, on the 12th of February, for the enrolment of members, election of officers, and the discussion of rules drawn up by the Provisional Committee. In order to facilitate arrangements for adequate accommodation, those who intend to be present are requested to send an intimation on or before February 11th to Mr. H. J. Whitlock, New Street, Birmingham.

## Specifications Published.

669. *January 14th*, 1890.—"Ascertaining the Requisite Time of Exposure in Photography." EDWARD GEORGE BALLARD, 1, Eversley Park, Chester, H.M. Inspector of Alkali Works.

A ready method of measuring the amount of actinic rays proceeding from any landscape or object has for a long time been a thing much desired by photographers, both amateur and professional. Many instruments with this view have been from time to time brought out, but none of them have proved very satisfactory. The same may be said of tables, which, although of great assistance in open landscape, have this drawback, that, wherever the quality of the light is interfered with, that is, in forest scenery, deep glens with overhanging trees where the very air appears to be green, interiors of churches, *etcetera*, where the light which enters perhaps passes through coloured glass, and so forth, you are compelled to guess at the exposure after all.

The apparatus about to be described purposes not only to measure the intensity of the rays of light proceeding from any object, but also the quality of the same.

The principle upon which the instrument is constructed is based upon (1) that luminous calcium sulphide or Balmain's luminous paint is only excited by those rays of light which usually act upon the photographic plate; (2) that when luminous paint is excited by exposure to light, either daylight or other white light, such as a burning piece of magnesium wire, and the source of light is suddenly removed, it will be observed that the bluish light emitted from the luminous paint gradually fades. The rate and manner in which this fading occurs are employed by me in this invention as a means for ascertaining the intensity of the light proceeding from any object, landscape, or sea view.

This is arrived at by noting the time required for the luminous paint to acquire the same degree of intensity as a portion of the light proceeding from the object, landscape, or sea view in question, and referring to a table specially constructed for that purpose.

In carrying out my invention into practice, one form of apparatus which I have found very successful is as follows, and is given by way of illustration only:—

A wooden or other opaque tube, coloured dull black inside, and open at both ends, and of convenient size and shape at one end to adjust to the eye, is provided at the other end with a second and similar but shorter tube hinged to it, so as to form a lid. This lid is glazed next the tube with blue glass capable of cutting off all rays except those corresponding with those which proceed from the luminous paint. A second glass is slipped into this, coated as regards about half its area with an opaque layer of calcium sulphide paint (Balmain's luminous paint); above this a number of layers of tissue paper or other uniform translucent material is placed, and a covering is added of ordinary or cobalt blue glass. The number of sheets of tissue paper to be inserted is found by experiment for each variety of dry plates. Their use is to lessen the intensity of light passing through to the degree requisite to give correct results with the instrument; this once found is constant for that variety of plate.

To use the instrument, allow the hinged portion to fall, and so get the side with the luminous paint fully exposed to daylight for thirty seconds. Place the eye at the end, then quickly close the hinged portion; a blue luminous ground and a dark ground will be seen side by side. Count the number of seconds it takes for the blue luminous side to acquire the same tint as the dark side—that is, note when the difference in blue disappears. Refer to the table mentioned, and, opposite the number of seconds required for the two halves to appear alike, will be found the correct exposure to be given to the photographic plate to which the instrument is adjusted.

The instrument I have constructed is adjusted to a plate of about 18 Warnerke sensitometer value, working with a stop or diaphragm in the lens of one-sixteenth of the focus of the same.

The actinometer can easily be adjusted to a plate of any degree of speed by removing or adding to the layers of tissue paper behind the glass carrying the luminous paint.

In adjusting the actinometer, any of the published tables of exposure may be employed, or, better still, that excellent little calculating machine for photographic exposures called the "actinograph," invented, after much labour and study, by Dr. Ferdinand Hurter and Mr. Driffield, of Widnes. Or in very perfect instruments a clockwork, or its equivalent, can be set in action by closing the hinged portion, and arrested by opening it; this can be arranged with a scale to show the requisite exposure in seconds.

2,671. *February 19th*, 1890.—"The Photometric Examination of Gases." WILLIAM FOSTER, 14, Clement's Inn, London, Consulting Chemist.

My invention consists of apparatus whereby the illuminating value of one and the same sample of gas can be rapidly ascertained when consumed in a number of different burners.

It consists of a tap or cock the plug of which is fixed. A channel or passage for the gas is made along a portion of the longitudinal axis of the plug terminating laterally.

Encircling the plug is a mass of metal carrying arms of equal length, at the end of each arm a particular but different burner being arranged. These arms, with the burners which they carry, rotate round the central fixed plug.

In using the apparatus a particular burner is brought round to the end of the bar of the photometer, whereby the lateral channel in the plug, the arm of the burner required, and the bar of the photometer are all three in the same straight line. All the other arms, and, therefore, all the other burners of the apparatus, are cut off from gas communication. When flat flame burners are used, I arrange a form of tap at the extremity of the radial arm, whereby the flat surface or the edge of the flame can be opposite to the disc of the photometer.

9,422. *June 18th*, 1890.—"Glazing Bars or Astragals for Roof-lights." WILLIAM RICHARD LESTER, 11, West Regent Street, Glasgow, Engineer.

My said invention has for its object to improve the form of glazing bars or astragals for roof-lights or windows, and to combine parts so that a soft material, such as lead, or an alloy thereof, may be satisfactorily used for securing the glass. Zinc, or other metals, or alloys, may also be used in combination with my improved bars.

In carrying out my invention according to one modification, I employ a steel or iron bar rolled so as to be of a section having an upper vertical member or web, and on each side of its lower part a member or web shaped to form a gutter. In addition, there is formed on each side of the middle part a shoulder or projection, on which the edge of the glass is to rest. But these shoulders are a little higher than the outer edges of the gutter parts, so that such outer edges do not touch the underside of the glass. The lead or other metal combined with the bar is made to cover the vertical member, and is riveted thereto, or otherwise attached, so that it cannot lift off the bar; and it is made with marginal parts, which are doubled close down to the shoulders, and which are folded down on the glass when it has been placed in position.

The vertical member of the bar may be made to extend in part above, and in part below the other parts. An inner gutter may be formed on each side, and so as to have the glass resting on its outer edge, but not on the outer edge of the outer gutter, by suitably doubling and bending the lead, the shoulders below the lead being relatively lower than in the first modification; or inner gutters may be formed by fixing suitably shaped strips of zinc or other metal to the bar.

In other modifications, the bar may be of cast iron or other suitable material; or it may be of wood, in which last case the parts are made of such dimensions as to be of sufficient strength; or the bar may be made of sheet metal bended so as to present an outward form like what is hereinbefore described for the steel or iron bar, wood or other suitable material being in some cases combined with such sheet metal.

19,658. *December 2nd*, 1890.—"Photographic Films." A communication from GEORGE EASTMAN, Rochester, County of Monro, State of New York, United States of America, Manufacturer. ALFRED JULIUS BOULT, 323, High Holborn, London.

Difficulty has heretofore been found in using photographic film—such, for instance, as is described in letters patent No. 19,897, dated December 10th, 1889, granted to me—composed of a film support made from a compound of nitro-cellulose camphor and other substances, and having applied thereto, after being dried, a film or layer of gelatino-argentic emulsion, especially if the photographic film be wide, owing to the tendency of such film to contract at the edges more than the central parts, so that it will not lie flat on the table or support of the roll-holder—such, for instance, as that of the Eastman and Walker roll-holder—but, when strained tight, the edges alone will be brought in contact with the table, while the central parts will bulge and buckle, thereby rendering it objectionable or unsuitable for photographic purposes. This unequal contraction and buckling is believed to be due to the drying out or evaporation of the volatile substance or substances used with the nitro-cellulose to make the compound from which the film support is produced, and which remain in it after it is dried. One reason for this belief is that it has been observed that such photographic film that has been kept on spools for some time becomes permanently set, and the buckling is more marked.

It has been discovered that, by coating and thus protecting or sealing the film support on both of its surfaces with some material such as gelatine—which, it is believed, prevents, retards, or modifies the evaporation of said substance or substances in the film support when dried—the film is prevented from unequally contracting or buckling to an objectionable extent, and is caused to remain in good condition, and so that it may be kept in rolls or on spools for a considerable period of time without materially changing, thus enabling it to be employed in all cases where paper films are used.

THE ROYAL INSTITUTION.—Lord Rayleigh's lecture on "Some Applications of Photography" did not come off last Friday, and we regret to say that it was in consequence of domestic affliction; its delivery has been postponed. In place thereof, Lord Justice Sir Edward Fry lectured on "British Mosses." Among the objects of interest exhibited in the library, were small photographs on Dagron and Co's. collodion films, illustrating the French pigeon post, by Mr. John Spiller; an excellent winter scene in the mountains, Piz Langard, Engandine, by Mr. Arnold Spiller; some good primuline prints by Messrs. Green, Cross, and Bevan; seascapes by G. West and Sons; views of the moon by F. S. Wells; camera with aluminium fittings by J. R. Gotz; opthalmic refractometer by A. Fournet; a "terpuescope" by A. Wrench; exposure meter by Mr. Watkins; Gravell's optical pointer, and his adjustable cut-off for limelight jets; Newton's new projection lantern for the Royal Institution; a table polariscope by Harvey and Peak; and photogravures by the Typographic Etching Co.

## Correspondence.

### DR. EMERSON'S RENUNCIATION.

Sir,—Can it be true, or is Dr. Emerson playing off a joke on us? It seems too good news for actuality that the prime instigator of the naturalistic racket has at last felt the error of his ways. If he means it to be a reality, he must earn by it the goodwill and thanks of all who truly desire the advance of pictorial photography. It is easy to understand how a cultured gentleman must be annoyed by the sickly manner in which those who have supported his former views have "out-Heroded Herod" with their long rigmaroles of meaningless *palabras*, which must leave even the most highly-versed students of modern critics' slang in perfect dismay in endeavouring to discover what these paper stainers are driving at.

Probably they do not themselves know, and, on the principle that "fine feathers make fine birds," sought, by the involved mysticism of their phraseology, to imbue the less intellectual of their hearers or readers with the idea that anything couched in such far-fetched terms necessarily contained considerable elements of nobility.

In his detail of the causes to which Dr. Emerson attributes his conversion there is nothing new to sensible men, but it appears to me strange that he should so long have overlooked these matters, which are common experience.

I venture to differ with Dr. Emerson on the final cause which seems to have determined his bravely offered renunciation. I do not think it is to be attributed to his examination of various studies in art *after* three and a-half months' solitary study of nature in his house-boat. I think, if he fairly analyses his inward reflections, he will find that his change of views rather results from the mentioned three and a-half months' study of nature away from access to art examples. He has at last appreciated what nature is, and how far away anything yet offered as art is from compared with it, and how infinitely farther still from it is anything emanating from the naturalistic schoolroom. He is the better artist for his unconscious training, for one who can produce the frontispiece to "Wild Life on a Tidal River" presents to his admirers a work which, in artistic value, is far ahead of the majority of those issuing from the studios of to-day.

All lovers of art photography must be delighted to find how Dr. Emerson throws off those who have striven to render themselves illustrious by clinging to his coat-tails; it really seems as though he had been for some years piling up a big joke on them previous to depositing them very carefully in the mire. Anyhow, as Wilkis declared he "never was a Wilkite," we have now Dr. Emerson's virtual declaration that he does not belong to the Emersonian school. Henry E. Davis.

28, *Leinster Square, Bayswater, London, W., Jan. 26th.*

---

Sir,—The fever of excitement caused by the news embodied in Dr. Emerson's essay of last week has probably by this subsided, and the manufacture of soft soap by the enemy commenced. If the word enemy applies to one who differed from Dr. Emerson on the question of naturalistic photography, it will not be surprising if a little glee, "small-souled" or otherwise, be forthcoming. Be this as it may, most questions, like tombstones, have two sides, and the epitaph of last week seems to be the one side, of which the following may be the other:— "Here lies a veritable bone of contention, being all that remains of an attempt to theorise. Born prematurely, and nourished insufficiently, it crawled through a short and chequered career, admired by few, derided by many, and dying very little lamented; the spirit of which, freed from personal ambition, may yet rise to honour and stability." This, I fancy, will embody rather more of the public opinion than that of last week.

Most people have heard the fable of the boy who called "Wolf!" until he fell a victim to that complaint. Dr. Emerson had probably forgotten it when he mentioned his intention of reconsidering the matter, and then calling for help.

In concluding, I cannot think of a more apt quotation than Dr. Emerson's own from Francis Bacon, "If offence come out of truth, it were better the offence come than the truth be concealed." H. Colebrook.

## Proceedings of Societies.

### The Photographic Society of Great Britain.

At the technical meeting of this Society held on Tuesday evening, the 27th inst., the chair was occupied by Mr. H. Chapman Jones.

The Chairman handed round for inspection a Wray's lens for detective camera work. It was of six-inch focus, constructed with Jena glass, and furnished with an iris diaphragm and index.

Mr. A. Cowan thought it better that there should be a click indicating when the aperture stood at the standard sizes marked on the index.

Mr. G. L. Addenbrooke would like to hear the experience of any who had worked with combination sets of lenses. A set of that kind which he possessed was not very successful, the illumination being unequal, and falling away at the corners.

Mr. Cowan had known Darlot's combination sets to work very well, but they were not intended to be used with large diaphragms.

Mr. Addenbrooke asked whether doublets—one component of which was of longer focus than the other—were not necessarily inferior to symmetrical lenses.

Mr. W. E. Debenham thought not, at all events, for lenses of the wide-angle character.

Mr. W. Bedford had had a set of lenses made for him by Darlot, with a somewhat more extensive range than usual, and found them work very satisfactorily. He did not notice any bad result from the combinations being unsymmetrical, even when using those of longest and shortest focus together.

The Chairman said that aluminium might now be used in these fittings, being so much cheaper than it formerly was.

Mr. Addenbrooke added that, for the last year or more, a good solder for aluminium had been in use. A piece of metal might be soldered with it, and beaten out to double its size without injury.

The Chairman thought it a mistake to use so large a plate as the quarter size when taking negatives for the lantern. If an oblong picture were intended to be made, there was no advantage in going beyond half the quarter-plate size.

Mr. Debenham thought it well to be able to select the portion of the subject to be used at more leisure than was practicable with detective camera subjects. Mr. Thomas Sutton had recommended the general use of a square plate large in proportion to the focus of the lens, so that the best portion of the view could be selected afterwards.

The Chairman said that, with a good finder, there was no difficulty, and he was never more than an eighth of an inch out. Finders, as sold, were often inaccurate.

Mr. W. H. Harrison asked whether there was any advantage in triple over double condensers for lantern slides of ordinary size.

Mr. T. E. Freshwater said that for illuminating a small surface the triple condenser was best, but there was no advantage when showing the whole of a slide of ordinary size.

Mr. Addenbrooke mentioned that an incandescence lamp for use in the lantern had been recently brought out, and asked whether anyone present had had any experience with it.

Mr. Freshwater thought it better to use the arc light when a current was available, but care must be taken not to heat the condenser, and it must be of long focus.

The Chairman remarked that it was generally considered that lantern slides should be very sharply defined. One maker had told him that if the slide appeared sharp to the eye, that would be sufficient. What would be Mr. Debenham's opinion?

Mr. Debenham replied that a three-inch slide, examined at a distance of nine inches, would subtend the same angle as when thrown on a six-foot screen and looked at from a distance of eighteen feet. If there was greater enlargement, or if the spectator were nearer, want of sharpness might be detected on the screen that was noticeable in the slide itself. He would like the slide to be defined as finely as possible, and for the image to bear closer examination on the screen if desired.

At the next technical meeting, in February, views of Australian and American scenery will be shown by Mr. Addenbrooke.

### The Photographic Society of Ireland.

A technical meeting was held at 15, Dawson Street, Dublin, on the 22nd inst., Mr. Herbert Bewley in the chair.

Mr. H. M. Smith, of the Eastman Dry Plate and Film Co., exhibited the various forms of "kodaks," including their new No. 4 folding kodak. He also explained the working of the rollable film, and gave instructions as to the best methods of enlarging on Eastman bromide paper, both by daylight and artificial light. He passed round some very fine enlargements from kodak negatives, and subsequently developed a 15 by 12 bromide print, and stated that the developer *par excellence* for the company's bromide paper was ferrous oxalate.

### The North Middlesex Photographic Society.

*January 26th.* — Mr. Goodhew, vice-president, in the chair.

Mr. G. R. Martin, in opening a discussion on "Halation and Light Fog," said he did not pretend to have more knowledge of these phenomena and their causes than other members of the Society, but proposed to give his opinions for comparison with the experience of others. He had, when the subject was first proposed some time ago, prepared negatives to illustrate his views. These, however, had been destroyed, and as he, most unfortunately, had not had time to repeat them, he would attempt to explain them with the aid of the blackboard. In the first place, he considered that the various kinds of halation and light fog were due to several causes, many or all of which were present at the same time, so that it would be futile to attempt to say to which cause any particular instance was due, and as light fog and halation were usually present at the same time, he proposed to take into consideration all species of fog which were impressed upon the plate during exposure in the camera. Halation in its usual form was a spreading of the high lights into the adjacent shadows, and was generally assumed to proceed from the reflection of these lights from the back of the plate. It had been objected that these rays would be reflected at an angle equal to the angle of their incidence, and so, in many cases, would appear in the form of a second image on one or the other side of the direct image. It was only necessary to remember that the film acted as a disperser of light, causing it to spread in all directions, and, consequently, to be reflected in the same way, to show that this objection was unfounded. The second cause might be attributed to the reflection of small portions of the light in all directions from the crystals of haloid salt in the film. This would probably be small in quantity and entirely on the surface, and could be removed by gentle rubbing with a rag moistened with methylated alcohol. Another cause of fog, when taking a negative with extreme contrasts, was that the light was sometimes reflected from the edges of a badly-finished lens, and even when the lens was perfect, uncondensed light entered and formed a halo on the plate. He then referred to ghost images, and showed by diagrams how they were formed. Prevention.—It had been suggested to back plates with some non-actinic matter, such as stained collodion, gamboge, and gum, or any medium which approached the refraction index of glass. He had in practice found that a piece of the Autotype Company's black film wetted and applied to the back of the plate was as good as any, was easy to apply and remove, and did not in any way injure the plate, even when kept in contact for two or three weeks. It had also been suggested to mask the windows or other brilliant objects with a screen, and either to take two exposures on different plates, giving a long exposure for the shadows with the screen in position, and a short one for the lights with the screen removed, or to combine the two exposures on the one negative. He had not tried this method, but did not doubt that it was practicable in certain cases. He preferred to mask portions of the negative during the process of printing, and referred to successful instances of this method shown by a member of the Society at a previous meeting. It had been proposed to stain the film previous to exposure with a non-actinic colour, but he could not recommend the practice, as the exposure would be immoderately prolonged, or the shadow portions of the negative would be wanting in density. It had also been proposed to stain the film with orthochromatic dye, or to use orthochromatic plates. He failed to see that any advantage would accrue from the use of either. A cause of halation not usually taken note of would be found in the motes of dust floating in front of the brilliant object. These would tend to disperse the light and produce fog. His attention had been called to a theory that, when the haloid salts in the direct line of the light had been reduced, they would absorb bromine from the adjacent crystals, and these in turn from those farther off, thus causing a spreading of the light. He thought it improbable, but understood that the Secretary had tested the theory. (The Secretary said his experiments were not conclusive.) Finally, he believed that the best method of preventing halation at the back of the plate, where it was impossible to remove it, was to use a slow, thickly-covered plate.

The subject led to an animated discussion, in which Mr. Marchant thought the use of a screen in front of church windows could hardly be seriously proposed.

Mr. Beadle had seen it adopted, several men with ladders being employed.

Mr. Cox was of opinion that backing plates was next to useless, but had heard a salesman of celluloid films state at a society meeting that with those which had a matt surface halation was impossible. When the halation was slight it was no more than was palpable to the eyes when viewing a brilliant light crossed by bright lines.

Mr. Mummery referred to the theory of the haloid salts being reduced by the mechanical action of the rapid vibrations of light waves, and thought it possible that the impact might be communicated to the adjacent crystals.

Mr. Beadle had found that ground glass plates and the backing of ordinary plates with Brunswick black mitigated halation. The black might be removed with kerosine. He also deprecated the use of powerful developers when halation was suspected.

Mr. Smith had found so much emulsion on the backs of his plates that he thought it would cost the manufacturers little to cover them entirely, when a piece of paper could easily be brought into optical contact.

Mr. Gill developed his photographs till the high lights were well up, washed them thoroughly, applied vaseline to the parts where development was complete, and then proceeded with the development of the shadows. The vaseline was easily removable from the dried negative with spirit.

Mr. Goodhew thought the amount of halation by reflection of light from the crystals of haloid salts would be but little. He preferred thickly-coated rapid plates for interiors, and had taken negatives in Canterbury Cathedral on them in twenty minutes, and had been little troubled with halations. He also deprecated rapid development, and although the practice had been condemned, he flooded his plates with water, believing that by doing so he obtained requisite density without developing the halated portions at the back of the film. He was of opinion that orthochromatic plates were useful for interiors, as they were super-sensitive to the yellow part of the spectrum, and the use of a coloured screen would hold back the violet and blue rays.

Mr. Martin answered several questions, and received a vote of thanks.

### The West London Photographic Society.

A meeting was held at Broadway Lecture Hall, Hammersmith, on January 23rd; Mr. W. A. Brown (president) in the chair.

The President read a letter from Mr. John A. Hodges, resigning his appointmsnt as Hon. Secretary, on account of ill-health. A cordial vote of sympathy with Mr. Hodges was carried unanimously, and ordered to be entered on the minutes.

The President then announced that the Council had appointed Mr. Harry Selby, 42, Ladbroke Grove Road, W., to the vacant post of Hon. Secretary, subject to confirmation by the members. The appointment was unanimously confirmed. The following appointments were then confirmed :—Mr. Leslie Selby to be Assistant Hon. Secretary, vice Mr. Lionel C. Bennett, who resigned; Mr. L. C. Bennett and Mr. J. Stein, to be Hon. Auditors, vice Messrs. H. and L. Selby, who vacate the posts on their new appointments.

After the PRESIDENT had presented the medals to the successful competitors at the recent Society Exhibition—

Mr. J. MARTIN DICKINS read his papers, "A Suggestion," and "A Photographic Yarn." The "Suggestion" was that papers read before the Society should not be confined entirely to the scientific side of photography, but that, especially when other papers were lacking, proceedings should be made more cordial and less frigid by the relation of photographic adventures and so forth. "A Photographic Yarn" consisted in the relation, in jocular verse, of the adventures of two travellers in Australia, and of their difficulties in loading their slides in the open air after losing their dark tent in a bush fire.

A question was asked in the question-box as to the effect of ammonia fumes on the lungs. There being no medical man present, no professional opinion could be obtained. Mr. C. Whiting mentioned the ammoniaphone in connection with the question.

A second question was asked as to the best toning bath for obtaining sepia tones on sensitised rough drawing paper. Mr. Bennet recommended platinum toning. Mr. Wilson had obtained good results with weak gold and borax. Mr. Hazeon suggested paper toned with a non-acid platinum solution. Mr. C. Whiting expressed doubt as to what was a real sepia tone, remarking that he found black tones easiest to obtain on such paper.

Mr. DIXON exhibited prints on matt-surface paper, and desired hints as to the method of procuring black tones. The general opinion seemed to be that the negatives were too thin for black tones.

Mr. H. SELBY exhibited a negative showing the sun with a distinct solar halo. The exposure was made on January 18th, at 3 p.m., with a quick shutter on a Mawson plate, with lens working at *f* 8.

The PRESIDENT made some remarks on the question of procuring a concession of cheap railway fares for photographers on the same lines as those granted to anglers and others.

Seven new members were proposed for election at the next meeting.

### THE HACKNEY PHOTOGRAPHIC SOCIETY.

SOME American slides were shown before this Society; the audience included a number of ladies.

At the conclusion, slides of members were shown, Messrs. Barton, Gosling, and the secretary contributing, to which were added some Woodbury slides of Niagara.

The SECRETARY announced that at the next meeting Mr. Henry Sturmey would give a lecture on "Norway," illustrated by the lantern.

### THE CROYDON MICROSCOPICAL CLUB.

THE annual meeting was held on January 21st at the Public Hall. In his presidential address, Mr. LOVETT congratulated the Society upon the position of the Club, and the successful year's work. Forty-four new members had joined in twelve months. Fifteen lectures and papers on subjects of general interest had been read during the year, and the meetings and excursions had been well attended. The exhibits at the meetings had also increased, and had given much zest to those gatherings. Mr. Lovett stated that he had succeeded in obtaining a room in the Public Hall, which he had fitted up as a dark-room and laboratory for the photographic section, and which he now desired to present to the Club for the coming year. This room, which is twenty-five feet long, and supplied with water, and warmed and lighted with gas, has a permanent screen fitted at one end, and will be useful alike for enlarging, developing, and general photographic work. The president said that with this room, and its many other advantages, the Club would no doubt increase in members largely during the coming year; the present membership is over three hundred.

Mr. Sturge was elected treasurer in the place of Mr. McKean (resigned), and the two vacancies on committee were filled by Mr. H. D. Gower (hon. secretary) and Mr. McKean.

### THE MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

THE sixth annual report (1890) of the above Society was read at the annual general meeting, held at the Manchester Athenæum, Princess Street, last Tuesday, and, among other items, set forth that 73 new members have joined the Society since the last annual meeting; 13 members have resigned, and 25 been struck off the books for non-payment of subscriptions; there are now 328 ordinary and 2 honorary members as against 293 last year. The treasurer's account shows a balance of £60 18s. 5d., as against £14 8s. 10d. last year. Since the issue of the fifth annual report, there has been secured on favourable terms a good room on the ground floor of No. 14, Ridgefield, John Dalton Street, Manchester. This room is now being fitted with all requisites, and will, it is hoped, be of much service to members who may desire to make enlargements for the forthcoming annual exhibition. It has been arranged, too, that the Society's library shall be placed in the room, and in order that the books may circulate more readily, it is suggested that the librarian should attend weekly instead of monthly as at present. Lockers will be provided at a small charge for the use of those members who do not happen to have offices in town.

Underneath this enlarging room is a cellar of the same dimensions, and in case of necessity it will at any time be an easy matter to fit up a large number of developing sinks therein. The oil and lime-light lanterns have been lent out 135 times during the year, and the slides belonging to the Society have lost none of their popularity. The Society has purchased a magnificent 10 by 8 camera with lenses and all requisites, and this has been constantly in the hands of one or other of our members, and has given satisfaction.

### THE GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual general meeting was held in the rooms, 180, West Regent Street, on Monday evening, January 19th. Mr. JOHN MORISON, junr., took the chair on his election as president. The following office-bearers were also elected for 1891 :—*Vice-President*—Mr. Thomas Taylor; *Treasurer*—Mr. Hugh Reid; *Secretaries*—Messrs. Wm. Goodwin and J. C. Oliver; and a council of six members.

Mr. THOMAS TAYLOR then gave a demonstration of "Platinotype Printing."

The meeting closed with the usual display of lantern views by members, shown by limelight.

### THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

*January 22nd.*—Mr. W. BEDFORD in the chair. Mr. Thomas Illingworth and Mr. F. Parsons were elected members of the Association.

Mr. T. E. Freshwater presented Mr. Lewis Wright's latest work on "Optical Projection" to the library. A volume of Ganot's "Physics" was presented by Mr. A. Haddon.

A demonstration was then given by Mr. L. WARNERKE on "Collography." The lecturer expressed his opinion that a wide future is open for photo-mechanical printing. There was a general belief that special appliances were necessary, and that generally all processes of this kind were troublesome to work. The demand for cheapness and quickness of production had proved detrimental to good work. The process he intended to demonstrate was simple, requiring no special apparatus of any kind, enabling amateurs to produce quickly an unlimited number of copies on ordinary paper, with printer's ink, from photographic negatives. For the purposes of demonstration, the lecturer had brought with him several sheets of exposed films in various stages. He proceeded to describe the process : A sheet of vegetable parchment, having a film of gelatine on its surface, is immersed for three minutes in a bath of bichromate of potash neutralised with ammonia. The sheet is then squeegeed to a glass plate that has previously been cleaned and polished with French chalk. The plate is now left to dry spontaneously. The drying should be completed in about ten hours, when the film will peel off its support. The maximum of sensitiveness would be reached in from two to three days after sensitising. The object of drying the sheets on glass is to produce a flat surface, thus giving perfectly even contact with the negative. The sensitised film is exposed in an ordinary printing frame. When sufficiently exposed, the image will be quite visible. An exposure of the back of the film for two or three minutes to diffused light will cement it to the parchment support. The exposed tissue is now placed in water, and allowed to remain about two hours until quite colourless ; it is then drained and blotted, and the following solution poured over it :—

| | |
|---|---|
| Glycerine ... ... ... ... ... | 70 parts |
| Ammonia ... ... ... ... ... | 3 „ |
| Water ... ... ... ... ... ... | 30 „ |

After soaking for an hour, the tissue is stretched upon a frame over a block of wood, and rolled up with printer's ink. For this purpose, the lecturer recommended using first a stiff ink, and afterwards a thinner kind. Authorities differed with regard to the materials for thinning the ink. The lecturer said he preferred lard for this purpose. Sufficient rolling having been given to the surface of swelled gelatine, a sheet of paper is placed on it, and an impression can be taken in an ordinary letter copying press. Mr. L. Warnerke, at the conclusion of the demonstration, pulled several proofs from a sheet of prepared tissue, and passed them round. In answer to several questions, Mr. Warnerke said he was unable to state the limit of the number of impressions that could be taken from one sheet ; he had taken as many as 300 himself. Any paper might be used. It was necessary in printing to lay strips of paper round the inked image to protect the sides of the sheet of paper receiving the impression.

Mr. T. Bolas, after referring to the very lucid manner in which the lecturer had described the process, said he doubted whether the use of vegetable parchment as a support for the sensitised film had any advantage over a glass plate. The latter process involved less labour, and he preferred the results produced by it.

Mr. W. England spoke in praise of the work of Mr. Ernest Edwards, a rigid support being used.

Mr. Bolas said that one of the faults of loose films was the production of a halo round any dark object in the picture.

Mr. W. E. Debenham said that this would only be found in the first impression taken.

Mr. Warnerke said that some of the finest collotypes he had ever seen had been produced by Balagny's machines, exhibited in the recent French Exhibition at Paris.

Process Work.—In everything constructed by the hand of man, from a thirteen-story building to a coal scuttle, or from a wash-tub to an ocean steamer, is found design presupposing designing, and nearly always decoration involving a question of taste. The order of creation in the human world is, first conception, next delineation, and last construction. Under the pressure of this enormous demand for illustration have developed those many processes of reproduction made possible by photography, by which the rapidity of constructive work is so very greatly facilitated, and the transient scenes of daily life in all quarters of the globe are laid before our eyes almost as soon as they occur. The limit of all process work, however, is existence. The non-existent can only find expression through the intelligence of man, and his hand must ever remain the instrument by which are called into being the creations of his mind.—*The Cosmopolitan.*

# Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

W. D. B.—*Donkin's Portrait.* Mr. Spooner, of the Strand, had an excellent portrait of the late W. F. Donkin, taken, if our recollection serves, by Mr. Barraud. Failing this, apply to Mr. F. A. Bridge, of Dalston.

Pharm.—*List of Members, Photo. Soc.* In our reply to you a fortnight ago, we inadvertently stated that the *last* printed list of members, Photographic Society, appeared in February, 1889. This was an error, as we now learn from the secretary ; there was another list issued in February last.

A. S. H. (Bury St. Edmunds).—*Recovery of Silver from Mixed Hypo and Chrome Alum.* The quantity of chrome alum you have been using is unnecessarily large ; one-fourth that quantity would have sufficed. Moreover, it introduces a difficulty in the recovery of silver, for when sulphide of sodium (hepar-sulphuris or "liver of sulphur") is added to such a mixture, there is a tendency to throw down oxide of chromium along with the desired sulphide of silver. To remove this contamination, you should filter it off and digest the black precipitate first obtained with dilute sulphuric acid, in which the chromic oxide alone is soluble. Now filter again, wash the black sulphide until free from acid, dry it, and fuse with an excess of nitrate and carbonate of soda to get pure silver.

E. P.—*Some Applications of Photography.* The lecture which Lord Rayleigh intended to deliver at the Royal Institution last week has been postponed until Friday, February 6th, in consequence of domestic bereavement.

H. J. B.—*Messrs. Hurter and Driffield's Paper.* Discussions have taken place at the Parent Society, Camera Club, and at the Liverpool section of the Society of Chemical Industry, where, in May last, the original paper was read. The latest communications will appear in the forthcoming official journal of the last-named society. They reach to great length, and it may not be possible to reproduce them *in extenso* ; that, however, is a matter for the decision of the editor.

A. M. M.—At this period of the year, when back numbers have been sent to the binders, one has to trust to the memory. Thank you for reminding us.

E. W. B.—The question you ask is one of the most difficult upon which to give advice. We will write to you in the course of a few days.

J. P. and Co.—The particulars asked for shall be sent to you.

W. E. M.—Mr. J. R. Gotz, of 19, Buckingham Street, Adelphi, keeps it in stock.

Lab.—*Vegetable Reds for Isochromatic Work.* We should be afraid to trust them ; for although, as you say, red cabbage, beet-root, and red currant seem tolerably permanent in stock bottles, there is always a tendency to change colour when exposed to the atmosphere. A trace of ammonia escaping from the developers in the dark room might be enough to change over the red to blue in plates prepared and stored in your dark cupboard. Try the experiment, and report the result. Much will depend upon whether you required the tinted plates for immediate use, and a little acetic acid might help to make the colour more permanent.

A. W.—*Bromide Printing and Finishing.* Mr. A. H. Bool's little treatise on "Photographic Painting" has a chapter devoted to working up bromide enlargements in black and white. With these few hints, and home practice, you ought to succeed ; and then you could offer your services by advertisement. Being far away from any recognised centre increases the difficulty of your getting practical lessons.

Darnley.—The burnisher can be got of Messrs. Marion and Co., or of the Eastman Company.

H. L. (Highgate), R. M., and other correspondents in our next.

Vol. XXXV. No. 1692.—*February* 6, 1891.

CONTENTS.

## PICTURE HANGING AT EXHIBITIONS.

The welcome disappearance of frost and snow will urge most photographers to hope that "the winter is past and gone," and that, with the singing of the birds, the time has come when they must think of the hanging of their pictures at the different exhibitions which will be soon opening their doors. The work entailed upon the organisers of a photographic exhibition is most arduous, and seldom is acknowledged as it should be. First comes the circularising, then the arrival and unpacking of pictures, next the most unthankful task of hanging the same, and finally the re-packing, labelling, and returning of the works of art to their respective owners. All this work, with little to show how hard it has been, and how much time it has occupied, has made many a willing but over-burdened secretary exclaim that he will never have anything more to do with an exhibition of photographs.

The question arises, "Can any of this work be dispensed with, and the business of conducting an exhibition be made easier and cheaper to all concerned?" We have no hesitation in answering this question in the affirmative, and will now point out how the much-desired reform can be carried out.

In the first place, there is no necessity why photographs sent in for exhibition should be framed, and when once this part of the reform is agreed to, we clear the ground of a great deal of difficulty. The framing of a picture, the provision of a packing-case for it, and the bother connected with sending it off by rail, are considerations which prevent many lazy persons from exhibiting at all. Others are obliged to consider the expense, and they, too, are often compelled to keep their pictures at home. Now and then, it is true, we see a portfolio of photographs lying on a table at a photographic exhibition, but few take the trouble to turn over its leaves. The pictures on the walls prove the greater attraction, and to these the majority of the visitors direct their attention. We must therefore adopt some method of showing the pictures in this popular manner, and the difficulty which presents itself is to do so without encasing them in ordinary frames, and, at the same time, protect them from dust and other sources of injury. This difficulty has been surmounted by the Bristol Academy, whose winter exhibition of sketches we visited last week; and it stands to reason that a plan which is applicable to sketches in water-colour, and which is found to work economically in practice, can be adapted to photographs.

To make the matter easy of comprehension, let us suppose that it is intended to exhibit a single line of pictures only. The mounts should be generally of one outside measurement, and a size can easily be adopted which will give a fair margin for all the larger sizes of pictures, the smaller ones being grouped together so as to fill in the same amount of space. Having fixed upon this size, two horizontal laths are nailed against the wall of the exhibition room at such a distance apart that the mounting boards will just fit in between them. The pictures, being mounted, are placed in position, and over each mount is fixed a glass of the same size, a couple of brads being driven into the edge of each lath to prevent glass and mount falling out. When the line of pictures is complete from one end of the wall to the other, the laths have tacked upon them a thin slip of wood which is about double the width of the original lath, and which, therefore, overlaps it on either side, thus hiding the holding brads. This wooden slip is painted white, and on it the printed catalogue numbers of the pictures are gummed. For the sake of simplicity, we have supposed that only one line of pictures is in question, but, in practice, there would be at least three, so that the bottom lath which we have described would form the top of another line of pictures underneath, and the top lath would form the base of another line above. In the case of pictures, such as portraits, having their longer diameter vertical, it would be necessary to cut out and raise a portion of the upper lath for their accommodation. But the best plan is that adopted at the Bristol Exhibition already cited, and that is to place, as far as possible, pictures of irregular and odd sizes together on one wall, where, by a little skilful arrangement and cutting of laths, they can be accommodated together.

This system, by which the expense of frames, packing cases, and risk of breakage are obviated, has been adopted at the Bristol Academy Exhibitions for the past five years, and is found to work well. These exhibitions are by no means small affairs, if we may judge by the present one, where nearly one thousand sketches are shown. The only initial expense is the glass, laths, and cardboard for mounts. The cost of these items obtained from a wholesale firm could be readily covered by a moderate fee, which would be willingly paid by each exhibitor. The pictures could be sent by post unmounted, or mounted ready for exhibition on the regulation sized cardboard for a few stamps. Last, but not least, no space would be required at the exhibition rooms to store the mass of packing cases which always accumulates at such places. We shall be very glad to elicit opinions from all interested in the subject upon the reform suggested.

## FEER'S DIAZO PRINTING PROCESS.

The primuline printing process of Messrs. Green, Cross, and Bevan having excited so much attention, there is naturally a good deal of interest existing concerning the diazo process of Dr. Feer, especially as the latter is more in line with the printing processes in constant use amongst photographers in the matter of yielding a positive print from the negative. The two diazo processes will probably find somewhat different fields of usefulness, differing as they do in important characteristics. From the following account of Feer's process, contained in the specification of the German patent, it will be seen that there is no after-development required, the print showing itself like the familiar silver print whilst still in the press, and the only subsequent treatment required is the removal by washing of the sensitive compound not affected by light.

*Process for the Production of Coloured Photographic Images. Patented in Germany, December 5th, 1889.*

The following process depends upon the fact, which the inventor has discovered, that diazosulphonic salts (R—N=N—$SO_3$ Na) with phenolalkali, and chlorides of or free aromatic amines, react under the influence of solar or of the electric light, forming an azo dyeing substance.

For carrying out the process, the inventor impregnates paper or textile fabric with a dilute molecularie mixture of a diazosulphonic salt (for instance, of aniline, amidoazobenzole, benzidine, and their homologues) and phenol alkalis (for example, phenol, resorcin, and β-naphthol) or chloride of, or free amines (aniline, naphthylamine phenylendiamine, and homologue). The paper or fabric is then dried in the dark, and exposed for about five minutes to the sun, or to the electric light. Thereby is formed in the illuminated portions an *insoluble* azo dye, whilst the parts protected by the opaque portions of the negative remain in their original colourless and soluble condition. The picture is thus developed while printing. It is, after exposure, washed with water, or with very dilute hydrochloric acid, whereby the unaltered sensitive preparation is washed from those parts not affected by light, through the negative. The picture is thus fixed, and only requires drying to finish it.

The following are some examples of mixtures with which the paper or fabric is treated:—

| | | |
|---|---|---|
| 1.—Toluoldiazosulphonate of soda ... | 25 | grammes |
| β-Naphthol ... ... ... | 25 | ,, |
| Caustic soda ... ... ... | 8 | ,, |
| Water ... ... ... ... | 1,000 | ,, |
| 2.—Ditolyltetrazosulphonate of soda... | 25 | grammes |
| *m*-Phenylendiamine ... ... | 8 | ,, |
| Water ... ... ... ... | 1,000 | ,, |
| 3.—Ditolyltetrazosulphonate of soda... | 25 | grammes |
| Resorcin ... ... ... ... | 22 | ,, |
| Caustic soda ... ... ... | 16 | ,, |
| Water ... ... ... ... | 1,000 | ,, |

The following examples will illustrate the application of ditolyltetrazosulphonate of soda mixed with resorcin and α, β-naphthol respectively, and phenylendiamine.

*Preparation of the Solutions.*

| | | |
|---|---|---|
| 1.—Ditolyltetrazosulphonate of soda ... | 30 | grammes |
| Resorcin ... ... ... ... | 20 | ,, |
| Caustic soda ... ... ... ... | 15 | ,, |

All, finely powdered, are dissolved by gentle heat in one litre of water.

| | | |
|---|---|---|
| 2.—Ditolyltetrazosulphonate of soda ... | 30 | grammes |
| α-naphthol ... ... ... ... | 25 | ,, |
| Caustic soda ... ... ... ... | 7 | ,, |

Dissolved in one litre of water.

| | | |
|---|---|---|
| 3.—Ditolyltetrazosulphonate of soda ... | 30 | grammes |
| Phenylendiamine ... ... ... | 20 | ,, |

Dissolved in one litre of water.

The solutions 1 and 2, or 2 and 3, may be mixed in equal parts.

The paper is impregnated with the above mixture, and then exposed for from ten to fifteen minutes to direct sunshine. After exposure, the picture is washed with very dilute hydrochloric acid, then with water, and finally dried.

*Patent Claim.*—A process for the production of coloured photographic images on paper or textile fabrics, consisting of the preparation of the material with an aqueous or alcoholic solution of a diazosulphonic salt and a phenol alkali, benzene, a chloride, or free amine; dried in the dark, then covered by a negative, exposed to the influence of solar or the electric light, whereby an insoluble azo dye is formed only in the parts affected by light, the picture being thus developed; and, finally, the preparation unaffected by light is washed out with water or dilute hydrochloric acid, and the picture is thus fixed.

## SUBAQUEOUS PHOTOGRAPHY.

Subaqueous photography of different kinds has occassionally attracted attention upon the Continent, and one of the latest applications of it has been the photographing of the movements of fish by means of a number of rapid successive exposures; this work was done in an aquarium, with the camera outside and the fish inside a glass tank. The Swiss have, some years past, devoted occasional attention to subaqueous photography, and one plan employed was to put a camera inside a small but heavy iron stove made water-tight, and with a plate of glass cemented in the round hole in the top of the stove for stoking. Probably, with a special camera resting on the river or sea-bed, and with its shutter and movable portions actuated by electricity, no extensive view will ever be taken even in the clearest water. The divers at work in making the new Folkestone harbour told us that, at the best of times, when the water was at its clearest, they could never see anything many yards from their point of view.

Should it ever be possible to photograph rapidly beneath the sea, revelations of the deeds of the inhabitants of the deep waters would sometimes be of dramatic interest. For instance, a recent number of the *Vancouver's News Advertiser* sets forth how, upon the Sunday morning, two divers, Llewellyn and McHardy, who were engaged in repairing the water-pipes in the Narrows, had a novel experience of a fight with an octopus, commonly known as a devilfish, and says that the chances of escape are small indeed for anyone who may be unfortunate enough to be once wrapped in the embrace of any of its eight tentacles. There are not many of the species in the waters about Vancouver, a stray one only now and again taking a trip up from Victoria, where they exist in large numbers. Once or twice only have any of them been met with in the inlet.

"It was, therefore, with some surprise that diver Llewellyn, who has met with them in the waters of San Francisco and Victoria, beheld one yesterday when he descended from the deck of the steamer *Clyde* to the bottom of the Channel. The octopus was lying beside the pipe, engaged at his matutinal meal. His simple fare consisted of crab, and that his appetite was good was evinced by the fact that crab shells were lying scattered along the pipe for a considerable distance. The octopus was reposing at the spot where the divers were going to work, and it was necessary either to remove him, or to wait until he saw fit to remove himself. Diver McHardy had followed Llewellyn to the bottom, and the two now held a conversation by means of signs as to how they should act, and it was decided to make the attack at once.

"Accordingly Llewellyn got on one side, McHardy stayed on the other side, and it was arranged that at a sign from the former, both should attack the enemy with the iron crowbars, about eight feet long, which they had with them. The octopus during this time was eyeing the divers with an intent gaze, as if sizing them up for a meal. He was also expectant of an attack, and awaited the beginning of hostilities with confidence. The divers, at a signal, approached the monster, who, raising a couple of his feelers, prepared to ward off attack from either side. A considerable time was consumed in fencing, but at length McHardy, taking what he considered a favourable opportunity, jumped forward and made an effort to run his crowbar through the body of the octopus. The blow was warded off, and at the same moment the diver's leg was caught by one of the tentacles of the devilfish. The habit McHardy wore protected him, however, and Llewellen, having the fish off his guard, so far as he was concerned, struck his crowbar through the brute's body, and then seizing the sledge used for hammering the pipe, worked away with commendable energy on the tentacle which held his companion. It took him about two minutes to sever the tentacle from the body.

"They then covered the body with large rocks, and when they had completed their work, they left it till they should return in the afternoon. When they did return the fish was still alive. They hoisted it aboard the boat and brought it to the city, where it was examined by a number of citizens on Tuesday."

Sir Frederick Augustus Abel, Kt., C.B., President of Committee on Explosives, War Department, has been appointed an Ordinary Member of the Civil Division of the Second Class, or Knights Commanders of the Order of the Bath.

## LORD MONKSWELL'S COPYRIGHT BILL.

BY C. FLEETWOOD PRITCHARD.

Lord Monkswell has just introduced into the House of Lords a Bill to consolidate and amend the law relating to copyright. This is a branch of the law which affects photographers very nearly, and the Bill proposes to make several alterations in it of considerable importance; it therefore behoves photographers to give the matter their earnest consideration. It must also be remembered that if the Bill should pass, it will in all probability be a long while before photographers have another opportunity of amending the law relating to this subject. The following are some of the more important of the proposed alterations.

In the first place, the Bill proposes to make an alteration in the duration of copyright. At present, copyright in a photograph is given for the life of the photographer, and for seven years after his death, and it is proposed by the Bill that it shall, in future, be for thirty years from the end of the year during which the photograph is published. This in itself appears to be an improvement, as it substitutes a fixed period for one of great uncertainty; but it will be noticed that in the case of paintings and sculptures the proposed term is the life of the artist and for thirty years after his death—a much longer period than that proposed for photographs. Engravings are treated in the same manner as photographs.

In the next place, it is proposed that where a photographer employs an assistant, then the copyright of any photograph taken by that assistant shall belong to the employer. In this way the difficulty which arose in the case of Nottage *v.* Jackson is overcome.

Under the present law, it will be remembered that, when a negative is sold for the first time, the copyright is altogether lost unless a written agreement is made between the buyer and the seller at the time of the sale. The Bill proposes to remedy this by enacting that, unless any agreement is made, the copyright shall remain with the seller. Similarly, the copyright of a photograph taken on commission is to belong to the photographer, and not to the person for whom the photograph is taken.

Then it is provided that where a photograph of any work of fine art—*i.e.*, a painting, sculpture, or engraving—is made to the order of the owner of the copyright therein, the copyright in the photograph is to belong to the latter, and not to the photographer. This seems rather hard on the photographer, as he would, in that case, be unable to prevent others from copying his work.

By Clause 41 of the Bill, where "a photographic likeness" of any person is taken on commission, neither the photographer, nor any other person, whether he owns the copyright or not, is to be allowed to sell or exhibit in public, in any shop window, or otherwise, any copy of the photograph without the consent, in writing, of the sitter, or of the person for whom the photograph was taken; and any photographer who contravenes this clause is to forfeit every copy of the photograph which he has in his possession, including the negative. This clause really carries the law very little farther than that enunciated by Mr. Justice North in the case of Pollard *v.* The Photographic Company, rather more than two years ago. In that case, it will be remembered, the judge stated that a photographer who had been employed by a customer to take his portrait is not justified in striking off copies of such photograph for his own use, and selling and disposing of them, or publicly exhibiting them by way of advertisement or otherwise, without the consent of the customer. At the same time, this is a question of very great importance to all professional photographers, and they should carefully consider whether it would not be well to propose some amendment.

As regards registration, it is not proposed to make many alterations of any importance. The principal seems to be the abolition of the Registry at Stationers' Hall, and the establishment of another to be called the Copyright Registration Office, under the control of a Registrar of Copyrights, and under the superintendence of the Board of Trade. The proposed form of "Request for Registration" is, in the case of photographs, much the same as the present form, except that the second and third columns (*i.e.*, the columns for the date of, and the names of the parties to, the agreement or assignment) are omitted, and another column is added for the date of publication. In all cases the fee and a copy of the photograph must accompany the form. Immediately on receiving the form, the Registrar is to give to the person requesting the registration a "Certificate of Registration of Copyright," which is to be *primâ facie* evidence of title to the copyright registered.

Instead of bringing an action against any person who infringes a copyright, it is proposed by the Bill to allow the owner, if he likes, to summon the offender before a police magistrate or other court of summary jurisdiction, and the magistrate may, if he is found guilty, order him to pay a fine not exceeding £5, which is to be given to the owner of the copyright by way of compensation. This would be a great advantage where the copyright is not of any great value, as the proceedings would be less costly and much more rapid.

It should be added that, according to the memorandum which is circulated with the Bill, the alterations proposed to be made in the law are for the most part those suggested in the Report of the Royal Commission on Copyright of 1878, and embodied in a Bill introduced at the end of the session of 1879 by Lord John Manners, Viscount Sandon, and the Attorney-General, on behalf of the then Government.

## A NEW WHEEL CAMERA.

A new hand-camera of that new class in which the plates are removed one by one from their receptacles by means of a wheel, then exposed, and afterwards stored away, has been issued this week by Messrs. Marion and Co., and contains features of striking novelty. Fig. 1. is a plan of the machine. At one end are seen the grooves in which

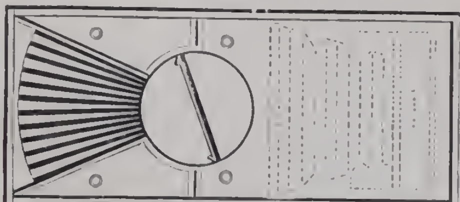

*Fig.* 1.

the plates are packed vertically. Any plate is picked out at will by means of the wheel apparatus, brought into position for exposure, and afterwards returned to any groove the operator chooses. Thus, supposing him to have charged the receptacle with rapid and slow plates, and a few which have been made orthochromatic, he can in a moment select any plate which will suit the particular subject before him. Fig. 2 represents the interior of the camera with its side removed.

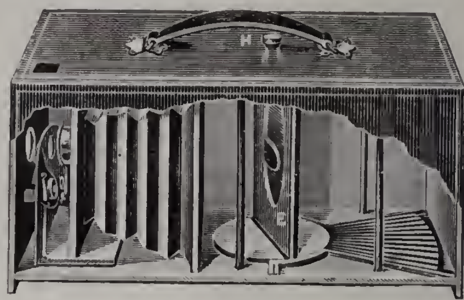

*Fig.* 2.

In order that the grooving may be true, it is made of electro-deposited copper thrown down upon a gutta-percha mould truly made into form by a die and heavy pressure. This mould is then blackleaded, and copper, by means of a suitable current. thrown down upon it in a malleable condition of molecular aggregation.

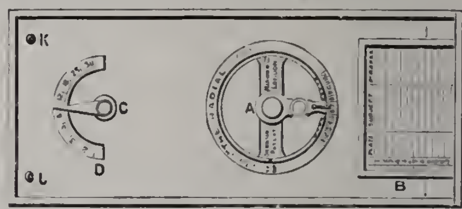

*Fig.* 3.

Fig. 3 represents the under part of the camera, with the governing and regulating parts of the apparatus.

Focussing is effected, when desired, by moving the pointer C to a suitable position on the scale D. By suitably turning the pointer A, a plate is released from any groove, and afterwards returned to it or any other desired groove. B is a removable card for recording exposures. The knob at J, attached to a cord, sets the shutter: a gentle pull at K makes the exposure.

The camera can be fitted with the purchaser's own lens, provided he possesses one of suitable focal length. The lens otherwise issued with it by the makers is a rapid one by Voigtlander. The grooves will take plates varying in thickness; the plates are pressed in the carrier by means of a spring, to ensure that their faces are in true focus. The camera is the invention of Mr. Dickinson, one of the members of the staff of Messrs. Marion & Co. Great pains have been taken to make it light-tight, and to prevent the plates getting jammed anywhere during the manipulation of the instrument.

The camera is a refreshing novelty, and, so far as can be judged from inspection, we think that when in practical use it is likely to justify the enthusiastically high opinion of its merits held by its manufacturers.

A Boy's Camera.—The Blackfriars Photographic and Sensitising Company has sent us for review a "boy's camera," which is a marvel of cheapness; it includes folding tripod legs, bellows camera, double dark slide for quarter-plates, and a lens. Photographs can be taken by its aid, as we have proved, and good ones can be taken by those who use a stop of suitable diameter, and allow in focussing for the difference of position of the visual and chemical foci. The first camera of many a boy has been made out of a cigar box and a spectacle lens, but the one under notice is a far more elaborate instrument. A lens of longer focus would suit it better.

## NOTES ON PORTRAITURE.

BY H. P. ROBINSON.

No. IV.

The greatest difficulty in portraiture has always been the group. This has been almost as much evident to the painter as the photographer. If the painter represents his subjects as simple resemblances they are too often stagy and stiff; if, on the other hand, he supplies them with a centre of interest, and presents them as "doing something," they look as though they were doing it for the purpose of being painted, and who does not recognise the air of conscious sham that pervades the representations of even such spectacular subjects as court ceremonies, although they may be painted by the greatest artists? What is the unfortuate artist to do? In his attempt to be pictorial he meets with many obstacles. He must not partly hide a face, or introduce a back view of a figure, often useful for obtaining variety of pose, and as a foil to other figures; he must show every one at his best; the chief personages must be conspicuous, even if they were not very visible in the real group. Of the painters, Wilkie and C. R. Leslie almost succeeded with these impossible subjects, but it was at some expense of truth. It was left for an impressionist painter to show us what would happen if such a subject were treated literally. In the *Art Journal* for January is a process block from a picture by Mr. John Lavery, representing the ceremony on the occasion of Her Majesty's visit to the Glasgow Exhibition, 1888. The principal object is an official in his robes filling a foreground corner, the reader of the address is a little figure in the distance, and Her Majesty is to be found, after diligent search, some way out of hearing distance of the reader. One half of the space is filled up with the steps of the spacious dais, under the canopy of which Her Majesty is seated almost out of sight. This may have been a correct impression of the scene; the picture may be full of air, and space, and truth of the subtlest kind; it may be full of expression and spirit, and all other impressionist qualities; but if we may judge by the engraving, it does not do justice to the portraits, and thus the principal object of the picture is not fulfilled.

Perhaps the most realistically natural group of two figures ever painted is to be found in the "Portraits of a Merchant and his Wife," by Van Eyck, in the National Gallery. It represents a man and woman standing to have their portraits taken. This is just what they must have been doing, and they look like it. Legends have been invented to explain the subject, and account for the pose of these two marvellously painted figures, but all that is apparent is that they were standing for the painter.

Now-a-days, when we want to make figures look "so natural," we are expected to make them appear to be doing anything but pose for their portraits, while they are doing nothing else all the time. What is the most natural thing a boy will do when he is asked to stand for his portrait? He will look at the camera, and be interested in what you are doing with it. This is an argument that may, of course, be carried too far, but there is exaggeration in the other extreme, which has been advocated to such an extent by recent writers on art who talk about nature without understanding, that the unfortunate photographer is now almost afraid to allow his sitter to look at him.

A portrait should not be a snap-shot accident of a man. It should be a deliberate presentment of the best that is in him, portrayed by the artist after a careful study of his subject, and cannot be other than to some extent a conventional representation. It is all very well if you can combine the natural with the portrait, but the effort, even with the greatest artists, almost always ends in the make-believe. Take, for instance, one of the greatest portrait pictures in the National Gallery, the "Family of Darius at the Feet of Alexander the Great, after the battle of Issus," by Paul Veronese. That event purports to be the subject represented, but the principal figures are portraits of the Pisani family. The picture was intended for a portrait group, and the artist has taken an historical incident of the year 333 B.C., so as to give his figures an opportunity of "doing something" and looking "so natural." To do this he has seen no absurdity in, and not scrupled to represent his sitters in, Venetian armour and robes of a period more than 1500 years later than the time of the incident portrayed. It is one of the great pictures of the world; is wonderfully painted; is marvellous in colour and handling; not one face looks "at the camera;" but if one looks for the nature that is expected in modern art, one cannot help feeling that the monkey on the balustrade is the most natural bit in the picture.

I do not pretend to argue that no portrait group should have a motive or leading idea, but I feel that this method of composing a group may be often carried too far, and is often strained.

In the last century the group was a favourite method of presenting portraits, and Zoffany, Hogarth, and a few others, in their "conversation pieces," of which we see examples in every exhibition of Old Masters at the Royal Academy, managed to maintain the just medium between the natural motive and the unnatural strain; with others the family group degenerated into burlesque, and was often ridiculed by the writers of the day. The description of the famous classical group in the "Vicar of Wakefield," "by a limner who travelled the country, and took likenesses for fifteen shillings a head," is an instance familiar to all who have read that delightful tale, and shows the perverted taste of the time. It will bear repeating. It was to be a large historical family piece, for all families of any taste were now drawn in the same manner, and designed to show the superiority in taste of the Primrose family over their neighbours, all the seven of whom had recently been drawn each with an orange a piece—"a thing quite out of taste, no variety in life, no composition in the world." As the vicar relates, "My wife desired to be represented as Venus, and the painter was requested not to be too frugal of his diamonds in her stomacher and hair. Her two little ones were to be as Cupids at her side; while I, in my gown and bands, was to present her with my books on the Whistonian controversy. Olivia would be drawn as an Amazon, sitting upon a bank of flowers, dressed in a green joseph, richly laced with gold, and a whip in her hand. Sophia was to be a shepherdess, with as many sheep as the painter could put in for nothing; and Moses was to be dressed out in a hat and white feather."

This is scarcely an exaggeration of the state of artistic taste at that period. Another less known anecdote may interest the reader, who knows the difficulty of composing a portrait group, and pleasing the whims and fancies of his exacting patrons.

One day a wealthy merchant drove up to the door of Hoppner, the portrait painter. Out of the carriage stepped a gentlemen and a lady, with five sons and seven daughters, all *replicas* of the parents; as well fed and comely a city-bred family as any within the sound of Bow Bells. "Well, Mister painter," said the father, "here we are, a baker's dozen; how much will you demand for painting the whole lot of us? Prompt payment for discount." "Why," replied the astonished painter, "why, that will depend upon the dimensions, style, composition, and"——"Oh, that is all settled," quoth the enlightened merchant; "we are all to be touched off in one piece as large as life, all seated upon our lawn at Clapham, and all singing, God save the King."'

## THE INTERNATIONAL CONGRESS AND THE PHOTOGRAPHIC SOCIETY.

The Council of the Photographic Society of Great Britain has appointed Captain Abney, Sir H. Trueman Wood, and Mr. Leon Warnerke to represent the Society at the International Photographic Congress, which will be held at Brussels this year. A notice has appeared in the Society's Journal, inviting the members to send suggestions as to subjects which they consider should be brought before the Congress by Captain Abney. As it is probable that several of the other photographic societies in the Kingdom will also appoint delegates to the Congress, it might be advisable for those so appointed to communicate with the delegates of the Photographic Society, so that the propositions made by this country may be supported by all its representatives.

The last Congress decided to adopt a decimal system for marking the diaphragms of lenses, but as two of the large lens makers have adopted the Photographic Society's standards, and as there may be many thousands of lenses in existence so marked, the question may possibly arise whether it would be advantageous if the forthcoming Congress would revoke the decision of the last Congress, and adopt *f*/4 as the unit aperture for diaphragms.

There would be an advantage if the decisions of one Congress were interfered with as little as possible by its successor, otherwise it will be years before anything practical is done. Last year was the time for the Photographic Society to officially have raised questions about its standards; either it was not invited to join the Congress, or did not accept the invitation. How this matter stands has not yet been published.

The determination of the speed of shutters was referred to a committee by the last Congress, so a report may be expected upon this subject.

At the Paris Congress the question of copyright was discussed, and a number of resolutions was passed; we think, however, the subject might again be brought up, and if an understanding were arrived at amongst the delegates, they might approach their respective governments with identical requests, and thus get this most troublesome question settled.

The Camera Club will not resume its Thursday evening meetings this month, because of the incomplete state of the new premises.

The *Gas World* states that somebody, evidently with the object of advertising a particular portrait process, suggests that all gas consumers should be supplied with a portrait of the accredited meter inspector, as a safeguard against imposters. To the horrors of the family album would then be added, "and that's our meter inspector!"

## PHOTO-MICROGRAPHY.

BY T. CHARTERS-WHITE, M.R.C.S.

Photographic delineation may be regarded from two different points of view; these are from the artistic point and the point of utility. The first case is that in which photography is employed for the purpose of producing pictures of landscape scenery modelled on the strictest canons of art, or as near to them as our limited capabilities will permit. In the second case usefulness alone comes in, apart from any consideration of art, such as in the copying of paintings, the reproduction of ancient documents and inscriptions, the recording of astronomical and meteorological phenomena, or in that branch of it which will occupy our attention for a short period this evening—viz., photo-micrography.

Photo-micrography may be considered under two heads, according as the practitioner may wish to employ low or high power objectives; whether he may be content with moderate amplification, or desire to perform feats of optical athletics in defining critical images. Under the first head he may find abundance of recreation, under the second he will find himself plunged into a maelström of worry and perplexity. But, presuming that he may be content with amplifications up to 200 diameters, I see no reason why anyone possessing a microscope and a camera should not be able to practise this branch of the photographic art with satisfaction to himself and instruction to his friends. I would, in all cases, recommend the beginner to commence with low powers—say, of about an inch focus, and pass up gradually to a quarter of an inch —and, after he has mastered some of those difficulties he will be sure to encounter at first, then pass on to powers of higher denomination.

In the practice of photo-micrography three things are essential, viz., a camera, a microscope, and a lamp. It will be convenient if I address myself to these several points; and first let me say that cameras for this work have been devised of every possible form, but the principle is the same. The one I particularly favour, and which, in my hands, has given me very good results, is not a camera at all in its usually accepted sense, but is a lidless box placed on its side, and containing the microscope and lamp, these, in working, being shut in by a velvet curtain to exclude the light from the studio. One end of this box is open to allow the protrusion of the microscope tube. The image of the object to be photographed is projected through the microscope on to a white paper screen fixed in the carrier, which also will hold, in subsequent operations, the sensitive plate; hence it follows that, if I can focus my object on this white screen with fairly good and sharp definition, I ought to get my negative as sharp as this image on the white screen; so you see the principle is the same as in ordinary enlargement. This carrier is mounted on a sliding base-board, and allows of the screen being withdrawn to the distance I think suitable for the work I have in hand. I can, by this method, cover a 7½ by 5 plate, or, by pushing the carrier within about a foot of the microscope, reduce my image to a size suitable for lantern plates. This, therefore, gives me a great range of amplification.

There is one point about this sliding base which I might mention, as by it I am enabled to decide the number of diameters my object is magnified. Starting with the lower power I use, I place a diatom whose known diameter is exactly $\frac{1}{100}$th of an inch in the microscope; I project its image on to the screen at one foot from the microscope, and, with a pair of compasses, measure off its amplification with that power on an ordinary rule, and thus arrive at the number of diameters it is magnified. I then do the same thing at two feet, three feet, and so on. I thus register the magnifying power of that object glass at these several distances. I adopt the same procedure with all the objectives I use, and thus form a table of measurements, to which I can readily refer in all cases. This apparatus of mine is comparatively simple and inexpensive, a matter to be considered in the absence of any regular department in the State set apart for our assistance in these matters. There is another advantage in this arrangement, and that is I can do all my work in one room, as the velvet curtain shuts in the lamp, and I can develop my negatives in the same room. But I must not take up more time in explaining this apparatus; a lantern slide to be passed through this evening will give a clear explanation of its construction. It may be necessary to say that all generally required is an ordinary bellows-camera, or, even better, a sliding camera, placed on a firm base-board of well-seasoned mahogany or teak, about five feet long and one and a-half inch thick, and sufficiently wider than the camera to admit of a wooden ledge on each side being fixed, to form a broad groove in which the camera can slide backwards or forwards as required, with a thumb-screw through its tail-board to clamp it at any desired distance. This base-board must be supported in such a manner that any vibrations from passing traffic, or persons moving about the house, may not be communicated to the apparatus. I accomplish this by standing it on a fairly good sized bundle of journals placed at each end, and I find this stops the vibrations so far that very little evidence of a tremor is manifest in photographs I have taken up to 200 diameters.

I now come to that division of my subject which treats of the microscope; it is essential that this should be a steady, solid monocular, having a good, fine adjustment, for this is very necessary in getting absolutely sharp definition. Another indispensable adjunct is a substage condenser, fitted with a revolving diaphragm pierced with holes of varying diameters. In my rotating diaphragm attached to the condenser the apertures vary from 1-16th of an inch, the smallest, to ½-inch, the largest. The smallest is of no use in photographing, but it serves a very important office in enabling me to centre the light. Presuming that your camera and microscope are axially centred with each other and the lamp, it does not follow that the beam traversing these must be central, and though a great deal of this excentricity may be overcome by moving the lamp, it is not entirely overcome, but if the substage condenser has adjusting screws—which it ought to have— perfect centricity can be attained in this way: put in a very low power, and, having turned the diaphragm to the smallest aperture, project its image in the middle of the focussing screen, and get its borders quite sharp; now rack the condenser back, and the field will be found evenly illuminated. Should the low power be now changed for one of a higher grade, a further slight adjustment may be required, but, having already a rough approximation, this may be readily obtained. The centreing of the light is a most important proceeding, for, unless this is attended to, one side of the object will have a dark and fuzzy border, while the opposite side will be light and coloured, and what is thus easily perceptible in the borders extends throughout the whole object, and detracts from the general sharpness of the photograph; therefore, too much attention cannot be devoted to this point. The tube of the microscope should be lined with a dead-black paper, or a flare-spot from internal reflection will make itself obnoxiously evident in your negative. Some recommend black velvet as a lining; this answers very well, but, being thicker than paper, it helps to diminish the already-constricted field. The tube in my microscope is trumpet-shaped, which allows the rays from the object to diverge immediately on passing through the lens, thus removing the constriction, and neutralising any tendency to a flare-spot. I might also say that I never use the eye-piece of the microscope, as I find for my purpose I can do better without it.

While we are discussing the microscopic division of this subject, I would especially recommend that the lamp should be kept burning for some quarter of an hour or so before attempting to photograph, to allow of all the constituent parts of the apparatus to warm up and expand. The necessity for this is easily demonstrated by focussing your object as sharp as possible, and let everything remain undisturbed for about ten minutes. When looking at your object again you will find all sharpness has disappeared, and nothing but a blurred, indistinct mass is evident: but let expansion once take place, and no alteration of focus will occur the rest of the evening. I may add that in working with powers less than one inch focus, a great advantage will be derived from interposing a piece of ground glass between the bull's-eye lens of the lamp and the sub-stage condenser, its ground surface being placed next to the object. This, while it makes the light a trifle less powerful, and slightly prolongs the exposure, gives a soft, diffused light by its acting as a radiant.

The plan I have always adopted for obtaining a sharp image on the sensitive plate is one that I may recommend straight away, and thus save you the trouble of trying the various expedients suggested by many practitioners, but without satisfactory results in my hands. I say, remove the ordinary ground glass focussing screen from your camera, and replace it by a plain glass having some fine lines drawn across it with a writing diamond, these lines being placed next the objective. Now set your focussing glass till these lines are sharply defined. These lines will closely approximate to the plane of your emulsion on the sensitive plate, and, therefore, if you get the details of your object into focus with the lines on the focussing screen, the probability will be in favour of a sharp image on the negative.

The lamp I employ is an ordinary microscope lamp burning Strange's crystal oil, in which some camphor is dissolved to increase the whiteness of the light. A plano-convex bull's-eye lens is attached to it. Much discussion has taken place with reference to the position of this lens, some saying that the plane side should be next to the light, others advocating the reverse. I have tried very carefully the results to be obtained in both positions, and I cannot detect any difference in them; but, if anything, I prefer the flat side away from the lamp, and next to the condenser. I don't pretend to any knowledge of the laws of optics, and I only speak from my experience.

Having got these three constituent elements—camera, microscope, and lamp—as accurately centred as it is possible, and the apparatus warmed up, we may proceed to operate; and here the question of exposures crops up, and the difficulty begins. Exposures vary in proportion to the magnifying power of the objective used, and the colour of the object to be photographed. Although exposure tables, as in landscape photography, may offer the tyro a rough guide, giving some kind of idea to help at first, yet nothing but a cultivated judgment founded on experience can be of any permanent service. I know of no table which assisted me more than that framed by Mr. Walmsley, of Philadelphia, and for which I have in my heart often thanked him, and which I append to these rather voluminous notes.

When using

| | | |
|---|---|---|
| $1\frac{1}{2}$ inch objective | ... ... ... | 3-45 seconds |
| $\frac{2}{3}$ „ „ | ... ... ... | 7-90 „ |
| $\frac{4}{10}$ „ „ | ... ... ... | $\frac{1}{2}$- 3 minutes |
| $\frac{1}{6}$ „ „ | ... ... ... | 2- 7 „ |
| $\frac{1}{10}$ „ „ | ... ... ... | 4-10 „ |

These times may be regarded as approximate, but to be controlled by the nature, colour, and general character of the subject, and to which nothing but experience can furnish the right cue. I have left out much that might be considered desirable to touch on; but my great desire has been to render myself more extensively serviceable to my fellow-men, and, in the hope that there may be some present this evening who may feel inclined to extend their researches in the direction of photo-micrography, I have been tempted to lay the subject before them in its barest simplicity.

## HOSPITAL PHOTOGRAPHY.

Last week some information was published in these pages about an American system of photographing the dead, and the disinterested work of Mr. Oscar Mason. Some additional particulars are appended about his hospital work, extracted from a recent number of the *New York Sun*, kindly sent to us by a correspondent because of the interesting information on photography which it contains. The influence of vulgar wealth over the mind of the reporter who gives the narrative is characteristic; he seems unable to understand that a man can lead a life of self-sacrifice for the benefit of others:—

### BELLEVUE'S PHOTOGRAPHER.

*Twenty-two Years of Unpaid Work for Humanity.*

Oscar Mason and the Department of Hospital Photography which he Founded—A Curious Figure of Unselfishness in these Money-chasing Times—Work which has been a Model for the World.

Oscar G. Mason has been photographer to Bellevue Hospital for over twenty-two years. For several years he did the entire photographic work for nothing, and gave his entire time to it. He has never since received payment for anything except the work of photographing the unknown dead in the Morgue. That very useful department was added to the hospital at his suggestion. When he proposed it, he asked no compensation for it, and for a long time received nothing. It was only when the city officials practically refused to accept his services any longer without compensation that he consented to draw pay for the Morgue work. The bulk of his services, those in the hospital, he has persisted in performing for nothing, asking only that the city pay the bare cost of the chemicals used, amounting altogether to less than 200 dollars a year, and furnish him studio room rent free. As his studio has always been in the hospital buildings, this exaction has cost the city no outlay of cash. Mr. Mason has never used this studio for personal profit. It has never been a public gallery, and such private scientific work as he has done in it has been done at times when the hospital did not require his services, and with instruments and chemicals purchased by himself.

Bellevue Hospital's photographic appliances are numerous and of fine quality. The instruments are various, and suitable for all sorts of indoor and outdoor scientific work. Much of the most careful picture taking cannot be done in the gallery, because of the helplessness of the patients to be photographed, or the many operating-room instruments and surgical appliances to be used in the operations photographed. Such pictures must be taken in the hospital wards in insufficient light. Hence the simple appliances of an ordinary gallery would not suffice. Several complete portable instruments are in stock, with hosts of appliances to overcome the defects of the hospital wards from the photographic standpoint. There are nearly sixty fine and expensive lenses on the shelves of the hospital gallery. But Bellevue does not own a single instrument or lens, or, indeed, any of the minor appliances for developing, printing, and finishing. Everything in the gallery, except the few cheap chemicals, is the personal property of the photographer, and was purchased by him especially for the hospital work, and very rarely used for any other purpose. The use, as well as the time and labour of the photographer, are presented to the hospital by Mr. Mason. There is also in the gallery a photographic library equal to any private library of a similar character in the country, and immeasurably better than any other at the command of any national State, or civic authority. Mr. Mason has collected this library during an experience of many years as a practical photographer and a student of his art. It also is devoted to the Bellevue work without charge.

The photographer himself is on duty every morning early. There is always plenty of work for him to do. If there are no new cases to be photographed, there are plates to be developed and prints to be finished and mounted. There are accounts to be kept, scrap books to be brought to date, and records to be prepared for ready reference. Beside the routine work of the hospital he is always ready to do any outside work suggested by a hospital physician of standing which bids fair to be of real value to medical science and the world. He is a unique figure in these days of universal money grabbing, especially in his capacity as an almost gratuitous holder of public office. He has served the public weal after this fashion for twenty-two years, yet so modestly and quietly has he performed what he considered to be his daily duties to humanity and science that he has attracted no attention, and his accomplishments have never been known to more than a few hundred persons who, as physicians or surgeons, have come more or less in contact with him.

It is not generally known, either, that New York has led the world by a good many years in the matter of a photographic department to a city hospital. Mr. Mason was the first photographer to a hospital in the world, and it is only within a very short time that he has had imitators. He initiated this extremely important department at his own expense practically, and the results of his self-sacrifice have spread over the world. Many of the great medical works of the world have been illustrated by him without profit to himself, and several of the greatest would not have been possible without his gratuitous assistance. A few years ago, London and Paris established photographic departments in connection with their public hospitals, modelled upon the plan of that which Mr. Mason had established at Bellevue years before. Of late, Chicago and Boston have waked up to the scheme, and written on to authorities here for hints.

Mr. Mason is willing to give all the help in his power to inquirers who write him for points in connection with the proposed establishment of photographic departments similar to his in hospitals elsewhere. He has personally avoided notoriety, and it was only by persistent efforts that a *Sun* reporter succeeded in inducing him to talk about himself and his work.

(*To be continued.*)

The Photographic Club.—The subject for discussion on February 11th will be "The Production of Reversed Negatives;" February 18th, "Blisters."

## RESULTS OBTAINED WITH THE AMYL ACETATE LAMP.*

BY DR. J. M. EDER,

*Director of the Imperial School for Photography and Reproduction Processes, in Vienna.*

As is well-known, the International Photographic Congress in Paris adopted the amyl-acetate lamp as a practical standard of light, and this standard is certain and easy to apply.

For a knowledge of the light-sensitiveness of various photographic preparations, a comparison with the amyl-acetate lamp is desirable.

For this purpose a reduction to the so-called *meter-candle* is necessary. If the amyl-acetate lamp is taken as a unit. the amount of light falling vertically upon a surface placed at a distance of one meter is called a meter-candle (meter-kerze). The amount of light necessary to produce a visible action upon a bromide of silver gelatine plate can be accurately expressed in figures. According to Dr. Michalke, with oxalate developer a visible impression is produced on a bromide of silver gelatine plate when the latter is subjected during one second to the action of a volume of light equal to 0·045 of a meter-candle.

Making use of the table of sensitiveness of various photographic preparations, prepared by me, the following table is obtained. The latter gives the volume of light, expressed in meter-candles, which must act during one second to produce a visible effect.

TABLE.—*Amount of light, expressed in meter-candles, which must act during one second in order to produce a photo-chemical effect.*

| Light-sensitive preparation. | Volume of light in meter-candles acting during one second. |
|---|---|
| 1. Bromide of silver gelatine plate with oxalate developer, sensitiveness = 23° Warnerke | 0·05 |
| 2. Bromide of silver gelatine plate with oxalate developer, less sensitive = 18-19° Warnerke | 0·15-0·20 |
| 3. Wet collodion plate... ... ... ... | 1·8 (average 2) |
| 4. Daguerreotype plate ... ... ... | 27-90 |
| 5. Collodion dry plate, with alkaline developer, tannin, &c. ... ... ... ... | 9-14·4 |
| 6. Chloride of silver gelatine plate with oxalate developer (Eder) ... ... ... ... | 14·0 |
| 7. Pigment paper ... ... ... ... | 1440-5400 |
| 8. Silvered albumen paper, direct copying ... | 4500-18000 |

This table has, of course, only an approximate value. It gives, however, a very good summary of the necessary exposure required by the various methods. Expressing the sensitiveness of photographic preparations according to the effect of a meter-candle during a second's exposure, has this particular advantage, that it gives at once the relative exposure required by the photographic methods in question.

It must further be mentioned that only the first six photographic preparations in the table could be tested directly with the amyl-acetate lamp, not the two last copying processes, which are not in the least sensitive to the light of a candle or amyl-acetate lamp. In order to be able to take account of pigment processes and silvered paper in this table, their sensitiveness with daylight was used, *e.g.*, pigment paper is in daylight 800 to 3,000 times less sensitive than a wet collodion plate with ferrous-oxalate developer. Since this last requires 1·8 meter-candles for a visible impression, then the volume of light necessary for the production of a picture with pigment paper would be 1·8 × 800 to 1·8 × 3,000, or 1,440 to 5,400 candle-meters.

With orthochromatic plates and the amyl-acetate lamp the light-sensitiveness appears (compared with ordinary bromide plates) proportionately higher, which is evidently the result of the different spectral composition of daylight and the flame of the amyl-acetate lamp, since in the latter there are relatively many more orange-red, yellow, and green rays than there are blue and violet.

* "Photographic Mosaics." The original title is "Photometrical Determination of the Amount of Light necessary to Produce an Impression with Various Photographic Preparations."

---

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—The next meeting, on February 12th, at the "Champion Hotel," Aldersgate Street, will be a lantern evening, when visitors are invited.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting on Monday, February 2nd, Lady Abel, Mr. John Aird, M.P., Mr. Henry Graham Harris, M. Inst. C.E., Mr. Sydney Turner Klein, F.L.S., F.R.H.S., were elected members of the Royal Institution.

AMATEUR AND PROFESSIONAL.—A correspondent sends the subjoined cutting from *The Cape Register, Exchange, and Barter* of January 3rd:—"Photography—'Prefer loss to an unjust gain.' This, readers, is a very old proverb, but nevertheless the advice it gives holds good. Our readers may wonder what we are alluding to. As it is the duty of every free and independent newspaper to expose meanness in all its various aspects, we unhesitatingly call attention to the fact that the various photographers of this town—professional men who have undergone, in many instances, a long course of study to master the art, gentlemen who are paying high rents and heavy taxes—are deliberately and coolly swindled by so-called amateur photographers who on week days and Sundays roam about the country with their photographic apparatuses, and cheat the professional men out of their just dues. We do not by any means allude to those real amateur photographers who take a pride in the art, and practise for art's sake alone, and not for gain, but we refer to those persons (we might use a stronger name) who, with their photographic instruments and appendages, prowl in the vicinity of picnic parties, gentlemen's houses, and other places of interest, and without invitation proceed to take a likeness (as a rule it is the greatest daub imaginable), and when spoken to they invariably answer that they are simply amateur photographers, and will be glad to send a gratis copy, when finished, to the leader of the picnics alluded to, or the proprietor of the estate they have encroached upon; but they further hint that if an order is given for, say, one or two dozen copies, they will be compelled to charge *just a little* (?) to cover expenses. As a rule the bait is readily swallowed, the money paid in advance, and the order given. When the photos arrive at their destination—and sometimes they do not—the innocents see that they have copies of a very inferior description. But what can the victims of this duplicity do in the matter? Why, simply grin and bear it. A few days ago one of the fraternity coolly came up to a house in the Gardens and commenced operations. He took the house, he took the children, he took the dogs, and, in fact, he would have taken anything presentable. In this instance he was doomed to disappointment, and sternly told to clear out before he was able to complete his peregrinations, and he marched off with a sulky and disappointed air. This is one of many instances, and we are of opinion that the legitimate photographers of this and other towns should resent the conduct of these individuals in a proper manner, and no doubt the public would assist in the matter. We have penned these lines simply to expose what we consider a gross fraud, and we further hope they may be the means of calling attention to this glaring evil and unfair proceeding on the part of those who try to increase their living in an unmanly and surreptitious manner, and who should be made to pay the penalty of their pernicious conduct, and then they will all be '*Muet comme un poisson.*'"

# Notes.

A favourite and simple light for the enlarging camera, sometimes employed by photographers, consists of two fish-tail gas-flames, one behind the other, and with a diaphragm in front with such an aperture as to help to yield an image of the requisite sharpness. The brilliancy of the light is increased by first passing the gas through a warm chamber which has previously been charged with solid naphthaline. Once Mr. Frederick Varley had a curious experience in charging common gas with hydrocarbon vapour. He passed the gas through a vessel containing benzole, and the result was that he obtained as much light in a room with a smaller number of burners as he had previously obtained in the same room with a larger number of burners, yet the gas bill for the quarter was higher; the next quarter passed, yet again more gas was consumed than with the larger number of burners. Here, then, was a problem demanding experimental investigation, and by a little research he discovered that common gas is reduced in volume when it comes into contact with benzole vapour. This, although ordinarily objectionable from an economical point of view, is not so for lantern work, in which a small flame of great brilliancy is desirable; in fact, the aforesaid condensation of the gas is then an advantage. We do not know whether reduction of volume takes place when it comes into contact with vapour of naphthaline.

The advantage of the adoption of a standard light for certain photographic purposes is well illustrated in the article in another column by Dr. Eder, for by the aid of the amyl-acetate lamp, adopted at the last International Photographic Congress, he has photometrically determined the amount of light necessary to produce an impression with various photographic preparations. Not many of these lamps have yet been made in Paris, we believe, and somewhat bad accounts have reached us of the way in which they have been constructed; instead of being made with a silver tube for the wick, a nickel-coated brass tube is said to be used, which is attacked by the acid vapours given off by the burning pear oil. The reservoir of the lamp is too small, so that the contents soon disappear when the lamp is in action. This makes it inconvenient to use in the developing room lantern, or for any purpose in which a long period of combustion is desirable. When a properly-made amyl-acetate lamp comes into the market, it probably will not be used with pear oil at all by photographers, should the light paraffin spirit with the trade name of "benzoline" be found to answer the same purpose practically, whatever may be the case theoretically.

An undertaking of permanent historical value to photography has just been inaugurated at New York, in the founding of a collection "in which every photographic book and periodical ever published in English, French, German, or any other language, will be accumulated and placed in the Library of Columbia College, which is open from nine o'clock in the morning till ten o'clock at night every day in the year, except Sundays and other legal holidays, and to which every responsible person may always have access." An active worker in this matter is Professor C. F. Chandler, Columbia College, 41, East 49th Street, New York.

There was a meeting of indignant show-folk the other day at the Agricultural Hall to protest against the proposed "Movable Dwellings Bill," which is calculated to interfere with their rights as citizens to a very uncalled-for extent. The Bill owes its origin to Mr. Smith—a name which to Englishmen is so common that it has become necessary to distinguish the particular Smith referred to—and, in this instance, the gentleman is known as Mr. Smith of Coalville. He has done good work in bringing the wandering population, represented by our canal folk, under legislative notice; but he has gone a step too far in describing honest show-folk as a dangerous and immoral class of society, and in seeking power not only to register all travelling vans, but to enter such vans between the hours of 6 a.m. and 9 p.m., with a view to overhaul the domestic arrangements of the interior. An Englishman's house, whether it be on wheels, or more solid foundations, is his castle, and it is only natural that the show people should rise indignant against the implied slur upon their good name.

At this meeting, the leader of the opposition, if we may call him so without offence, was Mr. Joe Caddick. Mr. Caddick is not actually a showman, but he owns a van, and we are quite ready to assume that he is guilty of dark deeds therein, and that his doings are often illuminated by a lurid light. He is, in fact, a travelling photographer, and, like most photographers, would object to the intrusion into his premises of any myrmidon of the law, unless, indeed, he came to have his portrait taken, and paid for it like a man. We sympathise with Mr. Caddick and all his friends. To brand any one class of human beings, who work hard for their living, as dangerous and immoral, is silly and immoral in itself, and Mr. Smith would do well to bottle up his zeal for a better purpose.

Many different media have from time to time been advocated for filtering white light for photographic purposes, and rendering it innocuous to the sensitive chemicals employed in the art. Glass naturally stands first, but it is sometimes difficult to get the safe colour required, and its brittleness is always objectionable. Paper stained with aurine is good for a certain time, but its colour quickly fails, like that of so many of the aniline dyes, if it be subjected to exposure to daylight, as it is bound to be if used to protect an ordinary window. Stained gelatine has also been used, and so has in recent times coloured celluloid; but the latter preparation, on account of its inflammability, cannot safely be employed for a dark room lamp. Bookbinders' cloth, which forms the basis of the well-known ruby medium, is perhaps the most satisfactory of all.

---

We have lately found a new material in the stained transparent paper which is sold for window decoration, as an imitation of coloured glass. This can be obtained in plain red, and is readily attached to the glass of a window by means of a gelatinous cement sold for the purpose. The colour of specimens which we have seen is a full ruby red, and, when that colour is desired, might be safe if a double thickness were employed. A similar material can be home-made, if preferred, by staining a thin paper with aurine or any suitable dye, and afterwards making it transparent with varnish; gum dammar in benzole, which dries in a few minutes after application, would be a good varnish for the purpose.

---

Lamps for dark rooms are infinite in their variety, but, up to the present, cannot be said to be quite perfect. M. Radiguet, a well-known electrician, has called in the assistance of electricity, and in *La Nature* describes a little apparatus which seems to possess many excellent qualities. The apparatus is formed of a glass jar, containing three bichromated divisions. The zincs are so fixed that it is easy to change them when worn out. The reflector attached to the incandescent lamp is mobile, and turns on an axis sending the light in the direction of the ground, and, by so doing, lighting the sink during the process of development. The reflector is furnished for photographic operations with a mobile lens of red glass. This lens may be changed for one of another colour, or done away with altogether if the lamp is only required for ordinary use. To obtain illumination, one has simply to dip the plates in the bichromate divisions, and light comes immediately. The light is extinguished, of course, by removing the plates. M. Radiguet has given to this dark room lamp the rather formidable name of "electrophotophore."

---

Photographers, as a rule, are scarcely attentive enough to the nature of the books which they place in the hands of their sitters. A powerful magnifying-glass sometimes makes some curious revelations. For instance, we heard recently of a case of an extremely devout divine who was taken apparently meditating over the tome he was reading. Naturally one would suppose it was some good book like Jeremy Taylor's "Holy Living and Dying," Whiston's "Commentaries," or the writings of the early fathers. The magnifying-glass, however, revealed the unfortunate fact that the book which was engaging the attention of the good man was nothing less than a quarto edition of the plays of Wycherly, Congreve, and Farquhar. Perhaps the best book to have handy is a volume of *Punch*. It is, at least, more entertaining to the general sitter than Sturm's "Reflections," or Harvey's "Meditations among the Tombs," samples of a class of book sometimes dedicated to the studio.

*Apropos*, a photograph of President Lincoln, which was highly popular, and was sold by thousands, showed him with a big book on his knee, and with his little son leaning against him and looking at the volume. It now turns out that this book, which was always thought to have been a bible, was nothing more nor less than a photographic album belonging to the photographer. This must have been a rather unpleasant shock to those simple-minded folk of New England who have always regarded the photograph as a sort of semi-religious picture enforcing a moral and an example.

---

The Post Office authorities have been studying the actinic values of various colours. They have discovered that the £1 postage stamp, which was formerly of a chocolate hue, was easily imitated, because the colour offered no difficulty to photography. They have accordingly decided to alter the colour to a bright green, which they believe will defy photography, and put an end to fraudulent attempts in this direction. One would have thought that the demand for £1 stamps was so extremely small as not to be worth the while of any forger to imitate them. Anyway, if there is a distinct market for stamps of this value, no doubt the ingenious forger, who is capable of taking an infinite deal of trouble, will immediately begin to make use of orthochromatic photography.

---

The bungling amateur must be a source of considerable income to the dry plate manufacturer. It would perhaps be difficult to ascertain the exact number of plates spoilt in proportion to the small number of those which succeed, but we fancy we should not be exaggerating when we say that, in all probability, the ratio resembles Falstaff's ha'porth of breath and intolerable quantity of sack. It was said recently that the Duke of Orleans, during a tour of a short time back, was very busy with his camera, and, on his return, he sent 400 plates to a photographer for development. Of these 350 or so were absolutely blanks, and the remainder hardly recognisable as scenes of any kind. The experience of the Duke of Orleans could, perhaps, be paralleled by hosts of amateurs.

---

Photography was one of the subjects for excelling in which prizes were offered at the Woman's Exhibition, held last week at the Westminster Town Hall. Considering the excellent work done by ladies in the Pall Mall Exhibition last year, the work was below that which one had a right to expect. The judges certainly had little difficulty in awarding prizes to Miss Mary C. Day for a head (described in the catalogue as two portraits), and for a second study of two heads (described in the catalogue as two groups). Mrs. Arnot was rewarded by honourable mention for two studies from life. We do not know who was responsible for the compilation of the catalogue, but it was marked by frequent eccentricities, of which the above are two examples.

## RETOUCHING.*

BY G. L. HURD.

Natural retouching may be said to be such corrective work as will be unobtrusive—supplementing only the shortcomings incidental to the process. Photography does not always render a face as we see it, and, in order to bring the picture to as close a representation of life as possible, more or less work is required to be done, and this needs no excuse. For instance, either from a slight under-exposure or heedless development, your image lacks that soft blending of lights and shadows seen in nature; the lines are hard, and a general exaggeration of the defects of the face is the result. It may be said that the most direct and effective way to remedy this is to make another negative, but there are often reasons why you had better not; you may have secured such a fine pose, and withal so pleasing and unconscious an expression—which has eluded you in every plate but that—that it makes one weary to think of renewed attempts. Perhaps the proofs have been shown, and the sitter will have that and no other. Clearly, then, you must make the most of that negative; you must coax the shadows down, soften hard outlines, and try to make the flesh presentable. It is hardly necessary to say that, when you have done your best, if you commend it to the sitter, it must be with some mental reservations regarding technical value. Still, retouching has helped you out, and made respectable what otherwise would have been wholly bad. Or supposing the exposure and development had left nothing to be desired, perhaps the skin of the subject has appeared upon the plate as an exaggeration of blemishes, or patches of colour have assumed the form of depression. Such work as will correct this is surely called for. Or, again, your sitter has a face full of angularities, which no lighting under heaven, unless accompanied by an over-exposure that will make it flat, can quite keep down to natural limits. Then the pencil is your friend again. Many people sitting in a light stronger than that to which they are accustomed will scowl a little. The expression can often be made wholly right by a little judicious softening of the lines in the lower part of the forehead. Perhaps the whites of the eyes in the photograph may appear darker than in nature by reason of a tinge of yellowness, often noticed in persons of bilious habit, or the same result may be had from a congested state of the minute blood vessels. Then it is very easy to bring back the relative whiteness by a few touches with the pencil. Other illustrations of what may be called natural retouching will readily suggest themselves to you.

Artistic retouching embraces all this and a good deal more; when elaborately done, the entire face, and even a part of the drapery, has been carefully worked over; the modelling of the face has been conscientiously preserved, the lights and shadows blended, the skin brought to a soft, textury appearance; a tendency to flatness, when present, has been corrected; a high light strengthened here and there to give a little more pronounced effect, and a general bringing of the face into tone and value has been accomplished. I need not say that a negative worked in this way can only be done by an artist.

A tremendous majority of all the negatives made in these days receive treatment of the most heroic character, and when the artist in banged hair has concluded her labours, nothing remains of the original negative but the outline. She proceeds in free and easy defiance of all the laws that govern the production of natural objects in light and shade. All the characteristics of the face go down before her ruthless pencil; wrinkles disappear, depressions are made to rise up, delicate tracings of muscles are obliterated; and when all is done, the eyes and mouth are the only features that remain intact, and they are so out of value with all that surrounds them that they appear like floating islands in a spherical sea of polished marble. I do not blame the retoucher; she works up to what is required of her, and what she is praised for doing, but this is the photographic portraiture of to-day. The highest ambition of the negative worker is to finish to a smoothness that rivals porcelain; no thought or care for the modelling, or all that subtle quality of rendering so vital to the likeness; no feeling for portrait effects—only a frenzy for a smooth, mechanical surface, and a struggle for rotundity. It is useless to remark how worthless such photographs are in the eyes of all people of artistic feeling, or even to those who seek a likeness, or how degrading it is to photography.

Well, what shall we do? The public have elected that a shining puff-ball is the *ne plus ultra* of photographic art, and the artistic world has decided that there is nothing so common and debased as portraits by photography. He who refuses to conform to the standard set up by the public will have to forego their orders. I know whereof I affirm, for I have tried it.

Still, there is a cloud in the sky, which, if no bigger than a man's hand now, is going to overcast the heavens by and bye. Already there are many people who are sick of this miserable representation, and the number might be greatly increased if men of the better class would drop their weak-kneed policy, and work for the best results instead of the most profits in the immediate present. Truth will prevail in photography as in all else.

I do not wish to be understood as inveighing against retouching, for we all know it is a great help when properly employed.

To the conscientious photographer, he who seeks to give present and permanent value to portrait work, the question of working the negative is a more serious and perplexing one.

* Extracted from a paper read at the American Photographic Convention.

---

Great Yarmouth and Eastern Counties Photographic Society.—This Society, which was started in October of last year, now musters fifty members.

The next meeting of the Newcastle-on-Tyne and Northern Counties Photographic Association will be held in the lecture hall of the Literary and Philosophical Society, Newcastle, on Friday, February 6th, at 7.30 p.m. Exhibition of 160 lantern slides by lime light.

Richmond Photographic Society.—A lecture on "Wild Animals in Captivity," illustrated by the optical lantern, is to be given by Major J. Fortuné Nott, president of the Society, at the Lecture Hall, Hill Street, Richmond, on Monday, February 16th, at eight o'clock in the evening. The proceeds are to be given to the Richmoud Hospital.

George Dawson, M.A., Ph.D.—With mingled regret and satisfaction we learn that this investigator—so well known in connection with photographic research—has been elected, on the Queen's nomination, to the Brotherhood of Charterhouse. We regret the necessity that urged him to seek refuge in the hospital, and are pleased that a home has been provided him for the remainder of his days. The record of Mr. Dawson's life-work is that of a journalist, editor, author, and lecturer on science. He attributes his present incapacity for gaining a living by work in the laboratory, or by the use of his pen, to age and serious injuries received in 1889 while stopping a run-away carriage horse.

## THE ENFIELD PHOTOGRAPHIC EXHIBITION.

Last Saturday afternoon the Photographic Exhibition of the Enfield Camera Club was opened, and in the evening a display of slides took place by means of the magic lantern. There was a good attendance on both occasions. With one or two exceptions, all the photographs exhibited were the work of the members, and of the more interest to their friends, the visitors, on that account. Among the best pictures on view were those by Mr. H. F. Knight, including views in Cumberland, seascapes, and other subjects. Some specimens of home portraiture, and views of Ely Cathedral, by a member whose modesty did not permit him to attach his name thereto, were of merit. Mrs. Henry Bowles exhibited a good photograph of a couple of swans, vignetted, but the background was not one well suited for a vignette picture. Among other exhibitors were the Graphotone Co., Messrs. W. Street, R. B. Lodge, W. H. Fellows, G. D. Pinkney, A. J. Ransome, S. James, V. Clements, F. Cresswell, J. Dudin, H. W. Stocks, and W. J. Biggs. Of course, with a proportion of new amateurs and a somewhat newly-formed club, some of the pictures mixed up with the good ones in the exhibition were chalky, others flat, and others without natural clouds; but the gathering was a friendly and social one, not intended for much outside criticism, and it gave pleasure to all who attended.

In opening the proceedings,

Mr. G. D. Pinkney, the president of the Enfield Camera Club, said that the organisation had been established for about nine months by a few individuals in the neighbourhood who were interested in photography. The Club held fortnightly meetings, at which papers were read, demonstrations given, and mutual information afforded. The Club had ladies among the members, and two of them were exhibitors.

Captain Henry Bowles, M.P., stated that he had great pleasure in attending to open that exhibition of works of art produced by residents in Enfield and its neighbourhood. He had a little to do with photography himself, because his wife had taken to playing with the subject, and he was the poor victim. He felt afraid to attend a meeting like that, lest somebody should be taking shots at him by means of a button-hole camera. Of late years photography had made great strides; it had produced wonderful pictures for the weekly papers and for one issued daily, so that people at a distance could gain a better idea of passing events; it had also been of great help in different branches of science. The medical profession, by its aid, obtained pictorial records of interesting cases, and astronomers had made great discoveries by means of photography, although once or twice it had led them astray, and produced two stars where there had really been but one. Photography had been much advanced by amateurs, for new discoveries were more likely to be made by those who followed it for pleasure than by those who pursued it more in beaten tracks as a business. He congratulated them upon their exhibition, and had pleasure in declaring it to be open.

Dr. F. Cresswell remarked that Mr. Bowles had spoken of photography as a science, but the members also wished it to be artistic, and that was one of the chief reasons for the recent formation of numerous clubs and societies all over the country.

After a few remarks from Mr. J. Dudin, those present proceeded to inspect the photographs.

---

Colouring Brass.—A steel colour is developed on brass by using a boiling solution of arsenic chloride. A concentrated solution of sodium sulphite causes a blue colouration. Black, as on optical instruments, is obtained from a solution of platinum chloride, to which tin nitrate has been added. In Japan, brass is bronzed by using a boiling solution of copper sulphate, alum, and verdigris.—*Invention.*

## THE WATER-COLOURS EXHIBITION AT PALL MALL.

The Gallery at 5a, Pall Mall is, in the minds of many photographers, so intimately connected with the yearly show of the Photographic Society, that seeing those walls covered with rainbow tinted water-colour drawings comes to some almost in the light of a revolution. This is, however, a limited and photographic view of the matter. The Royal Society of Water-Colour Paintings has now on view its twenty-ninth winter gathering, and an interesting and instructive collection it is.

Close by the door we find (No. 2) "The Valley of the Mawddach," by G. A. Fripp, a picture of considerable merit, warm in colour, broad in treatment, without excess. Close by is the first of many from the brush of Birket Foster, viz., (No. 6) "On the Rocks, Arisaig"; others from the same brush are (No. 49) "Isle of Rum," (Nos. 74 and 82) "Crofters' Cottages with Children," (No. 95) "Waiting for the Boats," a charming picture, (Nos. 154 and 178) "Children and Cottages"; but among them all, let the photographer carefully study No. 95 for composition, gradation, harmony, and design.

No. 13 is a large, clever picture, "First Breath of Autumn," T. Lloyd; possibly the thistle-down is a trifle heavy and solid, but the general result is decidedly good. No. 18, "White Cottage," is of the out-of-focus order, and is more curious than beautiful.

No. 26, "Gate of Justice, Alhambra," E. A. Goodall, is a valuable lesson to photographers in the matter of transparency with quiet detail in the shadows. It is the black, solid, heavy shadows of the ordinary photograph which so much offend painters. Nos. 23 and 42 should be noted as approaching somewhat in this direction; they are of what is sometimes called a blot-esque tendency.

Sir John Gilbert's study for a larger picture (No. 30) is interesting. No. 37, "Sculling," F. Powell, is a fine study in cloud reflection in water, a result difficult to attain in the camera. No. 46, "Loot," C. Robertson, is "very fine and large," a foreground with a superabundance of properties highly coloured. Another large picture (No. 56), "Haymaking," by A. Hopkins, has some fine parts, but the figures are rather wax-like in complexion as compared with ordinary haymakers. No. 70, "Low Tide," is an example of how to select a point of view and "make a picture out of nothing." No 81 is called "Scotch Fishing Boats," and is a view of Whitby Harbour; the only boats with harbour marks visible are N.S. (North Shields) and H (Hartlepool.) No. 88 is an exceedingly clever study of cattle and snow; No. 116, another of C. Robertson's clever oriental pictures. No. 110 is a cloud study of the rough style; No. 118, "Sandhills," and interesting to photographers as being rather a fashionable camera subject last year. Nos. 129 and 175, pastel portrait studies, which show the effect of having the head "too high up on the plate."

Henry Moore's "Prawners" (No. 142) is not so pleasing as some other of his handiwork, but close by is the gem of the show (No. 144), "Venice," by Miss Clara Montalba. The picture is a poem, or rather a beautiful dream of air, light, water, all palpitating with a mysterious life; note how the colours have been massed and grouped. From the same brush we have some others, No. 258, "Riva," No. 343, "Grand Canal," No. 367, "Rialto," and No. 292, a glorious flood of golden light, such as would have filled the soul of Turner with joy. No. 151, "Lower Valley of the Esk," should be studied to see how plane melts into plane.

No. 167, "The Jolly Miller," by H. Stacy Marks, is one of the few figure studies, pure and simple; it is simple, and yet strong in its simplicity. On the screens may be seen two bird studies (Nos. 294 and 309) by the same master. Sir Oswald Brierly, marine painter to the Queen, sends several masterly pictures and sketches. No. 172, "Waiting for a Breeze," a Venice sketch in his usual able style; No. 179, another Venice picture, broad, simple, and grey; No. 257, six small water and cloud studies; No. 333, Lowestoft boats; No. 345, H.M.S. *Meander*, a vessel in which the painter visited many foreign lands on a sketching tour, including Mexico, Peru, and Tongatabu.

No. 181, "Yarmouth Marshes," Henry Moore, is a beautiful painting. No. 185, "Stromboli," Albert Goodwin, a large and dramatic work, with some rather startling colour. No. 193, David Murray, shows the powerful effect of converging lines; a fine study in composition of line for photographers.

No. 204, "Country Girl," by Miss C. Phillott, a good example of ideal painting. Walter Crane sends the four seasons in design, Nos. 234-5, 247-8—splendid studies of graceful line. No. 241, "Wreck of the Halswell," is of course of the sensational order. Walter Crane sends several paintings of places dear to the camera man who "does" the south coast, *e.g.*, Nos. 261 and 265, Winchelsea Strand, and Gatechurch; nevertheless we prefer his beautiful designs. H. G. Glindon sends several character and figure studies (Nos. 232, 253, 278, and others), all in the same semi-French, vignette style, undoubtedly clever, yet not altogether satisfactory. Miss Edith Martineau paints a farm lad and his dog, "A Happy Couple" (No. 271), surrounded by appropriate buildings, in a skilful and satisfactory manner. Some of the lighter tones are perfect in gradation and luminosity. E. A. Goodall, in No. 295, scores decidedly in the happy hunting ground of painters, viz., Venice, and again in No. 363 a similar success is attained.

No. 303 is a curious and equally interesting monochrome allegorical study by Holman Hunt, showing a double rainbow. H. M. Marshall contributes a pleasing study of Whitby (No. 307); also a satisfactory view from London Bridge (No. 317).

On no account must the student omit to notice several highly characteristic black-and-white drawings from the pen of G. Du Maurier, viz., Nos. 350, 352, 357, 362, noting especially the well-known mouth and eyebrow in the two latter. A small black-and-white study by A. Hopkins, No. 353, is one of the cleverest things in the room.

There are many, many other pictures which every photographer should study in this room, even if he only were to learn from them a lesson which is sadly wanted in many quarters, viz., variety of subject. There is perhaps more sympathy between photographers and water colour workers than between the former and workers in oil medium.

This room shows that the general tendency of water-colour workers is towards the same class of subject which is most within the scope of the camera man—viz., landscape, with or without figures as part of and belonging to the scene. Another hint may also be taken from a gathering of pictures like this—viz., to glean information about some new, unexplored districts where food suitable for the camera is likely to be found. It is time that photographers gave Conway Castle its well-earned rest.

## PARLIAMENTARY ACTION IN RELATION TO THE DECIMAL SYSTEM.*

BY J. EMERSON DOWSON, M.INST.C.E.

For some sixy years or more the question of having a decimal system of coinage, weights, and measures in this country has received more or less attention, and several public inquiries have been held; but I venture to say that the subject has not been dealt with as comprehensively and as exhaustively as it deserves. So long ago as 1841, when the Houses of Parliament were destroyed by fire, the Commissioners appointed, in consequence of the destruction of the standards of weights and measures, referred incidentally in their report to the advantages of decimal coinage, weights, and measures; and, two years later, a new Commission referred to and confirmed this opinion. In 1853, the appointment of a Select Committee to enquire into the whole subject of decimalising moneys, weights, and measures was proposed; but, unfortunately, its scope was limited to moneys only when the appointment was made. This Committee reported strongly in favour of a decimal coinage, and recommended what is known as the "pound and mil system." In 1857 a Royal Commission was appointed to consider the introduction of a decimal coinage; and, in their preliminary report, the Commissioners said that the question of decimalising the weights and measures was early forced on their notice, but that they could not deal with it, as the terms of the Commission "restricted their investigations to the practicability and expediency of introducing the decimal principle into the coinage of this country, without contemplating any change in our present system of weights and measures." In their final report, two years later, they were, however, so far impressed with the intimate connection between the weights, measures, and coins, that they remarked:—"It does not appear desirable, under existing circumstances, while our weights and measures remain as at present, and so long as the principle on which their simplification ought to be founded is undetermined, to disturb the established habits of the people with regard to the coins now in use, by a partial attempt to introduce any new principle into the coinage alone." This was the last inquiry into the coinage question; but in 1862 a Select Committee was appointed to report on "the practicability of adopting a simple and uniform system of weights and measures." They reported strongly in favour of the metric system, but, incidentally, the question of decimal coinage was forced upon them; and they added in their report that "the evidence they have received tends to convince them that a decimal system of money should, as nearly as possible, accompany a decimal system of weights and measures," so as to obtain the greatest advantage.

All the seventy-two Chambers of Commerce of the Association of the United Kingdom have repeatedly pronounced themselves in favour of the decimal system, and the four large Chambers which are not members of the Association (Edinburgh, Glasgow, Liverpool, and Manchester) have taken the same ground. At the last meeting in March, 1890, the Association resolved "that a deputation be appointed to wait upon the Vice-President of the Committee of Council for Education to urge that steps may at once be taken to make the study of the decimal system of coinage and weights and measures a

*A portion of a paper on the Decimal System read last Wednesday night at the Society of Arts.

compulsory subject in all public elementary schools." Effect was given to this on June 16th, when an influential deputation waited on Sir W. Hart-Dyke, who acknowledged the importance of the body which the deputation represented, and of the subject under consideration. He said that he had long been in favour of such a system, and that they had his most cordial sympathy as far as the general policy was concerned. He thought his department would not be able to carry out the suggestions of the delegates before the system was legally authorised, but that, bearing in mind that the education given to the children must not only be the best, but the one most immediately suitable to their welfare, progress, and success in life, he would be glad if, in the future, he were enabled in any degree to forward the objects the deputation had in view.

### Specifications Published.

3,203. *February 28th*, 1890.—"Coating and Tinting Glass Surfaces." Charles Leigh, 128, High Street, Homerton, London, Artist.

This invention relates to a process of coating and tinting glass surfaces for the reception of paintings or other decorations. Although any glass surface may be treated, I have found that my process is particularly applicable to opal glass, which heretofore, so far as I am aware, has never been tinted, and any colour applied to its surface has had to be burnt in.

In carrying out my process, I roughen the surface of the glass to be treated by grinding or in any other suitable way. I then apply the coating, consisting of suitable gums and a solvent, preferably fusel oil. Any suitable colours are then applied to the coat, and are fixed on by any of the well-known mordants, such as chloride of tin, acetate of alumina, tannin, and the like. When I employ alcoholic solutions these mordants can be entirely dispensed with. I have found that a solution formed of the following ingredients gives satisfactory results, and for this purpose I dissolve 3 ounces of shellac, 1½ ounces of sandarac, 1½ ounces of mastic, 1½ ounces of benzoin, in 1½ pints of alcohol. I then add 1¼ ounces of Venetian turpentine, and after the whole has dissolved the solution is filtered and an aniline dye, either vegetable, mineral, or other dye, but preferably vegetable, soluble in alcohol, may be added.

I have also found that four parts of shellac to one part of borax dissolved in boiling water will make an excellent coating.

Good results may also be obtained if one part of shellac (or any other gum soluble in alcohol), dissolved in four parts of alcohol, be applied to the surface and immersed in a solution of aniline dissolved in boiling water with any of the well-known mordants. The coating can be applied to glass by a brush, rag, or other suitable means, or it may be floated upon the glass, or the latter may be dipped or immersed in the coating solution.

By means such as described, I am able to produce a tinted opal glass of any shade of colour, which will not only keep its colour and remain unaffected by atmospheric changes, but is also capable of being washed without being in any way damaged or affected.

3,392. *March 4th*, 1890.—"Detective or Hand Cameras." Walter Griffiths, Highgate Square, Birmingham, Manufacturer.

The object of this patent is to promote cheapness in hand cameras, and it describes one made of millboard.

3,482. *March 4th*, 1890.—"Photographic Cameras." Louis Van Neck, Brussels, Belgium, Merchant.

This invention relates to photographic cameras. The camera constructed according to the said invention has the appearance of a case covered with leather, and presents in front two circular openings, one being designed for the objective, and the other for the sighting.

At the upper part of the camera is arranged a handle for the transport, and a square opening provided with a deadened glass protected by a spring actuated shutter.

The camera possesses at its lower part a rectangular opening likewise provided with a deadened glass masked by its metallic shutter; the lever of the obturator having an exterior helical spring which can be detached at will, and expanded so as to act upon a series of tappets, and a knob provided on a rack designed for the focussing. On the side of the apparatus is arranged a presser of the disengaging device.

The camera has at its rear a closing device operated by a spring, which device enables a portion of the cover to be removed, and the bag which serves for changing the plates, or films, or the key of the roller frame to be uncovered or laid bare; furthermore a metallic handle, and an opening for the numbering frame.

My improved apparatus is composed of two distinct parts, one being fixed, and the other removable. The latter part includes the portion of the cover hereinbefore referred to. The anterior fixed part is formed of a reservoir upon which is placed in front the objective actuated by the rack for the focussing, and immediately preceding the obturator, having a mirror which exactly closes the opening on the side of the chamber for the plates or films placed behind. Above, the deadened glass is at the exterior, and reflects the image produced by the objective. A number of levers actuated by springs enables the obturator to be put under tension without uncovering the opening of the chamber towards the sensitive plates or films. At the moment of the disengagement, the mirror is raised and lowered with a velocity corresponding to the tension of the springs acting upon the levers. For prolonging the exposure, the obturator can be manipulated through the medium of a string or the like.

The posterior fixed part of the apparatus comprises a chamber which can hold, say, from twelve to thirty sensitive plates or films possessing frames of metal, celluloid, or other light material. Use can also be made of a roller frame having, say, from forty-eight to one hundred sensitive plates or films.

After each exposure the sensitive plate or film can be changed by means of a key; or giving a quarter of a turn to the handle at the rear, the last frame holding the sensitive by plate or film is raised in the impermeable bag in such a manner that the operator can seize it, and easily place the same before the others without fear of making a mistake. At the same time the numbering disc is caused to advance through the distance between two notches, and in the opening provided for this purpose appears the number corresponding to the figure indicating the number of plates or films used. In like manner a hand shows upon the roller frame the number of turns imparted to the rollers.

3,571. *March 6th*, 1890. — "Flash-Lamps." Robert Slingsby, 168, High Street, Lincoln, Photographic Artist.

In taking photographs by the aid of what are known as flash-lamps, difficulty has heretofore been experienced in effecting the release of the instantaneous shutter of the photographic cameras and the discharge of the flash-lamps simultaneously, in such a manner that the said shutters shall be open (for, say, one-tenth or less portion of a second, for example) during a fraction of the time in which the flash-lamps are illuminating the object to be photographed, which fraction may be, say, one-half of a second, for example ; and this difficulty occurs especially when it is required to discharge a number, or a battery, as it is technically called, of flash-lamps, and a number of corresponding photographic shutters at the same time.

The object of the present invention is to obviate the aforesaid difficulty by providing an apparatus whereby the release of the shutter or shutters, and the discharge of the flash-lamp or lamps, can be effected and controlled in such manner that the opening and closing of the shutter or shutters shall take place during the time the corresponding flash-lamp or lamps is or are giving its or their illuminating effect, the two operations of opening and closing the shutter or shutters, and of discharging the flash-lamp or lamps, being effected by one and the same mechanical movement.

For this purpose I employ a bellows connected by tubes with the flash-lamps to be discharged ; this bellows is actuated by a lever or other suitable device. The india-rubber ball, or other suitable device for releasing the shutters, is also connected by a tube or tubes to the shutter releasing apparatus of the camera or cameras, and is secured in position in the apparatus now being described in such manner that the same lever, or other instrument, that operates the lamp discharging bellows, also acts directly or indirectly upon and squeezes the said india-rubber ball. It will now be understood that, on actuating the aforesaid lever, or other instrument, the bellows and india-rubber ball are both operated upon at the same time, and, consequently, the flash-lamps connected with the bellows are discharged, and the shutters connected with the india-rubber ball are released at the same time also.

In order to provide for the necessity, which sometimes arises, of causing the shutters to be released at an earlier or later instant of time with reference to the moment of discharge of the flash-lamps, I provide adjustments whereby the lever or other actuating instrument is caused to act, sooner or later, on either the shutter releasing ball or on the flash-lamp discharging bellows, as may be desired.

The tubes connecting the flash-lamps to the bellows may be coupled to the latter in any suitable way, but I prefer to employ a nozzle connected directly to the bellows, of a diameter suitable for the greatest number of lamps the bellows is capable of supplying ; to this nozzle may be applied connecting pieces with apertures proportioned to suit the tubes of any number of lamps it may be desired to employ. I also sometimes connect the tubes from the flash-lamps to the bellows by means of a junction piece or distributor, consisting of a hollow box shaped somewhat like the rose of a garden watering-pot, and having short nozzles fixed in the side thereof corresponding to where the perforations are usually made in that article. The tubes from the lamps are connected to the said short nozzles, and the junction piece or distributor is connected by a suitable pipe to the bellows. Any desired number of these junction pieces or distributors may be connected by branch pipes to the main pipe leading from the bellows.

The employment of one or more of these junction pieces or distributors tends to equalise the pressure of air in the various tubes leading to the lamps.

3,730. *March 8th*, 1890.—"Machine Cameras." Mortimer Evans, Savile Club, Piccadilly, London, Civil Engineer.

This invention relates to certain improvements in or applicable to photographic cameras of the kind described in the specification accompanying application for Letters Patent No. 10,131, dated the 21st day of June, 1889, made by William Friese Greene and myself, in which cameras the consecutive movements necessary for the obtainment of a latent photographic representation, or of a series thereof, are caused to be effected automatically, and, if required, in rapid series, by means dependent for their actuation upon the rotation of a common shaft or its equivalent (hereinafter referred to as the "main shaft"), to which motion may be imparted by any suitable means.

The objects of the present invention are to simplify the means by which the successively adjacent or following portions of a sensitised strip (upon which successive or following representations are taken) are caused to be presented in position for exposure, arrested in position during exposure, and removed from position after exposure, and to lessen the period of each arrestment of the slip, so as to allow of, and cause the strip to be more gradually advanced into and from such position between its successive times of arrestment.

To this end, I cause the advance of the strip to be effected directly from the main shaft, or by parts operated thereby, in lieu of causing such advance to be effected by intermittently operating escapement devices independently and momentarily operating when released from the control of such shaft, as described in the aforesaid specification.

In such lastly referred to means, the portion of the strip in position for exposure is stationary during the whole, or nearly the whole, of the period between the successive operations of the escapement device, and the strip is momentarily shifted ; but by the present improvements, the portion of the strip in position for exposure is arrested in position only for the period required to effect the exposure, and the whole of the period between such successive times of arrestment is utilised in shifting the strip so that it is more gradually advanced.

I can effect this object by various modifications of suitably arranged devices.

According to one modification, I mount a take-up roller and a winding-on roller in opposite side rocking levers on the pivot or connecting spindle, of which I mount a roller guiding the strip from a suitably mounted let-off roller in alignment for exposure to the take-up roller, partly around which the strip passes on to the winding-on roller ; and I drive the latter by a frictional hub, and by connecting gearing from the spindle of the take-up roller at a relatively higher speed, such as may be practically most advantageous, such parts being so arranged as that the motion of the several rollers, and, consequently, the advance of the strip, is dependent upon the motion of the take-up roller. I impart the necessary movement to this latter roller from the main shaft (which may be continuously rotated) by driving it by frictional surface contact with a drum on such shaft, and I cause such movement of such roller to be intermittent by disconnecting such roller and its actuating drum at the time the arrestment of the strip, and the exposure thereof, is required to be effected. I can also effect this object by various arrangements of suitable means, as, for example, by mounting a pin or pins in the ends of the said drum, and by mounting disconnecting spring or gravity levers in arms extending from the said rocking levers, so constructing and arranging such disconnecting levers as that they will be automatically actuated by the said pin or pins at the times required, so to be caused to be effective in rocking the levers into position, and holding the strip in position for and during exposure, and until (immediately after the exposure) the actuating pin passes beyond the range of the disconnecting levers, which thereupon fall, or are caused to fall, into position ready for the next actuation of the pins, the take-up roller and its actuating drum being simultaneously automatically thrown into gear by a suitably disposed spring acting upon the rocking levers.

According to another modification, the winding-on roller is applied directly to the main shaft, being driven frictionally from the hub. Its winding-on and advancing action on the strip is caused to be arrested when required, as aforesaid, by pins or discs connected to the shaft, which intermittently engage with a conveniently mounted brake-lever, and cause the same to arrest the strip by nipping it against an opposite fixed part until the pins have passed beyond the range of the brake-lever, when the latter is automatically released by a spring, and the rotation of the roller and advance of the strip proceeds.

According to a further modification, the take-up device consists of a pair of rollers between which the strip is passed, and which receive a continuous feeding motion from a drum mounted on the main shaft, and are mounted in rocking arms, which, by a suitable arrangement of actuating parts, are caused to receive a reciprocating traversing motion equal to the speed of rotation of the rolls. Such means are effective in causing the rollers in their backward traverse (during which the portion of the strip in position for exposure is required to be stationary) to roll over the strip without effecting any movement thereof, and in causing the rollers during their forward traverse both to roll forward and to pull forward the same amount of strip, the strip being consequently advanced equal to the sum of the gathering motion of the rollers plus the traversing motion of their carrying levers.

19,488. *November 29th*, 1890.—"Adjustment for Photographic Objectives." ERNST GUNDLACH, 112, South Ave., Rochester, State of New York, U.S.A., Inventor.

My invention relates to such photographic objectives or lenses which are to be used with different openings or diaphragms according to light, distance of object, angle of field, and other circumstances. Such objectives are most generally composed of two achromatic lenses which are mounted rigidly on to the ends of a tube, and in such a distance from each other as is most favourable to the special purpose of the objective, the diaphragm being situated about midways between the lenses.

Such most favourable distance of the lenses, however, varies considerably with the diameter or opening of the diaphragm used, and also with the angle of field to be embraced by the objective. For instance, in landscape lenses, which require a wide angle of field, and are mostly used with small diaphragms, the best photographic result is obtained with a comparatively short distance of the lenses from each other, or from the diaphragm, while in portrait lenses, which have a much smaller angle of field, but are generally required to work with comparatively wide openings or large diaphragms, the distance of the lenses is to be correspondingly great, in order to produce the least possible focal distortion at or near the edges of the picture.

In fact, if the distance of the lenses is so regulated that the objective will, with a small diaphragm, produce the best possible picture, it will work very unsatisfactorily with a large diaphragm, producing a curved field, and much distortion at the sides. If, however, the lenses are brought farther apart, so as to have the most favourable position for a large diaphragm, then the picture produced with such will certainly show considerable improvement, while, on the other hand, it would then be much inferior if a small diaphragm were used.

A similar relation exists between the angle of field and the distance of the lenses. The wider an angle the objective is to embrace, the nearer the lenses must be brought together, or to the diaphragm, not for the immediate purpose of widening or increasing the angle of said objective, as is actually done thereby, to some extent; but to reduce the distortion at the sides, and the aberrations in the flatness of the field, which certainly increase with the angle. Thus, a short distance of the lenses will adjust the objective for small diaphragm and wide angle, and a long distance for large diaphragm and narrow angle at the same time.

Furthermore, if the object is very near to the objective, and the diaphragm of the latter is large, as is, for instance, generally the case with the portrait objective, then the proper or most favourable distance of the lenses of the objective also varies considerably with the distance of the object, and still more with the difference of the distances of different parts of the object, if those parts forming the centre of the picture have another distance than those near the edges. If, for instance, a person is to be taken in a sitting position, the hands are usually much nearer to the objective than the face, and consequently, if the image of the latter appears sharply defined on the focussing screen, the hands will be out of focus, the latter being too long, and lying behind the plane of the image. Provided, then, the image of the hands to be near the edge, and the face at or near the centre of the picture, the defect could be remedied by bringing the lenses of the objective nearer together, in order to shorten the oblique focus or that which forms the image of the hands. Thus, in this particular or exceptional case, a shorter distance between the lenses than that most favourable for general purposes would be proper.

The object of my invention is to provide for suitable means of conveniently varying the distance of the lenses of the photographic objective from each other or from the diaphragm at will, so that the same may be expressly and accurately adjusted for any size of diaphragm, and also for any angle of field or size of picture, if required, or, as in the case of the portrait objective, for any distance of object or difference of distances of different parts of the object.

## Correspondence.

### THE NATIONAL PHOTOGRAPHIC EXHIBITION.

SIR,—I am requested by the directors to inform you that the National Photographic Exhibition will be held at the Crystal Palace from the 13th April to the 2nd May inclusive.

S. G. BUCHANAN WOLLASTON.

*Crystal Palace Company, Crystal Palace, S.E., January 29th.*

### THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

SIR,—The annual general meeting will be held on Tuesday, February 10th, at 8 p.m., at 50, Great Russell Street, W.C.

No paper will be read at this meeting, which will be devoted to the consideration of the report of the council, the treasurer's report, the election of a new council, and other general business.

Members who wish to raise any question as to the management of the Society in any particular, are requested to bring the matter forward at the anniversary meeting, and it would be a convenience if notice were sent to the assistant-secretary of any motion which it is intended to propose.

The Progress Medal will be presented to Lieut.-Colonel J. Waterhouse. A. M. MANTELL, Captain R.E., Hon. Sec.

50, *Great Russell Street, W.C., January* 31*st*, 1891.

### THE PHOTOGRAPHERS' ASSISTANTS UNION.

SIR,—Will you oblige me by inserting the enclosed in the columns of the NEWS. ARTHUR FIELD, *Gen. Hon. Sec.*

*Maidstone.*

*Fellow Craftsmen and Lady Assistants.*

Now that we have, by a meeting in London, laid the foundations of a trade-union in photography, we beg to place our main proposals before you, subject to amendment by future meetings of the committee.

Roughly speaking, we appeal to all workers in the craft (male and female) of all grades of work, to unite for the purpose of safeguarding present trade privileges, and of mutually avoiding establishments notoriously unfair to their employées. In order that want of employment may not cause our members to accept or offer unfair terms of engagement, we intend to pay to all members of six months' standing "benefits" of from 8s. to 15s. per week. The payments for membership are arranged in classes according to the salary received, and range from 4d. to 8d. per week.

We do not intend to start on a "squelching" or other aggressive movement. We simply unite to refuse to accept engagements under sweaters and swindlers.* As for the good employers, we shall be pleased to act with them wherever they will allow us.

In return for fair treatment we offer *qualified labour.* We shall guarantee our members' ability by requiring them to have been for eight weeks continuously (at some date within two years of application) in receipt of at least the following wages:

*Minimum Salary to Admit.*—Operators or retouchers (or both), West-end of London, 40s.; East, 30s.; other parts, 35s. Printers (silver), West, 27s. 6d.; other parts, 20s. Lady

[* With present conditions we know of no law compelling a man to accept service under swindlers.—ED.]

retouchers and other artists, West, 30s.; other parts, 15s. Reception-room duties, 15s. and 10s. respectively; carbon printers, 30s.; monochrome artists, 40s.; photo-processes (operators, printers, etchers, photo-litho artists), 40s.; retouching, redrawing, opening-up, &c., 35s. Special arrangements for piece workers and workers in season towns. Membership restricted to workers under 40.

The above figures are subject to early amendment. Our work cannot be carried on without expenses, and the primary expenses will be the heaviest. Therefore we trust the necessary monetary aid will be forthcoming from all who have any interest in the new departure. All donations to be sent direct to H. Snowden Ward, treasurer, Bradford, Yorkshire.

We need hardly repeat the urgency of this question. However sure one may feel of the permanency of situation, yet unexpectedly it often happens that one is thrown suddenly into a helpless position—helpless because *isolated*. To prevent this we have started this movement for unity and mutual help. Let "Organisation" be the watchword of our disunited workers; let "Moderation" be our policy, and "Defence, not Defiance," our motto.—T. Bolas, Chiswick (*President*); H. Snowden Ward, Bradford (*Treas. and Sec. for Bradford*).

*Committee* (London)—W. Goebelhoff, G. J. Nield, Napier, Krauss, Phillips, Forbes. *Hon. Secretaries*—G. Nield, 44, Englefield Road, London, N.; F. Mann, 175, Malpas Road, Brockley, S.E.; C. Harrap, 8, Victoria Road, Plymouth Grove, Manchester; Arthur M. Henderson, 42, Frederick Street, Edinburgh. All information from Arthur Field, General Hon. Sec., Maidstone.

---

## PHOTOGRAPHY AND ILLUSTRATED JOURNALISM.

Sir,—The very interesting article on page 84 of your last issue entitled, "Photography and Illustrated Journalism" concludes with this sentence: "Mr. Russell Scott described a newly invented method of producing pictures of *various colours* at a rapid rate with *one impression from a single lithographic stone or block*." The italics are my own, as these few words seem to point to the solution of a problem that chromo-lithographers so far have completely failed to solve, and foreshadows a revolution in the cost and rapidity at which coloured reproductions can be turned out. If Mr. Russell Scott could be induced to give some farther particulars concerning this invention, they would, I think, be highly appreciated by those of your readers who, like myself, take an interest in all process work, and to the very large number who find that the photographic work connected therewith adds considerably to their income. M. P.

*February 4th*, 1891.

---

The Exhibition of the Manchester Photographic Society will open next Monday.

To-night Lord Rayleigh will lecture at the Royal Institution on "Some Applications of Photography."

Various correspondents are constantly sending us newspaper cuttings about the doings of those photographers who advertise "portraits for nothing," and then get something for them under the guise of charging for the frames. As all photographers have heard of the humbug, our correspondents had better send the paragraphs to local newspapers which have not already printed the particulars.

Pyrocatechin.—The recent decrease in the price of pyrocatechin is bringing it into prominence as a developing agent. The formula below is simple, and is said to produce excellent negatives:—

| | |
|---|---|
| Pyrocatechin ... ... ... ... | 1 gramme |
| Carbonate of potash ... ... ... | 10 ,, |
| Distilled water ... ... ... | 60 to 70 c.c. |

Another Discovery in Photography.—An interesting discovery has been made by Herr Dombeznfki, of the Lemberg Polytechnic Academy, Vienna, by which the area of the usefulness of photography is still farther extended. The professor, who has made a report to the Vienna Academy of Sciences, says that he has succeeded in obtaining photographic effects by electro-magnetic undulations, and explains the means he has employed.—*Photographic Times*.

# Proceedings of Societies.

London and Provincial Photographic Association.

*January 29th.*—Mr. A. Haddon in the chair.

Mr. W. E. Debenham presented to the library a work on the Autotype process.

Mr. Charters-White read a paper on "Photo-Micrography" (see page 102).

Mr. J. J. Briginshaw said that in order to facilitate the adjustment of objectives to the object to be photographed, he had devised a turn-table, which carried the microscope. He had found it a very convenient arrangement in practice.

Mr. T. E. Freshwater exhibited a lantern attachment, the use of which dispensed with the ordinary microscope. A revolving diaphragm plate rendered the light quite under the control of the operator. He also passed round Mr. Pringle's work on the subject.

The Chairman, in reply to questions, said that he did not recommend the use of the eye-piece; it restricted the field. With regard to the bull's-eye condenser, in his hands it had proved a very useful accessory. He had tried a yellow screen, but did not find any material gain from its use. For focussing he used a piece of plain glass with lines ruled across it with a diamond.

Mr. J. J. Briginshaw said that the ordinary ground glass screen was of no use whatever for fine work. A very good screen could be made by simply flashing a gelatine plate to light, and developing it.

A series of micrographs was then projected on the screen with the optical lantern, the work principally of Mr. Guardia and Mr. T. E. Freshwater.

---

The Sheffield Photographic Society.

The ordinary monthly meeting was held at the Cutlers' Hall on February 3rd, Mr. B. J. Taylor in the chair.

After the election of new members, a lantern exhibition was given, consisting of 180 slides, which had been awarded medals in their several classes in a recent competition.

---

The Sheffield Camera Club.

The annual meeting was held on January 28th in the Club's rooms, New Surrey Street. The Secretary's report for the past year was satisfactory.

The following were elected as officers for the ensuing year:—*President*—Mr. G. T. Newsholme; *Vice-Presidents*—Dr. T. H. Morton and Mr. H. J. Rawson; *Hon. Secretary*—Mr. G. E. Maleham; *Treasurer*—Mr. B. W. Winder; *Council*—Prof. J. O. Arnold, Drs. J. A. Munton and E. S. Rumio, Messrs. Wm. Gilley, jun., A. Copley, and P. Slater.

The Tooting Camera Club.

At the meeting held on the 27th January, with the President in the chair, the time was devoted to lantern slide making by Mr. J. F. Child.

The next ordinary meeting will be held on the 24th February, when Mr. Berger will demonstrate pyro development.

---

The Birmingham Photographic Society.

A meeting was held at the club rooms, Colonnade Hotel, on January 29th, Mr. W. J. Harrison in the chair. Eight new members were elected.

The exhibits of the evening were Hulm's cantilever enlarging apparatus, which was admired both for excellence of workmanship and portability, and two permanent photographs burnt into porcelain, which were shown by the Chairman. Neither of the latter appeared to have suffered by the burning-in process they had undergone.

The evening was then devoted to a developing competition and demonstration. Plates were first exposed behind negatives in the room, and then developed with pyro and ammonia, by Mr. J. T. Monsley; pyro and potash, by Mr. J. Simkin; hydroquinone, by Mr. G. A. Thomason; eikonogen, by Mr. A. J. Leeson; "Demon," by Mr. J. W. Pickard; ferrous oxalate, by Mr. W. J. Harrison.

The question-box contained the following question: "How are photo-etchings produced?"

The Chairman said that in principle he believed it to consist in imposing a carbon print upon a grained metal plate. A solution of perchloride of iron was then poured over the carbon picture, and this solution acted through the carbon image, biting or etching the metal beneath it. The metal plate could then be used to print from.

---

### The Croydon Camera Club.

The first annual meeting was held at the club rooms, 96, George Street, Croydon, the president, Mr. H. Maclean, F.G.S., being in the chair.

The report stated that no less than seventy members had been elected since the Society was founded on the 25th February, 1890. The accounts show a balance to the good of £16 15s. 4d.

The Club has the sole use of central rooms, open every day to members from 10 a.m. to 10.45 p.m.

The following officers were elected to serve for the current year:—*President*—H. Maclean, F.G.S.; *Vice-President*—Dr. H. J. Strong, J.P.; *Treasurer*—Mr. Sargeant; *Hon. Secretary*—G. R. White; *Hon. Assistant-Secretary*—E. F. Blow.

### The Liverpool Amateur Photographic Association.

A meeting was held at the club rooms, 3, Lord Street, on the 29th January. Mr. Paul Lange occupied the chair. The following were elected members of the Association: Norman Crook, A. C. Batty, Theodore Hubback, Miss Adams, F. W. Walker, E. S. Sole, and F. H. Elsby.

After a vote of thanks had been accorded to the retiring officers of the Association, the President distributed to the successful competitors the medals awarded in the prize competition of last November. The meeting was then made special to consider certain alterations in the rules of the Association, at the close of which Mr. F. Anyon gave an exhibition of a new lantern, with which he showed a series of fine slides, some of them of exceptionally high merit.

---

### The Bath Photographic Society.

A meeting was held at the Royal Literary and Scientific Institution on the 28th ult., Mr. W. Pumphrey (the president) in the chair. Miss Melita Bird and Mr. Cecil Bradshawe, Mr. Ernest Lambert, Mr. Graystone Bird, and Mr. C. W. Dykes were elected members of the Society.

The Chairman drew attention to the proposed visit of the Photographers' Convention to Bath next July, and a circular was read from the Camera Club inviting members to be present at their Conference, April 7th and 8th next.

Mr. J. Dugdale then showed the improved form of lanternscope he has recently devised for the purpose of viewing lantern slides. By its use the slide under examination is seen with both eyes at the same time, thus enabling the observer to form a more correct judgment as to the qualities of the work.

The Secretary showed a telescopic sliding metal tripod, sent by Mr. Pumphrey, of Birmingham. It could be extended to the usual height, or shortened to less than eighteen inches for microscopic work.

Mr. Pumphrey then continued his demonstrations of enlarging processes. In this instance a very simple apparatus was used—a dark chamber, in an aperture of which the negative to be enlarged was placed—in front of that an expanding camera minus the focussing and dark slide, and in front, and movable in three directions, an easel to carry the sensitive paper. A paraffin lamp, placed within the chamber, was used for focussing the enlarged image on the easel, after which it was removed to a tin lantern with a red glass front. A piece of oil ground glass was next placed before the negative to act as a diffuser, the sensitive paper adjusted on the easel, and the exposure made. This was done by means of magnesium ribbon; a string of ribbon six inches long and held by pliers was ignited at a spirit flame inside the chamber, and passed during combustion from side to side and up and down in front of the ground glass screen, this process being repeated as often as required. To produce a fully impressed enlarged positive on bromide paper, say from a dense half-plate negative, the enlargement being about three times, lens working at $f$-12, three such pieces of ribbon would be required. If a negative possesses great density in parts, the plan of illuminating offers distinct facilities for adapting the light to suit it. Mr. Pumphrey stated that this method was introduced by Mr. Monkhouse, York, and that it was by his special permission he brought it before the Society. The exposed paper was developed, and the result handed round.

An exhibition of lantern transparencies then took place; the president's oxyhydrogen lantern was used. First, there was a competition for the best set of slides, the work of the competing members, and also of the best individual slide. Messrs. Appleby Bristow, Hippisley, Peacock, Wells, and the Rev. E. A. Purvis competed. The judges were Messrs. Dugdale, Perren, Ashman, and Canon Williams, and the points of excellence sought for were four, namely, gradation, colour, composition, definition. Mr. H. G. P. Wells secured the highest number of votes for his series: "The Homestead, Milking Time," "The Glen, Summer and Winter," "Saltford Weirs," and "The Swans, Weymouth." Process: lantern plates, pyro development. For the best individual slide the award was given to Mr. Ernest Peacock, for a view of Uplyme. Process: lantern plate, pyro development. The competing slides were judged first by Mr. Dugdale's lanternscope, and then as they appeared on the screen. The remainder of the evening was devoted to an exhibition of non-competing slides, contributed by the chairman, Messrs. Bristow, Wells, Powell, Dugdale, Shackell, and others. Annual meeting February 25th, when, after the formal business, Mr. Wells will demonstrate the method of producing lantern transparencies.

---

### The Photographic Society of Philadelphia.

A stated meeting of the Society was held on Wednesday evening, January 14th, the president, Mr. John G. Bullock, in the chair.

The paper for the evening was read by Mr. Frederic E. Ives, being an abstract of his recent lecture delivered before the Franklin Institute on "Heliochromy, or Photography in the Colours of Nature." Four permanent colour-print heliochromes by his patented process were shown. He also repeated a suggestion which he made, incidentally, in his lecture at the Franklin Institute, and which was not published because the lecture was in print when the suggestion was made. After speaking of the insensitiveness of the old chloride of silver process, which is suitable only for printing-out under-coloured glasses and similar copy, he said he believed a far better printing-out process could be devised employing fugitive dyes, which, as is well known, are bleached by the light rays which they absorb. He said: "Suppose we take, for this purpose, three very fugitive dyes—a green-blue, a magenta, and a yellow. Every part of the spectrum can be represented by means of films more or less deeply stained with these dyes, separate or superimposed upon a white surface; and if the three fully coloured films are superimposed together, we get a good black. Project the solar spectrum upon this compound film, and what will it do? Sooner or later, depending upon the light sensitiveness of the dyes, the red rays will bleach the green-blue dye, which is the only one that absorbs those rays, and leave the yellow and magenta unaltered, making a full red. The yellow rays, which are absorbed by the magenta and the green blue dyes, will bleach them both, leaving only the yellow. The green rays, which are absorbed only by the magenta dye, will bleach it, and leave the yellow and green-blue dyes unaltered, making a full green. The blue rays, which are absorbed only by the yellow dye, will bleach it, leaving the green-blue and magenta dyes unaltered, making a full blue. Other parts of the spectrum, acting upon the same principle, will give intermediate tints by only partly bleaching the dyes by which they are not completely absorbed, and white light will bleach all the dyes, exposing the white support. It might be possible to mix the dyes so as to apply them together in a single film, as of collodion or gelatine. Should the light-sensitiveness of the dyes be unequal, evenness of action could be secured by the use of light-filters, as in orthochromatic photography. The process might be named 'heliochromography.' Turmeric exactly fulfils the requirements for a fugitive yellow dye, printing-out completely in a few minutes in bright sunlight. It will be only necessary to find equally fugitive dyes of the right shades of green-blue and magenta-red in order to obtain direct colour prints far brighter and truer than the best that have been made on the silver chloride plates. Cyanine, which prints out as quickly as turmeric, makes pictures that can be rendered permanent, but it is not exactly the right shade of blue to carry out the process with only three dyes. There are many coal-tar dyes so fugitive that they have no commercial value, and are not manufactured; among these it is quite likely that suitable dyes for carrying out the process may be found. Should it ever be found possible to continue, by chemical agency, the process started in the dyes by the light rays themselves, the picture could then be made in the camera, and if all the colours could be fixed, like cyanine, when sufficiently reduced, permanent photography in the natural colours would then be within the reach of every amateur. Meanwhile, we shall probably have to content ourselves with the more roundabout but no less scientific and capable method of composite heliochromy."

Mr. Browne said he would like to ask Mr. Ives one question. Some time about 1862 or '63 he remembered seeing a Daguerreotype plate sent from France, and which M. Becquerel claimed to have been made in the camera. It represented a Scotch plaid or shawl; the picture originally had very bright colours, but was then considerably faded. It was sent here as a very great curiosity, and was shown to some of the members of the Franklin Institute. Did Mr. Ives remember what process that was?

Mr. Ives said it was the same old chloride of silver process of which they had an illustration now on the President's table. It was considerably brighter than the pictures he had shown them, but it was substantially the same process, and was obtained by two days' exposure in the sunlight, using a portrait lens. A two days' exposure in the sunlight was, of course, entirely impracticable, no matter what the result might be. A method of fixing these pictures permanently had not yet been found; they had to be kept from light.

Mr. Earle showed and described a rubber-type outfit for printing titles and numbers on negatives. The novel feature was the fact that the types were positive instead of negative, as usual with type. As a consequence, they printed on the film of the negative in *negative letters*, and when so used a print from the negative showed the letters as *positive*, so that they could be read properly on the positive print. The types were easily set up, and could be read and corrected in the holder before any printing was done.

---

Received.—From Mr. Scholzig, some samples of gelatino-chloride paper, which we have tried and found to yield rich prints; the paper has a tendency to curl a little.——From Messrs. Iliffe and Son, "Photography in a Nutshell, by the 'Kernel.'" The compiler, in his preface, assumes in the reader an acquaintance with the rudiments of the art, and sets forth as his aim the addition, from personal experience and the produce of others, details of procedure which have been found useful. While acknowledging his indebtedness to articles in current photographic journals, the "Kernel" claims that the correctness of the views advanced by others has been tested by home practice.——From Bailliere, Tindal, and Co., the February number of "The International Journal of Microscopy and Natural Science." Among its articles is one by Dr. Charles Hacks, in *L'Illustration*, giving an account of an interview with Dr. Koch, in which the interviewer alludes to the extensive use made of photography by the celebrated doctor whose name is so intimately associated with the "cure of consumption."

---

D. W. E.—The matter about which you write is one for the police, and outside the functions of a newspaper unacquainted with either of the parties to the case.

S., Vienna.—Your article has been in type more than a fortnight. We are only waiting for space for its publication.

# Answers to Correspondents.

All Communications, except advertisements, intended for publications should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

H. L. (Highgate.)—*Foreground Shutters.* There are several forms of shutter which will give diminished exposure to the sky, and consequently, prolonged exposure to the foreground. Probably one of the best is Heath's patent foreground shutter with Cadett's pneumatic attachment, which is figured in Messrs. Marion and Co.'s catalogue. The "double flap" (Guerry's patent) shown in Mr. J. Fallowfield's catalogue, page 75, might also be suitable for your purpose.

R. M.—*Nominations.* Four out of the six names proposed for vice-presidents have also been nominated as members of council. Make your own selection, but it would not be proper to vote for the same individual in a double capacity. The progress medal is to be awarded to Lieut-Colonel J. Waterhouse, the intention having been officially announced both in the January *Journal*, and in a circular dated 31st ult.

J. H. (Sandwich).—*Collodion for Photo-litho Work.* 1. The recommendation to distil the methylated ether off quicklime was intended to keep back every trace of free acid, and it would likewise retain any admixture of water. If the alcohol also requires to be treated, you must do it separately; but in most cases you may rely upon *spiritus vini rect.* being sufficiently pure without such treatment. 2. Use iodide alone, that of cadmium preferred, without any free iodine, in the proportion of four to five grains per ounce of collodion, dissolving it previously in the alcohol. 3. Olein is the most liquid portion of olive oil, obtained by freezing the oil, and drawing off the uncongealed fraction.

W. S. (Bedford Square).—Either McKellan's or Watson's acme camera with rapid rectilinear and wide-angle lenses. The shutter you mention is reliable for work in a hot climate. We gladly note your approval of the Almanac.

L. T.—*Dr. Gunther's letter.* One can only guess that "water glass" or silicate of potash (or soda), may be the secret method of treating the lithographic stones, referred to on page 80 of last week's News.

C. L. B.—*Technical Examination in Photography.* The City and Guilds of London Institute holds an annual examination in May. It is not necessary that you should attend lectures at the Finsbury College, but you may get your knowledge anywhere, best by practical experience combined with reading for the theoretical points. Especially read up Professor Meldola's "Chemistry of Photography," and Captain Abney's "Instruction in Photography." Later on, ask the Secretaries for a prospectus of the forthcoming examinations.

One in Doubt.—*Framed Local Views.* Without actual inspection we cannot speak with confidence, but many of the glass pictures with narrow brass borders are simply silver prints mounted, with gelatine, in optical contact. They are not transparencies backed with white paper, as you seem to imagine. By uncovering at the back, and peeling off a little bit, you could, however, easily resolve your doubts.

A. W. (Bury St. Edmunds).—*Finishing in Black and White.* All depends upon aptitude and previous training; but we we should say less than six months ought to qualify you for undertaking this work. When prepared with specimens to show your capabilities and style, it would be easy to make a tour of your district and offer your services. It is quite impossible to answer your question as to average pay; high art should always be well remunerated, and we hope you will succeed in time. The little book on colouring and finishing is to be had of our publishers for thirteen stamps.

B. L.—*Albumenised Paper.* Ammonia increases the solubility or fluidity of albumen, but its use is not to be recommended.

Other Correspondents in our next.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1693.—*February* 13, 1891.

CONTENTS.

## NEW DISCOVERIES IN PHOTOGRAPHY IN NATURAL COLOURS.

In these pages to-day will be found an article from the Paris correspondent of the *Daily News*, telegraphed to that journal last Tuesday night, also a communication to us from M. Leon Vidal, about a new discovery made by Professor Lippmann, of the Sorbonne, in relation to the taking of photographs in natural colours. M. Lippmann has the idea that the phenomena of interference have some influence in the production of photographs in natural colours. The colours of thin plates, the colours of a thin surface of oil floating on water, and the colours of the soap-bubble as it grows thin, are phenomena of interference.

On perusal of the two articles just mentioned, it will be found that so little is stated about the process that nobody can work it until further details are received from Paris. A film of albumen containing iodide of silver is used, but how to prepare it is not stated, but the negative information is given that an emulsion is useless, the particles of the haloid then being too coarse. Whether the film must be as thin as a soap-film which yields colours is not stated.

The interference of light-waves is produced by means of metallic mercury at the back of the plate to send the rays back through the film; at least, the inference from a sentence in one of the articles is, that the mercury is in contact with the back of the plate, and not in contact with the sensitive film. The plates are developed and fixed "as usual." Does this mean that the ferrous-oxalate developer is used, or what?

As to the quality of the results obtained, the statements of the two correspondents differ extremely. M. Vidal describes them as poor, and the *Daily News* correspondent, who also has seen them, as excellent. The latter saw them last Tuesday, and M. Vidal saw some on the preceding Friday, so M. Lippmann may have made improvements meanwhile. The one describes some unfixed photographs in colours; perhaps those seen by M. Vidal were fixed, and had been nearly obliterated by that process.

At all events, a fresh advance in relation to photography in natural colours has been made, and we must wait for the details. Whether the first results be imperfect or otherwise is of small moment, for new discoveries are rarely of utilitarian value at the outset. If M. Lippmann wants a haloid film, free from granulation and rich in silver, perhaps a fluoride of silver film might answer, for that salt can be made in flexible films which can be cut with a pair of scissors.

## RETOUCHING—ITS USE AND ABUSE.

Since photographers have been compelled to pay more attention to the artistic qualities of their work, an outcome of the better art education of the public, it has become the fashion in many quarters to decry the use of the lead pencil, and to assert that every photographic portrait should be untouched, and that its native blemishes should not be glossed over. At many recent exhibitions many pictures of large heads have been shown in which this idea has been carried out, but it must be noted that these have generally been from picked subjects. We remember some most effective ones by Mr. Adcock, of Melton Mowbray, whose untimely death has only recently been reported, and one or two of these will serve as examples of portraits in which retouching may be entirely neglected with advantage. One is the portrait of a man, who appears to be a gipsy. His swarthy face is roughened with constant exposure to the winds of all seasons, and there are characteristic lines about his mouth and eyes which tell of cares which are almost inseparable from a roving, hand to mouth existence. His unkempt, curly black hair is covered with an old felt hat, which shades half the forehead, and a velveteen coat thrown open shows a ragged, white, collarless shirt. The picture is a striking one, and no touch upon the negative could possibly have given it improvement.

Another picture by the same hand represents a man who is more of a tramp than our gipsy friend. He has a rougher coat, and around his neck is one of those gaily-patterned scarves or comforters which are so dear to the hearts of our vagrants. He is lighting his pipe, and his rough, dirty hands are as full of character as his tanned face. His portrait, too, would be certainly the worse for being worked upon by the retouching pencil. In another picture, before us as we write, a far more wrinkled face belongs to a weather-beaten fisherman, for its surface is covered with ruts and furrows, which speak of constant exposure to cold winds and rain. These ruts give character to the honest face, and were we to attempt to soften them down, its picturesqueness would be gone. We may, indeed, say that in all cases where extreme age, or vicissitudes of life, have left deep markings on the face, retouching is inadmissible; but that in most other cases of portraiture it is not only legitimate, but necessary.

Those who are foremost in denouncing retouching as bad, and as merely ministering to the vanity of sitters, can hardly have had any practical experience in portraiture. Nor are they, apparently, aware of the undoubted fact that the camera notes certain markings on the human skin which are not visible to the eye. It is also guilty of exaggerating other marks which are visible, and of rendering such marks painfully prominent. In the first case we allude to slight discolourations, due to various causes, which no eye would readily detect, but should these be yellow or red in tone, they become most pronounced spots on the negative. Under the second head come freckles, which, light red in the original face, photograph as black as ink in the positive proof. It has been proved more than once that those sickening for an eruptive complaint will, if their photographs happen to be taken shortly before their illness, exhibit in their pictures the spots which, up to this time, are not apparent to the eye. We know of two such cases where the camera, to a certain extent, diagnosed in this manner the approach of disease. In each case the photographer attributed the spots to something wrong with his plates or chemicals, and did not guess that the patient was at fault until afterwards the illness was reported to him. Such extreme cases are, of course, few and far between, but it is an every-day occurrence that the smoothest face will show markings in the negative which are not apparent in the original countenance. It is most certainly legitimate to obliterate such markings by use of the lead pencil, and we may say the same of freckles, which are reproduced in such exaggerated fashion. It is certain that, if any photographer, in a fit of mistaken conscientiousness, were to send out proofs of his freckled client without touching up the negative, he would quickly find his occupation gone.

An instance of the abuse of the retouching pencil was recently placed before us as a specimen of what is done in a fashionable studio in Germany. The portrait was that of a lady who was well known to us, and—we hesitate to make the admission—we happened, by an accident, to be aware of her age. Time, who is most ungallant in his behaviour to the fair sex, had left certain markings upon her comely face, and the German photographer had, in his negative, pencilled them all out. Twenty years or more had by this base means been knocked off the lady's apparent age; and there was more than a suspicion that the artful pencil had at the same time removed a few inches from her waist. We were asked our opinion of the picture, and we gave it honestly: "A very good example of clever retouching." And so it was; but the face, in losing its slight wrinkles, and the expressive marks about the corners of the mouth, had been given a strong resemblance to a wax doll. It had a doll's prettiness, and a doll's utterly vacant stare—the intellect in had been pencilled out.

We have given extreme instances of the use and abuse of the lead pencil, but, of course, there is a golden mean which the wise retoucher will not o'erstep. In a word, the pencil should be used sparingly, and with judgment. Beyond the eradication of such foreign markings as we have indicated, it is hardly wanted at all, unless it be to gently strengthen the line of light along the nose and on the chin. The careful retoucher will never touch the eyes unless there is some accidental marking there which needs his help.

---

The Photographic Club.—Subject for February 18th, "Blisters"; on the 25th, the Monthly Lantern Meeting will be held.

London and Provincial Photographic Association.—The "Champion Hotel" 15, Aldersgate Street, E.C. February 19th, technical evening; March 3rd, lantern and musical entertainment.

Photography and Engraving.—Photography is naturally elbowing engraving out of the market, especially on the Continent. The *Architect* states that Belgian aquafortistes have been considering the present state of their art in response to an invitation from the Belgian Académie Royale. They offer the following suggestions about what is required:—(1) The creation of a printing office and a studio in connection with the Brussels Academy; (2) vigorous encouragement to the development of engravers' societies; (3) rewards for engravings after the works of the great painters of the country; (4) a gallery at the Musée of Brussels, which would be devoted to engravings in order to initiate the public in the knowledge of the art. In Antwerp there is an official printing office attached to the Academy, but it does not appear to be ever used. It would, adds our contemporary, be a pity for engraving to become one of the lost arts, but unless there is patronage from Government it is not easy to see how the highest class of work, which alone deserves encouragement, can be executed.

Geological Photography.—The past year has seen a new direction of enterprise in regard to the registration of geologic facts. The photographic art has been called into organised recognition. At the meeting of the British Association held at Newcastle-on-Tyne in September, 1889, a committee was formed to arrange for the collection, preservation, and systematic registration of photographs of geological interest in the United Kingdom. In some counties, as in our own, this impetus has taken a rather wider sweep, and aims at a general photographic survey of the county. As is known to many here present, an influential county council has been appointed for this purpose in Warwickshire, with Mr. J. B. Stone as president, and Mr. W. J. Harrison as secretary; and two members of this Society have been delegated to act thereon. Unquestionably many instructive geological sections have been lost to science through want of correct drawing, or photographing, at the time of their exposure; and it is hoped that this committee may aid in recording and retaining such facts. The result of the first year's work has been satisfactory; and the report to the Association at the Leeds meeting shows that 196 geological photographs have been sent in. It is to be hoped that in years to come this method of rendering permanent transient sections may be productive of good.—The Revd. G. Deane, D.Sc.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

New Process of Photography in Colours—Utilisation of Photography for Impressions in Colours—Sensitised Silk—Radiguet's Electro Photophore—Sulphite of Soda in Development—Plates with Chloro-Bromide of Silver—New Pressure Frame—Micro-Photographic Slides—Direct Carbon Prints.

*New Process of Photography in Colours.*—The leading feature of the meeting of the French Photographic Society is a discovery by M. Lippmann. This scientist made a communication to the Academy of Sciences on the 2nd of February, which has since caused considerable commotion. "Photography in Colours," such is the subject of this discovery. M. Janssen, president of the French Photographic Society and colleague at the Institute of M. Lippmann, brought to the meeting of the Society one of the plates shown by M. Lippmann, and, with his habitual precision, gave explanations, as complete as possible, of the phenomena serving as bases for this discovery. Let us commence by saying that M. Lippmann, after many experiments, thinks that he has succeeded in photographing luminous undulations in such a manner that the reproduction permits us to see, by reflection, red where red has fallen on the plate, yellow where yellow has acted, and so on. He appears to have succeeded in registering the interferences resulting from the meeting of rays reflected from a reflecting metallic surface and of incident rays. From this meeting there results, in the case of light, as in that of sound, intermittences of light and darkness analogous to the alternations of sound and silence. These interferences being produced in the body, or, rather, in the thickness of a sensitive film, give rise to more or less numerous films after development, of which some are black, and others, corresponding to the obscurations, are white.

Now, according to the action of the rays of different colour, the number of waves varying with the colour, it happens that the eye perceives the colour answering to each number of waves that characterise it. It is known that the length of the luminous waves is measured by millionths of millimetres. Thus the spectrum red has a wave length of 620 millionths of a millimetre. Now, supposing that the sensitive film traversed by reflected and incident rays has a thickness of one-tenth of a millimetre, there will be called forth in this film of 100,000 millionths of a millimetre 161 waves in the one direction, and 161 waves in the other direction, from which there results a sort of interior strata of black and white films superposed, corresponding to the succession of light and shade produced by interferences. In the same case, the violet, having the wave length of 423 millionths of millimetres, produces strata of 235 black and white films, producing to the eye precisely the effect of violet light.

Experience seems to confirm this theory. M. Janssen showed a photograph of the spectrum confided to him by M. Lippmann. On examining it carefully, and making the little plate yield reflected images in different directions, we finally perceived a sort of iridescence in those parts where we were told the spectral colours existed. We only saw them very imperfectly rendered, and certainly we should never have suspected, if we had not been told of it, that it was a reproduction of the solar spectrum with the colours. Viewed as a transparency, the plate showed a reddish stain in the part corresponding to the middle of the spectrum. Theoretically, we ought to see, as a transparency, colours complementary to those seen by reflected light.

M. Lippmann operates as follows. In the first place, he covers the surface of a glass plate with a coating of albumen sensitised with iodide of silver. The plate is placed on the surface of a mercury bath arranged in a vertical camera, and the spectrum is projected upon it. The exposure lasts for from one to two hours, and the development and fixing are carried out in the usual manner. The essential precaution is to use a film as continuous as possible, as free as possible from network and granulations. Gelatino-bromide of silver emulsion is unsuitable on account of the very marked granulations of the bromide of silver. No emulsion will serve, and it is necessary to produce the substance chemically in the material serving as the colloid layer, so as to have the most continuous film possible—the least granulated that can be realised. This will be understood from what has been said above. And now what have we to conclude from this communication? I find myself absolutely embarrassed in endeavouring to form an opinion or hope in any direction. Is this a discovery conducting to photography in colours? Up to the present the principle involved is so delicate, and the results so incomplete, that I can really say nothing. I must await farther and more crucial experiments before I can bring myself to believe in the possibility of finding a satisfactory solution in this direction. We do not desire to be sceptical, but we ought nevertheless to be prudent, and not to trust too readily to hopes that may very likely never be realised. It is certain that a solution, to be in the least practical, must be supported by something very different from what has been shown to me. However this may be, the fact in itself is of very great interest; it adds to our knowledge of luminous action, and the spectral embryo obtained by M. Lippmann may very well develop itself and produce a complete image of the spectrum. This is for the future to decide.

*Utilisation of Photography for Impressions in Colours.*—Mr. A. Gravier presented a collection of phototypogravures printed in three colours, published by the *Petit Journal.* His object was to demonstrate the services rendered by photography, as, thanks to its aid, the original—a water-colour drawing—had been reproduced. The photograph of the picture had been made on three blocks of wood, on which the engraver had created the monochrome blocks suitable for rendering the three colours. It would, perhaps, have been better still to print from three negatives in which the selection of colours had been photographically made. The interpretation of the subject for the engraver would certainly in this way be more complete.

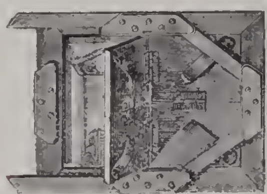
*Sensitised Silk.*—M. Tisseron has succeeded in preserving, without change, his sensitised silk. Samples and prints in support of this statement were produced. There is nothing remarkable in the process, but it is interesting to note the possibility of preserving the silk, ready for printing, for a long period without change.

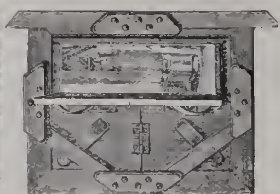
*Radiguet's Electrophotophore.*—M. Radiguet showed an electric lamp suitable for dark room illumination, called the electrophotophore. This apparatus consists of a bichromate battery of three cells, connected for tension. The globe containing the carbon filament of the incandescent lamp is itself enclosed in a box fitted in front with red glass. According as the zinc elements are plunged into the bichromate bath, or removed therefrom, the current is started or stopped. The duration of the light with one filling of the cells is only three hours, and the zincs are very rapidly dissolved. For ordinary work, then, this instrument will not be of much use, but there are cases where it will render certain service.

*Use of Sulphite of Soda in Development.*—The indiscriminate use of sulphite of soda has, with good reason, attracted the attention of M. Reel, who says that a developing solution containing ten per cent. of this salt may dissolve a film of bromide of silver. It is necessary, therefore, to limit the quantity to what the plate will bear without evil effect. It is true that reduced silver retards this action. M. Reel therefore advises the use of a developer sufficiently energetic to produce an immediate effect, so as to oppose the solvent action of the sulphite of soda.

*Chloro-bromide Plates.*—Messrs. Marion, Son, & Co. showed very fine results obtained upon their new chloro-bromide plates for transparent positives for lantern slides, &c. The plates are slower than those containing gelatino-bromide, but they are quicker than chloride plates, so that they may be used in the camera for enlargements and reductions, whilst yielding perfect transparency in the clear portions.

*New Pattern Pressure Frames.*—Messrs. Poulenc Frères exhibited pressure-frames of a new pattern. The illustrations will give a complete idea of them. The catches of the press may be opened in both directions,





and, consequently, allow the image to be seen in all its length and all its breadth, which cannot be done with the ordinary frame. This pattern will certainly replace the old type.

*Micrographic Lantern Slides.*—Amongst the many lantern projections exhibited, those by Messrs. Lumière and Son, of Lyons, were especially remarked. They represented the embryonic condition of the fowl from the first to the end of the third day. The photographic transparencies, printed in various colours by imbibition, are of remarkable delicacy and purity.

*Direct Carbon Printing.*—Mons. E. Vallot has made some happy experiments in producing direct impressions by carbon printing. The print is made in such a way that it is developed without transfer and without reversal of direction on the prepared paper itself. The process is analagous to that of M. Artigues—published in the Photographic News in 1889, p. 517. The latter not having disclosed his method, M. Vallot has been experimenting in the direction indicated, and his first results are very satisfactory. No doubt, with the manipulative skill that M. Vallot possesses, he will achieve remarkable success.

---

The Photographers' Benevolent Association.—At the meeting held on the 9th of February (Mr. Bedford chairman), Mr. Farrington was elected auditor; one grant was considered and refused; the report and balance sheet were adopted; and the annual general meeting was fixed for the 27th inst.

## PHOTOGRAPHY IN MANCHESTER.

### The Photographic Exhibition in Manchester.

The Manchester Amateur Photographic Society held an exhibition of the work of its members in the Athenæum at Manchester on Monday, Tuesday, and Wednesday this week, and in the evenings there were lantern displays, attended on each occasion by about 700 persons.

Among the photographs on view bromide prints were most numerous, perhaps aristotype ranked second in number, platinotype third, and ordinary silver prints fourth. Among the best exhibits are those of Mr. G. Wheeler, who has a screen to himself covered with views of Holland, and of scenes near Manchester; in the latter region he has detected, with an artistic eye, some pretty "bits" where nobody would expect to find them. Some views at Oberammergau by Mr. Lamond Howe, some of which he furnished to Mr. Stead, are interesting.

The Rev. H. J. Palmer had a great screen covered with enlargements, chiefly of Swiss views; he also exhibited photographs of French cathedrals. Mr. Palmer was formerly president of the Liverpool Amateur Photographic Association; he is now a vice-president of the Manchester Society. Miss Twist exhibited some excellent landscape photographs of small size, and by different processes. Mr. T. Glazebrook exhibited some good cloud subjects and fishing scenes; one of them represented a fisherman on the Wye, standing with his coracle on his back, and holding a fish in his hand; the title of the picture was, "What does it weigh?" Amongst Mr. H. Wade's exhibits was a sunset scene of an artistic nature; it was also exhibited on the screen on Tuesday night by means of the lantern, and warmly applauded by those present; he had taken the view with a hand-camera. Some autotype enlargements from quarter-plates by Mr. J. Davenport were of excellent quality.

Mr. J. W. Wade exhibited a platinotype print of "The Wounded Amazon," taken at the visit of the Photographic Convention last year to Eaton Hall; it had been printed by the cold process, and was of good quality; the same exhibitor placed on view a photograph of Chester Cathedral. Mr. G. A. Rigby exhibited some nice platinotypes, expecially Exeter Cathedral.

The following description of the Exhibition is from *The Manchester Guardian* of last Tuesday:—

The annual exhibition of work executed by members of the Amateur Photographic Society was opened to the public at the Athenæum last evening, and will remain open till Wednesday night. In photographic circles, an advertisement of a camera is well known in which occur the words, "You have only to press the button; we do the rest," the meaning of which is that the so-called photographer has only to hold or fix up his camera before a view or object, to "press the button," take out the plates when he returns home, send them to be developed to the place from whence they came, and in due time receive back a batch of negatives or spoiled plates as the case may be. If any of them be successful exposures, he may get a few beautifully printed and mounted specimens. Such button-pressers the Amateur Society, we are glad to say, does not acknowledge as photographers, and the work shown on its walls is not of this class, but is the genuine work of the person whose name it bears, except so far as the manufacture of the sensitive plates is concerned; nowadays, it may be said, no one makes these for himself. Enlargements are an exception to the general rule, and some of those shown are original only so far as the negative is concerned, the actual enlargement being made professionally; enlargement is, however, so much a mechanical matter that a picture may properly be spoken of as by the person who made the negative. The district round

Manchester has become a very much be-photographed one, and in many of the pictures shown we see, of necessity, the same places we have been accustomed to find at former exhibitions, and represented from very much the same positions. We may always know beforehand that Haddon will be to the fore, with Gawsworth a good second, and Miller's Dale, Alderley, and Marple not so far behind. This cannot be helped, but it is well that the midsummer holidays come to the rescue with a supply of less intimately known subjects.

Photographers are bimetallists, platinum and silver being their standards. The high price to which the former has advanced within the last few months may be one reason why fewer platinotypes are to be seen on the walls than usual. Another reason is the fact that an effect very much like that of platinum can be obtained by drying silver prints on a ground glass; indeed, so beautiful in detail and texture are many of the prints treated in this way that it is not to be wondered at that platinum is giving way, as also is bromide of silver, except for enlargements. Shiny surfaces, whether ordinary silver prints, or on Obernetter and other similar papers, continue to decrease in number, as it was foreseen some time since that they would do. That the ground glass plan worthily displaces bromide this exhibition abundantly proves; but if all operators could produce results in bromide equal to the screen of half-plate views shown here the case would be altered. It is difficult to see how better work could be done than this particular screen shows.

In an amateur exhibition of this kind it would be invidious to select special examples for commendation; as a whole the show is most excellent, and if we single out one or two special examples it is not because we feel that others are not equally to be admired. One exhibitor shows at the platform end of the room a very interesting set of 12 by 10 marine scenes, in which figures occupy a prominent place. This is certainly the most difficult branch of the art, and the exhibitor is to be congratulated on his success; some skies in the same series are also very excellent. A frame near the door fitted with the work of a lady is worth attention. Why ladies leave photography to men we could never quite make out. In many parts of the room will be found views that are the result of the "survey" undertaken by the Society, some of which show how necessary it is that such a scheme should be carried out. Among other buildings whose place shall know them no more is the Hyde Road prison, which is shown in six or eight capital views. Most of the enlargements are bromides, and some of them are as good as anything of the kind could well be—one of Fountains Abbey on the wall opposite the door, for example, and also some lake views at the head of the room. The few enlargements by the Autotype Company excel the others in richness; among them is a capital one by the President of the Society which, from a negative of $4\frac{1}{4}$ by $3\frac{1}{4}$, has stood enlargement up to 20 by 16. The only novelty in the room is shown in two bromide prints toned to a fine sepia brown by uranium; there is also a "cyanotype," or Prussian-blue print, as it is generally called, of Haddon, which is made into a moonlight scene by putting a moon up in the sky, and with not altogether an unpleasant effect.

The miscellaneous lantern slides by the members were shown last evening by Mr. J. Davenport, the president of the Society. The Rev. H. J. Palmer and Dr. Hamilton will exhibit a series this evening, and on Wednesday Messrs. J. W. Wade and J. Davenport will show a series under the title of "Holiday Rambles." These have been taken by members by means of hand-cameras; that is, by cameras held in the hand at the time of exposure. For the lantern exhibitions a fine "three-decker" lantern, well known to Manchester photographers, which has become the property of the Society, will be used.

The photographs on view were exclusively the work of the members, and all taken during the past year; it is a regulation of the Society that none of the pictures shall have been publicly exhibited before. All the photographs it is possible to accept are put upon the walls, that those who do inferior work may see how it looks alongside good work. This is found to produce a marvellous improvement in the general character of the exhibits the following year.

### The Lantern Displays at the Exhibition.

On Monday night local and other views, the work of the members, were exhibited in large number by means of a costly triple magic lantern, the property of the Society.

On Tuesday night, the Rev. H. J. Palmer, M.A., and Mr. A. Hamilton, M.D., exhibited a series of interesting views of the Rhone Valley district, and some of its lateral valleys. Mr. Palmer pictorially traversed the Simplon pass from Brieg to the Gorge of Gondo, and gave some excellent representations of the magnificent scenery. Next he gave the journey from Brieg up to Bell-Alp and the Aletsch glacier, but did not include the house there of Professor Tyndall. He next gave some leading features of the scenery from Visp and through Zermatt to the Gorner Grat; these included many excellent views of the Matterhorn. One series of the scenes had been taken in duplicate: a narrow-angle lens had been used in the one series, and a wide-angle lens in the other; those taken with the narrow-angle lens were much the better, as there was less dwarfing of distant mountains. Mr. Palmer was in the Rhone Valley in the hot season, when it is not pleasant. He described Visp as a malarious, unpleasant place, and told how, when panting for air one night, he opened the window of his bedroom, and in came a cloud of mosquitoes. He should first have extinguished the light. He stated how the people up the valley object to the railway, and said that he did not know why. The reason is, that the residents think that it will ruin Visp and places between Visp and Zermatt, for tourists will go straight to Zermatt, and require no horses, conveyances, or intermediate hotel accommodation. The "King of Zermatt," the chief hotel-keeper there, is also said not to like the new railway. The Swiss Government has overruled a variety of petty local interests, and the railway is now nearly finished.

Last Wednesday night, Mr. J. Davenport and Mr. J. W. Wade exhibited some lantern views illustrating holiday rambles and hand-camera work; among these were some by Mr. Wade of the pantomime of Cinderella, taken before and behind the scenes at the Comedy Theatre, Manchester. Those behind the scenes were taken by the aid of the flash-light; those taken in front were of scenes much illuminated by the lime and other lights, and with an exposure of half a minute; the lens had a stop with large aperture. The time seized for making the exposure was when one person was either singing or dancing, and all the others were still; Mr. Wade would then wave his handkerchief as a signal to the latter to keep quite still while he made the exposure; the one person dancing about the stage made no impression on the plate. Thus were theatrical views taken during public performances, without many of the observers present knowing that any photographing was going on; some of the views included a hundred figures. Mr. Wade is a vice-president of the Society.

### The Manchester Amateur Photographic Society.

The Manchester Amateur Photographic Society was founded five years ago, and, at the present time, has nearly four hundred members; twenty-three have been nominated for election at the next meeting. It is the largest photographic society in this country outside

London. Its president is Mr. J. Davenport, and its honorary secretary Mr. R. O. Gilmore, 1b, Cooper Street, Manchester. The Society has a new dark room, well fitted up, at 14, Ridgefield Street, Manchester; the carpenters who are making the lockers therein, the plumbers who are fitting up the sinks, and various other men employed, are all amateur photographers. The Society has a library of between 300 and 400 volumes, which will be stored in the developing room when the latter is finished. Some good enlarging apparatus is placed in this room for the use of the members, who appreciate it by making frequent use thereof. Development is performed in this room by means of variable daylight and a coloured screen. This a mistake; artificial light would be better. See the last Year-Book.

### The Manchester Camera Club.

This organisation was founded six years ago as a social club, limited to twenty-five members; since then the limit has been extended to fifty members. It has no managing body, and no officers but a treasurer and a secretary; the latter is Mr. J. Davenport, 6, John Dalton Street, Manchester, who holds office *pro tem.*; a new one will shortly be appointed. The meetings of the Club are held on the third Wednesday evening of each month at the Victoria Hotel, Manchester; a chairman for the evening is elected from among those present, and no proceedings are published. Most of the members are able photographers. They have "rambles" during the summer months, and each time there is a competition among the members. The taker of the best negative is presented by the Club with an autotype enlargement therefrom.

### The Manchester Photographic Society.

Last, but not least, of the three photographic organisations in Manchester, is the oldest of all of them, the Manchester Photographic Society, founded in 1850. In its earlier years it somewhat frequently shifted its abode, but is now settled in the Literary and Philosophical Institute, 36, George Street, Manchester, and has Mr. Alan Garnett for its president. Sir Henry Roscoe, M.P., was its president for three years; his time of office expired last year, and he is now one of the honorary members. The hon. sectretary is Mr. W. H. Farrow, of the City Surveyor's department, Town Hall, Manchester. Mr. W. I. Chadwick once held the office of hon. secretary to the Society for twelve or more years. At the present time the Manchester Photographic Society possesses about 140 members. It holds monthly meetings, also lantern meetings in the winter months. The library is well furnished with early and other works of historical and scientific interest on photography; the librarian is Mr. J. Schofield. The Society possesses apparatus of its own, and has an optical lantern in course of construction. In accordance with ancient custom, the meetings are preceded by a high tea among the members; this is found to soften asperities, and to get those present into a happy and sociable state of mind. The Society had an exhibition of the work of its members about a year ago.

---

*L'Amateur Photographe* appears this year with several improvements, including a new design on the cover. Its address is 24, Boulevard St. Germain, Paris.

Developers.—It must be clearly understood that, in our opinion, hydroquinone is somewhat inferior to ferrous oxalate as a developer for papers, and that to produce the best results on these the latter developer is necessary.—*Scraps.*

## THE DINNER OF THE PHOTOGRAPHIC SOCIETY.

Last Monday night the annual dinner of the Photographic Society took place at the Café Royal, London, Mr. James Glaisher, F.R.S., president, in the chair.

The President, at the close of the festivities, proposed "Success to the Photographic Society," coupled with the name of Captain Abney. He thought photography to be a blessing to mankind, for it had enabled even the poorest to obtain the likeness of members of their families as treasured memorials.

Capt. W. de W. Abney would rather do six hours' experimenting than six minutes' speaking. Papers at photographic societies should not be valued by their length, for the results of one which required experimenting for mouths, could sometimes be summarised on a sheet of foolscap. The interests of the Society had been much promoted by the work of its treasurer, Mr. Bird.

The President proposed "Prosperity and Success to other Photographic Societies," coupled with the name of Mr. Warnerke.

Mr. Leon Warnerke stated that, some years ago, their Photographic Society was the only one prospering in Europe; now, however, there are photographic societies in Berlin and elsewhere in flourishing condition. Next summer the Photographic Society will be represented at the International Photographic Congress in Brussels; he expected that there would be a large attendance, and that good work would be done.

The President next proposed "Success to Chinese Photography," coupled with the name of Mr. T. Chang. He should like to hear a few remarks from him in Chinese.

Mr. T. Chang, secretary to the Chinese Embassy, said:—"I thank you for the houour you have conferred upon me by so kindly proposing my health. I can truly say I am very pleased to be with you. This is the second time that I have had the pleasure of attending the annual dinner, and I hope to have this pleasure on many future occasions. As to our president's wishing me to say something in Chinese, I am rather nervous in speaking my own language amongst you, who cannot understand what I might say, so I prefer returning my thanks in English. I thank you again, Mr. Chairman, for your kindness."

Dr. Charters-White responded to the toast of "The Ladies," and Mr. W. H. Harrison to that of "The Photographic Press."

Captain Abney proposed "The President." He had known him for twenty years, and it had always been a great pleasure to serve with him on the Couucil of the Photographic Society; his heart was in the right place, and he hoped that he would long be their president, notwithstanding new rules. He had piloted the Society through many difficulties, and guided it into its present position.

The President, in his reply, said that he had always done his duty to the best of his ability.

The President next proposed the "Officers of the Society," coupled with the names of Captain Mantell and Mr. Bird.

Mr. W. S. Bird thought that the happiness of the present century had been much increased by the fact that photography had so much facilitated the easy obtaining of likenesses, which were disseminated by friends throughout all the world. Photography had done a great work in science; it had made new revelations in astronomy and microscopy, and it had progressed in its artistic features. Whatever a certain doctor might say, he thought that he never bore any malice, and that the photographic world would soon hear of the doctor again.

Mr. Sebastian Davis then took the chair, and proposed the health of Mr. William England, who had made all the arrangements connected with that social meeting.

Mr. William England spoke of his great interest in the success of the Photographic Society.

Various songs and recitations were then given; a song by Leistein, of Sweden, was much appreciated.

---

A Costly Gift.—During Sir H. D. Wolff's illness in Teheran, the Shah paid him every attention, and before he left he presented him with his photograph, handsomely framed with diamonds set in gold. The gift is of splendid workmanship, and is estimated to have cost not less than £2,000.

## NOTES FROM INDIA.

BY COLONEL J. WATERHOUSE, B.S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

### Preservation of Eikonogen.

Professor W. K. Burton's paper on this subject, in the latest number of the *Journal of the Photographic Society of India*, is very interesting and valuable, especially as he seems to have found a satisfactory solution of a problem on which I have been working, more or less intermittently, for some time past. I have not yet tried the method he recommends for washing the eikonogen crystals, and then keeping them in a twelve per cent. solution of sodium sulphite, but, from my experience in the same direction, I have no doubt that it will answer well; the sulphite, however, must be good, and not alkaline. From recent notices in the European journals, it appears that the German manufacturers of eikonogen have succeeded in making a product that does not darken or decompose with heat and moisture, and it is said that this is brought about by the addition of a bisulphite. The new product is a white powder, and is most probably thoroughly desiccated, so as to drive off the water of crystallisation, to which may, in great part, be attributed the darkening of the eikonogen crystals. In dry air at a low temperature they keep well, but in moist air at a high temperature, as is the case here and in most tropical countries, they rapidly get into a moist, pasty state, darken, and decompose. Some eikonogen of English manufacture lately received is in salmon or pink granite coloured crystals, and, so far, it shows no sign of discolouring, but whether it will stand the quickly approaching hot weather remains to be seen.

Although Professor Burton has succeeded with the treatment with alcohol I suggested in a former number of the News, I find that it does not answer so well as I expected it would. Some crystals that had been cleaned with an acid solution of sodium sulphite, much in the same way as recommended by Professor Burton, remained white for a very long time in spirit of wine; but some fresh crystals put into absolute alcohol did not keep nearly so well, and the alcohol has extracted a good deal of a yellow substance. As Professor Burton remarks, in order to make the treatment by alcohol efficient, the spirit must be changed two or three times, as it draws out and becomes weakened by the water of crystallisation from the crystals. Precipitation of the eikonogen by acids has also been recommended as a means of keeping it in good order. I have tried several acids in a cursory way without quite satisfactory results. Phosphoric acid seemed to have a powerful action in keeping the solution free from darkening. Eikonogen is such a valuable developer, and so pleasant to work with, that so satisfactory and simple a means of keeping it in good order in tropical climates as that recommended by Professor Burton is very welcome.

It may be noted, with reference to the use of the dark-coloured washings of the eikonogen crystals as an ink, that, although it does make an admirable writing fluid, it is so easily washed off the paper that it is quite unsuitable to serve as an ink to be used for any permanent record.

### Thio-Carbamide Reversals.

Since the warm weather in September and October, I have not been able to make much progress in working out the direct positive process till lately. However, on taking it up in cooler weather, it was found that better results were more easily obtained, and some new experiments seem to have brought me almost within reach of a practical method, though much has yet to be done in working it out and perfecting it, so as to obtain perfect positive pictures with certainty.

The principal difficulty all through has been to secure clear lights with good detail in the shadows. If the high-lights are clear, the shadows are too deep; and if the shadows are clear and well detailed, the high-lights are liable to be over-done and unreversed. This is particularly the case in outdoor work with sky and trees, or dark foregrounds. It was evident that something was wanted which would more completely reconvert the reduced silver in the more exposed parts into silver haloid salt, so that it might be dissolved out by the fixing agent. This, I found, could partly be secured by prolonging the development, and allowing the reversing agent plenty of time to act and complete the reversal. The image thus produced may be too dense for printing purposes, but can be reduced, after fixing, with bromide or chloride of copper, so as to gradually bring down the lights and details till they are sufficiently clear, though the operation has to be conducted with some care to avoid uneven reduction. A preliminary treatment of the plate with dilute hydrobromic acid was tried, but was not found better than the dilute nitric acid, previously used with advantage.

In a leading article on the process which appeared in the *British Journal of Photography* for October 24th, attention was drawn to a curious compound of thio-carbamide and ammonium bromide, which was first described by Prof. J. Emerson Reynolds in a paper published in the *Journal of the Chemical Society of London* for 1888, and to which he gave the name tetrathiocarbamid-ammoniumbromide. This salt is quite easily prepared from thio-carbamide, and a trial of it has given me some very good results, better in many respects than those obtained with other thio-carbamides, and it acted in every way much better than the plain thio-carbamide.

Prof. Reynolds' instructions for preparing the new salt are to dissolve 1 part of ammonium bromide in as small a quantity of alcohol as possible, and add it to a nearly-saturated boiling solution in alcohol of 3·04 parts of pure thio-carbamide. The boiling is continued for some time afterwards, and then the flask is allowed to cool. On standing, the contents will be found to set into a mass at the bottom, and may be re-dissolved in alcohol for use. I find that about five drops of the strong alcoholic solution of this salt to the ounce of developer are sufficient, but in some cases more may be added during the development. It is important that the alcohol should be strong, because water decomposes the salt. In making up some of the salt, a little water found its way into the flask, and the product so obtained seems to work quite differently to the proper compound salt.

It is remarkable with what very short exposures strong, vigorous positives can be obtained by the addition of only a few drops of the solution of this salt to the eikonogen developer. In a case where the ordinary exposure with pyro development would have been from sixty to ninety seconds, ten seconds was found to be more than sufficient, and the exposure was actually reduced to two seconds. This enormous shortening of exposure points to what may eventually be one of the most valuable applications of this curious process, and that is to astronomical photography. Already, by the use of gelatine dry plates, the photographing of stars, nebulæ, and other heavenly bodies has been greatly facilitated, and made to render thoroughly practical service by the shortening of the long exposures necessary with even the most sensitive wet or dry collodion plates. By a still farther large reduction in the time of exposure, much more could no doubt be done. The long hours of patient attendance at the photo-telescope finder could be saved, and plates would be obtained which could at once be transferred to copper to be etched and printed. The new process may also prove useful in spectrum photography.

Prof. Reynolds has found that thio-sinamine and phenyl-thio-carbamide do not form similar compound salts with ammonium bromide; but I have tried some other bromo-compounds of these thio-carbamides, and find that a mixture of bromine and thio-sinamine promises well, and gives rich, vigorous images, with good, clear lights and well detailed shadows. I have prepared it by adding bromine water to a saturated solution of thio-sinamine, about equal parts. After a time the solution turns slightly opalescent and cloudy, probably from the precipitation of sulphur.

Dr. G. McGowan has found that excess of bromine causes thio-carbamide to lose its sulphur, and become converted into carbamide (*Journ. Chem. Soc. Lond.*, 1887).

I have lately been working with a form of developer which seems to act satisfactorily in the reversing process, and is simple: —

| | | | |
|---|---|---|---|
| Eikonogen ... ... | ... 5 grains | or 1 | gramme |
| Sodium sulphite ... | ... 5 ,, | 1 | ,, |
| Lithium carbonate ... | ... 5 ,, | 1 | ,, |
| Water ... ... | ... 1 ounce | 100 | c.c. |

The carbonate of lithia is kept in saturated solution at about one per cent., and the other salts are dissolved in it as required. A paper on lithia and borax developers has been long in hand, and should have appeared some time ago, but I hope to give it in an early number of the News.

As both thio-sinamine and thio-carbamide can quite easily be prepared, a few notes on their preparation, from experience, may be useful to anyone wishing to try the method, and unable to obtain them in commerce.

*To make Thoi-Sinamine.*—Procure some *essential oil* of mustard from the chemists; the *pure* mustard oil is best, but not easily procurable. The common oil contains resinous impurities which are very hard to separate out without re-distillation, which is a troublesome process, though they do not seem to interfere with the reversals. Care must be taken in handling this oil, because it gives off unpleasant, strong-smelling vapours, which are very irritating to the eyes. Having put some of the oil—say two drachms—into a stoppered bottle, add to it about four to six times its volume of the strongest solution of ammonia—one to one and a-half ounce—and leave it for some hours till the oil has been converted into crystals of thio-sinamine, or taken up as much of the ammonia as it will. The conversion may be hastened by shaking the bottle from time to time; but if the oil is impure, it seems better to allow the ammonia to act quietly, and not take up the impurities. The solution is then poured into an open vessel, in order to allow the ammonia to evaporate. This must be done out of doors, or in an open place, because the smell is very penetrating and unpleasant. The solution may, if necessary, then be filtered and evaporated down, and left to crystallise. Re-crystallisation once or twice will be necessary if the impure oil has been used, and the crystals can be kept or made into solution, as desired. The pure crystals are white and inodorous. Impure crystals may be yellowish and have a slight smell.

The preparation of thio-carbamide was first described by the discoverer, Prof. J. E. Reynolds, in the *Journal of the Chemical Society of London* for 1869. A quantity of sulphocyanide of ammonium is thoroughly dried till it becomes white and almost powdery. When fairly dry, it may be pounded up and the drying completed. It is then put into a flask, and heated in an oil bath *gradually* to about 170° C. (338° Fah.), and kept at that temperature for about two hours, the temperature being regulated by a thermometer introduced into the flask. The sulphocyanide melts and gives off vapours, and is gradually transformed into thio-carbamide (sulpho-urea). After sufficient melting, the flask is allowed to cool down to boiling point, and a little hot distilled water (80° C. or 176° F.) introduced; the hot solution is rapidly filtered and allowed to crystallise. The crystals always hold a large quantity of unconverted sulphocyanide, which may be removed by recrystallisation, and, to a great extent, by draining out, especially in damp weather, the thio-carbamide crystals being permanent, while the sulphocyanide is deliquescent. Pure thio-carbamide gives no red colour with a persalt of iron, but it is difficult to get rid of all traces of the sulphocyanide. The crystals take many different forms, partly depending on their purity and other conditions. Sometimes they are in very short, fine needles, at others in long needles, or in long, glistening, fibrous, radiating wisps like asbestos or spun glass, or again in prisms; the latter form seems to be the purest.

Besides the application to astronomical and spectrum photography already noticed, the new process, if it can be successfully worked in ordinary practice, might prove of use for portraiture in the studio, especially in dull weather, or, under other circumstances, when shortening of exposure might be of advantage.

It might also prove of use to itinerant photographers, who could thus be able to take transparent positive portraits which could easily be framed in the style of the sixpenny ferrotypes, and delivered, if not on the spot, at any rate in the course of an hour or two, allowing time for washing after fixing. Another application might be to the penny-in-the-slot apparatus, though here, again, time would be required for washing away the fixing agent. For reversed negatives and lantern slides, it may also be found useful, as well as for a great deal of amateur work in which a single positive transparency might really be more useful and better worth keeping than a negative. Its possible adaptation to the new diazotype process has already been suggested in the News, and from rough trials I have made would, I believe, answer well.

Wratten's "ordinary" plates still continue to give me the best results, and the fresher they are the better. There are, no doubt, however, other brands which might work with more certainty. The great difficulty is to get rid of the first developed negative image; and, if obtainable, something is required which will develop up the positive image at once. From some of the results lately obtained with Prof. Reynolds's compound salt, I believe that the process is capable of giving perfect transparencies with suitable plates; but in this country one works under very great disadvantages and limitations caused by want of leisure, unfavourable conditions of climate, and distance from European commercial centres, so I hope that the process may be tried elsewhere with various makes of plates, and the results reported.

## JEAN LOUIS ERNEST MEISSONIER.

BY THE REV. F. C. LAMBERT, M.A.

On the last day of last month the art world lost, in the death of M. Meissonier, a man whose name will always be regarded as an essential element in the art history of the present century. Meissonier was born, the son of humble parents, at Lyons, Feb. 21st, 1811. At the age of seventeen he came to Paris to study under Léon Cognite. Five years later, his first work, "The Visit to the Burgomaster," made its appearance at the Sâlon, followed the next year by his "Joueur d'Echecs," which at once established the painter as a master in *genre*. From that time a stream of works flowed from his hand, and medals, ribbons, and other honours and distinctions were showered upon him. Perhaps the most famous of his works are the Napoleonic series showing the great soldier at various stages of his wonderful career—*i.e.*, 1805, 1807, and 1814. It is said that the '14 was sold to M. Chauchard for 850,000 fr. It is interesting to know that Her Majesty, Queen Victoria, is in possession of one of M. Meissonier's finest works. By many competent authorities, "Le Rixe" is pronounced the master's *chef d'œuvre*.

In appearance, Meissonier was short of stature, somewhat stern in feature, hair and beard long and flowing. Among his hobbies were billiards and riding.

To a great extent it is true that, in his work, he *made*, rather than followed, a school. Waging a long war against the accepted methods of classicism, and crashing through the dogmas of the academies, he devoted his long life and undoubted talents to transferring nature to his canvas, relying on the keenest power of observation and an unrivalled technique. Those who deny the existence of any great poetry in his work assert that his abnormal—almost microscopic—eyesight enabled him to see what was to others quite invisible; and maintain that while he surpassed the Dutch in "niggling," he yet lacked their power of *chiaroscuro* and general manipulation. On the other hand, there are quite as many who heartily subscribe to the criticism of Eugène Delacroix, wherein it is asserted that Meissonier was the most incontestable master of our epoch.

Thus among painters, as among photographers, there are the pinhole, big-brush, palette-knife men, and also the *f* 64, fine-point, Meissonier-finish contingent; each anathematising the other. Who shall be bold enough to predict the "sole survivor of the crew" hereafter? Is it not better to seek the *via tuta, via media?* To attempt to treat all cases alike, to cure all complaints with medicine out of one and the same bottle, is to call up the unpleasant nursery reminiscence of the infallible brimstone—with or without the treacle.

Corot, Millet, Bastien Lepage, and others have come and gone during Meissonier's four-score years. Each in turn had discovered the only way—the philosopher's stone wherewith to touch his canvas—and now Meissonier's hand will no longer hold the brush. Of all men whose names are most likely to become welded into the history of art, none will be so closely linked to photography as that of the Lyons master, for the very simple reason that probably no other hand ever had that dexterity and cunning for reproducing on his canvas what most closely resembles that marvel of modern science, a well-focussed image on the ground glass. This man, who saw the birth and growth of photography, with all its possible wealth of detail-drawing, has been for years working in a more or less parallel line, and, although he has had a countless herd of followers, yet never a competitor.

One may safely prophesy that photographers will always include in their ranks a large number of workers who revel in the boundless ocean of detail attainable by optical means, and to them Meissonier will stand forward, not only as a justification, but also as a master for whom they have the most unfeigned admiration. Thus, his illustrious name will have for many photographers a degree of interest which, in all human probability, is likely to remain unique—at any rate, until the photographers' millennium—in other words, the discovery of photography in natural colours. However much men may disagree as to the rightness or wrongness of Meissonier's method of work, yet all must substantially agree that he was *facile princeps* in the method which he selected; and none have approached him in his power of truthful accuracy in portraying what is seeable.

P.S.—There is a melancholy interest attaching to a work of M. Meissonier now on view at Messrs. Tooth's Galleries, seeing that it is the last work from the master's easel. It is a water-colour drawing of small size, and entitled "Quiet Moments." The subject is a young gentleman in picturesque seventeenth century costume standing near a white marble pillar. He seems immersed in pleasant memories; the ungloved hands are idly, yet gracefully disposed. The background is a rich tinted, antique tapestry. The whole work is eminently characteristic of the master's wonderful powers, both in wealth of finish, and the rainbow purity and harmony of colour.

### The Barbizon School.

Messrs. McLean have now on view, at their Galleries in the Haymarket, a most interesting collection of pictures, few in number, but all fine examples. Among them is a small Meissonier, date 1864, and valued at not less than £2,000. The subject is an officer on horseback riding along an open road, the daylight declining—and the whole in a quiet and sombre key. The other pictures are, in themselves, a little epitome of the Barbizon school, and include several paintings by Diaz (No. 9 is a masterpiece), Corot, Jacque, Daubigny, and others of the open air workers. Probably No. 17, "The Hay Cart," is the finest and fullest work of Troyon's, and that picture alone is well worth a journey to the Gallery. The sheep in No. 25 (Jacque) are probably the woolliest and most sheep-like ever put upon canvas; this is also a masterpiece. There is a picture by L. B. Hurt, which most people immediately assign to Peter Graham, and not far from it is a small painting by that last-named artist, which is simply splendid in the way the clouds are treated. The collection also includes work by H. W. B. Davis, James Orrock, Vicat Cole, J. W. Waterhouse, and others.

---

The Vienna Photographic Exhibition.—It would seem from indications thus far, that the United States will be well represented at the forthcoming exhibition in Vienna. It is advised that prints be sent unframed, but mounted, and each print larger than $3\frac{1}{4}$ by $4\frac{1}{4}$ must be mounted separately. Exhibits may be sent to Mr. C. F. Eckhardt, 32, Aldermanbury, London, E.C., or to the Committee of the Vienna International Exhibition, at the Imperial and Royal Museum of Arts and Manufactures, Vienna. Applications for admission must be in Vienna by February 1st, addressed to Mr. Carl Srna, Club of Amateur Photographers of Vienna, Wallfischgasse 4, Vienna, Austria. The New York Camera Club expects to have a good representation, and it is to be hoped that other clubs will fall into line at once.—*Anthony's Bulletin.*

## Notes.

An ingenious individual made a calculation the other day which should be interesting to carbon workers, as indicating that they never need be in want of one of the first necessaries in their work. It must have been obvious to all during the recent arctic weather, when the snow was lying unmelted for weeks upon the ground, that the surface of that snow became blacker and blacker each day until it was difficult to imagiue that it had ever been white. The ingenious one referred to took the trouble to collect the black surface of this snow for a space of eight inches square, and, after drying the product, he weighed it, and found that he had obtained just two grains of carbon. This quantity certainly would not go far towards the production of a carbon enlargement. But our experimenter was also given to statistics, and knowing the extent of the metropolitan area, and assuming that the same quantity of smut fell upon each part of it impartially, he was able to arrive at the astounding conclusion that one thousand tons of soot had deposited itself upon that area in about ten days. Economists ought now to call upon carbon workers to lower their prices.

---

We now know, if we did not know it before, where our black London fogs come from, by which photographers lose much more than they would gain if the heavens rained chemicals of greater value than carbon. It is difficult to point to any cure for these disastrous occurrences, so long as the open fire is maintained as one of the Englishman's most cherished rights. Perhaps some day electricity will give us a better and cleaner method of obtaining heat for our houses. In the meantime, advances are being made in the construction of effective gas stoves, and the increasing adoption of these will, at any rate, mitigate the nuisance to a certain degree. It is melancholy, but to some extent amusing, to note that every year, so surely as the fogs come round, the same abortive remedies for dealing with them are trotted out. Smoke abatement forms at these times the subject of innumerable newspaper articles, stoves which consume their own smoke are invented, lauded to the skies, and as soon forgotten. Perhaps the spring-time makes us all so light-hearted that we forgot too soon the dark days of the metropolitan winter.

---

Eikonogen is a developer which has, since its comparatively recent introduction, met with many admirers, both among professional and amateur workers. It is undoubtedly valuable in bringing out detail in negatives which have received a short exposure, or which have been taken in dark places. For portraiture it gives a delicacy and colour to the negative which are appreciated by both priuters and retouchers, hence it is used exclusively in some of the first studios. Eikonogeu has recently made its appearance in a new form—that is to say, it is made up into "cartridges." These each hold enough of the developer proper, together with sodic sulphite, to meet the demands of half-a-dozen average sized plates. For tourist photographers and travellers—the terms are really interchangeable, for all travellers carry a camera now-a-days—these "cartridges will be found most convenient, for they only require admixture with a given quantity of water to be ready for use. Most tourists prefer to leave development of their plates until they are home again, and surrounded by the conveniences of their dark rooms; but most of them know the advantages of trying a plate or two *en route*, and eikonogen in its new dress will help them to do so without the encumbrance of bottles among their luggage.

---

A method devised by Messrs. Lumière, the well-known manufacturers of photographic plates, of obtaining micrographic projections which will throw up, by a different colouring from that of the background, the interesting parts of the pictnre without using hand-painting, is described in *La Nature*. A gelatine proof is first made in colouring material. The printing and development are conducted in the same manner as recommended for all carbon papers, but so managed that the proof shall be very faint, hardly visible. To obtain the colouring, the watery solutions of colours employed iu micrography—violet and blue, magenta and red—are used. The solution is poured on the picture, and the gelatine is penetrated in a few seconds, the background remaiuing lighter than the picture, which takes a vivid tint identical to that of the microscopical preparation if the tiuting has been carefully chosen. When the colouring is too intense, it must be abundantly washed in water, and the discolouring will slowly and effectually take place. Iu certain cases alcohol may be used.

---

It is also possible to obtain double colourings, as in microscopical preparations. In a microbe preparation, for instance, the microbe is frequently coloured in red, and the background blue. To secure this result, the gelatine print is first of all treated with an intense red tinting, but one which is not affected by the subsequent discolouration. A proof is thus obtained coloured entirely in red, the microbe being of a dark red, and the background of a light red. The discolouring is then gone on with until the background loses its tint. It may be treated then with the colouring which one wishes to give it, a faint solution being employed. The editor of *La Nature* says that a series of projections of microbes made by Messrs. Lumière, when projected on the screen, showed very well that the positives obtained by this method produce an effect superior to that of proofs in black obtained by the ordinary process.

---

Old-fashioned people will probably ridicule the notion that it is possible to know when the planet Mars is visited by a snow-storm. This attribute of winter is, however, the latest news from the planet in question. Prof. Pickering has lately taken fourteen photographs of Mars on two successive days. On the second day the photographs revealed the fact that the southern polar white spot was much larger than on the first day. In the first day's photographs the spot was dimly marked, as if veiled by fog or by particles too small to be represented separately; but on the second day the region was brilliantly white. The date of the event corresponded with the end of the southern winter of Mars, or with the middle of our February; and Prof. Pickering attributes the appearance itself to the effect of a snow-storm.

---

Great disappointment has been caused by the refusal of the New York Circuit Court to grant a motion for an injunction upon dealers in the pirated edition of the "Encyclopædia Britanuica." This piracy, it will be remembered, was committed with the assistance of photography. A firm in New York secured au early copy of the "Encyclopædia," and had the pages photographed, and was thus able to produce a *fac simile* at a much lower price than the original could be sold at. It certainly does seem a monstrous thing that English and American publishers cannot agree upon a common ground by which their interests will be mutually protected.

---

It is to be hoped, for the sake of cartoonists and the general public, that Lord Randolph Churchill will devote a few hours to sitting to an enterprising photographer. He has returned to his seat in the House wholly unrecognisable by his friends. The characteristic moustache, which was of such iufinite value to the caricaturist, has now the accompaniment of a beard, and the consequence is that, unless the public get familiar with his present appearance, the comic papers will be unable to use his lordship as a vehicle for their fun. Lord Randolph appears to be following the example of Mr. Parnell, who, some five or six years ago, was perpetually changing his appearance.

---

The Spectacle Makers' Company contemplates an exhibition of spectacles in the City. No doubt an exhibition of this kind would contain a great number of quaint specimens of ancient mauufacture, but the scope seems rather limited. At a dinner of the Company, held recently, a member suggested that the exhibition should be extended so as to include optical and scientific instruments. He contended, and with great reason, that an exhibition of spectacles only would not do, because it would simply be a display by foreign manufacturers and commission agents in the city. Of all the branches of the optician's art that of the manufacture of photographic lenses must now be considered to take the first place, both in variety and in novelty. It is rather strange, considering that just now photography is supposed to be the object of attention in city circles, no mentiou of this fact should have been made at the dinner in question. We are afraid that the Spectacle Makers' Company, like nearly all the other companies, is chiefly composed of persons who know less about the handicraft of their own Company than most people. We do not kuow that auy decision has been come to respecting the forthcoming exhibition, and we would suggest, if it should go outside spectacles, that a splendid opportunity would be afforded for showing the world what has been done in the way of improvements in photographic lenses.

---

Our police, probably, have neither the education nor the taste for science which would render the system of identification of criminals by means of measurement successful. The matter has engaged the attention of the Home Secretary, who, in reply to a question put to him this week, said there were various objections to the introduction into this country of the system. What these objections were he did not state, but we fancy that they would originate with the police authorities. At the preseut moment the Commissioner of Police thinks that, under the present system of photographing prisoners, there is, altogether, a greater percentage of identifications than the French system affords. This may be so, but the question is whether the two systems cannot be tried together. If the present method of photographing the prisoners is really superior to the measurement system, the latter must be very defective, as the photographs usually taken in goals are not the very best specimens either of scientific or artistic work. But, of course, there are exceptions, such as those taken by Mr. Payne in Aylesbury Gaol.

---

The extraordinary rise in the price of platinum has caused iuconvenience in quarters other than where platinotype paper is manufactured. An optician is now waiting trial at the Central Criminal Court for having feloniously received about ninety-nine ounces of platinum, valued at £350. The prisoner called on Messrs. Johnson and Mathey, who probably are the largest consumers of platinum in the world, and asked them if they would buy a quantity of platinum he had for sale. Messrs. Johnson and Mathey had a sample analysed, and found in it traces of phosphoric acid. This was sufficient to tell these experienced chemists the origin of the platinum. It had, in fact, been in the form of "dishes" used in the manufacture of chemicals of which phosphoric acid forms a part. It was subsequently discovered that Messrs. Johnson and Mathey were right in their conjectures, for the platinum had been stolen from the premises of Messrs. Dunn and Co., chemical manufacturers, of West Ham. Had not the demand for this metal increased so enormously during the past two years, it probably would not have been worth anyone's while to run the risk which the prisoner in question has incurred.

---

Judging from a story in the *Chicago Mail*, it appears to be the fashion in the United States for young ladies to have their letters photographed, so that, in case of the originals being destroyed, or the ink fading, they have tangible evidence to go upon should the swain prove faithless. This shows an amount of shrewdness and caution to which, at present, our English damsels have not yet attained.

## HOW TO MANAGE THE LITTLE ONES.

BY J. M. BRAINERD.

In the treatment of children under the skylight, it must be remembered that they have very sensitive feelings, which are shocked by the immodest staring-at often given them by strangers, who thoughtlessly overwhelm them with familiarity. They cannot be introduced by formal phrase, and put at ease like a society belle. Who has not observed the pain depicted on the face of a retiring child caused by people who, desiring to show their love, shower on it well-meaning but tactless attention?

Preparations for photographing children should begin with a cordial reception of the mother, which assures her of your confidence in your ability successfully to take babies in general, and your pleasure in photographing her darling child in particular.

Sometimes several friends and relatives come along to help. As I am looking after future business, if they desire, they are allowed to enter the operating room, and gratify their curiosity while the accessories are being brought into position.

The mother is asked to be seated near where the child is to be posed. After a general focus has been made on the accessories, and I am about ready to turn my attention to the child, the rest of the party, except the mother, are politely requested to retire to the reception room. This part should never be omitted.

The next necessity is to instruct the mother in what is expected of her, assure her that she need have no anxiety about the child keeping still, that she is not to ask it to sit still, or to entertain it, but that you will do it as well as the posing, that she is to remain solely for company, that the quieter she keeps the easier it will be to get a good picture. Half the difficulties can be avoided by a few words of explanation. The mother, in her anxiety for the child to sit well and cause no trouble, will only increase it if allowed to help; but if she realises the principle involved, that the child's mind must be given up to the control of the mind of the photographer, she will usually keep quiet, though I have met some that could not.

I carefully avoid allowing the child, if bashful, seeing me looking at it, or think I am making any effort to entertain or get acquainted with it.

Close by the skylight is a cupboard well filled with toy cats, birds, dogs, dolls, bells, gay ribbon belled sticks, horses in hoops that can be rolled about the floor, also cloth elephants, monkeys, and jumping-jacks, besides what is called a "trick-with-a-hole-in-it." This is simply a 14 by 17 cardboard, six inch circular opening cut out of the centre; it is for "Peek-a-Boo" at short range. This always hangs outside the cupboard, and is the little joker that takes the most unpromising child with its most angelic expression.

I do not use all the toys at once. Girls are always interested in dolls; small ones can frequently be used in the picture to good advantage, as they hold them with a naturalness and grace born with their motherly instincts.

Boys like horses, dogs, and monkeys. It is unsafe to promise boys you will show them something unless you have the goods to fulfil. One day, after trying to take a three-year-old, and telling him about the monkey I was going to show him, but deferring it so long that he doubted me, he said, "You havn't got any monkey but yourself."

An excellent thing to put a group of children in a good humour is the jumping dog that is worked by a bulb and rubber tube.

These toys are only the embellishments that serve to illustrate the old stories about the bird or the three little kittens, as it is through the child's imagination and curiosity that we enchain the restless hands and lips.

Sometimes children are so much interested that they look with wide-open mouths, or, owing to the difficulty in breathing through the nose from colds, it will not keep together naturally. A pinch of pulverised sugar put in the mouth from a bowl always kept in the cupboard will close them satisfactorily every time; the taste will cause them to keep it shut long enough to get a shot.

With children from two to five years old, I often pretend to fix up a playhouse for them while getting the accessories in position; they are surprisingly ready to take any part in the play—from resting in the chair to sitting on top of the house while the circus goes by.

For cabinet size, I always have half a dozen 5 by 7 plate-holders fitted to my 8 by 10 camera within reach; for the plate must be ready to expose the moment the child is "mesmerized," as an assistant declared he thought I did with children. There is, at any rate, a golden moment that must not be lost by any hitch in rapid execution of the work.

If, for any reason, children become weary of the operation before a satisfactory sitting is obtained, they are at once taken down from the seat, and, if necessary, taken out of the room to amuse themselves. It is labour lost to spend time on them after you cannot hold their interest. They will soon be ready to come back with renewed interest. The first three minutes after an irrepressible has been seated is the easiest time to take him.

An average child can be photographed as well in five minutes' time under the skylight as an adult in fifteen. While it is easy to make a still negative of a child, a study of the show-cases in front of many galleries will indicate that little taste and thought have been expended on the subject, and the photographer has been satisfied to get simply a sharp negative. Other exhibits will prove that it is possible to make child-photographs that please the artistic eye of the patron, and bring reputation and financial success to the photographer.—*Wilson's Photographic Magazine.*

---

Celluloid for Printing Plates.—Among the objects exhibited during the last meeting of the "Fachtechnische Club," der k. k. Hof- und Staats-druckerei in Wien, Austria, there were some celluloid plates proffered by Mr. August Denk, proprietor of the Embossing establishment at Vienna. These plates contained transfers from copper engravings. These celluloid plates, which have a milk-white appearance, are somewhat transparent and flexible, and are so hard that they may be printed from the same as from a copper plate. The proofs exhibited demonstrate that the impressions are as clean and perfect as those made from the original plate. Celluloid may therefore be employed to good advantage in copper engraving establishments. If, on account of celluloid being so very ignitable, one should hesitate to use such plates, they may be employed with great advantage for reproducing original plates by making celluloid negatives instead of using silver, and making by means of these celluloid negatives printing plates, employing the electrotype process. Celluloid printing plates which were exhibited, and which had been rubbed in with ink, were really pieces of art, which could easily be used as window transparencies or tops for toilet and other fancy boxes.—*The Lithographic Art Journal.*

## THE OPTICAL LANTERN: ITS HISTORY AND DEVELOPMENT.*

BY WM. LANG, JUNR., F.C.S.

In compressing into a short paper a few facts regarding the optical lantern, I would wish at the outset to state that I do not presume to be able to deal at all exhaustively with my subject in the few minutes at my disposal, which might probably be extended to as many hours. I have simply collated a few facts, historical and otherwise, which, perhaps, to some of you may be sufficiently novel, and which I hope may interest.

I think we may take it that the lantern has long since ceased to be regarded as a plaything, and it almost seems unnecessary to state to a photographic gathering, such as we have here to-night, that the main factor in bringing about this result has been photography.

As a society we did well when we resolved to have a lantern of our own, ready to be used at a moment's notice, either to show a pleasing picture or to assist in illustrating papers which members may, from time to time, bring before us. As a means of education, the lantern is coming to the front; lecturers and teachers are now making use of the lantern, dispensing with cumbrous diagrams, and by means of a well-defined picture riveting the attention of the audience in a manner that was quite unattainable by previous methods.

The name which has been universally associated with the lantern's early beginnings is that of the Jesuit priest, Athanasius Kircher, a man of no mean scientific attainments, who flourished in the seventeenth century. The work which contains the earliest known representation of the lantern is Kircher's *Ars Magna lucis et Umbræ* ("The Great Art of Light and Shade"), published in Rome in 1646. An edition was also published in Amsterdam, but considerably later, in 1671.

Kircher was born in the sixteenth century, in 1598. He was a native of Hungary, and taught in Wurtzbourg. In addition to the work already mentioned, he was the author of at least a dozen treatises, embracing all sorts of subjects—optics, magnetic phenomena, Egyptian obelisks, Tower of Babel, &c. I have never yet been able to procure a copy of his *Ars Magna lucis et Umbræ*, but I have brought as a curiosity a folio volume, published in Amsterdam in 1669, of Kircher's entitled *Ars Magna Sciendi* ("The Great Art of Knowledge or Learning"). There are some quaint engravings throughout the book, and, although somewhat worm-eaten, the volume is not without interest. Kircher founded in Rome a museum of apparatus and antiquities.

To return to the more immediate subject we are considering. There are figured in the work, "The Great Art of Light and Shade," two forms of the early lantern; but it has to be noted that these pictures do not occur in the early edition of 1646, but only in the latter one of 1671. We will have one of these forms projected on the screen. It represents a square box of wood, with a sort of shaft in the upper portion to carry off the smoke of the lamp; the said lamp carries a reflector of a kind. Opposite the light is the projecting lens, and outside is shown the painted glass slide. To judge from the picture which is to be found on the wall of the apartment, the subjects chosen were certainly not the loveliest nor the most agreeable. The gentleman with outstretched arms is supposed to be an unfortunate individual surrounded with eternal flames, so that, you see, the early lantern was an instrument of education of a kind.

The other picture now shown shows a slightly different arrangement, inasmuch as the lantern itself is concealed, as it were, in a separate compartment. This was, of course, to heighten the effect. The oil lamp hangs suspended from the roof of the lantern by means of a chain, and the picture shown on the wall represents Father Time as a skeleton with scythe and hour-glass.

In a quaint work, "Recreations Mathematical and Physical," published in London in 1708, we find an engraving of a lantern very much the same as the foregoing. This work was a translation of a French one by Professor Ozanam, a professor of mathematics in Paris. I may be allowed to quote what the author there says regarding the lantern, and we will show, at the same time, the picture of the lantern in the book:—

"This is called magical with respect to the formidable apparitions that, by vertue of light, it shows upon the white wall of a dark room. The body of it is generally of white iron and of the figure of a square tower, within which, towards the back part, is a concave looking-glass of metal, which may either be spherical or parabolical, and which, by a groove made in the bottom of the Lanthern, may be either advanced nearer, or put further back, from the Lamp, in which is oil of olives or spirit of wine, and of which the match ought to be a little thick, that when 'tis lighted it may cast a good light, that may easily reflect from the glass to the fore part of the Lanthern, where there is an aperture with a prospective in it composed of two glasses that make the rays converge and magnifie the objects.

"When you mean to make use of this machine, light the lamp, the light of which will be much augmented by the Looking-glass at a reasonable distance; between the forepart of the Lanthern and the prospective glass you have a trough made on purpose, in which you're to run a long, thin frame with several little different figures painted with transparent colours upon glass or talc; then all these little figures, passing successively before the prospective thro' which passes the light of the lamp, will be painted and represented with the same colours upon the white wall of a dark room in gigantick monstrous Figure, which the fearful, ignorant people take to be the effect of magick."

The concluding sentence explains how the term "magical" or "magic" came to be applied. Ozanam's book is replete with curious formulæ and problems, and the copy which I possess can be examined afterwards by those interested.

Connected with these early facts, I came across quite recently a reference to the original prototype of our lantern which I do not think has been elsewhere recorded. A French traveller of the seventeenth century, De Moncorrys, describes in a volume devoted to what he had seen in England a dark lantern, which, having a demi-globe (that is, I presume, a bull's-eye), could project objects, or representations of objects, painted on glass and inserted between the light and the lens. This he saw in the establishment of a Mr. Rives, a microscope maker of Long Acre. This was in the spring of the year 1663, eight years previous to the edition of Kircher's work already referred to, which had the illustrations. It would be instructive to compare Kircher's two editions to see whether the lantern is actually described in the first edition, viz., that of 1646, seeing no illustrations of it have been furnished. I may mention that in Professor Ozanam's work, from which I have already quoted, Friar Bacon is credited with being the originator of the lantern.

De Moncorry's volume is lying on the table, and can be inspected afterwards. The spelling of Longueker rather puzzled me at first. Before dismissing De Moncorrys

* A communication to the Glasgow Photographic Association.

and his travels, it may be interesting to mention the fact that in the accounts he gives us of his journeyings in Italy—and he appears to have visited it on three separate occasions—he was several times in the company of Father Kircher. De Moncorrys may be described as a scientific Pepys.

From the end of the seventeenth to the beginning of the nineteenth century the magic lantern seems to have had an existence which can best be described as dormant. On the authority of Sir David Brewster, in his "Letters on Natural Magic," we find that an attempt was made by one Philipstal, in 1802, to awaken interest in the instrument by the exhibition of effects which were known under the name of phantasmagoria. In these, by means of a transparent screen interposed between the spectators and the lantern, and the latter being made to approach to or recede from the screen, the objects represented—generally of the most gruesome nature—were made to grow larger and larger, or, on the other hand, to diminish gradually. The figures painted on the glass had necessarily all the surrounding parts rendered opaque, so as to heighten the illusion. It is instructive to read what Brewster wrote in 1832: "Superior as the representations of the phantasmagoria are to those of the magic lantern, they are still liable to the defect which we have mentioned, viz., the necessary imperfection of the minute transparent figures when magnified. Even Michael Angelo would have failed in executing a figure an inch long with transparent varnishes when all its imperfections were to be magnified."

Now, what the hand of man could not do photography has been able to accomplish. In the photographic transparency we have not only the perfect picture, which can bear amplification to almost any extent, but complete fidelity to the original, be it a scene in nature or the reproduction of a work of art.

The imperfect oil lamp of the lantern's early days has been replaced by improved methods of illumination. We may for a moment just refer to these, and we will consider first the limelight. When a mixture of oxygen and hydrogen gases are burned together from a jet, a temperature is produced so intense that thick platinum wire is readily melted, and iron and steel burn with vivid scintillations. The oxyhydrogen flame is but feebly luminous in itself, but when it is directed on to a ball of lime, which does not itself fuse, a light of the greatest intensity is obtained. Formerly, it was known as the Drummond light, in consequence of a Lieut. Drummond proposing to utilise it in connection with the trigonometrical survey of Great Britain. As an instance of what the light could do, it is recorded that, on the 31st December, 1845, it was seen across the Irish Channel from the top of Slicoe Donard, in Ireland, by an observer stationed on the top of Mount Snowdon, a stretch of one hundred and eight miles. This was in daylight. In actual practice, as you are aware, the hydrogen gas is now replaced by coal gas, that is, of course, in towns where gas is universally used. Gas, being a hydro-carbon, is, however, not pure hydrogen, but a combination of H. and C. The so-called hydrogen supplied in tubes is, for the most part, a volatile hydrocarbon made from oil by what is known as Pintzch's process. The electric light has, on several occasions, been utilised for lantern work, but, as it is not so readily available, we need do no more than refer to it.

In the sciopticon, an American form of the lantern, the vegetable oils formerly made use of have been replaced by paraffin oil. On the authority of the *British Journal of Photography*, I find that this modification of the lantern was first introduced into our country by Mr. W. B. Woodbury in 1873, and the name associated therewith in the country of its birth is that of Marcy. It was originally a lamp of two wicks, but it is now universally made with three. The form of the sciopticon is well known to all, and the picture on the screen presents it to you.

In the optical arrangements connected with the lantern of the present day there are two essential components, viz., the condenser or condensers, and the objective. Taking the first-mentioned, its object is clearly to cause the light of the flame to pass through every part of the transparency. The diagram thrown on the screen shows very clearly what happens when a light from any source falls upon a glass picture where no lens is interposed. It will be seen that only the rays passing through the centre of the transparency can ultimately reach the screen. Let, however, a lens be interposed, as in the diagram now shown, and you will see how the rays are gathered together, and the picture in consequence duly illuminated. In actual practice, the condenser is not of the simple form shown in these diagrams. We will pass through the lantern one or two of the leading forms adopted. Perhaps the condenser most in vogue is that where two plano-convex lenses are mounted close together where the light is received upon the flat surface of the condenser nearest the light source. The light is projected to where the object glass must be placed. What is known as the Herschel condenser, as shown in diagram, consists of either a plano-convex, or meniscus, and a double convex. The plano-convex is made of flint, and the other of crown glass. Dallmeyer's form consists of a plain convex in front, and is made of flint, while the second lens has its two sides curved unequally in order to bring the rays of light to a point in front, which it is impossible to do by the other form. This form of lens is what is known as crossed, and is made in the present combination of crown glass.

In order still further to increase the illuminating power, triple condensers have been devised, where a smaller lens has been interposed between the radiant and the condenser. Mr. J. Traill Taylor is credited with the suggestion. The diagram shown will show how the increased illumination is brought about.

It has to be noted that defects in the condenser are of much more account than similar defects in the objective; hence every care should be taken to avoid scratches, for these become magnified on the screen, and a perfect disc will never be obtained.

As we have a large collection of slides to put through our lantern to-night, in addition to those sent down by Mr. Pringle illustrative of his paper, I think it will be well for me to break off at this point, leaving the consideration of the objective of the lantern for another occasion, as also several other matters which would require a very considerable time indeed in order to go into them properly. With your permission, therefore, I will simply stop short in my remarks, and in doing so, I will come under the obligation to resume the subject of the optical lantern, it being, of course, understood that you should wish it at another meeting. I would like myself personally to bring out in a manner, which I have been perfectly unable to do in the short time at my disposal, how very completely the optical lantern can be made to illustrate facts bearing on the laws which govern and regulate that marvellous manifestation of energy which we recognise under the name of light.

## PROFESSOR LIPPMANN'S DISCOVERY IN HELIOCHROMY.

The following is from the Paris Correspondent of the *Daily News*, telegraphed last Tuesday night by him to that journal, and published in its issue of last Wednesday:—

Photographing in Colours.

The scientific world has been startled by the announcement made by M. Lippmann (Professor of Physics at the Sorbonne), at the last sitting of the Academy of Sciences, of a new process of photography discovered by him, by which colours throughout the whole range of the spectrum can be reproduced on a sensitive plate, just as accurately (since colours are but numbers of light waves) as outline or shadow are fixed by the present photographic negatives and prints. M. Lippmann's first attempts to take coloured photographs have not gone beyond the experimental stage, and a long time must elapse before this branch of photography is brought to the perfection which its sister branch has attained. After a few weeks' attempts, M. Lippmann has succeeded in photographing a stained window in colours as brilliant as the original ones. His researches, however, quite apart from the magnificent possibilities which they bring within our view, claim the regard of every scientist as an illustration of the power of the inductive method.

M. Lippmann, whom I met yesterday at his laboratory at the Sorbonne, very obligingly showed me his coloured plates, and gave me an account of his discovery, drawing on a sheet of paper, as he proceeded, a number of interesting diagrams, which unfortunately cannot be sent by telegraph. The plates were all photographs of the solar spectrum. All the colours of the rainbow were there, including the infra-red and the ultra-violet, invisible to our eyes. The plates, however, had registered them and kept an impression of them, showing themselves in this respect superior to the human eye. These two mysterious colours were represented in their proper places by two distinct stripes, apparently of a jet-black colour. I say apparently, because it was only our imperfect vision which made them seem so to us, their real colours, of course, being infra-red and ultra-violet. The other colours between these two—red, orange, green, blue, &c.—were as vivid as any objects in nature.

As I was examining these plates, an assistant came to say that a coloured photograph, the first of a stained window, had just been taken out of the developing bath, and was in splendid condition. The stained window, as I saw on proceeding to the dark room, was a most primitive affair, four pieces of coloured glass—green, yellow, red, and blue—soldered together. "This is all we could put together," explained M. Lippmann, "but it is quite sufficient for my purpose." The plate, which was not yet fixed, was taken out of its box for a few seconds only, as this plate was precious, and we were afraid of injuring it by exposure even to candle light. To our great delight the colours were there, and rendered with photographic faithfulness. A second plate was undergoing exposure, the image of the stained glass design being thrown upon it by means of a sort of magic lantern lighted by electricity. The plate was pressed against the opening of a trough filled with mercury, which formed a mirror in contact with the plate. The rays of light pass through the sensitive film as in the old process, but on reaching the other side of the plate, instead of being absorbed by a dark background, they are sent back by the even surface of the mercury. In this mirror the whole secret lies, for apart from it the entire process is exactly the same as in ordinary photography.

Before explaining why a mirror placed on the back of a sensitive plate during exposure causes the silver precipitate to assume all the colours thrown upon it by the camera, the reader must be assumed to have a slight acquaintance with photography, and also with the laws ot light, which offer a striking parallel to the laws of sound. Light, like sound, is but a form of motion. Both appear to propagate themselves by a wave-like motion, similar to the ripples on a pond when a stone is thrown in. The only difference is that, owing to friction, the waves of a pond tend to lengthen out and to disappear, whilst the waves of light or sound preserve their original length throughout their whole course. For light the wave-length—or, rather, half-wave length—is small beyond conception. It is for red light 0·0002 millimetres; for yellow light, 0·00025 millimetres; for green light, 0·0003 millimetres. In other words, there are 5,000 waves of yellow light to an inch, &c. A curious property of sound or light waves is that, when they meet another wave of equal length coming in an opposite direction, the conflicting waves overlap each other, the continuity is broken, and a succession of dark and light, or silent and loud, intervals is produced. A French physician of the beginning of this century, Napoleon Savart, was the discoverer of the phenomenon called interference of sound. If the ear is placed at a short distance off a sounding or echoing plate, and gradually drawn away, it will be observed that the sound alternately dies away and comes back with two-fold intensity. The explanation of this is that the waves of sound, the direct and reflex waves, alternately neutralise and reinforce each other. The two conflicting waves of sound or of light might be represented by the two serpents of Mercury's rod, which form a dot at their intersection, and a wide space between each dot. Each is a wavy but continuous line, whilst the two combined give a sort of broken line or chain. It was Newton who discovered the interference of light, and was able to measure the wave-length of different colours.

Some time ago it occurred to M. Lippmann that if, instead of a continuous wave of light crossing the photographic plate, a broken line (produced by "interference") were sent across it, the silver, instead of being precipitated in one mass throughout the gelatino-bromide, would settle in layers (about the thickness of a soap bubble). By placing a looking-glass behind the plate, the red light, for instance, caused the silver to be deposited in layers of half the thickness of a red wave length. Blue light would cause the layers to be somewhat thicker wherever it passed, but these layers coinciding, exactly as they do with the length of a wave of light, can only let pass the same light which originated them. This is the whole principle of M. Lippmann's remarkable discovery, and practice shows that it will work in the case of the solar spectrum and of stained windows. Whether it may be applied to landscapes or portraits the future alone can tell; but there is nothing unreasonable in the hope that it will be so.

---

This afternoon, at 4.30, Captain Abney will lecture at the Society of Arts on "Colour."

We are reluctantly obliged to postpone publication of various articles and communications, the pressure upon space being now heavy.

The Derby Photographic Society.—At the annual meeting on Tuesday last at Smith's Restaurant, Victoria Street, Mr. C. B. Keene presiding, the secretary read the annual report and balance sheet for 1890, which showed the Society to be in a fairly prosperous condition.

The *Revue de Photographie* for February gives, as one of its illustrations, a phototypic portrait upon gelatine, produced by MM. Thevoz and Co., of Geneva, from a negative by M. J. Lacroix. No indication is given of the way in which the negative was obtained, but the result, owing to the semi-transparence of the gelatine support, which can be varied in tint as desired, is artistic.

A Spirit Level.—Most of our readers probably know a good deal about the ordinary spirit level, and that it is an instrument the use of which is to get things level and plumb. A new kind of spirit level seems to have been invented in the West, the probable effect of which will be to occasionally get things out of level, and out of plumb. The level is not a very accurate affair, we should judge, for it consists essentially of a pasteboard box with a bottle inside, the bottle containing the spirits and air bubble, which make it a spirit level. No adjusting screws or other refinements are provided, and the "glass" is quite large compared with other spirit levels, and is closed with a cork, so that the amounts of spirits within may be reduced whenever it is thought that the level will work better with less. Any kind of spirits desired may be had, and it is expected that the level will find its chief market in the prohibition States.—*American Machinist.*

## THE ROYAL INSTITUTION.

### Lord Rayleigh on some Applications of Photography.

Last Friday night Lord Rayleigh lectured at the Royal Institution upon "Some Applications of Photography." Sir Frederick Bramwell presided, and among those present were Professor Alexander Herschel, Dr. William Huggins, Mr. William Crookes, Mr. J. W. Swan, Capt. W. de W. Abney, Sir William and Lady Thomson, Lord Justice Sir W. Fry, Professor Hughes, Sir Henry Trueman Wood, Professor Oliver Lodge, Mr. Francis Galton, Professor A. Rucker, Mr. Frederick Varley, Mr. Friese Greene, Professor Dewar, Sir Frederick Abel, Mr. John Spiller, Professor Edward Frankland, Mr. Gambier Bolton, Mr. Roberts-Austen, Mr. Bevan, and Mr. J. R. Götz. The theatre of the Institution was well filled.

Lord Rayleigh stated that there is no such thing as instantaneous photography, because the taking of any photograph must occupy time, however short that time may be. Several methods may be employed to take photographs quickly. Mr. Muybridge had shown in that theatre how he had taken them by means of rapid shutters; another plan is to take them by means of a flash of light. He then caused a flash from a magnesium lamp to fall upon a wheel divided into black and white sectors. This wheel was made to revolve rapidly by means of multiplying gear, and when the wheel was illuminated by the flash the sectors did not appear to be motionless, showing that the flash was not of particularly short duration. It occupied, he said, about one-tenth of a second; other magnesium lamps will give flashes of shorter duration, up to, it is said, a fiftieth of a second.

He then exhibited a method of obtaining a much shorter flash by means of three Leyden jars, charged by means of a Wimshurst's electrical machine. The aforementioned revolving disc was driven at high velocity, and when illuminated by the spark due to the discharge of the Leyden jars, the sectors appeared to be absolutely motionless; they were also sharply defined. The electric spark is, therefore, enormously "more instantaneous" than the magnesium flash.

About twenty years ago, a scientific man in New York investigated the duration of the discharge of the Leyden jar, and found that the result depended somewhat upon the circumstances of the case; a small jar, for instance, gives a quicker spark than a large one. The duration of the spark is about $\frac{1}{25,000,000}$ of a second of time. These figures scarcely enable anyone to realise the velocity except by analogy; one million seconds occupy about twelve days and nights, and twenty-five millions occupy about one year; therefore, the duration of the electrical spark is, to the second of time, about what one second is to a year.

His method of photographing was to obtain the electric discharge in a box with a lantern condenser in front; outside the box, and in front of the condenser, was the transparent object to be photographed; facing this arrangement was a camera, with its lens focussed upon the object.

With this arrangement he had photographed bubbles of gas rising from a nozzle and then ascending through a liquid; in this case, the bubbles form almost at the first moment of leaving the nozzle. With a water-jet in air, the form is at first cylindrical; then the jet breaks into drops at some distance from the nozzle, in consequence of the water-cylinder being in a state of unstable equilibrium, or in what is known in the medical world as a "varicose" state; the varicosity goes on increasing until disruption results.

Another case of unstable equilibrium is that of sensitive flames. The flame is not an essential part of the arrangement, for it acts more as an indicator. He caused a solution of permanganate of potash to play into a solution of protosulphate of iron; the latter was used to quickly decolourise the purple liquid from the jet. This purple jet could be disturbed by shakes and sounds, and the instantaneous photographs taken prove that such jets become sinuous. There is an analogy between these jets and those which produce sensitive flames; there is also a very great difference between them in the forces under which they break up: symmetrical forces will not produce sinuosity.

### The Photographing of Bursting Soap-films.

The lecturer next spoke of a difficult feat, namely, that of photographing bursting soap-bubbles; the chief difficulty is to obtain the bursting of the bubble and the electric flash at the same instant. He caused two electromagnets to hold up two iron bullets, so that when the current was stopped the two balls should fall at the same time, and one of them fall through the soap-film at the same time that the other caused the electric discharge; this did not answer, for one ball would lag a little behind the other in leaving the electro-magnet. He then tried another device, which we shall describe next week, illustrated by diagrams, and accompanied by diagrams of the results obtained.

Another difficulty in this work is, that it is not easy to break a soap-film when you want to do so. Several bullets may sometimes be dropped in succession through a soap-film without breaking it, for they will go through without making a hole. He proved this by experiment. The passing bullet extends the film where it touches it; the film next closes up behind the bullet. Lorn Rayleigh overcame this difficulty by wetting the bullets with alcohol. In these experiments he used an electrometer to indicate when the Leyden jars were sufficiently charged for the purpose.

### The Connection between Aperture and Optical Definition.

The speaker next remarked that we cannot get as high definition as we please by constantly reducing the aperture. With too small apertures the definition gets worse. An optical image of even a mathematical luminous point has considerable extension, and the mathematical point cannot be correctly given at another point by any optical means; there is sure to be a certain amount of diffusion. He had prepared a series of photographs of gratings showing how, as the aperture of the lens was decreased, the images at first improved; but, as the apertures were still farther diminished, the definition began to get worse. Images of these photographs were then projected by him upon the screen by means of the electric lantern. When the aperture is much restricted, a lens is of no use whatever; as good an image can be obtained without as with it. Lord Rayleigh closed his lecture by exhibiting a photograph of some cedars, which he had taken without a lens by means of a hole in a shutter in a dark room, with the plate at a distance of seven feet from the hole. These photographs were of a pleasing nature when viewed at the proper distance of seven feet.

### Photographic Exhibits.

At the close of the foregoing lecture, the following objects of interest were on view in the library:—

Pinhole pictures of the cedars at Terling Place—Lord Rayleigh, M.R.I.; thaumatrope showing formation of water drops—photographs of water drops and of sparks—Professor C. V. Boys, M.R.I.; apparatus used by the French Explosives Committee—Sir Frederick Abel, M.R.I.; photomicrographs of Greek gems and coins—Mr. Wilfrid Godden; photographs of water lilies—Mr. Greville H. Palmer; photographic application of primuline—Messrs. Green, Cross, and Bevan; stereoscopic lantern and camera combined—camera for taking pictures from three to ten a second—direct reading photometer—photographs of clouds—Mr. Friese Greene and Mr. Varley; photographs of animals—Mr. Gambier Bolton; collodion pigeon dispatches—Mr. W. B. Tegetmeier; photograph of a view in winter from Piz Lingard—pigeon post dispatches—Mr. J. Spiller; photographs of moon and eclipse—Mr. F. S. Wells; monochrome portraits of residents in Aden—Mr. C. A. Long; new camera with aluminium fittings—Mr. J. R. Gotz; photographs from isochromatic plates—new camera and developing dishes—Messrs. Griffin & Son; specimens of typographic etching—Typographic Etching Company; Mr. F. Galton's reaction of time chronoscope—Mr. W. Groves; terpuescope lantern—Mr. A. Wrench.

### M. Dagron and the French Pigeon Post.

The illustrations of the French pigeon post, 1870-1871, which were shown in the library of the Royal Institution by Mr. J. Spiller on Friday evening last, are an interesting memento of M. Dagron's unique services in establishing communication between Tours and Paris during the siege and investment of the last-named city. On the 10th of November, 1870, two balloons, appropriately named "Nièpce" and "Daguerre," ascended from Paris, and one of these was immediately captured by the Prussians; but the other, the "Nièpce," carrying M. Dagron and a complete set of photographic apparatus, made a successful journey south, and succeeded in eluding the vigilance of the enemy until the outfit had been safely packed and transferred by its owner to Tours. Here postal messages were received, from first to last, to the number of about 50,000; they were despatched regularly every day to Paris by carrier-pigeons in the following manner: The words of the telegrams and written messages were first set up in common type, and printed in columns so as to form one large sheet; this was then copied by camera and collodion on to a little plate not exceeding $1\frac{1}{4} \times 2\frac{1}{4}$ inches, and from such negative a score or more transparencies in toughened collodion were produced, so as to provide for the failure or loss of the greater number of them. The collodion films were then stripped off their glasses and rolled up into separate parcels for insertion into a quill holder to be carried by the bird, whose ordinary load was a gramme, or twenty pellicles, attached to the feathers of his tail. A pigeon service was established, and the trained birds regularly sent out of Paris by balloon; these returning home again—or a fair proportion of them—carried the news into the beleaguered city. On arrival, the microscopic films were detached and flattened out between two glasses, and either publicly exhibited by the electric lantern, or copied direct by photography on a legible scale, and ultimately distributed to the persons to whom they were addressed. This system of intercommunication remained in force until the withdrawal of the German troops, in 1871, permitted the resumption of the ordinary postal service. In England press messages are usually tied to the legs of carrier pigeons.

## Patent Intelligence.

### Specifications Published.

15,091. *September 26th*, 1890.—"Preparation of Chemicals adapted to the Development of Photographic Plates." Abel M'Donald, 1, Lawn Terrace, Silloth, Cumberland, Photographic Engineer.

In the preparation of developers for photographic plates and the like it is necessary to possess a number of different chemicals, both in crystals and solution, such as liquid ammonia, nitric acid, &c., which are more or less injurious to the health; this necessitates the manipulator to have in possession a number of bottles of solution, from which an accurate portion must be mixed at the time of developing; by the aid of weights and measures, this causes loss of time, risk of breakage, and encumbrance when on a tour.

To dispense with the aforesaid disadvantages, I purpose manufacturing a combination of chemicals into one body possessing the essential properties of a first-class developer.

This I accomplish with the following chemicals, and in the following manner:

I fuse together one part of sodium oxide, three parts of sodium carbonate, and six parts of sodium sulphite, or in other proportion that may from time to time be necessary. I then form the compound into tablets or sticks of a convenient size and weight ready for dissolving in a given quantity of water without the aid of weights or measures.

The advantages of my invention are:—

1st. Being a combination of chemicals in one solid body the photographer does not require to have in stock a number of different chemicals.

2nd. Being of a convenient size and weight it can be readily mixed at the time of use without the aid of weights and measures by any inexperienced person.

3rd. It entirely dispenses with the burdensome practice of carrying developing solution in bottles, as it is used with the dry pyrogallic acid alone, thus the entire chemicals necessary for developing are light, and can be kept in a small compass.

18,369. *November 14th*, 1890.—"Shutters for Optical Lanterns." George Samuel Thompson, 5, Farleigh Road, Stoke Newington, Middlesex, Carriage Builder.

What I claim is:—

1. The plan and arrangement of sliding diaphragms, for magic and other optical lanterns, or combinations of lanterns, having two or more optical systems, whereby rolling up effects and rolling down effects may each be produced twice in succession.
2. The arrangement for a triple lantern whereby the effect of a curtain rolling up or down may be made, cutting off the light from two optical systems, appearing from one, and *vice versa*.
3. The arrangement whereby, after the production of either one or two rolling up effects, from a combination of two or more optical systems, every optical system can be opened free for dissolving purposes without removing the shutter from the lantern or causing a rolling down effect.
4. The arrangement with lanterns of two or more optical systems, whereby after all optical systems have been open for dissolving purposes, one or two rolling down effects can be produced without having either to insert the shutter in the lantern, or produce a rolling up effect.

To Prepare Glue which will remain Liquid.—A certain quantity of finely ground glue of best quality is soaked in a sufficient quantity of alcohol; there must be enough of the latter to always cover the glue. Let the mixture stand for twenty-four hours, and stir from time to time. If the glue does not dissolve entirely, add more alcohol until the desired result is reached. Then pour the liquid glue into a bottle with a wide neck, and keep it well corked. The glue may not be as strong as if it had been boiled, but it will remain liquid, and retain the full force of its adhesiveness.—*The Lithographic Art Journal.*

## Correspondence.

### ROUGH DRAWING PAPER.

Sir,—Dr. Emerson, in his renunciation, refers to my use of rough drawing paper as a "revival," and Mr. Davison, in his reply, remarks that there is no novelty in the use of rough papers. I quite admit this, but papers vary greatly in the degree of roughness they possess, and the paper I employ is the roughest drawing paper procurable, and the same effect cannot be produced on smoother paper. It is my impression that paper of the quality I employ was never used or suggested before the production of the photographs exhibited by me at the Pall Mall exhibition. I may, however, be mistaken, and if so, trust that the gentlemen named will put me right. I enclose a sample of the paper I use, for your inspection.

*Brighton, February 7th.* W. L. Noverre.

### THE RADIAL CAMERA.

Sir,—We observe, in your notice last Friday respecting our Radial camera, that it is stated we issue it with a Voigtlander lens; this is quite correct, but there is an omission that we also supply it with a rectilinear lens fairly good, and a Soho lens, thus giving the choice of three lenses. Your kind correction will oblige. Marion & Co.

*February 9th.*

### PHOTOGRAPHY IN THE CRYSTAL PALACE.

Sir,—On the 4th inst. I wrote a polite letter to Messrs. Negretti and Zambra asking their permission to take a few photographs in the Crystal Palace grounds, promising to make no use of them, except as an amateur, and I have received the enclosed from them in reply.

I bring this before you as I think professional photographers are very short-sighted in their treatment of amateurs, and that if we were to retaliate in a like manner, it might do some of the gentry good.

I may say I am both a shareholder and a season ticket holder in the Palace Company, and it certainly seems unjust that I cannot "openly" take a few shots of any pretty bits that are to be found in those beautiful grounds.

*Camera Club, February 9th.* Robert Schofield.

*Copy.*

Sir,—You will see by the enclosed slip that we have the sole right of photography in the Crystal Palace. To this we may add that we pay *very* large sums of money yearly. Any photographs that may be required we are willing and desirous of taking for our customers at a very reasonable rate, but we cannot, as you will understand, allow any second party to take photographs. During the thirty or thirty-five years we have had the privilege, no one, so far as we remember, has taken pictures in the Palace, although, as you may suppose, many have applied and been refused, and, in some instances, officers connected with the building. We shall be pleased to execute any orders you may favour us with, but permission for you or anyone else to take photographs in the Crystal Palace and grounds cannot be given.—We are, sir, yours truly,

(Signed) J. W. Zambra.

*Crystal Palace, Sydenham, February 6th.*

## Proceedings of Societies.

### The Photographic Society of Great Britain.

On Tuesday evening last, the 10th inst., the annual meeting of this Society was held in the Society's new premises, the president, Mr. J. Glaisher, F.R.S., F.R.A.S., in the chair.

The report of the council was read, and Mr. A. Mackie, in proposing its adoption, remarked upon the greater accuracy with which it had been prepared than had characterised the report of the last and several previous years. The papers that had been read formed a very creditable list. In connection with the reading of papers, he thought more time should be allowed for the discussion. Discussions were often of more importance than the papers themselves; but for the discussions, the papers need not be read, but might only appear in printed form. He had noticed that members of council were supplied with a copy of the paper that was being read, and this gave them an advantage in the discussion which ought to be shared by all the members. The cost of printing the necessary numbers of copies would not be great. As to the technical meetings, he considered that, compared with the meetings of many suburban societies, they were inferior both in the matter of attendance, and of the discussions. He thought this was due to there not being any fixed or pre-arranged subject, and that the secretary or council would do well to amend this. In the details of the report concerning the exhibitions, he observed that, for the last few years, there was a regular decrease in the number of members who sent exhibits. He wished to know how that could be explained; he thought it very serious. It was a thing to rejoice in that the Society had now a home of its own, but he regretted to find that the existence of that home depended upon a guarantee fund, which he thought put poorer members at a disadvantage. He believed that the expenses of the Society might be re-arranged and reduced so as to dispense with the guarantee fund. He thought that the council had exceeded its powers in electing honorary members. When the new rules had been prepared, it was expressly laid down what the powers of the council were, and, although a resolution had been passed a year ago, declaring that certain words in the rules were to be taken to mean other words, it would be better to come before the Society in a constitutional way, and get the rules altered as desired. He thought the council should be greatly enlarged, so that everyone who could be considered a representative man might have a seat on it.

Mr. J. W. Swan proposed an amendment to a paragraph in the report, replacing the words "should be devoted to the scientific rather than the artistic side of photography," by "having been chiefly devoted," &c. This amendment was carried.

Mr. T. E. Freshwater spoke to the desirability of having subjects arranged for and announced for the technical meetings.

The report having been adopted, and the treasurer's report being read, Mr. W. England said that he considered the Society was paying a great deal too much for the printing of the Journal. He proposed that estimates should be obtained from other printing houses.

Mr. G. L. Addenbrooke supported this proposition.

Mr. Mackie referred to the importance of the Society's exhibition in the financial statement, and said that there were rumours of some great photographic exhibition to be held in London. If that were properly carried out it would be disastrous to the Society's exhibition. The Journal involved a net loss of not less than £160, and though he admitted that it had been greatly improved latterly, he did not think it was worth the seven or eight shillings per member which was what it cost.

Mr. L. M. Biden considered that to many members the exhibition was the principal inducement to belong to the Society. The lantern evenings were always crowded, and he thought they might be held two or three times a week, and a charge made to all who attended them. For the sake of the members who did not attend the Society's meetings he thought the Journal ought to be improved, especially in the matter of illustrations.

The treasurer's report was then adopted, and votes of thanks passed to the president, treasurer, secretary, Captain Abney (the editor of the journal), the auditors, and scrutineers.

The President, in replying to the vote of thanks, said that he was much gratified that at last the Society had a home of its own. He was pained to hear complaints about the technical meetings; perhaps in the new home a new start would be made.

Mr. Biden thought that something might be done to federate the numerous photographic societies now existing. The railway companies might be approached to grant concessions for society outings similar to those given to angling clubs. Interchange of papers and other matter, too, might be arranged. Would the Society grant the use of its room for a meeting to discuss these things?

The President said that doubtless the council would accede to this request.

Mr. L. Warnerke said that he had been requested to give a demonstration of collotype printing, and it occurred to him that it would be better to choose an extra night for this purpose, and that a series of demonstrations and lectures on extra nights might be arranged. In this way the Society would commence in some degree the kind of work that the proposed Institute, when formed, would be expected to carry on.

Mr. W. E. Debenham supported this proposition, and assumed that these lectures and demonstrations would not be expected to be dependent on any fresh discovery made by the authors, but might take the form of lectures such as would be delivered at any institute of instruction.

The election of members of council resulted as follows:—*President*—J. Glaisher, F.R.S., F.R.A.S.; *Vice-Presidents*—Captain W. de W. Abney, C.B., R.E., D.C.L., F.R.S., T. Sebastian Davis, F.C.S., H. P. Robinson, and John Spiller F.C.S., F.I.C.; *Treasurer*—W. S. Bird; *Members of Council*—Messrs. W. Ackland, G. L. Addenbrooke, W. Bedford, V. Blanchard, F. Cobb, A. Cowan, T. R. Dallmeyer, Major L. Darwin, R.E., G. Davison, W. E. Debenham, W. England, J. Gale, F. Hollyer, F. Ince, Dr. L. Johnson, H. Chapman Jones, F.I.C., F.C.S., Captain Mantell, R.E., J. W. Swan, J. Traill Taylor, Leon Warnerke, and Sir H. Trueman Wood.

---

### The London and Provincial Photographic Association.

*February 5th.*—Mr. W. H. Cooke in the chair.

The Hon. Sec. presented "Inorganic Chemistry" (Meldola) to the library of the Association. Several volumes of the Photographic News Year-Book and the "British Journal Almanac" were also received from Mr. Charters-White.

Several specimens of Mr. E. Dunmore's "unique" black and white cloud negatives were passed round. The negatives were artificially produced on tissue paper with powdered plumbago and a stump, quick printing being one of the chief advantages claimed for them.

The Hon. Secretary showed the results he had obtained from some stripping films by first soaking them in bromide, and developing with ferrous oxalate. He also exhibited some prints on Fry's naturalistic paper; the effect on this paper is only seen when the print is held at some little distance from the eye.

A question from the box was read:—(1) "What, in the opinion of this meeting, is the best means of preserving for, say, one week's use, a one in ten solution of pyro and distilled water, so as to maintain its developing power most nearly equal to that of dry pyro? (2) Would the loss of developing power in such a solution be compensated by the use of a greater quantity of acid; if so, in what proportion would the amount require to be augmented?"

Mr. W. E. Debenham said pyro and plain water alone would keep for a week in a corked bottle. He preferred using water that had been boiled.

Mr. A. Haddon referred to some crystals of eikonogen that he had sealed in a glass tube a year ago and exposed to light. The crystals had undergone but very little change in colour.

The letter from the Photographic Society of Great Britain on the subject of the Photographic Institute was then read and fully discussed. The following resolution was passed: "That the establishment of the Institute, as proposed by the Photographic Society of Great Britain, is very desirable, and would be conducive to the progress of photographic science and industry."

The Hon. Secretary announced that on March 3rd a popular lantern exhibition would be given, to which visitors were invited.

---

### The South London Photographic Society.

*February 6th.*—At the meeting at Hanover Hall, a demonstration of enlarging on bromide paper was given by Mr. S. Wiles, using paper prepared by himself. Enlargements previously exposed to daylight were developed, and produced excellent results.

### The North Middlesex Photographic Society.

*Feb. 9th.*—Jubilee House, Hornsey Road.

Mr. Walker, the chairman, said that the subject for the evening was "The Best Treatment for Winter and Snow Scenes." He thought that views in which there were no heavy objects in the foreground were best, and a developer weak in the reducing agent most suitable.

Mr. Mummery had found that when the sun shone in winter there was more light than at first appeared by reason of reflection from the snow. He used Thomas's hydrokinone developer full strength.

Mr. Norris had given fifteen to twenty seconds with large stop, and developed with full strength pyro and ammonia.

Mr. Beadle had given fifteen seconds with $f/32$ on a hoar-frost view, and developed with pyro (Ilford formula) used full strength.

Mr. Gill showed some instantaneous pictures of figures in snow scenes taken at 8·30 a.m. in December, and developed with ferrous oxalate, the iron weak at first, and strengthened as development proceeded. The prints were much admired.

Referring to the widely different exposures, Mr O. Cox had seen negatives taken under similar conditions, but with exposures varying from four seconds to five minutes, yield equal results in the hands of an experienced developer. He warned the members that lenses kept in a cold place and taken into a warm, moist atmosphere would condense moisture on the surface and give trouble, the cause of which might not be suspected.

Mr. Goodhew recommended in cases of great contrast, as in snow scenes, that the plate should be flooded with the ammonia and bromide, and the pyro added by drops till the image appeared. When all detail was up, a new developer, strong in pyro and bromide, should be used to secure density and brilliance.

The Secretary had used eikonogen and ammonia with meta-bisulphite.

Mr. Pither had failed to get density with the weak pyro method.

Mr. Gill showed two hand-cameras of his own invention. The construction was ingenious, and the method of changing the plates simple and certain. One was for half-plates, which could be used on a tripod, and also for stereo views.

---

### The Richmond Amateur Photographic Society.

This Society, whose numbers are steadily increasing, has now started weekly meetings (instead of fortnightly as hitherto), at the "Greyhound Hotel," a more central and convenient location than the former quarters. The first meeting under the new arrangement took place on Friday last, a lantern night, when Mr. F. P. Cembrano, jun., handled the lantern, and slides by Messrs. Hunter, Faulkner, Richardson, Ardaseer, and Cembrano were shown and discussed, those of the last-named consisting of a series of views in Chester and North Wales, taken during last year's Photographic Convention.

At the next meeting (Friday, 13th), Mr. C. Hussey will give a demonstration of the collodio-bromide process for lantern slides and transparencies. On Monday, the 16th, Major J. Fortuné Nott, President of the Society, will give a lecture, with lantern illustrations, on "Wild Animals in Captivity," at 8 p.m., in the Lecture Hall, Hill Street.

---

### The Leeds Photographic Society.

At a meeting on Thursday evening last Mr. Godfrey Bingley, president, occupied the chair.

Mr. C. H. Bothamley delivered a lecture entitled "A Good and Bad Photograph." In introducing the subject, Mr. Bothamley referred to the absolute necessity for every photographer making himself acquainted with the leading rules of art; although it was impossible for a picture to be made artistic by a rigid observance of rules, yet, unless they were obeyed, except in a few exceptional cases, it was impossible for a picture to be pleasing, and, in a clear and interesting manner, Mr. Bothamley pointed out the necessity of the rules of composition and light and shade, illustrating his remarks by diagrams on the blackboard and a large number of choice lantern slides thrown upon the screen, thus bringing before his hearers the leading points in his address.

At the close of the lecture, a vote of thanks was passed to Mr. T. W. Thornton, the retiring president.

The Croydon Microscopical and Natural History Club (Photographic Section).

*February 6th.*—Mr. John Weir Brown in the chair.

Mr. J. Howson gave a demonstration on bromide and alpha papers.

This was the first demonstration of the kind that had taken place in the Club's newly-acquired dark-room.

The Glasgow Photographic Association.

*January 29th.*—The second popular meeting was held in the large hall of the Philosophical Society's Rooms, 207, Bath Street, Mr. William Lang, jun., in the chair.

M. A. Lindsay Miller gave an interesting and instructive lecture, entitled "Architecture from the Earliest Times to the Present Day." The lecture was illustrated with limelight views of the chief buildings of ancient and modern times; the features and characteristic style of each were fully explained by the lecturer.

*February 5th.*—The fourth general meeting, in the Philosophical Society's Rooms, 207, Bath Street. Mr. William Lang, jun., in the chair. The following were unanimously elected members: Messrs. J. T. Bottomley, M.A., F.R.S., A. Neilson, J. Adamson, jun., and W. M'Whirter.

Specimens of flash-light portraiture were exhibited.

A communication from Mr. A. Pringle (honorary member) on "Albumen Slides" was read by the Secretary, and a paper on "The Optical Lantern, its History and Development" (see page 129), was given by Mr. Lang.

A lantern exhibition of slides prepared by the method advocated by Mr. Pringle, and a collection of Ferrier and Senlin's slides, brought the proceedings to a close.

Received.—From the Scovil and Adams Company, N.Y., "A Cyclopedic Index to the *Photographic Times* Almanac for 1891," compiled by Prof. C. Ehrmann. This is a supplementary publication to the almanac, to which it is a fuller index than is given in the book itself. It contains useful information, arranged conveniently in alphabetical order. The same firm sends also a framed copy of the patented "Dial Calendar for 1891."——From Messrs. Hazell, Watson, and Viney, "Evening Work for Amateur Photographers," by T. C. Hepworth, and the "Art of Retouching," by J. Hubert. The name of the author is sufficient guarantee of the excellence of the first-named work, which contains valuable information educationally important to the modern amateur photographer as to the profitable occupation of his time during the winter months, and at times when no dependence can be placed on daylight. The book is divided into nineteen chapters extending to 196 pages, and is well illustrated with camera and pencil by the author. Mr. Hubert speaks with acknowledged authority on the subject he has taken in hand, and adds to his information on retouching, some chapters on portraiture and flash-light photography. The book contains a Woodburytype reproduction from a negative before and after retouching, as well as other illustrations in elucidation of the matters dealt with.——From Kegan Paul, Trench, and Co., *Sun Artists* for January. Mr. B. Gay Wilkinson is the subject of the descriptive essay, and the plates are from his four photographs entitled respectively, "Sand Dunes," "Prawning," "A Pastoral," and "A Windy Corner." The writer of the essay, Rev. F. C. Lambert, draws a parallel between Gay, the "poet born" and "word painter," and Mr. Wilkinson, who having community of blood and lineage with the poet, shows also, in his pictorial expressions, some measure of the "poetic fantasy in nature's boundless store."——From the Crystal Palace Company, a notice paper and entry form of the forthcoming National Photographic Exhibition to be held at the Crystal Palace from Monday, April 13th, to Saturday, May 2nd next.

# Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.**

**All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

C. C.—*Prints in Black and White.* There is no aniline process applicable to such a purpose and giving a jet black. The best method of sun printing should be either the platinotype or carbon process; but in the event of a large number of copies being required, one of the photo-mechanical methods of reproduction ought to be resorted to. This may be either collotype, bitumen process, or by photo-zincography, much depending upon the character and average size of the originals, and number of copies desired. By giving us further information upon these points, we may be better able to advise you.

T. P.—*Lord Rayleigh's Wire-gauze Experiment.* The object was to show that, by diminishing the size of the pinhole in the card, within certain limits, the structural definition of the wire gauze, as seen through it at a distance of three or four feet, becomes impaired. In like manner it was quite possible to use too small a stop with a lens, and so deteriorate its defining power; in fact, it might come to be worse than using no lens at all. The reference to astigmatism was centred in the fact that the same little contrivance could be used as a test for discovering this imperfection in the human eye. By examining the wire gauze in different positions between vertical and horizontal, any visual defect makes itself at once apparent, and the angle of imperfect definition could be noted.

Tyro.—*Cotton Wool Vignettes.* The stained oval glasses seldom give the best results. Each portrait requires specific treatment, and nothing is better than a thick card with oval aperture and gummed edges, upon which cotton wool fibres may be arranged and drawn out to suit the requirements of each negative about to be printed. Some prefer to use a double card with the loose cotton wool filled in between the two layers.

S. E. N. (Wisbeach).—*Impurities in Sulphites.* By long keeping in imperfectly stoppered bottles, sulphites are apt to become further oxidised, slowly passing into sulphates. To test for this latter impurity in any sample, dissolve it in distilled water, and add hydrochloric acid and chloride of barium, when the formation of a heavy white precipitate at once indicates sulphate. Small quantities are often met with, and may be disregarded.

A. L. (Ryde).—*Coloured Mounts.* According to the effect desired, you may either choose a tone which harmonises with the middle tints in your print, or shows a perceptible relief by contrast. Avoid violent variation, or too pronounced a colour for the mount, which is always distasteful.

F. C.—*Foreign Membership.* By the rules, if a member goes abroad and remains absent from this country for any length of time—notice of such intention having been given to the secretary—he is excused from payment, but the official papers are not forwarded.

Eastcheap.—*Plain Paper Printing.* The information you were seeking for is all to be found at pages 71 to 73 of the "Photographic Printers' Assistant" (price one shilling), published by Messrs. Piper and Carter. It is advisable to use a little gelatine, and ammonio-nitrate of silver is preferable; but you would find it rather tedious to apply this with a brush. A fine quality of cartridge paper ought to suit your purpose.

H. G. W. (Shoreditch).—Kershaw's instantaneous shutter answers to the description given in your letter.

Wanted, on loan for a few days, or to know where a copy of Messrs. Sutton and Dawson's "Dictionary of Photography" can be obtained.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1694.—*February* 20, 1891.

CONTENTS.

## PROFESSOR LIPPMANN'S NEW DISCOVERIES IN HELIOCHROMY.

Since last Friday some additional particulars about M. G. Lippmann's discoveries in relation to photography in natural colours have come to hand, and we give them in the order in which they have been received, reserving comment until the end.

The facts were first made known on the second of this month, at a meeting of the French Academy of Sciences, under the presidency of M. Duchartre, and much about them was published in these pages last week. The following is the notice of the meeting published in last week's *Nature* :—

On Photographing in Colours, by M. G. Lippmann.

The conditions said to be essential to photography in colours by M. Lippmann's method are : (1) a sensitive film showing no grain ; (2) a reflecting surface at the back of this film. Albumen, collodion, and gelatine films sensitised with iodide or bromide of silver, and devoid of grain when microscopically examined, have been employed. Films so prepared have been placed in a hollow dark slide containing mercury. The mercury thus forms a reflecting layer in contact with the sensitive film. The exposure, development, and fixing of the film are done in the ordinary manner ; but when the operations are completed, the colours of the spectrum became visible. The theory of the experiment is very simple. The incident light interferes with the light reflected by the mercury ; consequently, a series of fringes is formed in the sensitive film, and silver is deposited at places of maximum luminosity of these fringes. The thickness of the film is divided according to the deposits of silver into laminæ whose thicknesses are equal to the interval separating two maxima of light in the fringes—that is, half the wave-length of the incident light. These laminæ of metallic silver, formed at regular distances from the surface of the film, give rise to the colours seen when the plate is developed and dried. Evidence of this is found in the fact that the proofs obtained are positive when viewed by reflected, and negative when viewed by transmitted light—that is, each colour is represented by its complementary colour.—Observations by M. E. Becquerel on the above communication. M. Becquerel called attention to the experiments made by him on the photography of colours in 1849. His researches, however, dealt more with the chemical than the physical side of the question.

Last Monday we received a letter from our Paris correspondent, M. Léon Vidal, in which he says that he has had occasion to see M. Lippmann, who has shown him his results; he then had a better opportunity of examining them than was the case with those exhibited at the Photographic Society of France, and the spectrum was very well rendered in those which he saw at the Sorbonne. M. Vidal adds that when M. Lippmann possesses plates sensitive to the red rays, and when his present results are improved upon by experience, the images will be more complete; moreover, it remains to be seen what will take place when he uses compound colours, above all with a mixture of white light. He has made a beginning, and new developments must be patiently awaited; he will not be dilatory in the work. One result attained by the experiments of M. Lippmann is, that the polychrome impressions obtained by M. Becquerel, and by his imitators, Niépce de St. Victor, Poitevin, and others, appear all to be due to the physical phenomena presented by the interference of light; this is one of the most curious consequences of this fruitful discovery.

M. Vidal says, in a letter which we received yesterday, that, so far, those plates have worked best in M. Lippmann's hands which were prepared by the old Taupenot process; such dry plates, some of our readers may remember, had upon them one film of albumen and another of collodion. The plates should be orthochromatic, especially for the red rays, otherwise the time of exposure becomes too long. In photographing the spectrum, M. Lippmann uses an arc light of eight to nine hundred candle power, with the usual condensers, slit, and prisms. The colours presented by the finished photograph much resemble those of the soap-bubble. M. Vidal sends other particulars, but they are the same as those included in a memoir by Professor Lippmann upon another page of this issue.

Up to this date M. Lippmann has not published any definite working formula, but if his hypothesis of the nature of the coloured image be true, it is easy for every photographer to devise his own methods, and we will now give some speculative suggestions on the subject which may or may not hereafter prove to be erroneous.

In the first place, it seems evident that dry plates alone can be used to permanently photograph interference fringes in parallel layers, because any damp film would contract on drying, and bring the fringes nearer together, so that they would no longer permit the true colour to be reflected. In development the film will swell, but this does not matter if it returns to its original thickness on drying.

Any colour in the sensitive film before exposure one would think to be objectionable, because it would prevent some of the rays reaching the back of the film to cause interference by reflection from the mirror. This, perhaps, may account for iodide of silver having been found worthless in heliochromy in the days of old; it does not, however, explain M. Lippmann's statement to the correspondent of the *Daily News*, that he used iodide of silver in albumen. According to the working hypothesis, it also seems desirable that the developer employed shall give a pure neutral black tint by transmitted light, a silvery-white one by reflected light, and not a deposit possessing a special colour of its own. There should be no actual colour in the finished image, but the colours seen should be entirely due to the breaking up of the waves of incident light by interference.

No doubt Professor Lippmann prepares all his plates by dipping, and we suspect that they are thinly coated; whatever the thickness of the dried film, the amount of that thickness is of vital importance in getting the best results. The more particles there are in the film, the more will they scatter the light and deteriorate the system of hypothetical fringes; hence, the more transparent the sensitive layer the better. As fluoride of silver is soluble in water, and forms a colourless solution, it is possible that with this salt and an organic vehicle an absolutely transparent dry film may be prepared, and, should it be suitable photographically, it might turn out to be the best possible salt in the working of M. Lippmann's process. It is a salt somewhat liable to attack glass plates, so surfaces of polished silver would have to be coated with the sensitive layer; indeed, it is possible that M. Lippmann would get on better now by using silver plates, instead of giving ordinary photographic plates a backing of mercury next the film. Fused fluoride of silver is elastic, and can be cut with scissors, but it is black in thick films. Robert Hunt found fluoride of silver to be useful in heliochromy, and, if we remember aright, Messrs. Crookes and Spiller, a quarter of a century ago, investigated the value of fluoride of silver in ordinary photography.

At present, Professor Lippmann's plates are least sensitive to red light, and not highly sensitive to any of the rays of the spectrum; consequently, development can be carried on in red light. Should hereafter more sensitive films be formed, a suitable light for developing is likely to be that transmitted by superimposed sheets of cobalt glass and copper-oxide ruby glass. These will give the light of the very extremity of the visible red of the spectrum.

Professor Lippmann has given a great impetus to heliochromy by producing evidence tending to prove that the colours of the photographs are those of thin plates, and that they can be fixed.

## PHOTOGRAPHING JETS AND BURSTING SOAP FILMS.

OWING to the kindness of Lord Rayleigh in lending the original photographs, we are enabled now to give outline illustrations, photographically produced upon the blocks for the sake of accuracy, of some of his results in what the Americans call "lightning" photography. The substance of his lecture a fortnight ago at the Royal Institution on the subject was published in these pages last week.

Fig. 1 represents a jet of air blown up through water, and photographed by the electric spark; in this case it will be noticed that the jet breaks into bubbles close to the nozzle of the pipe.

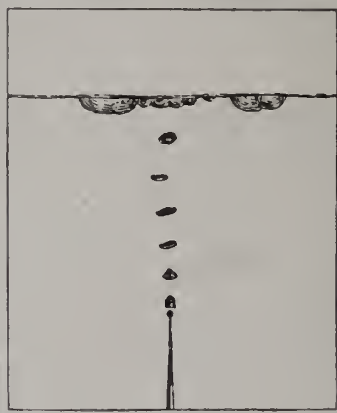


*Fig.* 1.

*Fig.* 2.

Fig. 2 is a jet of water falling vertically in air, controlled by a tuning fork, which throws the object into periodic vibrations synchronous to itself. The water does not break into drops close to the nozzle; it first forms an unstable cylinder, and each drop, before it quits the cylinder, is connected with it by a ligament. This ligament gathers itself into a little drop, which travels faster than the large one before it, and sometimes catches it and "cannons" with it.

*Fig.* 3.

Fig. 3 represents the plan adopted to burst a soap film while it is illuminated by an electric spark; the duration of the latter is about the $\frac{1}{32000000}$ of a second; the rupture of the soap film occupies about $\frac{1}{300}$ of a second, and these two events have to be made to occur together. A bullet is held against a piece of wood by a spring; to the spring a piece of soft iron is attached; when the latter is attracted by an electro-magnet, the spring is pulled back and the bullet falls. Two pieces of apparatus like this are employed, so that when an electrical current is sent, two bullets fall at the same instant; the one ruptures the film, the other completes the electric circuit sufficiently to allow the spark to pass.

Fig. 4 represents a soap film in the first stage of disruption, fig. 5 in the second stage of disruption,

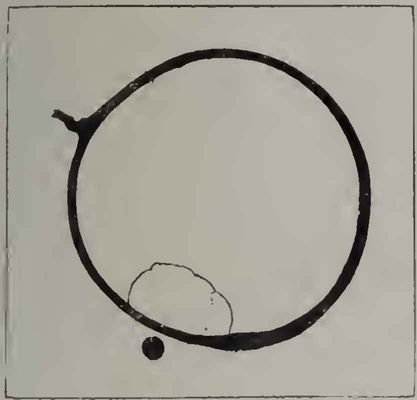

*Fig. 4.*

and fig. 6 in the third stage. The falling bullets are photographed in each case. The shots at the moment of touching the film had attained a velocity of about

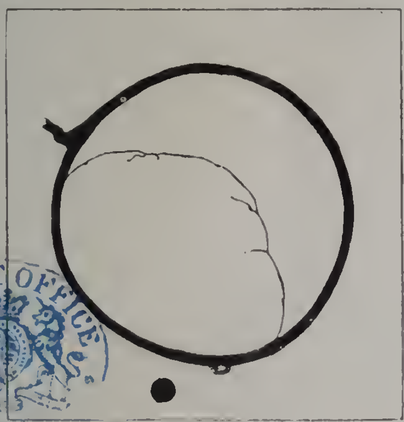

*Fig. 5.*

8 feet per second; the velocity of contraction of each film was about 48 feet per second.

The soap solution used, and which gives films of considerable durability, consisted of a solution of three

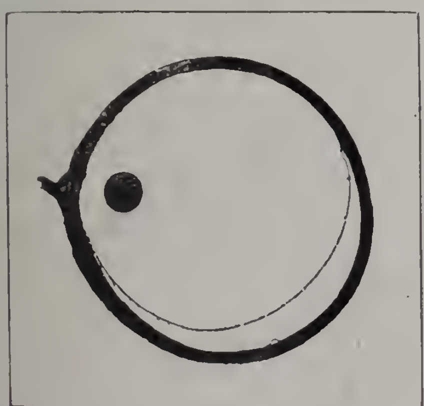

*Fig. 6.*

per cent. oleate of soda and twenty-five per cent. glycerine. The iron wire rings supporting the films were coated with solid paraffin; the films are more durable when supported by paraffin.

## THE BLOW-THROUGH LIME-LIGHT JET.

Ten years ago the lime-light was used almost exclusively by professional lecturers; but since oxygen gas has no longer to be made for the purpose, but is supplied compressed in bottles as a commercial commodity, the light is employed by many hundreds of amateur workers, either as a luminant for the optical lantern, or as a source of light by which to enlarge photographs. Hence the choice of a suitable jet—by means of which the two gases employed can be made to impinge upon the lime cylinder—becomes a matter of great importance to many. We propose to offer a few remarks upon the different kinds of jets available, and to point out the advantages or disadvantages pertaining to each.

Lime-light apparatus has of late been so perfected that the question of danger in its use may be almost, if not quite, eliminated. Accidents—and sometimes bad accidents—used to happen; but these were generally traceable to some malpractice in separating the oxygen gas from the compound with which it was associated, or to accidental admixture of hydrogen with oxygen in the bag or bags employed. We may now rely upon the gas supplied in cylinders being quite free from any such dangerous admixture, for the nozzles of the two bottles are furnished with right and left screw threads respectively, so that neither of them will fit the supply pipe of the compressing apparatus which is not intended for it. By this provision absolute immunity from this source of danger is secured. The substitution of cylinders for bags also obviates a number of minor risks, which it is not necessary to mention in detail.

In the choice of a jet the operator must be guided by his requirements. If he wish to be able to enlarge photographs, with the ability to show a few pictures occasionally by means of the optical lantern, and if he be content with the use of a screen or sheet about twelve to fifteen feet square, the blow-through or safety jet will suffice for all his needs. There is now no reason why this form of jet should be distinguished by the word "safety"; but the term is an attractive one to the tyro, and no doubt induces many to adopt that form of burner in preference to others. But the blow-through jet has other recommendations of a far more tangible nature. One of the necessary gases is obtained by the simple expedient of fixing an india-rubber tube to the nearest gas burner, and leading it to the hydrogen side of the jet. A cylinder of oxygen supplies the other gas, and by no combination of accidents can the two gases mix until they reach the point of combustion at the lime cylinder.

But in the choice of a blow-through jet some judgment is required, for many different patterns are in the market, and one kind will give quite double the light of its fellow without more expenditure of gas. A slight difference in construction makes all the difference. The cheapest—and, perhaps, the least efficient—form is where the O and H tubes are quite separate, and where the former bends over towards the mouth of the latter and projects a blow-pipe flame on to the lime. It is easy enough to manage, and, do what you will, you cannot make the flame go out with that sharp crack which sounds so ominously of coming disaster to nervous listeners. Far better is that form in which the oxygen outlet tube is embraced by the wider hydrogen tube, so that when you look down the latter you see the oxygen pipe hidden about one-eighth of an inch from the general outlet of the jet. In this case the gases mix, to some extent, before the lime cylinder is reached, and the gain of light from this circumstance is great.

Another point to which we may direct attention is the necessity for seeing that the bore of the O tube is something more than a pinhole. It should be sufficient to pass not less than four and a-half feet of gas per hour under moderate pressure. A less amount than that cannot give a good light.

But, with all these things provided for, some operators do not get the best out of their jets because they do not place the lime cylinder close enough to the outlet pipe. The distance between jet and pipe should never be more than one-eighth of an inch. Careless workers fall into another fault in neglecting to turn the lime cylinder every few minutes as it ought to be turned. The loss of light from this common error is enormous, with the farther serious risk of breaking the condenser of the lantern; for if a pit be formed in the lime, the flame will often be bent back towards the glass, and will fracture it. The successful operator with the lime-light must be continually on the alert to see that he is getting due efficiency from his jet. The gases must be regulated to a nicety until a point is reached when they give the best possible light without noise, and this point can only be ascertained by watching the effect upon the screen as the taps are manipulated. The lime must be turned to a small extent, but often; and the jet should have an arrangement by which this can be done easily, and without opening the door of the lantern. There are jets in the market which possess all the faults against which we have warned our readers, and we can only suppose that they are constructed from time-honoured models by those who can have had no practical experience of the lime-light.

In another article we shall treat of the more powerful mixed jet for lantern use.

---

The New Discovery in Heliochromy.—In an article in the *Daily News* of last Monday, its special correspondent at Paris says:—"I have had another conversation with Professor Lippmann, of the Sorbonne. The colours are permanent—he made use of the word "fixed"—and they are only seen by reflection in looking at the plate, and not through it. One sees the colours well in daylight or lamplight, but better in reflected than in direct artificial light. Thus, the professor covered the back of a glass plate on which he photographed a spectrum, and held the face towards the white side of a paper lamp-shade. In the light it threw back on them the colours took such a brightness as to be only comparable to the prismatic hues in a well-cut Golconda diamond. When he held the plate between my eye and the light I did not see a trace of colour on it. I never saw any effects more neat and perfect than those he has obtained. M. Lippmann has been at the Sorbonne five years."

## PHOTOGRAPHY IN COLOURS.*

BY PROFESSOR G. LIPPMANN.

I have set myself to the task of obtaining upon a photographic plate the image of the spectrum with its colours, in such a fashion that the image shall be permanently fixed, and last indefinitely in full daylight without alteration.

I have resolved this problem by operating with the ordinary sensitive substances, and photographic developers and fixing solutions, modifying simply the physical conditions of the experiment. The conditions necessary to obtain colours in photography are two:—1. The continuity of the sensitive film. 2. The presence of a reflecting surface behind this film.

I mean by continuity the absence of granularity; it is necessary that the iodide, the bromide of silver, &c., shall be disseminated in a film of albumen, gelatine, or other substance transparent and inert, in a uniform manner, without forming particles visible even under the microscope; if particles be present, it is necessary that they should be of neglegible dimensions in relation to the length of a luminous wave.

The coarse emulsions hitherto used must be excluded. A continuous couch is transparent, but usually has a slight blue opalescence. As vehicles to the sensitive salts I have used albumen, collodion, and gelatine; as sensitive agents, iodide and bromide of silver; all these combinations give good results.

The dry plate is placed in a grooved frame into which mercury is poured; the mercury forms a reflecting surface in contact with the sensitive film. Exposure, development, and fixing are the same as with an ordinary black negative, but the result is different; when the negative is finished and dried, the colours appear.

The image obtained is negative by transmitted light, that is to say, every colour is represented by its complementary tint. By reflection it is positive, the colour itself can be seen, and it can be obtained very brilliantly. To turn it into a positive, the image must be redeveloped or intensified, until the photographic deposit has a bright colour, such as can be obtained, it is said, by the employment of liquid acids.

Fixing is done by means of hyposulphite of soda, followed by careful washings. I have verified that the colours resist the action of the most intense electric light.

The theory of the experiment is very simple. The incident light, which forms the image in the camera, interferes with the light reflected by the mercury. It forms, consequently, in the interior of the sensitive film, a system of fringes, that is to say, at the maximum of luminosity and the minimum of obscurity. The maxima alone impress the plate; as a result of the photographic operations, these maxima remain indicated by deposits of silver more or less reflecting, which occupy their place. The sensitive film is thus divided by these deposits into a series of thin plates, equalling in thickness the interval which separates the two maxima; that is to say, half a wave length of the incident light. These thin films possess, then, precisely the thickness necessary to reproduce by reflection the incident colour.

The colours visible are thus of the same nature as those of the soap-bubble; they are only more pure and more brilliant—at least, when the photographic operations have given a good reflecting film. This results from the formation in the thickness of the sensitive couch of a great

* Read at the Academy of Sciences, Paris, February 2nd, 1891.

number of superimposed thin plates; about 200, for instance, if the couch has the thickness of one-twentieth of a millimetre. For the same reasons, the reflected colour is more pure as the number of reflecting films augments. These layers form, in effect, a sort of grating in depth, and for the same reason as in the theory of the action of gratings by reflection, the purity of the colours increases with the increase in the number of elementary mirrors.

## NOTES ON PORTRAITURE.

BY H. P. ROBINSON.

No. V.

There still remains something more to be said on the subject of "motive" in portraiture.

The question to be solved is whether the sitter should be represented as sitting for his portrait or doing something else. The former would be the absolute truth, and is often stiff; the latter must be the result of more or less make-believe, and may look natural. The one would be truth absolute, the other a slight falling away from that—in art—mysterious virtue. Now, here is a problem for the impressionists who insist on the whole, entire, rigorous truth. Which will they have: the truth, or something artificial so well done as to look more truthful than the truth itself? Without attempting to decide the question, I will endeavour to point out the practice of some of the great masters of portraiture. As it fortunately happens, there have just been added to the national collection, at enormous cost (£55,000), three pictures containing portraits by three painters who are recognised, by all shades of artistic opinion, as among the very greatest. The only subject on which all are unanimous is that Holbein, Velasquez, and Moroni are among the first half-dozen of the great portrait painters of all ages. These portraits have also the advantage of showing the contrasting styles of three separate phases of the art. An admirable and exhaustive article by Professor Colvin, accompanied by excellent engravings of the pictures, in the January number of the *Art Journal*, should be seen by all photographers. To this article I am indebted for a few extracts. In the Holbein we have an example of "the early maturity of northern art, when the grotesque strenuousness of the primitive Teutonic manner has been mellowed by the influences of the Renaissance, and a complete power of draughtsmanship has been attained, with a masterly precision in rendering both the characters and forms of humanity, and the appearances of natural objects in detail; but when the painter has not yet thought of attempting fully to express the relief of objects in space, nor their relations to each other as affected by the environing atmosphere. Of this phase of northern art Holbein is the chief master. It is he who best combined the accomplishments of the Italian Renaissance with the inherited energy and unsparing precision of his own school."

Looking at this picture for our present purpose—"motive"—what do we find? Two figures standing stiffly at each side of a high table, or, as it would now be termed, a "what-not." Both figures have their arms resting on the table, and both are set up to be painted, and both are "staring at the camera." Professor Colvin says that Holbein, who, in decorative and ornamental design, was one of the most inventive, adroit, and powerful composers that ever lived, has, in this instance, seemed to let his composition take care of itself. The figures are placed at either end of the desk with a certain *naïf* stiffness, almost recalling the pose of a photographic group. This is not flattering to the photographic group, but the attitudes are characteristic of the artist's portraits.

The second picture is Italian, and belongs to the Venetian school. Moroni is already well represented in the gallery by several portraits. Especially distinguished are the full-length "Portrait of an Italian Nobleman," and the famous "Portrait of a Tailor." Keeping to our purpose again, we shall find that, in the new Moroni, the figure is posing for his portrait, and "staring at the camera," while he has evidently had one of those marble columns, which we have banished from photography, broken to afford him a place on which to rest his helmet. It must be admitted that Moroni varied his practice, and sometimes represented his figures in action or suspended motion. Of this, "The Tailor" is a good example. In this portrait the man, who has been cutting cloth with a shears, is represented looking up from his occupation at the spectator.

The third picture, by Velasquez, is, perhaps, the most interesting of the three to the painter. Professor Colvin shows us how much can be said of a simple portrait. I quote a part only of his eulogy:—"In the last picture of the three we have no case of piling up of details; of the patient and strenuous imitation, part by part, of nature's multiplicity, with subordination and harmony imposed, as it were, from the outside by an effort of the artist's will and craft. We have the result, triumphant and in seeming more spontaneous, of what is really a far more complicated artistic process. . . . And this is an example of Velasquez at his best. Something of the rugged, flashing power and fierce eagerness of the sitter seems to have passed into the painter's hand, and the method of execution he has chosen emphasises and harmonises with the character of the subject. The rude soldier-sailor in his handsome suit stands in bodily and spiritual presence before us, and seems snorting with impatience to be off to the fight once more."

For technical qualities and assured mastery of the brush this picture is amazing, but with this we have nothing to do. Our enquiry is, how did the painter allow his sitter to stand for his portrait? He stood upright against a blank grey wall, nothing more nor less. The painter probably advised him not to stand too stiffly, just as a photographer may do, and painted him. Let it be noticed that in this case, also, the sitter "stares at the camera;" this time it is a scowl, and some photographers would have the presumption to say that the head was badly lighted, that there was too much top light, and that the head was under-exposed.

I, of course, have not brought forward these examples for the purpose of inducing the photographer to pose his figures stiffly because great masters of painting did so. These masters were great for other qualities, the attainment of some of which is not open to the photographer; such as colour, and the power (which some call a vice) to idealise their sitters; and some qualities which are within his reach—if his arm is long enough—such as expression, and the bringing out of character. The good name of photography is always suffering for the faults of its followers. It is not always the fault of the art, but of the artist, when the leading characteristics and sometimes the character of the sitter is not brought out; but it must be confessed that few have the ability to exercise this power. Rejlander had it in perfection, although we are told by a writer in the *Quarterly* (who has probably not seen) "there is little of art to be seen in the past history of photography."* I give these examples to show that great painters did not always strive after making their sitters "doing something," and looking away from the camera; that they, in fact, frankly accepted the situation, and painted the man as he was—that is, standing for his portrait.

Now let us examine the practice of one or two other portraitists. The next of my examples in order of date is Sir Peter Lely. All will acknowledge that his art was greatly inferior to that of the painters I have mentioned. He usually represented his sitters occupied with some employment, never at rest, and as often as not as somebody else. For examples, see his celebrated portraits of Charles II.'s beauties at Hampton Court, "Princess Mary as Diana," and many others. Here we have action enough and to spare, but it is very artificial and make-believe. Then we come to Sir Joshua Reynolds and his contemporaries, great men in English art, especially portraiture. When they posed their sitters easily, and simply painted them, using, however, their knowledge of art in the posing, they made great pictures, which are the envy and admiration of the painters of the present day, and the choicest possession of the millionnaire; but when they went beyond this, and set their figures to work, the amount of action they gave them was the measure of their failure. Exception must be made in favour of such slight action and occupation as is shown in the wonderful portrait of "Lord Heathfield with the Keys of Gibraltar," by Sir Joshua, but when it extends to the amount visible in a picture by the same great hand in "The Graces Decorating a Terminal Figure of Hymen," in which three healthy young Englishwomen are posing in affected attitudes as mythological young persons for the purpose of having their portraits painted, the dignity of "doing something" is doubtful.

So it will be seen that there are examples of great painters working in both directions, and that some have erred in the direction of common-sense, and, painting a portrait *as* a portrait, have found stiffness; others, trying to escape the prosaic, deviating into what they thought was grace, gave their sitters a motive—and failed.

The moral of all this is, that photographers did not invent stiff attitudes or bathos; the lesson is, that when photographers take a portrait they should accept facts, and understand that their duty is to produce a presentment of the individual—this should not prevent the pose being free, easy, and natural—and that when they attempt to do more they must beware of artificiality, affectation, and bathos.

London and Provincial Photographic Association.—February 26th, technical meeting; March 3rd, lantern and musical entertainment, with brief interlude consisting of a demonstration of the polarisation of light; March 5th, pictorial composition, illustrated by the lantern; March 12th, lantern night.

* It is curious and amusing that some photographers who have taken up photography comparatively recently seem to know so little of the history of the art that they think, or, perhaps, only assume, that its claims as art is a new idea, and have only been seriously made (with examples ?) in their own time, and by themselves. Even Mr. Davison—who is not usually a jocular writer—in his lecture at the Society of Arts, says of photography: "In regard, however, to its own direct claim to be admitted as a means of artistic expression, it has only happened with the introduction and application of these principles (naturalistic) that any serious demand to be recognised in the domain of art has been made." This apparent ignorance is another example of make-believe, for I credit the writer with more exact knowledge—to say nothing of these same principles having been renounced as unsound by their originator.

## PHOTOGRAPHY IN THE ORDNANCE OFFICE.*

BY COL. SIR CHARLES WILSON, K.C.B., K.C.M.G., F.R.S.

Up to 1853 all Ordnance Survey maps were engraved on copper; but in 1854 lithography was adopted for the $\frac{1}{500}$ and $\frac{1}{2500}$ scales. This was soon displaced by zincography, which has in turn, since 1889, given place to photo-zincography. The art of printing a line photograph in permanent ink from a zinc plate, or photo-zincography, was discovered in 1859: but, excepting for the reproduction of national MS., no practical use was made of the discovery until 1881, when the process superseded engraving for the production of the 6-inch map.

To obtain the full advantages of the process, the MS. $\frac{1}{2500}$ plans were drawn in a style suitable for reduction, *i.e.*, the buildings were coloured yellow to reproduce black, and the names, ornaments, and numerals were exaggerated so that their reduction might be of the proper size. This arrangement had its disadvantages. The $\frac{1}{2500}$, or parent map, still continued to be published by zincography, and was really sacrificed to its offspring, the 6-inch map, which was published months in advance of its parent. It also ruined the drawing which was formerly so much admired, for the draughtsmen, realising that their efforts were only directed to the preparation of a groundwork for a mechanically reduced map, lost interest in their work. In Ireland, however, where photo-zincography has never been introduced, the MS. plans continued to be very beautiful works of art. Photo-zincography has now been adopted for the publication of all new plans on the $\frac{1}{500}$ and $\frac{1}{2500}$ scales, with the following advantages: Fidelity of reproduction of the original; saving of cost in the case of close work; acceleration of publication; uniformity of execution; great improvement in the style of original drawing; and facility in revising town plans. The parent plan has also resumed its proper place in the publication in advance of the 6-inch map.

The photo-zinco process is so well-known that I need not describe it here, except to point out the larger scale upon which photo-copying is being carried out by the Ordnance Survey Department. The glass plates measure 45 by 30 inches, and weigh 33 lbs. The paper used for the photo transfers is Evans' thin paper; and it might be thought that a system of photographic reproduction, based on a flimsy paper transfer, would introduce many elements of inaccuracy. In practice, however, the process is found to compare favourably, as regards accuracy, with zinc etching methods, and engraving on stone or copper. Impressions varying more than one-sixth per cent. from the true scale are now cancelled. This result is very largely due to the skill that has been acquired by the photographic and printing staff.

The following method has recently been adopted for producing the $\frac{1}{2500}$ plans of large towns from the $\frac{1}{500}$ plans:—A convenient number of $\frac{1}{500}$ plans is pinned together, and a negative of the reduction obtained in the usual way. From this negative a cyanotype print is obtained, the result being a pale blue image on a white ground. The necessary drawing is now proceeded with on the cyanotype, and, when complete, it is fixed in its proper position with the surrounding $\frac{1}{2500}$ detail, and then re-photographed for publication.

The maps are now printed by a specially designed steam

* A portion of a paper on "Methods and Processes of the Ordnance Survey," read last Wednesday night at the Society of Arts.

zinc-plate printing machine, which, when necessary, can print 900 impressions an hour.

Until 1881 the 6-inch map was engraved on copper, the reduced detail being obtained from the $\frac{1}{2500}$ map by photography. In 1881 it was decided to abandon engraving in favour of photo-zincography, and the practice was to pin four $\frac{1}{2500}$ sheets together with their proper margin, and reduce them at once to a quarter-sheet.

The present system is to take a blue impression of each $\frac{1}{2500}$ sheet as it is being printed for publication, and, upon this, to pen into scale all detail that is to appear on the 6-inch map in black, whilst the names, ornaments, trees, and numerals are typed in an exaggerated style, so as to be of suitable size when reduced. All parcel and area numbers and unimportant detail are not penned in, and, being in blue, do not photograph. Four such plans, forming a 6-inch quarter-sheet, are placed together, and reduced at once by photography. The parks, mud, and sand are inserted in a tint by transfer from copper after the photo-transfer has been laid down on zinc.

The six-inch quarter-sheet was adopted partly for convenience, the size being much more handy than that of the full sheet, and partly for acceleration of publication, for a quarter-sheet can be published as soon as the four component $\frac{1}{2500}$ plans are received, without waiting for the other twelve.

It may be mentioned that, as an experiment, sixteen $\frac{1}{2500}$ plans were placed in position on a screen with proper margins, and a full six-inch sheet produced from them in one operation. There was a slight distortion towards the corners, but I believe this may eventually be overcome.

## THE PHOTOGRAPHIC SOCIETY.

OF the report of the council of the Photographic Society read at its last meeting, the following portions are of the more general public interest :—

The Exhibition was, on the whole, satisfactory, although there was a diminution in the number of visitors as compared with the corresponding number for 1889.

The following table, giving the results of the analysis of the last six exhibitions, shows the details for comparison :—

| Year. | Frames. | Photographs. | Portraits and Figure Subjects. | Landscape and Architecture. | Miscellaneous. |
|---|---|---|---|---|---|
| 1885 | 673 | 1620 | 482 | 803 | 102 |
| 1886 | 675 | 1494 | 603 | 580 | 36 |
| 1887 | 642 | 1784 | 864 | 549 | 179 |
| 1888 | 518 | 1098 | 442 | 611 | 45 |
| 1889 | 640 | 833 | 388 | 360 | 85 |
| 1890 | 658 | 808 | 381 | 348 | 79 |

| Year. | Professionals. | Amateurs. | Members. | Non-Members. | London. | Country. |
|---|---|---|---|---|---|---|
| 1885 | 103 | 119 | 103 | 119 | 103 | 110 |
| 1886 | 101 | 97 | 105 | 93 | 87 | 101 |
| 1887 | 110 | 102 | 121 | 91 | 100 | 102 |
| 1888 | 75 | 83 | 103 | 55 | 89 | 69 |
| 1889 | 100 | 88 | 102 | 86 | 84 | 104 |
| 1890 | 83 | 80 | 82 | 81 | 79 | 78 |

The following is the analysis of the 1890 Exhibition :—There were 163 exhibitors, comprising 82 members, and 81 non-members. There were 6 foreign exhibitors (America 2, France 1, Germany 2, India 1). The 163 exhibitors comprised 83 professionals and 80 amateurs. 658 frames were hung, containing 808 photographs, of which 328 were portraits, 53 figure subjects, 348 landscapes and architectural subjects, and 79 miscellaneous, including a few animals and marine views.

It is with great pleasure that the council has been able to take the new premises at 50, Great Russell Street, where the meetings are now held. The guarantee fund which was raised last year will probably save the Society from losing any portion of its invested capital through this new departure, and it is hoped that the increased conveniences which the Society now affords will attract a sufficient number of new members to enable the council to prolong the period of three years for which the premises have been taken. It is requested that members will bring this matter to the notice of others who are interested in photography, and that they will endeavour to obtain additional members for the Society.

Efforts to establish a library and a museum are being made, and to obtain copies of all English and important foreign photographic publications which we do not now receive. The reading-room and dark-room are already available daily for the use of members.

Mr. Edwin Cocking has resigned the appointment of assistant secretary, after having served the Society zealously for fifteen years. Mr. H. A. Lawrance, whose wide acquaintance with photography and photographic literature will be of great use in carrying out our new arrangements, has been appointed to the office. The *Journal* has been published as usual. It is believed that the "Abstracts," which have been prepared for it each month by Mr. Lawrance, have been found to be very useful.

The scheme for the establishment of a Photographic Institute has taken more definite form. A paper on the subject was read by Dr. Lindsay Johnson in February last. The ex-Lord Mayor (Sir Henry Isaacs) and several other prominent gentlemen have expressed great interest in the subject. A report has been drawn up showing the general lines on which it seems desirable to work, and a copy of this report has been sent to all metropolitan and provincial photographic societies, with a view to eliciting the opinions of the photographic public on the scheme which has been brought forward. It is hoped that, during the current year, substantial progress may be made.

During the year, a committee was appointed to consider the question of lens standards, and to report on the advisability of introducing other standards (such as for weights, measures, intensity of light, &c.) for use in photography. It was intended to continue the work carried out by the Society in 1881, but not to alter any of the standards then laid down. The committee has made a report so far as the extension of the lens standards of 1881 is concerned, and the amended memorandum of lens standards will be published as soon as possible.

It is regretted that no papers were read during the year on the application of photography to its employment as an art, the meetings of this Society having been devoted to the scientific rather than the artistic side of our subject. The council wish to state that papers devoted to artistic photography will always be welcomed.

As already announced in the *Journal*, the progress medal for this year has been awarded to Lieut.-Col. J. Waterhouse, B.S.C.

The council has elected Dr. Miethe, astronomer at the Potsdam Observatory, Berlin, an honorary member of the Society.

In the third paragraph from the end of the foregoing quotation, on the amendment of Mr. J. W. Swan, a wise alteration was made in the wording of the report where it originally read that the meetings of the Society "*should* be devoted to the scientific rather than to the artistic side of photography," a remark which would mean the voluntary abrogation of a large section of the influence of any society in the photographic world.

The following particulars are from the report of the treasurer, Mr. W. S. Bird :—

I have the pleasure to report that, while our losses by resignation, death, and default amounted to 20, we have enrolled 12 new members, and are dealing with fresh applications. The list of members comprises 5 honorary, 59 life, 369 ordinary, and 13 non-resident, a total of 446, as against 418 in 1889.

As to the Exhibition, I think we must look upon 1889 as marking the highest point of success we are likely to attain. Our last certainly suffered by the lovely St. Martin's summer contemporaneous with the first three weeks of its opening; boating and garden parties were in full swing, and nature, decking herself in autumnal beauty, invited worshippers to her shrine. Secondly, great as was the number of pictures, and marked as was the influence of artistic and impressionist ideas in their production, there was found by many to be a monotony of effort and effect, and a melancholy prevalence of a low key of colour expression. The record shows that members repeated their visits to the Exhibition less frequently than usual. The lantern display was inferior to precedent. If the Society determined to obtain the finest possible collection of slides, representative of triumphant photographic work illustrating nature, science, and art; arrange for capable exponents of the subjects, and limit admission to the number that can be comfortably accommodated, the rooms would, in my opinion, be crowded four nights a week, at such prices for admission (one scale for the public, one for members) as would cover incidental expenses, and beneficially augment revenue.

The museum fund is in existence, and doubtless waiting on the project of a Photographic Institute assuming some definite shape. Possibly, we may presently see the photographic community—amateur, professional, mercantile—loosening purse-strings in that direction, and setting an example to city companies and to a wealthy public: but I doubt if many of us have lively anticipations of so remarkable a demonstration.

If no grand scheme is likely to be started and sustained in influential quarters, it may be possible to affiliate all photographic associations with the parent society, and give it the strength to initiate an institute that may develop with years into proportions adequate to the actual and potential activities of photographic science, and its applications to physical and intellectual needs. We have recently dispatched copies of the report on the need of a Photographic Institute, and the work it should do, to no less than 195 established photographic societies.

If only one hundred of these could be affiliated to the parent society, with an average of fifty members each, upon mutually satisfactory terms, such a combination of numbers, income, and energy could at least do something to lay broad and strong the foundations of an efficient Institute.

I am roving into fields of speculation, and had best come back to my figures, and submit an estimate of ways and means for the current year. In the first place, the cost of establishing ourselves in these rooms, with furniture, fittings, and dark-room appliances, amounts to about £130, and this amount it is necessary to take from capital. Seeing that half of our outlay is on premises held by agreement for three years, a decent sum must be annually written off for depreciation, say, £25 a year, and allowing this and £25 for the unexpected, I estimate our balance sheet for 1891 will come out after this fashion:—

| *Receipts.* | £ | *Payments.* | £ |
|---|---|---|---|
| Entrance Fees and Subscriptions ... ... ... ... | 400 | Rent, Gas, Coal, Assistant-Secretary, General Expenses, No. 52 ... ... ... ... | 305 |
| Exhibition ... ... ... | 370 | Exhibition, with Rent of Pall Mall ... ... ... .. | 470 |

Photographic Club. — February 25th, monthly lantern meeting; March 4th, "Printing on Rough Surface Papers."

Obituary.—The death is recorded, on the 11th inst., at Edingthorpe Rectory, North Walsham, of the Rev. J. Lawson Sisson, aged 75. In the year 1853, the deceased published formulæ for making proto-nitrate of iron and formic acid developers. (See *Journal of the Photographic Society*, vol. i., pages 66 and 151.)

## THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The following is the report of the committee for 1890 of the above Association, to be submitted to the annual general meeting on Friday next, February 27th, at 50, Great Russell Street, London:—

In reviewing the work of the year 1890, and in presenting the balance sheet, it will be desirable to recall the position of the Association at the commencement of the past year. At the annual meeting, and at subsequent adjournments thereof, the new rules were passed, and they have since been duly registered. These rules, it will be remembered, were framed with the object of extending the limit of the Association's usefulness, as it was then felt that the sum of £18 distributed in relief would hardly justify the continued conduct of its affairs on the same lines as hitherto.

It will be seen by the balance sheet that the new scheme has had the effect then anticipated, and we, your committee, can now point with satisfaction to the fact that, after proper enquiry into each case brought before us, we have disbursed in grants and loans nearly seven times the amount thus distributed in 1890. With regard to expenditure, the printing of the new rules and providing collecting boxes and printed boards setting forth the objects of the Association, necessitated an exceptional outlay, which accounts for the large amount put down for printing, &c. The balance carried forward to the present year, in consequence of the large increase in the grants, shows a considerable reduction, being £84 4s. 10d. compared with £125 12s. 11d. brought forward from 1889.

Turning now to the receipts, if we exclude the sum transferred from the abandoned "Orphans' Fund" which exceptionally inflated the receipts for 1889, it will be seen that the donations and subscriptions have exceeded those of the previous year by £11 or £12. It is with much satisfaction that we refer to the amount derived from the annual benefit at the exhibition of the Photographic Society, from the Chester Convention, from the Drapers' Hall Exhibition, and from the entertainment given by the Photographic Club. These are signs of appreciation of the position and work of the Photographers' Benevolent Association, which may well be expected to act as an example and a stimulus to others.

But, while the Association cannot be too grateful for the support given by these societies, and by donors and subscribers, many of whom are old contributors, it is incumbent on us to call attention to the fact that, unless we receive still farther help, it will be impossible to meet the claims for assistance which are now constantly coming before us, and which are likely to increase rather than to diminish. The pension fund, except for accrued interest, still stands as at the commencement of 1889, though we had hoped to be in a position to add to it on the present occasion; but this course is manifestly out of the question while our expenditure so largely exceeds our income.

Now that the Association can show what has been done during the past year, it is hoped that its claims to support will be recognised by many of those who have hitherto held aloof, and we earnestly trust that all photographers, and all who are interested in photography, will consider those claims, and will respond liberally to the appeal we now make for further funds, as it is only by a cordial recognition of our aims, followed by a liberal response to our appeal, that the objects of the Association can be carried out with thorough efficiency.

It is with much regret we record the death of Mr. T. J. Collins, who for many years served the Association as deputy chairman of committee.—Signed, on behalf of the committee,

William Bedford, *Chairman.*

The Photographic Society of Great Britain.—The next technical meeting will be held on Tuesday, 24th inst., at 8 p.m., at 50, Great Russell Street, Bloomsbury, W.C. The subject for discussion will be "The Dark Room and its Fittings." A special lecture will be given by Mr. Leon Warnerke on March 4th, at 8 p.m., on "The Simplified Photo-collographic Process." It is hoped that a collection of English and foreign collotypes will be on exhibition. Anyone interested in the process will be admitted on presentation of visiting card.

## CAPTAIN ABNEY'S LECTURES ON COLOUR.

Last Friday afternoon Captain Abney delivered the first of a set of lectures and demonstrations on "Colour" in the great room of the Society of Arts. The lecture was of a popular kind, the idea being to convey instruction in an attractive form, and on the basis of not assuming previous technical knowledge on the part of the auditory. Captain Abney, in introducing the subject, said that no natural phenomenon gives greater pleasure than that of colour. The scientific mind is not satisfied with merely receiving the pleasure which colour offers to the senses, but requires to investigate the reasons for the appearance of colours of varied kind. Art pays no attention to numbers, but it is the business of science to reduce colours to numbers, to make a statistical description. He thought that one of Turner's pictures might be expressed by science by noting and giving description of the colour and intensity of each part of it.

Colour depending upon light, it is therefore necessary, in the first place, to go somewhat into the science of light itself. It is not possible, even if expedient, in that course to treat the subject of light exhaustively, nevertheless enough must be explained to make clear what had to be said with regard to colour. White light is composite; its components are retarded to a different degree by passing through glass or other media; in other words, these components are differently refracted. No medium being perfectly transparent, even air retarded and absorbed a certain amount of light.

Having explained that the light to be used in the experiments (the electric arc) depended upon the disturbance of the molecules of the carbon points, the lecturer proceeded to give an idea of the minuteness of molecules, and followed this by referring to the rapidity of the vibrations of the luminous rays. To illustrate this point it was mentioned that for certain rays there are as many vibrations in one second as there are seconds in twenty millions of years.

The rate of vibrations of molecules was then discussed, and the absorption of certain rays analogically illustrated by the taking up of certain sounds by strings tuned to vibrate with the same rapidity as that belonging to the sounds thus absorbed.

Colour was described as produced by the deprivation of white light of a portion of its constituents. It would, therefore, be an absurdity to speak of converting white into coloured light. That was an impossibility. When a coloured glass screen or bottle of coloured solution was placed in the path of a ray of white light, what happened was this. The atoms of the glass or of the solution were vibrating at the same rate as that of certain of the rays of light. The vibration of these rays was taken up by the atoms, and consequently did not pass through, whilst the vibrations of the remainder of the light were transmitted and produced the effect of colour.

An apparatus for decomposing and recomposing the elements of light was shown, and its work projected upon the screen. Following this, the subject of fluorescence was taken up, and it was shown how certain rays were absorbed, and the fluorescent substance then gave out rays having other rates of vibration; thus rays from the invisible part of the spectrum might be made to stimulate an action corresponding to and producing visible rays.

Interference was next described, and its effect in producing iridescence in thin films illustrated by the projection of an image from a soap film, a gorgeous display of colour.

Photographers who have the opportunity should find both interest and instruction from attending the present course of lectures, which, as has been mentioned, are upon a popular basis, although not on that account to be confounded with the trivial and often incorrect displays of popularised science which obtained a certain amount of favour many years since.

## OUR PHOTOGRAPHER, MR. BROWN.

BY JAMES MEW.

His name was Brown, and his ways were free,
And he opened his place a week ago;
But he only took of our portraits three,
Then married, and closed his studio.
By each of his customers hangs a tale,
And yet they were of the human kind;
There was not among them a single male—
But I'll tell you their stories, if you're inclined.

First came the parson's wife; with skill
Were her faded charms repaired by art;
Her face—thought Brown—though it makes me ill,
Might certainly make an artistic *carte*.
Ah! Brown has never been pardoned yet
By this lady, rendered by art so fair,
For he wrote on the back of her *cabinet*,
"Original (1) preserved with care."

Next came a widow advanced in years,
A widow as mean as mean could be;
But Brown, he managed to quell her fears
Of the cost, and showed her in poses three.
"How much would you take me for, Sir?" she cried,
As she thought of the charge of his rival, Green;
And Brown, as his guileless smile waxed wide,
Said, "I'd take you, Miss, for about sixteen!"

Last came to his door a maid of grace,
And riches, and beauty, your heart to rive;
Said Brown, as he covered his blushing face,
"Can I be content with her negative?"
"How will you take me?" that maiden smart
Asked. Said bewildered Brown, in verse,
"On the plate of my heart, a permanent *carte*,
For richer or poorer, for better or worse."

The Physical Society.—At the annual meeting of the Physical Society, held last Friday at the Science and Art Department, South Kensington, Professor A. W. Reinold, F.R.S., presided. Professor J. Perry read the annual report, in the course of which it was stated that the Society now has 365 members. Mr. G. M. Whipple, Superintendent of Kew Observatory, proposed a vote of thanks to the Lords of the Committee of Council on Education for the use of the lecture theatre for the meetings of the Society; also for the use of the scientific appliances on the premises for demonstrations. All this saved the Physical Society much expense, and gave it an advantage over the Royal Society in the giving of experimental illustrations. Professor Sylvanus Thompson wished it to be generally known that the publications of the Physical Society are accessible to the public, and can be purchased. A paper by Sir John Conroy was read on "The Influence of Heat on Coloured Media." He heated a piece of cobalt glass, but not to its melting point, by means of a small burner; of the three absorption bands which cobalt glass gives in the spectroscope, the outermost edge of the band in the red shifted a little in the direction of the ultra-red end of the spectrum when the glass became hot. Some farther particulars about facts made known at this meeting will be found in the "Notes" upon another page.

## Notes.

At a meeting of the Physical Society last Friday, Professor Minchin gave a demonstration of the working of his cells, which cells have been already fully described in these pages, for obtaining electrical energy by the agency of light. The "impulsion" cells were so delicate that the motion of the foot of an observer in the laboratory, or the vibrations set up by a passing cab, would frequently throw them into the insensitive state, or *vice versa.* A battery of the steadily working class of cells he connected with a quadrant electrometer, and when light fell upon the battery the needle of the electrometer moved and caused a platinum wire to touch a platinum plate; this completed the circuit of an ordinary local battery, and caused a bell to ring. A suggestion has been made that this principle can be applied to the protection of bankers' safes, so that when anyone enters the strong-room with a light a bell shall give the alarm; burglars cannot readily work in darkness. Professor Minchin stated that he hoped, and was disposed to think, that no chemical action was set up in the sensitive surface by light, but that a transformation of energy took place. He had kept up a deflection of the quadrant electrometer with one of them for a week, and no deterioration seemed to have taken place. Some of the cells had been made for several months, and had not deteriorated. If these sensitive surfaces do not undergo chemical change by the action of light, it is a strong point in favour of the dynamic hypothesis of the invisible photographic image.

Some pretty experiments relating to the phenomena of colour were described last Friday at the meeting of the Physical Society by Dr. J. H. Gladstone, who, it may be remembered, many years ago painted invisible designs upon white paper with sulphate of quinine, which designs came out dark in a photograph of the sheet of paper, because of the fluorescence of the salt. Some of the salts of cobalt are used to form what are called "sympathetic inks," which come out of a pink colour when a sheet of paper written upon with them is held to the fire; the pink colour is due to a change in the state of hydration of the salt. Dr. Gladstone stated on Friday that when such a salt is dissolved in alcohol the solution is pink, but gradually changes to blue when sufficient water is added. A blue solution in a little water changes gradually to pink as more and more alcohol is added.

A correspondent, who wisely omits to put his name thereunto, sends us the following:—"Is it really true that a photographer who has a glass eye, which turns with the other one, occasionally replaces it by a small detective camera? I was told that he used to walk about with the eyelid closed, and when he saw a suitable object with his working eye, he opened the eyelid of the other in a moment, and got the required exposure. But now he has added mechanism to the detective, and is able to have the eyelid open, like other persons, and when he wants to photograph, he just winks *in a particular way*, which sets some interior mechanism a-whirring, whereby, as soon as the eyelid is again open, an internal screen is removed and then replaced; and so the photograph is taken. He can change the detective for the glass eye, or *vice versa*, while he pretends to be sneezing with his handkerchief before his face. It is all too, too dreadful, but he must be ingenious."

Those who are fortunate enough to use the incandescent system of electrical illumination must be aware, to their cost, that the original estimate for their fittings is greatly enhanced by the somewhat frequent failure of the delicate carbon thread which forms the principal feature of the glow lamps. There is a tiresome uncertainty about the life of these lamps which must be taken into account with the general outlay upon the fittings. A particular lamp may last for years, while another close by it, and on the same circuit, may give way after a few hours' incandescence; and, owing to royalties to inventors, a lamp is an expensive item, and the replacement of several before they have yielded a fair amount of service is, to say the least of it, an aggravation hard to be borne.

Hitherto a broken incandescent filament has resembled Humpty-Dumpty in the inability of all the king's mounted men being able to put it together again; but a French inventor, M. Pauthonier, has recently described a method by which reparation may be made, and large users of the pretty fairy lamps will welcome the discovery. The faulty lamp is placed in the hands of a glass-blower, who, by means of the blow-pipe, makes in the bulb a hole sufficiently large to extract the useless film, and to insert a new one. The new filament is attached to the stumps of the old one, and after the bulb has been filled with a liquid hydrocarbon a current of electricity is applied which decomposes the liquid, and makes the joints good by the deposition of solid carbon all round them. The glass is next bleached, to get rid of the dark carbon deposit which is commonly seen in lamps which have been long in use; it is then once more exhausted of air and sealed up. It is now as good as ever it was, and is ready to enter upon a new lease of life.

The toning of lantern slides, by which operation various colours can be produced, is a recently introduced modification of slide manufacture which will be found extremely useful in many branches of work. In lantern slides of microscopic objects, the colour of the original can be closely imitated, while the blue tone which can be obtained after fixation by means of the gold and sulphocyanide bath will give, for certain subjects, the effect of moonlight. All brilliantly illuminated sky and sea pieces, where bright lights sparkle on the waves, are fit subjects for this treatment, while other pictures, where the lights and shadows are in strong contrast, are vastly improved by a blue tone.

The ease with which any colour may be produced on a slide prepared by the carbon process is not recognised as it should be. Workers who have always devoted their attention to other processes have neglected this one, not knowing, perhaps, how easy it is by it to produce beautiful effects. Carbon tissue is now specially prepared for transparencies, and when the worker cannot get the exact tint which he wants, it is not a very difficult matter to prepare it at home. The year before last, some blue (carbon) slides were shown at the Crystal Palace Exhibition, and were rightly awarded a prize by the judges. The process is especially valuable in the reproduction of astronomical subjects. These used to be drawn by hand, but now that the camera is being every day more and more wedded to the telescope, these rough diagrams should disappear in favour of actual photographs of the scenery of the heavens. A good photograph, well shown by a powerful light, would, if prepared in this way, be the most beautiful astronomical picture possible, second to nature herself.

---

Had Meissonnier chosen to adopt the arts of the modern fashionable photographer, there is little doubt he could have doubled his earnings, large as they were. Occasionally Meissonnier condescended to portraits, but, as in the celebrated instance of Mrs. Mackay, the wife of the American Bonanza King, he very rarely pleased. As one of his critics remarks, "He would paint womankind just as they came to him, with nothing extenuated, and with all their wrinkles, and the powder with which they tried to hide them, set down so faithfully that the disgusted sitters thought they were set down in malice. His paintings of painted women, marvels of accuracy in their absolute fidelity, are true types of realistic art." This is not the kind of talent which sitters appreciate. No wonder, therefore, that few examples of his skill in portraiture exist.

---

Meissonnier could never have become a court painter, although Oliver Cromwell would have delighted in his truth. We suppose an example of a court and fashionable painter who is absolutely true to nature is not to be found. The essential quality of a skilful artist of this kind is an elegant mannerism. As was remarked some time ago in the case of the Guelph Exhibition, the faces of the Kneller and Lely period are so much alike that they are untrustworthy as portraits, simply because the artist has adhered to a supposed type of beauty to which all his sitters were anxious to belong. If Sir Peter Lely had been a Meissonnier, how different the Hampton Court beauties would appear! But then had he been a Meissonnier he would never have been chosen to paint them.

---

It is easy to understand the difficulty which is experienced in obtaining papers to be read before photographic societies. So much has been written on every branch of the art that to expect any novelty is almost hopeless. At the same time, societies must live, and it is to be presumed they cannot live without having papers read at the meetings. We fancy that too much stress is laid upon this supposed necessity. Some of the best discussions frequently happen when there is no set subject set before the meeting.

---

The anxiety, however, of those who have the interests of the Photographic Society at heart in regard to the technical meetings can well be appreciated. We fancy that, in the new rooms, these meetings will be much better attended, and will have more vital ty than there used to be in the old quarters. It is, of course, desirable to have a subject to fall back upon when there is nothing before the meeting. It is a fact, nevertheless, that the absence of a paper induces those members who, under no circumstances whatever, would put pen to paper, to bring out orally some interesting point of practice which they otherwise would have kept to themselves, not willingly, but because the necessity for narration has not arisen. One of the objects of these technical meetings, we take it, is to give opportunities to those members who have had plenty of experience, but who dislike to place their experiences on paper. Hence the absence of a paper is not altogether an unmixed evil.

---

Photographers are not alone in their endeavours to make their productions permanent; artists have troubles from the same source. The question, indeed, has come to such importance in Paris that a committee consisting of distinguished painters has been formed to investigate the subject of the value of pigments.

---

The fact that Mr. Alfred Marks has been appointed manager of the Central Bank of London reminds us that Mr. Marks was the secretary for the society for photographing Old London. It has always been somewhat of a mystery why this society ceased to exist. The work it did was extremely valuable, but surely it did not exhaust the material. Is it not possible for some of the London photographic societies to take up the work as a speciality?

---

A photograph was the cause of a rather curious scene at the *Nouveautes* Theatre, Paris, the other evening. The leading actress in the play assumes the character of a young girl who has lost her parents, and who is anxious to find them. To assist her in her quest, she sticks into her enormous *chapeau en eventail* all the portraits of her friends. These portraits had been bought at random at a shop near the theatre. Early in the evening a young Russian, with several friends, entered a *baignoire*, when, to his great disgust, he discovered that one of the portraits sticking in the hat was of himself. He immediately rushed behind the scenes, and had a wordy war with the lady in question, terminating the affair by violently snatching her hat from her head, tearing his photograph off, and marching triumphantly back to his box! Such sensitiveness is indeed rare.

## PHOTOGRAPHY IN AUSTRIA.

### Professor Lainer on Developers.

Some years ago Professor Dr. Eder delivered some interesting lectures at the Vienna Photographic Society. In one of them that excellent scientist, speaking on the future of photography, remarked that the next important improvements were probably to be expected in the discovery of new developers. And, indeed, in a short time followed the hydroxylamine developer, suitable, however, only for developing silver bromide and gelatine papers, especially for enlargements. But after this came the hydroquinone and the eikonogen developers, which to-day have been brought to an incredible degree of perfection. One of the professors at the Governmental Lehr-und Versuchsanstalt, named Alexander Lainer, has now published very far-reaching investigations, which I give here at length (after the *Photographischen Correspondenz*).

Comparative studies of the developers at present known have shown that their final effect is pretty much the same, and that the chief difference is to be sought only in the duration of the development. For instantaneous photographs it is particularly important to possess quick-working developers, in order to register feeble impressions of light, with a sufficient thickness of reduction of silver. For portraits, it is desirable to carry out all chemical operations quickly, and in general one wishes also the dark parts to be rich in detail. To obtain these ends, different materials have been used, but without such a marked success being obtained with any one as to lead to the exclusive introduction of one developer. Two years ago I called attention to the beneficial influence of ferrocyanide of potassium in the pyrogallol developer, and emphasised the fact that its addition is to be recommended particularly for short exposures, and that dense negatives, full of contrasts, can be obtained with it. Captain Himly studied the effect of ferrocyanide of potassium on the hydroquinone developer, and came to the conclusion that the addition of some drops of a 30 per cent. solution of ferrocyanide of potassium is to be recommended in order to obtain more contrast. With it one achieves more than by an addition of potassium bromide, but yet without a restraining of the development such as takes place with the latter.

Lately I have occupied myself much with the hydroquinone developer, with the addition of hydroxide of potassium and sodium hydroxide, instead of carbonates, and after many experiments obtained proportions which reduce very powerfully without the addition of ferrocyanide of potassium. In rapidity it surpasses all other hydroquinone developers.

Recipe I.

*Solution A.*

| | |
|---|---|
| Hydroquinone ... ... | 10 grammes |
| Neutral sulphite of sodium.. | 25 ,, |
| Water ... ... ... | 60 cubic centimetres ($cm.^3$) |

*Solution B.*

| | |
|---|---|
| Caustic potash ... ... | 50 grammes |
| Water ... ... ... | 100 $cm.^3$ |

Mix per cabinet plate—

| | |
|---|---|
| A (Recipe I) ... ... | 60 $cm.^3$ |
| B (Caustic potash) ... | 3 $cm.^3$ |

This developer brought out a sensitomer image in ¼-minute to 21°, the negative quite clear. The image appears after about three seconds. It is not every kind of plate which allows the use of this developer, for in many sorts it produces a grey fog, an observation made by Eder and Lenhard with their potash hydroquinone developer. To the foregoing developer I added about 12 per cent. of ferrocyanide of potassium, and therewith achieved sharpness with those kinds of plates which, without the ferrocyanide of potassium, showed fog; yet the negatives were hard comparatively, the lights very dense. Changes in the proportions of the mixture led to a developer which is unequalled in its action. This developer, in rapidity of effect, surpasses also the French developer "cristallos."

Recipe II.

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... ... | 900 $cm.^3$ |
| Sodium sulphite ... ... ... ... | 40 grammes |
| Ferrocyanide of potassium ... ... | 120 ,, |
| Hydroquinone ... ... ... ... | 10 ,, |

Solution B remains the same, namely, potassic hydrate $1 \div 2$. For use mix per cabinet plate.

| | |
|---|---|
| A (Recipe I) ... ... ... ... | 60 $cm.^3$ |
| B (Caustic potash $1 \div 2$)... ... ... | 6 $cm.^3$ |

The image appears in about three seconds, and the development is finished in thirty to forty-five seconds, but then the fifth batch of sensitometer plates shows a vigour otherwise often exhibited only by the fourth; No. 25 was still recognisable with certainty. The fourth batch was surprisingly vigorous, and the first numbers showed a good density, without being opaque; the gradation was excellent. This developer distinguished itself by permitting the exposure to be shortened, by yielding details excellently clear in the shadows, and by allowing very rapid development. Of course plates considerably over-exposed must not be treated with any rapid developer. If one adds a larger quantity of caustic potash, the density of the negatives is diminished by the same length of exposure. A diminution of the hydroquinone, and an increase of the sodium sulphite, have a similar effect, which exactly determines the manner in which the ingredients act.

A good recipe is that of using less ferrocyanide of potassium, and substituting sodium hydrate for caustic potash.

Recipe III.

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... | 950 $c.m.^3$ |
| Sodium sulphite ... ... ... | 30 grammes |
| Ferrocyanide of potassium ... ... | 90 ,, |
| Hydroquinone ... ... ... | 10 ,, |

*Solution B.*

| | |
|---|---|
| Sodium hydrate ... ... ... | 30 grammes |
| Water ... ... ... ... | 90 $c.m.^3$ |

If one mixes 60 $cm.^3$ A and 6 $cm.^3$ B (caustic potash $1 \div 2$), one obtains similar results as with Recipe 2; but if one mixes—

| | |
|---|---|
| A. (Recipe III) ... ... ... | 60 $c.m.^3$ |
| (1.) Natrium hydric. depur. | |
| B'. (Caustic soda $1 \div 3$) ... ... | 12 $c.m.^3$ |

one has a modification of the rapid hydroquinone developer, which gives the negatives a softer character, and has a beautiful effect with many sorts of plates, while it produces quite clear negatives.

Both Recipe II. and Recipe III. give quite rapid developers, which, perhaps, bring out portraits too quickly for some practitioners. In that case I recommend Recipe IV., which admits of a somewhat slower, though still quite rapid development.

Recipe IV.

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... | 1,000 c.m.$^3$ |
| Sodium sulphite ... ... ... | 35 grammes |
| Ferrocyanide of potassium ... ... | 25 ,, |
| Hydroquinone ... ... ... | 10 ,, |
| (1.) Natrium hydric. depur. | |

Mix per cabinet plate—

| | |
|---|---|
| A ... ... ... ... ... | 60 c.m.$^3$ |
| B (caustic soda $1 \div 2$) ... ... | 6-9 c.m.$^3$ |

or

| | |
|---|---|
| A ... ... ... .. ... | 60 c.m.$^3$ |
| B$^1$ (caustic soda $1 \div 3$) ... ... | 10-12 c.m.$^3$ |

The image does not appear for about five seconds, and is fully developed in one to two minutes. The gradation is very good; the plate remains clear in the developer, and portraits, even though taken on dull, misty days, produce excellent results. As compared with the pyro-soda plates, they were excellent.

All these developers are convenient to handle. In the morning one may mix a sufficient quantity for the whole day, or for several days. As far as my experience goes, the mixture keeps well in *closed bottles*, and I could not notice any decomposition after eight days. If, however, one wished to produce the mixture in equal quantities immediately before use, it would be easy to calculate it out, *e.g.*, Recipe IV. into Recipe V.—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... ... | 550 cm.$^3$ |
| Sodium sulphite ... ... ... | 35 grammes |
| Ferrocyanide of potassium ... ... | 25 ,, |
| Hydroquinone... ... ... ... | 10 ,, |

*Solution B.*

| | |
|---|---|
| Water ... ... ... ... ... | 550 cm.$^3$ |
| Caustic potash... ... ... ... | 50 grammes |

or—

*Solution B$^1$.*

| | |
|---|---|
| Water ... ... ... ... ... | 550 cm.$^3$ |
| Sodium hydrate ... ... ... | 60 grammes |

Mix per cabinet plate—

| | |
|---|---|
| A (Recipe V.) ... ... ... ... | 30 cm.$^3$ |
| B or B$^1$ ... ... ... ... | 30 cm.$^3$ |

When travelling, it is advisable to keep a supply of the developer concentrated.

*Recipe for a Concentrated Rapid Hydroquinone Developer.*—A. Dissolve 25 to 30 grammes of sodium sulphite in 100 c.m.$^3$ of water and 10 grammes of hydroquinone warm; then 25 grammes of ferrocyanide of potassium likewise in 100 c.m.$^3$ of water. The two solutions are mixed, and produce 200 c.m.$^3$

B.—Dissolve 50 grammes caustic potash in 100 c.m.$^3$ of water, or 30 grammes of caustic soda in 90 c.m.$^3$ of water.

For a cabinet plate mix—

| | |
|---|---|
| A ... ... ... ... ... | 10 cm.$^3$ |
| Water ... ... ... ... ... | 40 cm.$^3$ |
| B (caustic soda $1 \div 2$) ... ... | 6 to 8 cm.$^3$ |

or—

| | |
|---|---|
| A ... ... ... ... ... | 10 cm.$^3$ |
| Water ... ... ... ... ... | 40 cm.$^3$ |
| Caustic soda $\div 3$ ... ... ... | 10 cm. |

If one mixes the 200 c.m.$^3$ of solution A with 100 c.m.$^3$ of B, one obtains a *mixed concentrated rapid developer*, which must be thinned for use—10 c.m.$^3$ to every 30 c.m.$^3$ of water for rapid developments. Thus, the concentrated solution of 300 c.m.$^3$ suffices for 1,200 c.m.$^3$ of the finished developer, but which may again be diluted with 1,000 c.m.$^3$ of water for slower developments, and with 10 grammes of hydroquinone one gets more than two litres of ordinary developer.

Solutions A could also be used in conjunction with potash or soda, and then one has ordinary, but very good, potash or soda developer, *e.g.*:—

*Soda Developer.*

| | |
|---|---|
| A (Recipe IV.) ... ... ... ... | 30 cm.$^3$ |
| Solution of soda ($1 \div 5$) ... ... ... | 30 cm.$^3$ |

Rapidly acting developer may be made also with potash hydroquinone, of which another time. The potash developer requires a developing of about five minutes, the soda developer of four to five minutes. All developers with sodium hydrate and caustic potash hydrokinone *may be diluted with an equal volume of water*; the development is restrained thereby, but the details do not suffer.

*Bromide of Potassium* ($1 \div 10$).—Ten drops to the quantity mentioned have a powerfully restraining effect, by which chiefly the details of the shadows suffer. It is quite different with *iodine and iodide of potassium*, the effect of which I have fully described. Antichlor acts restrainingly on the hydroquinone developer, but it is not to be recommended for that purpose.

The developed plates must be well rinsed, and fixed in an *acid fixing bath*. One must take care that the fixing bath produces an acid reaction, which may easily be achieved by an occasional slight addition of an acid solution of sulphite.* The fixing bath should be frequently renewed, because an accumulation of solution of sulphite would finally restrain the fixing. For fixing with the acid fixing bath, cuvettes are much to be preferred to trays. The fixing will proceed much quicker, particularly if the plate-carrier is moved up and down with the plate several times.

Now that with these developers the developing proceeds with a rapidity which hardly leaves anything to be desired, it would be well to artificially accelerate the fixing, which might certainly be accomplished by means of indifferent additions to the emulsion.

If one develops a large number of plates with the rapid developer, it is desirable to have at hand a vessel of water containing a few drops of sulphuric acid. When the fingers become slippery, one dips them into this acidified water, by which means the feeling is immediately removed. The developing trays after use should be rinsed first with the weakly acidified water, and then with spring water.

Photography and Painting.

I must add a postscript to my last letter.

In Germany, and formerly in Austria, photographs were considered as mere manufactured articles, but later, in Germany, somewhat better protection was afforded them by a new law. Nevertheless, copyright for life, or for a certain number of heirs, was by no means granted for them. In Austria, repeated judgments of the Supreme Court of Justice decided that photography is to be reckoned among the fine arts, and to be protected against unauthorised reproduction; but, for a long time, painters looked down on it, and would not recognise its co-ordination. The International Photographic Exhibition, planned by the Club of Amateur Photographers in Vienna, will be the first occasion on which a jury meets clearly recognising the co-ordination of photography, and, at the same time, containing men like Professor

* 1,000 cm.$^3$ of water, 300 g. of sodium sulphite, 70 cm.$^3$ of concentrated hydrochloric acid, or mercantile acid solution of sulphite.

Angeli, from whose brush there exists a portrait of Queen Victoria, which, on the occasion of her jubilee, was reproduced in colours by the *Illustrated London News*. In the brotherly co-operation of painters and photographers there lies a great success, for the latter have long considered themselves artists, for which the public often laughed at them. But now a photographic exhibition is to be judged of from an *artistic* standpoint, and that must be considered mighty progress, for this jury would have every right to judge of an exhibition of paintings. Hitherto this new International Exhibition has found the greatest support in England. There, where formerly water-colour painting was more cultivated than on the continent, photography found a public trained to appreciate figure and landscape pieces; therefore the hopes that were connected with your countrymen's taking part in this exhibition were not without justification; but even though, unfortunately, they refrained from doing so, that would not diminish *the fundamental importance* of this praiseworthy undertaking. STYX.

## ASTRONOMICAL TETESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

### NOTE ON A METHOD OF SILVERING GLASS MIRRORS.

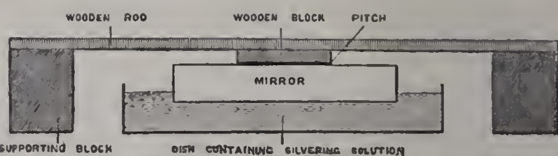
*Solutions.*—Make up 10 per cent. solutions of pure re-crystallised nitrate of silver, pure caustic potash, and loaf sugar. To the sugar solution add ½ per cent. of pure nitric acid and 10 per cent. of alcohol. The sugar solution is very much improved by keeping, its action being more rapid and the film cleaner when the sugar solution has been made for a long time. Make up also a weak solution—say 1 per cent.—of nitrate of silver and a 10 per cent. ammonia (90 per cent. distilled water, 10 per cent. ammonia, ·880 specific gravity). *Distilled water* must be used for all the solutions.

*Cleaning the Mirror.*—Thoroughly clean the mirror. To do this pour on a strong solution of caustic potash, rub well with cotton wool, rinse with ordinary water, wash again with absolute alcohol, and rinse; finally pour on strong nitric acid, and rub with a piece of cotton wool, inserted in the open end of a test tube. Rinse again thoroughly with ordinary water, and then place the mirror face downwards in distilled water in a dish sufficiently large to leave two inches margin round the edge of the mirror, and to keep the face of the mirror one inch from the bottom of the dish. The liquid should stand half an inch above the face of the mirror, which should not be completely submerged, and care should be taken to exclude all air-bubbles.

*For Silvering a 12-inch Mirror.*—Take 400 c.c. of the nitrate of silver solution, and add strong ammonia until the brown precipitate first formed is nearly dissolved; then use the diluted ammonia until the solution is just clear. Then add 200 c.c. of the caustic potash solution. A brown precipitate is again formed, which must be dissolved in ammonia exactly as before, the ammonia being added until the liquid is just clear. Now add the 1 per cent. solution of silver nitrate until the liquid becomes a light brown colour, about equal in density of colour to sherry. This colour is important, and can only be properly obtained by adding the weak solution. Dilute the liquids to 1500 c.c. with distilled water. All being ready, add 200 c.c. of the sugar solution to 500 c.c. of water. Then lift the mirror out of the dish, taking care to keep its face downwards during the time it is out of the water, pour the washing water away, add the sugar solution to the silver potash solution, taking care they are thoroughly mixed, and pour them into the dish. Place the mirror face downwards in this solution, taking care to exclude all air-bubbles. The liquid will turn light brown, dark brown, and finally black. In four or five minutes, often sooner, a thin film of silver will commence to form on the mirror, and this will thicken until in about twenty minutes the whole liquid has acquired a yellowish brown colour, with a thin film of metallic silver floating on the surface. Lift the mirror out, thoroughly wash with distilled water, and stand the mirror on its edge, or rest it in an inclined position until it is dry; if time can be allowed, the silvered mirror may be left to soak in distilled water, over night. Leave it to dry until next day, then the slight yellowish "bloom" can be polished off by rubbing softly with a pad of chamois leather and cotton wool. Carefully polish afterwards with a little dry, well-washed rouge on the leather pad. The film should be opaque and brilliant, and with careful handling will be very little changed with long use.

*Dishes.*—Use porcelain, glass, or earthenware dishes whenever possible; but, if these are not available, a zinc dish, coated inside with paraffin or best beeswax.

For small mirrors (up to 12 inches) the easiest method of supporting them during silvering is to attach them to a wooden rod by pitch, and arrange the dish thus—



*Temperature and Time.*—Half an hour is the usual time taken in silvering, but this is shortened by using warmer liquids. About 65° F. is best for silvering. In colder weather longer time must be allowed for the film to be deposited. In very hot weather a smaller quantity of sugar can be used, say 150 c.c. For a 12-inch mirror it is a safe rule to allow four times the time required to get the first indications all over the mirror as the total time for the mirror to be in the bath.

In cases when it is necessary to silver face upwards, a band may be put round the mirror, and the solutions poured on. It is necessary, in this case, to *leave out the potash solution*, and allow a longer time for the silver to deposit; as much as two hours being sometimes necessary.

If a very thick film is required, two silvering baths can be used, the mirror being left in the first for fifteen minutes, then lifted out, rinsed with distilled water, and at once immersed in the second bath, which should be ready in a second dish. The film must not be allowed to dry during the operation of changing from one bath to the other.

* Concluded from page 91.

THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—Lantern evening, February 23rd, "A Day at the Zoo.," by Lewis Medland.

## EASTMAN'S PHOTOGRAPHIC MATERIALS COMPANY.

The *Financial Times* of last Wednesday contains a long report of the first annual general meeting of the above Company, held at Winchester House, Old Broad Street, London, under the presidency of the chairman of the Company, Col. James T. Griffin, from which report we condense the following particulars.

The Chairman said that, about 1884, the Eastman's patents were taken up by a company on the other side of the Atlantic, and shortly they were found to be a great practical success. Towards the close of the year 1885 an agency was opened on this side of the water. The business on both sides continued to increase so, that it was found impossible for the company in America to supply the demands made upon it in Europe. The result was that, in 1889, a company was organised in England, and the shares were immediately subscribed for. The report dealt with the success attending the efforts of the first thirteen months. The demand in America has so increased that they have found it very difficult to keep pace with European requirements, and the English directors proceeded to make arrangements here for the erection of suitable buildings, and the supply of machinery necessary. They bought ten acres of freehold ground near Harrow, and buildings were erected which are now practically completed. The plans were all provided by Mr. Eastman, who has been over here, and who will soon be here again; but it will be some months yet before the Company will be in complete occupation, and ready to manufacture its own articles. What is called the bromide building, in which the printing will be done, will soon be in a position to meet the demands, which are growing month by month in Europe. In the first fifteen months after the agency was established on this side the sales amounted to £7,595; for the next twelve months, £12,900; for the succeeding twelve months, £15,807; for the next twelve months, ending Aug. 31st, 1889, the sales amounted to £26,576. Then the present Company was organised to take possession of the premises. The result is that, for the thirteen months ending Dec. 31st, 1890, the sales have reached the sum of £50,387. As stated in the report, frequently the Company has been obliged to decline orders, as it has been impossible to get the goods to fulfil the orders. Any questions that friends might desire to ask in connection with the report and balance sheet, he would answer to the best of his ability. Some friends might consider that the expenses are rather large. Under the heading of "trading expenses," they would find the sum of £10,775 3s. 10d.; but during the year they had been opening a good deal of new territory. Money had been expended in establishing agencies in different parts of Europe, and they were receiving very satisfactory reports from those agencies. These expenses will not be repeated, or not repeated to the same extent, or, if repeated, will be spread over a much larger return than they had received during the past year. The directors were pleased to be able to recommend a dividend of ten per cent. on the preference shares and five per cent. on the ordinary shares, and to carry forward to the next account £1,635 15s. 11d. He concluded by moving the adoption of the report and balance sheet.

Mr. Spiller had very great pleasure in seconding the chairman's motion.

Mr. Jay congratulated the board on the success they had attained on the year's working. The chairman had mentioned Mr. Eastman's name frequently, but he (the speaker) noticed that in the list of directors there was no mention made of Mr. Eastman.

The Chairman would ask the shareholders to alter that at that meeting.

Mr. Jay, continuing, said that they had already expended £1,400 in the purchase of freehold land. Was there anything more to be paid on the land.

The Chairman: No.

A shareholder remarked that the directors were very much to be congratulated upon the result of the first year's working, and it was a great exception that such a report and statement of accounts should be presented to a meeting of a company only in existence for a year. He thought they all must be satisfied—exceedingly satisfied—with what the directors had done.

Another shareholder: Are the dividends to be paid yearly or half-yearly? I might suggest that the time when the dividend warrants are sent out might be printed on the report.

The Chairman, in reply to the last speaker, read from the articles of the Association an article to the effect that it was optional with the directors whether they should pay yearly or half-yearly dividends.

A shareholder said that he had noticed that they had written off nothing for depreciation of the patents.

The Chairman replied that, under the advice of their auditors and solicitors, and by their own good judgment, they felt that the patents were as valuable, or, in fact, more valuable, than when they took them over. Most of them, he reminded the shareholders, were recent patents, and some of them had only been attained last year, and had scarcely yet been developed sufficiently for use. Therefore, they did not feel justified at the present moment in writing off anything under that head for depreciation.

A shareholder: Is there likely to be soon another call upon the preference shares?

The Chairman: At the present moment we are in no want of money, and from what we can see it is not likely we shall make another call.

The Chairman then put the motion for the adoption of the report, and it was carried unanimously.

Mr. Jay moved the re-election of all the directors, and said that the fact of all the directors retiring proved that the board was not afraid of the shareholders.

The motion was carried.

Mr. Eastman was elected a director of the Company, and the proceedings terminated.

## Patent Intelligence.

### Applications for Letters Patent.

1,856. W. J. Archer, F. W. Archer, and C. W. Huson, 43, Lord Street, Liverpool, "Lantern Slide Changer."—February 2nd.

### Specifications Published.

905. *January 17th*, 1890.—"An Improved Lens for Deflecting Light." Theophilus Coad, 31, Soho Square, London, Electrician.

The lens is made of the best glass or crystal, the base being preferably slightly convex, and the front of a parabolic form cut with a number of straight running facets from base to apex; the facets being preferably twelve in number.

A lens as above is primarily intended to be used with miners' incandescent electric safety lamps.

1,394. *Jan. 27th*, 1890.—"A Levelling Instrument." George James Heaton, 2, Coburg Villas, Albert Road, Old Windsor, Berks, Photographic Artist.

The object of this invention is to produce a levelling instrument which shall show at a glance whether or no the surface to which it is applied is level in every direction, such instrument being specially suitable for testing the verticality of the "swing-back" in photographic cameras, the said instrument being attached to the camera or otherwise. According to this invention I take a metal pillar, preferably square in section, having each face thereof accurately perpendicular to the adjacent faces, and its ends accurately parallel to each other and at right-angles to the sides of the pillar.

I next bore a hole longitudinally through the centre of the pillar, which hole is of two different diameters. In the lower fourth part or thereabouts of the length of the pillar the hole is about one-eighth of an inch in diameter, and the remaining three-fourths of the length of the pillar has the hole through it about three-eighths of an inch diameter.

In the larger hole I insert a piece of glass tubing, in the centre of which is suspended by a few fibres of silk, or other suitable material, a small rod preferably of metal, and about one-eighth in diameter, having the lower end thereof cut off at right-angles to the length of the rod.

I also firmly fix in the smaller hole, concentric with the glass tube, a similar rod cut off at right-angles to the length thereof, the upper face of which is just clear of the lower face of the suspended rod.

The metal pillar is cut away, except just at the corners, for about three-quarters of an inch, so as to form sight-holes, the contiguous faces of the two rods coming in the centre of the "sight." On setting the instrument on a flat surface, if the surface is level the two rods will appear as one; but if the surface is not level the upper rod will project beyond the lower one on that side of the surface which is below the horizontal. Similarly, if the instrument is held vertically against an upright surface, say the focussing screen of a camera, the position of the rods will indicate if the surface against which it is placed is vertical.

1,736. *February 1st*, 1890.—"System of Glazing." William John Hall, 16, New Market Place, Saint Helen's, Lancaster, Architect, and George Charles Whitfield, 1, Hardshaw Street, Saint Helen's, Manufacturer's Agent.

This patent is for constructing the frames of windows, especially shop fronts, as that the same shall in all cases be fixed with the rabbeted side outwards, in order to enable the glass to be glazed from the outside, either in the ordinary way, or be bedded in the rabbet with india-rubber, felt cloth, or other soft material, secured with beads or mouldings screwed, clamped, or otherwise fastened in such manner as to be easily removable either for new glazing or replacement.

3,446. *March 4th*, 1890.—"A Photographic Camera." Albert Peter Riley, 2, Upper Fenton Street, Commercial Road East, London, Photographic Material Dealer.

This camera is especially intended for use when travelling, but is also of general application and for indoor work. An important feature of my invention is that I employ only one moving part, which is actuated by the one hand only of the operator so as to move the dry plate into position, or focus of the lens, and so as to uncap and cap the latter for exposure of the dry plate. In the camera, or box, I provide an endless band of leather, sheet metal, or other suitable material, such band passing over a roller at each end, that is to say, at the back and towards the front of the camera. Means may be provided for keeping the band sufficiently taut, or to keep it from slipping. On this band I fix at equal distances apart any suitable number (say a dozen) of holders or clips. Each clip or holder is adapted to take a metal sheath, which contains a dry plate. The same lever, handle, push rod, knob, or pull serves to actuate both the endless band and to cap and uncap the lens.

By means of the apparatus instantaneous and time exposures may be effected conveniently by the use of one hand only rapidly in succession, and while the apparatus is carried under the arm in the bag, and without drawing undue attention to the operations.

17,012. *October 24th*, 1890.—"An Application of Xylonite, Celluloid, and the like." George Lee Auders and Charles Herbert Elliott, 10, Bush Lane, London, Electrical Mechanicians.

Our invention relates to a new or improved use for and application of any of the preparations known as xylonite, celluloid, and the like, by coating the surfaces of substances bearing devices or readable matter therewith.

In carrying our invention into effect, we print, emboss, indent, or otherwise prepare a fixed design or reading matter, or both, upon cardboard, paper, wood, ivory, metal, or any substance or material suitable for the purpose, in any colour or combination of colours, as may be required, and coat or cover the same upon either or both sides thereof with xylonite, celluloid, or the like, according to the uses to which the substance or material so treated may be intended. The coating thus given, being perfectly transparent and highly glazed, imparts to the design a high degree of finish, and, at the same time, renders it perfectly water-proof.

Our invention, in its salient points, is the application of the coating or covering previously mentioned to substances and materials bearing designs or readable matter that would be considered perishable or oxidisable when exposed to damp, or to advertisements that may require to be kept clean by washing, such as show cards and the like, prepared upon paper surfaces; or metallic advertisements that require periodical cleaning to remove oxidisation.

Our invention may be equally well applied to substances or articles not exposed to damp, and may be successfully used in coating business cards and the like, so that, if soiled, they may be sponged with clean water, and their original brightness restored.

20,820. *December 20th*, 1890.—"Applying Gum or other Liquid to Sheets of Paper." Hermann Wimmel and August Landgraf, Zimmerstrasse, Hamburg, Germany, Machine Manufacturers.

This invention relates to machines for applying gum or other liquid for the superficial coating of sheets of paper or other material placed upon the machines. The sheets are transferred from an adjusting table to a grasping device which is arranged on the circumference of a metal cylinder. After the locking of this device, which grasps the edge of the sheet, the cylinder begins to rotate, and carries along the sheet on its periphery. Underneath said metal cylinder is a small roller journalled in the frame of the machine, which roller lies with part of its periphery immersed in a vessel which contains the solution of gum or other liquid to be applied.

Whilst the sheet travels between the cylinder and the roller the latter transfers the gum or liquid to the surface of the sheet. The coated sheet, after the completion of a rotation of the cylinder, and after the grasping device has opened agaiu, is removed from the machine, aud a new sheet is iuserted under the fingers of this grasping device when the rotation of the cylinder is repeated.

## Correspondence.

### REDUCED RAILWAY FARES FOR PHOTOGRAPHERS.

Sir,—I beg to enclose you a copy of a memorial and letter sent this week to all the London aud suburban photographic societies. All interested iu the cause will, I am sure, feel deeply grateful for the co-operation and support of your valuable paper, and for any reference to the memorial in its columns that you may deem it advisable to make. Henry Selby,

*Hon. Sec. of the West London Photographic Society.*

42, *Ladbroke Grove Road, London, W., Feb. 14th.*

Dear Sir,—At a meeting of the West London Photographic Society, held at the Lecture Hall, Hammersmith, on the 23rd January, 1891, the president, Mr. Walter Adam Brown, in the chair, it was resolved: "That the question of cheap fares for members of photographic societies having been discussed for some time, the period has now arrived to bring the matter before the railway authorities, and that the memorial in favour of the scheme in the form presented to-night by the president be forwarded to all the metropolitan photographic societies for their approval, and on its return be at once lodged with the railways in question."

In pursuance of such resolution, I beg to enclose you print of the memorial, aud I should be glad if you will kindly lay it before your society at its next meeting, aud return it to me filled up as early as possible, with an intimation whether or not I may add the name of your society as one of the memorialists. Henry Selby,

*Hon. Sec. of the West London Photographic Society.*

42, *Ladbroke Grove Road, London, W., Feb. 9th.*

To the Chairmen and Boards of Directors of The Great Western, The Great Northern, The London and North Western, The Midland, The North London, The London and South Western, The Great Eastern, The South Eastern, The London, Chatham, and Dover, The London, Brighton, and South Coast Railways, and the other London and Suburban Railways.

My Lords and Gentlemen,—The humble petition of the under-signed London and suburban photographic societies and clubs showeth as follows:—

1. That the practice of photography is daily increasing, and that large numbers of those practising it do so, not as their sole occupation, but as an amusement, or in counection with other duties and occupations.

2. That a considerable number of photographers have joined societies established for the instruction and furtherauce of the art of photography, and those societies are governed by responsible boards of management.

3. That the greatest number of effective subjects suitable for photographs consist of landscapes and seascapes, and interesting spots some distauce from London, but the costs of the travelling expenses to those places is a serious drawback, and a reduction in the prices of tickets to your memorialists would be a great boon to them.

4. That concessions have been made by railway companies in favour of members of angling and other clubs, whereby any member of a duly accredited angling club can have issued to him a railway ticket at greatly reduced fares, on presenting his ticket of membership, and declaring that he is actually then goiug on a fishing excursion. Your memorialists ask that the same privilege may be accorded to them, and they further ask that as photographers cannot always go in a body to the same place at the same time, that any member of the memorialising societies may be entitled to the cheap ticket without the necessity of making one of a party.

5. Your memorialists submit that subjects taken of the route of auy line of railway fosters traffic on that line, and that the directors think so also is demonstrated by the fact that on many lines excellent photographs of places are exhibited in the railway carriages themselves. These are only seeu by actual passengers, whereas photographs taken by your memorialists would be carried into other hands, who otherwise might uot have known of such places at all.

6. Your memorialists are not unreasonable, and they think that some concession would lead not only to a large increase in the traffic, but to an increase in the profits of the railways themselves, and, at the very worst, it could easily be cancelled by a further order of the railways if found not to answer.

7. That your memorialists consist of the following societies, who have, by resolutions, approved of the memorial, and who would be happy to give further informatiou if necessary.

[Here follow the names of each society, its address, the name and address of the secretary, and the number of members on the books.]

### THE QUAGGA.

Sir,—I sent you a hurried note some little time ago *re* your remarks Mr. York and the last quagga. The holidays intervening, I have been unable to redeem my promise. The specimen copy of the quagga in the Year-Book is (I am almost convinced) one of my many negatives taken at the Zoo. It is now eighteen years ago, and it would be difficult to remember all the negatives taken. Mr. York considered I was singularly successful—at least I understood him to say as much. It was a kind of test of my ability previous to sending me out to this country. I give you a description of my iustrument and manipulations as far as I cau remember. I have many times since seen lantern slides from the same negative, and have had every reason to be satisfied with my work.

The apparatus was built by Meagher—a double camera, lenses placed so, ₒ°ₒ; the camera divided in half; the top part was provided with a Burr leus; the two bottom lenses, acting as stereo leuses, were Dallmeyer's 2B lenses, all identical in foci, diameter, &c. The equal of the lenses I have not seen either before or since. The top lens was used only as a finder; the shutter was immediately iu front of the plate, being slipped in position from underneath the camera, and was simply a blind lath of wood pulled down on to a spring, which sent it up when released. The plates were 8in. square, double stereo. The back was shifted after the first exposure. The slides were very solid, and had a roller shutter, the first, I believe, used in Great Britain, and were perfect in every respect. I invariably used the full aperture of the 2B's or the next stop to it. The average exposure, if I remember rightly, was about a second. All I had to do was, after getting into a suitable position, to sight the beast on the finder focussing glass, my head being under the focussing cloth, aud, with string in hand, pull down the shutter when I got a satisfactory position. I must confess I did not fiud much difficulty with my subjects; my left hand being on the rack screw, I could alter the focus or swing round as required. The collodion was what was then known as York's, rather uew. The developer was made from a saturated solution of ferri-sulph. with acetic acid, afterwards dissolved off with cyauide of potassium.

Perhaps my success was in a great measure due to a careful study of the animals. They, like ourselves, sulk at times, and you cau do nothing with them. Then there are ways of getting the fire iuto their eyes. I have barked at the carnivora, whistled to the reptilia, grunted at the antelopes, until I had a throat like a nutmeg grater. By the time I had finished in the Zoo, I knew the official name and habitat of every living thing in the place. I had several narrow escapes, as you may imagine. One especially I may refer to. I was photographing the two-horued rhinoceros; I was inside the paddock, to get rid of the bars; the keeper was with me with his whip. The beast was up against the palings, and the crowd outside were feeling his hide with their sticks and umbrellas. Whether they touched him in a tender part, or that he had some evil desigu on me wheu I was covered with the focussing cloth, I know not, but he charged me. The keeper shouted, and, in an instant I laid hold of the camera (a very heavy one) by the handle and ran into his den, and just got through the wide wooden bars when he came with a rush. I got through safely with the camera, after doing about the fastest on record. It knocked all the wind and zoology clean out of me for a time. This was one of many scenes. It was impossible, with the limited means at my command (I mean, as compared with the present time) to get rid of the bars in all cases; still, when I could do so I did, even at great risk. Then and now are two different things, and I am sure there ought to be no trouble whatever in securing every pose and position. The many hours required or wasted by Mr. Bolton in securing the lion I cannot understand. Some people make much of their exceptional studies, the time and money it has cost them, &c. What is necessary is to recognise in an instant what is required of you, and to be prepared to do it at once. I find that in my every-day work. I have had several assistants from England, and they all lack this essential quality. A man with a knowledge of the arts and sciences, as applied to every-day life, will invariably hit the thing straight off the reel. It is not given to everyone to "grasp the situation," as Gilbert says in "The Gondoliers;" still, those who will study the thing will find a very profitable employment—I mean to know what to do "when the unexpected happens," so that it will come out trumps.

*Re the Quagga.*—They are not extinct in this country. Down colony, near Sand Flats, is a place called Quagga Flats. I believe they run there still. Does the quagga breed? I am under the impression that the beast is the result of Birchell's zebra mixing with the donkeys on the different farms. I have often seen hundreds of thousands of spring bucks mix with farm flocks. All wild animals mix with the flocks when they are migrating.

The curses of the Pharoahs are still with us. Last week the sky was darkened with locusts, frightful and hideous, eating every living thing. They actually stopped the train. We have still the old plagues of frogs, locusts, murrain of beasts; well, yes, and Potiphars' wives, too, in galore. B. Harvey.

*The Kimberley Photographic Studio, South Africa.*

## GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

Sir,—Will you kindly intimate that an International Photographic Exhibition will be held in the Galleries of the Fine Art Institute, Glasgow, in September next, under the auspices of the Glasgow and West of Scotland Amateur Photographic Association. Full particulars will be announced very shortly. Besides the usual classes, there will be a section for photomechanical work.

It may not be amiss to remind our friends in the South that September is a favourite month for a trip to Scotland.

*Glasgow, Feb. 16th.* Wm. Goodwin, *Hon. Sec.*

## THE OPTICAL LANTERN: ITS HISTORY AND DEVELOPMENT.

Sir,—I would feel obliged by your correcting an error which has crept into your report of my paper read before the Glasgow Photographic Association. The name of the French traveller whose writings are referred to should read De Monconys, and not De Moncorrys. William Lang, Jnr.

*Cross Park, Partick, Feb. 15th.*

## PHOTOGRAPHY IN THE CRYSTAL PALACE.

Sir,—I, like Mr. Schofield, am both a season ticket and shareholder in the Palace Company, and have also applied, some time since, to Messrs. Negretti and Zambra for permission to take photographs, and with about as satisfactory a result. I cannot say, however, that I feel the same resentment that he appears to do, as, upon thinking the matter over impartially, it certainly seems hardly reasonable to expect the firm to sustain a considerable annual loss, seeing that, if they granted permission to one, they could hardly refuse another, with the probable result that the Palace would soon become a popular resort for amateurs, who, although pledged not to sell any photos, would be under no obligation not to give their friends copies, which they probably would do with a very generous hand—after the usual manner of amateurs—with the inevitable result of diminishing Messrs. Negretti & Zambra's photographic business, for the exclusive rights of which they pay a large sum annually, and cannot, therefore, be reasonably expected to return a different reply to the very courteous one sent Mr. Schofield. Ernest Dalton.

*Anerley, Feb. 17th.*

## HELIOCHROMY.

Sir,—There is in your last week's issue a mention about another discovery of photography in natural colours. It would be, perhaps, interesting to you to know some facts in connection with the described process. In my recent experiments with ferrotype dry plates I often came across the same kind of effect of colours by reflection as stated by Professor Lippmann. Herewith I send you a specimen which, held against the light, shows very prominently the said result. I will not try to explain it, from fear of putting forward some erroneous theory similar to the one developed by Professor Lippmann, which seems to me rather difficult to prove. In fact, the waves of sound can be compared with such of the white light only, and not with the waves of the spectrum, especially in the actual case; the number of vibrations of the sound and white light being constant, and of those of dispersed colours different with every hue. With the greatest attention paid to the direction of reflected rays, it is impossible to bring them back through the very point they traverse, even if the glass supporting the negative were as thin as paper; consequently, the green rays, for example, may, in their return, intercept the blue or yellow ones, the orange intercept the yellow or red waves, and so on. I shall be very glad to have made a mistake, and to see the report of discovery this time verified; but for a while I think that after more careful examination of Professor Lippmann's spectrum negatives, the colours will be found slightly misplaced, and that we are to-day as far from photography in natural colours as we were a month ago. L. Nievsky.

5, *Gransden Road, Shepherd's Bush, London, 18th February.*

## ROUGH DRAWING PAPER.

Sir,—If Colonel Noverre will turn to the Photographic News for 1873, page 354-5, he will find full instructions given of M. de Constant's method of printing on plain paper, where he mentions, amongst other papers, "Whatman's rough drawing paper." He also mentions a method of giving a coarse grain to smooth paper. I have never seen any of M. de Constant's productions, but I cannot doubt but that he used the roughest paper obtainable, as the word "rough" is especially mentioned, and not "hot pressed," the medium quality of Whatman's paper.

Again, in a leading article in the same journal for the year 1875, page 390-1, on "Drawing Paper for Photographic Portraiture," the phrase "rough drawing paper" is again used, and working directions for preparing the same are given.

You will doubtless have received many other communications referring to the early use of rough surfaced papers in photography, but I pick these two out of my commonplace book as being particularly applicable to the present question.

I do not think that there can be a moment's doubt but that rough drawing paper was used long before the 1887 Pall Mall Exhibition, but at the same time we must freely give Colonel Noverre all credit for the revival of this most artistic method of reproducing our æsthetic impressions in monotint.

Lyonel Clark.

As Professor Lippmann's photographs show the complementary colours by transmitted light, it seems to indicate that, by printing from them upon similarly prepared films, any number of truly coloured positives can be obtained from one negative. The latter might be stripped from a plate, and reversal of the sides avoided in the finished print.

# Proceedings of Societies.

The London and Provincial Photographic Association.

*February 12th.*—Mr. T. Bolas in the chair.

Mr. G. W. Atkins presented Capt. Abney's "Text-Book of Science" to the library.

Specimen prints from cloud negatives, issued by Mr. E. Dunmore, were passed round.

Mr. Atkins showed some slides he had made, using the collodio-bromide process. He also passed round a sample of pyroxyline that he had prepared from a formula published by Dr. Hardwich.

Mr. A. Haddon thought that sufficient attention was not paid by experimenters in making pyroxyline to the specific gravity and temperature of the acid used. He considered this the cause of the inferiority of some samples of cotton. He also exhibited a bottle containing a solution of eikonogen preserved with bisulphite; it had been standing several months, and was quite colourless.

Mr. A. Cowan had kept a solution of eikonogen two years in a bottle, quite full; it had not changed colour.

The remainder of the evening was devoted to the exhibition of lantern slides. An excellent series was shown by Messrs. Mawson and Swan, from negatives on their plates. Slides were also exhibited by Messrs. Atkinson, Pemberton, Kellow, and Wellington.

The Photographic Society of Ireland.

The annual general meeting was held on the 13th inst. at the rooms, 15, Dawson Street, Dublin; Professor J. Alfred Scott, M.B., vice-president, occupied the chair. The report of the council and treasurer's statement of accounts were read, and showed the Society to be both numerically and financially in a very satisfactory condition.

After the necessary business in connection with the election of officers and council for the ensuing year, Mr. Greenwood Pim passed through the lantern a number of slides by himself, and Dr. Cosgrave of pictures taken in Switzerland.

The Lantern Society.

*February 9th.*—Mr. J. Traill Taylor on "Lenses and Condensers for Lantern Work."

Mr. Taylor commenced by saying that in his remarks on condensers, the light was assumed to be small and intense. At present there was no perfect condenser on the market, and the subject was one that might profitably be worked out farther than it had yet been. Mr. E. M. Nelson was the only Englishman who had as yet tackled the subject; in America they had given much more attention to the matter. The back lens of a condenser should be fairly large to include as wide an angle as possible, and as thin as possible on account of the heat, the edges being ground thin for the same reason. The effective diameter of the back lens was considerably less than the diameter of the lens itself, and in the ordinary commercial condenser the margin of the lens to the extent of about half an inch inwards was not utilised. Mr. Taylor showed a drawing of a theoretically perfect condenser to transmit absolutely parallel rays from a small luminant. It was of triple form, and five inches in diameter. He also described Professor Morton's triple condenser, which included an angle of 93 degrees, and he gave the curves for both these condensers. In a perfect lantern, the third lens of the condenser (the one farthest from the light) should be removable, and replaceable by others of different focal lengths. The first two lenses would be arranged to give parallel rays, which could then be converged more or less, according to the purpose for which they were to be used, by the third lens. With reference to projection lenses, Mr. Taylor said that the Petzval portrait lens was the best form, and explained how the flatness of field could be improved by increasing the negative aberration of the back lens.

In the discussion which followed, Mr. G. R. Baker referred to the focal lengths of lantern condensers, and Mr. E. M. Nelson mentioned Professor Abbe's theorem, that the intensity of the light at different distances from the condenser varied as the square of the sine of half the angle included.

The West London Photographic Society.

A meeting was held at the Broadway Lecture Hall, Hammersmith, on the 13th February.

The President announced that he had forwarded a circular *re* cheap railway fares to photographers, to forty-nine London and suburban Photographic Societies for their consideration, and requesting them to fill up the same, with the number of members, to lay it before their next meeting, and say whether their names might be added to the memorial which was to be lodged with the several London railways. A favourable answer had already been received from two societies.

An inquiry from the question-box which had been held over from the previous meeting, as to whether ammonia fumes injuriously affected the lungs, was answered by Dr. Low, who thought that, considering the extent to which the ammonia was diluted before use in the developing bath, no harm could be caused to the lungs, but it might, perhaps, have an effect upon the eyes.

The President then introduced Mr. Wm. Schooling, F.R.A.S., who gave a lecture on the "Application of Photography to Astronomy," illustrated with slides from photographs taken at Harvard and other large observatories. Mr. Schooling said that photography had not helped them much with regard to the detail on the surface of the moon, and the spots on the sun—in fact, more truthful effects were got with sketches; but that with regard to distant stars, some of them were rendered with great exactitude on the photographic plate, though not visible to the eye through the most powerful telescope in use.

Mr. Whiting thought that astronomers might with advantage turn their attention to the discovering of some emulsion that would give a less coarse image than that given by gelatine; he suggested slower plates, and thought that at the present time albumen would be the best thing to use.

Mr. Schooling said that owing to the movement of the planets, it was necessary to use as rapid a plate as possible.

The Hackney Photographic Society.

Last Thursday Mr. Henry Sturmey gave an interesting and amusing lecture on "Norway," in which he described his trip there. About one hundred slides were put through the lantern, which was worked by the hon. secretary.

The Society now possesses a fine single lantern, together with all appliances. At the close of Mr. Sturmey's lecture, Messrs. Dean, Gosling, Barton, and Herbert Smith showed slides.

The Richmond Amateur Photographic Society.

At the weekly meeting on the 13th inst. there was a good muster of members; Mr. Cembrano presided.

A discussion took place on "Exposure and Exposure Tables," to which most of those present contributed—from the tyro who confessed that he had no ideas on the subject which could be of the smallest use to any-one else, to the veteran of wet-plate days, who looked upon exposure tables much as a man looks upon swimming-corks who has learnt swimming without them. The longest exposure on record was stated to be one of several months given to a dry collodion plate in the Catacombs, while the shortest went into millionths of a second.

Two new members were elected.

The Birmingham Photographic Society.

The above Society held a lantern evening on Wednesday, the 11th inst., at the Temperance Hall. Slides were lent by the Camera Club, Messrs. J. B. B. Wellington, Fry and Co., Sands and Hunter, Pumphrey, and others.

It was announced that the first meeting at the committee room of the Midland Institute would be held on the 26th inst., when papers on "Shutters" and "Instantaneous Photography" would be given.

THE PUDSEY DISTRICT PHOTOGRAPHIC SOCIETY.

On Thursday evening, February 12th, a meeting was held at Pudsey, near Leeds, for the purpose of forming a photographic society for the district; Mr. J. Goodman presided, and several local amateurs were present.

It was decided to hold the meetings fortnightly, at the Mechanics' Institute, and at the next gathering there will be an exhibition of members' slides. Mr. W. H. Hining will act as secretary until the election of officers.

THE DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

General meeting, February 12th; Mr. J. D. Cox, president, in the chair. This being a lantern evening the meeting was open. The members and their friends, through the kindness of Mr. A. R. Dresser, were enabled to view a large number of slides illustrating Brittany.

Several of Griffith's hand-cameras were sent for exhibition.

THE LEEDS PHOTOGRAPHIC SOCIETY.

On Monday evening last the second of the series of elementary lectures was given by the hon. secretary, Mr. T. A. Warburton; his subject was "Development." He advised the backing of all plates with burnt sienna in order to prevent halation. He said that, with respect to exposure, a little experience gained by exposing a couple of dozen plates upon, say, half-a-dozen different subjects, making three or four exposures of varying lengths of time upon each subject, carefully noting the conditions as to plate, subject, stop, and light, and, after development, making a note of the result, was worth all the exposure tables yet invented. An exposure book of this kind formed a record of actual experience, which would, with constant additions, in time become invaluable. In the course of his lecture, he said that he preferred the pyro-ammonia developer and the bichloride of mercury intensifier, followed by ammonia. In conclusion, a frame of negatives of different qualities, illuminated from behind by the lime-light, was exhibited. The class of negative most suitable for any particular printing process was pointed out.

The president, Mr. Godfrey Bingley, occupied the chair.

THE NOTTS AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual fortnightly meeting of this Association was held on Monday evening last, with Mr. S. Wells, president, in the chair.

Mr. Councillor Abraham Pyatt and Mr. Thomas Warwick were elected members.

Mr. Howson, of the Britannia Works Company, gave a practical demonstration on Alpha paper, printing, exposing, and developing several prints, and obtaining excellent results. Mr. Howson also exposed and developed several of the Alpha lantern slides.

The Hon. Sec., Mr. P. E. Knight, distributed, by the kindness of the Paget Prize Plate Co., samples of their specialities.

The Society has done much in lantern slide making, every evening having been devoted to demonstration. The results form a nucleus for a loan collection for exchange with other societies.

"The present state of the photographic profession I attribute entirely to want of union amongst its members, and the only remedy that seems possible is the encouragement of greater unity, and the formation of a strong photographic public opinion. For the formation of such a body of public opinion I can see no means so efficient as the photographic journals."—H. Snowden Ward.

H. W. Vogel, Berlin.—Received, and shall have attention.

C. P. Richards, Barrow-in-Furness.—The report of which you speak in yours of the 18th not to hand up to the time of going to press, and now too late. It should have been posted the day after the meeting at Birmingham.

Correspondents are requested to make their communications as short as the importance of the subject will permit; otherwise they may remain unpublished for a month or two for want of space. We are overpressed with surplus manuscript.

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

M. B.—*Camera Details.* Received your letter. We shall be prepared to act upon your suggestion when the time comes. The weight of camera is correctly stated, and the $f/16$ stop is manifestly only half the diameter of $f/8$; the ratios of exposure would, therefore, be as four to one.

J. H. C.—*Bitumen Process.* Instead of using your present mixture, which is almost sure to crack the film on drying, try the employment of a varnish composed of asphaltum in benzol. Do not fire it, or add any lamp-black, or only sparingly, as required for thickening, but dry on a levelled hot plate.

A. Corsi (Florence).—*Primuline Materials.* Apply to Messrs. Green, Cross, and Bevan, at 4, New Court, Lincoln's Inn, London, W.C., for samples and paper of instructions, sending postal order for ten lire.

M. T.—*Watkin's View-Meter.* The standard tint is obtained by two seconds' exposure to "clouded sunshine in June," but, as this mode of working cannot be available at the present time, the inventor prescribes, as its equivalent, the burning of two grains of magnesium ribbon at a distance of $4\frac{3}{4}$ inches from the sensitive paper. For further details see report of technical meeting, Photographic Society, of October 28th last.

W. D.—*Lord Rayleigh's Wire Gauze Experiment.* The pieces of wire gauze distributed to the visitors at the Royal Institution on the 6th inst. measured twenty meshes to the inch, and is known as No. 20 gauze. There is no particular necessity for this precise dimension, but the experiment answers capitally well with such material.

Subscriber.—*Photography in Natural Colours.* As usual, we prefer to wait for a fuller statement of the scientific details; for the published account from Paris, like that of last year from Vienna, records no more than has been known for thirty years. All turns upon whether these pictures are permanent in daylight, for hitherto they have never been successfully fixed. Did you read M. Leon Vidal's letter in last week's News? These rumours seem to crop up periodically, but one must not say they are altogether impossible of realization—only improbable, so far as the evidence goes at present.

S. H.—The case is one which might very well be brought to the notice of the Photographers' Benevolent Association. Report the facts to Mr. H. J. Beasley, Hon. Sec.

Photargus (Spain).—1. *The Graduated Background Material,* for vignetted heads and portraiture generally, can surely be obtained of Messrs. Marion and Co., in this country; but if you find any difficulty in getting it in your southern marts, nothing is easier than to prepare it for yourself by dyeing from a slow bath, out of which you lift the material gradually by winding it on a wooden roller. 2. The less said on this point the better, for recent accounts are not very encouraging.

F. L.—The person named is now in the United States of America, but we can write to him and put the enquiry.

Ed. J. B. (Cheltenham).—The publishers of Mr. Wilkinson's "Photo-Litho Manual" are Messrs. Hampton, Judd, and Co., 14, Duke Street, Adelphi, W.C.

Teignbridge.—*Eikonogen.* There is only one source of supply in this country, and you must go to Soho Square for the "cartridges."

G. A. N.—*Ferrotype Plates,* of sizes 14 by 10 and under, can be had of Mr. Jonathan Fallowfield, 146, Charing Cross Road, W. They can be readily cut of circular form with a pair of scissors.

F. D. T. (Edinburgh).—Let us know in the event of your having any difficulty in procuring one of the little specimen films, and we will try again to assist you.

THE PHOTOGRAPHIC NEWS.

VOL. XXXV. No. 1695.—*February* 27, 1891.

CONTENTS.

## HE NEW DISCOVERIES IN HELIOCHROMY.

HIS month of February, 1891, will long be celebrated the annals of photography. At the beginning of e month, photography in natural colours as a pracical working, every-day process seemed a problem likely to be solved during the present generation; at e end of the month the solution of the problem seems th possible and probable; moreover, in a scientific it uncommercial sense it has already been achieved.

Becquerel seems to think that his process is ifferent in principle from the new one, but that is pparently a mistake. His heatings of the sensitive lm on a silver plate probably gradually altered the cheesy" physical structure of the film to one of a mewhat more transparent nature, so that the bright irface at the back brought interference phenomena ito play, and yielded coloured images, which dissolved ith the rest of the film in fixing solutions. In somehat similar processes upon paper, the preliminary xposure to diffused light probably produced a number f minute particles or spangles of reduced silver, which cted as imperfect reflectors, and produced imperfect iterference phenomena. The film having been rencred an objectionable colour by the first exposure, the eliochromic photographs on paper never had the same rilliancy of colour or the more suitable background f those on plates of polished silver. Becquerel orked most industriously, yet empirically, with no amp to guide his footsteps, and, under the circumstances, the results were remarkably good, but would ot long resist the action of daylight. Professor lexander Herschel once published that he had seen a hotograph of the spectrum by Becquerel good enough o figure as the coloured frontispiece of a scientific ook. We also have seen one answering that descripion in the possession of the late Warren De la Rue, ho first exhibited it to us more than twenty years ago, nd again did so quite recently, but a few months efore his death. It did not seem to have deteriorated neanwhile, but its owner kept it excluded from light n a leather case, except when momentarily showing it o visitors. He had another of these photographs of the spectrum, which once belonged to Faraday, but this was a poor one, and required a certain amount of faith to recognise the colours. Probably it had not always been carefully protected from light before it reached Mr. Warren De la Rue.

The theory of Becquerel's photographs was not understood, but it was speculated that the colours might be those of thin plates, or that the molecular condition of the film was so modified by light that the particles threw off the particular colours by which they had been impressed.

Professor Lippmann has scientifically solved the problem by declaring them to be the colours of thin plates, and by using continuous and almost transparent films resting upon a brilliant reflecting surface, so as to get nearly perfect interference bands in the film, he has succeeded in photographing colours. He has also revealed that the layers of silver deposit in the film should be colourless, and that incident daylight would cause different colours to be reflected, according to the distances apart of the bands in any particular part of the film. This makes future investigation easy, for the practical photographer who seeks to perfect the process now knows what result he has to try to obtain, and how to set about the work. The secret also has been revealed how and why the photographs can be fixed.

Without having seen them, it is easy to realise the nature of the colours obtained, and to describe their pictorial character. They are those of the diffraction grating, and, like Daguerreotypes, can be seen best with a particular incidence of white light. They resemble the interference colours of mother-of-pearl, but are brighter, and M. Lippmann says that they are purer than those of the soap-bubble. Those who want to see the colours of the soap-bubble in perfection should blow bubbles from a solution like that used by Lord Rayleigh, and described in these pages last week; the bubble should be illuminated on one side only, and by a strong light, such as that coming through the condensers of a limelight magic lantern, and should be viewed by the light the bubble reflects. The correspondent of the *Daily News* describes the colours obtained by M. Lippmann as equalling in brilliancy those of a finely cut Golconda diamond; why "Golconda" we know not, for the Brazilian diamonds are of as "clear water," and can be cut in the same way. The working of the Indian mines was entirely or for the most part stopped years ago because the yield was not remunerative; we have not heard of any resumption there of the search for the gem. The lustre of the wings of some green and other beetles, also of the wings of some of the more gorgeous tropical butterflies, is supposed to be due to the interference of light set up by numerous transparent, horny layers.

The conclusion, therefore, is, that in these heliochromes we have brilliant colours not to be seen elsewhere at present in connection with any branch of pictorial art. Such pictures, somewhat less perfect in colour, were to be seen once, for Niepce de St. Victor, one of the imitators of Becquerel, appropriated the best of discoveries in heliochromy without acknowledgment, and succeeded in turning out some remarkable pictures by means of long exposures in the camera. If Niepce de St. Victor were allowed to dress a doll in such materials and of such colours as he chose, he could somewhat faithfully produce a photograph in the true colours of the doll, and one of the most remarkable facts was, that gold ornaments did not come out upon the plate of an ordinary yellow colour, but with metallic lustre, resembling gold itself.

Before long, in the light which M. Lippmann has thrown upon the subject, varieties of colour will give less trouble in heliochromy, because orthochromatic photography is now a fact, and will aid in the work. By cyanine and other agents the films used in M. Lippmann's may be made sensitive to the red; they can also be made sensitive in the usual way to the yellow. In most cases it will probably be necessary that the dye used shall be washed out of the film, and, possibly, the use of a faint yellow screen may be an advantage.

The quickening of the films used in M. Lippmann's process seems to be but a question of time and of experiment, chiefly by experienced photographers. The production of a dry plate and devising of a developer, which together shall yield an image silvery white by reflected, and of a pure black tint by transmitted light, is also a matter likely to be suitably accomplished with lapse of time.

Perhaps the most beautiful stereoscopic portraits ever produced were those upon Daguerreotype plates, with the images afterwards delicately tinted by hand. Some such were on view at and after the opening of the Crystal Palace at Sydenham, and they were exhibited, we think, by Claudet; they proved a great attraction to the visitors. How somewhat similar portraits, but with the rainbow-like hues produced by M. Lippmann's process would appear, has yet to be seen; he might make a beautifully-coloured doll sit for its portrait in the first instance, to reveal what is in store in this direction in the future.

With a mixed body of readers such as this journal possesses, many of them highly scientific, some semi-scientific, and others not scientific at all, but purely artistic, it is difficult to meet the mental requirements of all in one article, so the first-mentioned class may excuse us if a little be now said for the information of others about the well-known phenomena of the interference of light upon which the new heliochromic process depends.

If two stones be dropped vertically, and at a few yards from each other, into a pond of still water, each stone will initiate a circular series of waves, extending ring-like in all directions. If, when the two outer rings meet, the crests of one series of waves tend to coincide with the crests of the other series of waves, increased wave motion will be the result of their meeting. If, on the other hand, when they meet the crests of one series of waves tend to coincide with the depressions of another series of waves, as represented in figure 1, the

*Fig.* 1.

two series will neutralise each other; thus, two motions produce no motion. "Beats" in music are due to the same cause; at intervals two sound-waves of air occasionally meet in such a manner as to produce momentary silence. So is it with light. Waves of monochromatic light can be experimentally so mixed as to produce darkness in bands upon the screen of a lecture room, and it is often done in public.

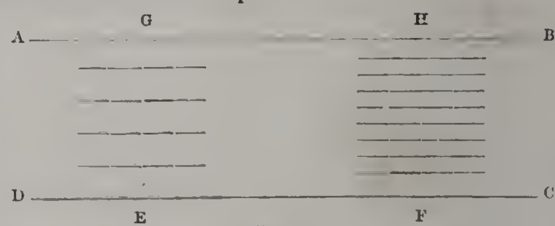

*Fig.* 2.

Let A B C D be a section of a sensitive film, and D C a mirror backing; red light falling in the direction G E will be reflected at E and sent back, producing interference bands, in the luminous spaces between which silver will afterwards be deposited by the developer. Let blue waves fall in the direction H F; the same phenomenon will be repeated, but the blue waves being shorter than the red, the interference bands will be closer together. Suppose, now, the plate to be developed and fixed, then exposed to daylight; the blue rays alone in white light will pass freely backwards and forwards through the area H F, and the red rays freely through the space G E; hence the difference in the colours of these spaces to the eye, although the silver deposits themselves are practically colourless.

All this suggests the use of a developer which will produce images more resembling stains than coarse deposits, so as to produce as perfect and clean a series of bands as possible; in fact, M. Lippmann has laid down a useful, practical working hypothesis, which seems at present a true theory, and may afterwards be proved to be such.

A few months or even a few years may elapse before photography in colours becomes an every-day, familiar fact, but such a result now appears to be within measurable distance.

## THE MAGIC LANTERN MISSION.

The accomplished editor of the *Review of Reviews*, amid his various schemes for the help of the poor, has propounded one which cannot but be of interest to the photographic world, for it centres round that now familiar instrument, the optical lantern, and, as everyone knows, photography has done more to make the instrument popular than anything else; for it has produced, at a marvellously cheap rate, pictures rich in detail, illustrating all parts of the world, and every branch of knowledge, before which the hand-painted slides of a bygone generation have all but disappeared.

The Magic Lantern Mission has a very wide scope, but its primary object seems to be to make religious services in Sunday schools, chapels, and even churches more popular by means of pictorial illustrations. It seems to be admitted that in this work difficulties will arise, for it is evident that photographs can have but limited application in the illustration of Bible history; indeed, beyond photographs of the Holy Land, and photographic copies of well-known drawings and paintings, it cannot go, unless the promoters of the enterprise are prepared to incur great expense in the employment of special artists to draw designs for them, or to photograph from living models. Beyond this, it is intended that the lantern shall be the prime teacher of a "democratic university," and shall help in a popular system of university extension teaching. Preaching Friars of the lantern are "to undertake to establish in every town and large village a centre of culture, illustrated history, and politics, which will be "attractive enough to command the attention of the corner boy, and yet sufficiently elevated to give instruction to the best informed." We learn incidentally that a certain tea company has in circulation a two hundred guinea lantern and a set of slides, and that they are willing to send the instrument and a capable operator to any town desiring a lantern service, on payment of expenses to and fro. Of the eighty slides "there are only three that can be said to be advertisements of the tea company." The commercial aspect of the enterprise peeps out in another place, for we hear of a firm of country opticians "who are sincerely devoted to the work of Christian Evangelisation," and are delighted to place their lantern at disposal for £2 per night. We fancy that most opticians would be content to provide apparatus for this sum without mixing up a business transaction with more serious considerations.

The Mission aims high. It is rightly stated that there is room for improvement in the art of colouring slides. There is a need, we are told, for a school of slide painters to be attached to the Mission—not mere slide colourers, but painters who feel with and for their subject. Many other hints and suggestions, which we have not space to particularise, are given with regard to carrying out the scheme.

It will thus be seen that the Magic Lantern Mission aims at a general system of education by means of pictures, and the scheme is one which is sure to prove attractive to those who are not acquainted with what has already been done in the same direction. In this respect it resembles the far vaster scheme propounded by the author of "Darkest England." But those who know how largely the lantern is already in use will be apt to regard the various proposals in the light of what our American friends call "chestnuts."

We venture to say that there is no town or village of any size where the lantern is not already a most familiar means of entertainment and instruction. Our wholesale dealers in lantern slides publish continually new sets of excellent pictures dealing with every conceivable subject which can teach or interest an audience. These sets are bought by all the chief opticians throughout the country, and are let out on hire, with capital readings written by experienced men, to amateur lecturers, clergymen, and others, night after night. It is true that the colouring is sometimes a little gaudy, but this is merely a question of expense. Beautifully coloured slides can be had if the artist is paid a fair sum for producing them, and directly the demand comes for such pictures it is certain that they can be supplied; in short, a most complete organisation for the production and circulation of slides already exists, and it seems childish that a work which is already being done so well, and which competition has made so cheap, should suddenly be placed in untried hands.

As to a new system of University Extension teaching, there is nothing new about it. The suggestion is another "chestnut." Every town has its literary institution or mechanics' institute. Failing these, it has some kind of lecture society, where good lecturers are constantly employed, and where the lantern forms a feature of the proceedings. The business arrangements are so well managed that a ticket admitting to every entertainment of the season can be purchased for a shilling or two. But free lectures are also common. Take, as an instance, those inaugurated at the East End by Dr. Barnado, to which an audience of more than three thousand are attracted every week. In some places, indeed, we learn on good authority that the lantern is almost too common. There are so many amateur workers, and they are so ready to give their services in aid of charities of various kinds, that the lantern does not attract as it once did. Of course this is due, to some extent, to incompetent operators and lecturers, for unless an entertainment of this kind is placed in experienced hands, and carried out by means of good apparatus, it is more dreary than amusing—to say nothing of the educational part of the work. As to the use of the lantern in religious services, that, too, is no new idea. In every optician's catalogue of slides long lists of hymns are given, together with such subjects as "The Pilgrim's Progress," "The Holy Land," and a large variety of semi-religious temperance tales.

If these things can be improved, the best way to do it is to make use of the existing organisation, and to place the matter in the hands of those who have for years made a study of the business. To commence anew on the same lines with amateur producers is to court failure.

## PLATES FOR HELIOCHROMY.

BY GABRIEL LIPPMANN, MEMBER OF THE INSTITUTE, PROFESSOR OF THE FACULTY OF SCIENCES, PARIS.

Every grainless plate I have tried has been found to answer. For instance:—

1. Common albumen plates, but it is best to have the coating of albumen thicker than usual.

2. Taupenot plates, with a double or triple layer of albumen.

3. Gelatino-bromide of silver prepared as follows:—In one hundred grammes of water dissolve ten grammes of gelatine, and half a gramme of bromide of potassium. Filter, spread on glass, and let dry. Sensitise more than five minutes in a twenty per cent. solution of nitrate of silver, with a little acetic acid; wash and dry. Develop with pyrogallol and sesquicarbonate of ammonia, in the same way as Taupenot plates. Wash with water, then with slightly salt water. Fix.

## THE CAMERA AND ITS VARIOUS MOTIONS.

BY PROFESSOR W. K. BURTON, C.E.

### Chapter VI.—Dark Slides, Changing Boxes, Roll-Holders, etc.

*Dark Slides.*—As in the case of the camera, so in that of dark slides, I should incline to put absolute light-tightness as the first essential.

It is scarcely necessary, in treating of appliances for landscape photography of the present day, to consider other than *double* dark slides, and these may be classified as slides that open in the middle, book form, the slide being thus opened for inverting the plates, and slides that do not thus open, the plates being inserted from one side, or from the end. It is the rule, in the case of the former kind of slide, that the shutter does not draw out entirely, but only far enough to uncover the plate, and then doubles back with two hinges, so that it will not catch the wind, or be in the way; in the case of the latter, the shutters generally draw out entirely, what may, perhaps, be called a *valve* closing across the opening left by the shutter. The former kind of slide has, at all times since double dark slides were first introduced, been the favourite in England; the latter has for long been preferred in America.

It is a matter of opinion which kind of slide is to be preferred. I confess, without hesitation, that I prefer what is commonly called the "American pattern," which does not open book-wise, but is so made that the plates are both inserted from one side, a sheet of blackened tin or zinc going between them. The advantages that I have found are greater lightness, and less danger of leakage of light; whilst I have often found the shutter, drawn from the slide just at the time of exposure, to be very useful as a sunshade for the lens.

The only objection that I know to this form of dark slide is that the plate that is last inserted, at least, cannot rest against a rebate, but must rest, at one end, at any rate, against small, metallic movable catches, and that the result is a possible slight want of register. With carefully made slides, however, this possible lack of register is so small that it is not of any consideration in the case of landscape work.

It is commonly said that the American pattern of slide is good enough for small sizes, but that it is of no use for those of large size. I cannot speak as to *very* large sizes, but I can state that, nearly ten years ago, I had three 12 by 10 slides of the kind in question made by the elder of the two Messrs. Collins, who has died within the last few years, the shutters being made of three veneers with grain crossed; that these shutters, in spite of the very roughest usage, served me well for some six or seven years, and that although, after that, they passed from my hands, I know them still to be in good condition. In America, vulcanite—a sort of thick cardboard—or sometimes ferrotype plate, is generally used for shutters.

Even when the "book-shaped" form of dark slide is used, I advise that the black opaque sheet of metal that separates the plates be not hinged to the dark slide, but be loose. It is thus possible to use carriers for two plates of smaller size than that of the dark slide, both plates being inserted from one side, an opaque sheet of the size of these small plates going between them. I consider that such a double carrier is to be preferred to two single carriers, as the latter have to be made so very thin.

Metallic dark slides have, of late, come much into use. The chief advantage that they offer is that, whilst so long as they are not actually indented by a sharp blow from any hard body they are as efficient and as enduring as wooden slides, they are very much cheaper. Moreover, they pack into a smaller space.

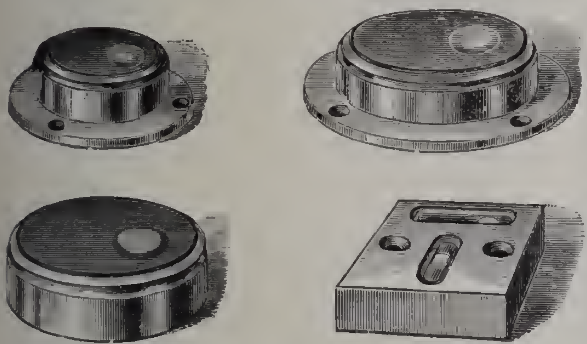
*Changing Boxes.*—A changing box is an appliance for storing a number—generally a dozen—of plates, any one of which may be brought into position for exposure. These are ingenious contrivances, but it would be quite out of place to go into details of their construction here. They are not to be recommended for large sizes. I know that the maker of one of the best changing boxes made, although he does not absolutely refuse to make a larger size than 10 by 8, tries to dissuade his customers from giving orders for such. It might, indeed, perhaps be said that dark slides are to be preferred to changing boxes for all sizes over 8½ by 6½.

*Roll-Holders.*—The difference between roll-holders of one kind and another is not, as in the case of dark slides, merely the difference between one type of apparatus and another. It is a case of the difference between the different patented inventions of different firms, and as, in such a case, it would be invidious to make comparisons, the roll-holder must here be dismissed with a word only. Indeed, the only thing I really want to point out here is that only a small fraction of the advantage of films is realised unless a roll-holder is used. The only objection to the roll-holder that I know of is, that it makes exposing so *very* easy that the user is liable to keep shooting away at all and sundry kinds of things without due consideration.

*Levels, &c., for Securing Vertical Adjustment of the Camera Back.*—When architectural work is done, it is essential that the back of the camera be vertical. A slight deviation from the vertical will not give appreciable distortion so long as the angle included by the lens is not great, but if a wide angle be included, a very small deviation from the vertical will produce a most noticeable effect.

For this reason, many modern cameras are fitted with some appliance for showing when the back is really vertical. The commonest is a spirit level fixed on to the top of the back. When this top is horizontal, the ground glass is vertical. If there be but one level, it is fixed pointing "fore and aft," as this direction—or, more strictly, in a plane at right-angles to it—is that in which verticality is of most importance. Any accidental tipping to one side or the other can easily be detected by "sighting" down one side of the camera back along with any vertical line in the building that is being photographed. Moreover, the effects of mere "side tipping" of the camera can always be corrected afterwards by sacrificing a little of the margins of the prints, trimming parallel with and at right-angles to vertical lines.

Moreover, two levels at right-angles to each other, or a circular level, which serves the same purpose, is used.



Subjoined are illustrations of levels for cameras as manufactured by Messrs. Taylor, Taylor, and Hobson. Another arrangement is to have a small brass plummet suspended at one side of the back, as will be seen in the cut, page 1001, December 26th, 1890.

Some photographers prefer to carry in their pockets a bullet, or other light weight, hung on a piece of thin string, and to hold this in the hand as a plummet. It may be worth while remembering that, if a knot be made at a distance of thirty-nine inches from the weight, and the weight and string be swung as a pendulum from the knot, each single swing will be practically a second. If the length be ten inches, it will be half a second.

So far as side tilting of the camera goes, it is often possible to avoid this by "sighting" any vertical line in the subject in front, and one side of the back of the camera.

---

THE ENFIELD CAMERA CLUB.—At the meeting on the 18th inst. five new members were elected.

ROYAL INSTITUTION.—Professor C. Meymott Tidy will on Thursday next (March 5th) begin a course of three lectures on "Modern Chemistry in Relation to Sanitation."

PORTRAITURE.—In a reprint, from *Poet-Lore*, of a paper read before the Melbourne Shakespeare Society on "Shakespeare's Face," the following remarks occur:—"If there is one thing more productive of utter despair than another, it is an attempt to reconcile the conflicting opinions provoked by portraiture. No two artists will give portraits of one individual that absolutely agree; no two critics will agree about their relative merits as likenesses, and ordinary people comparing portraits with faces invariably differ with varying degrees of disagreement."

THE PHOTOGRAPHIC CLUB.—This Club has issued a pamphlet, compiled by Mr. Mackie, about its early history. It was indirectly founded in 1879 by Mr. Arthur Brittlebank; the first meeting was held at his studio, 3A, Tottenham Court Road, London, on June 18th of that year. The Brittlebank meetings soon came to an end, but their advantages were so fully recognised that some of those who took part in them founded the Photographic Club. The foundation meeting was held November 7th, 1879, at the Freemasons' Tavern, with Mr. Jabez Hughes in the chair. The Club has just issued its annual report and balance sheet. The Club now holds its meetings every Wednesday evening at Anderton's Hotel, Fleet Street, London.

## LANTERN SLIDES.

BY F. GOLDBY.

DURING this exceptionally dull and inclement winter, out-door photography has been next to impracticable, and no doubt many amateurs have—as I have—devoted the greater part of their spare time to lantern work; so possibly the following notes, though they may contain nothing new to more experienced workers, may perhaps prove of some interest and use to those who, like myself, are beginners in this most fascinating branch of photography.

During a short holiday spent in Switzerland last August, I obtained some five dozen half-plate negatives of scenery in the Bernese Oberland, and from these and others taken nearer home I have been engaged in spare time for the last two months in making slides. In order to reduce from these half-plates to lantern size, I employed at first two cameras—my ordinary half-plate to take the negative in one of the double backs, and a smaller camera with lantern plate carrier and rectilinear lens: the lens of the latter being inserted in the lens aperture in the front of the former. But the two necessary adjustments for placing the image rightly upon the lantern plate, and at the same time focussing, proved so troublesome that I soon gave it up, and invested in one of the fixed focus reducing cameras now sold at a very low price by all photographic dealers. This last is provided with a single lens, which gives practically straight lines upon the lantern plate, and I have found it most convenient and useful.

One caution is, however, very necessary in using such a camera, viz., to take great care that no light enters during exposure except through the negative. I find it even necessary to mask the edges of the negative, and this is best done by pasting a narrow strip of black or orange paper on each side of the negative at the back, well covering the blank margins, and allowing the paper to overlap about an eighth of an inch, so that the pieces of thick cardboard used for filling up the side spaces may be pushed under the overlapping paper. If this be not carefully done, a marked difference in the brilliancy of the slide will be perceptible, and there will be a constant tendency to "veil." Most of my negatives are on celluloid, but the difficulty of getting these to lie flat was easily overcome by slightly widening the grooves at back of the reducing camera, so that they would admit the film between two thin plain glass plates.

The lantern plates I have been using have been chiefly gelatino-bromide, the chloride plates being tediously slow for printing in the camera with such a light as has been available for some months past; and at times, even with the bromide plates, I have found it much more convenient to use magnesium ribbon than to trust to the uncertain daylight, and have obtained very good results upon plates so exposed. The quantity required was from one to four or more feet, according to the density of the negative and the tone required.

As regards the development of lantern slides, there is no doubt that hydrokinone is the easiest and cleanest developer in working, and has least tendency to give fog; but for my own part I much prefer pyrogallol, as the warm tones it gives with full exposures are to me so much more pleasing than the cold blacks of the hydrokinone-developed slides.

In working with the pyro developer, a large proportion of bromide is necessary. The average developer should contain about three times as much bromide as pyro by weight, a little more or less according to exposure and tone required. Ammonia with the pyro gives warmest tones. The alkaline carbonates of potassium and sodium give dirty green images, which, however, are capable of taking a purple tone in a sulphocyanide toning bath. Purple and blue tones may also be obtained with hydrokinone by giving a long exposure, and adding to the developer, as a restrainer, in addition to the ordinary proportion of bromide, about two grains of chlorate of potassium to each ounce, and afterwards toning as above. The addition of chlorate of potassium was suggested by Mr. Fitch, whose negative films on celluloid I have been using. Possibly bromate of potassium may be better than the chlorate, but I have not yet had an opportunity of trying it.

Metabisulphite of potassium is recommended to be used with pyro developer by makers of some plates; it acts both as a restrainer of development, and as a preservative of the pyrogallol; but as, on dissolving the metabisulphite in water, it appears to be immediately decomposed, being reduced to sulphite with liberation of free sulphurous acid, I fail to see any advantage in its use above adding sulphurous acid to the solution of pyro with sulphite of sodium. The restraining power of the metabisulphite, I believe, is merely due to the neutralisation of a portion of the alkali used in the developer by the sulphurous acid liberated.

The following is a formula which I have been using latterly, and find to give good results :—

| | | |
|---|---|---|
| A.—Pyrogallol | ... ... ... ... | 30 grains |
| Sulphite of sodium | ... ... ... | 80 ,, |
| Sulphurous acid ... | ... ... ... | $2\frac{1}{2}$ drachms |
| Distilled water ... | ... ... | to 4 ounces |
| B.—Ammonia (·880) ... | ... ... ... | 1 drachm |
| Bromide of ammonium ... | ... ... | 96 grains |
| Ferrocyanide of potassium | ... ... | 40 ,, |
| Distilled water ... | ... ... | to 4 ounces |

Equal parts of A and B for development. This developer I find to work quickly, gives rich, warm tones with correct exposure, and the same solution may be used for at least two plates. I am rather doubtful as to the utility of the ferrocyanide, but am inclined to think it has some effect in preventing fogging or veiling. If the slide should, after development, show any fogginess—which will not occur if correct exposure has been given—it may be quickly removed by using Farmer's ferridcyanide reducer, consisting of a weak solution of hyposulphite of sodium, about one ounce to a pint, to which are added a few drops of a ten per cent. solution of ferridcyanide of potassium. The action is very rapid, and any filminess or veil soon disappears, when the plate should be quickly removed from the dish and rinsed well under a tap. If the fog has been caused by over-development, the reducing action may be allowed to continue until the image is of the right density; but if a case of over-exposure, it should be stopped immediately the veil is removed, and the slide intensified after thorough washing.

With eikonogen as a developer for lantern plates I have had little experience; like pyro, it has a tendency to fog if not well restrained with bromide. With comparatively short exposures it gives good black tones similar to those obtained with hydrokinone, and with long exposures and powerful restrainer an olive green image is obtained, which is capable of taking a fine purple tone in a sulphocyanide toning bath. I append the formula I have been using, and which I have found to give fairly satisfactory results with long exposures and after-toning :—

| | | |
|---|---|---|
| A.—Eikonogen | ... ... ... ... | 24 grains |
| Sulphite of sodium | ... ... ... | 160 ,, |
| Warm distilled water | ... ... ... | 2 ounces |
| B.—Carbonate of sodium | ... ... ... | 40 grains |
| Carbonate of potassium ... | ... ... | 40 ,, |
| Ferrocyanide of potassium | ... ... | 20 ,, |
| Bromide of potassium ... | ... ... | 12 ,, |
| Distilled water ... | ... ... ... | 2 ounces |

For toning I have used one of the baths recommended for the aristotype paper with good effects, as follows :—

| | | |
|---|---|---|
| Sulphocyanide of ammonium | ... ... | $\frac{1}{4}$ ounce |
| Alum | ... ... ... ... ... | $\frac{1}{4}$ ,, |
| Saturated solution of carbonate of ammonium | ... ... ... ... | 5 drops |
| Distilled water | ... ... ... ... | 5 ounces |

Dissolve, and add one grain of chloride of gold.

This bath will remain good for a long time, but should be replenished with more gold as it becomes exhausted.

The cyanide of silver intensifier is particularly useful in the making of lantern slides, especially when hydrokinone has been used as the developer. The disagreeable muddy tone caused by over-exposure may be entirely remedied by its means. In the case of such an over-exposed slide, it is better, before intensifying, to immerse the plate for a few seconds in the above-mentioned ferridcyanide reducer. This will remove any trace of fog which would otherwise be intensified with the image. Then wash perfectly free from hypo in running water, and soak in the following solution till well bleached :—

| | | |
|---|---|---|
| Perchloride of mercury ... | ... ... | 1 drachm |
| Bromide of potassium ... | ... ... | 1 ,, |
| Distilled water ... | ... ... ... | 8 ounces |

After bleaching, the plate must be again thoroughly washed; for a lantern plate, one hour in running water is sufficient; then immersed in this solution :—

| | | |
|---|---|---|
| Nitrate of silver (crystals) | ... ... | 1 drachm |
| Cyanide of potassium ... | ... ... | 1 ,, |
| Distilled water ... | ... ... ... | 8 ounces |

The plate should be removed from the cyanide as soon as it is thoroughly blackened; if allowed to remain, a reducing action soon commences. The cyanide of potassium, Dr. Reynolds tells me, should be the pure crystalline, not the commercial. This intensifier not only greatly improves the colour of the image, but also appears to give it greater brilliancy.

The use of a clearing solution after development does not appear to me to be always necessary. I have found that recommended by Mr. Edwards useful, consisting of ferrous sulphate, citric acid, and alum. If the slide has been, or is to be, reduced by the ferridcyanide method, the ferrous sulphate must be omitted, or a blue stain in the film will result from a deposit of Turnbull's blue.

After the final washing of the plate, it has been my practice to immerse the slide for five or ten minutes in strong methylated alcohol. I do not know if this has any bad effect, but it seems to me to have two great advantages: firstly, the spirit hardens the film; and secondly, the slide dries so quickly after this treatment that there is little chance of particles of dust collecting upon the wet gelatine film, which often occurs when slides are left for one or two hours to dry in an ordinary room.

For binding the slides when finished, I prefer a good stiff paste, and to choose my own coloured binding paper, to using the adhesive strips supplied by dealers; it is a convenience also to be able to cut the strip to any width required. A paste prepared as follows answers well, and is very adhesive:—

| | |
|---|---|
| Flour ... ... ... ... ... | 1 ounce |
| Alum ... ... ... ... ... | 60 grains |
| Camphor in fine powder ... ... ... | 30 ,, |
| Water ... ... ... ... ... | 5 ounces |

Mix well, and boil till thickened. This will keep well, but will remain good much longer if one grain of perchloride of mercury be added, and the paste preserved in a wide-mouthed corked bottle.

## THE PORTRAITURE OF THE MOON.

BY JAMES MEW.

"In what manner," asked the wise men, "did you see the moon?" He answered them: "As I was ascending the pass of the Edomites, and I saw her crouching between two rocks, with a head like a calf, ears like a kid, horns like a hart, and her tail between her legs, and, when I had given a glance at her, I trembled violently and fell backwards." Such is an early account of the appearance of the moon, given in the Babylonian *Talmud* in the treatise on the New Year in the commencement of its second chapter. Among the many strange pictures of the moon which have been presented to the world by—shall we say—impressionist artists, this is probably not the least strange. But there is, beyond all doubt, some esoteric explanation of this marvellous vision of the moon which would be found, upon examination, to support the latest revelations of science.

Dante, in the second canto of the *Paradiso* in his divine comedy, introduces himself to the reader in a novel situation. He is in the moon, and, being there, wisely takes the opportunity to ask his lady, Beatrice, who happens to be with him in that same "first star," a question which has interested mankind at large for many ages, and if ever satisfactorily answered, will be so, probably, by the aid of photography. "What," he says, "are those black marks in the moon, which make the good folk down below on earth to utter their fables about Cain?" (Cain, it will be understood, is the Italian individual equivalent of our generic man in the moon.) The answer of Beatrice is not wholly satisfactory; it is, in fact, American. Her reply involves another question: "What," says she, "do you think of the matter yourself?" Her own explanation is a little too complex and abstruse for the general public; but the photographer will, perhaps, be interested in an optical illustration, which she suggests to Dante, derived from three mirrors placed at certain distances, and illuminated by a light proceeding from behind the experimentalist.

In this matter of the moon the mind is astounded by the marvels seen by intelligent speculation. In the blessing of Joseph a benediction is invoked upon the territory of that patriarch "for the precious things put forth by the moon." What these precious things may be is not precisely clear. An erudite ecclesiastic has supposed them to be those vegetables which require a month to bring them to perfection, but refrains from further enlightening the public about what particular vegetables these are. May not rather these precious things put forth by the moon be the bounteous sheaves of interesting story, the entertaining portraitures, the thousand-and-one fancies of diverse growth, and place, and time, of which none are more celebrated than those which circle about her sole supposed inhabitant, commonly called "The Man in the Moon?"

It is for photography to explain to us who the man in the moon really is. Whether, indeed, the figure which meets our naked eyes be a man at all, and not, rather, a lion, as is the opinion of Albertus, or, as Eusebius prefers, a fox; or a hare, as is maintained by the Singalese; or the soul of a sibyl, as is suggested by Plutarch; or a woman, Mary Magdalene, according to the pretty mediæval legend, which explains the lunar spots by her repentant tears. Let, however, so much be granted that the figure is that of a man. What manner and condition of man must still be told by the camera. Is it, for instance, Luna's lover Endymion? Is it Cain proceeding—oh! how slowly—up the mountain to sacrifice his offering of the fruits of the ground, which had so little respect from his Lord in comparison with the bloody butchery of his brother Abel? Is it that unfortunate wight in Numbers, who, for gathering sticks on the Sabbath day, was stoned with stones till he died, by the congregation of his own fellow-men, including, possibly, his own family circle, as the Lord commanded Moses?

In the elucidation of one particular in the man in the moon's history even photography must be powerless. In Chaucer's "Testament of Creseide," Lady Cynthia, in a grey gown full of black spots, is shown to the reader with a churl painted upon her breast, bearing a bush of thorns on his back, which he is said to have stolen, and for that felony he is transported to the moon, and may climb no nearer heaven. The theft here is the crime, and not the Sabbath breaking, a circumstance which, though it diminishes the disproportion of the punishment, cannot, any more than that sin for which it is a substitute, be distinguished by the camera. To determine this business satisfactorily is the province less of the photographer than of the historian. He it is, also, who must explain the presence of the dog, an intrusive and later feature in the original legend, recognized in Shakespeare's time; for did not Caliban's fair mistress, Miranda, in "The Tempest," show him that dog, in addition to the man and the bush? And in "A Midsummer Night's Dream" the carpenter, Quince, is not satisfied with this, but must needs introduce a lantern in addition. One must come in, he says, with a bush of thorns and a lantern, and say he comes to disfigure or to present the person of Moonshine.

It is in the nature of all legends to grow, as this legend of the man in the moon has grown. Successive narrators imagine successive incidents to give a roundness to their romance. The dog and the lantern were brought into the picture as probable accompaniments of the man, and very likely from some far-off sense of the eternal fitness of things. It remains for the camera to relegate them to their proper situations—anywhere, indeed, except in the moon. Seeing is believing, according to a vulgar proverb, and when people find neither dog, nor lantern, nor thorn bush, nor man in the moon's photograph, they will, perhaps, cease to believe in them, except some few, who may urge that those are all to be discovered on that other side which has never yet been beheld by human eyes. Legend after legend will thus disappear upon comparison with the moon's true portrait. For instance, that of the New Zealanders, who speak of one of themselves in a far back time, a certain Rona, who went by night for water to his well; what time he slipped and fell, and sprained his ankle, he saw the moon falling also rapidly upon him. Then he seized the branch of a tree to protect himself, but the branch broke, and, by some mysterious law of nature or art, left by the New Zealanders unexplained, instead of the moon falling upon him, he fell himself upon the moon, and there remains with the broken bough up to this present. It will be clearly discovered in a photograph of the moon whether this story has any real or apparent, primary or secondary truth.

(*To be continued.*)

## PHOTOGRAPHING IN COLOURS.

The iuventiou which has recently been announced from Paris, of a method of communicating colour to a sensitive photographic film by the action of a ray of coloured light, will, if confirmed, awaken very widespread iuterest, for it is impossible to foresee all the applicatious to which such a discovery might be expected eventually to lend itself. The idea is credited to M. Lippmann, a professor of the Sorbonne, and a physicist whose name is already widely and favourably known in connection with some highly ingenious instruments of physical research. The theory which he is said to have successfully embodied in experiment is that the interference of two rays of light of the same wave length may be caused to produce a characteristic effect upon a sensitive film such as amounts to dyeing the film of the particular hue in question. So far as has at present been explained, the process appears to depend upon the doctrine that the chemical action, like the chromatic properties of a ray of light, is capable of being affected by the conditions which give rise to the phenomena of interference. In itself this seems likely enough. It is well known that if two rays of light having the same wave length travel along the same path simultaneously, they interfere with one another. It may and does happen that at certain points along the path, depending for their position on the wave length, the two impulses tend to counteract, and at other points to reinforce one another. A luminiferous particle—whatever that may be—which is acted upon by two opposing forces will remain at rest if the forces are equal as well as opposite; while if the forces be not equal, or not directly opposed, there will be some resulting disturbance, but still a disturbance different from that which would have been produced by either of the coincident forces acting alone. From this cause arise all those beautiful optical effects of interference which so strikiugly illustrate the undulatory theory of light. Now, if it be a fact that the chemical activity of a ray of light is subject to the same law, and can be either exalted or depressed by causing a second ray of the same wave length to act upon the seusitive reagent, it is quite couceivable that a pair of rays of light might be so directed through a photographic film as to cause, not a uniform, but a sporadic deposit of the precipitated element. These minute deposits would, in that case, be distributed at definite distances apart along the line of the common path of the active rays, because they would mark the points of co-operating and therefore exalted activity. Similarly, their intervals would occupy the spaces in which the antagonism of the two rays had reduced or even destroyed the actinic effect. Now, such a film would apparently be opaque to any light not having this particular wave length, because at some point it would necessarily be absorbed by the opaque deposit. But if a ray of the same wave length impinged, it might be able to pick its way successfully between the deposits. Professor Lippmann is said to have produced such a film by the expedient of placing a mirror at the back of his sensitive plate, and causing the focussed ray to return along its own path. The mirror is produced by making the plate one side of a mercury trough, which, when filled, constitutes a mirror in exactly the desired position. The expedient, if successful, is certainly charmingly simple, and, seeing that the healing art would undoubtedly benefit in as high a degree as any by a practicable system of chromatic photography, we look with lively interest for some further information upon the theory and practice so ingeniously originated.—*The Lancet.*

## A ZINC SULPHIDE COMPOUND SENSITIVE TO LIGHT.*

BY JOHN CAWLEY, ASSOCIATE OF THE ROYAL SCHOOL OF MINES.

Zinc sulphate, or chloride freed from iron, manganese, lead, tin, and so on, is precipitated by an alkaline or alkaline-earthy sulphide; the precipitate, consisting of hydrated zinc sulphide alone, or in admixture with a sulphate of an alkaline earth, is dried and iguited at a red heat; the red-hot product is thrown into water, levigated, washed, dried again, and reduced to fine powder. The pigment is then ready for grinding in oil as a paint.

This process, simple in outline, requires considerable skill and experience to carry it out successfully, but if well carried out it produces a pigment superior to the best white-lead in respect of whiteness, body, and covering power. It is, moreover, relatively innocuous, and is not discoloured by gases containing $SH_2$.

Iu general, however, it is subject to the grave defect of darkening wheu exposed to sunlight, the darkening apparently being due not only to light, but also dependent on the condition of the atmosphere in respect of moisture-contents and other iufluences. I have prepared pigmeuts so sensitive as to be turned almost black when exposed to bright sunlight for one or two minutes. A curious thing to be noted in this connection is that the darkened pigment will completely regain its whiteness when placed in the dark for a few hours, and when so bleached it appears to be somewhat less sensitive than it was originally. It would be too long a story to go into all the details of the experiments made by me in connection with this matter. I will, therefore, content myself by giving a brief account of the more important observations, interpolating here and there remarks of an explanatory character.

1. The dried hydrated zinc sulphide, before ignition, is not altered by exposure to light; after ignition it darkens readily.

2. The whitest and purest zinc blende obtainable was levigated and exposed to light. No darkening was observed, but the same blende calcined, so as to slightly oxidise it, was readily darkened.

3. Zinc sulphide was prepared in a very finely-divided condition, and freed from hydration by burning zinc in an atmosphere of sulphur vapour, and collecting the product in a chamber the temperature of which was high enough to prevent the condensation of sulphur. This sulphide was unchanged by light, but, like the blende, darkened readily after slight calcination.

In connection with the observations above-named, I may say I had been struck by the resemblance which the colour developed in the pigmeut by light bore to that of the finely-divided metal deposited from certaiu metallic solutions.

Noting that the pigment moistened with water was more sensitive than when in a dry condition, a sample was dried at 120° C., and while warm was placed in a glass tube, which was sealed before the blowpipe. Result, no discolouration after one year's exposure. A sample placed in a sealed tube without extra drying was readily darkened.

Taking a sample of pigment not very sensitive, *per se*, it was uoted that its sensitiveness was enormously increased by moistening it with a weak solution of zinc sulphate, from which it was inferred that the sensitiveness might be due to imperfect washing. The most thorough washing, however, would not remove the basic zinc sulphate formed in the process of ignition.

Attempts were made to decompose this basic sulphate into zinc oxide and an inert sulphate by treating the pigment with solutions of the hydrates of potassium, sodium, bariuu, and calcium; the first three were rejected, as they appeared to act on the zinc sulphide itself. Lime-water exercised for a short time a decidedly protective effect; afterwards it seemed to lose its power of making the pigment resistant to light.

Brixton and Clapham Camera Club.—The proceedings ou the 21st inst. included a limelight lantern display, discussion of the proposal in favour of cheap fares for photographers, and a flash-light demonstration.

## PHOTOGRAPHIC SHUTTERS.*

BY FRANCIS BLAKE.

At the outset, I will say that the word "shutter" will be used throughout this paper, not because I deem it a correct name for the apparatus, but because more than thirty years of bad usage have so fixed it in the photographic vocabulary that it would be quixotic to try to displace it. Of course, "opener" would be quite as appropriate—or, rather, inappropriate—a name as "shutter"; and, of course, "exposer" is the proper substitute for both, as its dictionary meaning defines precisely the function of the apparatus.

The earliest mention of shutters with which I am familiar is in a most excellent dictionary of photography, edited by Thomas Sutton, and published at London in 1867. On page 156, under the heading of "Instantaneous Shutters," he says:—"There are many methods of instantaneously admitting and shutting off the light from the sensitive plate. Mr. Wilson, who has been most successful in getting good pictures with rapid exposures, adroitly uses his Highland bonnet placed in front of the lens. Some use flap-shutters in front of the lens; some a similar arrangement close behind the lens; and Mr. England and others use a guillotine sort of shutter with a slot cut across it, which falls immediately in front of the sensitive plate. As the slot passes the plate, the parts thus exposed to light receive the full effect of the whole power of the lens. In some respects this is the best instantaneous shutter that has yet been devised; but it is apt to cause a vibration in the camera while in the act of falling." I have quoted the above because I feel sure that later on you will share with me surprise that the principle of the focal plane shutter, so clearly stated by Sutton, should have been entirely neglected by later workers in the photographic field.

Before beginning original work, it was thought best to test the speeds of the best market shutters. This was done by means of an apparatus which I devised, and had the pleasure of exhibiting to the Boston Camera Club some years ago. The principle of the apparatus is simply photographing the image of the sun as reflected by a freely falling silvered ball, and deducing the time of exposure by applying a law of gravitation to the linear value of the distorted image.

My apparatus consists of a vertical staff, about six feet in height, rigidly attached to an iron bed-plate. The staff is painted dead black, and is graduated downwards, on its front face, in white lines to feet and hundredths. At the top of staff is a movable piece readily adjusted to the height which brings the image of the sun, as seen upon the surface of the ball, exactly in line with the zero of the staff graduation. The silvered brass ball, $2\frac{3}{8}$ inches in diameter, and 2 lbs. 2 ozs. in weight, is suspended by a short piece of silk trant-line attached to a small vulcanite ring, which, in turn, is held by a spring-clip attached to the adjusting piece. On opening this spring-clip the ball is released, and, falling parallel to the graduated staff, is received into a padded box attached to the bed-plate.

It is perhaps needless to say that the exposure is made while the ball is falling, and that the length of the exposure is computed from the scale readings of the beginning and end of the black line which marks on the negative the path of the reflected image of the sun.

To facilitate the computation of results, I have prepared the subjoined table, which gives the time of falling to the ten-thousandth part of a second for each hundredth of a foot from 1·00 foot to 5·59 feet. The formula used in computing this table is that $t = \sqrt{\frac{d}{g}}$ when $t =$ time; $d =$ distance fallen; and $g = 16{\cdot}083$ feet—the gravity constant at our latitude. The manner of using the table will be made apparent by the following example:—An exposure having been made with a Prosch duplex shutter, the beginning of the black line marking the course of the sun's image on the negative was found to be opposite the 4·62 feet staff graduation, and its end opposite the 4·29 feet graduation. Referring to the table, it appears that—

| | | ft. | | s. |
|---|---|---|---|---|
| Time of falling | ... ... | 4·02 | = | 0·5000 |
| " " | ... ... | 4·29 | = | 0·5165 |
| | Time of exposure | | = | 0·0165 |

With a well-made shutter the accordance of the results obtained with this apparatus is remarkable. For example, three consecutive tests for fastest speed of a Prosch duplex shutter gave the following values:—

| | | s. |
|---|---|---|
| 1st test | ... ... ... ... ... | 0·0164 |
| 2nd " | ... ... ... ... ... | 0·0167 |
| 3rd " | ... ... ... ... ... | 0·0179 |
| | Mean | 0·0170 |

Each test brought into play a different part of the staff graduation.

TABLE GIVING THE TIME IN TEN THOUSANDTHS OF A SECOND FOR EACH HUNDREDTH OF A FOOT, FOR A FALLING BODY AT LATITUDE 42° 2).

*(To be continued.)*

* Paper read before the Boston Camera Club.

## Notes.

Mr. B. Harvey, in his letter from Kimberley last week, said in one line that the quagga is not extinct, and in another line that he "believes" it not to be extinct. Since then we have had a letter from him, in which he says that he has written to all the newspapers in the Eastern Province of South Africa, to learn whether quaggas still exist. He also entertains the ambitious idea of capturing one and sending it to Mr. Bartlett, the Superintendent of the Zoological Gardens, if anyone will pay expenses. If this animal—Beast, Mr. Harvey impolitely calls it, with a capital B—be not yet extinct, and the discussion which has arisen over the photographic frontispiece to the last Year-Book shall have been the means of the saving it, photography will have rendered one great service to zoology and to the world, and its votaries ought to keep a tame or wild quagga in memory thereof. Mr. Harvey might do worse than to send one live quagga to the Camera Club and another to the Photographic Society, to be kept as trophies on their new premises; a third might be sent to Messrs. York and Son. It is to be hoped that he will not ship striped jackasses of the wrong kind in mistake, so he cannot do better than to make all zoological or other suitable scientific societies in South Africa aware of the interest the subject has created in this country, and to get them to give the weight of their authority as to the existence or non-existence of the genuine quagga.

The Count d'Assche sends us from Paris a copy of *La Liberté*, containing a long description of Professor Lippmann's discoveries in heliochromy, but nothing more than has been already published in these pages. The writer of the article, however, called upon M. Nadar, and asked his opinion, as a professional photographer, upon the subject. The latter replied that it was an elegant and ingenious discovery, but not yet within the range of ordinary photographic work, chiefly because of the length of exposure, which, with plates of the sensitiveness at present employed by M. Lippmann, varies from a half to two hours. M. Nadar gave his literary visitor much information about efforts to solve this problem in the past, and described to him the curious process with glasses of three colours which Ducos du Hauron and Charles Cros communicated more than forty years ago to the Academy of Sciences at almost the same time, and in almost the same words.

Dr. Janssen, the president of the Permanent Committee of the International Photographic Congress, has written a letter, which appears in the last number of the *Bulletin Belge*, setting forth that the next meeting of the Congress will be held in Brussels during the second fortnight in August next. The Committee asks the president of the Belgian Photographic Association to suggest subjects for inclusion in the programme of the next Congress. All communications about the Congress, Dr. Janssen says, should be addressed to M. S. Pector, General Secretary, 9, Rue Lincoln, Paris. We do not know to whom in Brussels letters should be addressed on the subject; beyond printing M. Janssen's letter the *Bulletin* is silent on the subject. There is no doubt that if the Belgians think well to give a warm reception to the Congress, they will do it in a thorough manner. In the past we have seen much of their hospitality in this respect at Antwerp and other places.

Photographers, like others, have had their share of troubles from the bursting of water pipes by frost during the late severe weather, and this has often interfered with work in the developing room. The remedy is to use oval instead of round water pipes, and such pipes are in the market. On freezing, water expands instead of contracts, and this bursts the pipes; the force exerted is enormous; indeed, it was a favourite experiment by Professor Tyndall at the Royal Institution to burst bomb-shells by the freezing of water in their interiors. Water in freezing renders the bore of an oval pipe more circular, and as the latter has a larger capacity than the oval form, the strain upon the metal is less than with ordinary pipes.

Mr. Isaac Roberts, who has done so much valuable work in the field of astronomical photography, has contributed to the monthly notices of the Royal Astronomical Society a note on "Photographic evidence of Variability in the Nucleus of the great Nebula in Andromeda." It seems that, during the past six years, a large number of negatives were taken of this nebula, the exposures varying from five to sixty minutes. In some of these the nucleus of the nebula seems to have a decidedly stellar appearance, but in others quite a different appearance is recorded. Mr. Roberts infers from these different results in his photographic plates that the nucleus is variable.

Another astronomical note which should be interesting to photographers comes from Mr. Barnard, of the Lick Observatory, "On the Nebulosities of the Pleiades, and on a new *Merope* Nebula." In November last Mr. Barnard, while examining the Pleiades, discovered a new and bright cometary nebula close south, and following *Merope*. This nebula has been constantly observed since that occasion, and its position has been determined, but it has not yet been photographed, owing to the fact that the long exposure required for the nebula would over-expose *Merope* to such an extent that the luminosity of the two would coalesce.

We lately alluded to the bursting of a pressure gauge which was used in conjunction with a gas cylinder, and which, unfortunately, led to the serious injury of the person who happened to be handling it. Another accident of the same kind, but unattended by injury to anyone, has since been reported, and Mr. F. J. Smith, of Trinity College, Oxford, has sent some interesting particulars of the occurrence to *Nature*. The gauge was fixed upon an oxygen cylinder, and, from the fused appearance of the various fragments of metal and glass which resulted from its disruption, it is believed that, by some means, great heat must have been generated. Possibly this was akin to the air friction which causes a meteor, in its passage through our atmosphere, to become white hot. It seems certain that the accident could not have been brought about by any admixture of the oxygen with hydrogen, for we are told that a blow-through jet was in use at the time. It is not, however, stated whether the same guage had not been employed a few minutes before to record the pressure in a cylinder of hydrogen.

---

Messrs. Newton and Co., of Fleet Street, in commenting upon this occurrence, point out that such accidents must occasionally occur as gauges wear out—not a very comforting piece of information for lime-light workers; but they also give some valuable hints whereby danger from such accidents may be reduced to a minimum. This is what they say:—"There should be no cast iron in the gauge; the tubes and works should be mounted on a brass or gunmetal frame. The glass covering the dial should be mounted in a ring, fitting on the body of the gauge like a cap. When the gauge is in use this cap should be removed, thus avoiding all danger from the broken pieces of glass. The gauge should then be closed in a brass wire cage, so that should the tube burst, any portions of metal would be caught by the wire network, and if not stopped altogether, would, at any rate, be rendered harmless."

---

Mr. Fowler, a member of the Royal Astronomical Society, who thought he had discovered that *a* Lyræ was a double star, has not yet got rid of the trouble in which the alleged discovery has involved him. The duplicity was revealed to Mr. Fowler by means of a photograph in which the lines of the star were doubled, and he forthwith read a paper on the subject at the Society. Unfortunately for Mr. Fowler, Professor Vogel, of the Potsdam University, and the Brothers Henry at Paris, had also photographed this particular star, and not a trace of duplicity could they discover; whereupon Mr. Fowler had to own that his conclusions, owing to some cause which he could not determine, must have been erroneous. At the last meeting of the Astronomical Society a paper by Professor Vogel was read, in which he went fully into the matter, and showed that not only must Mr. Fowler's photographs have been erroneous, but that his calculations were also wrong. Mr. Fowler's answer to this was looked forward to with much interest; but all he could say was that he felt bound to acknowledge that *a* Lyræ was not a double star, and that he had no explanation to offer as to the discrepancy between his photographic observations and those of Professor Vogel.

---

Mr. Fowler had a sufficient reason for his inability to offer an explanation of the differences in the fact that the weather since November had been so bad that he had not been able to obtain any photographs, or to test the adjustments of his photographic instruments; but he was not so happy in his explanation as to the inaccuracies in the calculations; indeed, he said nothing at all on the matter until Capt. Noble drew attention to it and enquired, drily, whether they used Walkingham's arithmetic at South Kensington, or whether they calculated according to Cocker there, as the discrepancy was very great. Mr. Fowler, in reply, said that he worked out his figures by the graphical method, and laid no claim to great accuracy, also that it now remained for him to determine why the doubling of the lines was special to the instrument he employed; and so the matter remains. The moral of the incident is, that photographic observations are made up of so many elements that it is unsafe to rely upon any single result until it has been verified by repeated experiments. The alleged doubling of *a* Lyræ bids fair to be a precedent which astronomical photographers will do well to bear in mind.

---

Mrs. French Sheldon, the adventurous woman who is to put Stanley in the shade, has extensive views of photography. She lately told an interviewer that she takes with her eight or nine cameras, so as not to be beaten if the one or other fails her. If Mrs. Sheldon is similarly prudent in regard to other requirements, what an amount of baggage she will have! By the way, it is to be hoped that she is a little more thorough with regard to photography than she is as to astronomy. One of the studies which interests her, and which she hopes to make, is that of the constellations only seen in the southern skies; but she has had no time to take lessons in astronomical science, and contents herself with a few hints from Mrs. Richard Proctor. If Mrs. Sheldon has only had time to get a few "hints" in photographic manipulation, her eight or nine cameras may prove a thorn and a burden. Photography—like beer, which, according to Mr. Richard Swiveller, cannot be tasted in a sip—cannot be mastered by a hint.

---

According to a report of the latest edition of Mr. Muybridge's lecture on the movements of the horse, his opinion is that photography is an especial help to artists in assisting them to have a larger knowledge of nature in movement. His theory is that the ungraceful attitudes of animals need not be represented, but, at the same time, care should be taken not to fall into faults which, without hurting the eye, yet are not true to nature. This is just where the difficulty comes in. The artist—that is to say, the artist of the conventional school—is at one end of the scale, and Mr. Muybridge with his instantaneous photographs is at the other. The question is how the two extremes are to meet. Up to the present the subject has not been fully dealt with in the spirit of compromise. What is wanted is the happy medium which, while not losing sight of what may be termed the grace of art, yet imparts the spirit of nature as represented by instantaneous photography.

## PHOTOGRAPHIC TOURISTS IN ICELAND.*

BY J. REYNOLDS, M.D., F.R.G.S.

*Slide* 17.—We were now to have our first experience of lava fields and earthquake cracks; for a little while the road was very fair, but about four or five miles from the capital the real road or track began, and *such* a road! Imagine, if you can, a ploughed field strewn with huge masses of clinkers, each piece varying from the size of one's head to the size of a house, only a few feet apart, and you have a faint idea of the plains north of Krisuvick. As you approach the volcanic chains near the south coast, words utterly fail to convey an idea of the scene of gloom and wild desolation that presents itself far and wide as far as the eye can reach; nothing but calcined rocks, huge lava boulders, charred branches of shrubs, and disintegrated lava, not a blade of grass nor living thing to be seen. The dead silence, the fire-blasted appearance of the calcined rocks, is appalling; here and there on the edge of the volcanic chain puffs of smoke can be seen curling up from fissures in the ground, showing that the fires are close beneath our feet—in fact, in some places the earth is so hot as to burn our boots—but we go on until we begin to ascend the actual mountains, and now in crossing the chain we pass through and around crater after crater of slumbering, but not extinct volcanoes. We pass along a path fifteen inches wide, on horseback it must be remembered, having on our right steep precipices into the various craters, and on our left perpendicular lava walls, and in some places there is actually a gap of a foot or two in this narrow path, over which our careful little ponies carry us safely—we dare not cross it on foot. We reach the other side, and on descending into the plain below, a sight presents itself which is not easily forgotten. The slide gives a general view. Our guide tells us we had better pitch the tents on the grass, the blades of which are at least six inches apart, and so rank that the ponies will not touch it; and now what a view one beholds! On the sides and in the recesses of the hills are vast pits, or cauldrons, or shallow lakes, all in a state of violent ebullition, so violent as to make the earth around tremble. Jets of steam at very high pressure are escaping with a deafening roar, clouding everything, and smelling horribly of rotten eggs. Every little hole that one makes in the ground with a stick sends up a curling column of smoke. One feels that one is merely standing on a thin crust over a fiery furnace miles and miles in diameter, and such is really most probably the case. I must not omit to add that the ground in places is most brilliantly covered with a deep cardinal red, and in others with rich sulphur yellow powder, whilst the milk white edges of the lakes are tinted in alternate bands of every imaginable variety of colour, and when the sun fairly lights up this region, the total effect is a hazy purple, like the bloom on a hot-house grape.

*Slide* 18 gives a nearer view of one or two of these pits.

*Slide* 19 shows five of these pits, including the famous blue mud cauldron, where there is thin mud of a magnificent turquoise blue colour boiling with such violence that the bubbles are thrown up seven or eight feet high. We none of us ventured too near this terrible pit, for it made the firmest of us feel shaky.

*Slide* 20.—One of our party is here shown heating a kettle in one of the boiling lakes.

Having photographed everything of interest in this region of calcined rocks, we started at twelve o'clock next day, Monday, for Vogsasar, a distance of only sixteen miles, but such was the nature of the region we had to pass over that we were nearly eleven hours on the journey; this is said by competent guides, who know all about the Icelandic passes, to be the roughest road in the country. It appears that, at some period, a tremendous eruption of liquid lava from some dozens of craters, which can still be seen, occurred, which liquid flow, in solidifying, cemented together the huge blocks with which this place is literally covered, and that a subsequent earthquake rent this immense coating of cement, and heaped slabs of it, boulders and all, one on top of the other. The lava rocks also here show unmistakable signs of being torn asunder while in a semi-plastic state, and stand out like the fingers of an outstretched hand in their weirdness, awful to look at. We arrived at last at Vogsasar.

*Slide* 21 shows the appearance of the farm, and the beautiful lake Hlivarvatn.

*Slide* 22 shows the farm on a nearer view.

*Slide* 23 shows the sheep-house, with walls four feet thick, to protect from the intense cold of the Icelandic winter.

*Slide* 24 shows our camp beside the lake Hlivarvatn.

The next day (Tuesday) we started at 11·30 a.m. for Eyrarbakki, and arrived there at 7 p.m., crossing on our way the Olfusa river in a ferry boat, after which we walked three miles knee deep in loose volcanic sand, along the banks of the river to the house of Mr. Le Folli, in whose back garden we had obtained leave to pitch our tents.

*Slide* 25 shows our tent in Mr. Le Folli's garden. This slide was given me by R. Marsden, Esq., of Denbigh Castle, one of our party.

*Slide* 26 shows the main street in Eyrarbakki as seen from the sea shore.

*Slide* 27 shows side street in the town.

*Slide* 28 shows an Icelandic fisherman and family group in front of a house on the sea shore.

The next day, at 3.50 p.m., we started for Sandholaferja, where we arrived at 9.15 p.m., crossing the Thjorsa river on our way, and, passing the village farm Lopstadr, we stopped and had some skyr. We also passed and stopped at a farm called Sraun.

*Slide* 29 shows this farm.

*Slide* 30 shows us having lunch on the road to Heckla. From this place we had a splendid view of the mountain, being not more than twenty-three miles distant.

At 11.35 the next morning we started for Heckla, and, after a nine hours' ride over a fair road and horrible bog, into which one of our party got thrown, we arrived at Daltarlakr farm, about five miles from the mountain, having crossed the Rauvilloku river about twenty times. The next slides (31 and 32) were given me by Mr. Lange.

*Slide* 31 gives an idea how the cavalcade looked when crossing this river, which winds like a snake.

*Slide* 32 shows the peculiar lumpy state of the fields about six miles from Heckla, with the guide in the foreground pointing to the mountain in the distance.

*Slide* 33 shows the actual mountain as seen from our camp at Daltarlakr Farm.

The next morning, July 11th, three of our party—viz., Mr. Paul Lange, Dr. Irwin, and I—started to ascend Heckla, and, after seven hours' hard climbing, we entered the crater. Mr. Lange, having a hand-camera in his possession, photographed the said crater, with Dr. Irwin, myself, and the guide standing in the same.

*Slide* 34 shows us as having arrived at the first patch of snow during our ascent, about 1,500 feet up the mountain.

*Slide* 35 shows Dr. Irwin and myself picking up fragments of lava from the wall of the crater, specimens of which I can show you after the lecture.

*Slide* 36 shows chief guide, Dr. Irwin, and myself in crater. I must mention here that Mr. Paul Lange took these two photographs, and kindly furnished me with the slide from the same. He is the first man who has photographed Heckla's Crater. We only took four hours in descending, so much easier is it to go down hill than up.

The tracks to and from the summit lead through mountain torrents and lava flows of the wildest description, and one can see from the summit over a radius of at least seventy miles; in every direction the view is magnificent. Before leaving the farm, the friendly people came to the camp to bid us good-bye.

*Slide* 37 shows one of our party taking an affectionate farewell of the Icelandic ladies.

*Slide* 38.—The next morning, at 10·30, we started for Hruni *en route* for Gullfoss; soon after leaving Heckla, we crossed the Thjorsa a second time, and I took a view of ponies crossing.

*(To be continued.)*

* Continued from page 82.

## HELIOCHROMIC RESEARCHES.

M. Gaston Tissandier, the author of several books upon photography, has visited M. Lippmann, seen his results, and written about them in *La Nature*. He says that M. Lippmann has opened a brilliant outlook to experimenters, that the results will be fruitful, and that what has been done assures a brilliant future for photography in colours. He also describes the built-up mercury trough used by M. Lippmann, as represented in fig. 1. In this cut, G, No. 1, is the sensitive plate, actual size, with its film side in contact with the mercury, M. in the trough. C is a U-shaped length of india-rubber, rectangular in section. F is a small piece of glass to form the back of the trough. The whole system is held together by four strong clips, three of which are depicted in the cut. No. 2, fig. 1,

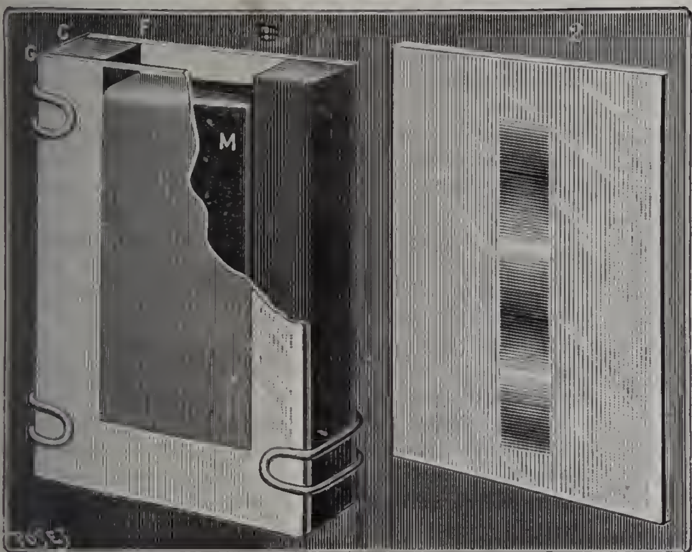

*Fig.* 1.

represents one of the plates with a spectrum photographed on its surface.

Fig. 2 is a diagram from *La Nature* representing the sensitive film considerably amplified, with its glass support on its right-hand side, and the mercury backing on the extreme left; the image is necessarily photographed through the glass. M. Tissandier remarks that near the

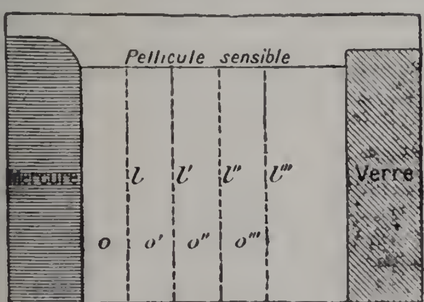

*Fig.* 2.

mercury, and near the adjacent surface of the sensitive film, there is a destruction of light at $o$; farther on, on the contrary, in $l$, the two waves coincide, and there is a maximum of light; farther on again, there is a new destruction of light at $o'$; farther still, at $l'$, another luminous maximum, and so on. The layers of silver in the film are of almost infinite thinness, being 00·00020 millimetres for the violet, 00·00025 for the yellow, and 00·00030 for the red.

At present, while using slow plates, not orthochromatic, the times of exposure given by M. Lippmann vary from half-an-hour to two hours, the latter being necessary at present when it is desired to photograph the red rays.

## PHOTOGRAPHY IN THE ORDNANCE OFFICE.*

In the discussion which followed the paper by Sir Charles Wilson, published in these pages last week—

General A. de C. Scott said that all new processes were more or less built up by the efforts of numbers, and that was so in the present case. Photolithography and photozincography were in part due to men like Mr. Pouncey, who discovered the use of bichromates in connection with pigments; Niepce, who had a process with bitumen; Asser, who used bichromated paper, which was rolled up and used something like a lithograph stone; and Appel, who showed that any print in fatty ink could be transferred to stone. His own particular process involved a change in the methods which had been employed, resulting in producing a transfer which could be applied to any metal surface, and be printed from zinc. That proved successful, and when he left the Survey the results were so far satisfactory. On looking round the room, however, he hardly recognised the process he had left, so much had been done to enlarge and improve it, and he could not sufficiently express his admiration of the success which had followed the efforts of those who succeeded him. He believed they were indebted to General Cooke for those very large photographs, and he remembered when it was considered doubtful whether a lens could be produced which would give such impressions without distortion, which, of course, would render the whole thing useless. Ultimately, however, with the aid of an eminent optician, Mr. Dallmeyer, a lens was produced which succeeded.

Sir H. Trueman Wood could also bear testimony to the value of the scientific work done by the Ordnance Survey Department. Everyone interested in the progress of photography knew how much that science owed to the work done by that department. The photographic work was carried on on a scale which could be seen nowhere else in this country, at any rate. The enormous negative now shown was a most magnificent piece of photographic work, and the regular production of such negatives must involve great difficulties. Photolithography and photozincography also owed a great deal to the Ordnance Department. Photozincography was really invented and perfected there, and great credit was due to the various officials, from the time of Sir Henry James down to the present, for the way in which they had adapted and improved the various processes placed at their disposal. He could not understand why the smaller maps were not produced by a photographic process, which would do in six or eight months what took as many years by the more ornamental but not more useful work of the engraver.

The Chairman, the Attorney-General, said that they were much indebted to Sir Charles Wilson for this paper, but he should have been glad if he had given a little information with regard to the difficulties connected with the actual survey work.

Sir Charles Wilson said that the question of expediting the publication by means of photography had been thought over, but it was considered that engraving was so much superior, and the time was so near when the whole work could be published in that form, that it was not worth while to issue a few sheets

* Abridged from the *Journal of the Society of Arts*.

in photozincography. The new map of London would not be an engraved map, or few present would live to see it completed; it was proposed to publish it by photozincography. This would be a great test of the process, because the portions already issued were so splendidly drawn and engraved. He had recently had a specimen sheet done, and the result was extremely good; the lines were quite as fine as the engraving. The map would be published as each sheet was drawn, and he hoped it would come out in a reasonable time. The map of Scotland on the wall had been produced by photozincography from the large scale map. Its engraving would have taken a very long time, but the whole map had been produced a good deal under twelve months, giving all the details required.

## THE HISTORY OF PHOTOGRAPHY.*

BY DR. J. M. EDER, DIRECTOR OF THE IMPERIAL INSTITUTE FOR INSTRUCTION AND RESEARCH IN PHOTOGRAPHY AND REPRODUCTIVE PROCESSES IN VIENNA.

Beginning with the first chapter of Schiendl's "History of Photography," entitled, "Knowledge of the Action of Light and of Optics in Ancient Times," I notice that this, as well as Chapters II. and III., are really taken from my "History of Photochemistry," a portion of which appeared in the *Photographische Correspondenz* of 1881.† Herr Schiendl only in two cases mentions my work as the source of information; these are with reference to Fabricius and Schultze. He does not do so with regard to Eudoxia, Hellot, Beccarius, Bergmann, Senebier, &c. He also omits to mention that I had found a predecessor of Niepce, viz., Hagelman, and that I had pointed out Berthollet as the discoverer of the first chemical photometer. I consider it necessary to put it thus clearly that this historian makes use of my researches without acknowledging their source.

It is farther interesting to remark that Herr Schiendl's "History of Photography" is interrupted just where my older fragment of the history of photochemistry breaks off, that is to say, from the beginning of the nineteenth century to the time of Daguerre. Thus it happens, for instance, that Schiendl gives a bare history of the photochemistry of chloride of silver (which is described in my earlier fragment), but says nothing of the—at the least as important—history of iodide and bromide of silver, although it is these alone that are applicable to the camera-obscura.

Also the recognition of the true discoverer of the sensitiveness to light of the chromic salts with organic substances‡ (in the absence of silver), which was wanting in my earlier fragment, is also wanting in Schiendl.

Having shown that Herr Schiendl, for the first three chapters of his work, has very *freely* drawn upon my historical work, with very *scanty* acknowledgment of the source of his information, let us take in hand another chapter of Schiendl's history referring to a later period of photography.

Herr Schiendl gives a very different history of photography with chromium salts from that to be found in other authors. He ascribes herein a notable rôle to Ponton and Vauquelin, and displaces and distorts priority. Let us see how Schiendl's account will bear criticism. It is known that I first recognised that Vauquelin discovered that sensitiveness to light of chromate of silver (*Photo. Correspondenz*, 1881, p. 145; also "Eder's History," 1891, p. 51), on which I observed: "The discovery of the sensitiveness to light of the first chromic compounds belongs to Vauquelin. It therefore appears unjust to ascribe the whole of the credit of the discovery of photography with chromic compounds to Ponton alone."

This view of mine Schiendl copies with an alteration of wording. He writes, page 17: "This discovery of Vauquelin's appears to be the foundation of all later publications (for instance, Ponton's) on the sensitiveness to light of chromium salts." With regard to the above-cited quotation, it should be read in connection with what Herr Schiendl writes on page 89 of his "History": "When the services of Ponton are depreciated (see Eder's History), we (E. Schiendl) must observe that Mungo Ponton's work was quite independent." Hereto I remark, in the first place, that I have not sought to depreciate the services of Mungo Ponton to photography, as would be inferred from the foregoing observation; in the second place, Herr Schiendl himself, on page 17, adopts my view, which pleases me much; in the third place, the author contradicts himself again on page 89 of his book. The author thus, in two different parts of his work, puts forth views conflicting with each other. To which of these views of the "Historical Writer" must the reader adhere—the one on page 17, or the one on page 89 of "Schiendl's History"?

In the first he holds that Vauquelin's discovery was the foundation of Ponton's discovery; in the latter he contradicts himself, and says that it was not so, but that this view depreciates Ponton's services, for Ponton has worked quite independently.

Ponton himself, moreover, distinguished the difference in favour of Herr Schiendl's view on page 17* *against* Herr Schiendl on page 89, for Ponton himself says expressly that he had begun his researches with *chromate of silver*, and from this we may conclude that he based his work directly on Vauquelin's.

Still more reprehensible is the manner in which Herr Schiendl treats of the farther development of photographic methods by means of bichromate of potash, for this part of his "History" rests on a remarkable error on his part, such as the writer of a history should by no means commit. Herr Schiendl writes on page 89 of his "History": "Mungo Ponton studied these salts (chromates) with exactitude, and discovered that they, especially the bichromates, were *decomposed in the presence of organic substances by light. The chemical change is such that the solubility as well as the stickiness of the compound is lost*, and, according to the amount of the action of light, *the power to absorb water is either partly or entirely lost.*"

(*To be continued.*)

* A critical examination of "Schiendl's Geschichte der Photographie," 1891, published by Hartleben.

† This part of the work is somewhat scattered. It will be found, however, in my complete "History of Photographie and Photochemie," published some months since (vol. i., "Ausfuhrliches Handbuch der Photographie," Halle), to which anyone may refer.

‡ Suckow, as I found later on. See Eder's *Geschichte*, 1891, page 94.

* That is the place where Schiendl copies from my "History of Photochemistry."—Eder.

---

A demonstration of lantern slide making and a lecture by Mr. A. R. Dresser has been given at the Fry Manufacturing Company's rooms, which were filled by appreciative listeners.

The London and Provincial Photographic Association.—On March 3rd this Association will give a lantern and musical entertainment, with a brief interlude devoted to a demonstration of some of the phenomena of the polarisation of light. Tickets are obtainable of the secretary. On March 5th a paper on "Pictorial Composition" by Mr. P. H. Newman; March 12th, lantern night; March 19th, a demonstration with gelatino-chloride paper, Mr. J. Howson; March 26th, "High Speed Shutters," Mr. A. S. Newman.

## ALUMINIUM.

BY G. L. ADDENBROOKE.

To all those who take an interest in the brass and glass elements of photography, few things offer a more pleasing and hopeful field for speculation at present than the possibilities which the cheap production of this metal opens out. Great as have been the advances of metallurgy in other directions, they have, during the last few years, been simply astonishing in this.

At the exhibition of 1851, some small bars of aluminium, reduced by the French chemist, Deville, at the cost of Napoleon III., formed one of the rarest and greatest curiosities. From that time the reduction of the metal has always been carried on commercially on a small scale, but until some four years ago the price remained steadily at about seven shillings and sixpence per ounce, while no method of soldering it satisfactorily was known, so that its use was limited to certain parts of scientific instruments, and to the best kinds of opera and field glasses, where its lightness was a sufficient set off against its expense and the difficulties of working it.

The old method of reducing this metal, which forms the chief constituent in clay, and is, therefore, the most abundant metal in nature, consists in acting with metallic sodium on a kind of spar called cryolite, which is a fluoride of aluminium. The cryolite is pounded up and mixed with small pieces of sodium, and the whole brought to a red heat, and kept for some time at this temperature in a closed retort, during which the fluorine combines with the sodium, leaving the aluminium in a metallic state. The price of aluminium made by this process is, therefore, entirely dependent on the price at which the sodium needed for its reduction can be procured. The improvements which have been made in the manufacture of aluminium by what is called the chemical process have chiefly lain in the direction of improved and cheaper methods of reducing the metal sodium. The Castner process is of this kind, and chiefly by its means the price of aluminium was brought down about three years ago from seven shillings and sixpence per ounce to twenty shillings per pound.

But during the past three or four years a third process has been worked out by which, with the aid of electricity, the cost of producing aluminium has still further been reduced. By this process the aluminium is reduced in an electric furnace—that is, one in which the heat is generated by the passage of a current of electricity between two carbon rods, or between a carbon rod and a plumbago crucible. The heat is thus actually generated in the furnace itself in the midst of the materials to be operated on, and is not communicated from outside in the ordinary manner.

The electric process, being a cheaper one to work than the chemical, when first introduced caused a sharp rivalry to spring up between the two, the result being that both processes have been still further perfected, and the price of aluminium is now brought down to eight shillings a pound, while there are prospects of still further considerable reductions.

The price of the metal is now brought to a point which admits of its being employed for numerous purposes where its cost has hitherto been prohibitive. In comparing its price with that of brass, it must be remembered that it is only one-third the weight—the proportions being exactly 2·67 to 8·4—so that, bulk for bulk, a pound of aluminium goes three times as far as a pound of brass; thus, at eight shillings per pound, the cost of aluminium is only about three times that of brass.

Already we have lenses mounted in aluminium, and there is now no reason why tripod heads and some of the other metal parts of cameras should not be made of it. Its use for constructing shutters is obvious. It might advantageously be employed for the framework of dark slides and changing-boxes, and, finally, it would make excellent developing dishes, both light and indestructible. Aluminium has, therefore, a wide and useful field before it in connection with photographic apparatus, while the possibilities of its application in other ways are almost endless.

---

## THE SCIENCE OF COLOUR.

Last Friday Captain W. de W. Abney delivered his second lecture on the above subject at the Society of Arts.

He said that, as a standard light, he always used the most luminous portion of one of the poles of an arc lamp. It was sensibly the same at all times, as might be expected from its being at the temperature of the vaporising point of carbon.

The variations in the brightness of daylight at various altitudes of the sun above the horizon had been much worked at experimentally by Professor Tyndall, and Lord Rayleigh had worked out the law. Much of the variation is due to small particles floating in the atmosphere, and there are differences of opinion as to the nature of those particles. He (Captain Abney) believes them to be chiefly small floating particles of water. Such particles will float for a long time if small enough; in fact, Stokes has proved that some of them do not fall more than one-tenth of an inch in an hour; coarser particles may sink as much as one foot in an hour. Lord Rayleigh says that the small particles in the air can discriminate between the waves of ether, and absorb some more than others. The lower the sun is on the horizon, through the more of these particles does its light have to pass.

He then proceeded to make a "mock sun" upon the screen by projecting a bright beam from the electric lamp, and making the light pass through a weak solution of hyposulphite of soda, into which he poured a little acid. Particles of sulphur were thereby slowly set free, and, as they increased, they more and more intercepted the light, so that the white disc on the screen slowly changed to yellow, then to red, and passed through all the changes of colour presented by the sun as it approaches the horizon.

He then described the sector photometer and the means of registering any colour the human eye can see.

---

## Patent Intelligence.

### Applications for Letters Patent.

2,880. T. R. Dallmeyer, 115, Cannon Street, London, "Means and Devices for Obtaining Projections of Photographs in Natural Colours."—February 17th.

2,934. C. Cloakly, 13, Northumberland Place, Bath, "Photographic Printing Frames."—February 18th.

2,935. W. J. Lancaster, 6, Livery Street, Birmingham, "Plate Carriers and Cameras."—February 18th.

2,956. W. G. Thomson and W. Ward, 8, Quality Court, London, "Photographic Focussing."—February 18th.

3,024. Marion and Co., 22, Soho Square, London, "Marion's Glass-Roller Hot Rolling Press."—February 19th.

3,042. J. Y. Johnson, 47, Lincoln's Inn Fields, London, "Artificial Light for Photography" (Paul Nadar, France).—February 19th.

3,071. Matthews and Son, St. John's Road, Ryde, "Frames for Exhibiting Photographs."—February 20th.

### Specifications Published.

2,828. *February 21st*, 1890.—"Opening and Closing Skylights." RICHARD FRIEND, 7, Culmore Road, Asylum Road, Peckham, London, Builder.

According to my invention, I arrange a frame of any suitable shape and material to carry a cog wheel such as is ordinarily employed for the driving chain of a tricycle. I also arrange this said cog-wheel to gear at one and the same time into a slotted flexible band or chain (by which motion is imparted to the cog wheel), and into a rack (which may be rigid, solid, or flexible, or jointed as a chain, so as to close down into little space) straight or curved, and of any suitable material, and which is fastened to the casement to be opened. The whole apparatus is operated from the flexible band or chain, to which cords and balancing weights may be attached for the greater convenience of manipulation.

20,876. *December 22nd*, 1890.—"Photographic Camera." RUDOLPH STIRN, 34, Sebastian Strasse, Berlin, Manufacturer.

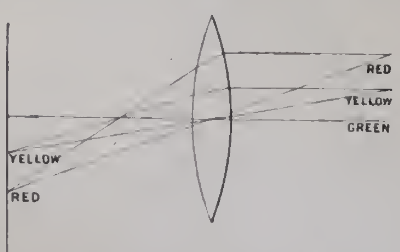
The invention relates to the construction of photographic apparatus, and its object is to construct the camera in such manner that the front part of the same, in which the lenses or objectives are mounted, is adjustable, by which a three-fold purpose is attained—viz., the employment of the camera for stereoscopic purposes, for the production of large photos (cabinet size), and for the production of two smaller photos (cartes-de-visite) side by side. The manifold employment of one and the same camera without having to remove the films, and by simply adjusting the lens box, offers the photographer many advantages: First, the apparatus may be employed for various purposes; and secondly, it enables the photographer to change from one style of photographing to the other without causing any further inconvenience whatever. Through the displacement of the lens box, one of the lenses is brought into a central position with the exposing chamber, the partition necessary for taking stereoscopic photos is folded down in the empty part of this chamber, and, simultaneously, shades for limiting the size of the cabinet photo are automatically brought into position.

In taking cartes-de-visite both lenses are employed, one after the other, whilst the lens box takes the same position as when used for taking stereoscopic photographs. For this the lenses, besides being provided with the necessary shutter mechanism for instantaneous or time exposures, have extra covers.

## Correspondence.

### HELIOCHROMY.

SIR,—To complete my letter of 18th inst., which you were kind enough to publish, and to substantiate my incredulity about Professor Lippmann's theory, I need only to draw the



attention of professional men to the elementary diagram of the action of a lens; I will take but three colours, to simplify the proof, and on the other side I will suppose (to give a fair play to the hypothesis) that the film is in direct contact with mercury, otherwise that there is no partition of glass between the incidental and reflected rays; well, the image being reversed, not one colour but the green meets again its own rays, the yellow rays intersecting the red ones, and the reflected red rays going astray. It seems to me as simple as two and two make four; but I am, of course, prepared to accept humbly my defeat if some more scientific man than I pretend to be will be able to demonstrate my error. L. NIEVSKY.

5, *Gransden Road, Shepherd's Bush, February 23rd.*

### THE NATIONAL PHOTOGRAPHIC EXHIBITION.

SIR,—Some slight misconception having arisen as to the construction of Rule 10, clause "*c*," affecting the challenge cup competition, as evinced by the letters received from various societies, I should esteem it as a favour if you will kindly explain (by the publication of this letter) that it means "the professional work *shall not exceed* one-fourth the number of whole exhibits." S. G. BUCHANAN WOLLASTON.

*Crystal Palace Company, Crystal Palace, S.E., Feb. 20th.*

### THE QUAGGA.

SIR,—Referring to letters which have appeared in the NEWS lately, and more especially to one in your issue of 20th inst., as to the photograph of the "quagga" (a print of which appeared in your last YEAR-BOOK), we beg to point out that Mr. B. Harvey has overlooked the fact that he was merely an operator on weekly wage while photographing in the "Zoo." for Mr. F. York. The camera, &c., he used there *belonged to Mr. York*, and was constructed by Mr. Meagher from special instructions given him by Mr. York. Mr. Harvey speaks of "*my instrument*," which, to say the least of it, is misleading.

We may mention that the said camera is still in our possession at the under-mentioned address. YORK AND SON.

87, *Lancaster Road, Notting Hill, London, W., Feb. 23rd.*

### THE FEDERATION OF LONDON PHOTOGRAPHIC SOCIETIES.

SIR,—I am sending the enclosed circular to all photographic societies in or near London, according to the most recent list in my possession. As, however, some societies may have been overlooked, or, owing to changes, may not receive the circular till too late, will you allow me to say, through your columns, that where a society cannot be officially represented, I trust that the secretary and a member of the committee will attend the meeting in a private capacity. Also I shall be glad to hear from the secretary of any country society approving of the proposed association. LEWIS M. BIDEN.

11, *Leadenhall Street, London, Feb. 20th.*

SIR,—I shall be glad if your Society can make it convenient to be represented by one or two members interested in the subject at a meeting to be held on Monday, March 2nd, at six o'clock, by the courtesy of the Photographic Society of Great Britain, at their rooms, 50, Great Russell Street, Bloomsbury (opposite the British Museum), to consider the following matters, and to make such arrangements as may be thought desirable:—(1) The association or federation of the London societies; (2) the interchange of lectures, papers, lantern slides, &c.; (3) as to obtaining the reduction of railway fares to amateur photographers on their outings; (4) whether any proposal can be made to the P. S. G. B. for admission of the various societies as corporate members of the P. S. G. B.; (5) how to assist in promoting the proposed Photographic Institute; and (6) generally to promote photographic knowledge and research.

I have long felt that it would be a great advantage to all concerned, particularly the junior societies, if they were brought more into touch with one another; the stronger could then help the weaker, besides deriving benefit from their own exertions.

Lecturers would be encouraged to devote more time and attention to the preparation of their papers; and societies, instead of being insignificant units scattered here and there, would feel that they were integral portions of some powerful body. See, for instance, the impetus given to association football by the formation of the various leagues and alliances. Thus we should be the better able to accomplish great works.

Which of our societies would undertake a survey of London? Some have made a commencement in respect to a small portion, but who will weld the portions into a homogeneous whole? Like the photographic chart of the heavens, one society alone can do little, but by united effort the work is comparatively easy of accomplishment.

If you are unable to send fully accredited representatives, I trust you, and one of the active members, will attend unofficially and represent your Society.

It will perhaps save time and assist me if you will let me have, in the course of the ensuing week, some particulars of your Society, especially all or any of the following :—Number of members, the terms of subscription, a list of the papers read, the names of any of your members who would read papers before another Society, or give lantern evenings ; also a list of sets of slides in the possession of your members would be useful.

I trust to hear from you by the 26th February, with any farther suggestions or subjects that may occur to you as suitable for the agenda paper.

LEWIS M. BIDEN, *President of the Toynbee Camera Club.*
11, *Leadenhall Street, London, E.C., Feb. 18th.*

## ANIMAL PHOTOGRAPHY.

SIR,—My note of December 1st, 1890, and my letter to you of January 19th this year, I had not intended for publication. It is my mistake. I sat down and wrote what I remembered, and what I knew to be correct. I am not in the habit of writing to newspapers, not possessing sufficient of the *suaviter in modo.* I hope I have done no harm, and surely none was intended. I received by this mail, along with my PHOTOGRAPHIC NEWS and *Journal*, a pamphlet by Gambier Bolton, on "Animal Photography." It would take time to write my opinion of it, but not very long to say right out what I think of it. According to his statement, it has taken him from fifteen to eighteen years to arrive at his present state of efficiency. There is a beginning to all things, great and small, and I would like to see Mr. Bolton's earlier attempts with his sixty-shilling Fallowfield. Ambition (without which no man is worth knowing) and an artistic training no doubt have led him to the goal, from the pinnacle of which he looks down with somewhat of scorn on his followers ; but that is no reason why he should make a stab at everybody and everything that comes in his way. The maker of his camera, lens, and, above all, of his plates, received not a "Thank you." No ! "Alone I did it," as Du Val would say. Yet methinks there is a soft place in his heart, for on page 7 of his pamphlet he says, "Forgive me if I have spoken too strongly on the subject." This is sufficient answer in itself that our worthy hero is of the right sort.

To my mind it would have been infinitely preferable if Mr. Bolton had published his experience with these animals in book form, instead of making such wholesale denunciations of former efforts and their producers. None of us are too old to learn. There has been an evident tendency for some years past for those who have reached the topmost rung of the ladder to decry the efforts of their less fortunate brethren. I will explain myself. Many of our leading photographers retired from business, when the cares of the profession lie lightly on them, are in the habit of writing down what should be done, and what should be left alone ; how high art should be cultivated, more of the picturesque chiaroscuro, &c., and how we should lift ourselves out of the mire we are "flummuxing" in ; drop retouching, and study the facial muscles, and not make a marble statue of everything we touch—All very well in its way, but they did not say the same when they were struggling for £ s. d. A fellow-feeling makes us wondrous kind, and I should like to see those who are enjoying honourable rest and retirement after they have fought the battle of life being a little more practical in their remarks. If they want anything to do, let them gird up their loins, and rid the country of the penny plain and two-penny coloured tribe, the parasites of the profession. Then will their light shine before men.

I am wandering from the pamphlet. On page 6 Mr. Bolton says : "Many of our oldest workers are the chief offenders, and, rather than lose some picturesque group, will take a negative of a horse, cow, &c., with tail or ears blurred. Might I say that professional photographers have no time at their disposal to wait for ears or tails. These are manufactured on the premises." Perhaps Mr. Bolton does not know this, but it is true. From the sketch of the lion on the cover of the pamphlet, the carnivora must be differently housed than at the time I photographed them. It would be next to an impossibility to have taken them without the bars. They are not the most difficult of the animals to take, but they made the most unsatisfactory pictures, owing to their appearing behind the bars. With such perfect instruments, and small lenses of great rapidity, one ought, I should think, to secure positions to satisfy the most fastidious.

Five minutes more, and this letter will be whirling on its way to London from the land of diamonds, the richest bit of earth under the sun. I must close. To Mr. Bolton *au revoir.* Don't think I have got "the hump," or "the needle," or whatever you call it in London. B. HARVEY.

*The Kimberley Photographic Studio, Feb. 2nd.*

## THE GLOUCESTERSHIRE PHOTOGRAPHIC SOCIETY'S SECOND TRIENNIAL EXHIBITION.

SIR,—Will you kindly favour us with a paragraph announcing the judges, viz., Messrs. H. P. Robinson, Valentine Blanchard, and Edward Brightman, in accordance with the prospectus conditions ; also calling attention to the date for closing entries, March 13th. The arrangements are well in hand, and we anticipate as great an all-round success as we had in 1888.

F. H. BURR, *Joint Hon. Sec.*

137, *Westgate Street, Gloucester, February 24th.*

## A RENUNCIATION.

SIR,—My attention has been called to a sentence or so of "A Renunciation," by Mr. P. H. Emerson, printed in the PHOTOGRAPHIC NEWS of January 23rd. I quote from it as follows : "Suggestions have been made that I got some of my ideas from a book called 'Naturalistic Painting.' I have a letter in my possession from an artist, wherein is stated clearly and exactly that Mr. Bate* had read a paper of mine on 'Naturalistic Photography,' *before* his first article appeared in *The Artist.*"

With reference to it, I would ask you, Sir, to publish the fact that before this I had not known of Mr. Emerson or his paper on "Naturalistic Photography," or any other work that is his.

This being so may not affect Mr. Emerson in the position which he takes with his footnote, save that, *ex fide bona*, he will probably be desirous of disclosing the letter to which he refers, and the name of the writer of it. FRANCIS BATE.

*Applegarth Studio, Augustine Road, W., Feb. 24th.*

## REDUCED RAILWAY FARES FOR PHOTOGRAPHERS.

SIR,—The following was addressed to the railway companies running out of Liverpool. I should be glad if local photographic societies would aid our efforts to obtain greater railway facilities than we at present receive. THOS. S. MAYNE.

*Liverpool, Feb. 24th.*

THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION, 1891.

SIR,—This important function (triennial) takes place this year from March 6th to April 4th. It will, without doubt, be on the largest scale of any similar exhibition ever held in the Kingdom. The Liverpool Corporation has granted the use of the greater portion of the Walker Art Gallery. We anticipate visitors to the extent of at least 50,000.

Probably interest in the Liverpool Exhibition is everywhere the feature of importance in photographic circles all over the country.

We now only want the help of the railway companies to double our number of visitors. The growing popularity of photography with the rising generation amongst all classes of our community, from the highest personages to the middle class and enlightened artizans, is not recognised to the extent it deserves by railway companies. Like cycling, it is only in its infancy ; photography and cycling are the landmarks of the nineteeth century as elevating pastimes.

* This does not imply that Mr. Bate took any ideas from my paper ; on the contrary, I feel sure his ideas were his own, as were mine.

What I now beg you to grant is return tickets at single fare (day tickets) during the currency of the Exhibition from all stations within thirty miles of Liverpool to holders of our season tickets, or purchasers of single admissions, which tickets I will provide you with (the shilling admission tickets). On hearing from you, I will circularise all the local and county photographic associations within this radius.

I have written this letter to your brother railway superintendents of the three chief railways terminating in Liverpool.

The favour of an early answer is requested.

Thos. S. Mayne, *Hon. Sec.*

---

PROF. MELDOLA ON PHOTOGRAPHIC CHEMISTRY.

Sir,—I have pleasure in enclosing a copy of the syllabus of the lectures on "Photographic Chemistry," which Professor Meldola is to deliver here. H. T. Wood, *Secretary.*

*Society of Arts, February 24th.*

Lecture I.—*March 9th.*—Photography as a branch of technology—Methods of giving instruction in the subject—The preliminary training essential—Photographic materials—Silver and its compounds—Reduction and oxidation occur simultaneously—The forms of reduced silver; grey and black deposits—Supposed allotropic modifications of reduced silver—The haloid salts of silver; their behaviour towards reagents; influence of solvents; formation of double salts—The state of molecular aggregation—Order of reducibility.

Lecture II.—*March 16th.*—The existence of subsalts of silver—Coloured forms of the haloids—Photo-salts—Colloidal organic compounds of silver—Silver albuminate and "gelatino-nitrate"—The principle of emulsification—Other photographic materials—Photo-physical and photo-chemical change—Modification of crystalline form under the influenc eof light—The action of light on asphalt—Photo-chemical study of iron compounds—Photo-chemical study of mercury and copper salts.

Lecture III.—*March 23rd.*—The action of light on the silver haloids—Accelerators and retarders of photo-chemical decomposition—The invisible products of the action of light on the haloids—Sensitive films—The function of the vehicle in modern emulsions—The invisible effect of light on the haloids—The photographic image—Development and subsequent processes.

## Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the technical meeting of this Society held on the 24th inst. Mr. Leon Warnerke occupied the chair.

As matter of historical interest, Daguerreotypes taken in 1842 and 1843 were shown by Mr. C. F. Hayward. It was stated that in those early days there was great difficulty in obtaining a sufficient polish on the plate.

The Chairman called upon Mr. W. E. Debenham to open the discussion on "The Dark Room and its Fittings," which stood for that evening's consideration.

Mr. Debenham said that, as he was responsible for the arrangement of the Society's dark room window, he would describe that to start with. There were four sliding frames, any or all of which could be drawn into or out of position, and outside all was a fixed frame containing deep yellow pot metal. One of the sliding frames was furnished with cherry fabric, one with two thicknesses of golden fabric, one with stained red glass, as recommended by Captain Abney, and one with a yellowish-green glass. A fitting for the dark room which he hoped would soon be provided was a cupboard for drying plates after being backed, or treated with orthochromatising solution. He would also like to have a levelled shelf in it suitable for drying collotype plates, but that would also require thermometer and regulator. Backing plates was a practice that, he thought, was not nearly so general as it ought to be, and that probably many were deterred from carrying it out on account of the difficulty of finding suitable means for preventing access of light whilst drying. A plan which might be considered makeshift, but which he had known to be quite successful where only a few were required, was to thoroughly dry, in an oven, ordinary cardboard grooved boxes; two or three plates put in shortly afterwards would then dry very well in such a box.

With regard to backing, the Chairman had very successfully employed a hygroscopic gelatine film spread on paper, and stained of a non-actinic colour, placed in optical contact with the plate.

Mr. Debenham had found great difficulty in getting optical contact with such a film, even on clear glass, and working in a good light. It would be all the more difficult to secure on plates covered with emulsion, and backed in the dark room. He thought there would be considerable surface of air spaces.

Mr. E. Clifton confirmed this view. He had not succeeded in getting optical contact all over the plate, even when using plain glass for experiment, and working with a squeegee in daylight.

A number of dark room appliances, including dark room lamps, celluloid dishes, glass measures, and dropping tubes, was then examined and discussed. A lantern presented to the Society by the Stereoscopic Company was shown and described by Mr. Clifton. In front there were grooves fitted with movable frames, one containing golden fabric for ordinary use, and another ruby glass for exceptional cases. There was an Argand burner in the centre, but, for developing, a small screen prevented the direct light from reaching the front of the lantern, which was lit only by reflected light from the yellow enamelled surface of the sides and back. The screen could be lifted from the outside, so as to allow of extra light towards the end of the development.

A travelling lamp of folding millboard, used with a night-light, and fitted on one side with cherry fabric, and on another with golden fabric, was then handed round. It was remarked that two thicknesses of golden fabric should be used, and there would still be plenty of light.

Mr. J. Desire England showed a candle lamp furnished with a hood, and supplied with discs of glass of different colours made by Messrs. Benham. It was recommended to have the face of the hood directed away from the operator, and towards a sheet of white material, the reflection from which served as the source of illumination.

Mr. Debenham suggested the use of a yellow material for the reflector.

Mr. Clifton had not heard a rocking table mentioned. It was a very convenient appliance, and he thought deserved to be more generally used.

On the colour of the dark room illumination, the Chairman said that he had taken the ruby glass out of his lamps, and replaced it by canary medium. He did not use ruby glass on any occasion.

The Chairman then introduced the question of photography in colours in connection with Professor Lippmann's recent announcements. He had begun experiments on the lines indicated, but the great difficulty he met with was in obtaining mercury sufficiently pure. In commercial mercury there were other metals dissolved which affected the silver compounds.

Mr. W. England offered to present to the Society a drying cupboard which he had had made in the collodio-albumen time.

A vote of thanks for this offer was passed; also to Messrs. Reynolds, Preston, Hayward, Vevers, Benham, and the Stereoscopic Company for the articles brought to the meeting or presented to the Society.

It was announced that Mr. Leon Warnerke would give a demonstration of a simple collotype process, and read a paper on it, on Wednesday, March 4th; that Sir David Salomons would exhibit an appliance for the registration of slides in the optical lantern, and read a paper, on March 9th. A discussion on hand-cameras will take place on March 24th, and on animal photography on April 28th.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

*February 19th.*—Mr. S. G. B. Wollaston in the chair.

Mr. W. Moran showed silver prints of some flash-light pictures of wrestling; these had been reproduced in the *Daily Graphic.*

The Chairman mentioned an instance in which he started developing six negatives at three o'clock in the afternoon; these were fixed, washed, and dried, and bromide prints were taken from them, and sent to the office of the *Daily Graphic* the same evening. They appeared the next morning.

The Hon. Secretary handed round samples of varuished wire gauze. It being uubreakable, he thought it might prove a good substitute for dark-room windows. It was made in various colours.

Mr. J. B. Wellington exhibited an optical lantern, the joint invention of Messrs. Pringle and Beard. The aim of the inventors was extreme portability. This is attaiued by an arrangement by which, when the lantern is uot in use, the jet is held in a receptacle at the bottom of the lantern. The lens is packed iu the body of the lantern, and the chimney in the place occupied by the slide carrier; the whole can then be packed in a box 9 by 8 by 6½. It was stated to be of the highest efficiency in working.

The Chairman asked for the opiniou of members as to the relative advantages of cylindrical and flat limes.

Mr. T. E. Freshwater was not sure that flat limes possess any material advantage over the usual cylindrical form. He had heard some operators speak in favour of them. The opportunity of testing the relative merits of the two kinds of limes did not often occur, the cylindrical form being the only kind of lime on the market. He had recently had some flat limes turned, which he intended to try, and he would communicate the result at a future meeting.

The Chairman had made a few experiments with flat limes. He was of opinion that he obtained better illumination. A flat lime was easier to revolve and adjust, the staging being more simple.

Mr. A. Haddon passed round a sealed glass tube containing crystals of eikonogen which had been exposed to light for over a year without change of colour.

Mr. J. P. Everitt said he had kept eikonogen preserved with bisulphite in an uncorked bottle for two or three months with but little change of colour.

The Chairman had recently taken some photographs of hoar-frost, using orthochromatic and ordinary slow landscape plates. With a clear atmosphere and bright blue sky, the orthochromatic plates gave the best negatives; but the reverse was the case when a thick London fog prevailed, and the sky was veiled. He thought this quite contrary to the usually accepted theory.

Mr. A. Cowan exhibited a series of negatives showing comparative results with various developers. An identical exposure was given in each case, aud the development limited to two minutes each. The following developers were used:—Eikonogen, hydrokinone, and soda; pyro aud ammonia; hydrokinoue and caustic potash; hydrokinone and soda. With the last mentioned, development was allowed to coutinue for six miuutes.

The general opinion of the members was that but very little difference was observable iu the results.

---

### The Glenalmond Photographic Club.

At the fortnightly meetiug held last Saturday, Mr. E. H. Cunningham Craig delivered a lecture on "Lantern Slide Making and Painting," after which there was a discussion.

Messrs. C. C. Robertson (Glasgow), A. M. Dykes, F. Moore, and F. Harrison were enrolled as members.

---

### The Croydon Microscopical and Natural History Club (Photographic Section).

*February 20th*—Lanteru evening; the President in the chair.

Mr. W. Low Sarjeant passed a series of slides through the lantern entitled "Round about Exmoor." The whole of the pictures, which were from negatives made on films, were of high order. Mr. Sarjeant operated the lantern, and Mr. Sheldon, who accompanied him on his tour, gave a brief description of each slide, coupled with accounts of numerous amusiug incidents that occurred on the way.

The next ordinary meeting will take place on March 6th, and lautern uight March 20th.

### The Birmingham Photographic Society.

A meeting of the section of this Society which has undertaken to survey, photographically, part of the county of Warwick, was held at the Colonnade Hotel, New Street, on Thursday evening, February 19th; Mr. Jethro A. Cossins, the well-knowu architect and archæologist, occupied the chair, and a large number of photographers was preseut.

The officers of the section for the coming year were elected as follows:—*President*—Mr. J. B. Stone, J.P., F.L.S., &c.; *Vice-President*—Mr. J. A. Cossins; *Treasurer*—Mr. S. G. Mason; *Secretaries*—Messrs. J. H. Pickard and W. Jerome Harrison; with a committee of eight members.

It was resolved that the work of the coming season should be confined to the Hundred of Hemlingford, which forms the northern part of Warwickshire, including Birmingham, Tamworth, Nuucaton, and Solihull. The six-inch ordnauce map is to be the basis of the survey, and each member was requested to undertake one of the sheets of this map, with a view to securing a photograph of every prominent, remarkable, or historic object contaiued in that sheet. It was farther resolved that each worker should "report progress" by the end of Juue.

---

### The North Middlesex Photographic Society.

*February 23rd.*—Mr. J. Saville occupied the chair.

Mr. Lewis Medland exhibited his collection of slides, about 250 in number, entitled "A Day at the Zoo," and, to the wonder of the nou-photographic visitors, these were preceded by a picture of the lecturer taking a snap-shot in Epping Forest at a gigantic liou, quite fifty feet in leugth from his mouth to the tip of his tail. Mr. Medland exhibited, among others, several fine slides of the lions, lionesses, and cubs; some of these were taken inside the cages, thus avoiding the bars. A spice of danger atteuded some of these shots; one lion nearly secured the lens as a memento of Mr. Medland's visit. One photograph was of the inside of the mouth of the hippopotamus. A good slide of the kangaroo with her young peeping from her pouch was exhibited. Mr. Medland incidentally described some of his owu adventures in South Africa and in Western America.

---

### The Richmond Amateur Photographic Society.

At the meeting last Friday Mr. Ardaseer occupied the chair. The award of Mr. J. B. B. Wellington on the recent competition in landscape photography was made knowu, and the batch of prints handed to the successful competitor, Mr. Ardaseer.

Mr. Cembrano gave a practical illustration of the difference in tone which can be produced in gelatine lautern plates by varying the exposure, using the same negative and same developer. He exposed and developed the plates, giving to the second four times, and to the third sixteen times the exposure of the first. Au excellent slide resulted in each case, but the tone varied from a brown black in the shortest exposed, to a warm purple in the longest.

An ingenious registering printiug frame for lantern slides, designed by Mr. A. Cowau, of Marion and Co., was shown by Mr. Cembrano, and some lantern plates sent by Messrs. Thomas and Co. were distributed among the members.

---

### The Bristol Amateur Photographic Association.

The annual meeting for 1891 was held in the new premises of the Literary and Philosophic Club, 28, Berkeley Square, Bristol, on Friday, Jauuary 16th, 1891, and was the first meeting of the Association in its new home. There was a good attendauce of members, iucluding Mr. H. A. Hood Daniel (president) and Mr. F. B. Bond (hon. sec.).

The Hon. Secretary presented the accounts of receipts and expenses of the Association to the New Year. With reference to an amount paid by the Association during the past year for hire of boats—a charge really incurred by a comparatively small number of members at the June excursion—it was proposed by Mr. J. W. Evens, and seconded by Mr. G. H. Wills, "That all members who send to the secretary a favourable reply to any notice of an excursion shall be held liable for their share of all general expenses connected with the same." This motion was carried.

Mr. William Molice was proposed as a member of the Association, and unanimously elected.

Mr. W. W. Boyden proposed that, seeing that no notice of resignation of any of the officers of the Association had been tendered, the present officers continue in their several offices for the coming year. This was carried.

Mr. Hemmons proposed, Mr. Lavington seconded, "That the remaining members of the council be re-elected for the ensuing year." This also was carried.

The President spoke of the new and favourable auspices under which the Association was starting the year, of the increase both in the number of members and in the heartiness of their co-operation, and the evident progress made by the Association.

A set of rules, drafted by the Committee, was submitted to the meeting, and passed unanimously.

Supper was served at 9.45 p.m., and fourteen sat down.

The February meeting of the Association was held at No. 28, Berkeley Square, on Friday, February 6th. Mr. H. A. Hood Daniel presided. Mr. Walter L. Stephens, formerly a member of the Association, was proposed for re-election, and, after a ballot, was declared unanimously re-elected.

The cash statements and balance sheet for the year 1890 were submitted by the Hon. Secretary, and read to the meeting. Mr. W. C. Hemmons and Mr. J. Phillips were appointed auditors.

Mr. John Lewis then proceeded to demonstrate to the meeting the new "Kallitype" printing process.

The Epping Forest Photographic Society, Leytonstone.

The first public display took place on the 18th inst., when an exhibition of some 300 pictures, chiefly the work of members, was opened. Among the photographs exhibited was a collection lent by the editor of *The Boys' Own Paper*, which was interesting as the work of young photographers.

The exhibition was followed by a lecture by Rev. J. Bradford, descriptive of the way to take a photograph, and the non-photographic audience was delighted when some flash-light exposures were made, and several plates developed in their presence, the hall being temporarily converted into a "dark-room."

After this some excellent slides were shown; those by members being specially appreciated.

At the next meeting, on March 16th, Mr. H. W. Bennett will read a paper on "Negative Making," and the Secretary (Mr. J. W. Spurgeon, Drayton Villas, Leytonstone, Essex) will be glad to hear before then from intending members.

The Glasgow and West of Scotland Amateur Photographic Association.

At the monthly meeting held in West Regent Street on the 16th inst. six new members were elected.

Professor Barr, of the University, showed and explained an apparatus of his own invention for photographing book illustrations and diagrams so that they may be projected on the screen by means of the optical lantern.

Professor Barr was complimented on the novelty and ingenuity of the construction.

The President made two enlargements from hand-camera negatives by means of the lime-light lantern, and Mr. F. L. Alexander passed about thirty slides through the lantern, illustrating a tour to Stornoway.

The Photographic Club.—Subject for discussion on March 4th, "Printing on Rough-surfaced Papers."

The Gloucestershire Photographic Society's second triennial Exhibition will open at Gloucester April 20th, and close April 30th.

Received.—From the London Sensitised Paper Co., some samples of albumenised paper, which we have tried, and found to work all right.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

The Photographic News is the oldest weekly photographic newspaper. See its consecutive number to-day on the front page.

F. D. T. (Edinbro').—*Historical Portraits and Specimens.* A fine portrait of H. Fox Talbot was published with the News of March 11th, 1881. Mungo Ponton's formed the frontispiece of the Year-Book for 1882. Frederick Scott Archer, from a negative by the late Robert Cade, appears in Mr. J. Werge's series, at page 58 of "The Evolution of Photography" (Piper and Carter). With regard to the other matter mentioned in your letter, we will call and make personal enquiry, and let you know the result.

H. S. (Eastbourne).—*Paper Negative.* At first glance, your "curiosity" appears to be both interesting and important, but you do not say how it is done. Whether printed out or developed, and what length of exposure?

J. R.—*Collotype Materials.* For rollers and ink, inquire of Messrs. Benjamin Winstone and Co., Shoe Lane, Holborn. Mr. Wilkinson's book will give you preliminary information, and explain the method of reversal.

A. D. (Boston, Mass.)—*Direct Portraits, Life Size.* In the year 1874 Mr. John Chaffin, of Yeovil, gained a first prize in the Crawshay competition, and as considerable interest attached to the mode of production of his life-sized heads, a paper was read before the Photographic Society, giving full particulars of process, studio, and appliances. The lens used was a 6½-inch portrait combination by Jamin, of Paris, having back focus of about 20 inches, and stopped down by the insertion of a 3-inch central diaphragm. Mrs. Cameron's work was done a few years earlier than this, but in the present day it cannot be necessary to revert to the old processes (collodion) and primitive methods then in use. Messrs. Robinson and Cherrill employed a Dallmeyer 7D lens for their life-sized heads, which took the first Crawshay prize in 1873. See *Photographic Journal*, vol. xvi., pp. 3 and 81.

M. T.—*Watkins' Exposure Meter.* In our reply to you last week, the standard tint was described as being obtained by two seconds' exposure to *clouded* sunshine in June, instead of which we should have said "unclouded." The magnesium standard, of more importance, was correctly stated.

Litho.—*Artificial Stones.* It is doubtful whether the artificial magnesium blocks will bear any comparison with the true Bavarian stone. Mr. Warnerke may possibly touch upon this point in his forthcoming lecture (March 4th) on "A Simplified Photo-Collographic Process."

A. T.—*The Sector and Grease-Spot Photometers.* The discussion is not yet finished, Messrs. Hurter and Driffield making long replies to Captain Abney and Mr. Chapman Jones at the Liverpool meeting. The authors likewise read an important paper on the "Relation between Photographic Negatives and their Positives," giving experimental proofs of their statement by printing transparencies on ordinary and instantaneous plates, which, although widely different as regards length of exposure, were allowed to have been perfectly timed.

F. C. S.—*The Chemical Society's Jubilee* passed off satisfactorily on Tuesday. The afternoon meeting at the University of London was addressed by the president, Dr. W. J. Russell, F.R.S., by Sir Lyon Playfair, Sir Wm. Grove, and Professor Odling. There were deputations from the Royal and Pharmaceutical Societies, and from many foreign chemical societies. An interesting feature of the proceedings was the presentation of an album containing the portraits (platinotypes) of forty-four of the original Fellows of the Society, only three of whom are now living. The evening reception at Goldsmiths' Hall was a grand success, an admirable selection of scientific objects being displayed. On Wednesday the function terminated with a dinner at the Metropole.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1696.—*March* 6, 1891.

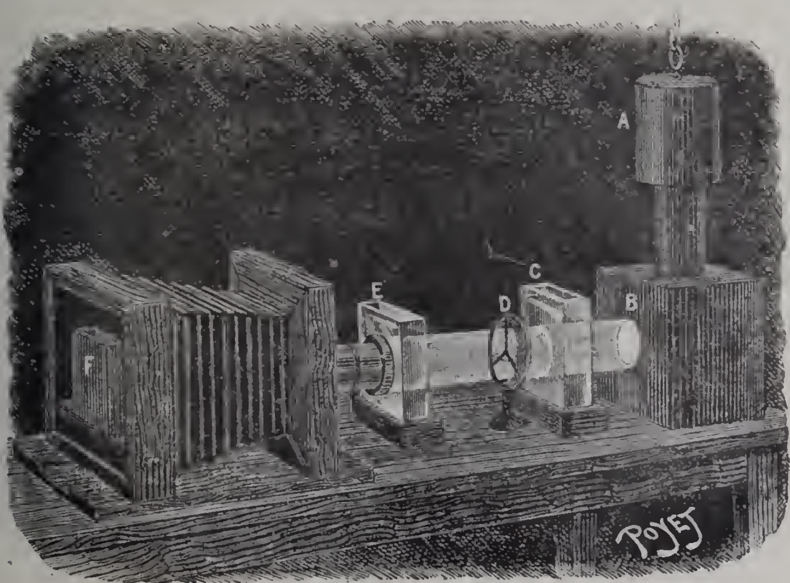
CONTENTS.

## THE NEW DISCOVERIES IN HELIOCHROMY.

Among the chief points in which experienced practical photographers might attempt to help to adapt the recent great discovery of Professor Lippmann to utilitarian purposes are:—(1) The production of an absolutely colourless and transparent dry plate highly sensitive to light; (2) to find a developer for the said dry plate which will give a shining silvery-white image by reflected light, and a pure black or grey one by transmitted light; (3) the application of suitable orthochromatic methods of rendering the plates more sensitive to red and yellow light.

By the wet-plate process there was no difficulty in getting silvery whites, as in the collodion positive process, in which an iron developer was used in conjunction with a suitable proportion of glacial acetic or nitric acid; a trace of nitric acid had a strong influence in the yielding of a brilliant white deposit. The wet process is, however, in all probability, not applicable to these heliochromic pictures, because of the film being expanded with liquid at the time of making the exposure; consequently, any interference bands registered by means of the film will not be of the same distance apart when the film shrinks in drying.

The *Photo-Gazette*, of Paris, in its number of February 25th last, gives the accompanying engraving of the apparatus used by Professor Lippmann in photographing what the *Daily News* correspondent called his "stained glass window." This window is represented at D, and it consists of three pieces of coloured glass, mounted in a circular frame. A is a loose cap over the chimney of the electric lamp, to exclude stray light from the room; B is a parallel beam of light from the electric lamp; C is a vessel of water to cut off some of the heat rays; E is a vessel containing elianthine to cut off the blue rays while giving a longer exposure to the red; F is the trough carrying the sensitive plate and its mercurial backing.



A communication from Lord Rayleigh, in another column, shows that he long ago published the idea that the colours in Becquerel's photographs were those of thin plates. He speaks of Wiener's experiments; Wiener seems to have been the first to photograph interference bands in thin, transparent sensitive films, and he just missed discovering the value of the method in heliochromy. A week before M. Lippmann announced his discovery at the Academy of Sciences, M. Cornu drew the attention of that august body to a paper by Herr Weiner, contained in *Wiedemann's Annalen*, vol. xl., page 203, 1890, giving the experimental solution of the problem of determining the direction of vibration in polarised light. "The method consists in letting a wide beam of polarised light fall upon a reflecting surface at an angle of 45°. As the beam is wide, there is a zone where incident and reflected rays cut one another at right-angles; and if interference phenomena are produced in this zone, the direction of vibration of the polarised light must be normal to the plane of polarisation, and perpendicular to the direction of propagation. In order to find the nodes and ventral segments, M. Wiener has used an extremely thin photographic pellicle, so transparent that it will allow a free passage to the two waves which cross at its surface, and yet sensitive enough to receive impressions. By means of this exploring pellicle, the existence of interference fringes has been made manifest."

Mr. Frederick Varley has been minutely studying the character of the planes of quiescence and disturbance in films, as prepared by M. Lippmann, and has come to the conclusion that they are not absolutely true planes, but are a range of little hills and valleys; the planes are speckled, so to speak.

M. Lippmann's coloured photographs have, like Daguerreotypes, to be viewed at a particular angle to the incident light, and the colours are seen best with a lack background to the plate.

At the meeting of the Photographic Club of Paris held on February 18th last, Dr. A. Berget, of the Sorbonne, exhibited some of M. Lippmann's heliochromes, and described the method of their production. The official report in the *Bulletin* of the Club says that repeated bursts of applause testified to the interest the assembly took in the scientific communication of M. Berget. The communication of the latter is printed in the *Bulletin*, so also is an illustrated article on the subject by M. Ch. Gravier, but they contain no additional information to that already published in these pages.

In *Le Moniteur de la Photographie* of February 15th, M. Léon Vidal says of M. Lippmann's photographs:—"The impression—or rather the sensation—of the spectral colours is very decided; certain proofs are even brilliant."

Merely as a matter of history, a translation of the statement made by M. Becquerel at the Academy of Sciences, the same evening that Professor Lippmann's discovery was first made known there, is hereunto appended, but we doubt the scientific accuracy of its contents. As stated in these pages last week, Becquerel's preliminary treatment of his films seems but to have made them slightly more continuous and transparent, so that interference phenomena could come more perfectly into play, but, no colloid support being present, the pictures dissolved away in the fixing solution. Becquerel argues that his pictures are not due to the action of the same principle as those by Professor Lippmann, but gives no evidence in support of the contention; the former produced the pictures empirically and industriously, the latter seems to have revealed the true theory of obtaining such photographs in colours, and to have evolved law and order out of chaos. Here is M. Becquerel's utterance:—

"I wish to point out the difference which exists between the purely physical process of M. Lippmann for reproducing the colours of light by photography, and the photo-chemical process which I discovered in 1848 for obtaining the coloured images of the luminous spectrum, as well as the images of objects in their natural colours. I attained this end by means of one chemical substance—viz., the subchloride of Ag formed on the surface of silver plates, the preparation and curious modification of which, under various influences, and notably under that of heat, I have already pointed out. Moreover, during the preparation of the sensitive substance, one can determine with precision the thickness of the layer required to produce the best possible results. This thickness may vary between one-four-thousandth and one-six-hundredth of a millimeter. These images are absolutely permanent in the dark, and I still possess reproductions of the solar spectrum made forty years ago, as well as images coloured by light waves, which were the base of Regnault's report to the Academy in 1849. They are only spoiled when exposed to the action of light, because the sensitive substance with which they were obtained was not completely transformed, and is still liable to be acted on by various coloured rays. M. Poitevin used the same substance in 1865 to obtain on paper the coloured images which were produced by me on metallic plates.

"When one submits photographic images thus coloured to the reducing action of one of the solvents of silver chloride, such as ammonia or hyposulphite of soda, the coloured shades disappear, and on the spot where the luminous rays have exerted their action, a light trace formed by a thin layer of metallic silver remains on the surface of the silver surface, which, as long as it is still moist, shows feeble tints, the complementary colours of which had existed previously in the same spots. These effects, which *à priori* are difficult to explain, show, perhaps, that the thickness of deposited films plays some *rôle* in the production of colour phenomena.

"This material, when duly prepared, enjoys the peculiar property of not only being sensitive to the action of various colour rays, varying from red to violet, whilst reproducing their proper tints, but also of receiving an impression which appears in marked manner to be proportionally to the intensity of the corresponding luminous impressions on the retina.

"At the moment when the chemical reaction takes place, this photo-chromatically sensitive substance produces an electro-chemical current whose intensity and electromotive force can be measured with my electro-chemical actinometer. This current may be utilised for comparing accurately the intensities of the different active coloured rays—*e.g.*, the red and blue rays—whilst the optical methods based on the impressions produced by these very same rays on the retina do not allow of being made with anything like the same accuracy."

The undercurrent of prevalent interest in photographic circles about the new heliochromic discoveries was indicated last Wednesday night at the Photographic Society, when Mr. Warnerke departed from his subject to hand round a strikingly iridescent negative, the colours on which, he remarked, were no doubt like those obtained by M. Lippmann. Probably this is true. A few days ago a photographer remarked to a well-known scientific man, "Lippmann's discoveries are nothing but iridescence." "Very likely," was the rejoinder, "but perhaps hitherto we have not paid sufficient respect to iridescence."

Professor Lippmann uses a hypophosphite to fix his pictures, but in his letter to us stating the fact, the words following "hypophosphite" are so indistinctly written, that we cannot state the exact salt.

---

The Photographic Society of Great Britain.—On Tuesday, March 10th, Sir D. Salomons will read a paper on the "Registration of Slides in the Optical Lantern." On Tuesday, March 24th, "Hand-Cameras" will be the subject for discussion. On Tuesday, March 31st, exhibition of lantern slides.

## DARK ROOM VENTILATION.

The modern photographer is very well catered for in the matter of literature. Not only has he many journals and periodicals, both English and foreign, all to himself, but he has a rich library of books all dealing with questions directly relating to the occupation in which he is engaged. A few years ago, before gelatine plates came into common use, such books were so few in number that they could almost be counted upon the fingers of one hand; but with the creation of the modern amateur there came a change over the scene, and text-books and hand-books without number were issued until it became a serious matter for an author to find a title for any new publication which he might be contemplating. Authors now seem to be attacking the art piecemeal and in detail. They no longer find it possible to compress an entire account of the various processes into one volume, and so we have separate *brochures* on such subjects as developing, retouching, portraiture, &c., which, in themselves, begin to form a complete library. There are so many workers, and the army is so constantly receiving recruits, that there is little fear of such books, especially if they are written with a fair amount of skill, not meeting with a ready sale.

But there is one subject which, we think, has not been treated as exhaustively as it should be, considering its great importance. We allude to the ventilation of the dark room, in which the photographic worker is obliged to pass so much of his time. An ordinary room is, as a rule, well ventilated, unless, that is, it belongs to one of those over-crowded dwellings in the East End of which we have lately heard so much; for an ordinary dwelling room has its chimney, its windows, and its doors, and, as most rooms are found in houses in which neither doors nor windows fit into their frames, and in which nooks and crannies in floors and wainscots let in the winds of heaven from every conceivable direction, there is little chance of suffocation. The favourite Parisian method of committing suicide by burning charcoal in a closed room has never found favour in England, most possibly because of the utter futility of attempting it. The jerry builder has made it impossible, and this seems to be the only good thing that a jerry builder has ever done.

But in the photographer's dark room the conditions are altered. There is often no chimney; the window is carefully covered up with opaque material, except a single red pane, and even the door is bushed with cloth all round to keep out any stray ray of light which may endeavour to find an entry. This is as it should be, but the photographer too often forgets that in thus shutting out the daylight which is so prejudicial to his proceedings, he has also been excluding the fresh air which is so necessary to health; and as good work is only possible if the worker be in good health, he indirectly is affecting the first by neglecting the second.

We constantly hear of operators who complain of the bad effect of certain chemicals upon their well-being. Ammonia, being the only chemical in common use which has a pungent smell, is credited with all sorts of direful effects. One worker told us gravely how continued use of that agent had made him deaf. Another spoke of the injury which it had caused to his respiratory organs. Many, also, have complained of the lassitude and headache which they suffer from after an unusually long spell of development. Now, we are quite satisfied, from the many opportunities which we have had of seeing all sorts and conditions of dark rooms, that in the majority of cases no fault can be laid to the door of the chemicals The mischief is almost always traceable to the want of ventilation.

Even in studios where everything is well appointed, where there is a handsome reception-room, and where all strikes the eye as being expensive and good, the dark room is often little better than a mere cupboard. Well may the operator call it his den. There he is condemned to work, and although he may not use ammonia, or any other strongly smelling chemical, he is giving off from his own lungs a far more poisonous product, in the shape of carbon dioxide, than anything that he has in the bottles around him. If he has a lantern as an aid to uncertain daylight, its lamp is also busy in the same work of vitiating the atmosphere. It is no wonder that the poor fellow feels done up at the end of the day's work. And the remedy is so easy. Let him bore a few holes in a row at the bottom of the door, and cover them with a sloping board, in order to give entry to fresh air from outside. Then, with a ventilator at the top of the room, which can be equally well shielded against light—to provide egress for the heated air inside, which is bound to rise upward—he will secure a constant current, which will make his work easier and more pleasant than it has been before, for he will no longer be suffering from deprivation of fresh air.

---

The Photographic Club.—Subject for discussion on March 11th, "Printing on Rough Surfaced Papers;" March 18th, "Estimating the Speed of Shutters."

There will be an exhibition of photographs and apparatus by members of the Croydon Camera Club, at the Braithwaite Hall, Wellesley Road, Croydon, on Tuesday, 31st March, and Wednesday and Thursday, 1st and 2nd April.

The Hackney Photographic Society.—The following is the programme for March and April, at Morley Hall, Hackney, Room No. 4:—March 12th, "Bromide Enlarging," Mr. A. R. Dresser; March 26th, "Lantern Slide Making," Mr. J. A. Sinclair; April 9th, "Hand-Cameras," Mr. W. D. Wellford; April 23rd, Members' Lantern Night, (all members are requested to bring some slides). Members are requested to note that nominations for Council and other official positions, together with any proposal of rules or amendments, must be sent to the Hon. Secretary in writing not later than April 14th next; W. Fenton Jones, *Hon. Sec.*, 6, Victoria Street, Hackney, N.E.

Soldering Glass to Metal.—At a recent meeting of the Société de Physique, M. Cailletet described a process of soldering glass and porcelain to metal. The glass tube to be soldered is first covered with a thin coating of platinum or silver, by treating it with a film of platinum chloride or silver nitrate, and heating to dull red. A ring of copper is next electro-deposited on the platinised tube, which can then be soldered like any ordinary metallic tube. Solderings effected in this manner are said to be very strong. The top of a tube attached to M. Cailletet's apparatus for liquefying gases terminates in a soldered end, and successfully resists pressures of over 300 atmospheres.

## THE HISTORY OF PHOTOGRAPHY.*

BY DR. J. M. EDER, DIRECTOR OF THE IMPERIAL PHOTOGRAPHIC INSTITUTE OF VIENNA.

On this basis Schiendl erects that foundation of his "History of Photography with Chromium Salts," and builds a castle in the air to prove what is not really contained in Ponton's communication to the Royal Society of Scottish Artists.†

There is nothing left but to conclude that Schiendl has not, for the purpose of his "History," read the original, for what he has put into Ponton's mouth is entirely an arbitrary interposition.

Equally untenable is the phrase on page 277 of Schiendl's "History": "Ponton, whom we may regard as the *discoverer of the sensitiveness to light of chrome gelatine (!)* . . ." for of the sensitiveness to light of *chrome gelatine* Ponton does not say the slightest word in the before-mentioned communication to the Scotch Society. Ponton dealt in his communication at the time (1839) exclusively with the change of colour of paper steeped in bichromate of potash solution, which became brown on exposure to light, and was fixed by washing. There was not a *word to be found* of what Schiendl relates Ponton to have discovered, that organic substances mixed with bichromate lost in the light their solubility and stickiness, and no longer absorbed water.

All Schiendl's "historical statements" drawn therefrom are therefore erroneous, and this consideration weakens very much the credibility of other statements for which Schiendl is responsible, and of the greater part of which he omits to mention the source. Very many readers will not search through the sources of statements, or do not know where to find them; on that account it is a duty to warn them of such a stumbling block against historical fact, for all such as have not time to study the originals, and who interest themselves in the history of discoveries, purchase a history believing that they may trust themselves to it.

We will, however, give a warning against some other stumbling blocks to historical fact in Schiendl's history.

For the historian, the discovery of the printing process with silvered albumenised paper is interesting, for it has ruled during many decades of photography. I note especially the following statement on page 58 of Schiendl's History: "Farther, *Legray* gives the application of albumen instead of salted paper, a *discovery* which, later on, *Fox Talbot* endeavoured to claim." The author credits *Le Gray* with the discovery of albumen paper, and dates it as *June*, 1850.

This statement of the discovery of a printing process of so much importance to photography is also incorrect, for, earlier than that, *Blanquart Evrard* employed albumen paper for positive printing, and described its properties in a communication to the French Academy of Sciences at a meeting held on *May 27th*, 1850.

In a similar way, Schiendl misdates the publication of the application of hyposulphite of soda as a fixing agent. The author, on page 48, says that *Herschel* recommended this fixing salt in the year 1840, whereas, in fact, this discovery was already made in the year 1839 by *Talbot*, with whom he was recognised to be in frequent communication, and was communicated to the Paris Academy March 1st, 1839.

* Continued from p. 170.

† This is the source on which Schiendl depends, and on which he bases the course of his argument.

The discovery of photography with collodion, Schiendl, in his History (page 57), ascribes to "Legray," whereto I remark that this was thoroughly gone into by me in the year 1884, and the recognition of this priority then made. In so far, I have nothing to say, except that the name should not be written Legray, but Le Gray, and that Schiendl's way of writing it is incorrect.

I must, however, distinctly dispute the language used as that of the first publication on collodion photography (page 57), which is incorrectly rendered. I bring this forward prominently, because Herr Schiendl prints his "citation" with quotation marks, and thereby would induce the reader to believe that he has a literal translation of the original before him. This is, however, by no means the case, although Schiendl expressly professes to quote Le Gray. As this may appear to be incredible, I will give the original communication of Le Gray in his own words, alongside Schiendl's pretended quotation, so that this style of history writing may be characterised:—

| Herr Schiendl's professed Literal Quotation from Le Gray. | Le Gray's Original Communication. |
|---|---|
| "I have, however, discovered a process whereby I produce a photographic picture on glass, by means of *hydrofluoric acid (!)* and fluoride of potassium (or sodium) mixed with alcohol of 40 per cent., together with sulphuric ether, and afterwards with thick collodion. A film of this kind is spread upon glass. I afterwards treat it with *nitrate of silver*, and can obtain a negative in the camera with an exposure of *five seconds* in the shade." | "Je travaille dans ce moment, un procédé sur verre par *l'ether methyl fluor hydrique*, le fluorure de potassium, et de soude, dissous dans l'alcohol à 10 mêlé à l'ether sulfurique, et saturé ensuite de collodion. Je fais ensuite réagir *l'aceto nitrat d'argent*, et j'obtiens une épreuve à la chambre noire en vingt seconds a l'ombre."* |

From this comparison it is seen that Schiendl's "original quotation" contains four errors:—

1. Herr Schiendl tells us that Le Gray employed *hydrofluoric acid*; Le Gray, however, expressly said "*methyl* hydrofluoric *ether*."

2. Herr Schiendl writes, "fluoride of potassium *or* sodium," whilst it should be fluoride of potassium *and* sodium.

3. Le Gray employed "*aceto*-nitrate of silver," and not "silver nitrate," as Schiendl tells us.

4. Le Gray only obtained his result with an exposure of *twenty* seconds, and not *five* seconds.

There is a great difference between "methyl-hydrofluoric ether," which is the substance mentioned in the original, and the old well-known hydrofluoric acid. The correct rendering of this point is important, because the "methyl-hydrofluoric ether" which Le Gray recommended was quite unknown; and so that the original receipt was practically impossible to be followed. A *History writer*, however, must by no means forcibly turn aside the meaning by arbitrarily altering the language of the original document, and all this under the flag of a literal translation with quotation marks.

*(To be continued.)*

* *Direct Translation from the French.*—I am working at present at a process on glass with methyl hydrofluoric ether, fluoride of potassium, and of soda, dissolved in alcohol of 40°, mixed with sulphuric ether, and afterwards saturated with collodion. I afterwards treat this with aceto-nitrate of silver, and I obtain a negative in the camera in twenty-five seconds in the shade.

## TESTING THE SENSITIVENESS OF COLOUR-SENSITIVE PLATES.

BY DR. H. W. VOGEL, BERLIN.

In your valuable journal of January 30th, page 81, you mention an article by Mr. N. Schumann, entitled, "Determining the Sensitiveness of Photographic Plates by means of the Spectrograph," printed in the *Chemical News*. The article is an abstract of a series of special publications upon the same subject in the *Photographische Correspondenz*, 1889. Though many of the assertions of Mr. Schumann in those articles seem strange coming from an experienced investigator in colour-sensitive plates, I made in 1889 only a few objections.* If I answer now more specially, it is for the reason that Mr. Schumann repeats his erroneous notions, and seems to believe in the sentence, "*Quis tacet consentire videtur*" ("Who keeps silence seems to consent").

The strange assertions Schumann makes are: (1) The sensitiveness of silver eoside plates for the yellow and blue rays of the spectrum of the sun at high altitudes (summer season, noon) is equal; (2) The sensitiveness of the same plates for the same rays of the spectrum of the *blue sky* or the clouds is also equal. These assertions are really puzzling.

A glance into the spectroscope shows us that the yellow and greenish yellow part of the solar spectrum is so intense that the human eyes cannot bear it, whilst the blue part can be easily observed. On the other hand, the yellow part of the spectrum of the blue sky is so mild that it can be observed without injuring the eyes. Therefore, it is obvious that the quantity of yellow rays *in relation to the blue* ones is by far greater in the sunlight than in the blue sky light. In spite of this fact, Schumann tells us that the action of both coloured rays should be the same in both cases.

Not alone eye observations, but also photographic observations, inform us how different are the actions of the blue and yellow parts of the solar spectrum, and of the spectrum of the blue sky. I have before me a great number of spectrum negatives from the sun and the blue sky, taken on *ordinary* plates at the same time. They show that an exposure of a quarter of a second to the sun will give, in the blue part, about the same intensity as four minutes' exposure for the blue sky; but whilst the action in the solar spectrum reaches the yellow (line D), the action in the blue sky spectrum ceases near F. This proves beyond doubt that sunlight contains really more yellow rays than does the blue sky. From this, it is obvious that if, according to Schumann, in the solar spectrum blue and yellow act equally on silver eoside plates, the action of the blue in the sky spectrum must be more intense than the yellow. Therefore, I conclude that Mr. Schumann's method of measuring the relative action of blue and yellow in the spectrum gives totally wrong results.

Schumann says that "to find the behaviour of plates towards any source of light, a series of spectra with regularly increasing times of exposure should be photographed, and the dried plates be examined in regard to the time required to produce a developable impression by different colours.† The different sensitiveness will then be found to be inversely proportioned to the time of exposure. *The intensity of the plate is of no importance.*"

* *Photographische Mittheilungen*, xxvi, p. 240.

† Photographic News, page 81.

Of no importance? I think the first weak impression upon which the observation depends is more easily perceptible when the intensity is greater. Of greater importance is the fact that the nature of development of a colour-sensitive plate is quite different from that of an ordinary one. This Schumann has entirely overlooked.

I published in the *Photographische Mittheilungen*, vol. xxvii., p. 63, a singular observation about the development of silver eoside plates. If such plate is exposed to a colour table and developed in any way slowly, the blue parts appear first; they increase in density; the yellow parts make their appearance later; they are at first thinner than the blue parts, but soon they increase in density, and often, according to the nature of the daylight,* at the end of the development they are denser than the blue parts. If the plate is turned over, it is easy to observe that the action of the yellows on the back is more visible than the action of the blues, proving that, under development, the yellow has penetrated the film more than the blue.

It is easy to explain this. The quantity of bromide of silver contained in a plate 5 by 7 inches, according to Eder, averages 0·417 gramme (French weight). The quantity of eoside of silver in the maximum case is 0·00018 gramme. From this it follows that the film contains about 400 molecules of bromide of silver to 1 molecule of silver eoside; therefore a white ray going through the film will affect 500 molecules of bromide of silver, and, at the same time, only 1 molecule of eoside. The blue ray acts only on the bromide because the blue is freely absorbed thereby; the greenish-yellow ray acts primarily on the eoside, which absorbs it, and this action is transferred to the neighbouring bromide molecules. It is obvious from these facts that the action of the blue on a silver-eoside plate begins first, the action of the yellow later, and more deeply in the film, as confirmed by the experiment above described.

The action of the blue increases in intensity by longer development before the action of the yellow is brought out.

For this reason, it is totally wrong to try to determine the numerical values of the sensitiveness for blue and yellow of silver eoside plates by the times of exposure necessary to make the first visible impression by the stated coloured rays.

The puzzling results of Schumann, who finds the action of blue and yellow equal, not only in the solar spectrum, but in the spectra of the blue sky, and even of dark clouds, are now explained. If Mr. Schumann says "all sensitometers have been superseded by the trustworthy spectrograph," I answer yes, but that the style in which Mr. Schumann uses the spectrograph is not trustworthy at all. Another method must be employed—that is to say, the principle first introduced in photo-chemical practice by such eminent men as Bunsen and Roscoe, in their pendulum photometer (*Poggendorff Annalen*, v. 124, p. 353). Both investigators observe not the beginning of the action (on sensitive paper), but the time necessary to produce a certain degree of blackness; the shorter the time for producing the required darkening, the more intense is the incident light.

The same principle is employed by Janssen for determining the chemical intensity of starlight. He makes

* Boissonnas and I have shown that a sky with clouds yields yellow rays remarkably more intense than it does the blue ones, whilst a pure blue sky gives the yellow rays with less intensity. (*v.* Eder's *Jahrbuch*, 1890.)

comparison pictures on the same plate, one from an artificial star, and then others by different exposures from a real star on the same plate; then he determines how long the exposure is for bringing out a star image of the same intensity as the artificial star. Exactly the same style of determining the sensitiveness of dry plates is proposed now by the *Congress International de Photographie* (*Rapports et Documents*, Paris, 1890, p. 72). I have employed the same method for determining the relative sensitiveness to blue and yellow rays of silver eoside plates, by exposing the said plates one. two, three, four, five, ten, and more seconds to the solar spectrum, and comparing the intensity of the different spectra in the regions of the maxima λ λ 450 and 580. If I find that I must expose ten seconds to get the same intensity in the blue as I get in the yellow in one second, then I say that the plate is ten times more sensitive to yellow than to blue. Such plates really exist.

Mr. Schumann reproaches me for having employed in these experiments a small spectrograph, whose set of prisms (of flint and crown glass combined) absorbs many of the blue rays. He accused me in Scolik's "Handbook of Photography with Emulsions" with having deceived in this way the photographic public to gain favour for the silver eoside plates. I have answered this very low and ignoble suspicion in my *Meittheilungen*, and declared that I have never used my small spectrograph with the mentioned prism set for determining the relative *quantitative* action of blue and yellow, or any other coloured ray. I would not have mentioned this fact again; but, inasmuch as I see that Mr. Schumann now publishes extracts from his special papers in English journals with special regard to my researches, I am obliged to do so. I employ for such researches only my large spectrograph fitted with two white flint prisms, which transmit the blue rays better than does crown glass.

Mr. Schumann tries to refute me with my own words,* printed in my "Hand-book of Photography" (third edition), when speaking of the intensity and sensitiveness of *wet* collodion, explaining that there are collodions giving very dense images, but which are less sensitive, and *vice versa*; but I have accentuated that these facts are true only for *wet* plates. "With dry plates the conditions are quite different." This sentence Schumann has not mentioned, though it is printed on the same page (92) as the above-mentioned sentence. Afterwards he charges me with "conscious inaccuracy." I despise this style of controversy as unworthy a scientific man.

Professor Meldola's first lecture at the Society of Arts on "Photographic Chemistry" will be delivered next Monday night at eight o'clock.

Prints with Salts of Uranium.—If a piece of paper be coated with nitrate of uranium and then exposed under a negative, a very faint impression will result, owing to the formation of uranous oxide. On immersing the paper in a bath of nitrate of silver a black image will immediately be obtained, owing to the precipitation of metallic silver upon the uranous oxide. In this case the silver nitrate acts as the developing agent. Prints obtained in this way must be fixed in a weak bath of hyposulphite of soda. If, however, the silver nitrate be mixed with the nitrate of uranium, we obtain a direct printing-out paper, which only needs to be fixed in hypo to become permanent. If in lieu of nitrate of silver we use ferricyanide of potassium, a chocolate brown to reddish picture will be obtained.—J. H. Stebbins, Jr.

* *Photographische Rundschau*, 1890, p. 572.

## THE FEDERATION OF LONDON PHOTOGRAPHIC SOCIETIES.

Last Monday night a meeting of between twenty and thirty representatives of photographic societies was held in the rooms of the Photographic Society, 50, Great Russell Street, London, which meeting had been called by a circular which we published last week, and which had been issued to the London and suburban photographic societies by Mr. Lewis M. Biden. The object was to consider the federation of London and suburban photographic societies.

Mr. Biden took the chair, and read the circular convening the meeting. He added that he had received numerous replies to the circular, and not one of them otherwise than favourable; almost all of them had promised to send representatives that evening. He considered it to be of little importance whether they called the scheme "federation" or "association"; the object was the union of societies for mutual help. For instance, the secretaries of many societies had difficulty in filling up their lecture list or to get papers; yet there were people who were willing to prepare papers with experiments if they knew that they would have a larger number of listeners than is usual at the meetings of local societies; but they did not care to give all this time and work for an auditory of, perhaps, twenty persons. One object of the federation would be to see that such time was not thrown away, by making arrangements whereby the author could read his paper before more than one society. Another object of federation would be to try to obtain special travelling facilities for photographers. If all the societies combined, they might be able to guarantee to the railway companies the sale of a certain number of tickets, or might get the privilege of going by one railway, and, after walking across country, returning by another line. The federation might deal with the collection of lantern slides, and the lending of them to the different societies in turn; it might also consider the question of the proposed Photographic Institute, and of alliance with the Photographic Society of Great Britain.

Mr. W. A. Brown, Pres. of the West London Society, said that the question of federation had been before his society at the last meeting, and the hon. secretary and himself had been deputed to attend that evening, and to report after learning what federation meant. He thought that any federation would be incomplete unless the larger photographic societies joined therein; without them, it would be useless to attempt to take any step in the matter. If a federation could arrange for an interchange of honorary lecturers, it would be a manifest advantage to all the societies. He did not know anything about the Photographic Institute.

The Chairman thought that Sir H. Trueman Wood or Dr. Lindsay Johnson would give the federation information on that point, if invited.

Mr. Brown continued that he thought that it would be a great advantage to the other societies to enter into alliance with the Photographic Society of Great Britain. The secretary to the West London Society had sent out to London photographic societies about fifty copies of a memorial for presentation to the London railway companies, requesting a reduction of fares to photographers; all the replies received were favourable, with one exception. Such a scheme was clearly a matter for a federation to take up, for no single society was strong enough to influence the railway companies, for the simple reason that if the directors granted the facilities, they would have to explain to the shareholders that commercial advantages resulted from so doing; in this matter the societies would clearly be stronger by union. That evening, he thought, they could but discuss general principles, and not go into rules or details. The societies want to know what good a federation will do for them, and how much it will cost.

The Chairman thought that they were hardly in a position to consider the question of cost, especially as they had not yet sufficient information about the number of members of the societies; the question of cost was one which alone could be dealt with at a meeting of officially appointed representatives of all the societies, and such a meeting could draw up a scheme. He would throw out merely as an idea for discussion that perhaps a payment of five per cent. of the gross income of each society, with a reduction for the larger organisations; thus the payment from the smaller societies might be about sufficient to cover the cost of postage.

Mr. H. M. Hastings wished to know whether the London and Provincial Photographic Association would join the federation.

Mr. R. P. Drage said that he was in attendance unofficially on behalf of that Association, with instructions to listen and to report.

Mr. A. Dean, of the Hackney Photographic Society, remarked that that Society once applied to the Great Eastern Railway Company for a reduction of fares to its members, and the Company replied that when the members took not less than twenty tickets they could go second class at third class fares.

Mr. Frank Cherry, of the North Middlesex Photographic Society, was in favour of a federation trying to influence the railway companies, and thought that it would be a good thing if it could get lecturers together.

A representative of the Holborn Photographic Club was invited by the chairman to speak, and replied that he was there only to watch and report.

The Chairman remarked that many others appeared to have attended with similar instructions. Any resolutions passed that evening, it should be clearly understood, would bind no society to anything. He then moved "that it is desirable to form an association or federation of societies and clubs whose members are interested in photography."

There was a large show of hands in favour of this resolution, and none against.

The Chairman next moved "that the London and suburban societies be requested each to send two delegates to discuss, and to appoint a committee to make the necessary arrangements, to settle the name, and to draw up the constitution of the proposed association, with terms of membership, &c.; such delegates to continue to act for a period not exceeding six months from the launching of the association."

This was passed without a dissentient.

The Chairman then moved that the following be the objects of the association:—(1) The association or federation of the London societies; (2) the interchange of lectures, papers, lantern slides, &c.; (3) as to obtaining the reduction of railway fares to photographers on their outings; (4) whether any proposal can be made to the P. S. G. B. for admission of the various societies as corporate members of the P. S. G. B.; (5) generally to promote photographic knowledge and research.

Mr. Brown asked whether the Photographic Society of Great Britain intended to join the federation.

The Chairman did not know, but he thought that federation would give an opportunity for the younger members of societies to assert themselves. The federation might invite the Photographic Society to join.

Mr. Debenham, speaking in his private capacity, said that the federation could not well invite the Photographic Society to join until the federation could tell the Society in what it was proposed that it should take part.

Mr. Brown wished the Photographic Society to be inside the federation, and at the head of it. Unless the Photographic Society would take part, he did not see the use of entering into federation at all.

Mr. White, of Ealing, moved, and Mr. Rumble, of Sydenham, seconded, "that the Photographic Society of Great Britain be requested to send representatives to the next meeting of delegates."

This was carried by a large show of hands.

The Chairman again remarked that it was clearly understood that the societies represented at that meeting were not bound by anything which had taken place that night.

The meeting of delegates was then fixed for Monday, the 23rd of March.

---

*The Eye*, Chicago, says that the Czar of Russia, on the occasion of the birthday of the Czarina, presented her with a beautiful album of views taken of the most beautiful spots in Russia and Denmark, from negatives taken by himself.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

COLLOTYPE SIMPLIFIED—INTENSIFYING NEGATIVES—LIPPMANN'S HELIOCHROMIC METHOD—TRANSFERS ON STONE WITHOUT GRINDING OFF THE FORMER IMPRESSION.

*A Simplified Method of Collotype.*—Mr. A. V. Lavroff, the editor of the Russian *Amateur Photographer*, gives, in a letter to the editor of the *Photographisches Wochenblatt*, the description of a simplified method of the collotype process, which is in some respects different from that published recently by M. Balagny. A plate-glass is prepared in the usual manner with bichromate of potash, exposed beneath a negative, developed with cold water, and then allowed to dry for twenty-four hours at about 70° F. It is next covered with the following etching solution:—

| | |
|---|---|
| Water ... ... ... ... ... | 100 c.c. |
| Glycerine ... ... ... ... | 200 ,, |
| Hyposulphite of soda ... ... ... | 2 grammes |

This solution is allowed to remain on the plate for one or two hours, according to the relief desired, when it is removed by the aid of a very soft sponge and blotting-paper, and the ink applied by means of a gelatine roller. To take prints in the ordinary copying press, the plate-glass covered with the ink is placed upon a piece of india-rubber cloth: upon the glass is laid a mask of paraffin-paper, then the printing paper, and finally a thin pillow of fine cloth, filled with cotton wool, and provided with a case of soft, smooth silk. This pillow enables the operator to press the paper into close contact with the plate, and so to obtain all the fineness and detail of the negative. If, after about twenty prints have been taken, the bichromate image begins to become grey at the light parts, it is only necessary to apply the etching fluid with a soft sponge, in order to restore the cliché to its former vigour. Mr. V. Lavroff states that by this method anyone can take hundreds of prints at moderate cost and without a special machine, a little experience and exactness being all that is required. The author has taken a thousand prints from a good printing plate, and he says that it is possible to take from ten to twelve prints within five minutes. Farther working details and particulars are promised by the author.

*Intensifying Negatives.*—Negatives intensified with chloride of mercury often become yellow-stained. To prevent this evil, Mr. Riesenkönig recommends the following method as a thoroughly trustworthy one. A strong solution of sublimate is taken and poured on the negative in the same manner as in the case of wet collodion plates; the plate is slightly moved, and then *at once* thoroughly rinsed with water. The blackening of the negative is accomplished in the usual manner. A negative treated in this way will always be perfectly clear and brilliant.

*Remarks on Prof. Lippmann's Heliochromic Process.*—In this country Prof. Lippmann's new discovery has created widespread interest, and almost all the photographic periodicals have translated the articles relative to it from English and French journals. Dr. F. Stolze, editor of the *Photograph. Nachrichten*, whom we esteem as one of our ablest authorities in photographic matters, referring to an article reprinted from the *Vossische Zeitung*, says that, with regard to the explanation of the actual phenomenon, the physical theory which is said to have been successfully embodied in experiment will not at all stand the test. It has been stated, he continues, that the colours in question are dependent on the phenomena of interference, and that the latter, so to say, are fixing the wave lengths of the colours in the sensitive film in the same way as the human voice is fixed on the cylinder of the phonograph. This sounds well, but it disagrees with our physical knowledge. It is true the colour of thin films, if viewed by transmitted light, is complementary to that appearing if viewed by reflected light; but colours altogether make their appearance only in the case of very minimal thicknesses of the films, and will disappear as soon as the thickness amounts to more than a minute fraction of a millimetre—in the case of atmospheric air, for instance, if it amount to more than 0·001 millimetre. In Prof. Lippmann's experiments, however, glass plates are coming into consideration, which, in most cases, will have a thickness of from two to three millimetres, and with which it will therefore be impossible to perceive the phenomena in question. Besides, it should be borne in mind that the spectrum comes into consideration, *i.e.*, monochromatic light at every single point. With the latter, the varying thicknesses of the film give rise to a more distinct luminosity and obscurity, the two interfering light-waves either reinforcing or counteracting one another. But this does not mean that certain points of the sensitive film are not at all disturbed, and others highly disturbed, so that consequently an opportunity is offered that at one point of the film a reduction of silver takes place during development, and at the other one not, but only that *all* the points of the film are vibrating more or less. Thus, even if the glass film be sufficiently thin to produce interference, it would be impossible that these luminous and obscure fringes should be produced in the film, as indicated above. But it would be even more unintelligible that plates, having really such fringes, should show complementary colours if viewed by reflected and by transmitted light, for all the conditions which produce this phenomenon on the actual examination of thin films are wanting here. Provided that the wave lengths be really, so to say, depicted in the layer, even then but one colour would be perceptible, either by reflected or by transmitted light. But, besides this, there is a much more important circumstance which should be borne in mind: by homogeneous, monochromatic light, which alone comes into consideration in the case of the spectrum, thin plates show the same colour by transmitted as by reflected light, and the difference consists simply in the fact that if, in consequence of the thickness of the film, reflected light appear more luminous, transmitted light will turn out more obscure, and *vice versa.* With regard to this point, therefore, the phenomenon, as indicated by Lippmann, is in direct contradiction to the physical phenomenon, and from this it will be evident that the explanation given is unsatisfactory. Dr. Stolze then suggests the backing of the glass plates with any black medium for positive examination, and to use them without backing for negatives. From such negatives, says the author, diapositives in any number could be produced, which again would serve for the production of positives for examination by reflected light. In the *Photographische Mittheilungen* Prof. Vogel credits Dr. Zenger with the first application of this method to heliochromic researches. The latter investigator is said to have used it many years ago at the time of collodion plates, but to have given it up as unsatisfactory.

*Transfers on Stone without Grinding off the Former Impressions.*—In a previous letter I mentioned a newly patented process of a German firm, consisting in making transfers upon the lithographic stone without grinding off the former transfer which had been made on it. Having received some inquiries for particulars of the process, I will give here the working details as far as it was possible to become acquainted with them. The new process is not only more simple than the old one, which required the grinding off of the former transfer, but it renders it also possible for the stone to be preserved ready for employment again without being ground off, so that it can be used for a much longer time than a lithographic stone treated after the old method. The working details are described as follows:—The stone is rendered sensitive to grease by treating it with sulphate of aluminium. The picture is then transferred to it; after this, the transfer paper is carefully loosened, and the stone well gummed, allowed to dry, and then freed from the gum by washing. The stone is then at once inked up with ordinary lithographic ink, dusted with resin powder, etched, and once more gummed. It is then ready for printing. When it is desired to use the stone for a new impression, the transfer is washed off with turpentine, and any grease which may have been left in the stone is removed by the use of acid. Thus the stone is again rendered sensitive to grease, so that it may receive a new impression without being ground previously. From ten to twenty minutes are said to be sufficient to make a stone ready for use anew, no matter of what size it may be, whilst with the old method the grinding off of larger stones required up to five hours. By this treatment the stone receives a polish, not as in the case of grinding, but a very fine grain which retains even the finest line or point, and which reproduces it equally finely.

---

Liquid Glue.—A good liquid glue, always ready for use, is made by filling a small jar with glue of good quality, broken up fine, and then filled with acetic acid. Keep the jar in a vessel of hot water for a few hours until the glue is all melted. It is always ready for use.

The Camera Club.—The dark rooms at the Camera Club are now available for members, and luncheons and dinners are now being served daily on the premises. The library and large club-room are open, and the Club's registered telegraphic address is "Monochrome, London." On Monday, March 16th, at 6 p.m., annual general meeting; at 8.30 p.m., lantern exhibition; slides by Mr. Fitz Payne (North Holland and Friesland), and by Mr. Stevens and other members. Thursday, March 19th, 8.30 p.m., Rev. T. Perkins, M.A., "Farther Notes on Church Architecture," illustrated by lantern slides. Thursday, March 26th, 8.30 p.m., informal meeting. Thursday, April 2nd, 8.30 p.m., Mr. Henry Sturmey, "Norway as a Field for Photographic Work," illustrated. In relation to the Conference week:—Monday, April 6th, 8.30 p.m., opening of the members' annual exhibition of photographs; open for about six weeks; visitors admitted by ticket or card from the hon. secretary and from members; smoking concert—the first in the new rooms. Tuesday, April 7th, 2 p.m., opening of Conference by the president at the Society of Arts; papers from 2 to 5.30 p.m., meeting and discussion open to all; 8 p.m., lantern slide exhibition in the Theatre, Society of Arts; special tickets required for this meeting. Wednesday, April 8th, 2 p.m., renewal of Conference at the Society of Arts; papers from 2 to 5.30 p.m.; 7.30 p.m. precisely, annual dinner for members and friends at the Criterion Restaurant. Thursday, April 9th, 8.30 p.m., ordinary meeting; flash-light demonstration with Messrs. Marion & Co.'s apparatus; other apparatus will be shown. Monday, April 13th, 8.30 p.m., extra lantern evening; members are requested to bring slides. Thursday, April 16th, 8.30 p.m., Mr. J. Howson, "Conventionalism in Colour." Thursday, April 23rd, 8.30 p.m., Mr. Frank Howard, "Photography in Bye-Paths and Field Lanes," illustrated by the lantern.

## PHOTOGRAPHY AT HARROGATE.

A meeting of the Harrogate Naturalist and Scientific Society was recently held in No. 3 Room, People's Hotel, Harrogate, the President (Dr. A. G. Russell, J.P.) in the chair, when a lecture on "The Chemistry of Photography" was delivered by Mr. A. A. Pearson, of Leeds. There was a crowded attendance, and the numerous experiments with which the lecture was illustrated enhanced the value of the paper.

Mr. Pearson said that the whole science of photography depends on the fact that certain substances are acted upon by light. We all know how the sunlight bleaches the colours of our carpets, curtains, and upholstery, though very slowly; the bright aniline dyes with which many silk ribbons are dyed lose their colour more quickly. The market gardener is unconsciously familiar with this property of light. He sows a bed of lettuce seed; when it comes up he thins it into rows, and, by the time the plants have grown a few good-sized leaves, he ties them up at the top to exclude the light; the result is a crisp, pale heart, the outer leaves of which are a pale green where the light has filtered through, yellow where less light has penetrated, and in the dark centre pure white. In the same way, he blanches his celery by banking up with soil. The green colouring matter of vegetation is a compound called chlorophyll, which is only formed in the presence of white light, so that here we have colour formed by light; whereas, in the case of dyes, the colour is destroyed by light. These processes are very slow, extending to days and weeks, but there are certain metallic salts, notably some of the salts of silver, which show a visible colour change in sunlight in a few seconds, and furthermore undergo an invisible change (which can, however, be rendered visible by the action of certain chemicals termed developers) in less than the 500th part of a second; nay, I have a photograph that I took of a single spark from a high tension electrical machine which cannot have lasted the 5,000th of a second. You will agree with me that it is a wonderful thing that a substance which keeps indefinitely in the dark, and remains unaltered a considerable time in a red or yellow light, should have its nature changed by exposure to white light for a shorter time than it takes you to wink. It is my purpose to-night to investigate this change, and explain its theory. In order to do this, I shall perform some experiments in visible changes, and argue from the visible to the invisible; just as when we see tree branches waving, or a hat scudding away from its owner, although we cannot see the disturbed atmosphere, yet we know there is a current of air in rapid motion, which we call wind.

After speaking of more elementary photographic matters, the speaker thus expressed his opinion about the disputed subject of the nature of the invisible photographic image:—

Let us see what happens when a ray of white light meets the extremely sensitive film of silver bromide. The ray of light is composed of several colours, from red to violet, and some invisible rays beyond that; the red vibrates the slowest, the violet and the ultra-violet the quickest. Those vibrations which do not correspond with the vibrations of the atoms of bromide are reflected, and we see them as reflected light; those that do correspond penetrate the film and amplify the movement of the atoms to such an extent as to loosen the bonds of affinity, and they are ready to fly apart on small provocation, like the iodide of nitrogen. To prove that a vibrating body will affect another one which is in unison with itself, I will return to the tuning-fork. I have another fork which is in exact unison with it. When I draw the bow across the first one, the second one is thrown into synchronous vibration, and sounds with it, and the boxes on which they stand infinitely reinforce the sound by vibrating in consonance. This would not occur if they were the least bit out of tune with each other. A very similar action seems to take place when the white light strikes the film of silver bromide and gelatine. A portion of the bromine appears to be set free, leaving the molecules in a very unstable position at the mercy of the developer. This is where the gelatine plays its part by absorbing the liberated bromine, for, as I explained before, single atoms cannot exist, but must have their affinities satisfied by company with other atoms, either of their own kind or others, they can combine with to form molecules. In certain cases, however, their loosened bonds can be loosely held together by the presence of a third substance, which, in this case, is the gelatine. The gelatine does not combine with the liberated bromine, but absorbs it in such a manner as to prevent the structure giving way. When the developer is applied, it acts by robbing this mainstay of liberated bromine and all the other besides, and the edifice tumbles to pieces, leaving nothing but metallic silver, which forms the image.

I have now only to conclude with a summary of the theory of the action of light on a sensitive dry plate in the process of taking a negative, as advanced by Captain Abney, Dr. Eder, Carey Lea, and others, and then bring this paper to a close by exposing a plate under a negative, and then placing it in a developing cell in the lantern so that you can see the development take place on the screen. First of all, our dry plates consist of a gelatine film in which is incorporated a compound of bromine and silver—the component atoms of this compound are in a state of vibration like a tuning fork, but infinitely more rapid; a ray of light formed of the subtle elastic ether, also in rapid oscillation at several different speeds, just as the air is when several musical notes are when sounded at once, partially penetrates this film and augments the movements of the atoms of silver bromide that are in tune with it to such an extent that the attraction is loosened, and some of the bromine is liberated and absorbed by the gelatine, leaving the molecules in a very shaky condition. The developer is applied which appropriates that absorbed bromine, and proves the last straw to the camel's back, for the structure breaks down, leaving more or less opaque metallic silver behind to form the visible image. The unaltered silver bromide is then dissolved out.

## THE SCIENCE OF COLOUR.

Last Friday, at Capt. W. de W. Abney's third lecture on the above subject at the Society of Arts, Mr. Francis Cobb presided.

Capt. Abney, by means of the colour-top, matched the colour of brown paper by means of four sectors—black, white, green, and bright red; these, when spun round, gave a brown paper colour. On another disc he had colours so painted that, when the disc was spun, it gave a fair representation of a spectrum, with the colours in their proper order. Pieces of coloured glass were spun round in a beam from the electric lamp, and gave a good imitation on the screen of a true spectrum; indeed, Captain Abney stated that it could be used as a spectrum in certain lecture experiments. He next spun a piece of the *Sporting Times* newspaper—usually, he believed, called "The Pink 'un"—with a sector of green paper bought at a stationer's shop; white was the result, and, he said, when two colours produce white they are complementary colours. Lastly, he described and experimentally illustrated a method of mathematically registering any colour whatever in terms of the wave-length of light; for instance, by these numbers anyone, he said, could, a thousand years hence, test the carmine of that day, and say whether it is exactly the same in colour as the carmine of to-day.

The Education Code and the Decimal System.—A deputation from the Decimal Association last June presented a memorial to the School Board for London, praying that the metric system should be taught in the fifth standard, and that decimal fractions should be taught in the fourth standard at latest. After due consideration the Board petitioned the Education Department to make the necessary provision in the new code, and this was subsequently supported by thirty-seven other School Boards. The Education Department has inserted the provision desired, the following foot note having been appended to Schedule 1: "The scholars in standards five, six, and seven should know the principle of the metric system, and be able to explain the advantages to be gained from uniformity in the method of forming multiples and sub-multiples of the unit. As a preparation for this, it will be useful to give in standard four elementary lessons on the notation of decimal fractions."

## Notes.

This week the subject of the smoke of London came before both Houses of Parliament on the same night, but nothing practical was done, perhaps because the Bill before the House of Lords was too drastic; it sought to make it compulsory on every householder to use smoke-consuming grates. There is no absolutely smoke-consuming grate, but plenty which will not send three-fourths of heat from the coals and volumes up smoke together up the chimney. Those natural enemies of the human race, ignorant jerry and other builders, are responsible for a vast proportion of the sickness and discomforts of those who dwell in towns; with the rooted conservative instincts of uneducated men who follow small mechanical trades, they build as their fathers did before them; ugly houses consequently arise, containing rooms without ventilation, bad drains running under the ground floor to cause sickness and death in the families of the tenants, aud they put in each room a grate as antique as Noah's ark, a grate which wastes fuel, and promotes the evolution of smoke. If legislation can be made to touch these men, and to prevent their misdeeds in the future, it would be good; otherwise the formation of an association to hang a few of them to the nearest lamp-posts seems a suitable remedy. Cannot *The Builder* newspaper do something to increase the intellectual capacity of the jerry builder? Photographers suffer commercially from smoke, because it cuts off so much light in the winter months.

Last Saturday, Lord Rayleigh exhibited, in one of his lectures at the Royal Institution, a column of mercury standing unsupported seventy inches high in a barometer tube, or at more than double its normal level. This was due to the play of cohesive forces. The bore of the tube had been made chemically clean, and all bubbles, even those of microscopic size, eliminated from the mercury. It was a most difficult experiment, and had been long in preparation before the result was publicly exhibited. In the same course of lectures, he mentioned that, in comparative experiments, it is sometimes necessary in a subsequent experiment to place an object, say a flask, in exactly the same position in relation to surrounding objects as in the preceding experiment. This can be done without any costly "fitting" by an instrument maker. It is necessary that the object shall have six points of contact. Take a three-legged stool with cylindrical legs, for instance. One of the legs may be placed in a triangular hole, of such a form as produced by pressing the point of a cube into a soft substance; this will give three points of contact. The second leg might rest in a V-shaped groove, giving two other points of contact, and the third leg simply rest on the floor, as the sixth point of contact. This stool can then be removed, and afterwards replaced in exactly the same position. These principles, he said, may appear trivial, but they are sometimes of considerable use in experimental research.

The remark is not unfrequently made that pyrogallol is not the easiest developer to work in the production of lantern slides, but that when good slides are turned out by its aid, they are superlatively good. Mr. Goldby is obtaining excellent results with pyro in the shape of rich and delicate purple tones, by means of the formula which he published in these pages last week. He has obtained the same rich purples with three separate brands of gelatino-bromide lantern plates now in the market. To get the purple tone the exposure must be about right; with too short an exposure a black image results, with too long an exposure the resulting image is too red. Mr. Goldby is a skilled chemist, and his published experimental results are thoroughly trustworthy.

Mr. Clarkson has patented an improvement upon the ordinary *Bourdon* pressure gauge, by which he claims absolute immunity from accidents by such ruptures—or explosions one might almost call them—to which we have lately more than once adverted. The matter is of such great importance, now that the gauge is used by so many workers, that we need make no excuse for once more making reference to it. Most people are aware that the principal feature in the gauge is a flattened tube bent to a semi-circular form, and that when pressure is admitted to the interior of such a tube it tends to become straighter according to the amount of such pressure, and this movement is communicated to the pointer which traverses the dial. We have already noted, by reference to one or two recent accidents, that this tube may, from age or other cause, give way, and that the sudden outrush of gas may lead to serious disaster.

Mr. Clarkson's improvement consists in filling the tube with a semi-solid substance, such as soft soap. The pressure of the gas upon this substance allows the tube to expand just as if it were not there, while in case of rupture the outrush of gas is quite prevented by another addition to the apparatus. This is a small metal plunger which is buried in the soap at that part of the gauge which screws upon the gas cylinder. Should the tube above give way, the pressure of the gas drives this plunger forward, so that it at once plugs the entrance to the tube, and effectually cuts off the gas supply. We understand that existing gauges can be fitted with this new form of *Bourdon* tube without great expense.

The Home Secretary's new Bill, the object of which is to deal with several matters relating to criminals and penal servitude, cannot, it will be thought by our readers, have any kind of interest for the photographic fraternity—unless, perhaps, any wanderer with the camera should be mistaken by an over-zealous officer to be "a suspected person frequenting any canal, wharf, or place of public resort with felonious intent." But taking a photograph is not yet a punishable offence—except iu France; yet there is a clause in this Bill which deals with matters photographic, for it proposes that, under certain circumstances, prisoners shall be photographed before conviction. This clause is likely to raise up much opposition from those peculiarly constituted persons who are so fond of championing rascality.

---

While the authorities are considering this matter, it would be as well if they also paid some attention to another important point in criminal photography. We allude to the necessity for photographing a man's hands as well as his face for purposes of identification. It is well known that, while faces are so often alike that one man may be readily mistaken for another, the lines on no two hands agree. How often has the novelist relied for identification upon the impression of a dirty thumb-mark; and the novelist is right. A good photograph would not only show these surface marks, but would detect other peculiarities of structure, and modifications caused by labour and work at different trades. Will not some member call attention to this important matter when the Bill comes on for discussion?

---

California is the favoured spot for the construction of observatories. In addition to the Lick Observatory, there are no less than five others constructed, or in process of construction. Prof. Pickering contemplates building one to contain the great photographic telescope of 24 in. diameter, the cost of which was defrayed by Miss Bruce, of New York. The instrument of Mrs. Procter will be somewhat similar to the portrait lens combination used by Professor Barnard when taking the photographs of the Milky Way, published in the July number of *Knowledge*, but will give pictures on four times the scale of Professor Barnard's photographs. The short focus of such a combination, as compared with an ordinary observing telescope, will enable fainter objects and larger outlying regions of nebulæ to register themselves on the sensitive plates than can be photographed with the telescopes which will be used for the international photographic survey of the heavens, or even with Mr. Isaac Roberts' reflector.

---

As we suggested a fortnight ago, the forthcoming Spectacle Exhibition has had its original scope extended, so that the collection will now comprehend optical instruments of every kind. Indeed, one of the speakers at a special court of the Spectacle Makers' Company, held last week, foreshadowed a rather liberal view of the matter, and it is possible that the schedule may contain certain instruments which cannot be said to be strictly comprehended as exemplifying the optician's art.

---

We believe that the Exhibition is not to be what is called a competitive one. There will be no prizes, and foreign firms, it is stated, will not be invited to exhibit, though importers who trade with England may be accorded the privilege of being allowed to take part. We are afraid this distinction will be the cause of a little heartburning, and perhaps the matter may be considered once more. Surely English manufacturers would like to see what their Continental rivals are doing. It is said that foreign competition has, of late years, affected the English optician. How the matter is to be mended by excluding foreign productions from the Exhibition we do not quite see. It is gratifying to note that the Astronomer-Royal accepted the invitation to be present at the meeting mentioned, and made a very practical speech on the subject.

---

Already M. Lippmann's discovery has sounded a note—a feeble one, it is true—of alarm on the part of a contemporary, representing the printing trade. If the news is true, remarks the journal in question, though it has nothing, of course, with the interests of true art, there is a section of our artists who may be moved to strike. Those whose art consists in the nearest approximation possible to the coloured photograph may kick, as the workmen kicked at the introduction of machinery. At the present moment we are inclined to think that lithographers may calmly rest at nights. There is nothing existing in M. Lippmann's discovery to disturb their peace of mind.

---

The retoucher's art has invaded the dark room. M. H. Fontier describes a process of chemical retouching which may be used during development. Its object is to delay the intensification of certain parts, such as the skies or the high lights. When these appear before there is any detail in the shadows, the development must be stopped and the plate washed quickly. It is then drained, and the high lights are touched with a brush dipped in the following solution:—Bromide of potassium, 4 grammes; citrate of potash, 2 grammes; water, 100 c.c. The development is then proceeded with in the usual manner, and as there is a cessation of action in the parts so treated, the development may be pushed without fear in order to obtain the details in the shadows.

---

The *Blackpool Times* has lately shown what it can do in the way of utilising photography. There was a terrific storm at that northern watering-place some time ago, and great damage resulted. During the gale photographs were taken of the sea-front at the moment when huge waves were breaking upon it, threatening to demolish the houses and buildings. These photos were made into excellent Meisenbach blocks, and printed, with a letterpress description of the calamity, on a separate sheet.

---

Human nature is very much alike. Whether in England or in America, men have a dislike to being photographed. An attempt has been made by the *Shoe and Leather Gazette*, of St. Louis, to obtain the photographs of the shoe and leather salesmen of the Western cities generally, and the editor complains that the response to the call for photographs was so slow that the original intention had to be reluctantly abandoned, and the *Gazette* had to be contented with furnishing a score or so.

## PHOTOGRAPHIC SHUTTERS.*

BY FRANCIS BLAKE.

I shall now give the results obtained for speed of a number of well-known shutters tested with the apparatus just described.

1. Common wooden guillotine drop with four rubber bands, 1¼ inch slot passing 1¼ inch lens—1st test, 0·009 s.; 2nd test, 0·009 s. This shutter passes only 50 per cent. of the light which would fall on the lens if it were wholly uncovered during the action of the shutter. Moreover, it is highly objectionable on account of the violent jar it gives to lenses, often reducing the balsam with which they are sealed to a fine powder.

2. *Gregg Shutter.*—In front of No. 3 euryscope lens; spring wound two turns—1st test, 0·034 s.; 2nd test, 0·035 s.

3. *Prosch Extra-Rapid Shutter.*—Attached to the *oo*-euryscope lens; fastest speed—1st test, 0·0028 s.; 2nd test, 0·0027 s.; 3rd test, 0·0021 s. This is a special form of shutter, in which a single narrow radical slot passes across the centre of the lens tube. So little light is passed that I cannot regard this shutter as of any practical use.

4. *Hoover Shutter.*—3D Dallmeyer lens; *d*/0 is the full and *d*/8 the smallest opening.

| | Quickest Speed. s. | Slowest speed. s. |
|---|---|---|
| *d*/0 | 0·058 | 0·195 |
| 1 | 0·043 | |
| 2 | 0·036 | 0·130 |
| 3 | 0·031 | |
| 4 | 0·025 | |
| 5 | 0·022 | |
| 6 | 0·017 | |
| 7 | 0·013 | |
| 8 | 0·008 | |

For want of light, anything less than *d*/3 would be of no practical use, so that the quickest effective speed of this shutter may be placed at 0·03 s., with a range up to 0·20 s.

5. *Hoover Shutter.*—Large size made for Falk, the well-known professional photographer at New York; euryscope No. 6 lens.

| | Fastest. s. | Slowest. s. |
|---|---|---|
| *d*/1 | 0·055 | 0·146 |
| 4 | | 0·096 |
| 5 | 0·029 | |
| 7 | 0·017 | |

6. *Prosch Duplex Shutter.*—3/*d* Dallmeyer lens. Full opening, about equal to *d*/2.

| | Fastest Speed. Strong Spring. s. | Slowest Speed. Weak Spring. s. |
|---|---|---|
| 1st test | 0·0164 | 0·0302 |
| 2nd ,, | 0·0167 | 0·0288 |

7. *Prosch Duplex Shutter.*—Euryscope No. 2 lens.

| Notch. | Strong Spring. | Weak Spring. |
|---|---|---|
| 1 | 0·021 | 0·032 |
| 2 | 0·016 | 0·028 |
| 3 | 0·013 | 0·027 |
| 4 | 0·012 | 0·026 |
| 5 | 0·010 | 0·025 |

8. *Prosch Duplex Shutter.*—*oo*, a euryscope lens; strong spring. The tests with this shutter were very interesting, as they disclosed a second exposure due to the rebound of the shutter wings after closing. Mr. Ed. H. Lyon had been unable to obtain satisfactory pictures with this shutter, and returned it to the makers immediately after the tests. The reputation of Messrs. Prosch and Co. for good mechanical work renders it almost unnecessary to remark that the subjoined results are unique.

| Notch. | | s. | Time from beginning of first to end of second exposure. s. |
|---|---|---|---|
| 1 | 1st exposure | 0·0122 | 0·0262 |
| | Closed for | 0·0036 | |
| | 2nd exposure | 0·0104 | |
| 2 | 1st exposure | 0·0100 | 0·0219 |
| | Closed for | 0·0030 | |
| | 2nd exposure | 0·0089 | |
| 3 | 1st exposure | 0·0084 | 0·0190 |
| | Closed for | 0·0029 | |
| | 2nd exposure | 0·0077 | |
| 4 | 1st exposure | 0·0077 | 0·0169 |
| | Closed for | 0·0031 | |
| | 2nd exposure | 0·0061 | |

9. *Newman Shutter.*—Attached to Beck lens. Property of Mr. W. G. Reed. Set at exposure marked $\frac{1}{100}$ second. 1st test, 0·045; 2nd test, 0·048.

On February 3rd of this year I tested a number of market shutters which were sent to me for the purpose by our president, Mr. Sweet. Of them all it seems to me that for "all around work," where the limit of speed is not desired, the Bausch and Lamb new style is the best adapted to an amateur's use. It is exceedingly well made, and has a very large range of automatic exposures extending up to two or three seconds.

10. *Bausch and Lamb.*—(New style.) Full opening about $1\frac{1}{16}$ inch:—

| Graduated Time. | | s. |
|---|---|---|
| $\frac{1}{100}$ | 1st test | 0·016 |
| | 2nd ,, | 0·018 |
| $\frac{1}{50}$ | 1st test | 0·050 |
| | 2nd ,, | 0·043 |
| $\frac{1}{10}$ | | 0·047 |
| $\frac{1}{100}$ | (½-in. opening) | 0·013 |

11. *Hand Release, Brass Shutter.*—Full opening 1⅝ inch: 1st test, 0·031 s.; 2nd test, 0·029 s. Shutter jars camera badly.

12. *English Two-winged Shutter.*—Two rubber bands. Full opening 1⅜ inch. 1st test, 0·035 s.; 2nd test, 0·034 s. Shutter jars camera slightly.

13. *French Flap Shutter.*—One rubber band. Full opening 1⅜ inch. 1st test, 0·038 s.; 2nd test, 0·035 s. Shutter jars camera slightly.

14. *Single-fan Shutter.*—Full opening 1½ inch. 1st test, 0·029 s.; 2nd test, 0·030 s. Shutter jars camera slightly.

15. *Long Single Slot Shutter.*—Full opening 1¾ inch. One test, 0·052 s.

16. *Round Black Brass Shutter.*—Full opening 1⅛ inch. This shutter was so slow that the ball in both tests reached the box before exposure was finished. I estimate its speed at about one quarter of a second.

17. *Plunge "Patent" Shutters.*—Perken, Son, and Rayment, London. Property of Dr. Tarbell. Fastest speed Notch 5, 0·054 s.; slowest speed Notch 1, 0·064 s.

18.—Haake and Albers, Frankfort, a.m.; Thury and Amey, Geneve 645. Euryscope No. 3 lens, received from Messrs. Benj. French & Co.:—

| | Fastest Speed. s. | | Slowest Speed. s. |
|---|---|---|---|
| 1st test | 0·009 | 1st test | 0·103 |
| 2nd ,, | 0·009 | 2nd ,, | 0·117 |
| 3rd ,, | 0·009 | | |

An exceedingly well made shutter, with a good range of automatic exposure.

## M. LIPPMANN'S DISCOVERIES IN HELIOCHROMY.

BY THE RIGHT HON. LORD RAYLEIGH, SECRETARY TO THE ROYAL SOCIETY.

Will you allow me to draw the attention of your readers to the accompanying passage from the *Philosophical Magazine* of August, 1887, p. 158, in which I propounded an explanation of Becquerel's coloured photographs, identical with that which has guided M. Lippmann in his recent experiments. I believe that a similar view had been expressed, unknown to me, at an earlier date by a German worker, whose name I cannot now recall.

"A detailed experimental examination of various cases in which a laminated structure leads to a powerful but highly selected reflection would be of value. The most frequent examples are met with in the organic world. It has occurred to me that Becquerel's reproduction of the spectrum in natural colours upon silver plates may perhaps be explicable in this manner. The various parts of the film of sub-chloride of silver with which the metal is coated may be conceived to be subjected, during the exposure, to *stationary* luminous waves of nearly definite wave-length, the effect of which might be to impress upon the substance a periodic structure, recurring at intervals, equal to *half* the wave-length of the light; just as a sensitive flame exposed to stationary sonorous waves is influenced at the loops but not at the nodes (*Phil. Mag.*, March, 1879, p. 153). In this way the operation of any kind of light would be to produce just such a modification of the film as would cause it to reflect copiously that particular kind of light. I abstain at present from developing this suggestion, in the hope of soon finding an opportunity of making myself experimentally acquainted with the subject."

Becquerel's instructions (*La Lumière*) are so complete that I found no difficulty in repeating his remarkable experiments and in obtaining very good representations of the spectrum. Any doubts that might have been felt as to the operation of stationary luminous waves in a nearly transparent sensitive film were finally removed by the important observations of Wiener, published about a year ago in Wiedemann's *Annalen*.

---

The Royal Institution.—At the general monthly meeting last Monday, with Mr. William Crookes, F.R.S., vice-president, in the chair, the following were elected members of the Royal Institution:—Miss Emily Aston, B.Sc., Mr. Henry Daw Ellis, M.A., Mr. Francis Fowke, Mr. Augustus William Gadesden, J.P., Miss Emily Dora Locock, Signor Alberto Randegger, The Hon. Frederick Hamilton Russell, and Mr. John Wilson Walter. Professor Victor Horsley, F.R.S., will give a discourse on "Hydrophobia" on Friday, March 20th, in place of Professor W. E. Ayrton, F.R.S., who is unable at present to give his promised lecture on "Electric Meters, Motors, and Money Matters."

A New Solvent for Cellulose.—Messrs. Cross and Bevan write to *The Chemical News* that, on dissolving in hydrochloric acid one half its weight of zinc chloride, a solution is obtained (of specific gravity 1·44) which dissolves cellulose instantly, and without sensible modification. The solution of cellulose obtained by heating it with concentrated solutions of zinc chloride may also be diluted with hydrochloric acid without precipitating the dissolved products; but the solution by the new reagent has the double advantage of being instantaneous, and of being prepared, therefore, with the minimum of resolution of the cellulose into bodies of lower molecular weight, which usually attends the somewhat prolonged heating necessary for complete solution in the aqueous solution of zinc chloride.

## THE PORTRAITURE OF THE MOON.*

BY JAMES MEW.

In photographing the moon, the artist will confer a benefit on mankind and upon himself. He will surely experience a certain freedom, an absence of that conventional restraint which hampers him so cruelly in his portraiture of humanity.

Positive and negative advantages alike fall to the lot of the lunar photographer. The latter are as notorious as they are numerous. First, there will be no necessity to travel, in taking the portrait of the moon, in any groove, cut by the hand of fashion through that well-known photographic rock against which the fierce waves of impassioned rhetoric have so often beaten, called, in the descriptive terminology of the trade, retouching; or if retouching must needs be, it will not flatter, and it will not lie. It will be artistic and not adulatory; its work will be in the cause of universal science and humanity, and not a contribution to individual conceit and spleen. It will present, to borrow a sharp saying from one of the fellest of its foes, a likeness, although a photograph; and this because the moon, although, if indeed not a Teutonic moon, a lady, and by this time so very, very old, is little anxious to conceal her age. It is not with her now as it was in those happy days of the infant world in which she flirted with Endymion in the vale of Latmus, a passage of love which has been described at full length by Keats, and by Shakespere in one line telling how she slept with him, and would not be awaked. Little recks Selene now in this age of iron of a pretty portrait, in this scientific age of doubt of her feminine personality, in this age of decadence, wherein no man, may be, is worthy of her love.

Again, nobody is anxiously desirous of a background to the moon. Nobody will fall foul of the unfortunate though elaborate chair, the elegant but much-abused curtain, the book, or the pedestal in the foreground, or in the distance the machicolated castle or the landed estate. None cares to lift the moon out of her sphere of azure to set her in new surroundings, gorgeous though unfamiliar, unsuitable though grand. Nobody, in fine, can complain of a lack of individuality—that all too frequent though not too distinctly intelligible complaint—in the portraiture of the moon. The pale queen of night rules supreme, and cannot by the most maladroit artist be confounded with the lesser stars. The governess of the floods cannot by any perversity of conception be mistaken for anything in the heaven above other than herself.

Draper in 1840, and in 1850 Professor Bond, of Harvard University, in the United States, were among the earliest important exponents of the assistance lent by photography to lunar portraiture. The experiments of Rutherfurd a dozen years ago, of De La Rue, of Vogel, and Janssen, and many later votaries of this watery orb, are well-known to every photographer. The pale, faint, borrowed, cold, and infertile light of this lantern of the evening sky, aided by the conjunctive instrumentality of the camera and the telescope, has revealed, little by little, its secrets, the subject of so much anxious inquiry since the days of Anaxagoras. We see defined with delicacy of discrimination a cinereous surface of pumice stone, diversified here and there by hill and crater, dotted and dashed with lurid discs of light, and with ragged fringes of darkness, with peaks and cones of polished silver, and

* Concluded from page 164.

with oval chasms of ebony, with seas of inky jet, and with summits of translucent pearl.

Clearer vision destroys, as always, ancient credulity. Faith grows weak in the doctrine that the moon is a treasury of lost articles, or that it is made of green cheese. Fewer, and ever fewer, folk believe in its single inhabitant or in his punishment for stealing cabbages, or for stealing vines, for refusing milk, or for churning butter, for mowing meadows, or for fencing fields on the Sabbath day.

It is for the magic wand of photography to dispel the mists of popular superstition by the help of her scientific godfather, her own darling and puissant agent and assessor, light. It is for the photographer, and for him alone, to give representations of this lesser luminary at once eminently picturesque and perfectly true. It is for him, and for him alone, to show to the curious observer Tycho with its *rilles* of thousands of miles of radiant silver, the ring plains of Copernic and Aristarchus, the crater of Messier, the walls of Catharina, the Prolific Sea, the Sea of Serenity, and the Sea of Rest. It is for him to display—in small, on carte, or cabinet—this faded remnant of a worn-out world; this type—if we may listen to the tale of our most learned astronomers—of our own earth's future, when all its busy turmoil, its hopes and fears, its loves and hates, its pleasures and its pains, shall be hushed into eternal silence, and all its warm life lie frozen and dead in dark, and mindless, and everlasting oblivion.

## THE MICA INDUSTRY.

With the extraordinary growth of the electrical industry in the United States for a number of years past, there has been created a new and steady demand for mica, which, curiously, has failed to stimulate the mica mining industry in this country; the most important mines, indeed, show a decided decrease in producing during this time, and the business is now in a depressed condition. In the construction of dynamos, electric motors, and some other electrical appliances, mica is a very important element, valued on account of its flexibility and excellent insulating qualities. For this purpose, however, there is a decided preference for foreign mica, the Canadian "amber mica" being generally used.

Mica is employed in dynamos and electric motors, mainly in building up the armatures, strips of various dimensions, but usually about one inch wide, and from four to eight inches long, being used.

The foreign mica is considered preferable to that of North Carolina for this purpose, in that while the latter can be split into thin sheets, it is by no means so tough, which is an important requisite. Such mica may, perhaps, be found in the United States, but up to the present time there is no doubt that some imported micas have proved more suitable for this purpose than the usual domestic grades.

Hitherto, the most important—in fact, almost the only important—use for mica has been in stoves, and the demands, and, consequently, prices of the article for this purpose have been such that mica mining was carried on at considerable profit.

The chief mines in the country are in New Hampshire and North Carolina, but principally in the latter state, these producing an excellent quality of the mineral. Several years ago changes were made in the patterns of stoves, whereby smaller and correspondingly less expensive sheets of mica were used, and the lower prices resulting depressed the industry greatly, especially in North Carolina, where many mines were closed. The total value of the product in the United States decreased from 368,525 dollars in 1884 to 70,000 dollars in 1890. During the same time the imports of mica, which, prior to 1884, had been of but trifling importance, increased from 28,284 dollars to 57,541 dollars.—*Engineering and Mining Journal.*

## COLLOTYPE PRINTING WITHOUT MACHINERY.

At a meeting held last Wednesday night in the rooms of the Photographic Society at 50, Great Russell Street, London, Mr. James Glaisher, F.R.S., presided, and Mr. Leon Warnerke gave a demonstration of a simple method of producing collotype prints, or, as he preferred to call them, "collograph" prints, according to the terminology adopted at the late International Photographic Conference at Paris. There was a crowded attendance.

The speaker stated that collography is fifteen or twenty years old, and that he had placed upon the walls of the room specimens of recent work executed by many home and foreign firms; he added that the exhibition would be open to the public for a month. He intended to show a simple method of getting equally good results, without the employment of costly machinery; in fact, the printing was done in a common screw copying-press.

Mr. Warnerke continued that the process which he was about to describe was based upon the use of vegetable parchment coated with gelatine, instead of employing a rigid glass or other support from which to print. He himself had no commercial interest in the process, but it might be a convenience to his hearers to know that it was devised and introduced commercially by M. Raymond, of Paris, and who now has agents in London.

The parchment paper is sold in rolls ready-coated with gelatine. A piece of the size required is cut off the roll, and floated for three minutes upon a three per cent. solution of bichromate of potash; the time of floating is of importance; when floated too long the film becomes too sensitive. The sensitising may be done by daylight, for the bichromates are insensitive while in solution, but the floated sheets must be dried in the dark; it is convenient to prepare them in the evening, and to allow them to dry in a dark place for use the next morning. A few drops of ammonia added to the sensitising bath will make it keep longer, perhaps for months. After the films are raised from the sensitising bath, they are squeegeed on to a plate of glass, the face of which has previously been rubbed with talc, better known under the name of "French chalk"; on this plate the film is allowed to dry in the dark, after which it can be peeled off, and with a face as smooth as that of the glass itself.

The sheet is next exposed under a negative in the printing frame, preferably to diffused daylight when the negative is of an average character and density. In direct sunlight, the proper time of exposure may perhaps be five minutes; an actinometer has to be used. When the details are out in the shadows, the exposure is finished. It is then desirable to expose the back of the sheet to diffused daylight for perhaps five minutes, to cement the print on the front to the back, and render the film better able to resist wear and tear; moreover, this supplementary exposure sometimes improves the picture. The print is then put into standing water for two hours, or into running water for a shorter time, to remove all the bichromate of potash. The print is next placed for one hour in a bath consisting of—

| | |
|---|---|
| Glycerine ... ... ... ... ... | 70 parts |
| Water ... ... ... ... ... | 30 ,, |
| Ammonia ... ... ... ... ... | 3 ,, |

This last bath is not absolutely necessary, but it makes the film last longer. The picture is now ready for printing.

The sheet next has to be placed in a special and simple frame, obtainable in the market, and of about the size of a common photographic printing frame for the same size of picture. The object of the use of the frame is to stretch the parchment upon a flat support, and to keep it smoothed and stretched during the subsequent manipulations. An elastic pressure obtained by means of felt is given in this frame.

The preparation of the ink to be employed is an important matter. An ink for collography is sold by the trade, but almost any stiff ink will do, including that used in letterpress work. Two inks have to be used in collograph work: the stiff ink attaches itself to the darker parts of the image; the soft ink is next applied, and brings out the half-tones. For diluting the stiff ink he used varnish, and for diluting the soft ink he used "suet"; he mixed his inks to suit each picture. The rapidity of the rolling of the sheet has an influence; if too much stiff ink have been applied, most of it can be removed again by the rapid motion of the roller. At this stage of the process the individuality and artistic taste of the operator can come in, and he has much more control over the results than in common photographic printing. Before the ink is applied to the wet sheet, the latter is covered with a piece of clean paper, and put in the copying press for a short time to adequately remove surface moisture. It is then taken out, the piece of paper removed, and the ink applied; for the stiff ink he preferred a leather roller, for the soft ink a gelatine roller. The ink attaches itself to the places at which the film has been acted upon by light, but not to parts unacted upon and consisting simply of damp paper.

Should the ink not come off the sheet when the first impression is taken, it is a sign that the film is too dry. Some of the glycerine bath should then be put upon it with a sponge, and dabbed over it with a clean rag: it must be dabbed, not rubbed, otherwise the film may be injured. Allow the film to rest for a few minutes, then re-ink.

The paper used must be sized, and the pressure which has to be applied by the press will be less the more the paper is sized. The paper is backed for printing by placing upon it two pads of felt and one of india-rubber. The earlier impressions are never so good as those which follow. To get clean, sharp margins, narrow slips of paper may be laid upon the edges of the sheet from which the printing is done. The working of any particular ink varies with the temperature, and ink which works well on a cold day may possibly not do so upon a hot one.

Mr. Warnerke stated that the applications of the process were numerous. The parchment sheet being flexible, it could be used to print upon wood blocks; printing upon canvas could be done by its aid, and prints produced with vitrifiable colours for photo-ceramic work.

The President had to retire early, after which Mr. John Spiller took the chair, and in the course of some remarks said that the Secretary had written to M. Lippmann to ask if he would favour the Society with some of his heliochromes to exhibit at its meeting next Tuesday.

DETECTION OF SODIUM THIOSULPHATE IN SODIUM BICARBONATE.—J. Lüttke (*Chemiker Zeitung*). If we add a few c.c. of a solution of barium nitrate to a solution of sodium bicarbonate previously saturated with hydrochloric acid, and not containing sulphuric acid, no turbidity or precipitate ought to be occasioned. If a thiosulphate is present, there is formed a turbidity or a precipitate on adding a drop of permanganate, which transforms the thiosulphate into a sulphate.

## A NEW HAND-CAMERA.

MESSRS. George Houghton & Sons have exhibited to us a new hand-camera, in which each plate, after exposure, is removed from the front to the back of the bundle of plates, without opening the camera or using a bag; this is done rapidly, and an opaque diaphragm always between the exposed and unexposed plates is useful as a guide when the operator is about to begin developing operations. The camera works automatically,

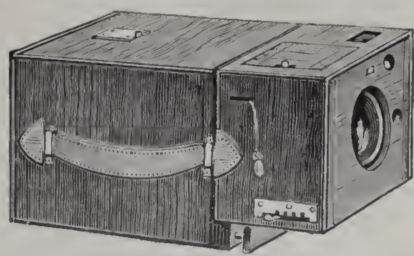

*Fig.* 1.

and is small in size; its general appearance is indicated in fig. 1. The one shown to us acted well, and seemed as if it would do good work in practice.

A, Fig. 2, is a catch releasing the front plate, and letting it fall

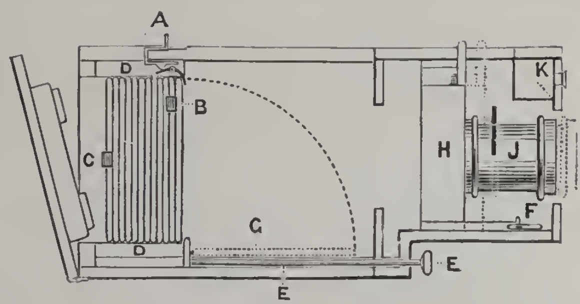

*Fig.* 2.

into the position G; B, springs preventing the second plate from falling; C, springs catching up the exposed plate after it has been brought to the back; D, movable reservoir holding twelve plates; E, brass rods with a wooden connecting bar, attached to the reservoir; F, lever acting on the shutter and lens for focussing: H, shutter; J, lens; K, view finder.

Fig. 3 represents the camera tilted for changing a plate.

D, reservoir drawn forward by the rods E after exposure; G, front plate after exposure, and having been released by the catch A; L, the position of the plate when the camera is first tilted, and the reservoir drawn forward; M, the position

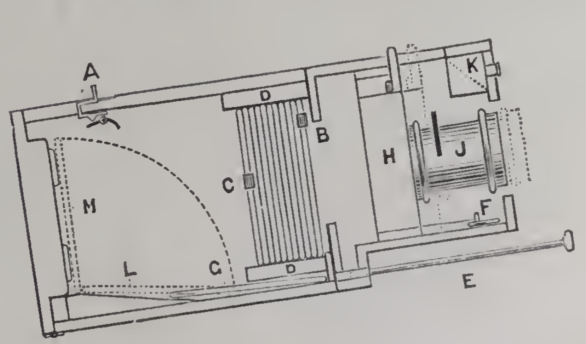

*Fig.* 3.

of the plate when camera is placed in a vertical position, and ready to be picked up by the reservoir when it is pushed home, which operation, at the same time, forces the next plate past the springs B, so that it is ready for next exposure.

Messrs. Houghton and Sons thus describe the working of the camera:—The plates are contained in a special form of sheath, and are placed one by one in the reservoir through the door at the back of the camera, the front one resting on the springs B, shown in fig. 2. After putting in the twelve plates place the wooden dummy sheath over them, and press it past the springs C ; then close the door, which is fastened with a lock and key. The use of the dummy sheath is to indicate when the twelve plates have all been exposed, as it is constructed so as not to pass catch A. When it is desired to remove any exposed plates before the whole have been used, open the back of the camera, and all those exposed will be found at the back of the dummy sheath ; the latter should then also be removed and the reservoir refilled, replacing the dummy sheet in its original position.

After exposure, in order to change a plate, press forward the catch A in fig. 2, at the same time inclining the front of the camera downwards to allow the plate to fall from B to G ; then draw forward the reservoir containing the remainder of the plates by means of handle E, and allow the exposed plate to slide back up the inclined plane from G to L by tilting the camera as shown in fig. 3, when, by raising the camera to a vertical position, the plate will fall against the back of the camera from L to M, and, by then pushing home the reservoir, the plate will be pushed into position at the rear of the other plates, and, at the same time, the front plate will move forward beyond the springs B, and be held by the catch A ready for the next exposure. It is important that the reservoir should be pushed well home until the handle E is held firm by the brass spring catch provided for that purpose.

## Patent Intelligence.

### Specifications Published.

2,628. *February 18th*, 1890.—"A Magnesium Flash-light." (A communication from Charles Lansiaux and Charles Merville, 42, Boulevard Boune Nouvelle, Paris, Photographic Apparatus Manufacturers.) Alfred Julius Boult, 323, High Holborn, London.

The subject of the present invention is a novel portable apparatus for the instantaneous production or generation of the magnesium light required for taking photographs in otherwise dark places. This extremely simple apparatus gives a light sufficiently powerful to permit of the taking of instantaneous photographs in the open air and during the worst weather.

The apparatus consists of a small box acting as a reservoir, and containing a bent tube which passes through the box, and is connected at one end with a collapsible ball by means of a caoutchouc or other flexible tube. This box, intended to be filled with magnesium powder, is closed by means of a screw or equivalent stopper. The bent tube within the box is cut away to admit the magnesium powder into its interior, and, in addition, has at its lower end a small conical tuyere covered by a single or double sheet of thin metal gauze. The upper end of the bent tube is slightly pointed or reduced in area for the purpose of converging or directing the particles of magnesium powder issuing from the box against the burning portion of a fuse or fusee. The fusee, the name of which indicates that it is a sort of match of which each portion remains a certain time in combustion after it has been lighted, is held in position by a socket soldered to the box and slightly inclined on one side.

The apparatus acts as follows : The reservoir box having been filled with magnesium powder through the removable stopper, a fusee is inserted into the socket or holder. When the moment has arrived for commencing an operation, friction is applied to the phosphorus-coated end of the fusee by the box in which it is contained, by which means it is lighted. The ball is then pressed so as to cause the air it contains to traverse the tuyere and the holes in the metal sheet, and to propel all the powder contained in the bent tube, and which had been admitted by the before-mentioned opening in such tube, against the fusee. The magnesium powder ignites instantly on coming in contact with the red portion of the fusee, and produces the magnesium flash-light. If it be desired to take a second proof, it is sufficient to place another fusee in position, and to light it and to press the ball for the purpose of expelling a fresh charge of powder. It is thus possible to go on producing flashes until the box no longer contains any powder.

The object of the before-mentioned metal gauze is to permit the air to pass into the bent tube when the ball is compressed, and to prevent, by the fineness of its holes or interstices, the magnesium powder from being sucked into the flexible connecting tube and collapsible ball when the pressure is removed from the latter, and when it re-inflates itself.

3,393. *March 4th*, 1890.—"A Sensitised Flexible Film." Edward William Foxlee, 22, Goldsmith Road, Acton, London, Photographic Expert.

This invention relates to the manufacture of improved flexible films, to be used as a substitute for the ordinary sensitised glass in taking photographic negatives or positives.

It is well known that thin sheets of celluloid, coated with a sensitive emulsion of gelatino-bromide of silver, have for some time been in use, so also have thinner films of the same material, for what are known as roller slides. In the manufacture of the former, sheets of commercial celluloid are simply coated with the emulsion. In the manufacture of the latter, the celluloid compound is spread upon a rigid surface and afterwards coated with the emulsion, and when this is dry the film is stripped off. By either method only sheets of limited size can be produced. As celluloid is a highly electrical substance, it has been found that friction upon its surface, as when stripping it from the rigid body, or by the rollers of the slide when in use, evolves electricity, the light from which is found to cause marking or fogging in the negatives. When the celluloid film is very thin and flexible, it has a tendency to curl owing to the expansion and contraction of the gelatine on being wetted or dried.

By my invention the film is made in continuous or long lengths or webs, and the celluloid is protected at the back with a coating of gelatine, which serves a double purpose, that of protecting the celluloid from friction, and, by its expanding and contracting in the different operations of developing, fixing, washing, and drying the negative, counteracts the tendency of the film to curl from the expansion and contraction of the gelatinous film on the other side.

To make my improved film, I take a heavily calendered paper in the roll or web, or a "surfaced" paper. I then coat it in any convenient manner with a material which is impervious to water, and which will not disturb the fibre or texture of the paper—such as a solution of india-rubber, for example. After the solvent has evaporated, I apply a solution of gelatine containing chrome or other alum sufficient to render the gelatine insoluble, or partially insoluble, when it is dry, combined or not with some soluble, non-actinic colouring matter. The proportion of gelatine to water may be about the same as that in the sensitive emulsion.

This coating I apply in the same manner as in making continuous or long lengths or webs of carbon tissue for photography, or in coating gelatino-bromide paper. The india-rubber solution can also be applied to the paper in the same way as the gelatine.

When the gelatinous coating is dry, I apply the celluloid or pyroxyline compound—preferably prepared with volatile solvents—either in a fluid or in a plastic condition, according to the film required. When the celluloid or pyroxyline compound is employed in the fluid state, it can be applied to the web in the same manner as the previous coatings above referred to. When such compound is used in the plastic state, it can be spread on the web in the same way as india-rubber and similar substances are spread. The celluloid or pyroxyline compound I employ is similar to what is known as xylonite, celluloid, &c., and is composed of nitro-cellulose and camphor dissolved in suitable solvents—the camphor being itself a solvent—of which there are many. Those I prefer to employ for the compound when the latter is used in the fluid condition, on account of their volatility, are such as methyl-alcohol (wood naphtha), methylated alcohol, ether, benzol, &c., or mixtures of two or more of the same. If the said compound is to be used in the plastic state, some of the other well-known and less volatile solvents are preferable. I would have it understood, however, that I do not confine myself to the use of any particular solvents or proportions, as they have to be varied to suit circumstances. A good proportion, however, for a fluid compound is from four to six parts of solvent to one of solid matter.

After the solvents have evaporated, the celluloid is coated in a darkened room with the sensitive gelatino-bromide of silver emulsion; when this is dry, the back of the paper is moistened with a solvent of the first coating, such as benzol in the case of india-rubber; the finished film is then separated from the paper support or backing; this may advantageously be effected by connecting the ends of the film and paper to two separate rollers, which, on simultaneous rotary motion being given to them, will act to separate the film from the paper and wind them up respectively thereon.

I would here remark that I am aware that a collodion film has been spread on paper whilst the latter has been attached to a sheet of glass, and such film has then been coated with sensitised emulsion, but in such case the paper has remained attached to the film, and was not separated therefrom until after the negative had been exposed, developed, and fixed. I am also aware that paper has been coated with soluble gelatine, which has then received the sensitive emulsion rendered insoluble with chrome alum, and that the back of the paper has been coated with insoluble gelatine to prevent the film curling. In this film the paper has formed part of it until after exposure, development, and fixing, when the film bearing the image is stripped off the paper, which latter carries with it the insoluble gelatine backing. In this case collodion or celluloid is not used. I am also aware that a photographic film has been prepared by first coating paper with insoluble gelatine, then with india-rubber containing grease or wax, then with collodion on which is put a layer of gelatine, and on the latter the sensitive emulsion. Sometimes the plain gelatine is omitted. When using the above film the paper is not removed until the picture is finished. It has also been proposed to produce photographic films by using a temporary support, such as waxed paper, which is first coated with soluble gelatine, then with algin, which is afterwards rendered insoluble, then with the sensitive emulsion, each coating being dried before the next is applied. In this case the paper backing may be detached from the film at any time by treatment with warm water; but no mention is made of the use of collodion or celluloid in the preparation of this film. Photographic films have also been prepared by spreading a collodion compound upon glass plates, on which, when dry, the sensitive emulsion is applied. I therefore lay no claim to the various methods of forming photographic films above referred to, nor do I claim any of the steps of the process herein described separately considered.

What I claim is: A transparent flexible film for photographic purposes composed of a nitro-cellulose compound, with a coating of insensitive gelatine on the one side, and a coating of sensitive gelatine emulsion on the other, made in continuous or long lengths or webs upon a temporary paper support, which is removed from the film before use of the latter, substantially as herein described.

5,436. *April 10th*, 1890.—"The Exhibition of Photographs." JOHN DEWE, now residing at the Hotel Métropole, Northumberland Avenue, London, Gentleman.

This invention is for an improved apparatus for the exhibition of photographs or other pictures, by exposing them to a strong light, and throwing on the back certain shades and colours, so as to enhance the perspective and scenic effects, as viewed from the front. It consists—

1. Of a frame adjustable (by hinges or other devices) to any required angle firmly fixed on a substantial stand, in the lower portion of which may be placed a drawer.

2. Of a removable shade which can be attached to the top of the frame, so as to exclude the light, and to give effect to the picture placed in the frame, as viewed from the front.

3. Of sliding panels on each side of the frame, and at the top of the frame, so that the opening can be adjusted to the size of the picture or photograph to be exhibited.

4. Of arms attached to each side of the frame, projecting backwards from the front, and furnished with notches, holes, or rings, for the purpose of holding wires on which can be suspended coloured media or shades; the arms being capable of elevation and depression, and adjustable to any angle that may be required.

5. Of a metal reflector or frame, on which reflecting surfaces can be placed, hinged on to the lower part of the back of the frame, and adjustable to any angle that may be required, by means of a cord or other mechanical device worked easily from the front of the frame.

6. Of a second metal reflector or frame, on which reflecting surfaces can be placed, hinged on to the end of the reflector above-described, furthest from the frame, and adjustable to any angle that may be required, by means of a cord or other mechanical device worked easily from the front of the frame.

7. The pictures or photographs to be exhibited should, as a general rule, be made transparent, although this is not in all cases required. They may also receive, in certain cases, a slight colouring at the back, either by paint, or by the attachment thereto of transparent paper, on which the colours could be painted or chromographed.

14,189. *September 9th*, 1890.—"Films for Use in Photography." VICTOR PLANCHON, Boulogne sur Mer, France, Chemical Engineer.

My invention relates to films for use in photography, and is designed to afford a support for such films, and thus render the same rigid, and keep them extended during the operations to which they are subjected.

According to this invention, I add to the film at any moment in its manufacture thin, rigid, and narrow frames, which form a body with the film when they are finished, and serve not only as supports, but also as extenders. These frames may be rectangular or circular, or they may be of elliptical or any other suitable form, whilst their size varies with the different sizes of apparatus employed in photography. The thickness of these frames can also be varied. They may be quite plane, rounded, slightly stamped at their edges, or partially hollowed or perforated; they may, if desired, be varnished or coated with any substance which is susceptible of augmenting its adhesion to the film, preventing their oxidation and their chemical action upon the substances which constitute the film, or obviating their alteration in photographic baths.

It will be understood that I do not limit myself to any form or size of the said frames, the mode of manufacture employed, the means of applying them to the films, or to the substance of which they are made, which may be of any metal or alloy, or any other rigid substance.

The above-described frames are employed in the course of the preparation of the films made by known processes. They are fixed by simple contact, pressure, or by means of an adhesive substance provided upon or between the layers which constitute the film. These layers are formed of gelatine, gun-cotton, albumen, glycerine, varnish, fatty substances, or other translucid or transparent substances, modified or not by physical or chemical agents which are sensitive or insensitive to light, these substances being employed alone or mixed with each other.

The application of the frames is effected prior to the evaporation or oxidation of the liquid or syrupy agents employed, such as water, alcohols, ethers, oils, benzine, and any other volatile or siccative liquids, in such a manner that the substances hereinbefore referred to are applied in a humid, swollen, or pitchy state to the sides of the frames, and will cause their intimate adhesion. The frames may be fixed by one of their surfaces, or put between any two successive layers.

In practice, the operation may be carried out in the following manner, which, however, I describe only by way of example, as I do not limit myself to the same: Upon any even surface which has been provided with talc, collodion, wax, silicate, or the like, the substances constituting the film are spread by mechanical or other means; then either before the total evaporation of the solvents, or when the said substances are still in a humid, swollen, pitchy, or molten condition, the frames are applied and fixed in the manner above described. After their complete desiccation the frames will retain the film and keep it rigid and smooth. The films thus directly extended are of very small weight and volume; they can undergo the necessary operations, such as exposure, developing, and fixing, without any more inconvenience for the operator than if glass or prepared plates were used.

What I claim is:—The application to photographic films of rigid frames forming one therewith, the said frames being designed to afford supports for the films, and thus render the same rigid and keep them extended during the operations to which they are subjected.

## Correspondence.

### THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Sir,—Will you kindly allow the committee of the above Association to thank, through the medium of your pages, those ladies and gentlemen who so kindly gave their services, vocal and instrumental, at the very successful entertainment on Tuesday, March 3rd. With reference to the demonstrations on "Colour Polarisation" and the "Lantern Microscope" which were alluded to in an announcement during the evening, they will be given on Thursday evenings during April by Messrs. Debenham, Haddon, Briginshaw, and Freshwater. All interested are invited to attend.

The Hon. Sec. L. & P. P. A.

*The Champion Hotel, Aldersgate Street, London, March 4th.*

The London and Provincial Photographic Association.—March 12th, lantern night; March 19th, demonstration on "Gelatino-Chloride Paper," by Mr. J. Howson; March 26th, "High Speed Shutters," by Mr. A. S. Newman.

A Photographic Entertainment.—Last Tuesday night the London and Provincial Photographic Association had a convivial meeting at which about 250 persons were present, and in which songs, recitations, and music were intermixed with popular scientific experiments. Mr. Debenham mixed red and green lights to show that by physiological illusion they would produce a yellow, indistinguishable by the eye from the true yellow of the spectrum. Mr. Briginshaw's demonstration of certain phenomena of polarised light was warmly received, and Mr. Freshwater and Mr. Wellington lent much apparatus for the production of various optical results exhibited. Among those who took part in the entertainment were Miss Jessie Drage, Miss Rosa Lake, Messrs. E. W. Parfitt, F. A. Bridge, P. Everett, A. Cowan, C. H. Cooke, J. S. Teape, F. P. Cembrano, jun., J. D. O'Connor, Russell Ward, H. M. Hastings, S. T. Chang, A. S. Newman, and H. D. Atkinson.

A Photographic Exhibition in New York.—The Fourth Annual Exhibition of the Photographic Society of Philadelphia, the Boston Camera Club, and the Society of Amateur Photographers of New York, open to all photographers—American and foreign—will be held under the auspices of The Society of Amateur Photographers of New York, at the Fifth Avenue Art Galleries, New York, U.S.A., May 25th to June 6th, 1891. The agreement heretofore existing between the New York, Philadelphia, and Boston Societies, to hold annual exhibitions under joint rules and a joint management, was cancelled in October, 1890, and a new agreement adopted whereby exhibitions are to be held in rotation annually in the respective cities, but under the exclusive management of the local society, and under such regulations and rules as it may adopt. Medals or diplomas will be issued in the name of the society holding the exhibition. The board of directors of the Society of Amateur Photographers in October, 1890, appointed a special committee of arrangements, to select judges, and manage the exhibition to be held in New York, May 25th to June 6th, 1891, inclusive.

## Proceedings of Societies.

### London and Provincial Photographic Association.

*February 26th.*—Mr. W. H. Harrison in the chair. Presentations to the library were made by Mr. G. P. Harris. A circular was read from the president of the Toynbee Camera Club, inviting a representative of the Association to attend the forthcoming meeting to be held at the rooms of the Photographic Society of Great Britain. A resolution was passed appointing the Hon. Secretary as a representative of the Association.

Mr. A. Cowan showed results with several developers when used with bromide paper—eikonogen and hydrokinone, singly and in varying proportions, in combination with carbonate of lithium. The best results were obtained with the following developer:—

| | |
|---|---|
| Eikonogen ... ... ... ... | 4 grains |
| Sulphite ... ... ... ... ... | 16 ,, |
| Carb. lithium ... ... ... ... | 2 ,, |

to the ounce. The times of development varied from three to ninety minutes.

Mr. A. Haddon exhibited two sealed tubes, one containing eikonogen, water, and air; the other eikonogen dissolved in boiling water and allowed to cool before sealing. Both tubes were subjected to the temperature of boiling water. The contents of the first-named tube turned black in five minutes. The treatment in the case of the second tube was continued for three hours without in any way changing the colour of the solution.

### The Bath Photographic Society.

*February 25th.*—Annual meeting, Mr. W. Pumphrey in the chair. The Rev. C. Reay Pughe was elected a member.

The Secretary read the report, in which the committee congratulated the members on the success that has continued to attend the operations of the Society. During the winter months of the year, the meetings of the members have been well and regularly maintained, and many communications of great interest have been made. During the summer months various excursions were arranged and carried out. A list of the places visited, and also of the papers communicated to the Society at its various meetings, was submitted, which have been duly chronicled in these columns from time to time. The report continued: "Since our last report, the arrangements with the Royal Literary and Scientific Institution, which were then in progress, have been completed, and we have now, in addition to the dark room in the basement of the building, a convenient room for a library, and for meetings of committees, while our ordinary meetings are held in the large lecture room of the Institution. Some addition has been made to the library of the Society, and now that we have a suitable place, we should be glad to receive any contribution of books that may serve to illustrate either the history or the practice of the photographic art. Well-arranged photographs of Bath and its surroundings—a good series of the points of geological interest in the district—incidents in the progress of our city, which would serve as mementoes in the time to come, would be of great value, and ultimately make our library a credit to the city." The present number of members is eighty-one; in the course of the year there have been seven resignations and twenty-one elections.

The Treasurer's statement showed that the Society is in a sound financial position.

The Chairman, in moving the adoption of the report, said that it was a very satisfactory one. The Photographic Convention, he said, intended visiting Bath in July, when he hoped a very cordial welcome would be extended to the members of that body.

The motion was seconded by Mr. Braham, and accepted.

The election of officers then took place, with the result that all who served last year were re-elected.

The Chairman announced the forthcoming Exhibition at the Crystal Palace, and spoke upon the good work of the Benevolent Association, prospectuses of which were on the table.

Apparatus and views were submitted by several members, after which Mr. WELLS discoursed on the subject of "Lantern Slide Making." The speaker, in opening, said that, before entering on the main subject of lantern transparencies, it might be as well to briefly glance at the history of the optical—or more generally designated magic—lantern. That its origin dates far back was obvious, for Kircher, in the fifteenth century, described a lantern of which the fundamental principles were similar to those of the present instrument. Until the middle of the present century, the optical lantern was used as an amusing toy for children, but with the development of science it became so much improved, that people of mature growth delighted in witnessing the exhibition of its pictures. The transparencies first used were of the crudest kind, being mere daubs in transparent oil colours of comic subjects, but, as the lantern became more popular, the public exacted better work in the pictures shown, and artists of repute began the painting of slides which were really works of art; but even in these there was a coarseness in the detail that compelled the slides to be of large size—some which were shown on the screen being 6 by 6 inches—to attain anything like sharpness. Until the introduction of the limelight by Lieut. Drummond, oil had been the only illuminant, and enlargements of small diameter only could be shown; but with the new light a fresh power was in the hands of the operator, and the piercing rays of the incandescent lime showed up the defects of the hand-painted slides. It was then that the introduction of the wet collodion process by Archer worked a revolution, and photography stepped in to the aid of the lanternist. By its aid reduced positives on glass were made from large negatives which were full of detail and rendered the most charming enlargements, everything being sharp and clean. The size was then reduced, and large condensers used, the standard size of slide now being $3\frac{1}{4}$ by $3\frac{1}{4}$. (A wet plate slide was then projected on the screen.) The lecturer next dealt with the various processes for slide-making, mentioning Barnard's litho transparencies, the Woodburytype, the Aristotype, gelatine chloride, silver citrate, and the gelatine bromide. He said that the introduction of dry plates had worked a reformation in the lantern, for now tourists can carry a small camera with them on their travels, and reproduce on the screen the beauties of spots visited, to the entertainment and instruction of their friends. Mr. Wells then practically demonstrated the making of a slide by contact, the same being made and developed and shown on the screen—pyro-ammonia developer and Thomas's plates were used. Reduction was next treated, and after explaining the kind of negative most suitable, the lecturer made a reduction by magnesium light. Exposure was then treated, and examples shown of over and under-exposed, and over and under-developed, plates. Varieties of colour by exposure, and modifications of development, were explained and shown on the screen. A few plates made recently by Mr Wells concluded the demonstration. During the delivery Mr. Pumphrey vacated the chair to manipulate the oxy-hydrogen lantern.

Mr. BRAHAM, who filled his post, moved a vote of thanks to the lecturer.

### THE RICHMOND AMATEUR PHOTOGRAPHIC SOCIETY.

AT the meeting on Friday, the 27th ult., Mr. C. H. DAVIS in the chair, the accounts of the recent lecture by Major J. Fortuné Nott were submitted, showing a balance of £4 available for the Richmond Hospital.

Failing a promised demonstration, there was no special subject on the programme, but an interesting discussion took place, turning chiefly upon devices in the development and mounting of lantern slides.

### THE SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE proceedings at the meeting held at the Masonic Hall, Surrey Street, on March 3rd, with Mr. B. J. TAYLOR in the chair, included the election of new members; the exhibition of prize medal lantern slides of views in Switzerland, Italy, Scotland, Yorkshire, and other places; and selections of vocal and instrumental music.

### THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE annual meeting of this Association was held on Friday last, the PRESIDENT in the chair.

The report of the Committee, recently published in these pages, was read and unanimously adopted.

The following officers were elected for the ensuing year:—*President*—Mr. J. Traill Taylor; *Trustees*—Captain W. de W. Abney and Mr. W. S. Bird; *Committee*—Messrs. W. Bedford (chairman), W. Benham, R. P. Drage, F. H. Berry, T. E. Freshwater, G. T. Harris, A. Mackie, J. S. Rolph, H. D. Atkinson, J. D. O'Connor, Parfitt, and Hudley; *Honorary Solicitor*—Mr. W. Benham, 4, Great James Street, Bedford Row, W.C.; *Treasurer*—Mr. John Spiller, F.I.C, F.C.S.; *Honorary Secretary*—Mr. H. J. Beasley, 65 and 66, Chancery Lane, W.C.

### THE BRECHIN PHOTOGRAPHIC ASSOCIATION.

*March 3rd.*—Mr. G. MACKIE in the chair.

Mr. J. C. MIDDLETON gave an address on lantern slide and transparency colouring, and strongly recommended the members to finish their slides with colour.

Mr. Ross, in moving a vote of thanks, said that he was not greatly impressed with the ordinary commercial coloured slides, and thought that good plain slides were better than most of the coloured slides in oil.

Bailie LAWRENCE then exhibited some slides of American and South African views.

### THE GREAT YARMOUTH AND EASTERN COUNTIES PHOTOGRAPHIC SOCIETY.

AT the meeting held on the 3rd inst., one of the principal features, after the election of several new members, was the adoption of a circulating portfolio amongst its members. Each member would be entitled to send not more than two unmounted prints, irrespective of size up to 15 × 12, with full particulars of the work to be written on slips to be provided by the Club. The portfolio to be sent to the members in the rotation in which their names appear on a sheet attached thereto. Each member to be responsible for sending it on to the next, after retaining it for not more than two days. A criticism sheet would also be attached for members to write their criticisms upon.

The President (Mr. ARNOTT) offered a silver medal for the member who should obtain the best criticism during the year, and Mr. HARVEY GEORGE (the secretary) promised a second silver medal for the second best contributor.

Mr. JOHN HOWSON then gave a description of various photographic papers and plates, and gave a demonstration of the methods of manipulating the same. A number of lantern slides to illustrate the results of the various processes was passed through the lantern.

It was decided, upon the proposition of Mr. RUMBOLD, that the first outing of the Society should take place at Easter.

### THE WEST LONDON PHOTOGRAPHIC SOCIETY.

A MEETING was held at the Broadway Lecture Hall, Hammersmith, on February 27th, Mr. W. A. BROWN in the chair.

The SECRETARY read a letter from Mr. Biden requesting the Society to send a deputation to a meeting he had convened to consider a scheme for federating the various societies, and other matters. It was decided that the President, the Hon. Secretary, and Mr. Hodges be requested to attend the meeting, but not to pledge the Society in any way.

It was decided that the Society enter for the Crystal Palace challenge cup, and that the members be requested to send pictures to be selected from by a committee of the council.

### THE BIRMINGHAM PHOTOGRAPHIC SOCIETY.

*February 26th.*—At a meeting held in the Midland Institute, Mr. ALEX. TUCKER, C.E., occupied the chair.

Mr. G. A. THOMASON said, in reply to a question, that he had made enquiries, and found the art of ceramic enamel was extinct in the United Kingdom, and that they were made in France principally.

Mr. H. M. SMITH (Eastman Co.) said that Mr. A. L. Henderson, of London, had made them for years, and no doubt he could give some information on the subject.

It was asked whether it were cheaper to buy bottles of compressed oxygen and hydrogen, or to make oxygen and use the usual coal gas, and bags, and pressure boards?

Mr. W. J. HARRISON said that, at present, although the bottles are handy, they are costly, and there is the difficulty and also delay in getting them filled. The Midlands will, however, soon have a factory at Saltby, where compressed gases can be obtained; till then, he should advise members to defer having bottles of gas, and to use the bags.

Mr. A. J. LEESON gave a paper on "Photographic Shutters." He said that the object of the paper was to bring before the members some of the different shutters at present in the market, with explanations of their mode of working, and, in some of the fastest, giving the speed as tested by himself and Mr. Jerome Harrisou, at the invitation of Mr. Underwood, who has brought out a shutter-testing chronograph, which was worked with an "Otto" gas engine. The shutter registering the highest speed was Marion's (Bain's patent) "Crown" shutter, which gave a speed of $\frac{1}{150}$ second; the "Caldwell" shutter gave $\frac{1}{100}$ second; Underwood's plate shutter gave $\frac{1}{100}$ second; "Kershaw" ($3\frac{1}{10}$ inch aperture) gave $\frac{1}{75}$ second; Underwood's "Instantolux" gave $\frac{1}{60}$ second; Shew's Eclipse gave $\frac{1}{60}$; Thornton Pickard gave $\frac{1}{60}$ second; "Voigtlander's Sector" gave $\frac{1}{35}$ second; Thornton Pickard (double blind $2\frac{1}{2}$ inch aperture), gave $\frac{1}{38}$ second; Sands and Hunter's gave $\frac{1}{38}$ second. Other shutters were exhibited, made by Messrs. Wratten and Wainwright, Wray, Marion and Co., Thornton Pickard (including the "Fan-break" with their stereoscopic), Shew and Co., Tylar, Place, Underwood, &c., and also the "Guerry flap," Wollaston's diaphragmatic, the new Kodak, &c.

Mr. W. J. HARRISON then gave a short paper on "Instantaneous Photography." He said that Goddard first made instantaneous photography possible in 1841, by his discovery of the extreme sensitiveness to light of silver bromide. Five things were necessary to secure an instantaneous picture viz., a good light, suitable shutter, lens, plate, and camera. The time of the year when instantaneous photography could best be practised was from March to September, and the time of day from about ten o'clock to three o'clock. Speaking of shutters, he said most of his successes had been achieved by means of the "Grimstone."

THE LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

*February 26th.*—Mr. PAUL LANGE, president, occupied the chair. The following were elected members of the Association:—Messrs. Robert W. Hill, James H. Wood, T. F. Lloyd, Thos. Cook, Wm. Cook, J. Bardsley, Mr. Marriott, and Jos. Robinson; Mr. Sinclair was elected an honorary member.

Mr. CADE (Messrs. Marion and Co's representative) exhibited and explained their new hand camera, "The Radial." The evening concluded with a paper and demonstration on "Eikonogen *v.* Pyro," by Dr. Jumeaux, of the Manchester Amateur Photographic Society.

THE PHOTOGRAPHIC SOCIETY.—Mr. William England exhibited a portable tent in which to develop or change dry plates.

THE DARKNESS OF LONDON AIR.—Mr. George White writes to *Nature*:—"Londoners need not be surprised to find black fogs when it is a fact that tons of soot float in the atmosphere every day. Hoping to get some fact on the subject, I collected a patch of snow, equal to one square link, that had lain from November 27th to December 27th last, and from which I obtained two grains of soot. Now, supposing London to cover 110 square miles, it would produce 1,000 tons of soot. Imagine a month's allowance being drawn off in a line by 1,000 horses! The line would extend to about four miles in length."

RECEIVED.—From Mr. E. R. Fletcher, of Edinburgh, samples of an "improved combined mask binder"; they are useful, and save some trouble in binding lantern slides; if the Irishism may be allowed, they are something like metal binders stamped out in paper.

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

The PHOTOGRAPHIC NEWS is the oldest weekly photographic newspaper. See its consecutive number to-day on the front page.

G. G. M. (Edinbro').—*The Pioneers of Photography.* Enquire of Mr. John Werge, 11a, Berners Street, W., who has a capital series of the pioneers of photography, and Robert Hunt's portrait is among them.

J. A. O. (Aldershot).—*Eikonogen Cartridges.* These can be obtained of Messrs. Marion and Co., Soho Square, W.

C. J. K. (Tunbridge).—*Salicylic Acid Preservative.* We should not anticipate any tendency to crystallise out from a gelatine mountant, nor any trouble to arise from its employment in the manner contemplated. Oil of cloves is another antiseptic equally available, and if dissolved previously in a little alcohol, could be stirred in so as to get an intimate mixture. It is only necessary to use a small proportion in either case to protect the gelatine from mildew.

F. ANKER.—*Sulphate of Quinine as a Non-Actinic Medium.* From experiments made and published many years ago, it was proved that quinine only cuts off some of the higher refrangible rays, and therefore could not be used as an efficient substitute for ruby glass. Mr. Crookes took some excellent photographs of variously coloured flowers behind a quinine screen. See the papers of Sir John Herschel, Mr. Robert Hunt, and Mr. Crookes, in the first volume of the *Photographic Journal*; also Sir George Stokes's earlier paper in *Philosophical Transactions of the Royal Society* for 1852; and J. Spiller on "Quinine as a Non-Actinic Medium," in the *Journal of the Photographic Society*, October, 1869. The last was a reply to Professor Morren's communication in the *Comptes Rendus*, in which it was asserted that a cell of quinine solution *could* be used as a substitute for yellow glass in photographic laboratories.

J. C. D.—*Standard Developers.* If you compare the details given by the Altenbourg photographer with Dr. Eder's proportions, as stated in the YEAR-BOOK, 1890, page 54, you will find them to be almost exactly the same, or as quoted in our "Standard Formulæ," top of page 228; so it is immaterial which you use. Do not dilute the developer, but use it as it is, and employ enough to cover the plate well at one sweep. We shall be glad to see your specimens of Australian photo mechanical work.

G. J. S.—*The Dry Weather.* February has beaten the record, and so small an amount of rain as ·02, or even ·01 inch, for the London district is altogether unprecedented, the average being 1·55 inch. The variations occurring during the past four years at Canonbury stand thus:—February, 1888, ·80 inch; 1889, 2·19 inches; 1890, 1·03 inch; and 1891, only ·02 inch; so that there is a wide divergence between the past month and the corresponding period of two years ago, when a hundred times as much rain fell. Damp fogs were prevalent, so that the absence of rain did not bring the best of photographic weather.

G. C. & B.—We note your remark about foreign exchanges the difference in value can yet be arranged between yourselves and our correspondent.

W. S. (Camberwell).—*Reversed Negatives and Dry Collodion Plates.* 1. It may be that you have Colonel Waterhouse's recent discovery in mind, but it is not easy to take a negative from a negative by the wet process, nor a transparency directly in the camera. 2. Would Mr. R. Manners Gordon's gum-gallic process answer for your dry collodion plate which is not to contain any albumen or gelatine?

M. P.—*Feer's Diazo Process.* The chemicals could be obtained from Messrs. Green, Cross, & Bevan, 4, New Court, Lincoln's Inn.

H. W. and F. D. T. received; also W. S. B., Boston, Mass.

CONTENTS.

## THE NEW DISCOVERIES IN HELIOCHROMY.

Some additional particulars in relation to Professor Lippmann's researches will be found in other parts of this issue, but a stage seems to have been reached at which experienced practical photographers can give substantial help. For instance, M. Lippmann has been making extensive use of pyrogallol as a developer, yet this substance is well known to favour the production of yellow and brown images, which are likely to deteriorate the quality of his results. Ferrous oxalate tends to throw down a coarse crystalline image, therefore, under ordinary conditions, may not be the best for his purpose; whilst eikonogen, with its black and white images, and its extremely minute rendering of fine detail, seems to be exactly the substance required, according to M. Lippmann's working hypothesis, which hypothesis is one which commends itself to experienced physicists and mathematicians, and has been long since foreshadowed by two or three of them. His hypothesis requires that a number of faintly perceptible layers shall be superimposed, to give the final result by accumulation.

The organic reactions of collodion are less forcible than those of gelatine and albumen, and not alone does this point to collodion as a suitable vehicle, but it has been asserted that M. Lippmann's most brilliant results have, so far, actually been obtained with collodion. Collodion films in this process will probably need longer and more careful development than others, with, perhaps, a considerable proportion of alcohol in the developers.

Assuming a slight trace of surface fog to exist in M. Lippmann's photographs, momentary treatment with an excessively weak solution of Farmer's reducer might brighten them up. At present the images are developed by the discoverer from the front; were the developers applied from the back the character of the resulting images might be modified for the better or the worse. This points to taking, developing, fixing, and washing them upon plates of polished silver, afterwards applying a layer of alumed gelatine, and then stripping the film, which is easily done.

For present experimental purposes, M. Lippmann's plan of using a mercurial reflecting surface seems to be the simplest and the cheapest. Mr. Warnerke complained at the Photographic Society that he could not get commercial mercury pure enough for the purpose. Such mercury can be purified to a considerable extent by shaking it up in a bottle for a prolonged time with broken iron shavings; certain oxides and other impurities attach themselves to the iron during this scouring operation, and are carried off by the solid metal. Mercury can be to some extent cleansed from oxidised matter floating on its surface, by twisting a sheet of paper into a cone, and leaving a pinhole at the point of the cone, then pouring the mercury through; the latter will come out clean and bright, to an extent depending somewhat on the nature of the physical surface of the particular sample of paper, to which surface oxidised matters will more or less attach themselves, and let the bright metal run through. We have been informed that common copy-book paper, rubbed over with soft chalk, such as is used for drawing on a blackboard, is an excellent thing for cleansing mercury, when the paper is twisted into a cone as already described.

## PHOTOGRAPHIC LIMITATIONS.

Now that spring is approaching, most good photographers will be looking up their apparatus, and looking forward to the happy time when opportunity will enable them to wander with their cameras into pleasant places. The minds of both professionals and amateurs will tend to this direction, and although the latter now outnumber the former, the earnest worker for profit finds his holiday to be no holiday at all unless he carries with him a camera of some kind. Spring brings with it, besides the opening of bud and flower, the opening of many a picture gallery, and the photographer takes a keen pleasure in visiting these, so that he may take hints from art as well as from nature. Indeed, so much is now written about the connection between art and photography that a camera worker is apt to take a great interest in what his brothers of the brush and palette are doing.

True it is that much overstrained language has been devoted to the connecting link between the work of the artist and that of the photographer, and anyone ignorant both of painting and photography, after reading some of these highflown compositions, would be apt to think that the owner of the camera has his subjects as much under control as he has who guides the brush. But experienced photographers know well enough that there is a very definite limit to their power. They may make careful study of a landscape, or any piece of still life, and, by choosing point of view, and the best light under which to work, they can arrive at a good result. Some, too—but they are very few—can, by careful grouping, produce a good picture of the *genre* kind. The difficulties of such work have been explained by its best exponent, Mr. H. P. Robinson, and there is no need to dilate upon them here. But to less gifted photographers these difficulties seem to be insuperable, and one of the greatest bars to success is the impossibility of that idealisation which constitutes the power of an artist. The camera worker must, to a great extent, take things as they are, while the artist with pencil can pick and choose, can select such things as he requires, and eliminate others. As a case in point, we may instance a certain photograph, taken by a most capable man, of a busy London street. It is without exception the finest street photograph which we have ever seen, full of that light, half-tone, and general sparkle which one values so much. But artistically it is spoilt by three figures in the foreground, each with the right leg outstretched in the act of walking. The photographer could not have anticipated such an accident, and it would be idle to blame him, but a painter would either have eliminated one or two of the figures, or would have changed their attitudes.

Another difficulty which assails the photographer, and which, as far as we know, has not been commented upon, is suggested by another photograph—a group of cattle—which now lies before us. As that group was originally seen by the worker, it appeared to be a favourable subject for his camera, for some of the animals were standing, some lying down, and the whole was nature itself. But the photograph is far from satisfactory, and chiefly for the reason that the animals look too flat, too much as if they had been cut out of card, and laid against one another. The head of one sticks palpably to the hind-quarters of another, while there is a feeling that the whole would have been much better if each had been shifted to another position. Why did not the photographer foresee the effect which would be produced on his plate? If he had been a one-eyed man he would probably have done so, but the ability of seeing the subject with two eyes conferred upon it the quality of distance, and so separated each creature from its fellow. In the photograph this effect is lost, and the picture is flat and unsatisfactory. Now an artist—such as our veteran cattle painter, Cooper—would have had the power of selecting from that group the animals he wanted, and would simply have left the others out of his composition. In a word, he would have idealised that group.

Such difficulties as these need not dishearten the photographer, but he will do well to recognise them, and to acknowledge frankly their existence. By carefully studying the works of artists who are not bound to produce all that they see before them, he will learn what to aim at. If nature has denied him the power to impart life to his works by the judicious use of figures, let him devote himself to pure landscape. It is the fashion just now to decry such works as representing a lower rung of the photographic ladder, but, in our opinion, a photographic landscape of good quality is a very delightful thing to look upon.

## HELIOCHROMY.

BY GABRIEL LIPPMANN, OF THE INSTITUTE, PROFESSOR OF THE FACULTY OF SCIENCES, PARIS.

My plates have been fixed in hyposulphite of soda; the use of the word "hypophosphite" was a lapse. Some plates, such as those with albumen films, have to be rapidly taken out of the fixing solution, but most plates stand it very well.

Most finished plates have to be looked at by reflected light from the free side of the film. On the other side you see nothing but a copper-coloured image. Lately, however, when working with Taupenot plates, I have noticed that when viewed by reflection through the glass, you see a bright coloured negative image—the red, for instance, appearing as green.

I am sorry that I have so few plates complete yet, and those in such great demand here that I have been unable to send any away. When able to comply with your request for one, I shall do so with pleasure.

The Croydon Microscopical and Natural History Club (Photographic Section).—On Friday, March 6th, Mr. H. S. Fry demonstrated and gave an explanation on "The Uses of Bromide Paper," illustrated by a fine series of examples, both contact and enlargements; some good examples of warm tones, obtained by toning with uranium, were also exhibited, illustrating that bromide prints are not confined to the usual cold grey, when brown tones are required.

Mr. H. S. Mendelssohn.—An evening paper says that Mr. H. S. Mendelssohn, the well-known photographer, arrived in England some twenty years ago as a political refugee. He actually took part in the last rising of the Poles, and when the corps to which he belonged dispersed, only got here after a series of quite marvellous escapes from being taken and shot. He first dodged into Warsaw, where some friends hid him until the vigour of the search after him had subsided. Then one night he had to follow a strange guide through strange fields and lanes until he came upon a waggon, in which he was driven to his next hiding—seemingly a hay-loft—where he stayed some weeks. In the same mysterious way he was moved from town to town until Hamburg was reached. Mr. Mendelssohn has been unable to this day to discover who his friends were. Once in England, his natural talent as an artist was turned to account in the photographic studio of Messrs. Downey. They both saw and remunerated his great abilities, and though he afterwards entered business on his own account, even now the senior member of the firm of Downey is Mr. M.'s close friend. Mr. Mendelssohn has photographed the royal family, and it is safe to say that not a single famous beauty, artist, sporting, or literary man or woman has escaped being operated on by him. Though Mr. Mendelssohn is too much engrossed by his art to take an active part in politics, his early experience of Russian injustice has fixed his sympathies on the side of all who are poor or oppressed. He is naturalised, and resents in a half serious way being called a foreigner.

## PROFESSOR LIPPMANN'S DISCOVERIES IN HELIOCHROMY.

Y FREDERICK H. VARLEY, MEMBER OF THE INSTITUTE OF ELECTRICAL ENGINEERS.

'he renewed interest taken in the subject of photographing 1 natural colours is due to the highly philosophical and ıgenious way in which Professor Lippmann has devised a ıeans for the solution of this problem, means so apparntly clear and simple that one cannot fail to foresee that, t no very remote period, their application and employnent will be so far developed as to render it a practical rocess entitled to enter into the domain of every-day hotography. And why not?

The requisite conditions are:—First, a film highly ensitive to all the colours of the spectrum: secondly, the lm to be as transparent as possible, in order that the ıcident and the reflected light shall be of nearly equal ıtensity, and for the bettter formation of the superposed eflecting layers, each a half-a-wave-length thick, in the ody of the film; thirdly, a perfect reflecting surface in ptical contact with the film; and when the conditions ave been fulfilled, and the plate exposed, fourthly, then omes the question of a suitable developer, which will loubtless prove to be one which reduces the silver in right reflecting deposits. These conditions are not eyond the prospect of reasonable attainment.

From M. Lippmann's paper, read before the Academy f Sciences, Paris, on February 2nd, one can gather all he main features of his discovery, and we learn why it is o essential that the sensitised film should be, at the time f exposure, in optical contact with a perfect reflector. 'or convenience, mercury is used by the inventor, but here is no reason why a surface of polished silver—a much etter reflector than mercury—might not be employed dvantageously.

The function of the reflecting surface is to turn the 'aves of light back upon themselves, and to cause intererence with the incident waves, by which a series of zones r planes of luminous activity is set up at half wave-length intervals in the body of the film; it is in these zones or planes that the latent image is formed, the number and thickness corresponding to the half wave-lengths of the colour producing them. These zones or planes are, of necessity, formed at the half wave-length, because, if the reflected wave be one length behind the incident wave, total absorption of undulatory energy occurs, whilst at the half

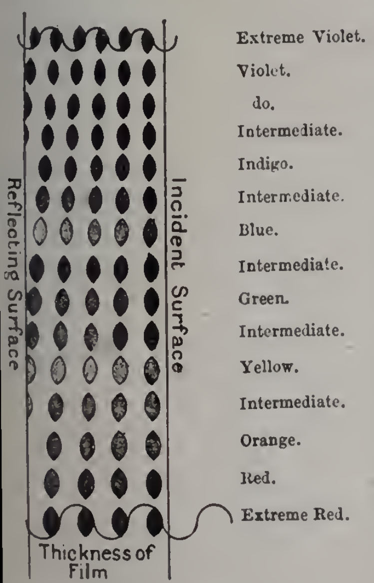

*Fig.* 1.

vave-length it adds its energy to the incident wave. t is here, then, that we expect to find the silver reduced by light. M. Lippmann considers that, in photographing the spectrum, the layers of silver are continuous, and not divided into gratings. I believe that we shall find, when we have the means of examining the deposits, they are not only arranged as a series of horizontal plates one above another, but that they are really divided into separate zones forming vertical gratings.

Fig. 1 is a diagram of layers and gratings made up of half wave-length interference zones, corresponding with the photo-molecular reaction deposits set up in the sensitive film, and is constructed to represent wave-lengths for the entire visible spectrum, and which, I believe, somewhat approaches the correct form of the several maximum deposits, as if seen at right-angles to the direction of the light-waves.

Fig. 2 shows the zone of light energy formed by the interference of the two waves. In the continuous spectrum the dotted line represents the reflected ray; the continuous line the incident ray; the dark nucleus the area of maximum silver deposit; the grey portion, fringes. The zones overlap and form a secondary series of interferences tending to scatter and not compress the molecules constituting the deposit. Thus, zones are produced in the direction of the wave constituting the nucleus of the deposit, and forming, by superposition, columns of gratings in the film, the so-called layers only being formed by lateral displacement at right-angles to the direction of compression.

Silver Deposit

*Fig.* 2.

Where these zones overlap, as in fig. 3, forming a continuous layer at the points of secondary interference, the deposit would be scattered, and thus the layer would be formed of a series of hills and valleys, the valleys being more transparent in consequence of the scattering of the deposit, whilst the hills would be proportionately opaque by their greater density, arising from concentration within the zone of luminous activity.

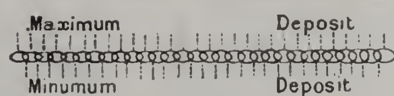

*Fig.* 3.

The photograph of the continuous spectrum in its true colours is a case not only of superposed thin layers in the body of the film, but is also due to vertical gratings.

All credit is due to Prof. Lippmann for furnishing a new physical proof of the correctness of the undulatory theory of light, by which he has obtained silver deposits which correspond to the figures Faraday produced from sonorous vibrations, by employing lycopodium powder to show the zones of maximum disturbance in the air.

In conclusion, I may add that M. Lippmann, in reply to a communication of mine, dated March 2nd last, says, ". . . . I am of your opinion that the thicker the film, the brighter the colour, up, perhaps, to a certain maximum, but I consider each separate layer of silver to be continuous, and not forming by itself a grating."

This letter was in response to the arguments I set forward in favour of the grating theory, and also in regard to the brilliancy of the colour increasing with the number of superposed reflecting surfaces. I hope soon to have the experimental proof one way or the other.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

Photography in Colours—Vitrifiable Photo-Collographic Prints—Photo-Collographic Blocks on Zinc—Orthochromatic Plates Sensitive to Red—Ilford Lantern Plates—Exposure Shutters—Double Action Finders—Collodion Emulsion Prints—A Kite Camera—Forgery of Bank Notes.

*Photography in Colours.*—The sensation which was made on the occasion of M. Lippmann's discovery has hardly quieted down. It may be said that the thing has travelled all over the world; it has been everywhere talked of, and often in the most fantastic manner. As we have already said, it is, for the present, a question of pure science, and it cannot yet be known whether, on the facts brought forward, any application may arise, either artistic or industrial. What appears to be probable is that the results obtained by Messrs. Becquerel, Nièpce de St. Victor, and Poitevin were only due to phenomena identical with that of which M. Lippmann has just furnished such an interesting demonstration. It remains to be seen what can be done with composite colours, and no one can as yet predict anything in this respect. This question of colour is very ardent just now. There are in Paris three distinct concerns based on processes or methods having for their object, not the reproduction of colours, but photography with colours. The public, which is not yet sufficiently initiated into a knowledge of this kind, always sees beyond what exists, and immediately believes that the thing has come to pass. We hear a door-keeper relating how his own son, a schoolboy, has had his portrait taken, and that the buttons on his tunic have shown in copper, whilst his watch-chain has come out in real gold. We were informed only yesterday that an inventor had discovered a means of printing in three colours on the same plate at one impression. We saw a result said to be thus obtained which puzzled us. It was evidently a collographic print. According to the statement made to us, the inventor passes three rollers over the same plate, which is endowed with different chemical affinities—those places which have to be blue will only take the blue ink, &c. This explanation did not satisfy me. Nevertheless, the print examined was curious, and it certainly exhibits a new method, and one apart. If I succeed in finding out anything more about it, I will return to the subject.

*Vitrifiable Photo-Collographic Prints.*—The French Photographic Society had a very interesting meeting on the 6th of March, under the presidency of General Sebert, in the absence of M. Janssen. The beautiful specimens of photographic enamels presented by M. Raymond, the author of the process of collography on parchment of which M. Warnerke has spoken, were particularly remarked. By the aid of his photo-collographic process, he prints proofs in fatty ink in which he has incorporated ceramic colours. The printing is made upon paper covered with a coating soluble in water, such as gum, tapioca, or other analogous substance. The image is afterwards attached by an adhesive varnish to porcelain or pottery. The paper is removed by immersion in water, and, finally, the picture is fired. The process is destined to render great service to ceramic photography. By the aid of inks of various colours we may also produce polychromatic vitrified images. Up to the present, attempts in this direction have only given very feeble images after firing. Those of M. Raymond, on the other hand, present remarkable vigour.

*Photo-Collographic Blocks on Zinc.*—Without leaving photo-collography, which is now taking a more important place than ever, we come to the collographic blocks of M. Balagny. These are pellicles of gelatino-bromide of silver cemented to sheets of zinc, which may be fastened by nails to blocks of wood, as is done with galvanotypes. Up to the present, M. Balagny has not used these blocks for printing simultaneously with an imprint, but this can be done, and I shall certainly succeed in making use of photography in this direction, as I pointed out myself at the meeting of the 6th of June, 1879. We are convinced that, by reproducing on gelatine grained or network negatives, so as to obtain places absolutely black and absolutely white, very good results may be obtained, printing simultaneously the collographic image and type. It is, however, necessary to cut the block to the size of the design, without having to leave a certain margin all round, and the blocks of M. Balagny will render important service in this direction.

*Orthochromatic Plates Sensitive to Red.*—Messrs. Lumière and Son, of Lyons, whose manufacture of sensitive plates is so well appreciated, have just placed on the market orthochromatic plates of two kinds, one sensitive to yellow and green, and the other sensitive to yellow and red. The fact was brought to the notice of the Society by myself, accompanied by some explanatory details, and by lantern slides. The result of the trials is that I can recommend the orthochromatic plates of Lumière as being excellent. Those sensitive to yellow are of about the same sensitiveness as their ordinary plates, and as good as those of other makers who produce good ones. I only call particular attention to the red-sensitive plates. This kind was wanting; commercial orthochromatic plates, generally speaking, only exalt the sensitiveness to yellow; the red, on the other hand, coming out no better than with ordinary plates. With these sensitive-to-red plates used with a yellow screen, I succeeded in obtaining, even with the most intense red, the true effect of normal vision. If an orange-red screen is used, we suppress the action of the blues, even the light blues, and we may push the effect of red to the extent of rendering it white in our positives. The example which we forward to the editor of the Photographic News will give a convincing proof of this statement. It results from the initiative taken by the house of Lumière that orthochromatism will not be long in taking its place in the current practice of photographers in France, professional and amateur. Farther, it alone is capable of attaining the highest results, since it is the only means for rendering the entire gamut in reproductions of many-coloured subjects.

*Exposure Shutters.*—New shutters do not fail to appear. This time it is one by M. Chavanon, very simple, and working both for time and instantaneous exposures. Then there is one by Messrs. Hanssen and Co. for binocular work. It is a copy of an American model marvellously adapted for binocular use; it gives instantaneous exposures that may be repeated without touching the apparatus.

*Ilford Lantern Plates.*—M. Moltani showed some lantern slides on Ilford plates giving black tones. These slides shown on the screen were much admired. There were some beautiful landscapes by M. Moltani, and an interesting series of Dahomian women, photographed by M. Bucquet in the Jardin d'Acclimatisation, in Paris.

*Double Action Finders.*—Several double action finders ere shown. They allow of the image being seen either the horizontal or vertical plane, as may be required.

*Collodion Emulsion Prints.*—M. Chardon showed some arming prints on paper coated with collodion emulsion. his preparation is evidently superior to gelatino-chloride silver; it gives images of a solid character, and the rability of the prints is probably greater.

*Photographs taken by a Kite Camera.*—Photographs taken the aid of a kite camera were presented to the Society M. Wanz. We have here, evidently, a means of taking otographs from a great height without having recourse a balloon—a costly, complicated, and, consequently, fficult thing.

*Forgery of Bank Notes.*—This does not come from the rench Photographic Society, but from a quarter whence derives great importance, and has made much sensation. . Schlumberger, a chemist in Paris, has published in the *oniteur Industriel* observations relative to the possibility photographing—and, consequently, forging—bank notes. *csimiles* have been shown in support of his statements. . Schlumberger, at the same time, points out how such rgery may be rendered difficult, and even impossible. e Bank of France, to whom the chemist made certain opositions, has not accepted them; it has, indeed, been question whether M. Schlumberger is to be prosecuted account of the publicity given to his directions. The mber of the *Moniteur Industriel* has been seized. The atter is one of great interest from a photographic point view.

## INTENSIFICATION.*

BY CHARLES L. MITCHELL, M.D.

presenting to the Society this evening these few notes intensification, it is not my intention to offer anything w, but merely to call attention to some of the most portant details of an old and well-known process, mely, that with mercury and sodium sulphite.

The following method, many of the details of which re elaborated by Mr. John Bartlett, a member of this ciety, can be depended upon to give satisfactory results every case:—The negative (film or glass) should, after ation, be thoroughly washed and then dried. The dry gative is then placed in a suitable dish, film side up, vered with clean water, the face swabbed over oroughly with a tuft of absorbent cotton to remove air bbles, allowed to soak for a few minutes, then the ter poured off, and sufficient of the following solutiou ured on to cover the plate—

| | |
|---|---|
| Citric acid ... ... ... ... ... | 60 grains |
| Perchloride iron (dry) ... ... ... | 60 ,, |
| Water ... ... ... ... ... ... | 1 pint |

is is kept in constaut agitation over the plate for about inute, then returned to its bottle, and the plate washed der running water for about five minutes. This solu- n can be used repeatedly for a long time before coming exhausted. Its use is twofold: it tends to nove any thin film of fog upon the surface of the nega- e, and also furnishes a groundwork for the subsequent posit of mercury. The plate is now bleached by being ced in the following solution:—

| | |
|---|---|
| Mercury bichloride... ... ... ... | ½ ounce |
| Common salt ... ... ... ... | ½ ,, |
| Water ... ... ... ... ... | 1 pint |

* Abridgment of a paper read before the Photographic Society of ladelphia.

The plate must be frequently rocked while in this solution, and allowed to remain in it until sufficiently bleached. This is regulated by the amount of intensification required. If considerable density is desired, it must be allowed to remain until quite white. This solutiou is then to be poured off, and can be either thrown away or used for several more plates; the best results are obtained, however, by using fresh solution for each negative. The plate is next covered with some of the following solution:

| | |
|---|---|
| Common salt ... ... ... ... | 2 ounces |
| Water ... ... ... ... ... | 2 pints |

This is allowed to remain on the plate for about a minute, then poured off and thrown away, and the plate well washed under the tap for about five minutes. The object of the salt is simply to dissolve out any mercuric chloride remaining in the film, and prevent the clear portions of the negative becoming clogged up with any reduced mercury in the next operation. The plate is now returned to the dish, and a sufficient quantity of the reducing solution poured on it to just cover it. This is made as follows:—

| | |
|---|---|
| Sodium sulphite (cryst.)... ... ... | 3 ounces |
| Acid sulphuric (conc.) 2 drs. or ½ oz., | by weight |
| Water ... ... ... ... ... | 1 pint |

The sulphite is dissolved in 12 ouuces of water, allowed to cool, and then the acid, previously mixed with 4 ounces of water, added. I should say just here to those not familiar with chemical manipulation, that in mixing sulphuric acid and water, the acid should always be poured gently and in small quantities into the water, not the water added to the acid, as in the latter case, owing to the violence and heat of the combination, some of the acid might be thrown in the face of the operator.

As soon as the reducing solution is poured on the plate it commences to turn brown and then black. The operation is completed when the *back* of the plate is perfectly dark, showing no traces anywhere of the whiteness caused by the mercury. The negative should then be perfectly bright and clear, and of a brilliant bluish-black colour. It is then to be placed under the tap, washed for five or ten minutes to free it from all traces of sulphite, swabbed off with a piece of cotton, and set up in a rack to drain and dry. The reducing solution can be used several times until it becomes exhausted, and is then thrown away. It should never be returned to the original stock bottle. This process can be depended upon to yield in every case good and satisfactory results, and the intensification produced is perfectly permanent in character. The main points to which attention must be directed in order to secure good results are these:—

1. All solutions used must be filtered, clear, and free from specks.

2. The negative must have been previously *well washed*, so as to *thoroughly remove all traces of hypo.*

3. The negative must be moistened before the solutions are poured on, so that they will act evenly and uniformly on the plate.

A negative can, if necessary, be intensified immediately after development, fixation, and washing, without being allowed to dry, but in this case the density obtained will not be so great as if the plate had been previously dried.

The partnership between Messrs. Fry and Hayman was dissolved on the 14th January last. Mr. Fry continues the business on his own account, and no change will be made in the style of the firm.

## THE HISTORY OF PHOTOGRAPHY.*

BY DR. J. M. EDER, DIRECTOR OF THE IMPERIAL PHOTOGRAPHIC INSTITUTE OF VIENNA.

The French investigator, Le Gray, comes off badly again in another place in Schiendl's "History" (p. 57). Le Gray put forward the view that the application of pyrogallic acid to photography was, owing to Regnault's discovery, a French discovery. Herr Schiendl thus refers to it (p. 57): "To this phrase I will observe, that although Professor Regnault is the discoverer of pyrogallic acid, nevertheless its application to the development of photographic pictures was first recommended by Professor Justus Liebig" (*Ann. Chem. Pharm.*, vol. 1, N.S. page 113).

In this proposition Herr Schiendl falls over two stumbling blocks. In the first place, one ought not to set down the discoverer Le Gray as a "phrase maker"† when one is not in the position to affirm that Liebig actually was the first to recommend the application of pyrogallic acid to the development of photographic pictures. *Regnault* made the discovery independently of *Liebig*, and they happened, as nearly as possible, simultaneously. Without doubt, however, Regnault first brought this developer into practical use. *Schiendl* owes to us the information that Liebig was before Regnault.

In another direction Herr Schiendl, in the part I have just criticised, falls over a hard stumbling block against historical truth, as I will point out. He asserts on pages 56 and 57 of his "History" that Regnault discovered, in 1850, *pyrogallic acid itself*—that is to say, the chemical compound, not its use as a developer, as would appear from the quotation given above. This statement is quite incorrect, for pyrogallic acid was already twenty years before prepared in a pure state by *Braconnot* and others, and recognised as a distinct chemical compound, for before then it had only been regarded as gallic acid purified by sublimation. Braconnot knew that pyrogallic acid reduced nitrate of silver more powerfully than gallic acid. All this can be found translated into German in *Schweigg. Journ.* of the year 1831, and the reader thereby be convinced of the inaccuracy of Schiendl's twice-recurring statements (pages 56 and 57 of his "History").

On page 93, the "historian" in question farther writes that *Hermann Halleur* published a photolithographic process with oxalate of iron in the year 1854. Herr Schiendl places this discovery between Paul Pretsch (1854) and Poitevin (1856), so that the year given, "1854," cannot be a misprint. The author makes the examination of the statement here indicated difficult by not quoting the source; nevertheless, one acquainted with the history of the subject is able to recognise that this arrangement of *dates* is incorrect. The book "Die Kunst der Photographie," by Halleur, wherein this process is described, had already appeared in 1853 (Simon, Leipzig). Herr Schiendl has thus incorrectly put the time of this discovery a year *late*, and *his date*, 1854, must be altered to 1853.

Not so simply to be dealt with is another statement. On page 169 of his "History" Herr Schiendl asserts that H. W. Vogel "published in May, 1884, his colour-sensitive collodion process, *on the foundation of Schultz-Sellack's observations, published in the year* 1871," and cites, in support of this statement, the "Berichte der Deutsche Chem. Gesellschaft" (1871) and "Poggendorf Ann." (1871).

* Concluded from page 180.

† *Phrase macher*, word spinner.

We now meet with the very astonishing fact that the sources on which Schiendl depends *in no way contain one word* that would justify his denial of the independence of Vogel's discoveries. When the sources are examined on which Schiendl in this case depends, everyone must admit that there is *not a word* to be found that takes from Vogel's notable discovery of colour-sensitive photography, or even touches it. H. W. Vogel studied colour-sensitiveness by the goal-reaching method of adding dye to bromide of silver; Schultz-Sellack used the old processes with iodo-bromide and iodo-chloride collodion, *without the slightest addition of a sensitising dye.* On this account the last-named process is quite inapplicable to the production of orthochromatic photographs, whilst Vogel's discovery worked a complete revolution in the photographic reproduction of coloured objects.

I bring forward this example in order farther to show in what an astonishing way Herr Schiendl treats weighty historical questions, and how the confiding reader may be led to suppose that the statements have historical basis, whilst a close examination makes it evident that the quotations of Schiendl are wrongly employed. The great service of *H. W. Vogel*, the discovery of orthochromatic photography, stands so high and unshakable that it cannot be disturbed by criticism of this kind.

The history of the most recent times is certainly difficult to write, that is for one who, on account of his photographic researches, has taken a decided part, and used sharp criticisms, so that further observations on this head may be dispensed with. I think that each word of Schiendl's which he writes concerning the deceased Dr. Monckhoven on page 303, applies in many cases to Schiendl's own work:—"*Moreover, these investigations do not show that impartiality which is indispensable in a scientific work; they seem much rather to be dictated by enmity.*"

It is not without interest to see how Herr Schiendl estimates his own photographic experiments in the historical development of photography. On page 66 *he places himself on the summit* of those experimentalists who sought to increase the keeping properties of wet collodion plates by the use of hygroscopic salts, and says *that he*, Schiendl, first made these researches *in the year* 1853, and that later *Spiller and Crookes* published the process.

Neither in the first case (Schiendl), nor in the latter case (Spiller and Crookes), is any original source of information supplied; the unversed reader will, therefore, if he trusts to the description in this history, give Schiendl the priority. The reader should remember that the author only recognises *priority of which there is evidence*, for he repeatedly asserts this principle. All this, however, is not observed when it is a question concerning himself. Schiendl has neither in the year 1853 nor in the thirty-seven years that have since elapsed, published anything on the matter, whilst *Spiller* and *Crookes* published their method in the *Journal of the Photographic Society of London* in the year 1854. There is not a trace of any confirmation of the statement that Herr Schiendl really employed the same or any similar process *before Spiller* and *Crookes*. It appears to me a very unjust thing, that on the ground of a statement without evidence, *Schiendl* should place *himself* before *Spiller* and *Crookes*, and seek thereby to lessen the credit of the latter for the priority of this certainly unimportant discovery.

The description of the history of the camera-obscura in the book before us is wrong, so far as concerns *Porta*. On this, however, I will no longer dwell, except to mention it as a warning to those who might be depending upon Schiendl's statements. The epoch-making discovery of objectives with great power of light by Petzval, in Vienna, he, with the exception of a mention in the preface, neglects in the most surprising manner; yet farther the name of this illustrious Austrian inventor, whom even the English without envy name the "Prince of mathematical opticians," is wanting in the register of inventors. Only in the frontispiece is the incorrectly spelled name *Petzwal* noticeable. That of Voigtlander is also wanting. The name, too, of *Carl Angerer*, who has done such important service, I have looked for in vain. His influence upon the modern photographic printing-press processes has extended far beyond local bounds, and he has done more towards the development of reproduction methods than many a dozen of the different photographers named by Schiendl.

Upon these omissions and other gaps in Schiendl's "History" I will not further dilate. The characteristics of the work are the decided and positive, yet incorrect quotations from important documents, wrong dates, and internal contradictions, of which I have given some examples. How many such exist in Schiendl's "History" I have not time and space to show. The critical examination of the foregoing faulty descriptions sufficiently show that Schiendl's "History" is no trustworthy and impartial guide. I will not farther weary myself with this dreary history, or take in hand the correction of other faults in Schiendl's book, which can lay no claim to the title of a serviceable "History of Photography."

The paper and printing of the book, however, are good.

*Vienna, February*, 1891.

## PICTORIAL COMPOSITION.*

BY P. H. NEWMAN.

Some one has said, somewhere, some time ago, that "there is nothing new under the sun." Someone was undoubtedly right, in the main, but he was not a photographer, or he would have had misgivings; misgivings, perhaps, not as to the newness of the art of photography, although the last Assyrian clay tablet has not been deciphered yet, nor the last of the Egyptian papyri unrolled, and although the old world goes on making revelations now-a-days in such a quite sensational and *fin de siècle* manner. No, his misgivings, had he been a photographer, I say—especially an amateur—would have been pretty general; he would have believed in most new things for a time, and certainly at least in the last, the very last, new thing, and as the advertisements advise, he would "see that he got it."

Yes, gentlemen, that insatiate and still unsatisfied craver for a new thing; that restless craver, who epitomises in one type the last quarter of the nineteenth century; that person possessed above all people by the demon of unrest, even in our time—the average amateur photographer—wants not only a brand new camera, and lenses which will do everything but think, with plates and developers to match, but he has wanted to make (and believed, at any rate for a time, that he could make) for himself new pictures by brand new rules, and in default of finding these ready to his hand has, now and then, had the temerity to formulate some for himself.

I open my address on pictorial composition this evening to you members of the London and Provincial Photographic Society with this preface because I wish it to be quite understood that I have nothing new to tell you; and if in your midst there should unhappily be one unfortunate possessed in any degree by this demon I have alluded to, as time does not serve for duly exorcising the unrestful spirit, I take the liberty in your interest, and his own behoof, of warning the unhappy being from the room. I have no message for him, and his presence will, while doing no good to himself, only disturb the placidity of those who believe with myself that photography, however new as an art it be, does not give its votaries new eyes, new brains, or new sentiments, but is ruled, like its elder brother and sister arts, by the same laws of pictorial composition we are content to think eternal, and more than suspect are divine.

Pray do not think me harsh in this serious admonition, nor personal in any quarter; bear with me, rather, and support me in my firmness, inasmuch as I know this disorder of unrestfulness is catching, and there is no knowing who amongst us may next take the insidious disease, nor to what lengths it may carry us; our ideas of pictorial composition might get inextricably mixed up with lengths of foci, a complication of the malady I have witnessed which is simply disastrous. I am not going to discuss foci at all—it is not my *métier*; there are gentlemen of eminence amongst you whose high qualifications are admitted and well known, who will tell you much better than I can what lenses will and will not do, and you may rely on their opinions. I will only caution you, however, in one particular, and that is, that some of them having, I suppose, a mild attack, an incipient unrestfulness, are not always quite decided what it is they want their lenses to do. Neither do I want to talk much about paper to-night, although, as I see a tendency lately to traverse and upset my dicta on printing surface, I must not let it pass altogether; my excuse must be, alas! that your art, gentlemen, can scarcely be accurately described as one of the arts of peace; for one of the features of photography is, as you know, that there is pretty generally a paper war going on. I will only say about paper, beware of the unrestful again. The desire to take the shine out of everything—that is no doubt part of our nature—is, under some circumstances, praiseworthy, and I do not at all mind the shine being taken out of paper, provided always you give me an adequate range of values in my shadows; but what I do object to is, that having succeeded in accomplishing a fairly pleasant pictorial composition, you should want me to mar the charm of that composition by making me look at it, so to speak, through a ridiculous reticulation; nothing will make me believe that roughness of surface is not a matter of absolute scale in works of pictorial art with the area of that surface; it were as reasonable to maintain that for a miniature painting, glass paper is preferable to ivory. Tastes undoubtedly differ. I can only regard those as curious which are satisfied only in a cabinet picture when it has the texture and grain of a fresco.

There are those who admire Constable. I am one of them, but I well know that his chief attraction does not lie in the roughness of his technique, a roughness which does not appear necessary when we look, as we do, with pleasure on the not despicable work of John Linnell or Turner. For my own part, while I have no sympathy, as I have shown, with this latest affectation, I look for no improvement in photography from the multiplication of landscapes where the sky appears equally ploughed with the fields; neither would a Venus born from the waves suggest a regeneration of art to my mind, or my sense of beauty and fitness be in any degree edified, however lovely she were in other respects, if that Venus were corrugated and pock-marked, and appeared rising from a pebbly sea. Craving your forgiveness, I say not another word on lenses or paper. Let us get to composition.

Now, I am quite prepared to be met at the outset by the outcry, "What stale nonsense! Whatever worn-out rubbish you may quote from Burnet or Harding, or derive from the old and delapidated masters, you can't take liberties with nature, and shift a group of poplars, a steeple, or a mountain, to suit your pedantic persuasions in photography, as you permit yourself to do in a sketch or water-colour drawing. Best let nature shift for itself," &c., &c. That we cannot do these things in photography that are the licences of the other pictorial arts, let us admit at once; so much the worse for photography, perhaps. But we have to make the best of photography, if possible, to-night, and the best of photography is this, that if you are really in earnest in search of the picturesque, the best photographer—*i.e.*, the man who is the best artist—will, other things being equal, give you the best picture. There is no

* A communication to the London and Provincial Photographic Association.

doubt about it, it is being proved every day. The worst and the best of photography, after all, lies in the man and not in the tools. Then what shall the photographer do? Is he to worship stocks and stones, taking the dross of nature for art, disbelieving that there is a subtle spirit anywhere, that she keeps back, except to the favoured few who know her face to face, and look her through and through, or to those seemingly almost as few who, with no divine afflatus, yet with simple faith and the intellect, such as they have, rubbed bright as God gave it them, will wrestle on any terms with nature for this treasure, and not too proud to profit by some of the counsel and experience of their race, wrest this spirit of art from the bosom of nature, delighting themselves and benefiting mankind?

"The man and not the tools," of course. For instance, look at Jones. "What in the world is Jones doing? He has been fidgetting about amongst those boulders for the last half hour at the risk of his neck and his sticks; he has only taken one shot this morning. I have taken a dozen. Why don't he fire away?" Listen to the hare and the tortoise. The hare's negatives are exuding hypo amongst the "spoilers" on a damp shelf now, but the tortoise has won a medal; for, not having either broken his neck or his sticks, he has, with infinite pains, found the very spot where the church tower comes in just right with the trees, so hence the straggling village creeps down to "the haven under the hill." Ah! and how he waited for the light, too! And it came, as everything comes to those who can wait, just in time to catch the fishing boat with the big white sail before she put to sea. Look how she comes out against the deep shadow, bringing the light down into that corner exactly where it is wanted. See, too, how the hill greyly softens off in the modified light of the lovely afternoon. "Yes, Jones has got a picture; I can't show it you, I regret to say. Why can't I get a picture? I am a better photographer, you know, than Jones," and so on. Well, let us see what Jones is made of, what manner of man he is, now we know what work he can do. And it turns out that Jones perhaps did not take lessons, even in a school of art; self-taught, and that sort of thing. But he was always fond of pictures, and it is said he can tell a Hobbema from a Cuyp when he sees them together, and he has said that he used, when a boy, to copy engravings, old steel-plate engravings—the kind of illustrations, you know, you don't find in books now, photography having improved them out of existence. Jones takes his sister to the Academy for their annual headache, and visits the National Gallery as a religious obligation twice a year. I am told he once borrowed Burnet, and actually possesses a copy of Harding. A curious fellow, Jones. Knowing something of Jones and a little of Harding, I thought I might do worse, perhaps, than bring some of Harding's ideas on pictorial composition this evening, that we might look over them together, for I think that many of the things he points out for the consideration of the painter may be made exceedingly useful to the photographer. Before, however, we try to assimilate and profit by any of Harding's teachings, let us see, as nearly as may be, where we are.

I think most of us will admit that, however simple may be the means of reproducing a scene by the camera, successful composition—in landscape especially—is unquestionably a far more difficult thing to accomplish in photography by an artist, than it is with the brush or the pencil. The most naturalistic photographer, though dangerously near it, has not gone quite so far as to say nature is art; and we are most of us pretty well agreed now that nature supplies the elements of art at our discretion, and in slightly modifying some of nature's arrangements in lanpscape, simple enough with the pencil, the photographer, if he has any art feeling at all, is often very hard pressed indeed to obtain an artistic result with the camera. It is all very well to say, "If the mountain won't come to Mahomet, Mahomet must come to the mountain," but, unfortunately, it is not always easy, but often most difficult for him to get to the mountain; and it is only by long study of composition in art, and considerable tact and practice in the field, that he is enabled to find the right spot to get a tolerable arrangement of nature's elements of beauty, even in very beautiful places. The scene looks so different in the natural vignette of our binocular vision to what it does when you cut a square or oblong out of the picture, and bind it by a hard and fast line with any lens of any angle.

But this is what the photograper has to do, and he stands all the better chance of doing it successfully if he is warned where he is likely to fail, and shown mistakes which the cleverest among us may fall into.

Let us turn now to J. D. Harding, who in his "Principles and Practice of Art," may do something for us with pen and pencil. Harding says:—"In the composition, the painter makes his first effort to convey the idea of the separation of the various objects, and to overcome those difficulties which have been pointed out as connected with the flat surface on which he paints. To effect this, none of the principal or leading features of his picture should be perpendicularly over, or horizontally level with, each other, because, if they be so placed, they either repeat actually or by suggestion the horizontal and perpendicular lines which artificially limit his picture, and which require to be concealed as much as possible from observation. The consequent advantages may be seen by comparing the Examples 1 and 3, 2 and 4, in Plate X. with each other. In Examples 1 and 3 the leading objects and features are so placed that they are neither level with nor over each other, and the expression of space is the result. Here, forgetting the surface and its boundaries, we feel able to penetrate into the pictures and move among the figures, trees, and buildings, to float in the sky, or walk along the ground. In Examples 2 and 4, however, no such feelings are suggested—at least, not by the composition. In Examples 2 and 4, a line drawn across the picture from C to D, and also from E to F, would show that several of the objects are on the same level, and, again, they are perpendicularly over each other. For instance, in Example 2, the church in the distance is over the man in the foreground, who thus appears to be supporting it on his head; the apex of the mountain is just above the spire of the church; and the castle on the hill is immediately over the bridge; each important feature of the distance surmounting another important feature of the foreground; all idea of space between the foreground and the background is, in consequence, negatived. As the artificial boundaries of the picture are thus emphasised and repeated, the flat surface is so continually suggested that the mind cannot free itself from it. If light and shade only were expressive of space, each of the four examples would express the idea of it equally. We, however, fail to obtain in Examples 2 and 4 the same idea of space as in Examples 1 and 3, although all have like advantages in other respects.

The most untutored eye may perceive that their effect is very different, though there has been no change in the features of the scenes, excepting such as was necessary to show the force of what I have brought before the student. Examples 1 and 3 are pleasing, varied, and spacious; 2 and 4 are bad because monotonous and flat; their comparative merits or defects are entirely owing to the composition.

We may take another illustration from Example 2 and 3, Plate XI. In Example 2, the castle is placed so as to come immediately over the basket which the woman carries; and, notwithstanding that the castle is faintly drawn, and small in size, in order to suggest the idea of distance, yet the contradiction given to it by faulty composition prevents it being entertained by the mind. The castle being immediately over the figure, is suggestive rather of the flat surface of a *picture* than of the permeable space of *reality;* but if we hide the castle, we then lose the impression of flatness, and, in its stead, receive the idea that we could walk round the figure. Compare this with Example 3, where the castle is removed to the right. Here we have the full expression of space, and, if we hide the castle, far from receiving in this instance, as in the other, any additional idea of space, we lose it greatly by so doing. It must be observed that the principle of placing the objects on different lines is not gained from a study or imitation of nature, but from an investigation of impressions made by art. Both the examples are equally true imitations of nature, as well in the objects themselves as in their juxtaposition.

(*To be continued.*)

## HELIOCHROMY—A PHOTOGRAPHICALLY DISCOVERED NEBULA.

BY DR. AUG. EISENLOHR, PROFESSOR AT THE UNIVERSITY OF HEIDELBERG.

As you printed in the last number of the Photographic News various interesting articles on photography in natural colours, I write to draw attention to a phenomenon I witnessed in the year 1857, and which I described in the article sent herewith.* Photography being at that time not much cultivated by amateurs in Germany, I learned from a travelling photographer how to make direct positive photographs on a dark glass—red or brown—with a collodion containing iodide of potassium with iodine and bromide, adding ten drops of bromine to an alcoholic solution of iodine. The photographs appeared of a white, silver colour.

When photographing a cousin of mine, who was a student, and wore a coloured ribbon with silver in it, I was much struck upon finding that the real colours appeared in developing, but that they vanished suddenly in the cyanide of potassium fixing bath.

I also send you a photograph of a new nebula in Orion discovered by photography by Dr. Max Wolf, Heidelberg, a friend of mine, astronomer at the University of Heidelberg. The nebula is only to be seen by means of photography, and not in the tubes. The photograph was taken by means of a double objective.

## PHOTOGRAPHIC TOURISTS IN ICELAND.†

BY J. REYNOLDS, M.D., F.R.G.S.

*Slide* 39.—Shortly afterwards we came to a magnificent gorge near Solheimar, on the Laxa River, represented in the slide. We arrived at Hruni 5.45 same day, and next morning (Sunday) at 9 a.m. we started for Gullfoss—four hours' easy ride—in lovely weather. We arrived at this splendid waterfall early in the afternoon, and photographed it.

*Slide* 40.—After examining the waterfall closely, we made straight for the Geyser, where we arrived 5.30 p.m. the same day, after fording a number of narrow, but deep and rapid rivers. Here we found our tents already pitched, and after supper we went out to explore this wonderful place. We saw the Great Geyser rise about forty feet, and the Strokkyr to full height; all the smaller springs—about thirty or forty in number—exhibit a general boil over.

*Slide* 41 shows basin of Great Geyser at rest at 11.15 p.m.

*Slides* 42 aud 43 show two views of Stokkyr in full action.

*Slide* 44 shows a remarkable underground boiling lake called "Blesi," with a portion of the roof broken in, revealing the caves and depths below. I am represented looking into it.

*Slide* 45 gives a general but poor view of geyser region with our tents in the distance.

*Slide* 45*a*.—The next morning, after completing our superficial survey of this extraordinary region, we started for Thingviller, a distance of close on fifty miles, resting on our way, of course, several times. The first place we came to of interest was the "Bruara," or bridge river, so called because a little bridge is thrown across an earthquake fissure in the centre of the river; a reference to slide 45 will show what I mean. We stayed here for luncheon, and, after crossing this bridge, we rode on as rapidly as the very rough road would permit us, arrived at Thingviller at 12 midnight, and then had to stroll about until 2 a.m. because our tents had been delayed in transit. However, we had a splendid supper at the parsonage of fried trout and other things, which made up for all other shortcomings. Thingviller is difficult to describe; it is actually a sunken plain, and the scenery around, the result of past volcanic action, is magnificent. Beside all this, it is a classic place, and has a history of its own. When, at last, our pack-ponies *did* arrive, we pitched our tent in the churchyard, and turned in for the night.

*Slide* 46 shows the parsonage and church in front of which our tent is pitched.

The next morning, July 15th, we took our cameras, and attacked the principal points of interest.

*Slide* 47 shows the spot in the Allmannaljia rift where the Oxara precipitates itself over the lava cliff, and takes a leap of about eighty feet; at the foot of this fall is Execution Pool, where the witches and murderers were drowned.

*Slide* 48 shows the rift itself, with the stream from the waterfall, just shown rippling through it. The scenery in this famous rift is superb, and the colouring exquisite.

*Slide* 49 shows the wild appearance of the extreme west end of the same rift, which consists of banks of lava, boulders, and clinkers.

*Slide* 50 shows the Lögberg, or Hill of Laws, where the old Althing, or parliament, used to meet hundreds of years ago. It consists of a tapering tongue of grass land, bounded on either side and at the end by immense fissures about fifteen to eighty feet in width, and about eighty feet deep. It is said that a murderer named Flosi, in order to escape capture, jumped over this part of the chasm, and hence it is called Flosi's Leap.

We had now come to the end of our very pleasant journeyings in Iceland, and we thought that before we parted company we would photograph ourselves in a group near the parsonage.

*Slide* 51, taken by me, shows such group.

One of our party went to have a day's fishing in the river Sog, and as he bagged thirty-five very fine trout in six hours, he was proud of the feat, and we photographed him presiding over the fish when we arrived back at Reykjavik.

*Slide* 52 shows these fish, which were exceedingly fine eating.

We started from this place July 16th, and arrived at the capital after five and a-half hours' sharp riding; then at once commenced to pack up our belongings in our own portmanteaus again, as we started on our homeward voyage on the 18th in the Danish s.s. *Romny*. We chose this steamer because she called at some of the ports in the Westmann Islands; also at some ports in the Faroe Isles, which we had a great wish to see. We could not, however, land, as there was not time; but we took some shots at the principal towns as we passed, and I managed, although the sea was rough, to get a good view of the Westmann Islands, the next three slides.

*Slides* 53, 54, and 55 will give a general idea of their appearance.

After leaving this group of islands, we went right through the Faroe Islands, and called at Westmannhaven, Klagsvik, Thorshaven, and Trangisvaag. Two of these ports I succeeded in getting a good view of while the vessel was moving, viz., Klagsvik and Thorshaven (the capital).

This completes the list of my views of places taken on this tour; but I have yet another slide. After we left Faroe until we sighted the Scotch coast we saw nothing but sky and water, and it occurred to someone on board to get up a ship concert, so eight or nine of us, including the Danish captain and chief officer, annexed various articles, such as a fog-horn for a trumpet, two tin saucepans for drums, a comb and piece of paper for a pan-pipe, a marling-spike [for a triangle, and a broken-down wheezy melodion, and with this collection we succeeded for some hours in breaking the monotony. While this was going on, I mounted the bridge and photographed them.

*Slide* 58.—Here they are. Now, my lecture being finished, I should like to tell you that I have here, in a case, a few specimens of lava from the crater of Heckla, also some siliceous deposit from the great Geyser; also a few articles of old Icelnadic work; and the *Reykjavik Journal* announcing our arrival.

In conclusion, I most heartily commend a trip to Iceland to those tourists who have the real enjoyment of travel, and who love to contemplate nature in her grandest and wildest aspects.

* The article alluded to is a reprint from Dr. Eder's *Jahrbuch* for 1888.

† Concluded from page 168.

## Notes.

Professor Meldola, in his lecture last Monday night at the Society of Arts, dealt with the problem of the training in this country of a class of photo-chemical specialists. A limited number of such men would be extremely useful in photography, in strengthening the machinery with which men of artistic taste have to work; moreover, such specialists could have certain technical branches of photography entirely under their own rule. No really thorough work is ever done in any branch of human knowledge without the aid of specialists, and the *dilettante* element in society often exercises an influence against such thoroughness. Still, men who are specialists, and nothing more, are not usually of an interesting nature. They know their own little grooves of existence thoroughly, but little or nothing outside them, yet frequently speak authoritatively on subjects outside their sphere, and with which they are not competent to deal. Two or three years ago scientific specialists received a little well-merited attention in pictures in *Punch*. Professor Perry once gave his engineering pupils some good advice, by telling them that when they went forth into the world, they had better, at night, when their work is done, study poetry, music, and other subjects for which they have a natural taste, and not confine themselves to one particular groove of thought. Professor Meldola does not confine himself to chemistry, but is well up in various other branches of knowledge, as the pages of *Nature* testify.

M. Bideaux recently stated at a meeting of the Photographic Section of the Society of Arts and Sciences of the Haute-Saône that he had been trying experiments in the sensitising of silk for positive printing, and had not found much difficulty in the work. A special silk is necessary, very fine in the filaments, hence it is costly. Vigorous negatives he had found to be best for printing upon silk, and they should be full of brilliant detail, otherwise foliage and grass will come out as unpleasant black patches.

Dr. Fischer, of Breslau, says Dr. Vogel, has succeeded in photographing, with their own light, luminous bacteria such as sometimes abound in stinking dead fish. Fischer also has cultivated luminous bacteria of different kinds; some were originally obtained from the North Sea, and when placed upon a cooked herring, the latter will become luminous in forty-eight hours, and can be used in the dark to reveal the time by a watch. Dr. Fischer began photographing luminous bacteria in a dark cellar three years ago; he used one of Steinheil's antiplanats, and gave exposures varying from thirty to forty-eight hours; the plates were exceedingly sensitive. He also succeeded in obtaining a passable picture of a watch which had been exposed for thirty-six hours in "the light of two luminous line-cultures"; the outside of the watch, the dial, with the hands and numbers, could be recognised. He exhibited some of these photographs at the Medical Congress in Berlin. In the days of old, the light of the glow-worm has occasionally been made to register itself upon a photographic plate. The light is rather strong considering its living source; Mr. Gerald Massey once told us that he wrote one of his poems by the light of a glow-worm crawling over the page.

It is the fashion in these days for everyone to write his biography, provided that his name has been at some time or other brought into prominence. In some cases, even an unenviable notoriety is considered sufficient excuse for running into print, as in the recent case of the "Jubilee Plunger." It is not often that any of these volumes are of interest to photographers; but one is about to be produced which is likely to prove an exception to the rule. This is the volume promised by the veteran photographer, Mr. Vernon Heath. Mr. Heath, during his long life, has had acquaintance with many eminent men, and those who know him well say that he is full of anecdotes about past times. It is not generally known that he is a nephew of the Robert Vernon who founded the Vernon collection of pictures, which may be regarded as the nucleus of the National Picture Gallery at South Kensington.

We have heard persons abuse the art of photography because of the many unflattering portraits which they say it turns out, and so it is a crumb of comfort to record an opinion to the contrary. Our contemporary, *Woman*, in a not too kind allusion to "Mr. Stanley's feminine rival," as it calls the lady who is about to enter darkest Africa as an explorer, speaks of her portrait in the following terms:—"The lady has been liberally interviewed, and flattering descriptions of her personality have been scattered broadcast by daily and weekly prints, sometimes accompanied by reproductions of a photograph, which does credit to the skill of Mr. Van der Weyde, and to the inventive powers of his camera."

But there is something more interesting to photographic readers anent this spiteful little notice regarding the lady explorer. It is illustrated by two little pictures—one a profile portrait, which certainly is not a very flattering one, whatever may be due to the inventive powers of the artist, and the other a full-length sketch of the lady equipped with rifle, dagger, and two revolvers ready for meeting any number of savages. These illustrations appear in the issue of the paper dated February 26th, and they are reproduced in the *Evening News* of February 28th. The copies are much coarser than the original, as might be expected in a journal which must be printed at high speed, but they are interesting examples of the tendency in modern newspapers to introduce sketches relating to matters of current interest. At the same time, this copying of such cuts from one paper by another is a practice which is hardly to be commended.

The Ceylon papers tell us that a number of instantaneous photographs was recently taken of a very curious pugilistic encounter, and it is to be hoped that some of the resulting pictures may reach this country. The encounter took place between a cobra and two mongooses (one feels inclined to write mongeese). At first the combatants were loth to begin the attack, but they soon warmed to their work, and then the fight began in earnest. The snake was a splendid specimen of the deadly cobra, but he turned out to be no match for his antagonists, for in the sequel one of them seized him by the back of the head and at once killed him. The photographs were taken while the fight was in progress, and show it at various stages.

It has been reserved for the New English Art Club to initiate a movement in connection with picture exhibitions which is almost certain to be at once popular and remunerative. The exhibition of the Club to be opened in April will be accompanied by a new feature, namely, the sale of photographs and reproductions of works in the gallery. The photographs must be supplied by the artist, who will thus have the satisfaction—or the reverse—of judging of the public's opinion of his work by the number of pictures sold.

The system of having photographs on sale might lead to greater facilities being offered for the reproduction of pictures. A good many studios are absolutely unfit for photographic operations, and the picture has to be removed to the photographic studio, there, probably, to remain for two or three days or more. It is not every artist who cares to trust a valuable painting to every photographer, and specialists in the difficult art of copying are not numerous. If there were attached to the Burlington House galleries a studio built and fitted up with a view to reproductions, which, of course, would be undertaken by skilled operators, the copying of paintings to be exhibited in the Royal Academy would become the rule, and not the exception.

In England, investigations in spectrum work are matters for private enterprise. In America there are funds from which assistance may be derived. Mr. Henry A. Rowland, in an article in *Science* (New York), gives a *resumé* of the progress in spectrum work during 1890, towards which financial assistance has been received from the Rumford Fund of the American Academy of Arts and Sciences, as well as from the fund given by Miss Bruce, of the Harvard Astronomical Observatory, for the promotion of research in astronomical physics; and the advanced state of the work is due to such assistance.

The spectrum work at Harvard may be summed up under the following heads:—1st. The spectra of all known elements, with the exception of a few gaseous ones, or those too rare to be yet obtained, have been photographed in connection with the solar spectrum, from the extreme ultra-violet down to the D line. 2nd. A measuring engine has been constructed with a screw to fit the above photographs, which, being taken with the concave grating, are all normal spectra, and to the same scale. 3rd. A table of standard wave-lengths of the impurities in the carbons, extending to wave-length 2,000, has been constructed to measure wave-lengths beyond the limits of the solar spectrum. 4th. Maps of the spectra of some of the elements have been drawn on a large scale. 5th. The greater part of the lines in the map of the solar spectrum have been identified, and the substance producing them noted.

Bicyclists are already a terror to nervous people, and if they follow the example of their American confrères they will be objects of hatred to local Boards and surveyors. In the United States the wheel-men are offering prizes for photographs showing the condition of the different roads, with a view of stimulating the authorities to do their duty.

There are wanted photographs of the common spectacle of the farmer's team and waggon hub-deep and knee-deep in the muddy road; photographs showing rough, rutty, and muddy roads in their worst condition; photographs showing the every-day break-down, caused by rough or muddy roads or steep grades; photographs showing smooth, hard-surfaced roads, and (if possible) teams hauling loads over the same; and other pictures illustrating the goodness of good roads, and the badness of bad roads. The prizes will be awarded before May 15th, 1891. A similar work performed as to the state of the London streets would do really good service.

A very exhaustive article on that almost inexhaustible subject, instantaneous shutters, appears in *La Nature*. The article is amply illustrated, and describes minutely the peculiarities of each recognised form. The author is M. H. Fourtier, whose concluding sentence sums up in a succinct form the *rationale* of instantaneous photographs. M. Fourtier says he does not desire to under-value instantaneous photography, for it has the advantage of giving to landscapes an animation which they would not otherwise possess, but he believes its function does not go beyond that. We should, therefore, not seek to record the exaggerated swiftness, which simply gives the silhouette of the movement while losing the details.

The apparatus recently constructed and invented by M. Damoizeau permits the photographing of the entire horizon in one short exposure. Until M. Damoizeau's invention there was but one apparatus, that of M. le Commandant Moessard, giving panoramic pictures; and this took in at most but half the horizon, and besides is based on another principle than that of the first-mentioned. Those who would like to thoroughly understand the method adopted by M. Damoizeau may study the elaborate article on the subject which appeared in the *Génie Civil* of February 21st.

## PHOTOGRAPHY IN LIVERPOOL.

THE LIVERPOOL INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

THE International Photographic Exhibition at Liverpool, initiated and carried out by the Liverpool Amateur Photographic Society, was inaugurated last Friday, and will remain open for a month. The Exhibition is a remarkably fine one, and the photographs are displayed in suites of rooms in the Walker Art Gallery, one of the finest public buildings in Liverpool, and situated in the centre of the city. The number of "frames" hung, as set forth in the catalogue, is 1,101, and this means a considerably larger number of individual pictures. A fair show of apparatus is also on view, chiefly the work of local manufacturers. The following are the officers and council for 1891 of the Society which has carried out this large undertaking:—

*President*—Mr. Paul Lange; *Vice-Presidents*—Messrs. Wm. Tomkinson and Joseph Earp; *Treasurer*—Mr. P. H. Phillips; *Council*—Messrs. R. Crowe, E. Roberts, A. Tyrer, J. Woolfall, A. J. Cleaver, W. P. Christian, W. Hughes, J. L. Mackrell, A. F. Stanistreet, Henry Luptou, F. B. Illingworth, aud B. Boothroyd; *Librarian*—Mr. A. Bradbury; *Auditor*—Mr. H. B. Millar; *Hon. House Secretary*—Mr. Thos. S. Mayne; *Hon. Secretary*—Mr. Edw. M. Tuustall, 3, Lord Street, Liverpool.

The following are the members of the Exhibition Committee:—

*Chairman*—Mr. Paul Lange; *Committee*—Messrs. A. J. Cleaver, C. O. Ellison, P. H. Phillips, and Wm. Tomkinson; *Hon. Treasurer*—Mr. A. F. Stauistreet; *Hon. Secretary*—Mr. T. S. Mayue, Fenwick Court, Liverpool.

The judges are Captain W. de W. Abney, Messrs. J. Gale, H. P. Robinson, Andrew Pringle, J. Pattison Gibson, and G. Watmough Webster.

The list of awards is here appended:—

THE LIST OF AWARDS.

| Class. | Medal. | |
|---|---|---|
| 1—Portraits | Silver | (*Withdrawn*) |
| 2—Portraits | Bronze | Harold Baker |
| 3—Portraits | ,, | Window and Grove |
| 4—Portraits | ,, | W. J. Byrne |
| 5—Landscape | ,, | E. Lloyd Edwards |
| 5—Landscape | ,, | F. D'Arces |
| 6—Landscape | Silver | Wm. Tomkinson |
| 7—No Award; Medal withheld | | |
| 8—Landscapes | Bronze | Thos Zacharias |
| 9—No Award; Medal withheld | | |
| 10—Marine and Cloud Studies | Silver | S. Bourne |
| 10—Marine and Cloud Studies | Bronze | Thos. Glazebrook |
| 11—Animals | Silver | Chas. Reid |
| 12—Groups (Outdoor) | ,, | F. M. Sutcliffe |
| 12—Groups (Outdoor) | Bronze | F. Bremner |
| 13—Architectural | ,, | C. Court Cole |
| 14—Architectural (8 × 5) | ,, | G. E. Thompson |
| 15—Scientific | Silver | R. Paulussen |
| 15—Scientific | Bronze | Cecil V. Shadbolt |
| 15—Flash-Light Pictures | Gold | Countess Loredano de Porto Boniu |
| 16—*Genre* | Silver | Shapoor N. Bhedwar |
| 17—Enlargement | Bronze | Chas. W. Huson |
| 18—Stereoscopic | Silver | H. J. Houghton |
| 19—Lanteru Slides | ,, | G. E. Thompson |
| 19—Lautern Slides | Bronze | John Carpenter |

Gold Medal—Ralph W. Robiuson, for his uuique collectiou of eminent artists (which forms so prominent a feature in the Exhibitiou), together with his other work.

On Friday evening last, a dinner to which the Liverpool Amateur Photographic Association invited a number of London and other guests connected with photography, took place at the Alexandra Hotel, under the chairmanship of the president of the Society, Mr. Paul Lange. He proposed the toast of the Queen and the royal family, and followed it with five of a highly practical nature, namely: 1. Everybody is allowed to smoke. 2. Those who wish for coffee, please order the same. 3. Ditto whisky. 4. Ditto kirschwasser or other liqueur. 5. Make yourselves at home. Next he proposed the health of the judges of the pictures, to whom, he said, the success of the Exhibition is largely due; he did not care whether anyone agreed with their decisions or not, but ruled that they were excellent decisions, for a chairman must be decisive, and is no good if he be not so; he therefore assured them that they had better judges than had ever acted at any other photographic exhibition. To this toast Mr. H. P. Robinson responded, and spoke highly of the Exhibition, so also did Mr. J. Gale and Mr. J. P. Gibson. As regards the quality of the photographs, Mr. Gale said that he did not know of any exhibition in which the average of merit had been so high as in that one at Liverpool.

The next toast from the chair was that of "The Presidents of Photographic Societies, and other guests present." Mr. Lange added that among the presidents at the dinner were some from London, Dublin, Manchester, Newcastle, Glasgow, and elsewhere. Without the societies photography would be in a barbaric state, and it would have been in the same state but for amateurs, who had done almost everything in the way of photographic invention and discoveries. To this Mr. Watmough Webster responded, and after a few more toasts, to which Mr. Henry Moore, R.A., Mr. Traill Taylor, Mr. C. W. Hastings, Mr. T. S. Mayne, and Mr. W. H. Harrison responded, the company adjourned to the Exhibition.

Here, at the opening meeting, Mr. C. H. Rathbone presided. Mr. E. R. Russell, in the name of the people of Liverpool, gave a warm welcome to those present, and spoke of how largely, of late years, the influence of photography has been making itself felt in connection with the daily lives of the multitude; also how it has progressed; it now presents features of artistic excellence which once might have been thought not to be possible. Photography, he said, is now the hobby of numbers of intellectual and artistic people.

*The Liverpool Daily Post* of last Saturday says of the exhibits:—

Naturally enough, in a collection of photographs the portrait is the first thought, aud in the catalogue of this International Exhibition the first four classes are given up to a collection of portraits, some of which (notably two sent by Mavius and Vivash) are marked by great softness—one having the appearance of a Bartalozzi. Two portrait pictures by W. Crooke deserve attention—one (No. 13) for the passage of light upon armour, and the other (No. 14) for the extreme delicacy of its treatment. An iuteresting quartet of figures of the *artistes* playing in "Ravenswood" is shown by Windsor and Grove; and Barraud and Co. have some fine portraits of operatic and theatrical *artistes* also hung. A new form of portraiture is exhibited by H. M'Michael, of Buffalo, U.S.A., who exhibits a number of portraits in character. There are two German figures, and also one the portrait of a man in "King Lear," which are charming studies—the latter beiug very free aud unforced. In another room Mr. M'Michael has a series of photographs graphically illustrative of the poem "Enoch Arden." Two charming pictures are those of W. J. Byrne, where a child is shown in the character of a "Water Nymph" (No. 95), and the same exhibitor also has some fine life-size portraits done in the orthodox form.

The most interesting feature of the Exhibition, however, is perhaps to be found in the small collection of "flash-light pictures." Time was when the photographer depended entirely upon the sun, but that time has now gone, and photographs moy be taken by means of artificial light. There are several fine examples of this process to be seen in the Exhibition, the most complete being, perhaps, the twelve pictures seut by Countess Loredana da Porto Bonin. In this instance, the artist—for, indeed, the photographs are capital *genre* pictures—has been most successful with her models. There is excellent humour in "The Village School" and "The Future Professor," the expression on the faces of the boys being very fine; and in "Training for the Choir" and "The Catechism," the artist has shown skill in dealing with the white tones in the drapery of the choristers. A series of four "flash-light" pictures of Professor Herkomer's "Philippo" (a poetic comedy played at Bushey), by F. Downer, show out very well; nor is Mr. Downer alone in this illustration, for several other exhibitors also send photographs of Professor Herkomer in this character. It may be sufficient to say that all these works show Professor Herkomer as impressive and dignified in the part. In this collection of "flash-light" pictures, attention ought to be drawn to the series of interiors by Johann von Campostellato Pasquali, some of which (such as the Alpine herdsman's hut) are very interesting. There is evidently a great future for this form of photography, and no doubt when the next exhibition is held there will be a larger collection of this particular form of the art.

The number of landscapes is very large, and in many instances striking effects in tone have been obtained. A series of very interestiug Icelandic scenes are showu by John Reynolds; and G. Bankart, in "A Crawling Burn" (No. 123), has a good effect of rushing water. The two photographs "Tall Poplar Trees" and "On the Exe" (Nos. 126 and 129), by E. Spencer, are skilfully taken; R. W. Robinson has a good work in "As the dreary, weak Suu goes Home" (No. 155) and J. G. Bullock, in his "Westward as far as the eye can reach" (No. 146), has shown that perspective can be attained in photography. Four very interesting studies of Spanish ports, which have all the fineness of line engravings, are shown by H. J. Menet (No. 166), and A. Hamilton has a quartet of Swiss scenes (No. 170), in which the snow is given with telling force. The series of pictures of Aysgarth by F. W. Stow (No. 198) is good, and a clever study of trees (No. 210) is shown by W. Bedford. There is very good tone in "The Hay Bridge" (No. 285), W. W. Naunton; there is a fine breadth in J. M. Brown's "Out with the Morning Tide" (No. 290), in which we have a view of Cowes from the sea, and E. P. Vulliamy, in "Three Cliff Bay" (No. 293), has a fine effect of distance. E. Lloyd Edwards has given a breezy feeling in "A Wild March Morning" (No. 385), and F. Anyon in the *genre* work, "Is Life Worth Living?" (No. 384), has succeeded in his humour. The cloud studies of T. Glazebrook (No. 407) are very fine; and in four marine studies (No. 419) H. R. Marsden has got a wonderful colour, the effect of moonlight being perfect. A series of studies of the Tyne are shown by L. Sawyer, all of which give a vivid idea of a busy mercantile place. Some clever photographs of animals are shown by F. M. Sutcliffe (No. 475) and by J. Catto (No. 491), the latter of whom shows great skill. An interesting Eastern scene is given by F. Bremner in an instantaneous photograph, and T. M. Brownrigg, in his Algerian photographs, has also done much to euable the visitor to understand the details of Oriental life. T. B. Sutton's grouping in "How Many Score's That?" is very fine, and a work which will attract a good deal of attention hangs near it, "Castle Street" (No. 706), which has that briskness and bustling feeling only to be produced by an instantaneous photograph. An interesting photograph is that by G. Plassy, "A Spider on its Web" (No. 684), which, taken by a flash-light, has been enlarged on Eastman's paper. The photographs of the works of Rossetti, Burne-Jones, and Watts, R.A., by F. Hollyer, are very fine, more particularly the "Happy Warrior" (No. 895), in which there is splendid light on the armour; and another work in which there is a clever treatment of light is "The Boat Builder" (No. 976), by L. Sawyer. There is good feeling in "Corbiere Rocks" (No. 1,006), A. R. Dresser, and "We Watch the Speckled Trout" (No. 1,019), J. P. Gibson, both of which are highly-finished works. The collection of portraits of artists at home, shown by R. W. Robinsou (No. 1,021), is most interesting; and a series of views iu Norway, by Paul Lange (No. 1,055), will well repay study, so highly artistic are they in their nature and execution.

The total number of exhibitors is two hundred and thirty; of these forty are foreigners. The chief prize, a gold medal, was awarded, as stated above, to the Countess Loredano de Porto Bonin, for some genre photographs, mostly of an amusing character, and in which the faces of the characters wore natural expressions. In the champion class one gold medal was carried off by Mr. Shapoor N. Bhedwar, and another by Mr. J. B. B. Wellington; the photograph exhibited by the latter is a landscape rendered in a somewhat "naturalistic" style. Another gold medal was awarded to Mr. R. W. Robinson, for his portraits of eminent artists.

As regards apparatus, Messrs. Sharp and Hitchmough exhibit an enlarging camera nine feet long, with cords running along the sides to adjust mechanism to place the negative in any desired position. Messrs. Archer and Sons have a show of optical lanterns, and Messrs. Taylor, Taylor, and Hobson of lenses. Mr. J. J. Atkinson, among other things, exhibits some "calcined flour," said to be good for rubbing down halation without scratching the film; he also exhibits a special piece of apparatus for testing shutters, with which he says that he is ready to test the speed of any shutter in the market; an optical method is employed. He has on view a complete set of lenses by Ross, and a new mechanical device for trimming prints.

Mr. W. Hume exhibits his cantilever enlarging apparatus, and Mr. Wood a reflecting stereoscope; the latter is an instrument rarely seen now-a-days, although it can be used for large pictures. Mr. Thomson exhibits a camera with a rather ingenious rising and falling front arrangement; and the proprietors of *The Daily Graphic* exhibit type-high photozinc blocks in various stages of preparation. The exposure meter of Mr. Watkins is on view, and Messrs. Wray and Son have a large show of lenses, several of them in aluminium mounts, which metal in mounts is a great blessing to photographic tourists. Messrs. Wood Bros. exhibit apparatus, so also do Messrs. Lewis and Co. Mr. A. Watt, F.I.C., exhibits a "dark developing bath," intended to avoid the necessity of using a dark room; and Mr. T. Miller exhibits a hand-camera of simple construction: he has a capital showman.

Various photographic visitors to Liverpool were hospitably entertained by the Liverpool Association at the Alexandra Hotel, a particularly comfortable establishment, ably managed. It is the headquarters of the Swiss Club at Liverpool, which club is the general place of social meeting for Swiss residing in and about the city. Its president, Mr. R. Engler, of St. Gall, says that at Neuchâtel the various amateur and other photographers had tried for some time in vain to get satisfactory pictures of the snow-clad Alps, seen across the lake, and about seventy miles off in the distance, and that they found that with ordinary methods by far the best time to get satisfactory photographs of them is shortly before sunrise, when they have deeper tints than later on, and have a bright and contrasting background. There is a Photo Club at Neuchâtel, and some of the professors at the University are among its members. The annual banquet of the Swiss Club in Liverpool was held on February 2nd last, and the Swiss Consul, Mr. Ehrensperger, was among those who attended.

Liverpool has long been noted for its hospitality. At the close of a British Association visit, we once heard Professor Huxley speaking thereof at the concluding meeting, more or less, so far as memory serves, to the effect that the Mayor had taken him in a gorgeous chariot, drawn by six cream-coloured horses, and surrounded by splendours to which he was totally unaccustomed, to a fairy palace, where he felt lost as in a dream, and fully expected that on the following morning his host would clothe him in a silken robe, and hand him a purse of golden sequins, in the good old Arabian Nights fashion. The Liverpool Amateur Photographic Association would have carried out that matter even better than the corporation; they would have had him drawn by six red unicorns and a basilisk; they never do things by halves.

The Liverpool Amateur Photographic Association has comfortable rooms of its own, well supplied with photographic literature, and has a dark chamber for the development of negatives. At present the walls of the meeting room are decorated with photographs by Mr. Gibson, of Hexham, one of the most popular photographers in the North of England. His excellent prints have a peculiar tone, due to the employment of Blanchard's platinum toning process.

### The History of Photography in Liverpool.

Liverpool has made its mark in the history of photography. The early work of Messrs. Sayce and Bolton in relation to the collodio-bromide process is well known.

Last Saturday Mr. B. J. Sayce showed us some of his early collodio-bromide negatives and prints. One of them is a positive print taken in 1873 from an old and scratched collodio-bromide negative taken Sept. 3rd, 1864. Another is a negative taken with thirty seconds' exposure on Sept. 5th, 1864. A third, dated June, 1865, is a negative taken on wet collodio-bromide with ten seconds' exposure; the date of another is June 19th, 1865. One of them, dated July 11th, 1865, is a negative of high quality taken at an out-door meeting of the Liverpool Amateur Photographic Association, near Corwen, North Wales. It was acknowledged to be the best in the competition on that occasion. All the other photographers were using dry plates of various descriptions, by the processes then in vogue, with collodion as the vehicle.

The Liverpool Amateur Photographic Association was established in December, 1863, and is stated to be the oldest strictly amateur photographic society in the world; it grew out of the old Liverpool Photographic Society, which broke up because of dissensions between amateur and professional members. The first president of the new Society was the Reverend T. B. Banner, and the first secretary Mr. John Glover; the latter was then well-known in the photographic world; he was a good experimentalist, and the author of a pamphlet on "The Art Bearing of Photography." He died about 1865.

In 1853, at the time of the Crimean War, Mr. John Thomas, of Rock Ferry, photographed the fort at New Brighton from the Lancashire side of the Mersey, at a distance of about three miles, and obtained as good definition as if he had exposed at a distance of a few hundred yards. He had to allow for the difference between the chemical and visual foci of the telescope object-glass employed. A feat like this was a novelty at that time, and it attracted the attention of the War Office.

At the present time professional photographers have no organisation in Liverpool. The existing organisations are:—1. The Liverpool Amateur Photographic Association. 2. The Liverpool University Photographic Society, established about two years ago; in this Society Dr. Kohn, Professor of Chemistry at University College, is an active member. 3. The Photographic Society, established about two years, connected with the Liverpool Young Men's Christian Association. 4. The Birkenhead Photographic Society, which holds its meetings on the south side of the Mersey. 5. The Wallasey Photographic Society, which holds its meetings on the south side of the Mersey, near Birkenhead; its president is Mr. H. Wilkinson, Massey Park, Liscard, Birkenhead.

Mr. J. A. Forrest is usually considered to be "the father of photography in Liverpool." His experience in the subject dates from about the time of Daguerre's discovery. He is an amateur, and was a glass manufacturer, but some time ago retired from business. He published, in January, 1888, in the *Liverpool Mercury*, some "Historical Notes of what Liverpool has done in the art-science of photography from its discovery in 1839 to the present jubilee year of photographic discovery, 1888." All the rest of this article is an abridgment of the said memoir by Mr. Forrest:—

Soon after 1839, the date of Daguerre's discovery in France, and the time when our countryman, Mr. Fox Talbot, produced a process on paper made sensitive by the salts of silver, Mr. Spencer, carver and gilder, in Slater Street, Liverpool, who afterwards became the discoverer of electro-plating, erected a photographic studio on St. James's Mount, and for some years carried it on successfully. Finding the time of his exposures increasing, he asked Mr. Forrest to see his studio, and try to find out the cause of the increase. He did so, and discovered that the glass on the studio roof had changed colour from a greenish tint to pink, arising from manganese forming one of the component parts of the glass; this led to the abandonment of manganese in the manufacture of glass, from its liability to change by the action of the sun's rays.

The moving spirit of progress in Liverpool in the early stages of the art was the late John Atkinson, of Manchester Street, whose shop became the rendezvous of all interested in the new art. He was a man possessing mechanical genius. The outcome of the existence of this general meeting place was the formation of the first Liverpool Photographic Society. Mr. J. T. Foard did great work in the Society by supplying it with papers of high-class merit.

Mr. John Glover, another member, was an indefatigable experimentalist, but, being of a weak constitution, he fell a victim to his own ardour. The Society subscribed £275, and appointed trustees to see it laid out in the education of his children. Mr. Thomas Higgin has devoted his efforts to the department of microscopic photography, and produced works of high merit. No member reached such a high state of perfection in the art as Mr. Osmond R. Green; his pictures were large—some of them 24 inches by 18 inches—and, although taken about twenty years ago by the collodio-bromide process, they command admiration at the present day. Frank Howard, an artist of considerable celebrity, was also an active member. Mr. John M'Innes, the first and most successful discoverer of the mode of coating ships' bottoms with material to prevent plants and barnacles adhering to the iron, rendered service to the Society on many occasions. Mr. James Newlands, the borough engineer, took interest in the Society's welfare. He was president for some time, and, along with Mr. Christopher Bell and Mr. Forrest, became joint proprietors of the *Liverpool Photographic Journal*, the copyright of which was sold to Mr. Henry Greenwood for £56. This sum was handed over to the treasurer to pay the Society's debts. Mr. Charles Cory was the editor. Mr. G. R. Berry, chemist, furnished some valuable papers, especially relating to the evolution of dry-plate photography. Mr. Sheridan, another member, was a lover of nature; he had extensive property in South America, and he was home in this country for some years, during which time he visited various places of note in England. He became a thorough adept in photography, and, with his energy and large means, pushed the Society to the front in every way. In returning to his adopted country, the steamer on which he was a passenger took fire; to avoid a rush for the boats, he strapped a lifebelt around him and jumped into the sea. The occupants of one of the boats searched for him and found him floating, but his spirit had fled. He was a gifted Irishman, greatly respected by every member of the Society.

Dissensions about the question of professional *versus* amateur broke up the old society, and another was started, the "Liverpool Amateur Photographic Association"; the old society also gave birth to a vigorous offshoot in the Birkenhead Photographic Association.

To judge of the value of a society, you must get at the percentage of working members, for in every society there are some "drones," who appear at monthly meetings, question everything, and do nothing. To establish an improvement in this respect, and enable members to estimate their relative skill in manipulation and artistic treatment of subject, the Birkenhead Society holds competitions under equal conditions at out-door meetings.

Mr. Isaac Roberts, of Maghull, is a Liverpool man, who is now engaged in astronomical photography. The old Liverpool society laid the foundation of this work, and the following extracts will show this:—Dr. Edwards, in 1854, read a paper on "Collodion Photographs of the Moon's Surface." He said that the Liverpool Photographic Society, recognising the importance of this subject, and the interest felt in it by the British Association at its last meeting, requested Mr. J. A. Forrest, its secretary, and Mr. J. Hartnup, of the Liverpool Observatory, and himself, to act as a committee for obtaining photographs of the moon by the Liverpool telescope, and to lay them before the present meeting. This committee had produced a large number of pictures with variable success, and some of the most perfect copies were then presented. The telescope is furnished with an excellent equatorial mounting, and clock-work motion of great firmness and steadiness. The object glass has a focal length of about 12½ feet, and a small camera box being substituted for the eye-piece, the image is received upon the ground glass or prepared plate in the ordinary manner. After much fruitless labour, the chemical focus was discovered to be about eight-tenths of an inch beyond that of the visual one, the glass being over-corrected to that extent in respect to its actinic focus. The focus once accurately obtained of course answered for all subsequent experiments, but it was at first difficult to decide whether the want of sharpness of outline observed was due to the motion of the object, or to imperfect focussing. The best specimens were obtained by the continuous motion of Mr. Hartnup's steady hand, in addition to the clockwork movement, while his eye was kept on the finder with an achromatic eye-piece of good power, by which he could maintain the position of a given point in the field. When the moon is off the meridian, her rate being variable, this seems the only mode of following her motion accurately. Such were the mechanical arrangements, and the chemicals which produced the pictures were collodion containing iodide and bromide of potassium, a neutral or slightly acid silver bath (thirty grains to the ounce), and a developing solution of sulphate of iron with acetic or formic acids. The fixing agent was cyanide of potassium. Collodions were employed, containing respectively iodides of ammonium, cadmium, calcium, or zinc, without obtaining any advantage in result; and, indeed, no marked advantage followed the use of very sensitive collodions, which seldom gave both the mapping and the detail on the dark limit with equal distinctness. Mr. M'Innes was successful in copying and enlarging these pictures for the lantern, and the effect of the illuminated images proved interesting at the soirée, when Professor Phillips lectured to the members of the British Association, of which he was one of the founders, in St. George's Hall, Liverpool. The entire image was shown on a screen fifty-six feet in diameter. He said nothing that others had attempted could at all compare with the results which had been obtained by the voluntary exertions of the photographers of the Liverpool Society. The Abbé Moigno, who was present, said that the general impression of his countrymen present was that the Liverpool Society had got farther into the skies than the French photographers had. Strange to say, Gaston Tissandier, in his History of Photography, published in 1878, entirely ignored what had been so ably accomplished by the Liverpool Photographic Society, and gave the credit to Padre Secchi, of Rome; Dr. Warren De La Rue, of London; Mr. Rutherfurd, and Mr. Grubb; none of whom commenced their operations until two years after the successful display at Liverpool in 1854.

Arago had said that photography was one of the most remarkable conquests of genius, and might rank with the telescope and the electric battery; but what would he have said to the following, which occurred at a meeting of the Liverpool Astronomical Society, when a paper was read on "Celestial Photography":—"At a joint meeting of the Literary and Philosophical and Astronomical Societies of Liverpool, Mr. Herbert Sadler, F.R.A.S., read a paper on 'Celestial Photography,' in which he referred to the great advances which had lately been made in astronomy by the assistance of photography. Starting from the first crude and imperfect pictures of the sun and moon, astronomy and photography had marched hand in hand until the present methods of manipulation enabled us to photograph objects which the eye can never hope to see. The paper was profusely illustrated by celestial photographs; and, in calling attention to a picture of Capella, Mr. Sadler explained that the rays which affected the plate started on their errand during the battle of Waterloo. As an illustration of the far-reaching power of the photographic eye, the map of the Pleiades constructed by M. Wolf contained 671 stars, and, after a careful sounding in this direction with the largest telescope in the Paris Observatory, the author felt assured that all beyond was darkness, and that he had absolutely reached the utmost depths of space; but a photograph of the same district taken by the Brothers Henry, with a much smaller telescope, in one hour showed 1421 stars against the 671 which had taken M. Wolf three years to map."

Not until Mr. Scott Archer, a London chemist, discovered, in 1851, a practical method of utilising a solution of guncotton in ether and alcohol, known as collodion, for creating a surface on which sun pictures might be produced with greater rapidity and beauty than formerly, did photography begin to make giant strides, and during a period of thirteen years his principle of a nitrate of silver bath as a sensitiser remained in force. But the times were marching on to greater development, and it was by the hand of the 1888 president of the Liverpool Amateur Photographic Association, Mr. B. J. Sayce, that the first practical negative emulsion process, which he called collodio-bromide, rendered the manufacture of dry plates simple, trustworthy, and inexpensive. This process was introduced in September, 1864, and after several modifications by the author, the principle of emulsion *versus* the nitrate bath revolutionised photography, and enormously increased the army of amateurs. Various improvements in manipulation have been introduced, and bromide emulsion is the process of to-day, but the vehicle for the suspension of the silver salts is gelatine. Twenty-one years later the jury of the International Inventions Exhibition, held at South Kensington in 1885, granted to Mr. Sayce a gold medal and diploma for the discovery.

---

Messrs. York and Son are keeping pace with the times by turning out lantern slides relating to the life of John Wesley at this, his centenary epoch.

Photographs on Looking-Glass.—Mr. Marcus Guttenberg, of Manchester, has sent us for inspection some of his coloured photographs on mirrors, produced by a process described a few weeks ago in our patent reports. Those with sharp edges somewhat resemble the paintings on glass now so common, and in which the effects of reflection at the edges are prominent and do not agree with each other, like the natural tail of the organ-grinder's monkey, and the tail of the red coat in which the little innocent is dressed. In another class of pictures by Mr. Guttenberg this objection is not prominent; he, in this case, first deadens the front surface of the mirror with hydrofluoric acid, then applies an oval background, getting pictorial results somewhat better than we chance to have hitherto seen on mirrors.

## PHOTOGRAPHIC CHEMISTRY.

### I.

Last Monday night Professor Meldola delivered the first of three lectures at the Society of Arts on "Photographic Chemistry." Mr. Francis Cobb presided.

The lecturer stated that of late years the applications of photographic processes in art and in science have been numerous. Photography now claims to be a branch of science, and that it should be taught as such; indeed, some progress has been made in this direction at certain schools and colleges in this country, but not nearly to the same extent as at the Technical High Schools of Berlin and Vienna. In this matter of education, it must be admitted, we have taken a secondary position, although this is the country of most of the great discoveries in photography since the days of Niepce and Daguerre; silver printing on paper, the blue process, bichromated gelatine processes, pigment processes, emulsion processes, and Willis's platinotype process originated here. Photography also has its physical side, and that should be taught in a scientific manner.

In some minds the idea of technical training is connected exclusively with the teaching of handicrafts, but this is a mistake, and especially so in relation to the training of photographic technologists.

One might begin the training by teaching the student the action of reducing agents upon silver salts. By adding ferrous sulphate to silver nitrate in a test tube, he would find silver to be precipitated as a grey deposit, finely crystallised. He might then be made to prove by tests that the deposit is really metallic silver. He might be instructed as to the action of reducers upon silver haloids, and that by submitting reduced silver on paper to action of solutions of gold or platinum, the dark deposit becomes more insoluble in nitric acid, proving that more or less of one of those metals has been substituted for the silver. He might be taught that the reducing agent becomes oxidised while doing its work, and how to prove this point in the case of an iron developer by the application of the ferrocyanide of potassium test.

It is believed that silver can be thrown down in different states of aggregation; ferrous sulphate throws it down from the nitrate in a grey crystalline state, but ferrous acetate throws it down from the nitrate in a fine and black condition. Such phenomena as these do not find expression in ordinary text-books; the deposit is said to be metallic silver in both cases, but in the last one there may be some trace of organic matter with the silver. Faraday has shown different forms in which gold can be precipitated, but on the other hand, silver and its salts have a special tendency to bring down traces of foreign matter. Similar actions occur in dyeing. Mr. Roberts-Austen has shown how the most minute traces of an impurity in a metal will sometimes affect the physical characteristics of the whole mass. In the case of Carey Lea's deposits from the organic salts of silver, the lecturer did not think that there was sufficient evidence that the precipitates consisted entirely of pure silver. Carey Lea had analysed some of the precipitates, and found in them 98·75 per cent. of silver, but Mr. Roberts-Austen had shown that two-tenths per cent. of lead in gold were sufficient to make gold brittle. A Dutch chemist, who has been repeating Carey Lea's experiments, and analysing the deposits, says that the latter always contain traces of iron as an impurity.

The student might be made to study the various actions of sodium thiosulphate upon silver nitrate. Silver thiosulphate, $Ag_2S_2O_3$, may be formed by adding the sodium salt to silver nitrate, and taking care to keep the latter in excess; in the presence of water the product gradually changes into silver sulphide and sulphuric acid. The soluble double salt, $Ag_2Na_2(S_2O_3)_2$, is formed by adding the silver solution to the sodium solution until a permanent precipitate is formed; this also tends to decompose with the formation of sulphide. The other salt is a soluble one, $Ag_2Na_4(S_2O_3)_3$: this salt is extremely soluble in water, but can be thrown down therefrom in a beautifully crystalline form by suitable treatment with alcohol. The utility of the performance of such experiments as these is obvious when learning the principles of the fixing process.

Professor Meldola then drew attention to the accompanying table, and proceeded to speak of the chemistry of

| Reagent. | AgCl. | AgBr. | AgI. |
|---|---|---|---|
| Cl | No action | AgCl formed | AgCl formed |
| Br | ,, | No action | AgBr formed |
| I | ,, | ,, | No action |
| HCl | ,, | AgCl formed at high temperatures | AgCl formed at high temperatures |
| HI | AgI formed | No action | No action |
| KCl | No action | ,, | ,, |

| KI | AgI formed | AgI formed | ,, |

the silver haloids. These haloids, especially the iodide, are soluble to some extent in strong silver nitrate; by considerably heating nitrate of silver in a test tube, he made it dissolve a large amount of silver iodide, which was precipitated again by the addition of water.

If silver nitrate be cautiously allowed to fall, drop by drop, into strong hydrochloric acid, the latter will dissolve a little of the former, and no precipitate will be formed; in other words, freshly precipitated silver chloride is soluble in hydrochloric acid to the extent of one-half per cent. When some of this solution is poured into water, a precipitate appears. The lecturer next added exceedingly weak solution of silver nitrate to largely diluted hydrobromic acid. In this case bromide of silver was formed in so fine a state of division that with long standing the particles did not fall to the bottom of the containing vessel.

## THE SCIENCE OF COLOUR.

AT the fourth of the course of lectures on this subject, given on Friday last at the rooms of the Society of Arts, Captain Abney commenced by referring to the statement at the previous lecture that any colour could be described in terms of the spectrum, *plus* some given proportion of white light. Purples, however, could not be directly described in this way, because there is no part of the spectrum which represents purple. They could, however, be expressed in terms of their complementary colour and white light.

The eye could not tell to what parts of the spectrum a colour truly belonged. It could only recognise an impression of the colour as corresponding with some part of the spectrum. This was illustrated in several ways, particularly by spectrum red and green being thrown on to a white surface to produce the effect of yellow. That it was not the same as the yellow produced by transmitted white light through a yellow medium was shown by patches of various colours being held in the two. This comparison was farther made by placing the several colours in the simple spectrum yellow, and in the yellow shown by ordinary filtration through the coloured medium.

The lecturer then spoke of primary colours. He said that there was more ignorance on this subject than on any other connected with light. It had been commonly taught that there are three primary colours—red, yellow, and blue. Taking primary colour to mean colour which could not be obtained by compounding others, there was one only of this triad, red, that was entitled to be called primary. Yellow was certainly not primary, as it could be made by green and red; and blue also could be made with violet and green. This was shown by experiment. Violet, green, and red were three colours that could not be produced by compounding others, and therefore these were the three primary colours. How was it that people had so generally gone wrong in their ideas of primary colours? It was because until the present age all knowledge of colour had been in the hands of the artists, who had to use impure colours. They were not aware of the laws of absorption. By superposing a yellow and blue screen, a green patch of light was seen to pass through them. This method was identical with that of the artists. In using mixed pigments, they had colours finely ground lying one on the top of the other, and seen through one another, or reflecting colours from one to the other.

### Specifications Published.

585. *January 12th*, 1891.—"Photographic Cameras." SAMUEL CALVERT, of Great Ormond Street, London, Artist. (Communicated from abroad by THOMAS ARDERN, Camera Maker, Melbourne, Victoria.)

This invention relates to the construction and arrangement of photographic cameras of field-glass form in such a manner as to afford great convenience in focussing, in working the shutters in accommodating a number of plates, and exchanging exposed for fresh plates.

The inventor claims:—

1. A photographic camera of field-glass form, having in front a pair of lens holders with shutter-box attached thereto, and their sliding tubes adjustable for focussing, and having in rear two compartments, the one compartment arranged to hold a pile of sheathed plates, or films, and advance them for

exposure in succession, the other compartment arranged for focussing and for transferring each plate in succession from the front to the rear of the pile.

2. In combination with the two compartments above referred to, a spring push with non-actinic glass for the one and a hinged door for the other, arranged and operating for transferring a plate from front to rear of the pile.

3. The modified construction and arrangement of the rear compartments and their appliances for transferring plates, substantially as described.

4. In combination with the focussing compartment, an adjustable eye-piece with objective lens.

5. In a photographic camera, the combination of a rotatable lens holder and coiled spring with a pair of sliding shutters having transverse slots engaged with eccentric studs on the lens holder, so that on the release of a trigger, or detent, the lens-holder is caused by the spring to make a partial revolution, opening and then closing the shutters.

6. In a field-glass camera, in combination with the shutter apparatus referred to in the preceding claim, a sliding shutter for the focussing aperture moved by crank and gearing from the rotatable lens-holder, aud a trigger with its pin and spring arranged within the tubular focussing screw.

2,150. *February 10th*, 1890.—"Improving the Appearance of the Human Body." (This patent might have been entitled "Retouching the Sitter.") Patrick Rowley, Curraghmore House, Hessle Common, Hull, Merchant Tailor.

My inveution has for its object to provide an appliance for improving the figure or appearauce of, and coucealing deformities in, the human body, and consists of an instrument or device to be applied to the shoulders of the wearer, whereby the coat or other outer garment is caused to present a graceful and uniform appearance.

According to my iuvention, I provide a rod or wire of any suitable material, preferably of a flexible nature, such, for example, as steel, and of a form to surround the back part of the neck of the wearer; the ends of the said bar or rod are made to extend to the front, and are so bent as to lie snugly against the upper part of the chest. Fitted to slide on this bar or wire are two collars or sleeves, to which are hinged epaulets or shoulder-pieces, suitably shaped to represent gracefully-formed shoulders, which, when worn beneath the coat or other outer garment, give to the said garment a neat and graceful appearance. These epaulets or shoulder-pieces may be made of any suitable light, and preferably flexible, material, such, for example, as steel, tin, leather, gutta-percha, vulcanite, or the like, and they may be padded on the interior with wool or other suitable material, so as to cause them to set comfortably on the shoulders of the wearer. By hiuging these epaulets or shoulder-pieces to the rod or wire, as described, they admit of the free movement of the arms of the wearer without inconvenience, whilst deformities of the shoulders of the wearer are effectually concealed, and a graceful appearance is given to the coat or other outer garment.

5,193. *April 3rd*, 1890.—"Photographic Cameras." George Dickinson, 144, Morley Avenue, Noel Park, London, N., Photographic Salesman.

This is the radial camera already described in these pages. The inventor claims:—

1. In a magazine plate changing camera, the combination of a turntable plate-holder having diametrical plate-holding grooves, with a magazine having sets of plate-holding grooves radial to the axis of the turntable holder, with any of which the grooves of the turntable holder may be made to register.

2. The combination, with the turntable holder and radial magaziue, as described, of the indicator for denoting the position of the turntable holder with regard to the magazine, and for fixing it in that or in the exposing position.

3. The combination, with the turutable holder and radial magazine, as described, of the axially-operated spring stop for retaining the plate in the turntable when turning the same.

4. The combinatiou, with the turntable holder, of the abutments for preventing the passage of light past the plane of exposure.

5,215. *April 3rd*, 1890.—"Instantaneous Shutters." Francis Beauchamp, The Poplars, Chadwell Heath, Essex, Engineer.

This invention relates, firstly, to improvemeuts in the construction and arrangement of instantaneous shutter mechanism in which the shutter is intended to work in the ordinary diaphragm slit of a photographic lens.

The invention relates, secondly, to improvements in mechanism for regulating the time occupied in opening and closing instantaneous shutters.

The invention relates, thirdly, to improvements in the operating mechanism of instantaneous shutters whereby a number of exposures, with any desired interval of time between each, can be made with one winding up of the shutter actuating spring.

5,458. *April 10th*, 1890.—"Detective Photographic Cameras." Henry Robert Hume, 6, Allen Terrace, Kensington High Street, London, W., Dentist, and Edward William Parfitt, 18, Gatcombe Road, Tufnell Park, London, N., Musician.

This invention relates to improvements in hand or detective photographic cameras, aud has for its object affording increased facility for successively bringing into position the sensitive films or plates employed.

According to our invention, we mount each of the sensitive plates or films within the well-known holders or carriers, preferably coustructed of thin sheet metal or other suitable material, and provide each of the said holders or carriers with a pin or pins projecting laterally from each side of the upper part thereof, for the purpose hereinafter described. Within the outer case of the camera is a sliding frame or tray, the upper edges of the sides of which are provided with corresponding equidistaut notches or slots.

The sensitive plates, contained within their respective holders or carriers, are placed one above the other in a horizontal position, the projecting pin or pins of the lowermost holder or carrier engaging with the rearmost notch or slot upon each side of the sliding frame before referred to, whilst the front of such holder or carrier is supported by a convenient stop or stops carried by the case.

The said sliding frame or tray is connected with a suitable arrangement of mechanism operated from the exterior of the case, which we shall hereinafter describe, in such manner that it may be shifted backwards (or away from the lens) by successive operations, a sufficient distance at each time to free the lowermost holder or carrier from the before-mentioned stops supporting one end thereof, and allow it to swing upon its projecting pin or pins and drop into a vertical position, at the same time bringing the next pair of notches or slots in the upper edges of the sliding frame beneath the projecting pins of the next holder or carrier, and so on throughout the series.

9,118. *June 12th*, 1890.—"Photographic Apparatus." (Communicated from abroad by Dr. Rudolph Krugener, of Bockenheim, near Frankfort-on-the-Main, Germany.) Henry Harris Lake, of the firm of Hazeltine, Lake, & Co., Patent Agents, 45, Southamptou Buildings, London.

This invention relates to photographic apparatus, and comprises devices for exposing, measuring off, winding up, numberiug, and cutting off sensitive celluloid film which is wound upon a roller.

This pateut cannot be adequately described without the drawings.

The Photographic Club.—Subject for March 18th, "Testing Speed of Shutters"; March 25th, lantern night. Visitors invited.

Exhibition of Collotype Prints.—The walls of the rooms of the Photographic Society are hung with between two and three hundred examples of collotype printing sent for exhibition by The Autotype Company, The London Stereoscopic Company, Messrs. Bemrose and Sons, of Derby, Rommler and Jonas, of Dresden, L. Ronillé, of Paris, F. Thevoz and Company, of Geneva, and Waterlow and Sons. The exhibition will remain open for a month, for the inspection of visitors who present their cards. The pictures were originally lent for the illustration of Mr. Warnerke's lecture, which we published last week.

## Correspondence.

THE NATIONAL PHOTOGRAPHIC EXHIBITION.

Sir,—I have the pleasure to hand you herewith our list of [ju]dges for the ensuing exhibition, and I should be obliged if [yo]u will notify your readers that appplications for space will [be] received up to Monday, 30th inst., a week later than [pr]eviously announced.

Judges:—Messrs. Frank Atkinson, Val. Blanchard, F. P. [Ce]mbrano, F. M. Good, Frank Howard, P. H. Newman.

Lantern and Scientific.—Messrs. G. Baker-Creswell, T. E. [Fr]eshwater, Comd. C. E. Gladstone, R.N., E. M. Nelson, R.M.S.

S. G. Buchanan Wollaston.

*Crystal Palace Company, Crystal Palace, S.E., March 8th.*

## Proceedings of Societies.

The Photographic Society of Great Britain.

[At] the ordinary meetiug of this Society held on the 10th inst., [th]e chair was occupied in the first instance by Mr. J. Glaisher, [pr]esident, and during the latter part of the meeting by Mr. [A.] Spiller, vice-president.

A paper on "Standard Registering Slides and their Mode of [Us]e" was read by Sir David Salomons, and illustrated by [ex]amples. He poiuted out the desirability, iu an instrument [wh]ich now had acquired such a scientific value, of being able [to] register at once aud truly all slides that might be used with [it]. For this purpose it was at one time the custom to adjust [th]e stops by means of picture subjects. A better plan had [be]en introduced by Messrs. Steward, by using "Standard [Re]gistering Crosses," but for exact work he had uot found [the]se sufficient, and uow showed a set of registering plates [rul]ed with squares having an upright and vertical line through [th]e centre. By etching these squares it was practicable to [pro]duce a number alike, so as to preserve the staudard. The [bot]tom of each glass was true, and so was one end, that which [lo]cked against the stage stop. After explaining and showing [the]se standards, the three lenses of a triple lantern were set by [hi]m, and various "effect" slides passed through. These [slid]es were of high quality, and the registering excellent.

[T]he Chairman (Mr. Spiller) expressed his interest in all [im]provements of the lantern; he had, he said, been admitted to [the] secrets of the Polytechnic lantern arrangements in the time [of] Mr. Pepper. He believed that Mr. Debenham had some [col]our screeus, and called upon him to show them in the lanteru.

[M]r. W. E. Debenham said that it had beeu suggested that [the] members might be interested to see these screens projected, [as] they had been recently at another society. The first set [con]sisted of three discs partly overlapping on the screen—red, [gre]en, and blue respectively—and it was particularly pointed [out] that where green and red light came on the same place the [effe]ct was yellow. Green, which was formerly supposed to be [com]pounded of blue and yellow, could not be thus formed. [Blu]e and yellow screens were used to show that the effect of [the] two lights combined was to produce, not green, but white. [The]n, for the comfort of those who knew that blue and yellow [did] make green—for they often made that colour by mixing [the] two first-named—a slide was shown in which films of these [colo]urs overlapped, and the overlapping part showed as green. [The]re was not time that night to go iuto the explanation of [wha]t might seem, to the uninitiated, contradictory; but he [had] undertaken to deal more fully with the subject at a meeting [of] the London and Provincial Photographic Association, and [the] well-known hospitality of that body justified him in saying [tha]t any members of the Photographic Society of Great Britain [who] might be interested would be welcomed.

[M]r. Chapman Jones asked Sir David Salomous whether the [hea]t of the lantern was not sufficient to put slides out of true [regi]ster. With regard to Mr. Debenham's colour slides, he [tho]ught members might iufer that all yellow was a compound [of] red aud green, whereas there was a simple spectrum [yell]ow.

Mr. Debenham did not intend to convey the idea that all yellow was composite. He had been limited by time on this occasion, and done little more than show the effects.

Sir David Salomons said, in reply to Mr. Chapman Joues's question, that the warmth of the lantern would slightly alter the true register; also the temperature of the room in which the slides were kept. He therefore recommended that, before an exhibition, all slides to be used should be for some time in the room, so they should be of equal temperature.

The Chairman proposed votes of thanks to Sir David Salomons and Mr. Debenham, and, these being accorded, it was giveu out that at the technical meetiug ou March 24th, the subject of haud-cameras would be discussed, and it was desired that members should bring their own apparatus of this kind, so that comparisons of many patterns might be made. March 31st is to be a lantern night; members are requested to bring slides. On April 14th Mr. W. Willis is to read a paper on "Platinotype." At the technical meeting of April 28th animal photography will be discussed, and on May 12th a paper will be read by M. Leon Vidal on "Photographic Methods of Obtaining Polychromatic Impressions."

Messrs. C. Braham, W. Grove, G. McDonald, and H. Young were elected members of the Society.

The London and Provincial Photographic Association.

Mr. A. Collier iu the chair. Several presentations of books were made to the library.

The Hon. Secretary reported about the meetiug he had attended at the rooms of the Photographic Society of Great Britain on behalf of the Association on the subject of the federation of London Photographic Societies.

Mr. Haddon spoke about the necessity, when experimenting with developers, of knowing the condition of the sulphite used. Different samples of sulphite would influence results. It was, therefore, of great importance in comparing developers to be quite sure that the sulphite used was neutral.

Mr. P. H. Newman then read a paper on "Pictorial Composition (see page 203).

The remainder of the evening being occupied with lantern illustrations in connection with the paper, a discussion was not taken.

A vote of thanks was unanimously accorded to Mr. Newman for his very able lecture.

The South London Photographic Society.

*Friday, March 6th.*—Mr. Edwards in the chair. Mr. W. Groves read a paper on "Shutters," illustrated by three sheets of diagrams to show the efficiency of various forms of shutters. Messrs. Marion, Houghton, and Watsou leut specimens of shutters; the members also brought several, so that about twenty were on view.

The Society resolved to enter for the Challange Cup at the Crystal Palace.

The North Middlesex Photographic Society.

*March 9th.*—Mr. Goodhew in the chair.

In the unavoidable absence of Mr. Friese Greene, who was to have addressed the Society upon "A New Sensitive Salt," the eveniug was devoted to Society business.

A field day at Rickmansworth was arranged for Easter Monday. Visitors who wish to join the party are requested to communicate with the secretary.

The Richmond Amateur Photographic Society.

*Friday, 6th inst.*—Lautern night; Mr. F. P. Cembrano presided.

Mr. C. Hussey, of Croydon, gave a demoustration of the collodio-bromide process, and, after a few general remarks upou lantern slide work, and the advantages he claimed for his favourite process, went on to describe the *modus operandi*. His practice was to use no mineral acid in cleaning, and no substratum iu coatiug the glass, for fear of contaminatiug the emulsion. Next, three plates were successively exposed, developed, and fixed, and the demonstrator proceeded to illustrate the advantage which he claimed for his process, namely, that whereas a gelatine plate, after development and fixing, passes practically out of control, a collodio-bromide plate is, at that stage, as a cliché to work upon, being readily susceptible of being made to give almost unlimited variation in density and tone.

After a few remarks from the Chairman on the merits of rival processes, some slides by Mr. Hussey were exhibited by means of the lantern, and presented a large range of tone. Slides by Messrs. Williams (a visitor), Ardaseer, Lowry, Davis, Ennis, Irvine, Hodgkin, and Cembrano were then displayed.

The next meeting will be held to-night; the subject is "Photometers and Actinometers."

The Lewes Photographic Society.

*March 3rd.*—The President in the chair. Demonstrations were given as follows:—Mr. J. G. Braden, "Matt Surfaced Prints Toned with Platinum"; Mr. J. Tunks, "Silver Prints Toned with Gold"; Mr. G. J. Wightman, "Hot Bath Platinotype." Great interest was taken in the demonstrations, and specimen prints by each process were shown.

At the next meeting, on April 7th, there will be a lantern slide competition; this will be the last lantern night of the season.

The Sheffield Camera Club.

The opening meeting of the session was held on Friday evening, March 6th, and took the character of a social evening.

The President, Mr. G. T. W Newsholme, in the course of his remarks, made reference to the aims and objects of the Club, pointing out that the science of photography could be promoted by the comparison of work and discussion of the various methods of production, without the stimulus of competitive exhibitions. He held that the production of good work should be sufficient reward in itself. There was an excellent exhibit of work by members during the past year.

During the evening an exhibition of slides by limelight took place. Cameras, stereoscopes, and photographic apparatus of all kinds were also exhibited.

Enfield Camera Club.—At a committee meeting held on the 24th ult., it was resolved that for members residing outside a radius of ten miles from Enfield, the subscription shall be reduced to two shillings and sixpence per annum. The following is a programme of the meetings to be held up to the 15th April:—March 18th, demonstration on "Platinotype," Mr. R. B. Lodge; April 1st, demonstration on "Bromide Enlarging," Messrs. Fry and Co.; April 15th, lantern night.

The Formation of an Explosive Substance from Ether.—Professor P. T. Cleve has written a letter to the Chemical Society, in which he describes a remarkable explosion occasioned by impurities in commercial ether. On distilling about 250 c.c. of the ether, it was noticed that a viscid residue remained; after drying on the water-bath, this formed a transparent, amorphous mass, estimated to weigh about 0·75 grm. Prof. Cleve states that, having poured a little water on to the substance, he proceeded to stir it gently with a rounded glass rod; this occasioned a most violent explosion. A number of the pieces of glass which were projected about perforated the windows just as if they had been revolver bullets. The explosive substance was probably ethyl-peroxide, as it gave the well-known perchromic colouration, besides liberating iodine and discharging oxygen from silver oxide; it was at once destroyed by reducing agents; it exploded with as much violence as if it had been chloride of nitrogen or fulminate. Professor Dunstan remarked that several cases had been recorded of explosions during the distillation of impure ether, one a few years ago by Schaer in the *Archiv der Pharmacie* for 1877.

H. W. (Felouita de Mallorca, Spain).—Glad to hear from you again. Such circumstances are not suitable for printing unless publicly authenticated by names and addresses, and evidence strong enough to hang a man in a court of law. The enclosure has been burnt as desired.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

The Photographic News is the oldest weekly photographic newspaper. See its consecutive number to-day on the front page.

J. E. H.—*Photo-Spectroscopic Apparatus.* A pair of quartz prisms and meniscus lens are absolutely essential if you want to photograph the most refrangible rays of the solar spectrum, and it is further necessary to wait until midsummer, and for the clearest weather, in which to prosecute such researches. See Mr. Crookes' spectrum camera figured and described in the *Journal of the Photographic Society*, vol ii., page 293. Much preliminary work could, however, be done towards getting your apparatus in order, and testing the capabilities of your photographic media. Do you intend going out to Zermatt, the peak of Teneriffe, or other elevated station, so as to take advantage of the more rarefied state of the atmosphere?

A. M. M.—*Calculations of Cost.* The wisest course is to appeal to some high authority of greater professional experience, and this we have done. Later on we hope to give you such a report.

J. R.—*The Manual of Photo-Engraving, &c.*, can be had either of Messrs. Hampton, Judd, and Co., 14, Duke Street, Adelphi, W.C., or Messrs. England Brothers, 25, Charles Street, Royal Crescent, Notting Hill, W. Send a postal order for five shillings.

C. E. Webber.—*Mr. Warnerke's Lecture.* As you say, we had a very interesting meeting last week, and we are glad you availed yourself of the opportunity of being present. Noting the fact mentioned in your letter, we may, perchance, find occasion to refer to you as being prepared to undertake this class of work.

C. Holliday.—*Tottenham Loan and Fine Art Exhibition.* Our thanks are due for sending us a copy of the regulations governing the loan collection, which is to be exhibited for ten weeks subsequent to April 15th next. We are glad to learn that photographs will be included.

G. G. M. (Edinburgh).—The portrait was forwarded to you last week, and by letter, just received, has been duly acknowledged.

W. S. B. (Boston, Mass.)—*Life-sized Heads.* You will find one of the points answered in the News of February 27th, in reply to your fellow citizen, A. D. We are expecting to receive definite information on the specific matter which stands over, even now, unanswered.

Unit.—*The Acetate of Amyl Lamp.* 1. If you have any difficulty in procuring the lamp in this country, send over to the French maker, M. Pellin, 21, Rue de l'Odéon, Paris. Burn the lamp under a hood, or within a fume chamber, so as to avoid inhaling the vapours, which often cause headache. 2. The International Congress will meet this year in Brussels, about the third week in August, and resume the consideration of a number of questions left open from last year's programme, and take in hand any fresh matter that may arise.

Tom Don.—*Artistic Copyright.* By the Act of 7 George III., cap. 38, sec. 7, which deals with the copyright in engravings, protection is given for twenty-eight years after publication. As this period expired about eleven years ago in the instance mentioned in your letter, you are at liberty to copy the print. The Copyright Act of 1862 does not affect your case. For reference in doubtful cases, you cannot do better than consult "The Law of Artistic Copyright," by R. Winslow, which, unlike many legal treatises, is brought down to the comprehension of ordinary mortals.

C. B. K. (Derby).—*Reversing Mirror.* Enquire of Mr. Ahrens, Selhurst Villa, King's Road, Kingston-on-Thames.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1698.—*March* 20, 1891.

CONTENTS.

## HELIOCHROMY AT HOME.

A popular idea is current, to some extent, that, in order to try experiments with Professor Lippmann's process, costly apparatus is necessary, including an electric lamp, and an optical system for the casting of a pure spectrum, assuming pure colours to be necessary. The pure blue colour of the spectrum, however, is one of those which can be obtained by transmitting daylight through suitably coloured glasses. Mr. H. G. Madan has discovered that if a piece of Chance's "signal green" glass be laid upon a piece of rich cobalt blue glass, the two together transmit only the pure blue of the spectrum. In all such devices, the depth of colour of the glasses should bear some proportion to the intensity of the incident light, for, when sufficiently thin, all coloured films are practically colourless and transparent. A tolerably pure red is transmitted by oxide of copper ruby glass.

As the photographic films used are most sensitive to the blue rays, the novice in the process may well confine his attention at first to the taking of blue prints, and obtain a pure blue light to work with by means of the two sheets of glass just described. He will require, in addition, but M. Lippmann's mercurial trough, already pictured in these pages, and one or two other simple appliances. The blues thus photographed will not resemble pigmentary blues, but possess a metallic iridescent lustre, in some cases, perhaps, like the blue in the tail of a peacock, in others like the blues sometimes seen upon steel, and so on; in fact, by discovering how the shade of colour varies with different emulsions, colloid vehicles, developers, and modes of the treatment, the experienced photographer is likely to aid considerably in the practical development of the new discovery.

An idea is current that when light strikes the reflecting mirror at an angle, it is reflected in another direction, so that the waves do not come straight back upon themselves to produce interference phenomena. There is some force in this, but its utterers forget the excessive thinness of the dry sensitive film with which they are dealing, and that that thickness can only be advantageously increased up to a certain maximum. Theoretically, no doubt, the more the rays fall at a right-angle to the plane of the plate, the better. In printing by blue light, it might be well to put the blue screen in an aperture of one end of a long diaphragmed box blackened inside, and the mercury trough and sensitive plate at the other, so as to work with rays as nearly parallel as can be conveniently obtained. In trying to print from a negative in this way, a disadvantage of Professor Lippmann's process would come in, for the printing would have to be done through the glass of the sensitive plate, so there would be blurring, but less than many would expect if the glass be excessively thin. Perhaps, at first, the experimenter might simply gain experience in photographing different shades of blue, and when he becomes expert he may abolish the mercury trough, and use plates of polished silver bearing sensitive films; he can then print on a surface in close contact with the negative, and, in addition, get more brilliant colours, because silver reflects light more powerfully than does mercury.

A popular error in relation to the process has reached our notice from several different directions. The colours seen in the prints are those of thin plates, so some persons think that there ought to be a tangible thin plate, which they bite if they like, somewhere in the apparatus; others think that a layer of air between the mercury and the film forms a thin plate, and that no colours at all can be obtained if the emulsion be in optical contact with a plate of polished silver. The real hypothesis is, that when light strikes the reflecting surface at or near a right-angle, there is interference close in front of that surface, but we cannot see it in the surrounding general flood of light. Hence the ingenuity of Herr Wiener, who employed nearly transparent sensitive films to search for these interference phenomena, and to make them register themselves inside the film for subsequent examination; hence, also, the ingenuity of M. Lippmann, who has registered colours by interference in the same way; and hence, likewise, the ingenuity of Lord Rayleigh, who published two or three years ago the principles of producing photographs in colours, which M. Lippmann has just proved to be practically true.

## FILM PICTURES FOR THE LANTERN.

Every practical lanternist knows well that his glass lantern slides are by no means the lightest part of his apparatus. They are, indeed, double the weight of negatives of the same size, for of necessity each picture must be protected by its cover glass. And although glass can now be obtained which is as thin as an egg-shell, the question of brittleness comes in, and there is a limit to thinness beyond which it would be foolhardy to go.

This consideration has led many operators to wish that there might be some material other than glass upon which his pictures could be supported, in the same way that the negative maker has long hoped for a similar substance. The demand of the latter has been met in films of various kinds, of which celluloid at present represents the survival of the fittest. The question naturally arises, "Can celluloid be employed for lantern slides?" And it has been answered to a certain extent by the manufacture of celluloid films which have been prepared for that purpose. They have been introduced by Messrs. Hinton, and, as we have lately had an opportunity of trying them, we are in a position to make some comments upon their suitability for lantern use.

These films seem to differ in no particular respect from other celluloid films, except that they are, perhaps, more transparent after fixation than those prepared for negatives. This, of course, is a very necessary feature in lantern slide pictures, in which the slightest haze is so detrimental to good effect. But although the films are transparent enough for lantern purposes, the celluloid retains a yellowness which seems to be inherent in that material. This tone is not pronounced enough to constitute an actual bar to the use of celluloid as a support for lantern pictures, and provided there is plenty of light available, as there always is with a good lime-lit lantern, it would be hardly noticeable on the screen. So that we may say broadly that celluloid lantern pictures, so far as their production and development are concerned, can easily be prepared. We have next to consider how far their use possesses advantages over glass slides which would cause them to supersede the older material.

The particular films which we have submitted to trial are cut to the standard size for lantern plates, and they exhibit a common characteristic of celluloid films in assuming a curved form when dry, caused probably by the gelatine surface shrinking to a certain extent, for the concave side is always that upon which the emulsion lies. This is the first mechanical difficulty which their use entails. Experiment shows that, when the film is submitted to warmth, the curve becomes more decided, and in a few seconds the picture is actually cylindrical in shape. Now the heat from a lime-lit lantern is so concentrated on the slide by the action of the condensing lenses, that it is impossible to handle a glass picture comfortably if it has remained in position beyond a minute or so. A celluloid picture under the same conditions, and held in a carrier, becomes so bulged that it is difficult to remove from the grooves, while, at the same time, it is of course forced out of focus. These considerations would, therefore, seem to indicate that such pictures cannot be used unless the lantern be furnished with an alum tank, or some other means by which the heat rays cannot affect them. But, supposing that this first difficulty be conquered, there remains another formidable one in the difficulty of keeping the film clean and free from dust. With an ordinary glass picture there is no difficulty here, for it can be breathed upon and polished with a leather on both sides, and good operators know well the advantage of thus keeping their slides bright and clean. But we dare not for a moment treat a celluloid film with such roughness, unless, indeed, each picture is furnished with a cover glass, and then, naturally, the chief advantage in employing celluloid—its light weight—is at once counteracted. Talc, if it were possible to obtain it of sufficient clearness and freedom from cleavage marks, would certainly answer the purpose of a covering material, and it is also a good heat interceptor; but, granted these conditions, it would furnish at once a better support for the sensitive film than celluloid itself. One more consideration, and an important one to reckon with, is that the newer material is more expensive than glass.

We are, therefore, compelled to admit that until manufacturers find it possible to make celluloid which shall preserve its flatness in all temperatures which are likely to assail it in lantern use, and can give us some protecting medium to take the place of a cover glass, it cannot hope to oust glass from its place as a material for lantern pictures. We hope and believe that these difficulties, like most mechanical problems, can be overcome. But when that time comes we may feel quite sure that the ideal method of showing lantern pictures of which many of us have lately dreamed is within reach. We mean the use of a panoramic arrangement of the roll-holder kind, by means of which the operator will be able to reel his pictures into view one after the other by the turn of a handle. We know that the old colossal panoramic pictures, which have been almost wholly superseded by the optical lantern, were wound up in this way, and it seems only reasonable to hope that the same device will be in time adopted by the modern teaching instrument.

At the same time we trust that what we have said will not dissuade any of our readers from putting the new lantern films to practical trial. The heat difficulty, which to us is the gravest, will not affect those who use small instruments. The undoubted advantages which celluloid possesses in the matter of portability, lightness, and freedom from brittleness, will perhaps tempt them to experiment with it, in order to see whether some of the drawbacks which we have indicated cannot in their hands be surmounted.

Newcastle-on-Tyne and Northern Counties Photographic Association.—Next meeting at Mosley Street Café, Newcastle, on Tuesday evening, the 24th March, at 7 30 p.m.; subject, "Bromide Contact Printing."

## ELECTRO-CHEMICAL REVERSALS WITH THIO-CARBAMIDES.

BY COLONEL J. WATERHOUSE, B.S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

IN the course of my experiments on photographic reversals with thio-carbamides, it struck me that the complete reversal by transfer of deposit from the exposed to the unexposed parts of the photographic image must be more or less connected with, if not caused by, some electro-chemical action, and that if this was the case it might be possible to obtain similar reversals by means of an electric current.

Becquerel showed, several years ago, that if two silver plates, coated under similar conditions with a haloid silver salt, and arranged so as to form part of an electrical circuit, are immersed in a suitable conducting fluid, the action of light falling upon one of the plates only, and not on the other, is accompanied by distinct electrical action. Professor Minchin has quite recently found that the same rule applies to silver plates coated with emulsions in gelatine or collodion of haloid silver salts, and immersed in very weak solutions of alkaline chlorides, iodides, or bromides. It may, therefore, be taken for granted that the action of light on an ordinary gelatine silver bromide plate is accompanied by more or less electrical action, and it did not seem necessary to repeat these observations.

The next thing to ascertain was whether, during the process of development, there was any similar electrical action between an exposed and an unexposed silver bromide film, or between the different parts of such a film partially exposed and partially covered, sufficiently strong to be detected with a galvanometer. Several attempts were made in various ways with this object, but unsuccessfully—partly owing to the want of a sufficiently sensitive galvanometer. It only remained to try the effect of passing an electric current from a galvanic cell through developers made up with and without thio-carbamides, and the apparatus was being got ready to do so when the PHOTOGRAPHIC NEWS and other journals, received by the mail of 23rd January, brought out the accounts of Professor Minchin's very interesting and important experiments in photo-electricity. From these I found that he had, to some extent, anticipated me by his discovery of the fact that, if silver plates coated with a silver bromide emulsion are attached to the poles of a battery, and half immersed in a weak solution of potassium bromide, the film attached to the carbon pole was visibly blackened on its immersed part, while no visible effect was produced on the other; but on developing this plate with pyrogallic acid and ammonia, its immersed part also became dark, exactly as if it had been exposed to light for a few seconds.

From this result it seemed probable that my own experiment would succeed. I had intended to use platinum plates for the electrodes, as recommended by Becquerel, in carrying out the photo-electrical observations above referred to, but, as the necessary supply of such plates would have been very costly, and pure silver plates were available, they were used, as Prof. Minchin's observations showed that they would answer as well, at any rate for the purpose in hand; but it would be very desirable to repeat the experiments with platinum plates. The silver plates used were about $1\frac{1}{2}$ inches wide and 4 inches long, and fixed, by means of a block of varnished wood, at a distance of about two-fifths of an inch apart. They were marked in varnish with C and Z respectively, so that in these parts the electrical connection between the silver plate and the silver bromide film was cut off.

The developers generally used have been the same as for the photographic reversals, viz., the eikonogen soda (Nicol's formula) or eikonogen lithia, both with sodium sulphite, as given in previous papers on these reversals; also ferrous oxalate slightly acid and with a little bromide. The developers were contained in small vertical glass cells holding about two ounces. The battery used was a small bichromate cell (bottle). A tangent galvanometer (Govt. telegraph pattern) was included in the circuit.

I have tried gelatine silver-bromide films and Eastman's bromide paper in contact with the silver plates, and with all of them have obtained reversed deposition when using an eikonogen developer containing thio-sinamine, but the films were difficult to manipulate and of doubtful character, while the paper increased resistance very largely, and the most decided result, and one which is also quite in accord with Prof. Minchin's observations, was obtained with silver plates treated with bromine water.

A pair of such plates, marked C and Z, and attached to the carbon and zinc poles respectively, were immersed in a plain eikonogen soda developer. A second pair of plates, marked $\frac{C}{TS}$ and $\frac{Z}{TS}$ were immersed in some of the same developer, to which about five drops each of a saturated solution of thio-sinamine and of bromide of potassium at ten per cent. had been added, or about the same proportions as used for the photographic reversals. The film sides of the plates were placed inwards face to face. After immersion in connection with the battery, the plates were washed and fixed as usual.

The immersions of the plates and passage of the current were, in all cases, carried on in the dark, and thus the results are in no way *photographic.*

The C plate showed fairly clear of deposit, but was slightly blackened, especially where the plate had not been quite clean; the top immersion edge was darker, as with reduced silver. The immersed part of the back of the plate was darker than the front, and also had a black edge at the top.

The Z plate showed a very strong dark deposit all over, with a clear line at the top. The varnished Z did not seem quite free from deposit. The back of the plate was also quite dark with deposit. This accords with Prof. Minchin's observation that the film in contact with his similar silver plate attached to the zinc pole was developable, though it had no visible image on it, being only immersed in potassium bromide solution.

Of the other two plates, $\frac{C}{TS}$ showed a strongish black deposit, with a dense black line at the top, and then a clear band above. The back of the immersed part was *very black*, with a light line at top. The black deposit looks like a silver sulphide.

The $\frac{Z}{TS}$ plate was almost quite clear on the face, and free from deposit, showing only a slight discolouration or tarnish, with no deposit on the varnished Z. At the top of the immersed surface was a clear band. The back of the plate was more strongly tarnished than the front, with a slight powdery deposit.

It will be seen that the results with the two developers are quite different, and may be represented by C and **Z** in the case of the plain developer, and by $\frac{\mathbf{C}}{\mathbf{TS}}$ and $\frac{\mathbf{Z}}{\mathbf{TS}}$ in the case of the developer with thio-sinamine, the black letters representing deposit, and the light ones freedom from it.

Similar results were obtained with bromide paper and gelatine dry plate films, but it may be remarked that, whereas the C plates showed with both developers a clear image of the varnished C, surrounded by more or less dense deposit (much denser and yellower with the thio-sinamine), there was a marked difference in the Z plates, that immersed in the plain developer showing a dense deposit with a clear Z, while, with the thio-sinamine developer, the Z is shown dark on a clear ground.

Ferrous oxalate does not seem to give such marked reversals—at any rate with bromide paper—as eikonogen does, and this agrees with the photographic results. With gelatine dry plate silver bromide films, it was noticed that, in the ferrous oxalate developer, the Z plates darkened first, and with the thio-carbamide the C plates blackened first and most strongly.

The developers seem to be good conductors of the electric current, and do not increase the resistance very much.

It may also be noted that pencil marks made at the back of the papers were found to be reproduced very strongly on their film side, in contact with the silver plates, and were strongest on plates treated with the thio-sinamine developer.

Having obtained these results with bromised silver plates, a further trial was made with similar plates to see if a current could be detected between an unexposed and an exposed plate without the aid of the battery, and this time with a more successful result. The plates were, as before, treated with bromine water, washed, and dried. The developer used was made up of 1 part each of eikonogen and carbonate of lithia, and 2 parts of sodium sulphite, in 100 parts of water. One plate having been exposed to a weak yellowish light, the plates were attached to the poles of the galvanometer, and the unexposed plate immersed in the developer. On dipping the exposed plate, the needle at once deflected some ten degrees, but quickly returned to zero. Another pair of plates gave the same result. A third pair immersed in the same way in some of the same developer, to which thio-sinamine and potassium bromide had been added in the proportions given above, showed a similar deflection, but the needle remained for some time at about five degrees, and only very slowly returned to zero.

It may be noted that after fixing, the exposed plate of this last experiment showed a black deposit with a dark line at the immersion edge. It showed little or no tarnish, and, in most respects, corresponded with the $\frac{\mathrm{C}}{\mathrm{TS}}$ plates of the experiments with the battery. The under-exposed plate, on the other hand, showed a very considerable yellow tarnish, stronger on the back of the plate than on its face, and no marked line at the immersion edge. Generally it corresponded with the $\frac{\mathrm{Z}}{\mathrm{TS}}$ plates of the battery experiments with the thio-sinamine developer.

The two plates used with the plain developer showed very little difference. There was deposit on both, but the exposed plate showed a light line at the immersion edge, and the unexposed one showed a black line.

On repeating the experiment, but with the plates attached to the wooden block, so that they were immersed together, it was found that, with the plain developer, no distinct current was produced on immersing the plates, or afterwards, though there seemed to be very faint indications of a current, which might be visible with a more delicate galvanometer. With the thio-sinamine developer, however, although there was no immediate deflection, the needle slowly turned in the same direction as before, to about five degrees, remaining there for some time, and then again slowly returning to zero. This action seems to correspond with the gradual change of the photographic image under the thio-carbamide developers.

On repeating this experiment with a fresh pair of plates, in fresh developer containing only one per cent. of sodium sulphite, and about 5 drops to the ounce of an alcoholic solution of Professor Reynolds' compound salt of thio-carbamide and ammonium bromide, exactly the same result was obtained.

The strong initial deflection of the needle when the plates were immersed separately appears to be due to polarity, and was noticed by Becquerel. On immersing two *unexposed* plates in the same way in plain developer, the same deflection was noticed, and very much stronger. These results cannot be taken as conclusive, and a great deal of farther investigation is necessary with other developers and thio-carbamides, as well as with other silver haloid films, used with and without the silver-plate conductors. The products formed at both poles by the electrolytic decomposition have also to be examined.

As far as the experiments go, however, they seem to show: (1) That the same kind of reversal of the deposit can be effected by a developer containing thio-sinamine, both electrically and photographically; (2) that the reversal of the photographic image on bromide of silver films by thio-carbamides is, to a great extent, if not entirely, due to electro-chemical action; (3) that the development of the photographic image on silver bromide is accompanied by electrical action.

Taken in connection with Professor Minchin's recent observations, and the earlier ones by Becquerel and others, they appear to point to the conclusion that photographic action, at any rate as regards the haloid salts of silver, is influenced by electricity, both in the action of light upon the silver haloid film, as well as in the development of the invisible image so produced, to a very much larger extent than has usually been recognised. This aspect of the theory of photography appears to have been somewhat neglected, but it seems likely that farther investigation in this direction would be rewarded with valuable results, and throw some further light on the mystery which still surrounds the formation and development of the invisible photographic image.

---

Putney Amateur Photographic Society.—Six new members were elected at the meeting on the 28th of February, when there was an exhibition of lantern slides.

Photographic Society of Great Britain.—March 24th, technical meeting; subject for discussion, "Hand-Cameras"; members are requested to bring their cameras with them. March 31st, lantern evening, and discussion on lantern matters. April 14th, Mr. W. Willis will read a paper on "Platinotype." April 28th, subject for discussion, "Animal Photography." The exhibition of collotypes will remain open till April 14th.

## THE PHOTOGRAPHIC CHART OF THE HEAVENS.

BY WILLIAM E. PLUMMER, M.A., F.R.A.S.

The proposal of Admiral Mouchez, the director of the Paris Observatory, to photograph the entire sky has been so long before the public, and so much has been written and said about it, that some hopeful persons may be under the impression that considerable strides have been made towards its accomplishment. Such sanguine persons may be surprised to learn that the scheme is not yet even commenced as a whole, but is still in its initiatory stage. The art—or, at least, the practice—of photography is now reduced to such simple and mechanical processes that it is feared this bold assertion, without any explanation, will suggest to many that astronomers are either very incompetent to the task, or very lukewarm in the undertaking. Such a suspicion would, however, be very unjust. Many difficulties and delays have supervened between the conception of the project and the putting it into execution. Possibly, if all the difficulties that have been successfully met had been present in the minds of the projectors, the scheme would never have entered the field of practical astronomy. As a matter of fact, some eighteen or twenty observatories have responded eagerly to the invitation of Admiral Mouchez: but the directors of these observatories have, in most cases, had to wait till callous and indifferent governments have voted the inevitable money grants. All have had to obtain the necessary instrumental appliances from a few competent artists, who required considerable time for the completion of the contracts. In order to ensure uniformity of action, many details have had to be settled by general conferences of all the participating astronomers, who cannot, of course, be frequently called together; but it is hoped that the next conference, summoned for this month, will be the last, for all the astronomers who have given their adhesion to the scheme will report that they are in possession of their instruments, and have made some progress in acquiring a knowledge of their peculiarities and facility in their use.

The principal optical difficulty, it goes without saying, is the construction of the lens. Photographers are so accustomed to make pictures covering wide angles that they will probably not appreciate the difficulties that opticians have encountered in the construction of a lens, which should give a sufficiently accurate field of two degrees in diameter. This is the same thing as photographing a picture of approximately six inches square at a distance of fifteen feet, and it would be thought a very poor lens that could not satisfactorily accomplish this task. But astronomers are exacting in their demands; they may not reduce the aperture of their lens (13 inches) by any "stops," and they have to submit the resulting pictures to considerable magnification, when many defects which would otherwise escape notice become apparent. It is then found that the images of stars, though perfectly round in the centre of the plate, become very elliptical near the edges. The size of the plate, it may be mentioned, is about six inches square, the focal length being about eleven feet; but to "cover" a six-inch plate is not generally thought a very severe trial in photographic manipulation.

We have said that the image of a star in the centre of the plate is round, but when seen under a microscope of moderate power the image does not present the appearance of a simple, round black disc, varying in size with the brilliancy of the star and the time of exposure, but rather exhibits itself as the condensation of many minute black points, very dense and compressed towards the centre in moderately bright stars, but towards the periphery the condensation is much less marked, and the total area covered by the star image is generally ill defined. In faint stars the condensation is scarcely noticeable; a larger or smaller number of particles of the silver salt are decomposed, but these particles are not necessarily in contact, and, therefore, complete blackness does not result. A more or less nebulous appearance, possibly a three-hundredth of an inch in diameter, therefore accompanies the images of faint stars on the negative, and, since the distance between these images has to be measured to about the ten-thousandth of an inch, it will be readily seen how important it is to procure small, hard, black discs. A peculiarity in stellar negatives, which is not yet fully explained, is the considerable spread of these images. In an ordinary telescope a faint star is a very minute point, approaching the geometrical definition, but on a sensitised film after long exposure, the size of the image is of a very measurable extent; and the rate of increase is peculiar. Allowing for some irregularities, the diameter may be said to increase as the fourth root of the time of exposure; that is to say, if, after an exposure of a minute, a star has a certain diameter, then, on the exposure being continued for sixteen minutes, it will be found that the diameter has doubled. This spread of the image may arise from two causes, either operating as an irradiation from the centre of disturbance; but whether this irradiation is produced by scattered reflection among the separate particles of bromide of silver, or is due to a species of fluorescence, or some similar property in the sensitive film, is undecided. Be that as it may, a plate after development exhibits a number of these small black discs, differing in size and intensity according to the brightness of the stars, and therefore giving, in addition to their relative positions, the photographic magnitude of the stars themselves. These negatives can be printed on either silver or bromide paper, and thus a picture of the heavens of great accuracy is always at the command of astronomers, who, to some extent, may, therefore, hope to continue their studies irrespective of clouds and bad weather, while to successive ages is secured a picture accurately representing that portion of the sky at the period at which that negative was taken.

The measurement of these plates is, however, not a simple business, for over and above the distortion likely to be introduced from the necessary imperfection of the object glass and the employment of a plane plate, there is the additional difficulty that the film, in some of the processes of developing, fixing, washing, and preserving, may shift locally on the plate itself, carrying with it the images impressed, and so giving a faulty representation of the relative positions of the stars. This difficulty has been met in an ingenious manner. On a plate—the size of those to be subsequently employed—a film of silver has been deposited, and on this film a network of lines about one-fifth of an inch distant is ruled at right-angles, in such a manner as to remove the opaque silver and leave the glass exposed. Before a plate intended to obtain a picture of the stars is exposed in the telescope, this reticulated plate is placed against the film, and, by means of parallel light, a latent picture of the reticulations is left on the sensitised surface. The silver, of course, prevents the light affecting the other parts of the film; therefore, after exposure, in developing, this network picture and the star images come up together, and if there be any local shift in the film a method of correction is supplied.

The development of a plate, also, is not without its difficulties. If there be no bright stars on the plate, and there are many spots of two degrees square on the heavens in which the eye cannot detect a single star, the growth of the picture is a matter of guesswork, and generally decided by the discolouration of the plate. It has been promised that the whole question of the preparation of the most suitable and most sensitive emulsion, as well as development and subsequent preservation of the negative, should be threshed out under the auspices of the well-known photographer, Dr. Eder. The results of the experiments, which, it is understood, have been carried on in his laboratory, have not yet been published, but are looked forward to with interest. Among other difficulties in development there is the old question of the adequate treatment of violent contrasts in light.

If you have a star of the first magnitude, and one of the sixth, you have in the former one hundred times the light in the latter, while, if the range extends through twelve magnitudes, the light of the brightest star is to that of the faintest as unity to sixty thousand. Therefore, there must be stars both violently over-exposed and under-exposed, all to be developed together, and the images often in contact. The effect of this violent contrast will be appreciated when we say that the images of the brighter stars are usually seen reversed, that is to say, the centre is white instead of black.

The manipulation and the subsequent discussion of a single plate does not seem to offer insuperable difficulties, but it must be remembered what a very small portion of the entire sky is a district of two degrees square—the portion which is represented on a single plate. On a globe there are approximately 40,000 square degrees, so that ten thousand plates will be necessary, and since—to secure accuracy, and to be certain of the elimination of untoward specks and spots on the plates which have much the appearance of stars, but are not—it is proposed to cover the whole area of the heavens *twice*, twenty thousand plates will be required. To some large photographers the manipulation of this number of plates may not seem a very extraordinary undertaking, but then it must be remembered that the exposure required for the production of each plate is much longer than anything to which they are accustomed. In order to secure impressions of the stars of the faintness thought necessary by those who are responsible for the scheme, an exposure of probably fifteen minutes for each plate will be required, while, to carry out the grand scheme in its integrity, exposures of probably not less than ninety minutes will be necessary. When it is farther remembered that these exposures can only be made at night, and when the sky is transparent, it will be admitted that astronomers are courting a sufficiently onerous task, but one which, it is hoped, they will be able to carry to a successful issue.

It is altogether premature to guess at even the number of stars which will record themselves on the sensitised films, but one thing is certain, all stars of a definite degree of brilliancy will be secured. There is no possibility of a photographic plate overlooking or neglecting to record the position of a star, though, of course, in the discussion of the plates afterwards, human infirmity may and will fail to describe all the facts recorded on the film; but the negative remains for re-examination and re-discussion, and much negative evidence is effectually excluded. The places of all the stars depicted on the plates, obtained with the shorter exposure mentioned above, it is hoped to form into a catalogue, which may possibly grow to the dimensions of a small library. But the results from the longer exposure must be left in a chart-form, from which astronomers of the future must pick out the precise facts for which they are seeking.

*Oxford University Observatory.*

## A RAPID SENSITIVE SALT FREE FROM SILVER.

Little in accordance with scientific custom is it to publish much about new results when the means of arriving thereat are kept secret for commercial or other purposes, but having the trustworthy assurance of Mr. Frederick Varley that, in the experiment which he performed at the close of Professor Meldola's lecture at the Society of Arts last Monday night, there was no silver salt in the sensitised paper or in the developer, or in any of the solutions he used, and that the materials employed were all excessively cheap, we append a few particulars.

Mr. Varley said that the process was the result of researches made by Mr. Friese Greene. Mr. Varley exposed some paper sensitised with the salt under a negative to the diffused gas-light of one of the reading lamps, in which a great amount of the light, to the extent of at least forty per cent., was cut off by having to pass through an opalescent shade and dish; under these conditions an exposure of about half a second was amply sufficient to secure a good picture full of detail in the shadows. We are informed by Mr. Varley that in some recent experiments he has made in conjunction with Mr. Greene, he has found means to render this salt four times as rapid. He says that had the exposure last Monday been made to a naked gas flame, one-fifth of a second would have been sufficient. By Mr. Varley's additional discovery, he claims that under like circumstances he could have given one-twentieth of a second. Some months back we made some mention of the discovery of this new sensitive salt, and have in our possession a print of a doll taken by its use at that time.

The Photographic Club.—March 25th, lantern night; April 1st, adjourned discussion on "Shutters." Bank Holiday outing at Leigh, near Southend.

Aluminium.—Among the uses of aluminium suggested by Mr. Eugene H. Cowles, according to *Modern Light and Heat*, are the following:—At 50 cents per pound, the new metal will compete with copper at 17 cents, the latter being 3·56 times as heavy as an equal bulk of aluminium; but the electrical conductivity of aluminium, that is, 98 per cent. pure, is only 75 per cent. that of copper, so that one-third more area would be required to do the same work. A reduction of 45 per cent. in weight of motors for electric cars can be secured by using the new metal, which in itself is no small advantage, seeing that the latter promise to come into extensive use in the near future. The coating and lasting qualities of aluminium far surpass those of tin, and it will cover three times as much surface for equal weights, making it necessary to sell tin at 16 cents per pound in competition with the other at 50. Nickel at 70 cents would no longer be used for plated ware or coinage, the new metal being much cheaper and cleaner. He expects to see it sell at 200 to 300 dollars per ton, and at these figures it will be the cheapest metal next to iron and steel. The price must fall lower and lower as the facilities increase for making the material, and the market adapts itself to the absorption of larger quantities of the new metal.

## PHOTOGRAPHIC SHUTTERS.*

BY FRANCIS BLAKE.

19. *Prosch* (*Special*) *Duplex*.—Made to order for euryscope wide-angle lenses. Time exposure, squeezing the bulb as quickly as possible, 0·211 s. Instantaneous exposure, direct compression of bulb, 0·031 s. Instantaneous exposure, released compression of bulb—1st test, 0·020 s.; 2nd test, 0·021 s. This is a most conveniently arranged shutter, as it is attached to the front-board of the camera; and carries on its front face a flange which receives any one of a set of wide-angle lenses.

Now, the results which have just been given hurriedly have probably made but little impression on the minds of most of those who are present. A few of you may have had an intelligent interest in the statement of results obtained with some particular shutters with which you are familiar; but, in general, you probably have but an indistinct memory of a lot of unintelligible figures. Nevertheless, if you had had time to carefully digest the results obtained, I feel sure that you would have reached the conclusion that the average working speed of commercial shutters is about three hundredths of a second, and that while a few of these shutters may be forced to come well within this average speed for test purposes, they are made to do so at the expense of so great a loss of light that they are of but little practical use when so forced. Three hundredths of a second is too slow a speed for photographing the quickest motions of animate or inanimate nature, and the successful pictures obtained with shutters of that speed are due to the fortunate coincidence between the moment of exposure and a slower phase of motion. Thus, with such a shutter, the most rapid phases of motion produce blurred plates, which are thrown into the waste box; and science receives but a few special—and, therefore, misleading—data in place of the many which the art of photography should be made to yield. This generalisation forced itself upon Mr. Hubbard and myself after two years of patient experimentation with every conceivable form of shutter applied before, between, or immediately behind the lens; and, at his suggestion, we then abandoned all work in that direction, and devoted ourselves to the perfection of the focal plane shutter as described in the quotation from Sutton at the beginning of this paper.

I have known of no commercial shutter which passes more than 50 per cent. of the light which falls on the lens during its action; while the focal plane shutter has been lying idle for twenty-five years, in spite of its ability to pass close on to 100 per cent. What may be called the "light advantage" of the focal plane over an ordinary shutter is well indicated by the following considerations. With any form of shutter in which a slot one inch in width passes at a uniform velocity behind a lens one inch in diameter, the sensitive plate will receive but 50 per cent. of the light which falls on the lens during the action of the shutter. Supposing the lens to be five inches in focal length; if the slot is merely moved backward to within one-quarter of an inch of the plate, 95 per cent. of the light falling on the lens during the action of the shutter will reach the plate.

Farther consideration of the subject shows that in any single shutter placed immediately before, between, or behind a lens of one-inch opening, the percentage of light passed is equal to the number of inches of slot travels less one times the units of light per inch. Thus, a one-inch slot travels two inches in uncovering and covering the lens. Calling the total light falling on the lens during the action of the shutter equal to 100 units, we have 50 units to each inch of the slot travel. Slot travel two inches minus one$=$1 inch $\times$ 50$=$50, which is the percentage of light passed. A two-inch slot would travel three inches, and there would be $33\frac{1}{3}$ units of light to each inch:—

$3-1 = 2 \times 33\frac{1}{3} = 66\frac{2}{3}$, the percentage of light passed. Continuing the computation, it will be seen that a 3-inch slot would pass 75 per cent.; a 4-inch slot 80 per cent.; and so on until, in order to pass 90 per cent. of the light, it would be necessary to have a slot nineteen inches long pass by the lens in the same time that the focal-plane slot passes over five hundredths of an inch, which is the diameter of the cone of rays from a one-inch lens of five inches focus at a point one quarter of an inch in front of the sensitive plate. Opposed to this tremendous advantage, there is only one theoretical objection to the principle of the focal-plane shutter; and that is, that all parts of the sensitive plate are not exposed at the same time. But practically this objection does not hold good, since the velocity of slot motion may be made so great that there is no sensible distension of the phase of motion of the moving object. Moreover, the possibility of any distension may be eliminated by setting up the camera at such a distance from the moving object that the angular value of its image on the sensitive plate shall be equal to, or slightly less than, the width of the shutter slot.

The focal-plane shutter which I now show you is the outcome of the experimental work carried on by Mr. Hubbard and myself during the last four years. It consists of a mahogany case attached to the back-board of a $6\frac{1}{2}$ by $8\frac{1}{2}$ camera. The case is $18\frac{1}{2}$ inches long, $9\frac{1}{2}$ inches high, and $\frac{7}{8}$ inch thick outside measurements. At its centre is an opening in which may be placed a focussing screen on a 4 by 5 plate-holder.

Within the case are two screens, $5\frac{1}{2}$ by $5\frac{3}{4}$, and $4\frac{1}{2}$ by $5\frac{3}{4}$ inches in size. They are made of a very light frame-work of bamboo covered with thin tissue paper rendered thoroughly light-proof by the application of a mixture of lamp black and shellac. These screens run freely on two brass wires strained lengthwise across the wooden case above and below the plate-holder opening.

Attached to the base of the larger screen is a piece of thin sheet steel pivoted to the corner of the base at one end, and divided on its lower edge into ten notches one-tenth of an inch apart. Attached to the opposite corner of the base of the smaller screen is a screw stud, over which the notched piece may be slipped. By this simple bit of mechanism the two screens may be, at will, attached to each other with a slot between them varying from one-tenth of an inch to one inch in width by tenths. The exposure is made while this slot is passing over the sensitive plate, motion being imparted to the screens by means of a steel pin connecting them with a wooden piston, which, in turn, is driven through a brass tube by compressed air.

With a one-tenth inch slot, in connection with a 2B Dallmeyer lens, three tests for speed of this shutter have given the following results:—

| | |
|---|---|
| 1st test ... ... ... ... ... | 0·0006 |
| 2nd ,, ... ... ... ... ... | 0·0006 |
| 3rd ,, ... ... ... ... ... | 0·0005 |
| Mean | 0·0006 |

* Continued from page 188.

This speed, which we may call half a thousandth of a second, is a severe tax upon the ability of the most rapid lenses and plates to produce pictures. It is obvious that the speed of the shutter may be increased to any desired extent by simply narrowing the width of the slot; but, until the market affords us quicker lenses or plates, there will be no practical advantage in making exposures of less than half a thousandth of a second.

The lantern slides of pigeons in flight which will now be thrown upon the screen were made from negatives taken with this shutter, using a slot two-tenths of an inch wide. The length of the exposure was, therefore, one-thousandth of a second, but you will note that the eyes and feathers of the birds are as sharp as if they had been standing still.

[Enclosed with the foregoing paper was a print from a plate recently made from one of Mr. Blake's negatives. The original negative was made during November, 1889, on a 4 by 5 Cramer 50-plate, 1,000th of a second exposure, and developed with Elliott's single solution hydrochinone developer; 3B Dallmeyer lens full opening was used. The photogravure plate was made from a negative which was taken from a positive about two diameters larger than the original, using Cramer 30-plates and pyro carbonate-soda developer for both steps of the work.—Ed. P. N.]

## THE ANTWERP INTERNATIONAL MICROSCOPIC EXHIBITION.

Dr. Henri Van Heurck sends us the prospectus of the forthcoming International Microscopic and Photomicrographic Exhibition at Antwerp, which will be open during the months of October and September next, a lengthy document, which can be had on application to the general secretary, M. Charles Van Geert, Jr., vice-president of the Floral Circle of Antwerp. The president is M. Charles de Bosschere, the vice-president Dr. Henri Van Heurck, and the other members of the executive committee are MM. Edmond Grandgaignage, Gustave Royers, and Ferdinand Van Heurck.

Two other exhibitions will be open in Antwerp at the same time, the one of vegetable products, and the other of horticultural products.

At the Microscopic Exhibition, which will take place in the Royal Athenæum at Antwerp, almost all objects directly or indirectly connected with microscopy will be received, so far as can be judged from the programme. The honorary presidents of the Exhibition are Dr. Abbe, Professor at the University of Jena; Mr. Crisp, treasurer to the Royal Microscopical Society; and M. Nachet, optician, of Paris. Honorary committees representing various nations have been formed; the English one consists of Sir J. D. Hooker, honorary director of Kew Gardens; Mr. John Mayall, Jr., secretary to the Royal Microscopical Society; Mr. Julien Deby, Dr. Maddox, Dr. Dallinger, Mr. Andrew Pringle, and Mr. A. Comber.

Prizes will be given in recognition of the best exhibits. The prizes will consist of diplomas of excellence, diplomas of honour, gold medal diplomas, silver medal diplomas, bronze medal diplomas, and diplomas of honourable mention.

Leeds Photographic Society.—On Monday evening last Mr. Godfrey Bingley, president of the Society, gave the third of a series of elementary lectures, his subject on the present occasion being "Albumen and Aristotype Printing." Prints illustrating the processes of printing dealt with were handed round.

## THE FEDERATION OF LONDON PHOTOGRAPHIC SOCIETIES.

The following circular has been sent to London and suburban photographic societies:—

11, *Leadenhall Street, London, E.C.*
*March 14th*, 1891.

Dear Sir,—I have just heard from the Photographic Society of Great Britain, kindly granting the use of a room at 50, Great Russell Street, Bloomsbury, W.C., for the meeting held there on Monday, March 2nd, and adjourned to Monday, March 23rd, at 8 p.m., and trust your society will be represented by two delegates.

Will you please fill in and return to me the enclosed form not later than Friday, March 20th.

By way of agenda paper, I append a copy of the resolutions passed at the meeting of the 2nd inst. Will you please be prepared to vote as to whether the first delegates should continue in office till the first annual meeting.—Yours truly,

Lewis M. Biden.

Agenda.

*Resolutions passed at the meeting convened by Mr. L. M. Biden, of Delegates from the London and Suburban Photographic Societies, on the 2nd March,* 1891.

1. That it is desirable to form an association or federation of societies and clubs whose members are interested in photography.

2. That the London and suburban societies be requested to send two delegates to make the necessary arrangements to settle the name and draw up the constitution of the proposed association, and to fix the terms of membership, &c., the delegates to have power to appoint a committee for this purpose, such delegates to continue to act for a period not exceeding six months from the launching of the association.

3. That the delegates take into consideration the following objects first: (*a*) The interchange of lectures, papers, lantern slides, &c.; (*b*) the obtaining the reduction of railway fares to photographers on their outings, either singly or in parties; (*c*) the admission of the various societies joining the federation as corporate members of the Photographic Society of Great Britain; (*d*) generally to promote photographic knowledge and research.

4. That the delegates be requested to prepare a list of honorary lecturers, who, when disengaged, will, without charge or fee, lecture, read papers, give demonstrations and lantern evenings before other societies, and to make rules in connection with the expenses, and otherwise.

Mr. Biden adds:—Mr. Buchau proposes to ask for secretaries to furnish prints of London photographs from all negatives in possession of their members, with a view to using them as a commencement of a survey of London.

Appended is a copy of the "enclosed form" of which Mr. Biden speaks in his letter:—

The following Members of the Photographic Society are willing to lend Lantern Slides and to Lecture without fee or payment, except expenses (limited to ) for travelling (and gas?). This is conditional on no special engagement preventing, and the lecture hall being sufficiently easy of access:—

| Name of Lecturers. | Their Private Address. | If possessing a Lantern and Screen. | Name or Subject of Lecture or Paper, and if written. | If he will only lend Slides. | Number of Lantern Slides. |
|---|---|---|---|---|---|
| | | | | | |

London and Provincial Photographic Association.—March 12th was a lantern night, and the evening was occupied with the exhibition of members' transparencies. A large number of slides was projected on the screen, contributed by Messrs. Howard, Chang, Wellington, and others. Mr. W. H. Prestwich occupied the chair.

## AMERICAN INTERNATIONAL COPYRIGHT GRANTED FOR PHOTOGRAPHS.

The following is the full text of the United States International Copyright Act, just passed, and which includes photographs:—

Be it enacted,—That section 4,952 of the Revised Statutes be, and the same is hereby amended so as to read as follows :— "Section 4,952.—The author, inventor, designer, or proprietor of any book, map, chart, dramatic or musical composition, engraving, cut, print, or photographic negative thereof, or of a painting, drawing, chromo, statue, statuary, and of models or designs intended to be perfected as works of fine arts ; and the executors, administrators, or assigns of any such person shall, upon complying with the provisions of this chapter, have the sole liberty of printing, reprinting, publishing, completing, copyiug, executing, finishing, and varying the same, and iu the case of dramatic composition, of publicly performing or representing it, or causing it to be performed or represeuted by others, and authors or their assigns shall have exclusive right to dramatise and translate any of their works for which copyright shall have been obtained under the laws of the United States."

*Section* 2.—That section 4,954 of the Revised Statues be, and the same is hereby amended so as to read as follows :— "Sectiou 4,954.—The author, inventor, or designer, if he be still living, or his widow or childreu, if he be dead, shall have the same exclusive right continued for the further term of fourteen years, upon recording the title of the work or description of the article so secured a second time, and complying with all other regulatious in regard to original copyright within six months before the expiration of the first term, and such person shall, within two months from the date of said renewal, cause a copy of the record thereof to be published in one or more newspapers printed in the United States for the space of four weeks."

*Section* 3.—That section 4,956 of the Revised Statutes of the United States be, and the same is hereby amended so that it shall read as follows :—"Section 4,956.—No persou shall be entitled unless he shall, ou or before the day of publication in this or any foreign country, deliver at the office of the Librarian of Congress, or deposit in the mail within the United States, addressed to the Librarian of Congress at Washington, district of Columbia, a printed copy of the title of the book, map, chart, dramatic or musical composition, eugraving, cut, print, photograph, or chromo, or a description of the painting, drawing, statue, statuary, or a model or design for a work of the fine arts, for which he desires a copyright, nor unless he shall also, not later than the day of the publication thereof in this or any foreign country, deliver at the office of the Librarian of Congress at Washington, district of Columbia, or deposit in the mail within the United States, addressed to the Librarian of Congress at Washington, district of Columbia, two copies of such copyright book, map, chart, dramatic or musical composition, engraving, chromo, cut, print, or photograph, or, in the case of a painting, drawing, statue, statuary, model, or design for a work of the fine arts, a photograph of same ; provided that in case of a book, photograph, chromo, or lithograph, the two copies of the same required to be delivered or deposited as above shall be printed from type set within the limits of the Uuited States, or from plates made therefrom, or from uegatives or drawings on stone made within the limits of the United States, or from transfers made therefrom. During the existence of such copyright, the importatiou iuto the United States of any book, chromo, lithograph, or photograph so copyrighted, or any edition or editions thereof, or any plates of the same not made from type set, negatives, or drawings on stoue made within the limits of the United States, shall be, and it is hereby prohibited, except iu the cases specified in paragraphs 512 to 516 inclusive in section 2 of the Act, entitled 'An Act to reduce the revenue aud equalise the duties on imports, and for other purposes,' approved October 1st, 1890 ; and except in the case of persons purchasing for use, and not for sale, who import subject to the duty thereon not more than two copies of such book at any one time ; and except in the case of newspapers and magazines not containing in whole or in part matter copyrighted under the provision of this Act, uuauthorised by the author, which are hereby exempted from prohibition of importation ; provided, nevertheless, that iu the cases of books in foreign languages of which only translations in English are copyrighted, the prohibition of importation shall apply ouly to the translation of the same, and the importatiou of the books in the original language shall be permitted."

*Section* 4.—That section 4,958 of the Revised Statutes be, and the same is hereby amended, so that it will read as follows : "Section 4,958. The Librarian of Congress shall receive from the persons to whom the services designated are rendered the following fees :—First, for recording the title or description of any copyright book or other article, 50 c. ; second, for every copy uuder seal of such record actually given to the person claiming the copyright or his assigns, 50 c. ; third, for recording and certifying an iustrument of writing for the assignment of a copyright, 1 dollar ; fourth, for every copy of au assignment, 1 dollar. All fees so received shall be paid into the Treasury of the United States, provided that the charge for recording the title or description of any article entered for copyright, the production of a person not a citizen or resident of the United States, shall be 1 dollar, to be paid, as above, into the Treasury of the United States, to defray the expenses of the list of copyright articles, as hereinafter provided for. And it is hereby made the duty of the Librarian of Congress to furnish to the Secretary of the Treasury copies of the entries of titles of all books and other articles wherein the copyright has been completed by the deposit of two copies of such book, printed from type set within the limits of the United States, iu accordance with the provisious of this Act, and by the deposit of two copies of such other article made or produced in the United States ; aud the Secretary of the Treasury is hereby directed to prepare aud print at intervals of uot more than a week catalogues of such title eutries, for distribution to the collectors of customs of the Uuited States, and to the postmasters of all post-offices receiving foreign mails, and such weekly lists as they are issued shall be furnished to all parties desiring them at a sum uot exceediug 5 dollars per annum ; and the Secretary and the Postmaster-General are hereby empowered aud required to make and enforce such rules and regulations as shall prevent the importation into the United States, except upon the couditions above specified, of all articles prohibited by this Act."

(*To be continued*).

Photographic Subjects in Polynesia.— *The Colonies and India* describes a new field for photographers, and photographs of the ruins meutioned would be of considerable interest : "Mr. H. B. Sterndale, who passed to and fro among the Pacific Islands with an observant eye a few years ago, has lately been making public the result of his researches among the Cyclopean remains to be found in various parts of the Polynescau archipelagoes. Ponapé, where the Spaniards are now busy carrying on a war of extermiuatiou against the unfortunate natives, has long been knowu to travellers in that region for its curious relics of an earlier civilisation, and evidence of the remains discovered upou the Easter Island some years ago are at the present time to be seeu in the rude statues which stand at the eutrauce to the British Museum. Mr Sterndale appears to have gone further afield, and in the island of Lele he made some interesting discoveries. Lele is situated in 98deg. south latitude, aud 160 deg. east longitude, and is described as a volcanic islaud, with an extinct volcano scarped and walled to the summit. Here is to be found a wilderuess of ruined castles, the walls in some cases 12ft. thick and from 30ft. to 40ft. in height. They are iu the form of parallelograms, 200ft. by 100ft. for the most part, but some are described as being very much larger. Many of the buildings appear to have been erected upon artificial islets, which are surrounded by canals liued with stoue. The theory put forward by Mr. Sterndale is that early Hindoos reached not only Polynesia but Central America, and he points to the use by the Polynesians of the word 'meru' for paradise, aud the word 'dewa' for spirit, as distinct evidence in support of his contention."

## Notes.

Belgian photographers, in their official organ, the *Bulletin Belge*, have expressed few or no opinions about the coming International Photographic Congress in Brussels, which, it is to be hoped, will not be held at the same time as the meeting of the British Association for the Advancement of Science, at Cardiff. At a recent meeting of the Brussels Section of the Belgian Photographic Association, the chairman, M. Alexander de Blochouse, stated that he had been to Paris to attend a meeting of the permanent committee of the Congress; that committee will soon cease its functions in Paris and move to Brussels. At the same meeting a letter from M. Declercq de Grammont was read, urging that the next Congress should recommend that every photographic lens should have engraved upon its mount the size of plate which it covers perfectly with the largest aperture, also the amount of angle included.

S. Simon, in relation to our remark last week about unicorns, the Liverpool Amateur Photographic Association, Professor Huxley, and the basilisk, is prepared to believe in the unicorns, although he has never seen one, because they are mentioned in Scripture; but he is inclined to think the statement about the basilisk to be a mistake. He may, therefore, be informed that the basilisk is also mentioned in the Old Testament under the name of the cockatrice. Pliny and other celebrated authorities describe the animal. It is a serpent born from a cock's egg, has plenty of legs and claws, and a fine long tail; on its head is a kind of crest. Its glance is so fell that when a man catches its eye the man falls down and dies; when he sees another variety of the basilisk all the flesh falls from his bones. The only living things the basilisk fears are the weazel and the cock, which is why they keep so many of the latter birds, and other poultry, at the back of the Alexandra Hotel at Liverpool. The best time for photographing the basilisk in the forests near that city is after dinner, when there is plenty of sunshine about, and when the adventurer is guided by any suitable member of the Corporation of Liverpool. Basilisk hunters carry a piece of looking-glass to catch and throw back the deadly glance of the creature, thus causing it to slay itself. It is useless, in these dangerous photographic excursions, to carry any other than a demon camera; if one of the blue demon description be employed the quest is all the more likely to be successful. Professor Lippmann might be invited to join in the next hunt to try the efficacy of his mercurial mirror. Those photographers who wish to join the next basilisk hunt have our permission to write for an invitation to Mr. Paul Lange, president of the Liverpool Amateur Photographic Association, and to enclose their portraits. Those who wish to know more about the habits of the animal should write to Mr. Bartlett, the superintendent of the Zoological Gardens, London.

A committee of one person never loses time in talk or in idle contention, but carries out all its designs promptly without let or hindrance from colleagues. Washington Irving tells of a fierce debate in Congress, in its early days, as to which department of the State fell the duty of stopping up a hole in the wall of the Parliament House, through which hole the winds of heaven blew, and gave the legislators colds in their heads. The debate had waxed hot for three nights, when a member of Congress resolved himself into a committee of one, and paid a bricklayer to stop up the hole. This brought the debate to an end. Instead of originating palavers at society meetings and in newspapers, Mr. Lewis M. Biden, of the Toynbee Camera Club—whatever and wherever that Club may be—single-handed called a meeting of delegates of London photographic societies to consider the question of the federation of such societies, which now find themselves half way to practical federation before they know much about the matter or have had time to breathe. Mr. Biden can say, with one of old, "Alone I did it." In accordance with a resolution passed at the last meeting, he has called another meeting of delegates for Monday evening next at the rooms of the Photographic Society; in his circular doing so, dated March 14th, he gives some of the resolutions passed at the last meeting, omitting the one to invite delegates from the Photographic Society to attend. The so far suggested objects of the federation seem to be of a reasonable and useful nature.

M. Janowski has been trying experiments on the action of light upon the typhus fever bacillus, and finds that it tends to kill it, no doubt by oxidation, and that the more actinic rays of the spectrum exercise most power in this respect. They tend to kill protoplasmic matter. They have the same influence over the diphtheria bacillus. Perhaps a conclusion may be drawn from this, that the dirty air of London not alone is an obstacle to the rapid taking of photographs, but promotes the disease of human beings by cutting off the supply of the most actinic rays. The intense blue colour of some Alpine flowers, a richer blue than ever seen in the lowlands, has often been speculated to be in some manner due to the rich supply of violet and ultra-violet rays which vegetation receives in those regions of pure air.

A recent action, brought by a photographer against a lady client for the price of copies of portraits supplied to her, indicates a carelessness in business arrangements which is as unfortunate as it is indefensible. According to the defendant, she was asked by the photographer, "by way of compliment," to have her portrait taken, and for this she received a few copies for herself, while the complainant "sold thousands of her photographs to the public at a very handsome profit." We presume, therefore, that the lady had attractions which gave her pictures a considerable value. At any rate, she refused to pay for the pictures, and she was supported in her contention by the Court, who gave a verdict in her favour, with full costs. It is so much against the interests of a photographer to treat his clients in this manner, to say nothing of the moral aspect of the case, that it is probable that the unfortunate dispute is due more to carelessness than anything else. Still, it is to be much regretted.

---

It has been suggested that, at public complimentary dinners, photographic portraits of the guests should be distributed at the table, not in the form of pictures mounted on card, but burnt-in by the ceramic process on the plates. Such decorated chinaware is not unknown in private houses, and we are told of one household where the cups, saucers, and plates used in the breakfast-room are so ornamented. Each member of the family is provided with his share of the table equipage bearing his own likeness, so that, as he drains his cup, he can view himself "as in a looking-glass." The idea might be extended by using the portraits of public characters, and such pictures would often stimulate conversation, which, in too many assemblies, is apt to flag.

---

It is a truth which no wise man will dispute, that most persons who quarrel with photographers for giving them portraits which are the reverse of prepossessing, should blame Dame Nature for defrauding them of those gifts which they lack, rather than the innocent owner of the camera for not reproducing that which does not exist, save in their own imaginations. Those who are deficient in perfection of personal appearance have now, we are glad to see, their remedy, and, for the cost of a few shillings, can supply what nature has denied them. They need no longer abuse the poor photographer for fancied slights, for the cure is in their own hands; at least, we presume so from what we are told in a certain advertisement which has lately appeared in one, or possibly more, of the London papers.

---

The advertisement is to the effect that an artificial nose can be supplied for 42s. (we presume that Grecian, Roman, or the tip-tilted variety can be obtained according to the taste of the purchaser). An instrument for outstanding ears—and most persons who reply to the advertisement are apt to have this disfigurement in an exaggerated form—can be had for half a guinea. Splints for crooked limbs are quoted at the same price, as are those for enlarged toe-joint. A bust improver is one guinea, a finger nail ditto 3s. 6d. Knee-caps, for increase of height, aro 7s. 6d., while, strangely enough, a leaflet code of laws for increase of stature, which seems to our unenlightened minds to be much the same thing, can be had for half a crown less. This advertisement is almost as sublime as a better-known one of American origin, which advocated the use of a cement which was warranted, among other virtues, to mend a sinner's wicked ways.

---

Dr. Gill, the Astronomer-Royal of the Cape, had an enthusiastic reception at the Royal Astronomical Society, when he gave an interesting *resumé* of the stellar photographic work which has been carried on at the Cape Observatory. While Dr. Gill says that he makes no claim to have initiated the idea of applying photography to stellar astronomy, an idea which has its latest outcome in the elaborate chart of the heavens, in the preparation of which so many astronomers are now engaged, he says that his photographs of the comet of 1882 first directed the attention of Admiral Mouchez, and that of the brothers Henry, to the application of photography to star charting. This photograph, which was secured with the assistance of a local photographer, who lent the astronomer a camera, bids fair to become an historical one, for it was taken under peculiar circumstances, the comet being plainly visible, although the sun was shining.

---

It is well known that photo-micrographs frequently give an erroneous rendering of the different tints seen on delicate and transparent objects in the microscope. When this erroneous rendering is supplemented by the artificial contrasts due to chemical intensification of the original negatives, or to the after-processes of copying and enlarging, it becomes of the first importance, in cases where photographs are brought forward in illustration of certain points, that either the original negatives, or reproductions of them as exact as possible, should be exhibited. When, says Mr. Mayall, as in many cases—notably by Dr. Van Heurck—enlarged photographs are brought forward without any precise description of the process of their production, and without the original photo-micrographs for comparison, useful criticism is difficult, if not impossible. The moral of this clearly is, that all microscopists should be skilled photographers, because, unless they are able to distinguish between negatives, of what use is the exhibition of the original negative and the enlargement therefrom?

---

A retired actress of Louisville has taken to photography, and also advertises her proficiency in the art of "making-up"; in other words, she undertakes to instruct ambitious amateurs how to transform their ordinary countenances into those of the characters which they wish to impersonate. This combination of photography with "making-up" suggests the desirability of having a skilled person attached to the studio who will prepare the face of a sitter for being photographed, so as to save the subsequent labour of retouching. If faces have to be improved, it would surely be more sensible to put in the improvement before rather than after being photographed, because, as every artist who has to make use of photographs knows, the retoucher frequently destroys every essential line which makes up the character of a face. Now, if it were possible to make up the face photographically, so to speak, the sitter would be flattered without having the individuality destroyed. It is a subject, of course, which requires some study, and not a little will depend upon the quantity and nature of the colours employed by the retoucher of the living subject.

## PHOTOGRAPHIC CHEMISTRY.

### II.

Last Monday night Professor Meldola delivered the second of his three lectures at the Society of Arts, under the presidency of Mr. Francis Cobb. There was a large attendance.

Professor Meldola said that the existence of sub-salts of the silver haloids has not yet been conclusively demonstrated, and he gave a list of the chief researches of the past in relation to this subject, including some by a British Association committee. By analogy, he said, it seems improbable that sub-salts of silver would be highly coloured, and the products obtained by those who sought to make them by reduction have all been highly coloured. It has been suggested that these products contain oxygen, and, in fact, the whole matter requires additional careful and minute study.

If silver foil be placed in cupric chloride, during the process of chlorination films of brilliant colours are formed, and a study of these films may throw light upon the phenomena of heliochromy: many of the colours are optical and not pigmental. All the heliochromic results obtained, from those of Seebeck down to those of Lippmann, he thought to be dependent more or less upon thin films, which yield colours by the interference of light. The lecturer next spoke of the coloured products obtained by Carey Lea, and produced one of them by experiment; he added that no complete analysis of such products has yet been made, and that it is not known whether they do not contain traces of some impurity, such, for instance, as iron. It must also be remembered that silver haloids have a tendency to carry down with them traces of other metallic salts.

The combinations of silver and its salts with organic compounds should be investigated by the student, and attention should be given to the chemical technology of the colloids, especially albumen, collodion, and gelatine. Albumen acts somewhat like an acid; on adding nitrate of silver to it, the so-called albuminate of silver is precipitated; if the surplus nitrate be then washed out, and the white deposit exposed to light, it darkens. Gelatine has a tendency to combine with silver, and gelatine treated with nitrate of silver will darken in the light. He then dealt with the subject of emulsions, and made a gelatino-bromide of silver emulsion.

Another thing which the photographic student should investigate is the chemistry of all the metals in any way connected with photography, also the action upon them of reducing agents; such study is likely to bring out facts of practical value, and to throw light upon the nature of the latent image. The action of light upon selenium is interesting; the action is of a purely physical and not chemical character. So also is it with a saturated solution of sulphur in bisulphide of carbon; when this solution is exposed to the light of the sun the crystallised form of sulphur separates, but there has been no chemical decomposition. It is the same with the action of light on silver iodide. If a piece of silvered glass be exposed to the vapour of iodine and then be exposed to light, it becomes yellower and more opaque, simply because of change in physical structure.* Some change takes place in the structure of the crystallised silver iodide under the action of light, for it then all falls to powder. Red cinnabar undergoes physical change beneath the action of light, and many organic compounds undergo polymerisation when light falls upon them.

The action of light upon asphalt is interesting, but whether it is a case of photo-chemical oxidation or of polymerisation is doubtful; the insoluble form of asphalt produced changes to the soluble form again by fusing. Alcohol and ether will take up portions of asphalt; the insoluble residue remaining is the portion which is most sensitive to light. Most samples of asphalt contain sulphur, but the sensitiveness to light does not depend thereupon, for samples are sensitive which contain no sulphur. Asphalt consists of a complicated mixture of hydrocarbons, and it would be well to make farther experiments in the attempt to separate the most sensitive constituent.

There are numerous cases in which light sets up actual chemical decomposition. A two or three per cent. solution of ferric chloride may be mixed with oxalic acid, and exposed to light; a little alcohol in the solution acts as an accelerator. Reduction takes place, and carbonic acid gas is given off, in the luminous rays, and the presence of the ferrous oxalate formed in the solution may be proved by the ferricyanide of potassium test. The carbonic acid given off is due to the oxidation of the oxalic acid.

Professor Meldola then dealt with production of blue prints. He added that when a common blue print is treated with a solution of an alkali, such, for instance, as caustic potash, the Turnbull's blue is decomposed, and an oxide of iron print is left; then it becomes possible to play upon this oxide of iron with other reagents. If the yellow print be well washed, then be placed in a solution of gallic acid, a black print in common writing ink results. Or the oxide of iron print may be placed in a solution of some colouring matter with which the oxide combines, such, for instance, as alizarine; in fact, there is scarcely any limit to the variety of coloured prints obtainable on these principles.

The reduction of uranic salts should be studied by the learner in the same way. The photo-chemical reduction of chromates in the presence of organic matter should be examined by him, as well as the photo-chemical relations of mercury and copper. Mercurous iodide, a greenish yellow substance, is rapidly decomposed by light, and the nature of the chemical change is known. Dr. Eder once employed a mixture of solutions of ammonium oxalate and corrosive sublimate (mercuric oxide) to form a solution as transparent and colourless as water when the proportions are properly adjusted, and this liquid, when placed in the light, at once begins to precipitate the white and insoluble mercurous chloride, which can afterwards be separated and weighed to obtain photometric results. Cuprous chloride is exceedingly sensitive to light. Indeed, photography with silver salts may be but a passing phase in the history of the art, to be superseded by the employment of other materials. He had pleasure in introducing to his hearers Mr. Varley, who would show them an important departure in the way of cheapening photographic processes; he could not reveal the nature of the materials used in relation to a discovery which had not yet passed through the Patent Office, but Mr. Varley had assured him that no silver salt was used in any part of the process.

Mr. Frederick Varley then exhibited a piece of paper of about carte-de-visite size, with a good portrait in black-

* Carey Lea proved that a developable image can be impressed upon pure iodide of silver, and that if the image be not developed it will gradually die out, and leave the plate ready for another exposure. This is one of the facts made use of by those who hold the dynamical as opposed to the chemical hypothesis of the invisible image.—Ed.

and-white on both sides of it, to show that although the salt used was very sensitive, both sides of a sheet of paper could be printed upon, each exposure not being sufficiently long to set up fogging action through the paper. He next exposed a piece of sensitised paper under a negative to weak gaslight for about half a second, as described in another column, developed it with ferrous oxalate, washed it, and exhibited it unfixed to the chairman and others present. He said that the hour being late, he would not detain them while he fixed it, but that the unfixed image would go on slowly darkening. Mr. Friese Greene had discovered the sensitive salt, and he (Mr. Varley) had found out last Saturday how to accelerate its already great sensitiveness. The process was expected to be useful for book illustration.

## THE SCIENCE OF COLOUR.

LAST Friday, at the Society of Arts, Captain W. de W. Abney delivered the last of his five lectures on "The Science of Colour," and dealt chiefly with the subject of colour-blindness. He said that out of every hundred men in the streets between four and five, on an average, were colour-blind, wanting absolutely the power of seeing either green or red. The green-colour-blind man sees everything purplish, and lives as if in a world of perpetual sunset; the red-colour-blind man sees the world as if through blue spectacles. To a green-colour-blind man emerald green looks grey, and to the red-colour-blind man blue appears white.

Here, then, we have two large classes of people going about in the world with totally different ideas of colour to ourselves, and yet we never seem to come across one of them. Why is this? Perhaps one reason is, that when we have a defect we seem to try to hide it; some people, again, do not know that they are colour-blind, until at last they discover it by accident. Colour-blindness is hereditary; but, like the gout, it usually skips one generation, and passes from the grandfather to the grandson. Among women not more than two per cent. are colour-blind; why this is so is not known. Colour-blind people cannot see so long in the twilight as we can.

Colour-blindness is sometimes induced by disease, also by smoking tobacco; in the latter case the tobacco must be strong and plentifully used; the individual also is usually in a state of mental suffering, such as that due to family bereavement. The colour-blindness then usually affects a part only of the eye, at and near the "yellow spot"; outside that region the vision is normal. To detect colour-blindness in such cases coloured peas are employed, and the individual has to gaze straight at them. He can make true selections from larger coloured objects, such as skeins of silk.

The importance of the application of tests for colour-blindness to engine drivers and naval officers and men is obvious.

The Chairman, Mr. Francis Cobb, proposed a vote of thanks to Captain Abney for his lectures, and pointed out that some of the illustrations were quite new, and had never been made public before, especially the method of mathematically registering colours so that any particular colour could be exactly reproduced after the lapse of ages.

The vote of thanks was accorded with acclamation.

THE LIVERPOOL INTERNATIONAL PHOTOGRAPHIC EXHIBITION.—Optical lantern demonstrations. To-night, 20th March, Mr. A. R. Dresser, "'Hand-Camera' Slides"; Mr. Christopher Naylor, 8.30 p.m., "A Tour Round the World." To-morrow, Mr. Paul Lange, 8 p.m., "The Wonders of Iceland," with personal adventures, and embracing one hundred photographs; Mr. Fred. Clibborn, "Up and Down North Holland," illustrated by one hundred and twenty lime-light lantern slides taken by Mr. G. E. Thompson. A promenade concert every evening, 7 till 8, and two lantern demonstrations every evening, 8 till 9.30. A promenade concert every afternoon; Miss Emilie Scott on Errard's grand piano at 3 o'clock. Mr. J. Busfield's band at 4 o'clock.

## PICTORIAL COMPOSITION.*

BY P. H. NEWMAN.

To feel the force of this principle still more we must turn to Division A, of Example 1, of the same plate. All the figures, horses, and trees might be found in nature exactly as they are here placed; but when so found they are ill-adapted to pictorial representation, and if so represented they impede the imagination in its efforts to realise the scene, in consequence of the following defects in their composition: The heads of the two horses in the foreground are exacly level with each other; the back of one slopes towards the right, the other equally to the left. The heads of the three figures are equidistant, and repeat the line of rising ground beyond them, and this, again, is repeated by the line of shadow behind the figures. The trees on the hill are exactly over the heads of the figures, and although they differ in intensity of colour and in size as compared with the figures, they hardly appear more distant; indeed, if the space between them and the heads of the figures be for a moment hidden, they will appear as if actually resting on them. The falcon, which has just taken flight after the heron, is represented at the moment when he is crossing the line of the hill, and the heron is perpendicularly over the head of the lady. Such an arrangement of objects, though aided in light, shade, and colour by the united efforts of the most distinguished painters the world ever saw, would yet fail to express space in the same degree as it is expressed in Division B of this example. In the latter, every error enumerated has been avoided, the flat surface is now lost sight of, and it is impossible to receive from this example that impression of flatness which we cannot escape in the other.

The observations concerning the objects not being level with each other are not confined to their several heights; they equally apply to the inequality of their bases; and although here the differences of level cannot be so great, yet there must be a difference, since, however small, the idea of flatness is thus destroyed, and that of space suggested. Proof of this is found in Plate XI., especially in Example 4, where, because these facts have been observed with regard to the placing of the feet of the horses on the road, and the roots of the trees on the right, we are sensible of the expression of space.

Harding makes some important strictures on some of the old masters, especially Claude, who is unquestionably a great defaulter in points of composition; and in a footnote it should be remarked that Turner is mentioned as (at the time Harding writes) having produced works better calculated than any modern pictures to be of use to students and amateurs in art.

"Nature," says Harding, "has given to all objects specific forms, and, although they may be found, 'in sportive mood,' occasionally to take each other's shapes, yet their difference in all other respects is so manifest that we can rarely confound them with the objects whose form they for a moment assume, and consequently the mind never loses a distinct conception of whatever distinguishes the one from the other. But how widely do circumstances differ when nature is represented by art! What are all objects then? What, then, are clouds, trees, rocks, mountains, figures, &c., &c.? Paint. Art in this respect makes all things alike, and is unable, except in the remotest degree, to imitate the nature of things; it is sameness all; and this defect would be fatal, and even insuperable, but for the power the artist has over his composition and the forms of his objects. So far, then, is the repitition of forms from being an advantage, that, on the contrary, their marked difference is his sheet anchor; for, seeing that with him everything is reduced to paint, and that this, of necessity, tends to confuse the mind by presenting to it every variety of nature by the same material, he relies solely on his control over the variety and distinct differences of forms at once to impress the mind with clear and distinct ideas."

Harding, you will remark, says "paint." If these precautions of composition are so vitally necessary where the artist has the advantages of polychrome to assist his effects, how much more are they demanded in dealing with black and white, or monochrome, and how supremely necessary for the photographer to take every advantage of accidents of position,

* Continued from page 204.

seeing he cannot shift anything, and be an absolute master of pictorial composition besides, to obtain the most desirable point of view, before he ventures to take his picture; and, as this necessity grows upon him in his progress in art, how few are the pictures he finds really worth taking, and how eclectic he becomes. It will need all his determination and powers of mind not to be discouraged, as in the nature of things, with the practical limitations of photography. He must not be discouraged, however, and need not be, if he is content to exercise great patience, and profit by every scrap of study he can get outside the dark room, or that darker place, the gloomy valley of artistic suicide, where, casting all else to the winds, he throws himself on the bosom of nature.

I now show two views from Harding in confirmation of the disadvantages of repetition of line in landscape – Plate XIII., 1 and 2. His comments on these are, it is needless to say, relative to modifications in treatment by the painter (shown in Example 2). They, however, serve a useful purpose to the photographer if they demonstrate the dangers and pitfalls he is constantly having put in his way, and exercise his mental powers of how best to obviate these dangers in the field. Harding goes on to say, however, that "it requires all the vigilance of keen and long-tutored observation to detect the identity of line in things dissimilar which is perpetually insinuating itself unobserved into the different forms depicted by the painter, to the consequent loss of the proper influence of every object wherever it happens to be, and sometimes to the production of results which are even ridiculous."

For a still stronger confirmation of the principle that one object or one feature of interest must not be placed perpendicularly over or under another, Harding refers the student to the next illustration, Plate XIV. As it is a view from nature, and composed of objects whose forms would be readily recognised by those who know, they must, therefore, be strictly true in kind and relation. Not so, however, the figures, except in costume. These are left to the will of the artist, and we can now examine how far the observance of this principle operates to assist him. Take first the leading features, those which come against the sky and strike at the first glance; the church and the two turrets right and left of it, seen over the roofs of the houses, and also the most prominent gables.

If the eye be allowed to travel down the surface of the picture, it will be found there is no object of remarkable interest under any of them, and that the figures themselves have also been thus arranged in relation to each other, as, for instance, the man and the cart in the distance are placed over the space between the heads of the centre group of figures in the foreground. It will also be observed that this, the principal group, is made to occupy precisely that portion of the scene which of itself—that is, without aid from extraneous features—would possess no interest; for if a slip were cut out between AA and BB, no object of importance would be removed. Hence, then, this is unquestionably the proper and only place for the principal group.

It will also be perceived that these figures are so placed that neither their heads nor their feet are on a level, for what has been said of the principal features is equally true of the subordinate, equally applicable, and attended with a like result—the expression of space. It will also be found that these groups, like all the other features constituting the pictorial beauty of the scene, are of different forms and quality. Now, if these principles be true, it should be difficult to make any change in contravention of them without damage by removing any of the figures or objects; or when applying them, to discover if the composition be perfect or not; then it should be impossible that any change in conformity with them should not make the picture better. Let the student try, for he is not to take these things on trust; conviction of their truth and utility must come from reason and experience.

There is no need to follow Harding in his further illustrations on this subject of composition. Much is, of course, applicable mainly to the painter, but I think most people who have any artistic sympathies will agree with him in some of his concluding paragraphs. He says: "Beauty in pictorial composition is as superior to individual beauty as a beautiful structure is to any of its parts. The richest collection of materials amount to little more than a confused and useless heap unless arranged in graceful order." And again: "Composition is of the highest importance to the artist as the field for the exercise of his talents in combining and arranging his objects so that each may derive an additional charm by association not belonging to it separately. With all this he must include considerations of the light and shade and colour; for whilst he assigns to each object its proper place to develop a beauty arising from one form operating on another, whilst he places the large in opposition to the small, the dignified against the humble, the near opposed to the remote, the flexible against the rigid, lines suggesting motion and others tranquility, and the perpendicular against the horizontal, he obtains but a part of the beauty derivable from composition if he fail to anticipate and prepare for those effects which he must derive from the aid of light and shade and colour."

In treating of light and shade, Harding says: "In painting the compound termed light and shade—the 'chiaroscuro' of those who prefer a foreign technical term to one supplied by their own language—simply means, when used in reference to an individual object, that relative degree of light and darkness in the colour or colours which causes it to assume the appearance of having the same external qualities of form that it naturally presents to the eye. When used with reference to a group, or groups of objects, it means their comparative lightness or darkness in relation to the whole picture; and in this, again, the light is said to be well managed where all the parts, having their proper degree of relief, contribute to the production of a good general result."

I propose to show two or three of his illustrations in reference to this subject, and, without wearying you with his long treatise of general principles, quote only his comments on these pictures, which, however, speak for themselves. Every picture produces a different impression upon us from the difference of light and shade, or what is called its "effect," as well as from the difference of subject. All kinds of effects are not suited to every kind of subject; and of the various ways in which the light and shade may be thrown or distributed at the will of the painter, some effects are, or rather must be, better than others. Let the student examine Plates XX., XXI., and XXII., and he will find that they are precisely the same in composition, alike in manipulation, alike in everything but the light and shade. The difference of their effect upon us arises from neglecting or observing an important principle.

Plate XXI. differs in sentiment from Plate XX., as well as in light and shade; and it is a question to be decided by our own feelings whether the repose of evening be more agreeable than sunshine and showers. In each the several important features are displayed with nearly equal effect.

In Plate XXI. the principal object, the castle, arrests the attention at once, in consequence of it being strongly contrasted with the sky; and although we are here more sensible of its picturesque contour, we yet lose much of the variety of its different parts in uniform obscurity. On the whole, there is not the same amount of space expressed, because the objects do not generally separate by alternate light and shade, as in Plate XXII., and the trees on the right do not detach from the sky. The monotony which prevails throughout the light and shade would not, however, be felt in colour.

There can be no doubt that, of all the three, Plate XXII. is the least satisfactory, and this is clearly owing to the disregard of placing the most conspicuous object in light. The principal light is on an uninteresting and unimportant feature, namely, on the hill on which the castle stands; and thus, as there is a light immediately behind the group of trees in the centre of the picture, our attention is drawn to them as well as to the castle, the picturesque form of which is all that we see in feeble contrast with the sky. Thus the castle, though of primary importance—for without it the subject has little or no interest—is all but lost sight of in the rivalry of what is insignificant. Nor is this all. The light on the water is immediately under the light on the castle hill, and the light on the rock is also under the light in the sky, and the bridge is nearly extinguished. The whole picture wants space and concentration of interest;

and the subject, though good, is reduced in its effect to the level of the commonplace. The value of the principles enforced is here shown by the consequence of their infringement.

Were light and shade only a matter of feeling, as is frequently insisted on, and dependent on the caprice of the painter, there is no reason why the feeling should not have suggested just such light and shade as is here given, the faults of which, be it observed, would be less easily detected in combination with pleasing colour. But are the feelings satisfied with what is done, or can the undirected feelings suggest a change for the better? Is there anything to assure their being nearer the truth in the second effort than in the first?

(*To be continued.*)

## PHOTOGRAPHY AT THE ROYAL METEOROLOGICAL SOCIETY.

LAST Wednesday night the annual exhibition of the Royal Meteorological Society of photographs, photographic apparatus, rain gauges, and apparatus relating to meteorology, was held at the Institution of Civil Engineers, Great George Street, Westminster.

In the early part of the evening a meeting took place under the presidency of Dr. C. T. Williams, M.A., in the large theatre of the Institution, and Mr. A. W. Clayden, M.A., projected various meteorological lantern pictures upon the screen. He said that last year the British Association had appointed a committee on meteorological photography, of which committee Mr. G. J. Symons was president, and he was secretary; and the committee had issued instructions to those of the public who knew anything about photography how to take pictures likely to be of use to meteorologists. He thought that their Society should exert itself to develop the popular side of meteorology, and try to remove the prevailing impression that it is an excessively dry subject. Photography can do much in this direction, and, at the coming meeting of the British Association at Cardiff, he hoped that the Society would help the committee to show a considerable collection of photographs of meteorological phenomena. The committee wanted photographs from everyone who knew how to use a camera, and the lantern pictures he was about to exhibit would illustrate some of the kind of photographs required.

Mr. Clayden then projected upon the screen a series of interesting pictures of clouds; in one of them the clouds were hanging downwards in the air like festoons. In taking these cloud pictures, he had employed a mirror of black glass placed at an angle in front of the lens; each photograph was an image of the cloud as reflected by the surface of the black glass into the lens. By this device, when light, stratified clouds were just visible against a bright blue sky, he had been able so to differentiate them that the sky came out dark behind the white cloud. He had obtained photographs by this method which he had been totally unable to get in any other way. When he first announced the method, he believed himself to be its discoverer, but afterward found that it had been previously described by Professor A. Riggenbach, of Santis Observatory, Switzerland. Perhaps he had previously read the account and forgotten it, or, perhaps, by what Dr. Carpenter called "unconscious cerebration," Dr. Riggenbach's thoughts found their way again into the world through his head.

We may here remark that this plan of using a black reflecting mirror may be of use sometimes in photographing difficult, brightly illuminated objects other than clouds. Dr. Riggenbach thinks that the polarising of the light has something to do with the result, but Mr. Clayden finds that as good results are obtained at other than the best polarising angle.

We suppose it to be possible that the front surface of the black glass exercises some kind of selective absorption to bring about the result, and that it might be well to try experimentally what photographic results are obtainable by the use of reflections from various coloured glasses well polished. By the use of black glass Mr. Clayden photographed a part of a solar halo invisible in the heavens to the eye, but visible by reflection from the surface of the glass. The mirror used was a finely ground piece of patent plate, blackened on the rough side.

Mr. Clayden projected various photographs relating to other meteorological phenomena, one of them exemplifying how hoar-frost attached itself more to the thorns of a briar than to other parts, a phenomenon, he said, which he believes has not yet found an explanation.

At the close of Mr. Clayden's lantern picture display, the company adjourned to the exhibition and inspected the contents thereof. An interesting picture, photographically and historically, was one of the Tower of the Winds, at Athens. Mr. Clayden's cameras and black reflectors were among the objects on view.

## HOSPITAL PHOTOGRAPHY.*

THE photographic rooms of Bellevue Hospital are on the top floor of the cook house. They have been there ever since the department was established. They are incommodious, out of the way, and insufficient, to say nothing of being decidedly dingy and unsavoury. New rooms are now being fitted up on the top floor of the main hospital building, which will be bright, airy, and commodious. You enter Mr. Mason's rooms through a dark passage. You find yourself in a long rectangular room, with skylights in the roof, and a camera upon the floor facing a photographer's chair placed in front of lead-coloured screens. It would look like any photographer's gallery if it were not that two sides of the room are lined to the ceiling with shelves upon which are ranged innumerable books, all bearing upon the sciences of optics and photography. You also see numerous big record books, a table covered with experimental paraphernalia, several large microscopes under cases, a number of instruments not commonly seen in photographic galleries, and no end of dust. You find nobody in this room, and you pass on to the next. This is long and narrow, with several windows. There are any number of shelves on both sides, which hold a great quantity of boxes containing negatives and other material commonly seen in a photographic establishment. On one of the walls, near the ceiling, is a series of fine large photographs of the moon in its various phases, and elsewhere are seen other photographs of a scientific nature. On wide shelves outside the windows, which have a south exposure, are a number of printing frames, exposed to the rays of the afternoon sun. There happens to be nobody in this room either, but presently the door opens from the dark room at one end of it, and an elderly man appears with a wet negative in his hand. He holds the negative up before a window, examines it critically, nods approvingly, and stands it in a drying frame. The negative represents a man of enormous proportions, photographed nearly naked. His legs appear in the picture nearly the size of an average man's waist, and his feet are almost as shapeless as those of the elephant in the circus.

"A very interesting case," says the elderly man, nodding in a gratified manner to the visitor. "A case of elephantiasis which involves several unusual features. The negative is first-class, and I have hopes that it will yield photographs which will lead to investigations for the cure of the disease which have never before been attempted. Do you know anything

* Concluded from page 104.

about medicine? If you do I can point out to you just what these new features are."

The elderly man looks both healthy and happy. He is of medium height and well built. He is fairly stout. He has hair and beard which are whiter than iron grey, notwithstanding that he is only fifty-four years old. He has a square face, a high, expansive forehead, and clear, direct, and good-humoured eyes. He impresses you at once as a man of parts, as the phrase goes, a man born a student. By the time you have talked to him five minutes you are also certain that he is a man of poetic temperament and an idealist. He has thrown off his coat, and put on a white apron which covers him from neck to toes. He wears a black silk skull cap on the back of his head, but not to cover any baldness. He receives you courteously but cautiously. He is not immediately communicative. He wants to know who you are, and what your errand is. He is Photographer Mason.

If you are curious about the department, he shows you everything with the utmost freedom. There is nothing to be concealed. He opens his library to you, all except the case which is covered with muslin and contains gems not consulted except on special occasions. He shows you his collection of expensive lenses, and explains the scientific speciality of each. He explains the mechanism of the many photographic devices which he has invented but never patented. He tells you, with a little pardonable vanity, that he has been the secretary of the American Institute for twenty-three years, the secretary of the American Microscopical Society for fifteen years, and belongs to several other scientific societies.

Then he explains the system upon which he conducts the photographic work of the department. He is not willing to take all the pictures he is asked to, because experience proved many years ago that his time would be so taken up with photographing the first surgical cases of very young hospital surgeons and other work of a purely personal sort, that the serious and valuable work of the hospital would be practically shut out. So Mr. Mason refuses to photograph any patient or operation except upon the presentation of an order, signed by the visiting physician or surgeon, and by the warden. This insures him that no unnecessary work will be required of him. The necessary work, however, takes up most of his time. If you appeared very much interested in his rooms and work, and the photographer has a half-hour at his disposal, he will bring out his scrap-books, and show you the sort of work he does. You will not care to spend much time over the scrap-books, for the photographs, though finely executed and clear in detail, are very far from attractive to the eyes of unenthusiastic laymen. They depict disease and deformity of every character, and surgical operations showing an array of ugly-looking knives and saws and other instruments. But you notice that where a picture of a diseased or deformed person has been taken, there is almost sure to appear also the photograph of the same person as cured or operated upon. Perhaps there will be several intermediate views. You also notice that Mr. Mason's interest in his work is not only that of the photographer. He knows all about the cases in their medical or surgical aspects, and he calls the minute nerves, blood vessels, and muscles of the body by their correct names.

Mr. Mason goes to his library and shows you a number of bulky books on special departments of anatomy and physiology written by noted doctors, and illustrated by himself. One large and very handsome work in several volumes he is especially proud of. It is the famous "Topographical Anatomy of the Brain," by Dr. John C. Dalton. In his preface, Dr. Dalton thanks "Mr. O. G. Mason, photographer to the Bellevue Hospital, New York, by whom all the original negatives were taken, and without whose persevering skill and technical resources it would have been impossible to overcome the difficulties of the situation."

"This," says Mr. Mason, fingering the book lovingly, "is the first copy issued. Dr. Dalton promised me I should have the very first one from the binders. He and I worked on this book day and night for over two years."

Mr. Mason got no other reward for his work than the pleasure he took in helping so effectively in its production. He replaces it on the shelves, and, as he does so, glances proudly over his big library, and says that even in Washington there is not another such a collection. He has frequently been called upon by the courts to furnish volumes in evidence in cases involving photographic technicalities. He always willingly lent his books until once he failed to get his treasure back. Since then he has photographed pages in books which the courts needed, but has never allowed a volume to go from his library. In the library you see a number of volumes on microscopy. Mr. Mason answers your questions by saying that he has made a specialty of applying photographic processes to microscopy, and is regarded as an authority in this branch in the Microscopic Society, of which he is secretary. When you ask about those photographs of the moon, Mr. Mason says he has done a great deal in the way of hitching cameras and telescopes together, too. The moon photographs he made in the Rutherfurd Observatory in 1865, when that distinguished scientific experimentalist and lawyer, Lewis M. Rutherfurd, was pursuing his personal studies of the moon. Mr. Mason explains that he eked out his scanty income considerably, a few years ago, by his scientific photography applied to publications, but that the hospital work had grown so of late that he was compelled to almost abandon this outside work.

"But why," you ask, "are you satisfied to work for nothing, when with your reputation, your skill, and your photographic outfit, you could make a great deal of money?"

"There is something better in this world, young man," says Mr. Mason, smiling, "than the accumulation of money. If I were to bend my energies to making money out of my profession, I would have little time to do the work, which, in such a place as this, tells strongly in the interests of humanity, and for the advancement of science. The work that pays is not the work that discovers, and applies, and originates. At least, that is so of my profession. I get my pay in feeling that I am doing something every day which will live after me. It is nothing to me that I make no name at my work, or that such of my accomplishments as live after me are thrown into the common lot of human advancement without attaching honour to my name. My object in living is not reputation or money, but accomplishment. It is enough for me to know that the world and science are better off because I have lived, and if it is necessary for me to forego money and live very simply to accomplish my object, why, I do so willingly."

"But how is it that you refuse to accept salaries for the very work that you are now doing? I understand that not long ago you refused a salary of 2,000 dollars."

"That is so," says Mr. Mason, "and I'll tell you just how it is. You know yourself how this city is run, and what a scramble there is for offices with salaries attached. You also know as well as I do that if 2,000 or 1,000 dollars, or even less, were paid for this work, that I would be hustled out of the place inside of a year. I've not the slightest doubt that if it were proposed to put me out, the whole hospital would protest, for I have scores of friends among the physicians and surgeons here, and have beside very many influential friends in city practice, with whom I have worked, who would also protest. But what difference would all that make? There are very many big political officials in this town who have friends to oblige with places, and, though the protests of the doctors might hold for a time, I would eventually have to go. Now I do not want to go. I feel that right here I have such an opportunity at my command to benefit humanity and help along the cause of science as I could find nowhere else. I am sure I am accomplishing something here, and I propose to stay here. I very early realised that, in order to keep my grip upon my opportunities, I would have to work for nothing, and so, from the first, I rejected all offers of payment. Twenty-three years ago my attention was called to the chances of inaugurating a great work in connection with Bellevue Hospital which had never been done elsewhere. I had previously been called up to photograph hospital cases, and I had worked very harmoniously with the physicians and surgeons at that time in charge of the hospital. Finally, the Commissioners asked me to accept the honorary title of Photographer to Bellevue Hospital. I considered it. I wanted to know just what rank that meant, and, finally, took the honorary title with the understanding that the city was to furnish me a room, and pay for the chemicals used, and that I was not to be a servant of the hospital, but to rank even with the visiting physicians and surgeons, and be responsible directly to the Commissioners. I at that time agreed to give my services, and specified that I should receive no compensation. Even then I saw the necessity of keeping this very important department entirely out of politics. From that time on, the whole object of my life has been to render the first department of hospital photography in the world perfect. What success I have had, and how I have been of benefit to the world, it is unnecessary to say, but I have been satisfied myself with my sacrifice.

"Well, some eighteen or twenty years ago I suggested to the Commissioners that I should also photograph the faces of the unidentified dead in the Morgue, in the hope that these records would lead to identification. They accepted the proposition gladly, and at that time urged me to take a salary for my work. I refused the salary; but a few years later the Commissioners again insisted upon my accepting compensation. They urged me so that I could scarcely resist, and at length, as a compromise, I suggested that I should receive 5 dollars each for the Morgue pictures, and still continue to do the hospital work for nothing. This was accepted, and I have been working since on those terms. I only make 400 or 500 dollars a year out of the Morgue work, and that is too little to tempt any one to take my whole job away from me. My position is further strengthened by the fact that the hospital work requires the use of a great many very fine and costly instruments, and that the city does not own a single one of the hospital stock. I have bought and paid for them all myself, and, in order to substitute another in my place, the city would have to make a considerable outlay, or else compel the other man to buy the stock himself—something that he probably would not care to do. My lenses are all of the finest and most expensive quality made, and were bought with the special peculiarities of the Bellevue work in view. I used to do considerable outside work purely of a scientific character, but the hospital work is so increased now that I have little time left for it. I won't do outside gallery work. I dislike to spend my time upon work which has no permanent value."

It takes some time to induce Mr. Mason to say anything of his history before he settled down over the cook room of the Bellevue Hospital twenty-two years ago. Finally, he says that he was born in Vermont, and was educated at Le Molle Institute, at Johnstown. He studied optics, and was among the first to take up the Daguerreotyping process. When the ambrotype was invented he bought out a share of the patent and opened a studio at Springfield. He made money and reputation, and finally was induced to come to New York by the then famous firm of Meade Brothers. He sold out his establishment at Springfield. Shortly afterward a review that he wrote about the then newly-discovered photo-lithographic process attracted the attention of Horace Greeley, who sent for him. The result was the formation of the American Photo-Lithographic Company, of which Ezra Cornell was president, Horace Greely secretary, and Mr. Mason manager. This was the first process company established. Soon after Mr. Mason dropped this and his other money-making work to establish the gratuitous department in Bellevue, over which he still presides.

## Patent Intelligence.

### Specifications Published.

,498. *March 22nd*, 1890.—"Machine for Cutting, Grinding, and Polishing Glass." Charles Marlow, 142, Park Lane, Aston, near Birmingham, Metal Plate Worker and Machinist.

One part of the improvement relates to the method of holding the glass, and the means used for removing it from one process to another without disturbing it; another to the collection and re-distribution of the sand, water, or other substance used as an abradent; and to the general distribution of the parts, which are so arranged as to reduce the space occupied; and to protect all moving parts from water, sand, or other substances; and to economise labour and time.

With this machine I propose to operate upon any form of surface, whether flat, raised, or depressed, by means of rotating cutters or rubbers guided in some such manner as those in use in wood-working machines, with such modifications as the nature of the work demands.

This machine is rendered so nearly automatic that one attendant may manage two or more machines, according to the size of the work thereon. The movements of the machine can, by guide rods, ropes, levers, or other suitable means be brought so as to be easy of control from one seat or position, however large the machine.

5,158. *April 2nd*, 1890.—"Apparatus for Holding and Changing Photographic Plates." Charles Henry Stanbury, 91, Fleet Street, London, Trunk and Portmanteau Maker.

This invention relates to a holder or box for containing sensitive plates both before and after they have been exposed, and to means for transferring the plates to and from the camera.

The box is provided with a number of slides with spaces between for receiving the plates, and the back of the camera is provided with two slides having a space between to receive a plate.

The outer ends of the slides carry flanges which come against the ends of the partitions between the slides so as to make as light-tight a joint as possible.

In order to transfer a sensitive plate from the box to the camera, the back is put on to the bottom of the box, and the lower slide of the box and the upper slide of the camera back are pulled out, whereupon the plate drops from the box into the back; the slides are then pushed in again. After the plate has been exposed in the camera, it is put back into the box, but this time at the top. In order to make room for it, the slides in the box are pulled out, one by one, in succession, allowing each plate to drop down into the next space below that which it previously occupied, so that now the top space is empty whilst the bottom space contains a plate. The back of the camera is then placed upon the top of the box, and its slide and the top slide of the box are pulled out; the plate drops into the box, and the slides are pushed in again. The next, or second, plate, which is now at the bottom of the box, is transferred to the camera in a similar manner, and so on.

5,681. *April 15th*, 1890.—"Frames and Suspenders for Pictures." Charles Rivington Shill, 67, Oakhurst Grove, East Dulwich Green, London, Accountant.

The portable mountings to consist of moulded or stamped devices made in wood, metal, *papier maché*, or other substances, the said devices to be attached or fixed to framable objects by means of cords or wires passing through suitably arranged wings or lips formed on the back of the said devices, whereby the whole arrangement is held in position by the cords or wires passing through the same, the whole forming complete furniture for mounting and suspending pictures, prints, looking-glasses, mirrors, or other objects suitable for framing.

5,753. *April 16th*, 1890.—"Operating Skylights." William Leggott, 27, Park Road, Bradford, Yorkshire, Brass Founder and Finisher.

This invention relates to certain improvements in the connection or coupling between the rotating vertical, or angular, operating rod or shaft and the rod or shaft attached to a pitched ceiling or roof, for opening skylights, fanlights, and the like; and has for its object the combination with the said rods or shafts of a connecting joint so arranged that it is applicable for coupling the said rods or shafts at any angle within a range of 90° or thereabouts, in such a manner that, on rotating one shaft, the other is also operated in like manner.

I accomplish my object in the following manner:—

To one end of a rod or shaft is secured a forked joint, between the arms of which is placed a cross-bar so arranged that it will move on its axis, and to which is attached a similar forked joint at right-angles to the first-named.

To the second-named forked joint is firmly secured at right-angles thereto another of similar construction, which is attached to a forked joint secured to the other shaft, and with a movable cross-bar similar to the one before described.

By connecting the shafts with a coupling constructed as described, they can be rotated without bevel wheels, with this advantage, the coupling will adapt itself, connect and rotate shafts placed at any angle within a range of 90° or thereabouts, whereas bevel wheels have to be made to suit the angle of the two shafts.

## Correspondence.

### THE LIVERPOOL INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

Sir,—The reference to the portraits of Professor Herkomer is somewhat in error; all are the work of Mr. F. Downer. I am aware this report was some oversight on the part of *The Liverpool Daily Post*, and for which your publication is not responsible. I thank you for the full and friendly words you have published. You will be glad to know that everything goes on most satisfactorily; 1,600 visitors on Saturday. Judges awards meet confirmation in every case, I think.

T. S. Mayne, *Hon. Sec.*

### THE NEW YORK MAY EXHIBITION.

Sir,—It will be of interest, perhaps, to all amateurs and other photographers to know that arrangements are now in progress for a very large, select, and important exhibition of photographs, including specimens of the best foreign work, to be held in New York at the Fifth Avenue Art Galleries, between 34th and 35th Streets, May 25th to June 6th, under the auspices of the Society of Amateur Photographers of New York. It will be the fourth of the joint series of exhibitions undertaken with the aid of the Photographic Society of Philadelphia and the Boston Camera Club.

The prospectus and entry forms have already been sent out, and the judges selected are, Thomas Moran, Will H. Low, and Edward Bierstadt—men well known in the respective branches of art which they represent.

Medals are to be awarded instead of diplomas, the number being limited to twenty-five. Exhibitions of slides will be held four nights during each week, and in a separate room there will be an exhibit of new and novel apparatus.

Foreign exhibitors may send pictures unmounted, which will be mounted and framed by the committee.

Exhibits should be sent to the Galleries by May 11th to ensure attention. The committee prefers that the very choicest work be sent, rather than a large quantity of ordinary pictures. Exhibits are invited from all photographers, and, when received, will be carefully attented to. Entry forms will be sent on application, and all correspondence should be addressed to—

F. C. Beach, *Chairman of Committee of Arrangements*, 113, *West 38th Street, New York.*

Fluorography.—Fluorography is, according to a contemporary, a process of transferring lithographic or phototypic prints to glass by means of fluorated ink, which, in contact with sulphuric acid, disengages hydrofluoric acid, which eats into the glass. The phototype is inked with the following compound:—

| | | |
|---|---|---|
| Soap | ... | 50 grammes |
| Glycerine | ... | 200 ,, |
| Tallow | ... | 50 ,, |
| Water | ... | 100 ,, |
| Borax | ... | 25 ,, |
| Fluorspar | ... | 50 ,, |
| Lampblack | ... | 15 ,, |

Negatives are taken and transferred to the glass. The latter is surrounded with a border of wax and covered with sulphuric acid of a density of 64° or 65° Beaumé. After fifteen or twenty minutes the acid is poured off and the glass is washed with water and cleaned with a solution of potassa, then washed with water again, and dried with a cloth.

## Proceedings of Societies.

### The Photographic Society of Ireland.

A meeting was held at the Rooms, 15, Dawson Street, Dublin, on the 13th inst., when the chair was occupied by Mr. Herbert Bewley.

A discussion on "Hand-Cameras" was introduced by Mr. J. White, who exhibited a number of different makes, but stated his preference for Rouch's "Eureka," the camera with which he had taken all his prize pictures. He stated that portability and simplicity were, in his opinion, the main features to be aimed at in the construction of a hand-camera.

A large number of members exhibited different makes of hand-cameras, a great many of such were home-made.

After the exhibition of hand-cameras; a number of slides, the works of the members, were put through the lantern.

A "Parveuu" flash-lamp was presented by Mr. Hedley for the use of members.

### The Lantern Society.

*March 9th.*—Mr. E. W. Maunder on "Photography as Applied to Astronomy."

Mr. Maunder commenced by dealing with solar photography, the sun having, he said, been the first celestial object which was photographed for scientific purposes. Soon after the discovery of the Daguerreotype process, photographs were taken of the moon, and also of some stellar groups, but these views did not serve any scientific purpose, and it is from the sytematic use of the photo-heliograph for obtaining photographic records of the state of the solar surface that the application of photography to astronomical purposes may be said to date. Mr. Maunder next spoke of the first photo-heliograph erected at Kew, and described in detail the later instrument now used at Greenwich, the work done by the instrument being illustrated by a series of slides showing portions of the solar surface. Other views were also exhibited prepared from the beautiful photographs taken by M. Janssen at Meudon, these being, as Mr. Maunder remarked, the finest solar photographs yet produced, showing as they do most admirably the details of the structure of the surface of the sun and the faculæ. While dealing with solar photography, Mr. Maunder also pointed out the strong grounds for connecting the periods of maximum solar disturbance, as marked by the frequency and extent of sunspots with terrestrial magnetic disturbances, and he farther alluded to the manner in which the periods of maxima and minima were marked by variations in the latitude of spots occurring. The next portion of the subject treated was the application of photography to the observation of total solar eclipses, the instruments used being described, and a number of photographs shown illustrating the structure of the corona as seen at recent eclipses. Leaving the sun, Mr. Maunder next proceeded to treat of the photography of the planets, illustrating his remarks by slides of Jupiter and Saturn taken at the Lick observatory, and by Professor Pickering, of Harvard. The task of photographing a planet was, he remarked, one of great difficulty, inasmuch as the very moderate light available did not admit of instantaneous exposures such as sufficed in the case of the sun, while the rapid rotations of Jupiter and Saturn on their axes prevented recourse being had to the long exposures which could be employed when photographing fixed stars. Altogether, up to the present time, although remarkable progress had been made, photographs of the planets left much to be desired, and could not compare favourably with the records obtained by skilful draughtsmen. In illustration of this, there were thrown upon the screen reproductions of a number of the best drawings of the planets of which direct photographs had been shown. Dealing next with stellar photography and photographs of nebulæ, Mr. Maunder remarked that in these departments photography left all records founded on visual observations far behind; in fact, the details of structure of nebulæ, as shown by the magnificent photographs of Common and Roberts, had been a complete revelation, and had resulted in an extension of our knowledge of such bodies, the value of which it was difficult to overestimate. For comparison, there were shown on the screen photographs of the Orion nebula and the great nebula of Andromeda, and reproductions of the best drawings available prior to the production of these photographs. In dealing with stellar photography, Mr. Maunder paid a well-merited tribute to Dr. Gill, of the Royal Observatory at Cape Town, whose photographic survey of the southern hemisphere—carried out largely at his own cost, and now practically completed—may be fairly said to have originated the scheme for the general photographic survey of the heavens determined upon by the International Congress, and the arrangements for which are now in an advanced stage. In treating of these matters, Mr. Maunder spoke at length on the admirable work done by Messrs. Paul and Prosper Henry, of the Paris Observatory; his remarks were illustrated by a large number of lantern slides showing the instruments used, photographs of the Pleiades, a portion of the constellation Cygnus, &c. In conclusion, Mr. Maunder dealt with the application of photography to solar and stellar spectroscopic research, and he exhibited on the screen the wonderful photographs obtained by Mr. Higgs from the red end of the solar spectrum, and examples of the spectra obtained by Professor Pickering from stars the duplicity of which had been revealed by the spectroscope, the spectra obtained on some days showing the duplication of the lines due to movements of the stars in the direction of the line of sight. This duplication of the lines showed that the spectrum in which it occurred was compounded of the light from two stars moving at different velocities with regard to the line of sight, and, by collating the observations at different dates, it was possible to calculate the periods of revolution and the masses of two stars which had never been separated visually by any telescope yet made, and, probably, never would be.

At the next meeting of the Lantern Society on March 23rd, the slides sent to England by the American Lantern Slide Interchange will be exhibited.

---

### THE WEST LONDON PHOTOGRAPHIC SOCIETY.

*March 13th.*—Mr. W. A. BROWN in the chair.

The PRESIDENT announced the result of the meeting called by Mr. Biden on the subject of federation, and said that he considered the smaller societies would be greatly influenced by the action of the Parent Society in the matter. The council had, however, resolved to send two delegates to attend the next meeting on the 23rd inst.

Mr. ROLAND WHITING then read a paper on "The Laws of Art as Applied to Photography," which he illustrated with sketches on the blackboard.

A long discussion ensued, principally on the subject of improving or otherwise the composition of photographic pictures by combination printing.

---

### THE LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

*March 11th.*—Mr. J. PORRITT in the chair. One new member was elected.

A communication was read by the HON. SECRETARY from the Midland Railway Company, in response to an application from this Society for reduced fares for members when travelling on photographic excursions, to the effect that, having considered the question, the management do not see their way to grant the request. It was resolved: "That this Society places itself in communication with the secretaries of various neighbouring societies, with a view of forming an association for obtaining facilities in this direction."

Mr. GEORGE BANKART then gave a demonstration on "Autotype or Carbon Printing." He prefaced the demonstration with a short description of the principles of the process, and the various results from different conditions of exposure and heat in development, and then proceeded to develop two 11 by 9 pictures printed on the Autotype Company's tissue; and the various stages of development, from squeegeeing on to opal, to the finishing of the process by development of the picture by hot water, were watched by many to whom the process was entirely novel. The demonstration was good, and yielded artistic pictures.

It was announced that at the April meeting Mr. Porritt would read a paper on "Photography, Past and Present," with notes on the quality of dry plates and lantern slides, and a few remarks on the object of our discussions.

---

### THE PUTNEY AMATEUR PHOTOGRAPHIC SOCIETY.

*March 11th.*—Mr. G. DAVISON gave a lecture on "The Art Side of Photography." After a few brief remarks on the relation of art to photography, he divided his lecture into the following sections:—Tone, balance of lines and focus, illustrating his remarks under each heading by handing round for inspection numerous prints, all of which were thoroughly appreciated. The printing-in of clouds, the trimming of prints, and the mounting and framing in the most effective manner, received his attention, as did the effect of an addition of mercuric chloride to the platinotype bath, the use of lenses and stops, and finally, pinhole photography.

At the close of his lecture, a discussion on the subject took place.

---

### THE DERBY PHOTOGRAPHIC SOCIETY.

THE monthly meeting was held at Smith's Restaurant, Victoria Street, on Tuesday; Mr. RICHARD KEENE presided.

After the business was transacted, Mr. J. A. COPE, of the Derby Society, gave his paper on "The Chemistry of Photography." He explained the composition of a photographic dry plate and the action of light upon the same, together with all the chemical reactions which take place during development. He then touched slightly upon the different printing processes now mostly used in the practice of photography. A large number of negatives made by members of the Society was handed round for examination and discussion.

The Secretary distributed several samples of the Barnet plate, sent by Messrs. Elliott and Sons.

Six new members were elected.

A number of the members of this Society journeyed to Leicester on Thursday evening to a conversazione under the auspices of the Leicester Photographic Society, on the invitation of the vice-president, Mr. F. Pierpoint, who gave a lantern exhibition. At the close of the conversazione the Derby Society were entertained by the vice-president.

---

### THE HACKNEY PHOTOGRAPHIC SOCIETY.

THE ordinary meeting was held last Thursday, when Mr. ROLAND SMITH presided.

A paper, with demonstration, on "Bromide Enlarging" was read by Mr. S. H. FRY. He prefaced his demonstration by explaining the best kind of lens to use, and the diaphragm, advising the use of as large an aperture as would be consistent with sharpness and atmospheric effect. For vignetting he made a hole in a card, and obtained the vignetting effect by a rotary motion. If one part was not properly exposed, it could be treated locally or re-exposed (by washing off the developer, and bearing in mind that the paper was only about one-third as sensitive as it was before). As a good way to gauge exposure, when in doubt, say, for a matter up to three minutes, he advocated the placing of a strip of paper across the exposure board, and giving a number of exposures right across, taking a record; then after development the correct exposure could be decided on. The lecturer advised the use of plenty of safe orange light, and when judging the density it could best be done by looking through the paper. With respect to developers, he preferred the ferrous oxalate at present, though eikonogen may eventually usurp the place. The lecturer said he had found the acid baths unnecessary, provided the developer was perfectly washed out of the paper, and, moreover, if acid was conveyed to the fixing bath, there was danger of a formation of deposit of sulphur. He advised the soaking of the paper prior to development in distilled water.

Mr. GOSLING asked whether ordinary water would not do, but was informed that there would be oxalate of lime formed.

Dr. Gerard Smith asked if the paper would not become slower if wetted.

Mr. Fry said not if plain paper were used.

Mr. Harverson asked what would the exposure be for artificial light, and was informed that it depended on the quality of light; if oxy-hydrogen, just about the same as daylight.

Mr. Law wanted to know whether an ordinary lens would do for enlargement.

Mr. Fry thought it perfectly suitable. Other members took part in discussion.

The demonstration then took place; no acid bath was used; the paper and opals were washed with a large piece of cotton wool. A stain was perceptible as of fog, but on being treated by the lecturer with tincture of iodine it disappeared. In answer to a question by the secretary as to the extra cost of opals over bromide paper, Mr. Fry informed the members that there had to be such great care exercised in the cleaning that extra cost was incurred thereby, the slighest finger-marks affecting result.

The next meeting will be on April 9th, owing to adjournment for the holidays.

---

The Glasgow and West of Scotland Amateur Photographic Association.

A meeting was held in the Association's rooms on Monday, 16th March, when five new members were elected.

Mr. J. W. McKenzie gave a description and demonstration of the parchment collographic process recently brought before the London societies by Mr. Warnerke. Mr. McKenzie produced a number of prints, and the process was watched with interest by the members.

Mr. Hugh Reid exhibited a camera fitted with a telescope as a focussing finder, and showed negatives of vessels in motion taken with the apparatus.

The meeting closed with the usual show of lantern slides, amongst which were ninety-five views in the Yellowstone Park, U.S.A., and a number of miscellaneous slides by members.

---

Mr. Shapoor N. Bhedwar, who won one of the gold medals at the Liverpool International Photographic Exhibition, was a photographic pupil of Mr. R. W. Robinson.

Photogravure Prints.—We have received from Messrs. Annan and Swan some specimens of exceedingly fine prints by the photogravure process, which is noted for its capacity to give highly artistic results. One of the prints is an admirable likeness of Mr. J. W. Swan, which ought to be on public sale because of the great scientific services he has rendered to photography and electricity.

Received.—From Messrs. Perken, Son, and Rayment, the sixteenth edition of "Intensity Coils," being a beginner's guide to electricity, describing the way to make batteries, bells, coils, electric light, telegraphs, phonographs, and so on.——From Mr. H. Park, a catalogue, including a useful list, with prices, of camera fittings, with illustrations of the latter in exact sizes.——Another catalogue to hand is that of the Thornton-Pickard Manufacturing Co.'s photographic specialities, including shutters and shutter accessories, and cameras with accessories. The Company call attention to the improvement made in the "time and instantaneous" shutter, whereby the pointer does not require setting for each exposure, as in the earlier patterns.——From David Nutt, specimen pages containing Appendices and Vocabulary for Cyclists and Photographers, to appear in a new edition of "Swan's Colloquial French for Travellers."——From Ross and Co., a new catalogue, from which we learn that they have erected large new works near Clapham Common, and putting an improved form of iris diaphragm in their lens mounts.

---

All communications should be as brief as the importance of the subject will permit, when speedy publication is desired. Our space is overcrowded, and we now have contributions waiting for insertion which have been in type for some weeks.

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.**

**All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

☞ *The Photographic News will be published on Thursday next, on account of the Easter holidays. All communications should therefore reach the office not later than Wednesday morning.*

L. A.—*London Rainfall.* Our results do not quite agree; slight differences are, however, to be expected. We had, at Canonbury, an unbroken period of thirty-four dry days, viz., from February 1st to March 6th inclusive; then heavy rain fell on Saturday, 7th inst., amounting to ·47 inch, followed by more rain on the 8th, and then the blizzard.

W. A. & Co.—*Postage Stamp Portraits and Cheap Enlargements.* Several houses undertake reproductions of this character; amongst others the Artistic Photographic Company, Imperial Mansions, Oxford Street, W., and Mr. Harold Godwin, 2, Crown Court, Cheapside, E.C.

Exhibitor.—*Liverpool to Crystal Palace.* The dates are so close that it seems hardly possible for you to get your picture back from Liverpool in time for reception on the 6th April at the Crystal Palace Exhibition; but as the entry form for the latter need not be sent in until Monday week, 30th inst., there is still left to you the possibility of enquiring whether any grace is allowed to the Liverpool exhibitors.

A. M. M.—*Calculation of Cost.* From information received from a most trustworthy source, confirmatory of our own past experience, it seems almost impossible to work out a fixed ratio between profit and gross returns in any professional photographic business. As a rule, "the larger your return, the larger the proportion of profit," but much will depend upon outlay for rent and character of the work executed. The prices of platinum and hyposulphite are advancing, and silver also has been oscillating in recent years, facts which add to the difficulty of making a close calculation. In the same establishment profits have varied from 25 to over 50 per cent., according to the amount of business going, and this was one where spoilt prints and plates were, by good practice, assuredly kept down to very moderate limits. With a lower-class business, according to the locality, the profits might be either higher or lower than the scale now given.

C. T. (Sheffield).—*Photo-Mechanical Prints* In your district probably Mr. Graham Glen, of 2, Commercial Street, Leeds, could undertake the work.

E. Fischel (Amsterdam).—*Blue Carbon Paper.* This was made formerly by MM. Marion & Cie., Courbevoie, Paris, but there is not now much demand for a pigment paper of that colour.

W. M.—*Fluoride of Silver.* You are under a misapprehension with regard to this body; it cannot be *precipitated* within the texture of the paper, like chloride of silver, for it is extremely soluble in water. The easiest way of making it is by dissolving granulated silver in hydrofluoric acid contained in a platinum basin. Be careful not to inhale the fumes, and make it neutral by stirring in, finally, a little oxide or carbonate of silver.

E. W. F.—The papers have been sent on to you by post. We are told that the proviso on top line may now be disregarded.

D. H.—*Yellow Colouring Matter.* So far as can be judged from the small sample sent, the peculiar tint is got from fluoresceine. This body is soluble in water, especially in presence of alkalies, and gives with bromine a pink colour due to the formation of eosine.

J. T.—*Bronze Printing.* A reliable test is to moisten it with nitrate of silver. Pure gold leaf is not at all affected, whereas the imitation article at once reduces the silver from solution. By blotting off and touching the filter paper with yellow prussiate, you will see by a red-brown stain the indication of copper.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1699.—*March* 27, 1891.

CONTENTS.

## THE THEORY OF THE NEW HELIOCHROMIC PROCESS.

From the time of the production of Becquerel's heliochromic photographs half a generation ago, it has often been speculated that the colours might or might not be those of thin plates, and it is pleasing that the true theory of their production was first put forth in this country by Lord Rayleigh, the successor of Professors Tyndall, Faraday, Davy, and Young, as Professor of Natural Philosophy at the Royal Institution.

As Lord Rayleigh set forth in these pages on March 6th last, he published the explanation in the *Philosophical Magazine* of August, 1887, in which he says of Becquerel's photographs that the film "may be conceived to be subjected during exposure to *stationary* luminous waves of nearly definite wave-length, the effect of which might be to impress upon the substance a periodic structure recurring at intervals equal to *half* the wave-length of the light." He then speaks of hoping to follow up the subject experimentally, but did not do so; M. Lippmann, later on, working with the same theory, has obtained brilliant results. It is some satisfaction to know that the true fundamental principle of heliochromy was first enunciated by one of the ablest mathematicians and physicists in this country, although, afterwards, first proved to be true in France.

Early in 1888 Lord Rayleigh brought under the notice of the Royal Institution some remarkable researches and experiments of his own on the diffraction of sound, and, by the suitable manipulation of sound-waves, he produced phenomena analogous to those of the interference of light; in other words, just as in M. Lippmann's films, waves of light, by interference with each other, produce stationary bands of darkness, so did Lord Rayleigh cause waves of sound to act upon each other to produce in mid air stationary bands of silence. Just as Wiener applied a photographic film to search for and register interference bands of light, so did Lord Rayleigh employ a sensitive flame to indicate the presence of interference bands of sound.

The waves of sound to which the human ear is sensitive are long; the wave-length of middle C on the musical scale is four feet, and of the C one octave above it two feet. The sound-waves used by Lord Rayleigh were about half an inch in length, so short and sharp as not to be audible to the human ear; they were made by causing a current of air to blow steadily through a kind of small whistle. This was placed opposite the flaring sensitive flame and at a few yards distance; whenever the lecturer placed his hand between the whistle and the flame a sound-shadow was cast; the flame then ceased to flare and became quiescent, but whenever the hand was removed began to flare once more.

He then placed a board on the opposite side of the flame to the whistle, to act as a sound-reflector, and said:—"The places of greatest variation of density are the places of no motion; the places of greatest motion are places of no variation of density. By the operation of a reflector, such as this board, we obtain a system of stationary waves, in which the nodes and loops occupy given positions relatively to the board. You will observe that, as I hold the board at different distances behind, the flame rises and falls. I can hardly hold it still enough. In one position the flame rises, farther off it falls again; and as I move the board back, the flame passes continually from the position of the node—the place of no motion—to the loop or place of greatest motion, and no variation of pressure."* Here, then, in sound, we have a reflecting board exercising functions analogous to a reflecting surface in light; in the one case we have alternate bands of sound and silence in front of the board, and their presence indicated by a sensitive flame; in the other case—in M. Lippmann's process—we have bands of light and darkness in front of the mercury, and their presence indicated by effects produced in the interior of a transparent photographic film.

The ingenuity of this production of silence bands by means of sound-waves of air reflected from a wooden board is obvious; but the phenomenon is not parallel at all points with that of the interference of the waves of light, for the interstellar ether is almost entirely

* *Journal of the Royal Institution*, vol. xii., page 189, January 20th, 1888.

destitute of viscosity or fluid friction, whilst air is far from being such a perfect fluid. Still, the phenomena are closely enough related for our illustrative purpose.

No pigmentary colours are produced in the finished photographs, which merely break up white light so as to reflect the right prismatic colours from the right places. Diffraction gratings for producing diffraction spectra have no proper colour of their own. They are merely pieces of glass or polished white metal, ruled with innumerable fine lines by means of a machine-guided diamond point; yet they afterwards break up white light, so as to yield all the colours of the rainbow with brilliancy.

## THE PRIMULINE PROCESS IN COMMERCE.

The primuline diazotype process, which attracted so much attention last year at the British Association and elsewhere from its refreshing novelty, has been taken over by Messrs. Watson and Son, who are about to introduce it into the regular channels of photographic trade. This news is interesting, for the process is one of which the utilitarian possibilities are, for the most part, as yet undeveloped, but are likely to be evolved when experienced photographers begin experimenting in relation thereto. Two leading features of it are, that it is excessively cheap, and produces results marked by their brilliancy and by the variety of the resulting colours.

The largest class of profits is usually made by the first introduction of novelties to the public; as processes and methods grow old, competition does its work, and cutting prices become the order of the day when the results have to be sold to the masses of the population. High-class work of any kind, however, is always likely to hold its own when the results have to be sold to the cultured class of the community, which is more competent to judge artistic and scientific merits.

Should the primuline process become a fashionable "craze" like that of ornamenting china, it is likely to be in great public demand. Any photographer who has transparencies of any of his sitters, can borrow their white handkerchiefs, and, with their permission, in a few minutes on a sunshiny day, present them their likenesses printed thereon in brilliant colours, and so fixed as to resist the action of hot soap and water. This is certain to attract their attention, and to send them home talking about the matter among their friends. Indeed, this primuline process seems to well deserve the attention of professional photographers. Full details about the working of the primuline process are to be found in our last Year-Book.

The Chicago International Columbian Exhibition, 1893. —A proclamation by the President of the United States, Mr. Benjamin Harrison, has been made to the effect that satisfactory proof having been presented as to adequate grounds, buildings, and finances for this proposed great Exhibition for celebrating the 400th anniversary of the discovery of America by Columbus, he, in the name of the United States, declares that the Exhibition will be opened on May 1st, 1893, in the city of Chicago, Ill., and he invites all nations to take part in the commemoration.

## SEASONABLE PRECAUTIONS.

Now that this truly dreary winter, which has brought us so much snow and general discomfort, has nearly past away, we shall forget all about its cold and its cruel fogs until the dark days come round once more, when, perchance, we shall remember that it is time to commence grumbling again; but, for the present, we have something better to do, in looking forward to the speedy budding of the trees, and the general awakening of nature after her long sleep.

This refreshing change in the aspect of the world is even more welcome to the photographer than it is to others, for his work, as well as his pleasure, depends in great measure upon that same sun which causes the birds to sing and the flowers to bloom. And, in the case of out-door photography, whether it be professional or amateur in character, dependence upon the sun naturally becomes still more emphasised. Photographers, indeed, are looking forward to their first day in the field as eagerly as sportsmen of another kind anticipate with pleasure the first of September. In both cases, too, the implements of sport must be carefully overhauled to see that there is nothing wanted to mar the expected enjoyment; but, whilst the sportsman has little to do beyond seeing that his weapon is clean and bright, the photographer has to be far more particular before he can hope to win success.

As a knight of old had to try every joint of his armour before going into the lists, so must the photographer look most carefully to see that his apparatus has not deteriorated during its enforced period of rest. In spite of the best cabinet work—and there is little to complain of in the manufacture of cameras now-a-days—the best wood will sometimes warp after experiencing the vicissitudes of an English winter. A crack which is almost imperceptible to the eye will be quite wide enough to admit a glint of light, and such cracks will often make their appearance without apparent cause. Another weak point where light will occasionally creep in, is where the leather bellows of the camera is attached to the woodwork. Even the bellows part of the instrument itself is liable to injury, especially from the attacks of insects; and, although we have no such destructive creatures in this country as white ants, we have the ubiquitous cockroach, which appears to be able to make havoc of, and to digest any substance, with the exception, perhaps, of cast steel. Mice, too, will nibble away at leather if they cannot find anything else with which to appease their hunger, so that the bellows of the camera has at least two pests which hanker after it more or less. There are other parts of the camera which require looking to before work is recommenced, notably the rising front, and the junction of the metal flange of the lens with the woodwork. The dark slides, too, may be of the best make, and may have proved to be reliable against ingress of light, but this is no guarantee that they will remain so for ever. A corner joint may have given way just sufficiently to admit a tiny pencil of light, which will spoil every negative entrusted to its care. All these things should be most carefully examined, so as to save disappointment, for prevention is better than cure, especially in the case of damaged negatives, where cure is next to impossible.

But it is not alone the portable photographic apparatus that must be looked to at the beginning of a fresh season; the dark room and its appurtenances must also be overhauled. The most important feature to deal with first is the light-filtering medium, whatever it may consist of. All ruby media, whether of cloth or paper, are liable to change, especially if they have been exposed for any time to the action of daylight. We have seen specimens so situated that have, in a few months, changed from a rich and absolutely safe red to a washed-out pink that would hardly be a protection to a plate prepared from comparatively insensitive silver chloride. Even glass is not safe, but is liable to change, although the bleaching action here is not nearly so marked as in the case of paper or cloth. The medium protecting a lamp is not liable to such rapid deterioration, for it is not usually exposed to that energetic bleaching agent which we have in sunlight; but still the lamp should be looked to. One more word. At the beginning of a new season, clear the decks for action by eliminating from the dark room everything that is not absolutely wanted for work. Dismiss the empty bottles, pour away solutions of uncertain composition, make good all labels, clear away cobwebs and dust, and your work will be all the better for the trouble incurred.

## ELECTRO-CHEMICAL REVERSALS WITH THIO-CARBAMIDES.

BY COLONEL J. WATERHOUSE, B.S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

Farther observations made with silver plates coated with a film of precipitated silver bromide in pairs of one exposed and one unexposed plate, connected with a very delicate suspension galvanometer, showed not only a distinct electric current between the plates immersed in the plain eikonogen-lithia developer, but a reversal of the current with plates immersed in some of the same developer to which five drops per ounce of the compound salt of thio-carbamide and ammonium-bromide had been added. With the ordinary developer, the exposed plate forms the negative pole of the circuit, whereas with the thio-carbamide developer it forms the positive pole. The same rule has been found to hold good with thio-sinamine. With the thio-carbamide developers the current is more powerful than with the plain developers. Farther experiment is, however, necessary with other plates to confirm this reversal of the current, which seems highly probable, and was to have been expected.

Blue Prints on Albumenised Paper.—Sensitise the paper with the following solution:—

| | |
|---|---|
| Citrate of iron and ammonium ... | $3\frac{3}{4}$ drachms |
| Water ... ... ... ... ... | 3 ounces |
| Red prussiate of potash ... ... | $2\frac{1}{2}$ drachms |
| Water ... ... ... ... ... | 2 ounces |

Mix equal parts (at the time of using), and float the paper for about half a minute, then dry. The prints may be mounted and burnished. The sensitised paper does not keep. —*Scientific American.*

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Colouring Silver Prints—Diapositives from Engravings and Prints—Printing on Wood—Combined Pyro and Hydroquinone Developer—Turpentine as an Accelerator.

*A Novel Method of Colouring Silver Prints.*—Dr. Miethe reports on a new method of colouring albumen prints, suggested by Ogonowski in his book on photochromy. It consists in the following. Ordinary salted paper is floated on a silver bath, printed rather weakly beneath the negative, washed out, toned and fixed as usually. The weak print thus obtained is placed, whilst still moist, on a sheet of wet blotting-paper, and together with it on a glass plate. The print, which by this procedure is kept moist, is then coloured with water-colours, only natural colours being, however, applied, and white body-colour; vermilion, chrome, and cadmium yellow are avoided. The whole is then allowed to dry, and the print floated from once to three times on a solution of salted beaten albumen, when it is again sensitised, and placed in the right position beneath the negative in the printing frame. It should now be printed as usually on albumen paper, then toned and fixed. The colours, which are prevented from coming off by the albumen film, are perfectly preserved, and the pictures obtained by this method are said to give splendid effects.

*How to Make Diapositives from Engravings and Prints in the Original Size.*—The following simple and trustworthy method is described by E. Ammann in the *Archiv.* A well-polished plass plate is coated with one of the well-known sensitive gum and bichromate solutions, as used in the powder process, and dried. The copper engraving or the wood-cut from which the transparency is to be taken, is placed with its back outwards in the printing-frame, the prepared glass plate being laid on it. It is then exposed, dusted-in with suitable colours, washed out, dried, and varnished. The transparency is then finished. In order to prevent the paper of the engraving from adhering to the bichromate film of the plate during printing, the back of the engraving or print is previously rubbed in with turpentine, and then laid aside for a few minutes. The paper is thus not only provided with fatty matter which prevents adherence to the glass, but it is at the same time rendered transparent, so that in dusting on the colours the grain of the paper remains invisible. If pure and clear turpentine is used, no trace of it will remain on the paper after evaporation.

*Printing on Wood.*—A professional photographer who does a great deal in making prints from negatives on sensitised wood blocks for the use of wood-cutters, was kind enough to demonstrate to me the other day his mode of working. It will, perhaps, be of interest to some of your readers:—

| | |
|---|---|
| Gelatine ... ... ... ... | 8 grammes |
| White soap ... ... ... ... | 8 ,, |
| Water ... ... ... ... ... | 500 ,, |

The gelatine is allowed to swell, dissolved by means of a hot water bath, and the soap added gradually with constant stirring. Finally, the solution is filtered through muslin. With this mixture, to which some zinc white is added, the wood block is well rubbed in, and allowed to dry; the film should be as thin and even as possible. The wood block is then, by means of a broad brush, coated with the following solution :—

| | |
|---|---|
| Albumen ... ... ... ... | 30 grammes |
| Ammonium chloride ... ... ... | 1·2 gramme |
| Citric acid ... ... ... ... | 0·2 ,, |
| Water ... ... ... ... ... | 24 c.c. |

The albumen is beaten up to a froth, and allowed to settle; then the water, the ammonium chloride, and the citric acid are added in the order indicated. After the coating has dried, the film is sensitised by means of—

| | |
|---|---|
| Silver nitrate ... ... ... ... | 3·2 grammes |
| Water ... ... ... ... ... | 31 c.c. |

Of which solution a little quantity is poured on and distributed with a glass rod. The surplus is poured off, and the block allowed to dry. Printing is done as usually, but it is not necessary to over-print. After printing, the surface of the block is immersed for about three minutes in a weak solution of common salt in water, in which the print will be bleached to some extent. It is then rinsed under the tap, and fixed for from four to five minutes by means of a concentrated solution of hypo. Finally, it is washed for about ten minutes under the tap, and then dried.

*A Pyro-Hydroquinone Developer.*—Dr. C. Schleussner, the well-known dry plate manufacturer of Frankfort-on-Main, whose plates have a very large sale in Germany, prefers the following combined pyro and hydroquinone developer to all others. The following stock solutions are prepared :—

*Stock Solution* No. 1.

| | |
|---|---|
| Hydroquinone ... ... ... | 20 grammes |
| Distilled water ... ... ... | 2,000 c.c. |

*Stock Solution* No. 2.

| | |
|---|---|
| Carbonate of soda ... ... ... | 100 grammes |
| Distilled water ... ... ... | 500 c.c. |

*Stock Solution* No. 3.

| | |
|---|---|
| Distilled water ... ... ... | 400 c.c. |
| Sodium sulphite ... ... ... | 60 grammes |
| Diluted sulphuric acid ... | 10 to 20 drops |
| Pyrogallic acid ... ... ... | 20 grammes |

The sodium sulphite should be dissolved and acidulated with sulphuric acid before the pyro is added. For use mix—

| | |
|---|---|
| Solution No. 1 ... ... ... | 40 parts |
| Solution No. 2 ... ... ... | 10 ,, |
| Solution No. 3 ... ... ... | 10 ,, |

The development may be accelerated by heating the mixture a little. It is well to commence development with an old solution, and to finish it with the fresh solution as soon as the high lights have made their appearance. This developer gives negatives of the character of wet collodion plates, *i.e.*, very fine details and high lights, combined with excellent printing quality.

*Turpentine as an Accelerator in Development.*—M. Wolf and P. Lenhard have discovered that turpentine oil, if added to the hydroquinone developer, acts as a powerful accelerator. They state that if a few drops of this oil be added to the developer, the reduction takes place much more quickly than without this addition, and that, at the same time, the shadows of the negative turn out much denser. Turpentine seems to act here similarly to hyposulphite of soda in the ferrous oxalate developer. Care should, however, be taken not to use too much of the oil, as this causes patches. The following formula was used by the authors :—

| | |
|---|---|
| Water ... ... ... ... | 100 c.c. |
| Soda ... ... ... ... ... | 8 grammes |
| Caustic soda ... ... ... ... | 0·5 gramme |
| Sodium sulphite ... ... ... | 5 grammes |
| Hydroquinone ... ... ... | 1·2 gramme |

To one-half of this quantity 3 drops of turpentine were added. I do not know, however, whether the *quantities* given here are quite correct, since the authors (Eder's Year-Book, 1891), in the formula for the hydroquinone developer, are talking of "parts," and in the case of the turpentine which was added, of "drops."

## AMERICAN INTERNATIONAL COPYRIGHT GRANTED FOR PHOTOGRAPHS.*

*Section* 5.—That section 4,959 of the Revised Statutes be, and the same is hereby amended, so as to read as follows: "Section 4,959.—The proprietor of every copyright book or other articles shall deliver at the office of the Librarian of Congress at Washington, district of Columbia, a copy of every subsequent edition wherein any substantial changes shall be made; provided, however, that the alterations, revisions, and additions made to books by foreign authors, heretofore published, of which new editions shall appear subsequently to the taking effect of this Act, shall be held and deemed capable of being copyrighted, as above provided for in this Act, unless they form a part of the series in course of publication at the time this Act shall take effect."

*Section* 6.—That section 4,963 of the Revised Statutes be, and the same is hereby amended so as to read as follows :—"Section 4,963.—Every person who shall insert or impress such notice, or words of the same purport, in or upon any book, map, chart, dramatic, or musical composition, print, cut, engraving, or photograph, or other articles for which he has not obtained a copyright, shall be liable to a penalty of 100 dollars, recoverable one-half for the person who shall sue for such penalty, and one-half for the use of the United States."

*Section* 7.—That section 4,964 of the Revised Statutes be, and the same is hereby amended so as to be read as follows :—"Section 4,964.—Every person who, after the recording of the title of any book, and the depositing of two copies of such book as provided by this Act, shall, contrary to the provisions of this Act, within the term limited, and without the consent of the proprietor of a copyright first obtained in writing, signed in the presence of two or more witnesses, print, publish, dramatise, translate, or import, or, knowing the same to be so printed, published, dramatised, translated, or imported, shall sell, or expose to sale, any copy of such book, shall forfeit every copy thereof to such proprietor, and shall also forfeit and pay such damages as may be recovered in a civil action by such proprietor in any Court of competent jurisdiction.

*Section* 8.—That section 4,965 of the Revised Statutes be, and the same is hereby amended so as to read as follows :—"Section 4,965.—If any person, after the recording of the title of any map, chart, dramatic or musical composition, print, cut, engraving, or photograph, or chromo, or of the description of any painting, drawing, statue, statuary, or model or design intended to be perfected and executed as a work of the fine arts as provided by this Act, shall, within the term limited, contrary to the provisions of this Act, and without the consent of the proprietor of the copyright first obtained in writing, signed in the presence of two or more witnesses, engrave, etch, work, copy, print, publish, dramatise, translate, or import, either in the whole or in part, or by varying the main design with intent to evade the law, or knowing the same to be so printed, published, dramatised, translated, or imported, shall sell or expose to sale any copy of such map or other article as aforesaid, he shall forfeit to the proprietor all the plates on which the same shall be copied, and every sheet thereon either copied or printed, and shall further forfeit 1 dollar for every sheet of the same found in his possession, either printed, copied, published, imported, or exposed for sale; and in case of a painting, statue, or statuary he

* Concluded from page 225.

shall forfeit 10 dollars for every copy of the same in his possession, or by him sold or exposed for sale, one-half thereof to the proprietor, and the other half to the United States."

*Section* 9.—That section 4,967 of the Revised Statutes be, and the same is hereby amended so as to read as follows:—"Section 4,967.—Every person who shall print or publish any manuscript whatever, without the consent of the author or proprietor first obtained, shall be liable to the author or proprietor for all damages occasioned by such injury."

*Section* 10.—That section 4,791 of the Revised Statutes be, and the same is hereby repealed.

*Section* 11.—That for the purpose of this Act each volume of a book in two or more volumes, when such volumes are published separately, and the first one shall not have been issued before this Act shall take effect, and each number of a periodical shall be considered an independent publication subject to the form of copyrighting above.

*Section* 12.—That this Act shall go into effect on the 1st day of July, A.D. 1891.

*Section* 13.—That this Act shall only apply to a citizen or subject of a foreign State or nation when such foreign State or nation permits to citizens of the United States of America the benefit of copyright on substantially the same basis as its own citizens, or when such foreign State or nation is a party to an international agreement which provides for reciprocity in the granting of copyright, by the terms of which agreement the United States of America may, at its pleasure, become a party to such an agreement. The existence of either of the conditions aforesaid shall be determined by the President of the United States by proclamation made from time to time as the purposes of this Act may require.

---

PHOTOGRAPHIC PRINTS OF CRYSTALS (formed under a pressure of 1,500 atmospheres).—M. Amagat, Professor of Physics at the Faculty of Lyons, has devised an appliance which not only allows us to see the solidifying of certain bodies under considerable pressure, but also to obtain crystals that are perfectly sharp, and to photograph them. He placed under the eyes of the Academy of Sciences four directly enlarged prints of these crystals, obtained with the appliances and with the assistance of M. Donnadieu, Professor of Geology of the same Faculty. We have here a very interesting application of photography called upon to give the proof of some curious phenomena, whose existence might be contested were it not for this important mode of vision and record.—*Moniteur.*

THE ROYAL INSTITUTION.—The following are the lecture arrangements after Easter:—Mr. J. Scott Keltie, three lectures on the Geography of Africa, with special reference to the Exploration, Commercial Development, and Political Partition of the Continent; Dr. E. E. Klein, three lectures on Bacteria: their Nature and Functions (the Tyndall Lectures); Mr. William Archer, four lectures on Four Stages of Stage History (the Betterton, the Cibber, the Garrick, and the Kemble Periods); Professor Dewar, six lectures on Recent Spectroscopic Investigations; Dr. A. C. Mackenzie, four lectures on the Orchestra considered in connection with the Development of the Overture; Professor Sylvanus P. Thompson, four lectures on the Dynamo; Mr. H. Graham Harris, three lectures on the Artificial Production of Cold; Professor A. H. Church, three lectures on the Scientific Study of Decorative Colour. The Friday evening meetings will be resumed on April 10th, when a discourse will be given by Sir William Thomson on Electric and Magnetic Screening. Succeeding discourses will be given as follows:—April 17th—Professor A. W. Rücker, Magnetic Rocks; April 24th—The Rev. Canon Ainger, Euphuism, Past and Present; May 1st—Mr. James Edmund Harting, Hawks and Hawking; May 8th—Professor W. Ramsay, Liquids and Gases; May 15th—Professor G. D. Liveing, Crystallisation; May 22nd—Professor J. A. Ewing, The Molecular Process in Magnetic Induction; May 29th—Mr. David Gill, LL.D., H.M. Astronomer at the Cape of Good Hope, An Astronomer's Work in a Modern Observatory; June 5th—Mr. St. George J. Mivart, M.D.; June 12th—Professor Harold Dixon, The Rate of Explosion in Gases.

## THE BRITISH ASSOCIATION.

### METEOROLOGICAL PHOTOGRAPHS.

THE Committee on Meteorological Photography of the British Association for the Advancement of Science, consisting of Mr. G. J. Symons, F.R.S. (chairman), Professor R. Meldola, F. R.S., Mr. John Hopkinson, F.L.S., and Mr. Arthur W. Clayden, M.A. (secretary), has issued the following circular:—

Photographs are desired of clouds, lightning, hoar-frost, remarkable hailstones, snow-wreaths, avalanches, glaciers, storm-waves, waterspouts, tornadoes, dust-whirls, halos, parhelia, or any other meteorological phenomena or their consequences.

### GENERAL INSTRUCTIONS.

1. As soon as possible after exposing a plate, number it and fill in the details relative to it on one of the forms supplied. The more completely these are filled in, the more valuable will the photograph be.

2. The size of the plate is immaterial, provided that the focus is sharp. Use a magnifier when focussing, and for objects like clouds focus upon a distant tree or building.

3. Use a lens which does not distort the image.

4. Do not touch up either negative or print.

5. When photographing any object which is moving or changing, a series of views taken at short intervals, so as to show the progress of the phenomenon, will be of especial value.

6. Whenever possible, a figure or other object of known dimensions should be introduced, in order to serve as an approximate scale.

### CLOUD PHOTOGRAPHY.

For heavy clouds no special apparatus is required, but exposure must be shorter than for ordinary landscape work. For very thin clouds exposure must be extremely short, and development very cautious. Fair results may then be occasionally obtained without special means.

In order to obtain better and more certain results three methods have been adopted:—

(*a*) Using a slow plate and rapid lens, with short exposure; (*b*) using an ordinary plate and lens, but with a sheet of pale yellow glass in front of the lens; (*c*) using an ordinary plate and lens, but placing a plane mirror of black glass in front of the lens so that its surface makes an angle of about 33 degrees with the axis of the lens. The image reflected in the mirror is fairly easy to photograph.

The Committee hope to receive examples of each of these processes, as well as examples and descriptions of any other special devices which may be adopted by observers.

### LIGHTNING PHOTOGRAPHY.

When a thunderstorm occurs at night it is very easy to photograph the flashes of lightning.

Fix the camera rigidly (do not hold it in the hand), and expose it to a part of the sky where flashes are frequent.

As soon as one flash has crossed the field of view, change the plate.

Whenever possible, count the number of seconds between seeing the flash and hearing the beginning of the thunder. Note this time on the print or form.

If you have two cameras, some useful results may be attained by using one as described above, and holding another in the hand, pointing in about the same direction, but kept in constant oscillation. It is hoped that two photographs of the *same flash* may be thus secured.

Another desirable experiment is to fix both cameras in the same direction, change the plates in one after each flash, but leave the plate exposed in the second until six or eight flashes have crossed the field of view.

If the camera is placed in a window this must be open, as the interposition of a window pane may give rise to multiple images.

Be particularly careful to note the exact time and direction of each flash photographed.

A rapid lens, with a stop $f/8$ or thereabouts, should be used for lightning.

Prints, which may be mounted or unmounted, should be sent as early as possible to the Secretary, at Warleigh, Tulse Hill Park, London, S.W.

## AN INTERESTING LETTER BY SIR DAVID BREWSTER.

BY WM. LANG, JUN., F.C.S.

When in Edinburgh recently, I secured a relic of early photographic days in the shape of a letter by Sir David Brewster, which is sufficiently interesting, I think, to bring before the readers of the Photographic News. The contents of the letter are devoted to an account of an accelerator to be used in connection with Niepce de St. Victor's albumen process. As is well known, one of the principal drawbacks inherent to the Frenchman's process was the long exposure required in the camera. There is no Christian name attached to the Mr. Ross to whom Brewster had been writing; we are, therefore, only able to surmise as to the actual recipient of the communication. From the fact that Messrs. Ross and Thompson, of Edinburgh, were at that time engaged in working the albumen process, it may be a safe assumption to go upon that the Mr. Ross of the firm indicated was the individual to whom the letter was addressed. Without farther preface the letter may here be given:—

*St. Leonard's College, Sept. 10th, 1850.*

Dear Sir,—I have just received an account of the new method of M. Niepce de St. Victor for accelerating the process in albumen. It consists in adding 3 or 4 grammes of honey to one white of an egg along with 30 or 40 centigrammes (or 3 or 4 grammes) of iodide of potash. The albumen, when dry, is immersed for ten minutes, at the utmost, in a solution of—

| | | |
|---|---|---|
| Nitrate of silver | ... ... ... | 6 grammes |
| Combustible acetic acid | ... ... | 12 ,, |
| Distilled water | ... ... ... | 60 ,, |

A white ground is placed behind the plate of albumen in the camera, and the picture is brought out with hot gallic acid, the best pictures being those that remain several hours in the acid. The albumen of old eggs is more apt to peel from the glass than that of fresh eggs, and to prevent this the albumen, after the picture is upon it, and quite dry, may be covered with a thin layer of gelatine or picture varnish.

The time for a landscape in diffused light is two or three seconds, the time for a portrait from five to six seconds. The time is shortened by using a thicker plate of albumen, by using old eggs, and the longer the aceto-nitrate solution has been used the quicker is the process, which is also accelerated by a more thorough washing of the plate of albumen.

The albumen of a duck's egg peels less from the glass than that of a fowl; the albumen from blood is very accelerating, but it does not adhere well to the glass unless it is previously coagulated with azotic acid. Syrup and the serum of milk (whey) answer as well nearly as honey.—I am, dear sir, ever most truly yours, D. Brewster.

The year 1850, in which the foregoing had been penned, was one of varied experiences to Brewster. In the first month of the year he had the misfortune to lose his wife, a daughter of the famous Macpherson, known generally as Ossian Macpherson. In the spring, Brewster, along with his daughter, visited Paris, where he renewed his acquaintance with Arago, the famous astronomer, a tie of friendship which had first been formed in the year 1814. Other celebrities no less famous in their own particular walk were at this visit thrown into Brewster's company; notably, Guizot, the historian, Leverrier, the astronomer, and De la Rive, the electrician. A week or two having been spent in London, Brewster and his daughter afterwards visited Fox Talbot at Windermere, who, during the summer, repaired to his residence there. We can well understand how congenial would the company of these two philosophers be to each other, and that among many other topics of scientific interest, the possibilities of photography would be by no means overlooked.

It may be here stated that the two scientists had—if not before—formed a friendship in 1836, for on the occasion of the sixth meeting of the British Association, which was held in Bristol, we find Brewster spending the previous week at Lacock Abbey, the ancestral home of Talbot.

Brewster may be said to have been one of the chief promoters of the British Association. It was, therefore, peculiarly appropriate that when this body visited Edinburgh for the second time, in 1850, Sir David Brewster should have been elected president. It was the twentieth meeting of the Association, and the opening took place on July 23rd.

Enough has been said to indicate that the year in which the letter we have brought before our readers was written was one of the most eventful in the whole of Brewster's career.

It will be noted that the address heading the letter to Mr. Ross is that of St. Leonard's. Brewster, at the time of writing, was still principal of the United College of St. Salvator and St. Leonard in the university of St. Andrew's, an appointment bestowed on him in 1838, and which was held by him for twenty-three years. In 1860 he was made principal of the Edinburgh University, and his connection therewith was only severed by his death in 1868, having reached the advanced age of eighty-six years. In the memoirs of Sir David Brewster, published by his daughter, Mrs. Gordon, in 1869, under the title of "The Home Life of Sir David Brewster," we find the following:—"My father's connection with photography and photographers might well furnish a chapter of his life in competent hands. A large correspondence was kept up with Mr. Fox Talbot, M. Claudet, Mr. Buckle, Paul Pretsch, Messrs. Ross and Thompson, and other eminent photographers." Could these past memorials not be yet gathered together, and a compilation made? One of the last acts of Brewster's life was to bear testimony to the scientific worth of a former friend of his—M. Claudet, the eminent London photographer. Brewster was the first president of the Photographic Society of Scotland, a society founded in 1856. In connection with the stereoscope, Brewster's name is generally put forward as the inventor, but this he always disclaimed. It was only a modification of the original idea which he sought to get credit for, viz., the lenticular stereoscope, but, all the same, it was this particular form which popularised the instrument. There is one optical appliance of Brewster's, however, and one which seems to be now-a-days overlooked altogether, regarding which there can be no dubiety as to the author. I refer to the kaleidoscope. Many other optical arrangements were devised by this philosopher, but it would be beyond the limits of this communication to enter upon these. Brewster had a facile pen, and his works remain testifying to a beauty of expression combined with intellectual gifts of the very highest order. His "More Worlds than One," "Life of Newton," and many others, are well worth being perused by those to whom Brewster is little more than a name.

Cool as a Cucumber.—"The coolest man I ever knew in my life," said a Congressional arrival, "was a native of Kansas. A cyclone had set him down, with his entire family and a portion of his furniture, within twenty feet of my house. I said to him: 'Hello, Sam! what are you doing over here?' 'Oh,' he replied, as he dumped a handful of tobacco into his pipe, 'I just took a snap-shot, and now I want to get a *time*-exposure before the next gust comes on.'"

## THE PERMANENCY OF PHOTOGRAPHS.*

BY FR. WILDE.

*Translated from the German by J. F. Sachse.*

'HE following communication to the *Photographisches 'ochenblatt* (Berlin, Nov. 27, 1890), by Fr. Wilde, of örlitz, a photographer of over forty years' experience, iould be carefully read and studied by all photographers. rofessionals as well as advanced amateurs. We have ideavoured to reproduce the paper with all the idiom of ie original, and trust that it has not lost any of its excel-ence in the translation from the language of the Fatherland.

With great injustice has the reproach of instability been often cast upon our silver prints. Usually this has een done for advertising purposes. In the commence-ient of the seventies it was done in the interest of the arbon or pigment process; in later years, to boom up ie platinum process. I, however, claim, according to iy own experience and observations, that when a silver rint changes or fades, it is entirely due to carelessness in ie process of its production, such as insufficient fixing or on-elimination of the hyposulphite of soda, or the use of nsuitable paper or faulty preparation of the same. Out f my long practice as a photographer—since 1848—I ossess specimen silver prints from each year, and all are ultlessly preserved. The oldest photograph in my ossession was made in the fall of 1850. Prior to that me I made Daguerreotypes exclusively; the demand for iese ceased only with the introduction of the collodion rocess. At that period photography was not so easy or onvenient as it is to-day. There was no extensive echnical literature, in which thorough professionals so isinterestedly published their experiences for the good of ie profession in general. No paper especially manu-ictured or prepared for photographic purposes was to be btained in the trade, nor were the necessary chemicals to e obtained in their requisite purity without the greatest ifficulty.

Prior to the introduction of the collodion process the egatives were made on paper, which the photographer ad to prepare, as well as that for the prints. The latter emained the case for a long time, even after glass was ubstituted for paper. All causes of failure had then to e sought for at home, and could not, as now so often ie case, be shifted upon the shoulders of the manufacturer, 'ithout cause or justice. Those who went through this poch of photography—and there are but few of such eterans—must admit that the progress which the art has iade with such giant strides is not altogether due to the rofessional photographer, but that to the amateur, with is equipment of greater scientific knowledge, much of he credit is due. On paper prepared merely with the alts, the image invariably sunk more or less into the aper; to remedy this defect, additions of various ubstances were made to the salting solution, such as ifferent kinds of starch (arrowroot paper), or decoctions f various mosses (algein paper), of gelatine, whey, or asein, in connection with such acids as tartaric, citric, or uccinic acid. The best results which I ever obtained vere on a strong, somewhat rough Steinbach paper, which vas prepared with casein, sodium chloride, neutral citrate f potassium, and floated upon an eight per cent. silver olution. They were more vigorous than prints on lbumenised paper, and reproduced the finest detail and eauties of the negative better than the latter.

* From the *American Journal of Photography*.

The gold baths for toning prints were not known. With sulphurous fixing baths the prints were simultaneously fixed and toned—a method valueless for albumen; therefore it was only used occasionally for landscapes and architectural subjects. It was not until the discovery of the gold toning bath that we were enabled to give the desired tones.

To return to our subject, even such prints as were produced by the silver-sulphide toning bath, which have been in my possession since the commencement of the early fifties, have kept perfectly, without exception. This is the result of the great care which I always insisted upon to thoroughly eliminate all traces of hypo from the prints. The method I follow was communicated to me by Lutze. Although it is but rarely practised, I would recommend it to all the craft, on account of the excellent results. The method is as follows. The well-fixed prints are placed direct from the hypo into a solution of common salt for sixty or ninety minutes, during which time the solution is frequently renewed until, when a piece of the paper is chewed, the taste is clear salt, without any disagreeable after-taste. Then the prints are to be washed in clear water until the same test shows that the saltiness has also disappeared. This method may seem to many home-baked and mechanical; still, it is valuable in the practice.

I have already mentioned that faulty or unsuitable preparation of the paper may cause an instability of the silver print. This is especially true of prints on albumenised paper if the albumen is more or less coloured with pink or violet. Prints on such paper in the course of time all assume a dirty colour, while on paper coated with a film of uncoloured albumen the prints remain unaltered. When albumenised paper was first introduced, it was prepared by the individual photographer from pure egg-albumen, without the addition of any colouring matter. It is only since the wholesale production of photographic papers that the various shades of colour have been introduced. In later years, however, a little more caution is exercised in the use of such papers; the use of a decided pink shade is especially on the decline. The thickness of the albumen coating on the paper is also a factor in the stability or permanency of the photograph. Photographs made by myself thirty years ago, on paper with a thin, colourless coating of albumen, have kept much better than many made in later years on paper which was heavily albumenised.

The object in introducing albumenised paper was not to obtain a high gloss, but mainly to keep the image upon the surface of the paper by the aid of its thin, hard surface. The small form "visite" whole figure, which dominated for several years, gave the incentive for a paper with a heavier, glossier coating. At present, in carte and cabinet sizes portraits only are required, and in these we can well dispense with the exaggerated gloss so often seen. It is a matter of taste whether the addition of a high gloss is desirable for portraits, about which we will not argue. Taste and demand are regulated by fashion. Many of our fashions are extremely ugly; nevertheless, the public demand them because they are the fashion. Many of our best artists abhor the highly glossed photographic portraits, and find in the platinum print all requisite requirements.

Albumen films after a time all incline to become yellow, even if ever so little. As I became aware of this fact, years ago, I tried the means taken by our domestics to keep their washed linen white, viz., before hanging up to dry they draw them through a blue water, to prevent yellowness and keep the linen perfectly white. The photographic prints on uncoloured albumen paper, after being fixed and well washed, were placed for a short time in a bath of water coloured with the finest cobalt blue. Even if the water appears dark it leaves but a slight tinge, which suffices to remove the yellow tinge so apt to show in the white surfaces on the print.

*(To be continued.)*

## THE FEDERATION OF LONDON AND SUBURBAN PHOTOGRAPHIC SOCIETIES.

ON Monday evening last, the 23rd inst., a meeting was held at the rooms of the Photographic Society of Great Britain, to consider the proposals for a federation of London and suburban photographic societies on the lines sketched out by Mr. Biden in the circular convening the assembly.

On this, as on the previous occasion, Mr. Biden occupied the chair.

The Chairman said that many of the photographic societies to whom he had sent notices of the photographic meeting, and requests to appoint delegates to attend it, had done so. Others had expressed themselves as desirous, above all, to know whether the Photographic Society of Great Britain would place itself at the head of the federation, as they thought that was the main point. That Society had sent two representatives to attend this meeting, Mr. Leon Warnerke and Mr. Addenbrooke. The object of the Photographic Society of Great Britain being rather the advancement of the photographic art than the benefit of the individuals forming the Society, he thought those present would do better to consider, in the first place, what were the requirements to be met in a set of rules that should suit themselves. They could not ask the Photographic Society to put themselves on an equality with societies that might only have existed for three years. This primary object was to benefit the smaller societies, which were those that felt the want of such an arrangement. He therefore proposed the first resolution : "That it is desirable to form an association or federation of societies and clubs whose members are interested in photography."

Mr. A. Mackie suggested that it would be better that resolutions should be proposed and seconded in the usual way, and for a time an effort was made to carry this suggestion into effect.

Mr. W. Bedford would like to know whether there was any understanding that speakers at this meeting were those only appointed as delegates to speak in the name of their societies.

It was decided that Mr. Bedford should be heard, although not an appointed delegate.

Mr. Leon Warnerke said that the question of federation had been partially discussed by the council of the Photographic Society of Great Britain, and that Sir H. Trueman Wood, Mr. Addenbrooke, and himself, had been appointed to consider the question, and report thereon. Sir H. T. Wood was not able to be present that evening, but Mr. Addenbrooke and himself would report upon the decisions that might be come to.

Mr. Brockhurst, of the Holborn Camera Club, thought that it was a weak point of the present scheme, that it took no account of those individuals, of whom there was a very large number, who did not belong to any society. He thought that the federation might adopt the principle of being a union of individuals, and if those individuals happened also to be members of a photographic society, they might, perhaps, be admitted at a reduced rate.

The Chairman said that he did not propose to enter into competition with the existing societies by starting a new one. His object was to help societies by obtaining facilities such as could only be got by union or federation.

Mr. Bedford thought he would be justified in saying that the Photographic Society of Great Britain was favourably disposed to the idea of a federation, and was only waiting for a move to be made.

Mr. Warnerke said that the Council of the Photographic Society wanted to know something definite as to what was proposed by federation before it could say whether it was prepared to join in it or not. At a recent meeting of the Council, a definite proposition from the Milan Photographic Society for interchange of privileges was received and at once agreed to.

Mr. Malby, of the Toynbee Camera Club, proposed, and Mr. Goodhugh, of the North Middlesex Photographic Society, seconded, the resolution affirming the desirability of forming a federation, and this was carried.

Mr. Brown, of the West London Photographic Society, said that the members of his society considered that it depended principally upon whether the Photographic Society of Great Britain would join in the federation as to whether they themselves would think it desirable to do so. If there were to be two federations, the one adopted by the Photographic Society of Great Britain, and the other not, the latter would do no good.

A resolution was then passed to form a committee to consider the proposed rules and articles of association, and the following were nominated members of that committee :—Mr. Biden, Toynbee Camera Club ; Mr. Barrett, People's Palace ; Mr. Brockhurst, Holborn ; Mr. Clark, North London ; Mr. Cherry, North Middlesex ; Mr. Edwards, South London ; Mr. Rumbold, Sydenham ; and Mr. White, Ealing.

A vote of thanks was passed to the Photographic Society of Great Britain for the use of its rooms, and one to the chairman, and the meeting was then adjourned till the committee appointed should be prepared to report.

IT is only by labour that thought can be made healthy, and only by thought that labour can be made happy.—*Ruskin.*

THE AMERICAN ABROAD.—Brown (to Robinson, who has been abroad) : "And so you have returned from your long-looked-forward-to journey to the famous scenes of the Old World, to the tombs of statesmen, martyrs, and philosophers, to the sublime Alps, great London, and gay Paris. Tell me, old man, what have you done ?" Robinson (proudly) : "I have exposed seven hundred films !"

MR. CHUGWATER ASSISTS.—Mrs. Chugwater, arrayed in her best gown, was sitting for her photograph. "Your expression —pardon me—is a little too severe," said the photographer, looking at her over his camera. "Relax the features a trifle. A little more, please. Wait a moment." He came back, made a slight change in the adjustment of the head rest, then stood off and inspected the result. "Now, then. Ready. Beg pardon—the expression is still a little too stern. Relax the features a trifle. A little more, please. Direct your gaze at the card on this upright post and wink as often as you feel like it. All ready. One moment again—pardon me—the expression is still too severe. Relax the——" "Samantha !" roared Mr. Chugwater, coming out from behind the screen, and glaring at her savagely, "smile, darn you ! smile !"—*Chicago Tribune.*

ACCELERATING IRON PHOTO-SALTS.—The following paragraph appears in last week's *Nature* : —"In the second of the Cantor Lectures on 'Photographic Chemistry,' delivered on Monday, the 16th, at the Society of Arts, Prof. Meldola called attention to the importance of the principle of associating other substances with the compound undergoing photo-chemical decomposition, so as to increase the sensitiveness of the latter. As an illustration of this principle, the lecturer alluded to a discovery which has recently been made, and which was practically demonstrated by the discoverer, Mr. F. H. Varley, at the conclusion of the lecture. By associating iron salts with suitable sensitisers, it has been found possible to prepare films quite as sensitive as any of the modern gelatine emulsions, and containing no trace of any silver compound. The advantage of such films, from an economical point of view, is obviously very great, and a new departure in the applications of photography to scientific and other purposes is likely to originate with the exaltation of the sensitiveness of iron salts." The preceding paragraph erroneously ascribes the discovery to Mr. F. H. Varley ; it was made by Mr. Friese Greene, and subsequently improved by Mr. Varley.

## THE NEW HELIOCHROMIC DISCOVERIES.*

BY LEON VIDAL, EDITOR OF "LE MONITEUR DE LA PHOTOGRAPHIE," PARIS.

RECENTLY considerable attention has been given to the communication of Professor Lippmau to the Academy of Scieuces iu relation to the photography of colours. It may be interesting to the readers of *Wilson's Photographic Magazine* to be posted in regard to this discovery, and to have these details from au eye-witness of the results obtaiued. For this reason I dedicate to them this explanatory note made just after an interview with Professor Lippmann himself. He was good enough, in his laboratory at the Sorbonne, to show me his results, his appliances, and to explain thoroughly his method. The prints of the spectrum which he showed me have, for the most part, a brilliaucy which has never been possessed by the colours of the spectrum reproduced by other methods (processes of Becquerel, &c.). In fact there is colour, brilliant colour.

M. Lippmann's experiments are based on interferences, consequently he acts with the aid of a sensitive film resting on a reflectiug surface. The incideut rays pass through the film until meeting with a metallie surface (this is mercury); they are then reflected and again pass through the sensitive film. From this meeting of the incident rays aud the reflected rays is produced what is called interference. There is formed in the body itself of the sensitive film a succession of *maxima* corresponding to the phases of light, and of *minima* correspouding to the phases of obscurity. The length of a luminous ray is but a very small portiou of a millimetre, aud, admitting that the thickness of the film is one-twentieth of a millimetre, there is produced iu this thickuess considerable quantities, giving, ou an average, from 150 to 200 white and black rays, and resulting from the development after the actiou of the light. This development blackens all the zones in which the *maxima* have been produced, whilst in the zones of the *minima*, obscurity having reigued, there has been no photographic action, aud consequently the sensitive film remaius uuchauged. It follows that after development and fixiug iu the ordinary mauner, we have a film divided into an infinity of black parallel laminæ, separated from each other by white spaces, and the iutervals have exactly the length of the wave characterising each colour. In the present case we only refer to the spectrum, either for the primary colours isolated from each other, or mixed in definite relatious.

If it were possible to cut through the film, and to count the laminæ in the portious correspondiug to each of the seven colours, we would find unequal quantities of laminæ, and especially unequal distauces between each lamiua for each of the colours. But in reality no colour would exist, except the network having the faculty of causing the light to produce for the eye the seusatiou of colour. There would be no more colour than in soap-bubbles, although these appear to us most richly coloured. The phenomenon is also produced with laminæ of mica, so that, according to the thickuess of these laminæ, we have any desired colour of the spectrum, although the mica lamina is absolutely colourless.

The analogy is striking betweeu the results obtaiued by Professor Lippmann, and the examples giveu above. In order to obtain theur he covers a glass plate with a coating, serving as a vehicle for a seusitive silver salt, but in such a manner that the film is continuous, and free from granulations. He applies the sensitive film direct to a mercury bath, aud he causes the image of the spectrum to fall on the sensitive film through the glass. The exposure lasts from about one to two hours. Development and fixing as usual. With orthochromatic plates sensitive to the red, especially, the time of exposure would be much reduced. This method is somewhat analogous to that of storing souorous vibrations in the phonograph. The sensitive film stores away luminous vibrations which will show themselves as soon as the surface comes in contact with the luminous rays. We may say with reason, therefore, that the colours are permanent, as they caunot disappear unless the physical condition of the film is modified to the poiut of destroying the laminæ by crushing them.

It is not possible yet to draw any practical conclusions from the interesting facts which have just been explained, but there must be a beginning to all things, and we fiud ourselves here in the presence of the most rational starting point, one the most likely to lead to the true solution of the difficult problem of the representation of the colours. There are, however, two serious objections to oppose to the easy practical use of this ingenious and seductive process. The first is based on the uuequal sensitiveuess of the plates for the different colours; the secoud, because the interferences are only produced in a regular manner with pure colours. In this case the *maxima* aud *minima* are equidistant for rays having a given leugth of wave; but if the colours are complex or mixed with white light, the equidistauce yields to some period from which results an irregularity iu the arrangement of the films of reduced silver, which no louger give the seusation of the complex colour which has produced this particular dispositiou. It is this last objectiou, especially, which seems to us the most serious. We shall have to wait new experiments on mixed colours iu order to exactly ascertain if the corresponding vibrations are produced in the midst of the profusiou of waves of all lengths. We cannot yet say that this will not be, but it will be necessary to verify this discovery by experiment before being able to affirm its truth.

* Abridged from *Wilson's Photographic Magazine*, Philadelphia, March 7th.

---

HE: "Do you think the photograph I mailed you the other day was like me?" She: "I hope not; when it came it was broke."

GROTESQUE PHOTOGRAPHS.—It happens to all amateurs, and, alas! to professional photographers, to have failures in making their negatives. We think to please them by indicating a means of utilisiug what, in any less noble art than photography, we would designate as "botches." Here is the method:—Take the sacrificed negative—a portrait, for example—and, if dry, soak it for a moment in water; then expose it, the gelatine film on top, to a source of heat—in the sun, for example. The gelatine melting under the action of the heat makes it slide skilfully in any direction of the negative by giving it the proper inclination. You will uow see the uose of the patient become longer or shorter at the will of the operator, and the rest of the face will take on very strange expressions. A practised hand will chauge a profile into a crescent, and a full face into a full moon. This artistic operation properly done, dry the uegative aud print iu the ordiuary manner. As is seen, the operation is ridiculously simple, and the result positively hideous. We will offer, however, a last recommendation to our readers. Before operating, make sure that you can obtain the assistance of two friends as seconds, in case the subject should happen to see your work.—DIAFRAGME, in *Photo. Gazette*.

## Notes.

Mr. Clayden said last week at the Meteorological Society, that his re-invention of the black mirror devised by Dr. Riggenbach for use in photography for special purposes may have been due to the thoughts of the original inventor, by unconscious cerebration, coming into the world again through his (Mr. Clayden's) head. A good bit of unconscious cerebration seems to have been going on of late years in relation to the old heliochromic process invented by Ducos du Hauron, of taking negatives through glasses of three colours, and then, by photo-mechanical means, printing from each of them with different pigmentary colours, to form one coloured print by superposition. Several instances have occurred in this country. If, when this process and variations thereof are brought before the public as photography in natural colours, the populace believe them not to be pigmentary colours, they are misled.

Most of the rooms in the new premises of the Camera Club are now sufficiently out of the builder's hands to render the establishment a comfortable one, even in its present incomplete state. The large room in which the meetings are held is well adapted to its purpose; at the farther end some of the wall is whitened to give the best class of screen for lantern displays. A new lantern is in course of construction, with lenses for the optical system made upon true principles, and adapted to throw a good image from the extremity of the opposite end of the room to the screen, so that the lantern and its platform may not be in the way of any of the observers. Physical and chemical laboratories are needed in an organisation like the Camera Club to make the establishment complete, for it ought not to be without spectrum cameras, heliostats, and other instruments useful in original research. Had it possessed such, before this Professor Lippmann's experiments would have been repeated within a few days after the news reached this country, and the research been pushed forward in various directions. In Brussels such facilities for photographic and other research are provided for the free use of the public by the Government, and are to be found in the Old Museum in that city.

The Photo-Club of Paris is, in that city, an organisation of the same description as the Camera Club here. This year it began to issue a *bulletin*, and the first two numbers have reached our hands. The president of the Paris Photo-Club is Dr. Dujardin-Beaumetz; the committee of administration, Dr. H. Labonne, president; MM. Maurice Bucquet, secretary general; Paul Bourgeois, librarian; Paul Gers, treasurer; Achille Darnis, Count Desmazières, Henri Guérin, Paul Houdé, Dr. Jouslain, and Emmanuel Mathieu. Its first number contains much about M. Lippmann's discoveries, illustrated; in fact, most of the French photographic journals have given considerable attention to the subject. The Photo-Club of Paris has been established for two years. At one of its meetings M. Demeny, the able co-worker with M. Marey, exhibited to the members the remarkable work which has been done at the physiological establishment in the Park of the Princes, to determine in a precise manner the diverse attitudes of men and animals in motion. The Photo-Club *bulletin* is edited by a committee, and its general appearance is elegant. At a recent meeting of the Photo-Club, on the proposition of M. Delbruck, a member of the Camera Club of London, M. Alvarado, who was shortly to leave for England, was delegated by the committee to take steps for the exchange of publications, and the establishment of relations between the Photo-Club of Paris and the Camera Club. The address of the Photo-Club is 40, Rue des Mathurins, Paris.

We have received from Herr C. Schiendl, of Vienna, a personal attack upon Dr. Eder, containing nothing about photography or photographic history, but charging him with hatred and untruthfulness, and answering nothing contained in the lengthy criticism of Herr Schiendl's book recently published in these pages. We cannot open these columns to such personal attacks. Whatever the general tone of Dr. Eder's criticism may have been, he gave chapter and verse for what he had to say, thereby giving Herr Schiendl the power of refuting him, if inaccurate, by reference to the original text of published historical documents. Herr Schiendl has the right of reply when the reply is one in fact.

The rapidly increasing use of electricity as a light-giver is patent to everybody, and certainly no one is more interested in the exchange of old lamps for new ones than the progressive photographer. We are most of us aware that, under the recently amended electric lighting Act, various companies have been formed for the purpose of supplying different parts of the metropolis with the necessary electrical energy to produce the new light. But it is not so generally known that the Vestry of St. Pancras have, from the beginning, turned a deaf ear to such schemes, and have resolved to keep the game in their own hands. Considering that it is now time to be up and doing, they have arranged to commence an installation which will provide for the south-western portion of the parish, a section which will embrace Tottenham Court Road and other important thoroughfares. They believe, moreover, that in the absence of shareholders they will be able to supply the need at a lower cost than has yet been believed possible.

With a view to make their future clients alive to the advantages of electric illumination, the authorities have organised an exhibition of electrical appliances at the Vestry Hall in St. Pancras Road, which was formally opened by the Lord Mayor and Sheriffs last week. This exhibition, although a small one, is by no means insignificant, and we strongly advise those of our readers who can do so to pay it a visit before it closes at the end of this month. There they will be able to see both arc and incandescent lights in action, besides numerous examples of the manner in which the obedient "fluid," if fluid it can be called, is made to do all kinds of mechanical work. There are here shown many domestic labour-savers in action, such as sewing machines, washers and wringers, boot-cleaning contrivances, and various other things of a similar nature.

---

Such an exhibition as this will make the enterprising photographer dream of the advantages which electricity will presently confer upon him. First and foremost, of course, there is the arc light, which will make him independent of sunbeams. Then he will see how his reception-room can be pleasantly illuminated by incandescent globes of different tints fitted to the most artistic brackets and electroliers. He will also see before him the possibility of using the current in various ways as a motor. His developing dishes will rock automatically, and his washing machine—albeit somewhat different in character to the washers shown at the Exhibition—can be made to work so regularly that every trace of hypo must quickly disappear. There is little doubt that, with the current at hand, the ingenious worker will find out many ways in which it can be made useful in his every-day practice.

---

A photograph was recently published in an American paper which purported to represent a shell in flight, fired from an eight-inch mortar, every part of the landscape being in good focus, with an exposure of 0·0000076 of a second. An expert photographer thereupon wrote to the editor of the paper, and pointed out that, at any time of day, when a shadow as long as that cast by a certain figure in the foreground occurs, with a lens stopped down sufficiently to give such sharp outlines to distant woods, and a shutter speed sufficient to get the ball at all, such a picture is an impossibility, and that nothing more than the faintest outline of the highlights would be developed. Inquiry led to the acknowledgment on the part of the picture producer that he had touched up and intensified that ball. This is an example of cooking a photograph which all honest men will condemn, while they must admire the acumen of the intelligent critic who took the trouble to expose the fraud.

---

The old controversy between the advocates of microphotography and those who believe in making drawings by hand has a good chance of being revived. There was certainly material enough at a recent meeting of the Royal Astronomical Society, to which meeting a reference was made last week. Mr. Mayall's contention is, that certain chemical manipulations may give a false rendering of the microscopic preparation when reproduced by photography. Some workers, for instance, had been led away by the energetic action of powerful reducing agents such as hydroquinone, and induced to aim at producing photo-micrographs of exaggerated contrast, instead of contenting themselves with a simple reproduction. The chairman seemed also inclined to hold this view, for he advanced the opinion that, contrary to a common doctrine, it was quite possible for a photograph to lie. It would almost seem, from the tone of the discussion, that microscopists now-a-days are photographers first and microscopists afterwards, whereas the reverse should be the case. It is a serious matter if it be true, as Mr. Mayall said: "In twenty years hence the student who should examine the Society's collection of photographs would be sorely puzzled to determine what the present generation of photo-micrographers had really been aiming at."

---

A platinum mirror is the latest scientific toy. A platinum mirror has the peculiar property of both transmitting and reflecting light, and this property has been utilised by M. M. Dodé in the following way:—Behind the mirror they place a movable panel or shutter, and between this panel and the glass is placed a picture or photograph. When the panel is shut the picture is invisible, and the person gazing in the glass sees his or her reflection. When the panel is opened the reflection disappears, and the picture or photograph appears. These platinum mirrors may be used for other purposes. Placed in the panels of doors, they will light up a corridor or a gloomy room, and on the other side they form mirrors, so that, standing on the reverse side—that is, the platinised side—one can see through the glass without being seen. Anyone who is curious to try the experiment will find the formula for the preparation of the platinum solution in the last issue of *La Nature*.

---

Collectors of early editions of Dickens have reason to rejoice that photography was not discovered when Pickwick was written. The sale of the work, we are told, so greatly exceeded all expectation that new sets of plates had to be prepared for the successive editions. There was no means, as now, of reproducing the plates by automatic process, so they were copied by hand, and, in copying them, the artist took any liberty he thought proper. Sometimes he left out one detail, such as a lady's bonnet-strings, and sometimes he added another. The different "states," therefore, are most distracting, and one has to be an adept to know the very first at a glance. But this variety it is which gives value to the early editions, and the keenest of pleasures to the enthusiast when he secures a copy. Could the first plates have been photographed, all the exercise and nicety of judgment which the connoisseur likes to display would be lost.

---

We have before written upon the curious resemblance between the portraits of the Oxford and Cambridge boating crews. Every year these sixteen young experts are all photographed; but, for any great difference that exists, the same photographs would do year after year. We are not alone in noting this fact. The *National Observer*, in an article on the race, says: "The illustrated journals will, as usual, give portraits of the members of the crews, printed all from the same negative, with moustaches added to order." This really is no exaggeration.

## PHOTOGRAPHY IN JAPAN.

BY PROF. W. K. BURTON, C.E.

A word or two as to what is going on here, photographically, at the beginning of 1891 may be of some interest. The progress during the three years and a-half that I have lived in the country has certainly been great, yet a mere sketch of it will be enough, as it really amounts almost entirely to the adoption of western methods that are already well known.

The greatest advance has arisen from the general introduction of the dry plate process. Three years ago dry plates were pretty extensively used, but I think no single professional photographer used them exclusively in his studio; many did not use them at all, and the majority used them only in exceptional cases, as when the weather was bad, or restless children had to be photographed. Now collodion is the exception, except with the "tin-typist," of which class there are many, especially at holiday resorts, such as Asakusa. The result of the change is a general all-round improvement in the quality of work that is very marked. A tendency to adopt larger sizes, done direct, is a natural outcome of the change from wet to dry plates.

In printing methods not nearly so much advance has been made. The ordinary albumenised paper is still almost the only medium for prints issued in moderate numbers. This is not from want of appreciation of better methods by the Japanese; the beauties of the platinotype process are fully appreciated, and about a year and a-half ago it seemed likely that the practice of platinum printing would spread; but the sudden and enormous rise in the price of platinum put a stop to the use of the paper, as photographers found they simply could not get the prices they had to charge for prints to make the printing at all remunerative.

The carbon process is worked a little; indeed, it is worked with great success by Maruki, but the total number of prints turned out is but small.

Bromide paper is used to some extent, but only, so far as I know, for enlargements, which do not seem to be much run after. It is likely, however, that the recent action of Mr. S. Cocking, of Yokohama, may bring this paper more prominently before the public. Mr. Cocking presented a large quantity of the paper to the Photographic Society of Japan, and offered three prizes for the three best pictures done on the paper. An exhibition of results will be held toward the end of January, and the prizes will be awarded.

The only thing that is at all "running" silver printing on albumenised paper, at present, is collotype, as worked by Ogawa. Ogawa's best work is as good as any that I have seen, but it is dear for collotype, and, of course, is not applicable unless a considerable number of prints has to be done from the same negative—say fifty at least.

Among the few really active and enthusiastic amateur photographers that we have, printing on silver on various kinds of plain paper or other fabrics, and toning with platinum, is very popular.

Zincography, intaglio, copperplate engraving in half-tone, and various other photo-mechanical processes have been worked out to success on an experimental scale since I have been in the country, but none of them is yet worked commercially.

The only thing I know of that is really new in photography that has originated in Japan, is the photographing in metallic gold on a basis of lacquer, mentioned in my notice of last year's exhibition as the invention of a Yokohama photographer. It is intended to produce the effect of the "gold lacquer" for which Japan is so famous. I passed the house of the inventor the other day, and examined all the samples to be seen at the time, and I must say that some of them—large panels, for example, with designs in gold on black lacquer—appeared to me to be of very high merit from a decorative point of view. I do not know whether any samples of this kind of work have yet reached America, but I should think that it would be popular.

The Photographic Society of Japan must be pronounced a most decided success. Of all the various societies in the country, consisting partly of Japanese, partly of foreigners, it seems to run on the most easily. It would be a much greater success than it is were it better supported by professional photographers, but it must be admitted that the great bulk of professional photographers here take no interest in photography beyond its commercial aspect, and that there is a deal of the meanest kind of jealousy amongst them, so that the fact that a certain professional photographer is a member of the society will be a reason why some half dozen others will refuse to join. Moreover, there are many who are actually inimical to the society, because demonstrations are given at the meetings of processes the secrets of which a certain class of professional photographers would like to see strictly guarded. There is a good deal of the same kind of feeling with regard to the *Shashin Shimpo*, the Japanese *Photographic News*. The fact is that the older hands could only learn the "mystery" of photography by becoming the apprentices of established photographers, often paying the latter for the privilege, and that they look with ill-favour on the giving away gratis of that information which they so dearly bought.

Fewer Japanese have taken to amateur photography than I expected would. We have a good many names of Japanese on the list of the society who must be classed as amateur photographers, but they are mostly men following scientific pursuits, who either take a purely scientific interest in photography, or who use it merely as an aid in their pursuits.

On the other hand, the pursuit of amateur photography is greatly on the increase among the foreign community. I refer here to the permanent foreign community, who are to be clearly distinguished from the "globe-trotting" floating community, of which we now have an extraordinary number at nearly all times of the year.—*The Photographic Times.*

The Permanency of Water-Colours.—Prof. V. Wouwermanse, of Vienna, has made some investigations as to the permanency of water-colours. He painted a number of surfaces of equal area with various water-colours, and divided them into two equal parts; one portion was exposed for two weeks to the sunlight, whilst the other was kept in the dark. Gamboge and Indian-yellow suffered only slight change; yellow ochre, burnt sienna, sepia, and the blues, underwent no change; vermilion, however, lost almost entirely its fire; some vermilion tones became a dirty brownish-violet, and carmine lake, as well as pure carmine, changed to a scarcely perceptible rose. Neutral tint, a mixture of carmine, and pin's-blue took a much bluer tone. As neutral tint mixed with burnt sienna gives a handsome grey, which is much used by retouchers, it is preferable to use, instead of neutral tint, the much more certain indigo-blue.—*Photo. Archiv.*

## Literary Notices.

Evening Work for Amateur Photographers. By T. C. Hepworth, F.C.S. (*Hazell, Watson, & Viney, Ltd., London*, 1890.)

This book is interesting to read at all times, and is likely to be practically useful to the photographer during the season of dark evenings, for it treats of the production and exhibition of lantern slides, the management of the lantern, frame-making and guilding, enlarging, and the electric light in the optical lantern. It is written in an easy narrative style, and exhorts beginners at lantern exhibitions to do likewise, by accompanying the pictures which they throw upon the screen with a suitable descriptive narrative or tale. Often, indeed, have we seen a picture projected upon the screen representing some scene of absorbing interest in legendary lore, and in which a strong interest might have been excited in the minds of the observers had the exhibitor known anything and told something about the scene he was presenting, instead of letting the slide pass with only a name, and nothing more. If photographers, before going on tour, would read up the history of places they are about to visit, their travels would be more interesting to themselves, and, when in the locality, they would know better what to photograph and why they should do so.

Not far from the beginning of Mr. Hepworth's book comes the following useful little item of information about the cutting of gelatine-coated glass plates with glaziers' diamonds :—

> In the case of cutting through a dry plate, it may be cut from either side, but it is best to apply the diamond to the film side. There is more than one reason in favour of this course. If we make our cut on the back—that is, on the glass side of the plate—we are pretty sure to raise a few tiny filaments of glass which may lead to scratching of the film subsequently ; we find, too, that when the cut is made in this manner, and the glass is broken into two halves, it still remains united by a tough hinge of gelatine, which cannot be parted without some effort, and which will often lead to partial stripping of the film. But by cutting through the gelatine in the first instance, this last difficulty cannot arise, and there will be no spicules of glass to cause after-scratches of the film. A difficulty arises in the circumstance that all glaziers' diamonds will not cut through gelatine. Mr. B. J. Edwards tells me that it is his practice to send to the manufacturers for a number of diamonds at a time, and to try them one by one, so as to sort out the minority which will cut through a glass plate on the film side. He tells me that a diamond which will do this, and one which will not, do not differ in appearance in any way, even when subjected to the closest scrutiny. The only way of finding out the right kind is by careful trial, and not by mere examination.

In one part of the book the author deals with the question of inexpensive condensers for enlarging and reducing purposes, and devotes a few pages to the out-of-the-way subject of water-lenses, made by cutting the tops from well-formed glass shades, supporting them horizontally by a wooden or metal ring, then filling with water the glass bowl thus formed. This is one way of getting plano-convex lenses of seven or eight or more inches in diameter. In one of the diagrams he represents one of these water lenses, supported a little above another, so as to form a double-lens condenser ; a plane mirror below, placed at an angle of forty-five degrees, sends the light from the flame upwards through the condenser ; another mirror above the lenses, and at an angle of forty-five degrees, sends the condensed beam of light in a horizontal direction. One obvious defect of this arrangement is that the flame is so far from the lower lens that there must be considerable loss of light, and that any plan of bringing the flame directly underneath the lens would tend to boil the water. In any case, conditions are likely to occur occasionally under which moisture would be deposited on the under surface of the upper water-lens. These crude arrangements seem to be mentioned more as curiosities than anything else ; nevertheless, a little scientific work has sometimes been done with them.

Another subject dealt with in the book is that of clouds in lantern slides, a subject which will attract more and more attention as time passes on, and we near the period when blank skies will no more be tolerated in slides than in paper prints. We think that one of the best ways to get natural clouds is to give two exposures on separate plates, one for the landscape, and one for the clouds ; the combined result is sure to be natural, and the lighting of all parts of the picture true. By the use of suitable shutters, and by special methods of developing, some operators are much more expert than others in securing the landscape and the clouds in the same negative. Mr. Hepworth recommends the use of sky negatives, not necessarily one taken on the spot, and gives practical information how to employ them. He also has something to say about shutters to assist in securing clouds.

Mr. Hepworth deals with the subjects of photographing by the magnesium light, and the employment of the electric light for the optical lantern, and various photographic purposes. In our opinion, the electric light is at present too expensive for practical use, when the cost of maintenance, and all items, are included ; so much so that, except in a few fashionable studios, and in photo-mechanical printing works, it is not likely to be much used in photography, except by those who can afford luxuries.

---

Jahrbuch fur Photographie und Reproductionstechnik fur das Jahr 1891. By Dr. J. M. Eder. (*Halle : W. Knapp.*)

Always welcome is the appearance of Dr. Eder's Year-Book. We can expect with certainty to find in the volume some pieces of new and valuable scientific information from some of the first workers in the several departments of photography ; and the photographic process illustrations are a pleasure to look at and to turn to again and again. There is one point, however, in which the present volume differs somewhat from its predecessors : it contains a large number of reprints from the current journals of the past year, particularly from the English journals. The number of references taken or condensed from our own pages of the past year can only afford us gratification, as showing the interest excited in Germany by the progress which has had to be chronicled amongst ourselves. We do not mean this to be understood in any carping or ironical strain. One of the most useful offices of the photographic *litterateur* is to bring to the notice of his brethren the things which, being printed originally in another language, might escape their observation. There are, moreover, many original articles, some of them evincing great thought and an immense amount of work in their preparation.

Of the original articles we may refer to a few without disparagement to the others. The photo-mechanical processes, which are now so extensively practised in Germany, always receive considerable attention in Dr. Eder's Annual, and this year it opens with an article by Carl Angerer on typographic colour printing. Then we have one on photo-lithography by Adolf Franz, the director of the bank-note printing office in Vienna; one on phototypy, by G. Fritz; on defects in photo-lithographic transfer, by Aug. Albert; the preparation of photo-printing surface on stone, by Jos. Eberle; photo-mechanical colour printing, by F. Jasper; a new method of making artificial substitute for lithographic stone, by Jos. Semling; on improvements in printing photo-lithographic transfers, by Prof. Husnik; notes on printing from flat zinc surfaces, by C. Kampmann; heliographic etching process without the employment of a positive transparency, by Oskar Pustet; half-tone zinc etching, by L. Schrank; the future of collotype, by F. Silas; on line plates for half-tone zinc etching, by Ad. Tuercke; the present condition of photo-mechanical process, by our esteemed contributor, L. Vidal; the nickelling of printing surfaces, by O. Volkmer; the preparation of colours for photochromy, by Dr. W. Zenker—a goodly array of workers in this important field. In other departments we may mention the contributions on optical subjects—G. Fritz, Hugo, Kruss, and Dr. Stolze. The latter writer refers in one of his papers to the discussion on "Naturalistic Focussing" that has taken place during the last twelvemonth in England, and quotes the arguments against large diaphragms and consequent want of sharpness that were then brought forward, giving mathematical calculations to further elucidate them.

Space does not permit us to deal with the many other valuable literary contributions to the "Jahrbuch," but we cannot omit reference to the collection of photographic process illustrations at the end of the work. The first of these, a study of fruit and foliage, is a beautiful specimen of technical excellence in its own kind, and, like the second, is given as the work of scholars at the Imperial and Royal Institute for Instruction and Research in Photography and Reproduction Processes in Vienna. Work like this makes us look longingly for the establishment of the projected Institute of Photography in our own country. Then we have specimens of Moss-type from New York; a photo-zinco process print by Husnik and Haüsler; another specimen, this time of a retouched head, of the work of pupils at the Imperial Institute. Türcke's zinc-etching, with which our readers will be familiar; several illustrations of groups taken by R. Slingsby, of Lincoln; and one of similar character photographed with Hezekiel's flash-lamp. After a photographic print of a stalactite cavern, comes a plate with half a dozen illustrations of a bullet in flight, and the waves of compression and rarefaction of air thereby caused. Other scientific illustrations are, one of a part of the moon's surface, and a particularly interesting one of a window, taken with that minute optical instrument, the eye of a glow-worm. A peculiarity of the insect eye is that objects are not inverted by it, but seen erect. Photo-lithography in half-tone is illustrated by a particularly sunny-looking picture of a building, very much the reverse in appearance of the smudgy-looking things at one time considered passable specimens of photolithographic work. We have next "pupils' work from Cronenberg's Instruction Institute," a beautiful production which any professor might well be content with. A photo-engraving of Heidelberg Castle is a fine, vigorous specimen of its kind, and a good kind too; and a photo-zincograph partly printed in colour, completes a set of illustrations which would make the "Jahrbuch" a desirable acquisition even to those unable to avail themselves of its literary contents.

Beitrage zum Problem des Electrischen Fernsehens. (*R. Ed. Liesegang: Dusseldorf*, 1891.)

This "first volume" of "problems of the present time" is devoted to the consideration of the possibilities of constructing an electrical telescope, and—what would naturally be expected to follow—the photographing of distant objects by means of an electrical current somewhat analogous to that which serves for telephonic purposes. Whatever may be the view of the reader as to the ultimate practicability on the one hand, or the visionary character on the other, of such an idea being ever effectively carried out, the philosophic tone of the work will commend it to readers who appreciate the strife for something ideal at the same time that they require that certain elements of probability should be present. One or two extracts from the preface will give some idea of the tone of the work.

"It would be in many aspects interesting," quotes the author from Carus, "and a worthy task, to write a book in which should be collected the hundreds of instances in which the construction of mechanical apparatus, to the perfection of which our epoch is striving so vehemently, has its origin in the imitation of portions of the animal organisation, and how, now recognised and now unrecognised, the image of man and of the animals has served as a model for innumerable tools and appliances which, in our every-day life, are of indispensable use.

"Kapp has written such a book. In his basis of a philosophy of technics, he shows that almost all tools, machines, and so forth are unrecognised imitations of some portion of man. The hammer is a lengthened fist, pincers are a grasping hand, or a biting pair of jaws. The achromatic lens is an imitation of the crystalline lens of the eye; the camera of the photographer, the complete eye; musical instruments, such as the harp and the piano, the internal ear; the organ, the voice; the arrangement of the bones, the model of certain architectural work; and the telegraphic current is analogous to that of the nerves."

The author, a son of Dr. E. Liesegang, is a worker who has made an important advance towards the solution of the problem which he attacks, and the present condition of which he fully sets out.

Der Entwicklungsdruck auf Gelatine Emulsions: Papier und die Vergrosserung direct nach dem Negativ. By G. Mercator. (*Dusseldorf: E. Liesegang's Verlag.*)

When any department of photography becomes so extensively worked as to warrant a literature of its own, we should be surprised if the house of Liesegang were without a work dealing particularly with the subject. The process of printing upon gelatino-bromide paper has, indeed—especially in connection with making enlargements—come into such extensive use as to justify the publication of a book such as the present, a book which, in its hundred and odd pages, illustrated with twenty-eight wood-cuts, contains all that can reasonably be required in the way of information to an amateur or professional photographer who desires to make his own enlargements by the bromide process.

## PHOTOGRAPHIC CHEMISTRY.

### III.

Last Monday night Professor Meldola delivered his third and last lecture on the above subject at the Society of Arts.

The speaker stated that when light falls on silver bromide or silver chloride it darkens in colour, and gives off gas which acts upon paper prepared with potassium iodide and starch; in these cases it is evident that chemical decomposition has taken place, but silver iodide does not undergo decomposition under like circumstances except in the presence of an iodine absorbent.

When the silver haloids, free from nitrate, are spread upon paper, different substances can be applied to the paper with them, which substances act either as accelerators or retarders; reducing agents accelerate, and oxidising agents retard or stop the action of light altogether. Sodium nitrate is sometimes an oxidising and sometimes a reducing agent; when applied to a silver haloid it acts as a reducer. Sodium sulphite is also a reducing agent. Silver nitrate is usually considered to be an oxidising agent, but in this case it is a reducing agent because it acts as a halogen absorbent. Mercuric chloride is an oxidising agent and a retarder, so also is a solution of bichromate of potash.

In all cases in which a visible image is formed there has been photo-chemical decomposition, but in the example of an ordinary plate in the camera, the exposure is too short to permit the formation of a visible image, and the question arises whether the action is the same in both cases. He was personally inclined to think that the deposits are the same in both cases; still, in the way of direct proof, there is a gap, and the conclusion cannot be treated as an established fact; in relation to this matter our knowledge is in the same state as it is in relation to the coloured products dealt with in the previous lecture.

As regards the darkened products, there is proof that they contain a little less chlorine than the unaltered silver haloids, but they are not definite chemical compounds; they contain also a great excess of unaltered haloid; they are a mixture of silver haloids with unstable coloured products of photo-chemical decomposition. These coloured solid products may be compared, though it may seem strange to do so, to saturated solutions. Dr. Otto Witt is also of this opinion.

After this saturating point is reached, light produces no additional effect unless a reducing agent be present to absorb the halogen as fast as it is liberated. For instance, if silver chloride be put in a tube, and submitted to the action of light, while moist hydrogen is passed over it, and that hydrogen be then made to bubble through silver nitrate, in the latter solution a precipitate of silver chloride will fall, and much more than if air had been used instead of hydrogen. This experiment was originally devised by Robert Hunt.

The dark deposit in the case of chloride of silver is certainly not metallic silver, for it can be formed in the light while the chloride is under nitric acid. Whether the deposits contain oxygen is a problem demanding additional research.

The speaker, after showing a few experiments to prove that water in contact with silver haloids acts as a weak sensitiser, said that silver chloride will darken in a high vacuum, but when the bulb is taken into the dark, the deposit in its interior soon absorbs the chlorine again, as Mr. Crookes has experimentally proved. He next spoke of the chemical and physical theories of the latent image, and argued that the probabilities are in favour of the former being the true one. He incidentally mentioned that Dr. Hurter does not hold this view.

As regards the ripening af emulsions, he said that some experiments he was making tend to show that some amount of chemical reaction is set up between the silver haloid and the gelatine. In investigating the problem, less attention should be given to the state of molecular aggregation of the haloid, and more to the sensitive substance formed, upon which a developable image is afterwards produced.

A very slow reducer acting upon a photographic film for a short time has the same effect upon it as a short exposure to light, and can be made to form a developable image. Glucose, with a little alkali, is a feeble reducing agent, and can be used for this purpose. That the kind of pressure called "shearing stress" will do the same was first revealed by Carey Lea, but, by pressure, the lecturer had been unable to make developable images upon any of the pure haloids; it was necessary that some foreign substance should be present to act as a sensitiser. Mr. Spring, of Liége, has proved that by sufficient pressure chemical reactions can be set up; so in the case of an invisible image produced on a gelatine plate by shearing stress, it is probable that the pressure has produced a chemical effect.

The Chairman, Mr. Francis Cobb, moved a vote of thanks to Professor Meldola for his three lectures, and said that it is his personal opinion that the invisible image is not of a physical nature.

Last week, in our summary of Professor Meldola's second lecture, we, by an obvious slip, described corrosive sublimate as mercuric oxide instead of mercuric chloride. When the full text of Professor Meldola's utterances on the invisible image is published, we may make some criticisms thereupon.

## PICTORIAL COMPOSITION.*

BY P. H. NEWMAN.

The successful application of light and shade is but a poor achievement if unaccompanied by sentiment, although the flat surface of the picture be entirely overcome. We demand the magic influence of mid-day, sparkling in abrupt transitions; the mingling shades of dawn and twilight; by the powerful influence of light and shade we crouch at the storm and shiver in the breeze; its poetical influence is independent of subject. In proportion as a subject is poor, compensation must be made by the interest given to the sky. It is the sky which unites the several parts of a landscape into one harmonious whole—it enriches poverty by supplying new forms, or by affording contrast to those which the subject itself possesses. It is to the sky that the landscape painter must look as the great source of pictorial effect worth his recording. Varying for ever in form and colour, its fitful changes are communicated to the landscape—now obscure, now bright. *Terra firma* may, indeed, afford a good subject; but from cloudland we must derive impressive sentiments. Often when the student has roamed far and wide in search of something "worthy of his pencil," he would have done better to have remained at home, and besides looking to the earth for subjects, have looked upwards to the sky for sentiments in which to clothe them. Without sentiment the painter of landscape would make his mountains high, but not inaccessible to all but thought; large, but not immense; his gulfs might be deep, but they would not be profound or terrible; he might paint a storm or a shipwreck, but he would to fail suggest "the remorseless dash of the

* Concluded from page 231.

billows," the "rushing mighty wind," or the "live thunder" from the dark cloud where "Tempest sits enthroned."

Now, will somebody say, "All you have told us is very good, and distinctly applicable to the arts of painting, but why fetter another form of art with all these restrictions and narrowness of scope? For if it cannot give all the manifold charms you and Harding desire without so much pains and abnegation, yet photography gives the world something that the most elaborate art has never given. Does it not give detail and accuracy of drawing that was never observed before, unless it be in the microscope? The camera may be called the microscope of the field." Verily this is so, and in that sense I would be the very last to fetter photography; it is an invaluable sense; but it must be remembered that this is a scientific sense, and not an artistic one. I am talking of pictorial composition—the science, if you will, of fine art. Harding says, "Individuality or identical imitation is not only absolutely impossible, but is not required; for, otherwise, to perfect the charms of sculpture or painting, we must add colour to the one, and rotundity to the other. Were identical imitation necessary, we could not stop short of any of the attributes of reality."

I have already said I have nothing new to tell you, and as I have already notified your Society that better than my own teaching would be, at this lecture, to give other people's ideas, I shall make no excuse for quoting now from an essay on "Imitation in the Fine Arts," by Qatremère de Quincy. He says: "Do we remark that there is matter in the masterpieces of sculpture? Do we wish for the addition of colour; or the step nearer to verisimilitude which it might bring? Do we, in paintings, regret that the beautiful scenes are presented to us only on one side, or that their figures are motionless? What, then, would we have? Are shrieks wanting to the torments of the Laocoön, or the accents of lamentation to the anguish of Niobe? It will hold good as a general remark that, according as the imagination is more active, we possess in a higher degree the necessary capability of supplying the kind of deficit common to every work of art, and the better, also, are we contented with the specific illusion. In fact, the pleasure of illusion arises, more than we allow for, from a sort of working of the mind, by which itself finishes the work of art.

"In imitation which is limited to the senses in the choice of its subjects and its mode of representing them, it may fairly be asked what its images can teach me, restricted as they are to the gratification of the eye? What do they show me more than I already know? What do they put me in a position to receive over and above their model? What impressions depending on art do they communicate? What new acquisition can such imitation promise me or give me reason to hope for? It does not carry my imagination beyond the confines of reality.

"I shall be told it gives me what nature—whose portraiture it is—gives me. I answer, no! It does not give it precisely, because it is only a portrait, and because a portrait is only a part of the resemblance of the natural object, and presents only a single aspect. Wherefore should I wish for a copy? What need have I of the appearance of things whose reality I am indifferent to? What worth can I attach to the image when I hold its model in contempt, more especially since there is nothing beyond to compensate for the absence of all those properties which nature denies me?"

It seems almost needless for me to add that he means that which a picture often supplies, but unassisted nature rarely.

We might carry this further, and, indeed, its application, I am sure, comes home to everybody in this room when they think of past suffering. What weariness has overcome them while contemplating an album—nay, how one almost shudders at the word—and what tortures have been endured in visiting the local photographer and inspecting his views, those deadliest of dead seas, and his none the less veracious valleys—valleys of the dry bones of nature without a scintilla of art in their bald presentment to redeem them; irredeemable, indeed, and hopeless, because matter without spirit is, and must be, hopeless.

What this spirit is that may redeem, irradiate, and warm the bleakest landscape, I have endeavoured to put before you this evening, not in my own feeble language, but from the text of another, who, in his turn, has learnt and compiled from the teaching of the past. I have told you nothing new; he has told you nothing new; art is the next oldest thing, perhaps, to the hills, and its canons are the outcome of the very nature of things, and as irrevocable. Nothing is more talked about to-day, and of nothing is there less to say; it cannot be taught, it may be learnt; it is much more likely to be felt after long, patient years of study, felt imperceptibly at first, than in a flash and in full revelation. Perhaps a picture, perhaps a dream, a sonnet, or a sympathetic voice, or a swell of mighty music—who can say; it will depend on your idiosyncrasy when and how you are capable of analysing that which to the multitude is beyond analysis.

What have I told you? Pictorial composition is the art of putting picturesque things in a picturesque way—that is, not putting them absolutely side by side, or immediately one on top of the other, nor at equal distances, nor four square, nor putting the least important thing in the most important place; if you can do this, and can arrange the lighting to get contrast without patchwork or spottiness, and obtain a breadth of effect conducive to the prominence of your principal object, you will be carrying out in photography what is aimed at in painting; and, while satisfying yourself and your beholders, you will be doing much to lessen the flood of bad photographs that are giving your ignorant brethren the basest ideas of art, and doing not a little to lift it out of the mire to its proper place again.

In art, as in all things, history repeats itself. The refined æstheticism of ancient Greece was debased by the Roman architects, and even Greek artists of the late imperial times were employed, and prostituted their glorious traditions by travestying them in the luxurious villas of Herculaneum and Pompeii. It required that art should die and be born again in the last throes of the empire at Byzantine, and be inspired by a new faith and a northern fervour in the Gothic periods, before it was fit to be married to the sleeping beauty of the centuries, the bride of the Renaissance, who, bringing in her train and as her dowry the new learning, the perfumed breath of the garden of the intellect, the Greek and Latin classics, to add the graces of refinement to the life of the fifteenth century. This marriage we know was fruitful in an abundant family of great names—masters in every form of art, and whose works remain to us now, for the most part unrivalled. Then, within a century or two, this mighty offspring we see dies down, and art appears again to be entering a chrysalis state, as taste declines in the times of the later Louis of France, and assumes utterly monstrous forms in the Rococco and our Georgian periods.

Who, then, shall wonder that in these days art has to make enormous struggles, and, half blinded by what she has passed through, her true path is not distinctly traced before her? Who shall wonder if sometimes she staggers with uncertain step and lifts up an uncertain voice? Who shall wonder at her calls for æstheticism on the one hand, or her clutches at realism on the other? None. No! we should rather wonder and be thankful, in a materialistic age, that she is alive at all; and let us, trusting to those clear lights that have burnt for our guidance through the ages, do what we can to assist art to take her stately way again, and keep its even tenor.

To do this as it behoves us to do, unless we would be branded by posterity and puerility, and stigmatised as blind guides, if we pretend to make pictures, or play with art in any way, it should be in no careless and selfish spirit, but for the ennoblement of the race. Pictorial composition is a great power to this end; and if, at the risk of weariness, I am earnest in pressing upon you the importance of its study and comprehension, it is, gentlemen, because I feel and know its eternal truths will, as they should be, be paramount when those passing fancies whose experiments, as futile as they are frivolous, have passed away.

---

Still More Like Him.—Photographer—"Your son, the student, ordered this likeness from me." "It is certainly very much like him. Has he paid for it?" "Not yet." "That is still more like him."—*Fliegende Blatter.*

# Patent Intelligence.

### Specifications Published.

4,704. *March 26th*, 1890.—"Cameras for Photographing Objects in Motion." Frederick Henry Varley, 82, Newington Green Road, London, Civil Engineer.

My invention consists in a special method of employing drums or spools for paying out the sensitised paper or film, and in gearing the spring work which gives the initial revolutions to the spool to another drum for winding up the film so that the tension upon the paying out spool and the winding up drum are equal or nearly so, and in the use of an adjustable displacement lever, which removes the exposed surface of the film and sets the apparatus for taking the next picture; also the employment of a frame or hollow screen in front of the sensitised film pierced with one or more holes for the purpose of correctly registering each picture.

3,718. *March 8th*, 1890.—"Photographic Studios." Richard Williams Thomas, 121, Cheapside, London, Artist.

My improved portable artificial light studio is composed of adjustable rods carrying white canvas, or other sides or walls, and, when erected, such sides or walls are fixed at desired angles whereby the artificial flash or other light is thrown on to the wall or side immediatley facing the lamp, and thence reflected on to the other walls or sides of the studio, whereby the sitter is reproduced in the photograph without shadows or similar defects usual in taking artificial light photographs.

I employ a number of metal upright rods (usually five) fitted with necessary feet, or stands, and capable of extension to desired height. The top of each upright rod is formed to receive the ends of other rods of similar thickness and of the desired length, which extend from one upright rod to another, so that when fixed they form the framework of the studio; the lengths of these rods are so arranged that the front, or entrance, of the studio is narrower than the sides and back, the back and sides being arranged at suitable angles.

Suspended from the top rods to the whole of one side, and part of the other side, are stretched sheets of canvas or other white material, a suitable background being provided for the back.

The entrance to the studio is supplied with looped curtains or other suitable arrangement. At the back of the said stretched sheets, I suspend from the said upper rods curtains of any dark material for the purpose of resisting the penetration of light.

At one side of the studio, near the entrance, I erect a lamp for burning methylated spirit or similar liquid, this lamp being erected upon an adjustable stand for the purpose of regulating the height desired.

This lamp is placed at that portion of the side of the studio which is not supplied with the stretched sheeting, and it is surrounded at the back by a similar curtain or material, with which I enclose the sheeting round the studio, the space being provided for the lamp by means of another upright rod with necessary top adjustments.

Suspended from the upper rod in front of the lamp, I place muslin or similar material as a continuation of the sheeting at that point. The lamp itself is supplied with a cavity for holding the magnesium powder or other substance used for producing the flash or other light similar to lamps now in use for that purpose. Connected with this cavity is a tube extending to any desired place, and the end of this tube is attached to an air-pump or bellows, or similar contrivance for the storage of air, so arranged that the operator can, by hand or otherwise, regulate the pressure of the air through the tube, and, by this means, slowly force the magnesium powder into the flame of the lamp, securing a longer duration of light than obtained by the ordinary artificial flash process; or he can, by quicker pressure, by the same means obtain an instantaneous flash.

By means of the arrangement of angles I employ for the erection of my said studio, the light strikes the sheeting immediately facing the lamp, and thence to the background and across to the opposite side of the studio, the sitter being surrounded by light without seeing the lamp or having the inconvenience of the flash direct upon him. The casing of the lamp is so arranged as to carry off in any desired direction the smoke and heat necessarily arising from the use of the magnesium powder or similar material.

The use of the said stretched sheeting at the proper angles, and the position in which I place the lamp for artificial light photography, enables photographs to be taken by electric or other artificial light, with much shorter exposure than by the ordinary artificial means, in consequence of the intensification of the light by the reflection produced from one side of my improved studio to the other.

6,239. *April 24th*, 1890.—"Ascertaining the Distance of any Object for Photographic Purposes." Henry Mitchell Hastings, 54, Edith Road, West Kensington, Fulham, London, Analytical Chemist.

The special purpose of this apparatus is to ascertain correctly the exact distance of the object, so as to be able to adjust the lenses of cameras where the image cannot be viewed on the ground glass. I employ a lens of suitable focus fixed at one end of a telescopic body in such a way that the image of the object required is thrown on a disc of ground glass or other suitable material fixed within the telescopic body itself, such image being viewed through an adjustable focussing eye-piece, placed at the opposite end of the telescopic body to that carrying the lens which throws the image; the focussing of this image to be obtained by rack and pinion, or other suitable means, such distance being registered on a scale attached.

As an alternate method, an apparatus may be made of the ordinary telescope, opera, or field glass type, provided with sufficient length of draw, and with a scale showing the different distances. In this case the object is viewed direct, the intervention of the disc of ground glass not being necessary.

# Correspondence.

### SHOWING CELLULOID FILMS IN THE LANTERN.

Sir,—I have found the following plan answer for showing celluloid films in the lantern. Fasten two cover glasses together along one side by a slip of silk about ½-inch wide. They will now open and shut like a book. Shut the film to be shown between them, and place in the slide carrier. By having two of these a film can be placed in each alternately, so as to cause no delay while exhibiting.

I find that, using the oxycalcium jet, I can show film slides six to eight feet across on the screen; above that size they will not allow enough light to pass. I may add that I find coaguline the best thing for holding the silk to the glass.

H. G. M. Conybeare.

*The Hut, Ingatestone, 23rd March.*

### THE NATIONAL PHOTOGRAPHIC EXHIBITION.

Sir,—Arrangements are being made with a view to facilitate the transmission of Liverpool exhibits to us, by sending a representative to sort and overlook the pictures entered here, and to see to their speedy dispatch.

We have already the promise of a great number of exhibits from Livepool, including the wonderful flash-light pictures by the Countess Loredana de Porto Bonin.

S. G. Buchanan Wollaston.

*Crystal Palace Co., Crystal Palace, S.E., March 24th.*

Cementing Glass or Porcelain to Metals.—A method for uniting glass and porcelain with the metals, for scientific and experimental apparatus, has been brought before the Société de Physique by M. Cailletet. He slightly heats the end of a glass tube, for instance, and platinises it by brushing it over with neutral chloride of platinum mixed with essential oil of camomile. On the vapour of the latter passing off, the end of the tube is brought to a dull red-heat, when it is found to be coated with a thin layer of platinum, suitable for receiving a ring of copper by electro-deposit. All the metals capable of being soldered by tin may then be united to the tube, the union being so perfect as to stand a pressure of 300 atmospheres,

# Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the technical meeting of this Society held on the 24th inst., the chair was taken by Mr. W. Bedford.

Two volumes of *Excursions Daguerrennes*, published in the years 1841 and 1842, and containing engravings drawn from Daguerreotype pictures, were shown by Messrs. G. Houghton and Sons, together with a catalogue of Daguerreotype goods issued by their firm in 1841.

Mr. Chapman Jones introduced "Hand-Cameras"—the subject of the evening—by describing the Memorandum Camera, an apparatus made for plates of $3\frac{1}{4}$ by $2\frac{1}{8}$; that being a size which would give an oblong picture in the circle of a lantern plate. He always used a finder, and preferred to have a loose one, so that it could be applied to the top of the camera, whether it was placed in a vertical or a horizontal position.

Mr. Leon Warnerke showed several hand-cameras. The first was one which had been made some time since for him in Moscow. A mirror between the lens and plate served as a finder. He also showed a French camera made of metal and very light. The front of the camera was of hemispherical form, and in this hemisphere the shutter partly revolved. The dark slides were exceedingly well made. He also showed a German made camera furnished with roller slide for paper or films. The end of one of the spools was continued to the outside, where it bore a brass plate having spiral convolutions. An indicator worked in these convolutions, which were so arranged that, whether the spool was full or nearly empty, the same length of film would be wound off.

Mr. Biden thought it would be desirable to know the price of the camera.

Mr. Warnerke replied that it was very cheap considering its effectiveness, about thirty or thirty-five shillings of our money.

Messrs. Mawson and Swan showed a "Reflex Camera." The chief novelty was stated to be the mirror, which, set between the lens and plate, reflected an image on to a ground glass on the top, and served for focussing and finding.

"Kodaks" of various sizes were sent by the Eastman Company, furnished with lenses of foci ranging from $2\frac{5}{16}$ up to $8\frac{1}{2}$ inches.

Messrs. Houghton & Sons showed the "Automatic Hand-Camera." The apparatus was furnished with a Thornton-Pickard shutter and the usual finders. A novelty was the way in which the plate was brought from the store chamber in the back of the camera under the middle to the front, by way of a shallow well, so that that the depth of the camera was only increased by about three-quarters of an inch. This was spoken about by the chairman and Mr. W. E. Debenham.

Messrs. Robinson & Sons showed photographs taken by the "Luzo Camera" of various sizes, and explained the working of the instrument.

Messrs. Griffiths & Sons showed a "Dines' Camera," in which there was a changing box for a dozen plates at the back, and an arrangement by which these plates could be brought out, one at a time, from any particular groove that might be desired, so that plates of different sensitiveness could be used if required. The changing box at the back could be removed, and replaced by another in full light.

The Zodiac camera was exhibited by Messrs. Griffiths.

Mr. E. W. Parfitt showed the Quadrant camera, the combined invention of Mr. Hume and himself. Each plate was contained in a sheath, and the object of the construction was to diminish bulk as much as possible.

Messrs. Marion exhibited the Radial camera. This was another contrivance for drawing plates from a store at the back—arranged in radiating grooves—to their position at the focus of the lens. The grooves were made of metal electrically deposited, and the plates worked very smoothly in them.

Messrs. Adams showed two cameras, the Ideal and the Adams. It was especially pointed out that there were no projecting knobs.

A hand-camera called the "Photographic Repeater" was shown by Mr. Cusworth. Each plate was attached to a thin piece of wood by a rubber band stretched over either end.

Messrs. Parker and Co. showed their "Companion Camera." They claimed for this instrument great simplicity in the manner of shifting the plates.

Mr. Shew showed a camera which, although for whole-plate, could be worked in the hand. The novelty which had been introduced into it since last shown was the method of focussing. There was a jacket attached to the front board, into which any lens might be screwed. Springing from the side of this jacket, and lying on the front board, was an arm which, by moving round, brought the lens nearer to or farther from the plate. A scale on the board might be marked, to correspond to the various distances at which objects would be in focus.

Mr. Samuel spoke of the various characteristics and requirements of hand-cameras. He held particularly that—as had been pointed out by Mr. Debenham—there should be a means of raising the lens in both positions, and showed how this was accomplished by the U-piece which he adopted.

Mr. Warnerke mentioned the experiments of Professor Lippmann, and said that up to the present he had not succeeded in getting like results, but he had some results which he showed. He had noticed strong iridescent colours in plates made by the dusting-on process with graphite. By rubbing graphite on to glass or ebonite and coating with collodion, he could produce these colours at will. He had prepared a colour screen with strips of glass of various colours, and found that a piece of albumen paper exposed under this screen, and floating on mercury with the albumen side downwards, took colours corresponding, though not so bright, with the colours of the screen. With glass coated with sensitised albumen, however, only darkening took place, and no specific colouration.

Mr. Debenham said that this experiment, in which the colour showed quite through the thickness of the albumen paper, and was the same by reflection as transmission, seemed to be rather following Becquerel than Lippmann.

Votes of thanks to those who had sent objects for consideration, closed the meeting, which was kept up to an unusually late hour.

THE CAMERA CLUB.

The Camera Club commenced photographic meetings in the large room of its new premises on Monday, March 16th, with a lantern exhibition. Sir George R. Prescott presided, and opened the proceedings with a few remarks on the state of the premises and the progress of the Club. About seventy members were present.

A large number of slides was passed through the lantern; the pictures were the work of Messrs. Wellington, Cembrano, Stevens, Sands, Barton, and Chang.

On Thursday, March 19th, a paper on "English Church Architecture" was read by Rev. T. Perkins, M.A.; Major J. Fortune Nott occupied the chair.

The Hon. Sec. drew attention to a notice from the Meteorological Society, and handed round a trimming board, devised specially to ensure certainty in securing parallelism of the horizon with the top and bottom edge of the print trimmed.

Mr. Perkins began by apologising for any shortcomings in his paper, and gave as one reason that he had had to take part with one other person in a ceremony in an ecclesiastical building of modern date. In photographing the interiors of churches, he said, it is astonishing how people can walk about in the field of view without affecting images due to long exposures. On one occasion, however, the head and no body of a friend of his appeared in a photograph, due, he thought probable, to a gleam of sunlight falling on his face for a moment. As some interest had been expressed after his last lecture about the few remains of churches built before the Norman conquest, he had since been photographing some of them, especially in Northamptonshire, which is rich in Saxon remains; in fact, the geographical distribution of churches in these islands is not without interest, because of the light it throws upon the history of this country He preferred the word "Danish" to "Saxon." He then ve some interesting information about pre-Norman churches Bradford-on-Avon, Dover Castle, and elsewhere, gave interesting information about ecclesiastical architecture and its anges, and condemned the flamboyant style. He said that uch useful work in connection with ecclesiastical architecture n be done by photography; but it must be done at once, for e restoring fiend is at work. His suggestion was, that a imber of the members of the Camera Club should band gether, each to photograph objects of interest in his own ighbourhood, reproduce them as lantern slides, and send em in to the Club to be architecturally classified. He then ojected on the screen a number of his pictures of churches.

The subject on Thursday, April 2nd, will be, "Norway as a hotographic Field," by Mr. H. Sturmey.

### The South London Photographic Society.

*Friday, March 20th.*—Hanover Hall was well filled to hear r. Gambier Bolton, F.Z.S., lecture on "Animal Photoaphy." About 100 slides of a high class were exhibited; the ints of the different animals were well brought out. While e lecture was well adapted to a mixed audience, the photoaphic side was not lost sight of, some valuable advice and struction being given about photographing animals.

### The London and Provincial Photographic Association.

*March 20th.*—Mr. E. P. Everitt in the chair. Mr. F. romley Smith was elected a member of the Association.

Messrs. T. E. Freshwater, W. E. Debenham, and R. P. rage were elected as delegates to attend the meeting on the bject of the federatiou of the Londou and suburban photoaphic societies.

Mr. J. Howson, of the Ilford Co., exhibited a series of ints ou Alpha paper, drawing attention to the importance of e tone of the print being in harmony with the subject, and nveying in some degree the aspect under which the picture s taken. He then procceded to give a demonstration of the velopment of Alpha paper, which, he said, was capable of elding a wide range of tones, according to manipulatiou, or e toning bath used. Some prints that had previously been posed were then developed with ferrous oxalate—one part of weak solution of iron to three of oxalate, well restrained, ing used. The prints were immersed, without washing, in the earing solution, consisting of :—

| | |
|---|---|
| Water ... ... ... ... ... | 80 ounces |
| Sulphuric acid ... ... ... ... | ½ ounce |

ter washing iu several changes of water, the prints were insferred to a combined toning and fixing bath—

| | |
|---|---|
| Hypo ... ... ... ... ... | 2½ ounces |
| Acetate of soda... ... ... ... | ½ ounce |
| Sulpho-cyanide of ammonium ... ... | ¼ ,, |
| Chloride of gold... ... ... ... | 4 grains |
| Water ... ... ... ... ... | 10 ounces |

is bath has the effect of causing the prints, when first mersed, to change to a yellow colour and lose vigour. This ultimately regained, and toning is complete in about uarter of an hour. Mr. Howson showed a frame of six transrencies that had received exposures ranging from one-anduarter minutes up to three minutes. The plates were, after posure, each cut into four parts. Two of the parts of each te were simply fixed after development, the remaining two re toned—the object being to show that by judicious judgent with regard to the developer and toning baths, a similar sult could be obtained with a wide latitude of exposure. plying to various questions from the members, Mr. Howson d prints on Alpha paper could be developed with hydrokinone th advantage, but he would give preference to ferrous alate. The best results were from the use of an old veloper freshened with a proportion of new just before use. ints should not be allowed to remain too long in the acid th, as it had a tendency to reduce the image. In this pect the bath would be found useful as a means of corctiug over-exposed prints. The exposure recommended was out two-and-a-half minutes at a distauce of six inches from a batswing gas burner. The distance from the light for larger sized prints should be increased in order to get uniformity of illumination.

During the progress of touing, Mr Howson tore off portions of one of the prints at intervals, that comparisons of colour might be made at different stages of touing.

It was claimed that a better result could be obtained on this paper with a thin negative than with ordinary albumenised paper.

The Chairman asked if spottiness were due to the emulsion.

Mr. Howson said not. It would be more likely due to age, or from the paper being kept in a damp place.

### The West London Photographic Society.

*Friday, March 20th.*—Mr. Brown in the chair.

Letters and papers from Mr. Biden on the subject of the federation scheme were read, and remarks made by the president, followed by a long discussion; after which it was resolved to send delegates to the meeting on the 23rd inst., with discretionary powers.

Mr. C. Whiting then read his paper, repeated by special desire, on "Lantern Slide Making by the Wet Collodion Process." The paper was followed by a practical demonstration. One exposure was made by reduction in the camera, and two by contact. The processes of coating the plates, sensitising, exposure, development, intensifying, fixing, and toning were followed with great interest, and questions were put, and answered by Mr. Whiting, who subsequeutly explained the method of printing-in clouds.

The President then, iu the name of the Society, presented the late honorary secretary, Mr. John A. Hodges, with a lens (by Messrs. Taylor and Hobson, with an iris diaphragm) and a suitable inscription. He made some flattering remarks on past services to the Society by Mr. Hodges, who warmly thanked the Society.

### The Brixton and Clapham Camera Club.

The secoud annual meeting was held on the 19th inst., when a satisfactory report and balauce sheet was presented. The officers for the ensuing year were elected as follows :—*President*—Mr. A. R. Dresser; *Vice-President*—Mr. J. Reyuolds, M.D., F.R.G.S.; *Committee*—Messrs. T. J. Bartrop, W. Bevins, J. W. Coade, M. O. Forster, F. W. Kent, and F. W. Maile.

The occasion was thought to be an appropriate one for presenting to the secretary a whole-plate camera subscribed for by the members as a mark of their appreciation of his services.

The next meeting will be held at Gresham Hall, Brixton, on April 9th, when Mr. Bevins will read a paper on "Light," with lantern experiments.

### The North Middlesex Photographic Society.

The anuual dinner was held at Beale's Restaurant on March 21st, the President, Mr G. Humphries, F.S.A., in the chair.

After the various toasts had been duly responded to, the President presented to Mr. G. R. Martin, the late secretary, a handsome microscope suitable for micro-photography, the gift of the members, and added to it, as a mark of his personal esteem, a high power objective to complete the instrument.

Mr. Martin, in acknowledging the gift, said that the friendly appreciation of his work accorded to him by the members had been ample reward.

The President then presented to the following gentlemen the certificates awarded to them by the judges, Messrs. J. Gale and Ralph Robinson, for work shown at the late exhibition :—Silver Prints—(First) G. C. S. Mummery, (Second) W. S. Goodhew; Platinum and Bromide—(First) F. W. Cox, (Second) W. S. Goodhew; *Genré* (First and Second) W. S. Goodhew; Portraiture—(First) E. S. Hiscock, (Second) F. Cherry; Enlargements—(First) C. Beadle, (Second) W. Taylor; Lantern Slides—(First) W. Taylor, (Second) E. S. Hiscock.

The evening was genially passed with music and song.

On March 23rd, Mr. H. Smith in the chair, a lantern slide exhibition was held. A collection of slides lent by Messrs. Mawson and Swau was first passed through the lantern, and then the following members exhibited their work: Messrs. Wall, Mummery, Cox, Smith, Chaug, Marchant, Ainsley, and Gill. The slides comprised snow scenes, forest glades, woodland nooks, and silent pools, mountain glens, pastoral scenes with the cattle knee deep in the long bush grass, the quays and bridges of busy seaports, barges with towering sails gliding placidly along the sedgy broads, solemn minster aisles, and the excited throng of the race-course, the bustle of city life alternated with quiet home scenes and sleepy villages.

The Croydon Microscopical and Natural History Club (Photographic Section).

*March 20th* was a lantern night, when Mr. Edward Lovett presided, and 200 slides were put through the lantern, the work of members, viz.:—Messrs. Baldock, A. H. Allen (animal studies), Coldwells, J. A. Carter, Mariott, C. F. Oakley, W. Goode, A. W. Hurst, A. S. Wild, and W. Low Sarjeant. Messrs. Carter and Mariott showed some slides of the recent severe snowfall, and Mr. F. C. Oakley also put on the screen some photo-micrographs of rock sections taken by polarised light.

The next ordinary meeting will be held in the old school of art room on April 3rd, when Mr. A. R. Dresser will read a paper entitled, "The After Part of Hand-Camera Negatives" (illustrated).

The Enfield Camera Club.

The ordinary meeting of the Enfield Camera Club was held on Wednesday eveuing, the 18th inst.

Dr. F. Cresswell showed the capabilities of the process unfortunately called "kallitype" to a large number of members. The demonstratiou, which was an exhaustive one—some dozens of prints were developed—was a full explanation of the principles of production given.

Mr. Otto Schölzig sent samples of Dr. Jacoby's chloride of silver emulsion paper.

Four uew members were elected, and it was resolved that two delegates from the Club should attend the adjourned meeting for the proposed federation of London photographic societies.

The Richmond Amateur Photographic Society.

*March 26th.*—Mr. Ennis in the chair.

Mr. Ardaseer iutroduced the subject of "Development and Developers." He touched upon the theory of the action of light upon the sensitive surface and the development of the latent image; noticed the different action in the development of wet and dry plates; explained the functions of the various ingredients employed in development; and enlarged upon the advantages of slow development, of re-development in certain cases, and of the judicious use of certaiu dodges, such as the use of the brush, intentional fogging, and intentional staining, and others.

Mr. Cembrano mentioned that, in cases of under-exposure, he had used with advautage re-development with hydroquinoue after eikonogen, the latter giving detail, the former density.

The Photographic Club.—On April 1st, the adjourned discussiou on shutters. The Bank Holiday outing will be to Leigh, near Southend; members meet at the booking office, L. T. & S. Railway, Fenchurch Street Station, at 9.45; return ticket (to Southend) 2s. 6d.

Photographers' Benevolent Association.—March 18th, Mr. W. Bedford chairman. Two grants were cousidered and assistance granted. The following were elected as subscribers, viz., Messrs. Hargreaves, Matthews, Kerr, Misses Howe, Haigh, and Clarke.

We have been informed that perhaps such great purity of the mercury for M. Lippmaun's process as mentioned in these pages a few days ago may possibly not be necessary, but that Mr. Waruerke used a film which probably contained an undecomposed soluble silver salt, and did not employ spectrum colours.

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Elitor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and or the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

The Photographic News is the oldest weekly photographic newspaper. See its consecutive number to-day on the front page.

Viator.—*Federation of Photographic Societies.* A joint committee, presided over by Mr. L. M. Biden, has this matter in hand, and your suggestions should be laid before that gentleman (c/o Assistant Secretary, Photographic Society, 50, Great Russell Street, W.C.). The *Association Belge de Photographie* has such a constitution, meeting at Brussels, Antwerp, Liége, and Ghent, and so, likewise, has the British Association for the Advancement of Science, so far as the reception of country delegates is concerned. The Society of Chemical Iudnstry (2,600 members) is composed of five or six sections, meeting in different centres, with head-quarters in London. The *Bulletin Belge* aud the *Jour. Soc. Chem. Industry* provide reports for all, but this fact does not stand in the way of the proceedings being farther discussed by independeut jouruals.

W. S. B. (Boston, Mass.)—*Life-Sized Heads.* Mr. H. H. Hay Cameron writes to say that most of the large portraits taken by his late mother were done with Jamin's lens, but she also used a large rapid rectilinear by Dallmeyer. As is well kuown, Mrs. Cameron aimed at art excelleuce in her work, rather than being piuned dowu to sharp optical definition, so that the lens employed was not, after all, a very important consideratiou. As previously reported, Messrs. J. Chaffin aud Sons, of Yeovil, used a Jamin lens, whilst Messrs. Robinsou and Cherrill employed a 7D Dallmeyer for their respective Crawshay prize portrait heads.

F. Smith.—*Registration of Designs.* Our publishers will undertake to lodge your specification and design on sending them thirteeu stamps. There seems a doubt, however, whether the main feature of your plan will be new, but the motto may carry it.

F. D. T. (Edinburgh).—*Mungo Ponton's Portrait.* There was no mistake in the reference. Be so good as to look again at the News of February 27th, top of last coloum, where it is said to form "the frontispiece of the Year-Book for 1882." We should be glad to see the details of your exchange scheme, which ought to interest those of us who are south of the Tweed.

A. M. M.—*Cost of Materials and Wages.* Your letter to hand; but, as we go to press so early, there is no time for calculatious of even greater difficulty than those given in our last. Leave the matter with us to think well over before reply.

H. J. B.—*Mr. Benham's Death.* We called on Wednesday at Mr. Benham's office, and when your letter came to say that he died on that same evening, whilst the committee of the Photographers' Benevoleut Associatiou were assembled in his office, we experieuced a most paiuful feeling of regret, which will be shared by all who are aware of the self-sacrificing labours of our amiable colleague, the late honorary solicitor.

A Correspondent reports that he has just developed a six years' old portrait exposure ou a dry plate, and that instead of getting a negative, the image came out as a transparency, which shows, moreover, traces of colour indications.

F. C. S.—*Cantor Lectures, &c.* The lectures recently delivered at the Society of Arts by Capt. Abney and Prof. Meldola respectively will be published later on, in the summer recess.

CONTENTS.

## QUITE ANOTHER THING.

### Concerning Some Photographic Societies.

BY H. P. ROBINSON.

This is an age of progress, as I think has been often observed of other matters than those which are photographic. We ferment in photography, but I am not sure that we move as fast as we ought to do; indeed, I am equally uncertain whether some of us know exactly what photography is, or, like the Prince in Tennyson's "Medley," "know the shadow from the substance." Some mistakenly think our art is a pure science; others look upon it as a substitute for drawing in sepia; some rightly say it is a mechanical process; others, also rightly, graciously admit that it is a fine art; while the vast majority take it as an amusement pure and simple. It is a Protean affair altogether; but, whatever it is, unquestionably it is not a chemical industry, nor an optical problem.

It has become a great industry, if not a great art. If we have not been brilliant artistically in the past, we may become so in the future. There are some signs of an awakening. We have had fifty years of talk, and at least two of them at high pressure; we have achieved our jubilee; the tributary chemical and mechanical arts have done their duty in supplying us with inventions, perhaps greatly beyond our need; the Camera Club has gone into new premises; the Photographic Society of Great Britain has taken an attic all to itself, and there is some talk of confederation; besides which, the Institute is looming in the future. These accomplished and coming changes may cause the thoughtful to pause and consider if it is for the advantage of the art to continue on the old lines, or to attempt a new departure. As a contribution to the consideration, the following revolutionary suggestions are offered, not, however, without apology to those who prefer keeping to the old ruts, and to follow the old traditions.

We have, I believe, something like two hundred photographic societies in the United Kingdom, and on the Continent and in America they are increasing like —like rabbits. Is it not time that some of these societies became associations of photographers? "So they are," will be the almost universal reply, but in many cases it will be quite untrue. This proposition is not difficult of proof. As I understand, the plain meaning of the term a photographer is, one who photographs; who uses photographic materials either for making pictures, mapping the stars, taking the portraits of Mr. Pringle's little friends the microbes, or for lending a hand to almost every industry, and assisting every art. The application makes the photographer. In the smaller societies attention is certainly often called to the question how to do it; but it is a curious fact that the more important the society, the less is thought of application and the more of theory, the manufacture instead of the use of materials, until we get to the universally acknowledged head of all societies, the Photographic Society of Great Britain, when we seem to soar into the calm regions of undiluted science, uncomprehended by and useless to the real photographer, and, if one may judge by the last report of the Council as it was first presented to the annual meeting, very little else but pure science is wanted.

The report, graciously patronising the *art* of photography, said: "Although the meetings of this Society *should be devoted to the scientific rather than the artistic side* of our subject, an occasional paper on practical picture-making would be welcomed." This, it is true, was altered by the meeting, but it shows how the wind blows, and is scarcely encouraging to those who would be of practical use.

Now, what should we think of painters if they associated together, as they often do, under the name of sketching clubs, if they did nothing at their meetings but talk over the manufacture of their pigments, brushes, easels, and what not? Would they not rather deserve the name of artists' colourmen than artists? And why should those connected with photography mistake the materials for the art? I do not deny that the Royal Academy keeps a professor of chemistry, as it also does a chaplain, but it is carefully provided that he does not profess too much and swamp the art.

The usual subjects discussed at the Photographic Society bear about as much relation to photography as colour-making does to painting, type-founding and paper-making to printing, or copper-plate planishing to engraving. If we look down the list of papers read before the Society during the past year, we shall find them all interesting to those who care for such subjects, all desperately clever, but not more than one, or perhaps two, of any use to the practical photographer.

But there is a bright side to the shield. Our Society redeems itself in its exhibitions. Until lately—and it would do so now if it were not for Liverpool—it has held the principal exhibitions of photographs, not only in England, but the whole world. Even now it holds the best *annual* exhibitions, to which all the choice first-fruits of the year's art are sent, and—it must unfortunately be confessed—some of the worst. So that we who practise photography, and show our work in October, have not much to complain of except that the pictures shown at these exhibitions, as far as the chief feature, art, is concerned, are not the outcome of anything taught at the meetings of the Society, or by the Society in any other way, but of knowledge gained elsewhere. The curious issue is, that the Society teaches one thing, and shows another as the result. After all, everything is in order, for the first of the Society's rules tells us that its object "shall be the advancement of photography, and the branches of science and art connected therewith." But this rule was made for an infant which wanted feeding and nursing; photography is now full grown, and wants increased education.

The coming Institute should give us a chance of reformation. Before anything is done it should be thoroughly decided whether it is to be an Institute of Photography or an Institute of Photographic Chemistry, Optics, &c., which, as I have already pointed out, is quite another matter. I will go on the supposition that it is to be an Institute of Photography, although I don't find much encouragement to suppose so in the first proposals issued, which ask only for "the encouragement of photographic research, and the perfecting and practical teaching of photographic processes," with a very faint-hearted reference to art in the shape of "probable" exhibitions.

The first consideration in a Photographic Institute should be to teach photography as an independent art; the next as a handmaid to other arts; afterwards, as applied to industry and science; and I would make a strict law that the students should be compelled to select their department, and not flutter through the whole of them. The departments should be kept strictly separate. For instance, if, in the art department, a student was found wasting his time over a new developer, or a modification of an old one, he should be dismissed without benefit of clergy. The aspirants to the art department would have to pass a simple examination to discover what they know of the ordinary processes of photography, and a more severe one to disclose how much they would have to forget.

The Royal Academy itself, in its early days, admitted coach-painters as members, and the works of artists in hair to its exhibitions; we have, therefore, no precedent in that august body for drawing the line too closely, and I have not made up my mind as to whether a student with some knowledge of science should be admitted.

The principal visible use of photography is for portraiture; that I would have taught first, for comparatively few know how to take a portrait, and the crying want of the photographic world is the removal of the contents of the hideous show-cases that shock the eye of the artist, and degrade the taste of the multitude. Then I would tackle the amateurs, and teach them how to place a figure in a landscape, instead of weakly giving it up as too difficult. I would have lectures, illustrated by aid of the lantern, on composition, light and shade, and the history of art, with (as we profit by our failures) an occasional extra on artistic misfits, fads, and fashions. And then—and then, that decimal percentage of students who become artists must be left to evolve themselves.

The tributary arts, whether scientific or mechanical, I would encourage, on "a more removed ground," but not so that they should swamp art, as they try to do at some of our present societies. I would even, with the greatest generosity, endow research, but I would bar any more modifications of developers.

Just as much profit can sometimes be got by the use of improved machinery from the waste of old mines; there should be a department for reviving old arts and investigating discarded inventions by the light of modern science. I am nothing if not practical, and will give a well-known instance of what I mean. Every reader of the works of a certain great traveller in the last century knows that at the famous Academy of Lagado there was a professor engaged upon a project for extracting sunbeams out of cucumbers, which were to be put in phials hermetically sealed, and let out to warm the raw air in inclement summers at a reasonable rate. We have got used to inclement summers, and, personally, I enjoy the most artistic atmosphere on earth, and would not like to have it altered; but if we could bottle the cucumber-given sunbeams, they may be a convenient substitute for our present clumsy, but most effective, flash-light derived from magnesium. Neither would I exclude the impossible. The sunbeam extractors may also undertake the discovery of photography in colours, if it were only for the sake of supplying the much-believing outside press with exciting periodical paragraphs calculated to stimulate the interest of the public, and enable them to tell every photographer that it can be done, for they "have seen it in the papers."

Disputation should not be allowed in the general body; but, if a member felt an inward compulsion to prove that two and two made four, or that A was as good as B, other things being equal, and another to deny the proposition, there should be a quiet and retired room provided for them—to "press the button" in; the "rest" should be done by pamphlet. For it has been wisely observed that every community is volcanic and requires a crater, just as every steam engine should be supplied with a safety-valve; therefore the Institute should be provided, as Cornelius grippa recommends, with a place where "everye man ight plentifullye dispute of what matter he wolde, nd, with a certain artificial and huge heape of nownes nd verbes, symbols and figures, invente and dispute."

There may be some who will say that I do not mean ll this. Well, perhaps not in the letter, but unoubtedly in the spirit. I would reverse the intention f the sentence from the report I have quoted, and nake it run thus: "Although the meetings of this ociety *should be devoted to the artistic and practical side f our subject*, the council wish to state that papers on he theoretical and scientific aspects of photography vould occasionally be welcome on technical evenings." Every exhibition shows that if we do not know too nuch of science, we certainly know too little of art.

## THE CAMERA CLUB CONFERENCE.

The fifth annual conference, exhibition of members' picures and lantern slides will take place on Tuesday and Vednesday next, April 7th and 8th. The conference roper will be held in the Theatre of the Society of Arts by kind permission of the council), and will open each ay at 2 p.m. The following programme will show that here is a treat in store for all who are interested in hotography, and who care to take advantage of the nvitation to attend which is extended unconditionally to ll photographers.

Tuesday, April 7th.—Conference at the Society of Arts, 18, ohn Street, Adelphi, to be opened by the President at 2 p.m. Papers to be read from 2 p.m. to 5.30 p.m. in the Theatre:— 1) Captain W. de W. Abney, R.E. C.B., D.C.L., F.R.S., residential address; (2) Mr. Lyonel Clark, C.E., "The Use f Uncorrected Lenses"; (3) Mr. Joseph Pennell, "Photography as a Hindrance and a Help to Art"; (4) Rev. F. C. Lambert, M.A., "Note on the Physiological Aspect of Some Problems in Art." At 8 p.m., exhibition of lantern slides in he Theatre.

Wednesday, April 8th, 2 p.m.—Renewal of Conference in he Theatre, Society of Arts. Papers to be read from 2 p.m. o 5.30 p.m.:—(1) Major J. F. Nott, "Photography and llustrated Journalism"; (2) Mr. C. V. Boys, "An Application of Photography"; (3) Prof. Minchin, "A Review of Photo-Electricity." At 7.30 p.m., annual club dinner for nembers and friends at the Criterion Restaurant.

The annual exhibition of photographs by members will be on iew in the Club House Meeting Room, Charing Cross Road, rom 10 a.m. to 4 p.m. Admission by card from any member f the Club, or by ticket from the hon. secretary. The exhiition will be open under these conditions for about six weeks rom Tuesday, April 7th.

The meetings at the Society of Arts are open to ladies.

Those who have a large stock of negatives constantly inreasing in number are often apt to ask themselves what is to e done with them all? There is a natural repugnance to lestroy that which has cost knowledge and pains to produce, ut yet something must be done with the useless lumber. An American photographer lately solved the problem by applying is old negatives to hot-house purposes, but that the transction was not altogether satisfactory the sequel, quoted from Virginian paper, will show. A short statement of the facts s as follows: Davis, the photographer on Broad Street, some ime ago sold to a florist a lot of refused negatives, which he vanted to use to cover his hot-house. Foster bought some our hundred of the negatives from the florist, and from these rinted photographs and exposed them as specimens in his gallery on Ninth Street. Davis obtained an injunction to prerent Foster from so using the negatives, and the court perpetuated the injunction.

## THE PORTRAITURE OF THE STARS.

BY JAMES MEW.

It is said that Chaldean shepherds were the first astronomers. They certainly possessed two essential conditions of stellar study: their climate was clear, and the practice of their profession probably left them a large amount of leisure time for the contemplation of the spangled skies. With the people of a later age and a far removed position, with the English folk of the end of the nineteenth century, these two conditions of time unoccupied and a pellucid air are commonly absent. The great majority of mankind are now so pressed by the business of the day, that the season of the night is devoted to relaxation or pleasure or sleep, while those few who have an inclination for what is commonly called "star-gazing," with all the means and appliances to boot, are prevented on nine occasions out of ten by inauspicious and inclement atmospheric caprice from the fulfilment of their desire. And so the greater part of the modern world, though formed not with prone faces as other animals, but to bear aloft their erected features to the skies, is content with little regard of them, looking upon the heavens—with more poetry than intelligence—as an immense sea sprinkled with phosphorescent isles, or a field full of nocturnal flowers, as a vast plain sown with dust diamonds, or an azure vault of crystal studded with myriads of golden nails. The most glorious of nebulæ in our northern hemisphere, the flaming cluster in the handle of Orion's sword, is hardly for them that mass of incandescent gases which the photographer has discovered by the aid of the spectrum. Nay, for them Orion and Eridanus are all one. They can recognize no difference between Corvus and Columba. They are capable of confounding Fomalhaut or the mouth of the fish with Fornax, and the Corona Borealis with Bootes or Berenice's Hair. They are familiar with the rhyme of their infancy, chanted to them by their nurse while watching those far-distant shaking fires—

Twinkle! twinkle! little star,
How I wonder what you are;

and, unlike Arago, they are content to wonder at this archipelago of worlds.

This same twinkling star

Up above the world so high,
Like a diamond in the sky,

which has obtained the dignity of a translation into Latin by the Rev. H. Drury in the *Arundines Cami*:—

Mica, mica, parva stella,
Miror quænam sis tam bella;
Splendens eminus in illo
Alba velut gemma cœlo,

the original is not commonly known. It is to be found in "Hymns for Infant Minds," by Ann and Jane Taylor, and consists of five stanzas, of which the lines quoted make the first. The remaining verses express the gratitude of the traveller in the dark—

He could not see which way to go,
If you did not twinkle so;

and conclude with the author's confession of ignorance as to what the twinkling star really is. The poem well expresses the state of popular—perhaps scientific—knowledge on the subject.

The sacred record is concise: "He made the stars also," of which expression "he made" is not in the original. This sublimity is diluted, for the sake of a little sermon, by Adam Clark's commentary, which says that in

1792 Dr. Herschel found "258,000 stars passing through the field of view in his telescope in forty-six minutes. What must God be, who has made, governs, and supports, &c.?"

In a pamphlet by Professor Pickering, we learn that stellar photography originated in an experiment made upon three stars at the Harvard College Observatory in 1850. A sensitive Daguerreotype plate was then and there placed in the focus of the 15-in. equatorial, pointed by a driving clock upon α *Lyræ*. A satisfactory image was obtained. The double star α *Geminorum* gave, owing to its two components, an elongated portrait. No impression was obtained from the Pole star, however long the exposure continued. In 1857 the machinery of the clock was improved, and photographic sensitiveness was increased by the introduction of collodion. The *Astronomische Nachrichten* (vols. 47 to 49) will furnish to the curious reader much valuable information on this subject of early stellar photographic investigation.

Professor Vogel has lately shown that Spica in the Virgin is double, consisting of a light and a dark star, with a revolution period of four days; and Professor Pickering states that ζ in Arcturus, and β in the Wagoner, have their spectrum lines, one single, one double, with periods of fifty-two and four days respectively. These are therefore ordinary double stars, but their distance from one another is so small that no telescope can determine their separation. Pickering afterwards found also a periodic doubling of lines in Ophiuchi. In a late number of the Photographic News it was shown that stellar photography is sometimes self-corrective. It was formerly supposed that there was spectroscopic evidence of the duplicity of α *Lyræ*. Later on, photography showed that this duplicity was rather in the spectator than in the star. Since 1888, Prof. F. C. Vogel has taken eleven pictures of the spectrum, and the lines in all were perfectly sharp and single.

α *Lyræ* has indeed been a bone of photographic contention. Mr. Fowler proved the duplicity of the star in a manner satisfactory to himself, by a picture produced, it would seem, by a special instrument in which the lines were doubled. But then rose up Vogel, and the Brothers Henry, and also proved, from pictures made by their own instruments, that no trace of duplicity in α *Lyræ* was discoverable. Either therefore, if these authorities be considered, Mr. Fowler's photographs or his calculations were inaccurate. A little quirk of witticism was then let off by Captain Noble, involving allusions to Cocker and Walkingham, to celebrate the occasion. The moral of this business has been thus neatly summed up by the Editor of the Photographic News. Since photographic illustrations are made up of so many elements, it is unsafe to rely upon any single result until it has been verified by repeated experiments. The alleged doubling of α *Lyræ* is a precedent which it behoves the astronomical photographer to bear in mind.

Dr. Huggins seems first to have used photography as an instrument of research into stellar physical conditions. In 1863 he obtained microscopic prints of the spectra of Sirius and Capella. These were merely characterless streaks without lines. Thirteen years later, with the 18-inch speculum, prisms of Iceland spar, and lenses of quartz, he obtained a photograph of the spectrum of Vega, a white star, with seven strong lines. In 1879 he kept the image of Vega, by continual adjustments, exactly projected upon a slit $\frac{1}{350}$th of an inch wide, during an hour, in order to get the characters of its analysed light on a gelatine plate of the highest sensitiveness. The ultra-violet spectrum showed twelve strong lines intersecting it at intervals diminishing regularly upwards, and denoting the substance of hydrogen. In the yellow stars, Capella and Arcturus, the series was associated with many other lines, their state approximating to that of the sun.

Of the red stars, Betelgeux is a star of the first magnitude in the eastern shoulder of Orion, called by the Arabs *Aljauza*. Abdarrahman Assufi, in his astronomical treatise, says the "second star (of Orion) is the bright, the large, the red, which is on his right shoulder." It is of the first degree, and is called *mankib al jauza*, or *yad al jauza*, indifferently. The word "Betelgeux" (the French *Betelgeuse* is nearer the correct pronunciation) has arisen from a confusion of this star with the astrologers' *bait al jauza*, or House of the Twins. This Betelgeux is so remarkably deficient in actinic rays that, with an exposure forty times that required for Sirius, only a faint, spirit-like impression could be obtained; while from Aldebaran, the brilliant red star in the eye of the Bull, counted by Alfargani among the fifteen stars of the first magnitude, no impression whatever was perceptible. According to the shaikh Ahmad ibn al Muaddim, this star is so called because it comes after the Pleiades. It is so called, *par excellence*, just as the Pleiades are, by Arabian astronomers, called "the stars."

The same process was successfully applied to the Orion nebula in 1882. Five lines were the result of forty-five seconds of exposure. Of these, four were the known visible rays, and the fifth seemed to agree with one of the hydrogen set of Vega. The bright rays were connected by a faint, continuous spectrum derived from the nebulous "knots" near the trapezium. This was thought to indicate the beginning of an orderly revolving system reserved for the future habitation of so-called rational beings. "It may be so," says Agnes M. Clarke, from whom this account has been derived: "the ways of creative power are dark."

In 1886 a simultaneous impression was obtained with an exposure of thirty-four seconds of the spectra of some forty Pleiades. The hydrogen lines were in all predominant. In 1883 Mr. Common, with an exposure of thirty-seven seconds, obtained a splendid picture of the Orion nebula in the focus of his three-foot silver on glass mirror. Photography then definitely assumed the office of historiographer to the nebulæ.

Mr. Isaac Roberts has lately given photographic evidence of variability in the nucleus of the great nebula in Andromeda. From a large number of negatives taken with exposures varying from five minutes to one hour in duration—of which some only have a decidedly stellar appearance—this inference of variability in the nucleus has been drawn. Mr. Barnard, of the Lick Observatory, during the month of last November—intent on the nebulosities of the Pleiades—discovered a new cometary nebula close south of them, and following Merope. But though the position of this nebula has been determined, it has not yet been photographed, owing to the fact that the long exposure necessary would over-expose Merope to such an extent that the luminosity of the two would coalesce.

Of course, in these sidereal investigations, the camera and the telescope are mutual friends. Of them may be quoted that old fable of Menenius, called the "Belly and its Memers." In an able paper lately published by Mr. Common, we learn that the aperture of the refracting telescope has greatly increased. In 1863 Cooke completed the 25-inch refractor now in the possession of the Cambridge University. Alvan Clark manufactured the 36-inch telescope lately erected at Mount Hamilton, California, under the direction of Professor Holden. The reflecting telescope has grown *pari passu* with its elder brother. In France there is one of four feet at the Paris Observatory. In England, too, this form of telescope is largely used, and, says Mr. Common, mirrors up to five feet in diameter have been made and mounted equatorially. Reflecting telescopes give images absolutely achromatic, but their mounting is less perfect than that of the refracting.

"It is well known," says Dr. Duner, the astronomical professor in the Swedish University of Upsala, "that the subjects of photographic portraiture are either self-illumined, or so strongly lighted that their reflected rays are able to reproduce their picture." To show, by means of photography, the existence of a heavenly body which can produce no impression upon the bromide silver gelatine has been reserved for the present time. As long as two hundred and twenty years ago, it has been known that there was great variation in the degree of light emitted by the star Algol (β *Persei*) in the head of Medusa. The Arabs call the head of Medusa held by Perseus the head of the ghoul, a malignant supernatural demon of variable form devouring men and well known to the readers of the Arabian Nights. The marked fluctuations of light in this member of the constellation of Perseus was already noticed in 1669 by Montanari. Algol is indeed the leading light of a small group containing about a hundred of so-called variable stars. Amongst these, after Algol, Mira (ο *Ceti*) and (η *Argus*), of the southern hemisphere, exhibit variations of the most extraordinary character. Mira in Cetus, so called from this peculiarity, appears at its brightest of the second magnitude, whence it gradually wanes to the twelfth, and then increases to its former splendour. An interval of some 330 days occurs between its periods of greatest brightness. Algol is best seen on the early evenings. In autumn, after sunset, it shines low down in the north-east of the heavens, in spring low down on the north-west, and in winter it flashes high in the north, not far from the zenith. The variations of its radiance were first accurately observed in 1782, when it was shown that its light was constant and steady as that of a star of the second magnitude for 2 days, 20 hours, and 49 minutes, after which it gradually faded till it reached a minimum, or that of a star of the fourth magnitude, in 4½ hours, recovering its original splendour in 4 hours. Of this change of 9½ hours, only about 5 hours is distinctly perceptible. The diminution of light is also strictly impartial. Its pure white radiance is the same in kind, however decreased in quantity. Professor Vogel, of the Astrophysical Observatory of Potsdam, has shown by the spectrograph that the old hypothesis of the cause of the change of light in Algol is undoubtedly true, and that Algol is a double star consisting of a light star of 1,725,000 kilometres diameter, and a dark of 1,350,000, of which the former weighs four-ninths, and the latter two-ninths of the sun, while they are at a distance from one another of 5¼ million kilometres, or one-tenth of the distance of Mercury from the sun.

Vogel has also, by the aid of the camera, determined the velocity of some of the so-called fixed stars. Of course fewer waves of light enter the eye in a given time as the star recedes, and more as it approaches. This causes a shifting of the lines in the spectrum of the star's light, which can be photographed. It is hardly necessary to add, except for those whose knowledge of astronomy is represented by Miss Taylor's hymn, that this light is not of the present but of the past. Photographs of the great nebula of Orion show the light of that nebula, supposing it not to be absorbed in any degree in space, as it was not less than sixty thousand years ago. All that vast period of time has been consumed in its attempt to penetrate that which intervenes between us and it, and its shaken splendour is probably due to the difference of velocity of rays traversing strata unequally warm or unequally cold, unequally humid or unequally dry.

To judicial astrology the science of photography has aided other sciences to administer a destructive stroke. The faithlessness of our later age attributes no more virtue to Antares (α *Scorpionis*), the scorpion's heart and the red rival of Mars, or to Rigel (β *Orionis*), which derives its name from its situation in the left foot of that strangely generated giant, than, as Burton complained in his own time, to the signs at an inn-keeper's post or a tradesman's shop. The great book in whose flaming letters are written, if we may believe ancient learning, so many strange things for such as are able to read them; that excellent harp made by an eminent workman, on which he that can but play will make most admirable music—both are still studied, but in a fashion far different from that of yore. The pictorial stellar maps of Ptolemy's Almagest have given place to the *Sternverzeichniss* of Argelander. The animal configurations attributed to the heroic age excite now only a lukewarm interest; but the method of Bayer of Augsburg, involving the use of the Greek and Roman alphabets, invented more than two and a-half centuries ago, is now fast attaining universal learned recognition.

If all these matters are too recondite to attract the public interest, the popular eye may delight itself with pictures of Cygnus and the Pleiades taken at Paris by the brothers Henry, and by slides of Jupiter and Saturn taken by Pickering in America; by the details of the nebulæ of Orion and Andromeda revealed by Common and Roberts, and by a photographic survey of the whole southern hemisphere by Dr. Gill, of the Observatory at Cape Town. Thus may the observer learn to appreciate that picture of the entire sky proposed by Admiral Mouchez, when the good time arrives of its realization.

Photography has already done astronomy yeoman's service, and gives rich promises of doing still more. The new method of investigation has not only greatly lessened the difficulty of variable stars of the Algol type, and generally increased our knowledge of double stars; it has also acquainted us with the diameter and weight of fixed stars, concerning which subjects, except with regard to our own sun, the world hitherto has been wholly ignorant.

---

Limit of Magnification for Photo-Micrography.—Mr. Nelson, says the *Journal of Microscopy*, puts this at 1,000. He has reached 1,500, and, in special instances, even 1,650; but he regards 1,000 as a useful limit. This can be obtained by an inch objective, with an eye-piece giving twenty times the initial power of the lens.

Friedrich Jamrath.—The *Photographische Nachrichten* of March 26th records the death on the 19th inst., after a short illness, in his eighty-first year, of Friedrich Jamrath, portrait painter and Court photographer at Berlin. The deceased had been a zealous member of the Photographischen Vereins zu Berlin from its establishment.

## THE PRESENT STATE OF THE PHOTOGRAPHIC PROFESSION.

BY J. VINCENT ELSDEN, B.Sc. (LOND.), F.C.S.

The time has long since passed for the discussion of the once-debated question whether the practice of photography properly ranks amongst the professions. In the present case, however, the use of the word *profession* is unavoidable; for the term *trade*, including as it does all who devote their business energies to the production of photographic materials, carries us far beyond the limits of the ordinary occupation of the professional photographer. It is the latter, and not the manufacturer of photographic materials, whose interests at the present day are so rudely assailed by the ever-increasing number of amateurs, who do not hesitate to encroach upon the domain of professionals by making what profit they can out of their hobby.

In considering the present state and prospects of photography as a business, the first question which we have to approach is whether we have yet seen the full extent of the mischief done by the interference of amateurs, or will these amateurs still further increase in number until the demand for professional work stops entirely?

Let us first, therefore, briefly examine the causes which contribute to the increase in their number. In the first place, every simplification of the details of the process, everything which makes the taking of a good photograph easier than before, will necessarily entice a larger number of persons into attempting it. In the early days of photography, when the wet process reigned supreme, when photographers had to contend against all the freaks of the nitrate of silver bath, to say nothing of the cumbrous appendages necessary for the immediate development of the negative when away from the studio, with all the accompaniments of stained fingers and noxious smells, then the amateur held aloof, and professionals enjoyed a monopoly which brought with it a rich harvest of profit.

In addition to the greater ease and simplicity of the dry plate process, another factor no less important in connection with amateur photography is the expense of the necessary apparatus. The greater sensitiveness of modern dry plates no longer necessitates the employment of such expensive lenses, and various kinds of apparatus are now to be obtained at prices which lie within the reach of all.

Then we have to consider the advance of the popular knowledge of photographic matters. What was, a few years ago, looked upon as a mystic art, difficult to acquire and impossible to understand, is now considered easy of attainment, and ceases to excite the wonder even of the country urchin.

Above all these incentives to the practice of photography is the fascination of a process which gives to all the power of accurately delineating nature, and makes an imaginary artist where no single idea of art existed before.

Surely all these factors have now operated sufficiently long for the adjustment of the natural balance which invariably regulates popular fancy. Amateur photographers cannot go on increasing in number to a much greater extent, and professionals must certainly soon have felt the full force of their influence.

It is small consolation, perhaps, to consider that this amateur question is not confined to photography alone. It has for a long time influenced other callings, but the excitement in these cases passed away when it was seen how little real harm was done. Consider for a moment the professional position of those engaged in education, music, painting. Are there no amateurs here? Does not the teaching profession swarm with empirics, destitute alike of qualifications to teach or of knowledge to impart? Is the position of an able musician injured by the thousands of young ladies who imagine themselves qualified to give lessons on the pianoforte? Does a first-class artist suffer much real harm from the many who dabble in oil or water-colour? Yet if these professions had ever enjoyed a similar monopoly to that formerly possessed by the photographer, their hardships would have been just as pronounced, and their outcries as loud as those now raised against the photographic amateur. In point of fact, we find the position of these professions improved in the long run by the stimulus given to the public taste by the efforts of amateur exponents of their art, and by the increased appreciation in which the superior abilities of professionals are held by the public.

Will not photographers experience in time some, at least, of these same benefits? The general public is gradually becoming endowed with an ability to appreciate good work, and with the power to discriminate good work from bad. The frequent failures of amateurs and their generally indifferent results will gradually lead to a universal desire for the very best work that can be produced, and the more widespread the knowledge of photography becomes, the more will it be utilised, until at last what has hitherto been considered a more or less extravagant luxury will be regarded as almost a necessity.

It is not necessary here to dwell upon the reasons why the ordinary amateur can never compete with the professional in technical excellence and artistic finish, and herein lies the safeguard of the photographic business. Nor do we class with ordinary amateurs those scientific workers in photography whose researches have been mainly instrumental in producing the present state of perfection of the art. There is as much difference between the scientific investigator and the ordinary amateur as there is between the manager of a first-class photographic business and the itinerant photographer who works at a low profit on the sands at Margate.

Leaving, now, the amateur question, it remains to consider what other causes contribute towards the disappointment in the existing state of the photographic business. Chief amongst these will undoubtedly be the large reduction in profits since the palmy days of old. Here, at least, the amateur is not so much to blame as the professional himself. The struggle for existence has resulted, as usual, in an almost universal cutting of prices. The want of a proper trade organisation, combined with the violent internal opposition of what may be termed second-rate workers, has necessitated a general lowering of the scale of charges; and this, too, just at a time when the expenses are more than they were formerly, for no one will deny that the old wet process was far more economical, and left a wider margin of profit than is possible now.

Another cause which retards the professional photographer is himself. The art is still so young, and discoveries have followed each other so closely, that the professional has scarcely had the time, even if he has had the inclination, to follow up all the newest developments. For this reason he is very apt to become wedded to the old methods in which he has already won success. His ientific knowledge, too, is often insufficient, and this one prevents him from keeping pace with the rapid rides of his art; but advance he must if he wishes to old his own. The successful professional photographer the future will be he who, by careful technical training, as qualified himself for a profession which, besides all e usual requirements of business capacity, demands ientific and artistic attainments of the very first order. aving once acquired these, he need not fear that his ture success will be endangered either by the opposition his own class or by the imitation of the amateur.

## BROMIDE PAPER AND ENLARGEMENTS.

BY CHARLES HUFFELL (RIO GRANDE DE SUL, BRAZIL).

SUPPOSE there have been many in the photographic rofession situated at one time or another as I have been -viz., in want of a piece of bromide paper, and without e means of supplying that want at the moment. An t-repeated experience of this kind was the means at last my making myself independent, and I hasten to give y formulæ for the benefit of others. I do not say that e method is the best, but in my hands it has proved apable of giving results equal to those produced upon me commercial papers.

Place 200 grains of Coignet's gelatine in a thoroughly ean stone bottle having a tight-fitting cork; add 82 of romide of potassium, 2 grains of citric acid, 2 grains of hrome alum, and 8 ozs. water. Shake the bottle well ntil the salts are dissolved, then heat in boiling water for bout ten minutes, shaking well at intervals of three inutes. Remove to the dark room, and, excluding all hite light, add 110 grains of nitrate of silver in large rystals to the already melted bromised gelatine. Cork he bottle tightly, and shake very thoroughly for about ve minutes; then stand for the froth to subside. After bout fifteen minutes the emulsion may be poured out nto a shallow dish to set. When it is thoroughly set, crape the emulsion up and place it in a canvas bag; ring the bag, so that the emulsion will be forced through he meshes of the canvas into a basin of clean water; enew this water six times at intervals of ten minutes; at he end of that time gather the shreds of emulsion and lace them upon a hair sieve to drain for about six hours—onger will not hurt. After it has drained well, place the mulsion in a milk jug with a spout, and melt; then add drams of alcohol, and if your emulsion measures less han 10 ozs., make it up with distilled water to that quantity; hen filter through two thicknesses of flannel into a horoughly cleaned stone bottle, and the emulsion is eady to coat the paper.

The kind of paper I have used, and found better than nything else, is ordinary albumenised paper. The albumen I coagulate by passing the paper through boiling water; this forms an excellent substratum, keeping the mulsion on the surface of the paper, and rendering the mage more brilliant. Take a piece of this paper of the ize required, moisten it in water, and place it, albumen ide upwards, upon a piece of glass of the exact size of the paper; pass a wet sponge over the face of the paper until t lies perfectly flat; take care that it *does* lie flat. Prepare as many of these as you require before commencing o coat the paper.

Now light the dark room lantern, and, having previously ccurately levelled a board or piece of plate glass by means of a spirit-level, take one of your paper-covered glasses, and pass a *slightly* damp sponge evenly over the surface of the paper; then take the emulsion (already melted, but not at all hot, for if it is hot it will cause blisters) and pour a pool in the centre of the paper; tilt it from corner to corner so that the emulsion may cover the surface entirely, and return the surplus to the bottle. Do not drain too much, as a rather thick coating gives the best results. Then rock the plate evenly for some seconds in a horizontal position, and place it upon the levelled board to set. It will be found that wetting the surface of the paper slightly before coating will cause the emulsion to flow as easily as collodion does on a glass plate. When the emulsion has set, the paper may be stripped from the glass and hung up in the drying room to dry; it is then ready for use.

This paper will be found rather slow, but that I maintain to be an improvement, as the exposure is more under control, and the risk of fogging from imperfect insulation from light is much less than with a rapid class of paper. An enlargement of a quarter-plate up to 12 by 10 with a small stop will require about eighty seconds' exposure on a bright day; but the time in each case can only be determined by experiment, as, no doubt, the actinic power of the light in England is inferior to what it is in this country.

I prefer, after exposure, to thoroughly wet the paper in a dish of water, and then place it upon a piece of glass, and develop in the same way as a wet collodion plate, by pouring the developer upon the paper, and allowing it to run over every part. If the paper be at all repellent, a broad camel-hair brush charged with the developer, and brushed over the surface, will make the developer flow evenly. Ferrous oxalate is the one used, with the addition of a small quantity of a restrainer. When development is completed, the paper must be thoroughly acidified with citric or tartaric acid before it is washed, or else pure whites must not be expected. After washing, it is fixed in hypo 5 ozs., water 16 ozs.; thoroughly washed again to eliminate every trace of hypo; then dried and mounted.

Care must be taken in every stage, or success will not be attained, as it is more easy to fail than to succeed; but, with ordinary care and cleanliness in all the manipulations, there is no reason why anybody should fail.

## ON ENAMELLING PHOTOGRAPHS.

BY H. C. R. HARLEY.

As only a few short formulæ are to be found in the photographic journals one comes across on the above subject, the following has been compiled for those who may be anxious to try the process. I must, however, acknowledge that no part of what follows is original; but is a précis of the process published under the heading of "A Practical Treatise on Enamelling and Retouching in Photography," by P. Piquepé.

It is important that the glasses used to squeegee the prints on to should be without any flaw, and patent plate; the next important point is their cleaning; the following is recommended as a good solution for this purpose, viz., alcohol 100 parts, tripoli 5 parts, and iodine 1 part: shake well before using. When required for use, pour a few drops on the glass, rub well all over until quite dry, then with a wash leather rub hard, but not too hard, and in a few seconds the glass will be clean.

The first operation in enamelling consists in interposing between the collodion and the plate an isolating substance to facilitate the transfer of the finished print; the simplest and safest for this purpose is talc, or French chalk, to be used thus: Take a piece of old calico, rather fine, pour into it a certain quantity of talc, tie up the corners, and squeeze it all to the centre till you have got a ball as big as an egg; with this rub the plate all over with a rotatory movement from the centre towards the edges till quite brilliant; the lump of talc can be used over and over again till exhausted. Now take a damp cloth, and pass it round all the edges of the glass to the depth of about one-sixth of an inch, so as to remove the talc from the place along which the damp cloth has been passed. Another method is to pass round the edges of the glass, instead of the damp cloth, but to the same depth, a brush dipped in albumen. The plate, having been treated as above, is put into a rack to dry. When dry, take plain collodion as fluid as possible, and, after lightly dusting the surface of the prepared plate, pour the collodion on the plate in the ordinary way, taking care that every part of it is covered, including the edge, off which the talc has been wiped, or brushed over with albumen; otherwise the print would begin to detach itself in that spot. The layer of collodion should be very fine and transparent.

While plates so prepared are put aside to dry, take fine, white sheet gelatine in sufficient quantity for the number of plates to be done, and, placing it in a clean tray, add sufficient cold water to cover it; allow this to soak for some hours, then put it into a saucepan, which stand inside another full of water, placed in a quick fire, and stir it from time to time till thoroughly dissolved. A quart of gelatine prepared as above will cover 250 plates; what is over need not be thrown away, but put aside for future use.

When the gelatine is dissolved, filter through very fine linen into a bottle strong enough to stand heat, and, having filled it to the top, wait a few minutes till all the air-bubbles have come to the top, which should be blown off; then take a very clean dish, which should have one end of it raised by a piece of wood or any other support, and into this pour the gelatine very slowly, so as to avoid air-bubbles, until the liquid just covers the raised end. Now take one of the collodionised plates by a corner, and, having the coated surface towards the gelatine solution, rest one end of the plate on the raised end of the dish, and, supporting the other end on a silver or ebonite hook, gently lower it until the collodionised surface rests on or touches the liquid in the dish, without allowing the gelatine to get on to the back of the plate: then lift up very slowly, and, having drained it for a moment, lay the plate flat on a shelf well protected from dust. Do this in a good light, and very slowly. The plates thus coated should be left to dry for ten or twelve hours in a warm room, and when dry can be stowed away for use, and will keep good for a long time.

Plates of a large size should receive at least two successive films of gelatine, leaving plenty of time to dry between each coating. The greater the number of films the plate receives, the greater will be the depth, strength, brilliancy, and delicacy of the enamel. This completes the preparation of the plates, which ar now ready to receive the photographs to be enamelled. But before doing anything, see that everything is in its place, so that the work may proceed rapidly and with certainty.

To begin with, prepare the following solution:—Gelatine 4 ounces, water 54 ounces; soak the gelatine in the water for some hours, and complete the melting by putting it into a saucepan over a slow fire and stirring it every now and then; while this is being got ready, place on your left side and within reach the box containing the collodionised and gelatinised plates; near this have a rack to receive the plates after the photographs have been fixed to them, and near by have a stove with a large chop tin dish full of hot water; it will be well to have two handles to this dish, so that when necessary it may be moved off the stove with facility. In the hot water in this dish, stand two porcelain dishes large enough to contain the prepared plates and photographs to be enamelled. Have ready also a sponge and a squeegee. Now filter the dissolved gelatine into both these dishes, taking care to avoid air-bubbles as much as possible. This done, take the vessel containing the hot water and the two dishes with the gelatine solution off the stove, or the solutions will become too hot, and immerse a few of the prints in the dish on the right-hand side. Then take one of the prepared plates and lay it with the collodionised side in contact with the solution in the left-hand dish. *Raise the plate immediately this is done*, otherwise the preliminary pellicle will become softened, and, taking one of the prints from the gelatine solution, lay it with its face in the collodionised surface. Hold it in its place, and with a squeegee rub, not too hard, the back of the print to get rid of the excess of gelatine and air-bubbles. Turn up the glass, wipe it over with the sponge soaked in warm water, and make sure that there are no air-bubbles; if any, run the squeegee along the back till they are got rid of.

All these operations should be done quickly, so as not to give the gelatine time to coagulate. Put the plates on the rack to dry. The rack for these plates should have very wide grooves, so as to avoid rubbing the pellicle, which at this stage is very tender and soft.

The solution of gelatine should not be too hot, or the prints will turn yellow. If the water in which the dishes containing the dishes with gelatine solution begins to cool before the pictures are all mounted, it must be re-heated. It is difficult to say how long these plates will take to dry. In very hot weather choose a very airy room, and not too warm, in which to dry them. An enamel can never be too much dried; on an average it may dry in twelve to fifteen hours, but it is best to allow it a longer time. As soon as it is quite dry to the touch, with the point of a penknife cut the pellicle inside the albumenised edge, and insert the knife so as to get hold of the print between it and the thumb, and raise it gently. If sufficiently dry, the pellicle will, in detaching itself, make a dry, hard sound like tearing a piece of parchment or calico. After they are detached, the prints must be kept quite flat. The prints can now be trimmed and mounted as suited to each individual fancy, but care should be taken that the enamelled surfaces are touched as little as possible with the fingers.—*Journal of the Photographic Society of India.*

---

*The Beacon*, a photographic journal published at Chicago, is responsible for the following:—Crystallos is a new transparent substitute for glass, manufactured by M. Jumeaux, the great doll maker of Paris, and is said to be the outcome of three years' work and study, and at a cost of over 300,000 francs. It is not a plagiarism of the Eastman film, not xylonite, nor collodion, nor gelatine, nor rubber. It is simply crystallos, a new material; bright, pure, transparent, inextensible, splendid, and—perfect; so, at least, says a correspondent; and it is also comparatively cheap, the $6\frac{1}{2}$ by $4\frac{3}{4}$, coated with a very rapid emulsion, being retailed at about a dollar a dozen.

## THE PERMANENCY OF PHOTOGRAPHS.*

BY FR. WILDE.

I will now call attention to another troublesome matter, which has not been obviated notwithstanding the repeated warnings given, viz., the use of cards for mounting prints which have been printed with bronze powder. The fine bronze powder never adheres so fast to the mount but that some particles, in packing or handling, become spread over the mount. If these particles are not carefully removed, they will cause spots and blemishes, for whose appearance you will not have long to wait. We ask, must bronze powder be used? No. Why so thoughtlessly use a medium which destroys the photograph? Fine coloured inks can be used to produce just as fine and tasteful effects, and give no cause for destroying the photograph in the course of time. I cannot, while upon this subject, refrain from calling attention to the tendency, lately evolved, which has resulted in the mounts being overloaded with gaudy decorations. Simple embellishments with good taste are certainly easily combined, and are far preferable. While we complain about the shrinkage of the prices for photographs, yet at the same time we reduce the margin of profit still more by extravagance in the gaudy and useless embellishments on our mounts.

In several of our leading and most frequented galleries the experiment was tried to again return to the use of plain mounts, without any noticeable diminution of patronage. It is well to be cautious in the use of dark-coloured mounts, and especially in all where the colour is coated, it is best to confine ourselves to neutral mounts—either white or faint tints of grey or buff.

Silver prints are also made on argentic chloride collodion paper—argentic, chloride, gelatine, and bromo-silver-gelatine papers. Regarding the first of these three specialities, I have had an experience since 1876, and can testify that they are permanent. I must, however, mention that, in isolated cases, the film or coating is apt to strip or peel off; possibly the emulsion used in such cases was too stiff. Many photographers are in the habit of using argentic collodion prints in their show-cases, as they are supposed to be more permanent than prints on albumenised paper. This is true only in the case of pink-tinted albumen paper, which, if continuously exposed to bright daylight, soon looses its delicate shade, and becomes tawny like a piece of chamois leather. In tinted argentic collodion papers the pigment is not incorporated with the emulsion, but is added to the coating of barytes on the paper, and which serves as the support to the sensitive film. In colouring barytes more stable pigments can be used than with albumen.

Regarding prints on chloro-silver-gelatine and bromo-silver-gelatine papers, my experience regarding the first extends over a period of eight years; regarding the latter, six years, and are of such a character that I do not doubt their stability. Notwithstanding the advantages offered by these three latter processes, they have for some reason interfered but little with the production of the albumen print. When I ventured the query, why? the answer has usually been: Our operator can turn out enough work with the easier albumen process. This may be true, but if so little opportunity is given to our apprentices to learn the various processes in photography, where are the experienced experts of the future to come from?

* Continued from page 244.

I repeat what I have before stated, that the photographer who is careful to conscientiously eliminate every vestige of hypo from his prints, and exercises the necessary caution in the selection of his materials, may safely guarantee the stability of his albumen prints—of course, provided nothing is wrong with the paper, which unfortunately will occur, and is altogether out of the control of the photographer. With Steinbach paper, as well as that bearing the water-mark "Rives," I have never discovered any fault. Other papers may be just as reliable, but none should be used for photographic purposes until proven to be so beyond doubt.

About the year 1855 I bought a number of fine engravings from the most renowned art institute in Munich—pictures which had no connection with photographic baths or processes—and yet they discoloured and turned yellow. The first became apparent in one where the glass was broken. I then noticed that where the paper was protected by the mat it had remained perfectly white, but where exposed to the light it had become noticeably yellow. In this case the paper alone was to blame. If similar paper had been used for photographic purposes, and the same result ensued, the blame would have been cast upon the means and materials used in producing the photographic image.

Carbon prints, in which the reproduction of the beauty of a high-class negative is so decidedly superior to a silver print, are of undoubted stability, provided that only such colour or pigments are used to colour the gelatine whose stability in the light has been proved. It was with the object in view to supplant the wholesale production of albumen prints that pigments were used which would reproduce the favourite tints of the albumen prints. To achieve this object, pigments were requisite which were not permanent, and seemingly faded still more rapidly, and assumed a dirtier shade when used with gelatine, than when used with albumen. Thereby the manufacturers of pigment papers committed a grievous error, and placed a weapon in the hands of the enemies of the carbon process, and such photographers who opposed any substitute for the albumen process, with which the introduction of the carbon process was successfully opposed. With permanent pigments beautiful pictures can be made, which well deserve the approval of a critical public. However, any process where the necessary depth of printing cannot be watched will scarcely ever gain the favour of the bulk of professional photographers. Carbon prints, consequently, have this in common with the silver print, viz., that the selection of the materials is also responsible for the permanency of the prints.

*(To be continued.)*

Faversham Institute Photographic Society.—The first annual exhibition will be held in the Faversham Institute, on Tuesday, Wednesday, Thursday, and Friday, April 27th, 28th, 29th, and 30th, 1891. There will be a photographic competition confined to members of the Society. The competitive prints and slides will be on view at the exhibition from April 27th to 30th inclusive, in addition to which, in order to make the exhibition as interesting as possible, outsiders as well as members are invited to send in any kind of photographic work for exhibition only. This invitation to outsiders is a new departure, which, we think, other societies, while in their infancy, might copy with advantage. They will, as time rolls on, learn to run alone. Such exhibits to be sent to the hon. secretary, Mr. Frank Crosoer, 13, Market Place, Faversham, not later than 23rd April.

## Notes.

Those whose knowledge of astronomy is limited to a vague conception of the solar system as implanted in their youthful minds at school, are apt to be somewhat disappointed when they see photographs of the planets. They have heard so much of the wedding of the telescope with the camera, and the marvellous results which that union has brought about, that they have been prepared to expect the photographs of Jupiter and Saturn to be as clearly defined as those of the moon, not understanding the great difficulties in procuring pictures of the more distant bodies. Mr. E. W. Maunder, in a paper on "Photography as Applied to Astronomy," recently read before the Lantern Society, dealt with these difficulties in a masterly manner, and reminded his hearers that the very moderate light available did not admit of quick exposures, while the rapid rotation of the planets on their axes prevented those long exposures being resorted to which had been productive of such wonderful results in the case of the fixed stars and of the nebulæ. The photographs, under such conditions, naturally left much to be desired, and could not compare favourably with the records obtained by a skilful draughtsman.

---

The artist has another advantage over the photographer in the delineation of planetary wonders in the use of colour. That this is an important point may be shown by a consideration of the appearance of the ring-girdled Saturn. To the naked eye, this planet is far inferior in brightness and general appearance to either Jupitei or Venus, and we all know how the ancients associated it with the dullness and heaviness of lead. How different it appears in the field of the telescope is well described by the late Mr. R. A. Proctor. He writes: "We turn a powerful telescope on some calm, clear night, when the air is well suited for observation, and we see the most beautiful picture conceivable—a glorious orb, the surface resplendent with the most beautiful colours, blue at the poles, yellow elsewhere, crossed by a creamy white central pelt, and flecked with spots, which, under favourable circumstances, show brown, and purple, and ruddy tints. The most wonderful part of the picture, however, is the amazing ring-system," &c. The beautiful tinted pictures which have been drawn by skilled artists of Jupiter and Saturn must be compared with the photographs—those, for instance, published in Admiral Mouchez's *La Photographie Astronomique*—before it can be seen how the latter fail in rendering a true interpretation of the objects which they profess to portray.

---

In the case of the nebulæ, as Mr. Maunder remarked in his lecture, photography leaves all records founded on visual observations far behind, and the details of photographs taken by Mr. Common and Mr. Roberts have resulted iu a great extension of our knowledge of such bodies. The lecturer did well to illustrate his remarks by the lantern, for he was able to show his audience how, in the case of the planets, the artists were ahead of the camera, and how the latter far outdistanced all competitors in the case of the nebulæ. By comparing the drawings in both cases with the photographs of the same objects, the matter was made clearer than it could have been by any other possible means.

---

Among the capital pictures produced some years ago by the Society for Photographing Relics of old London, was one of the house in Bishopsgate Street occupied in the reign of James I. by a merchant prince, and since sunk to the level of a "public" called, after his name, "The Sir Paul Pindar." It was hoped that this interesting old place, with its projecting stories and carved wooden front, would have for some further time escaped the hand of the destroyer; but modern improvement and the demands of a railway company said no, and Sir Paul Pindar's house has gone. But we were glad to think that someone at least has had the foresight to preserve something more than the photograph for future generations to look upon. The handsome wooden frontage of Sir Paul's mansion is now being erected in the architectural section of the South Kensington Museum, where possibly it will attract more notice than it did in the busy thoroughfare from which it has been removed.

---

It has often been demonstrated that gelatine plates, besides being extremely sensitive to light—as they are expected to be—are also most sensitive to the attentions of less desirable acquaintances. Damp is naturally the most dangerous of these, but cases have been recorded where a strongly smelling compound placed in the same receptacle with a packet of plates has fogged the latter beyond redemption. In one case that we know of plates were sent by parcel post in a box which had contained curry powder, with the lamentable result just named.

---

Messrs. Wratten and Wainwright have recently adopted a means by which such accidents to plates may be altogether obviated. They are supplying a well made tin box in which will tightly fit a packet of their plates of any standard size, and at such a cheap rate that no careful photographer will omit to make use of them. Such boxes, it is evident, will not only be useful for the storage of plates, but will also be invaluable for the safe keeping of negatives, especially as they are of such a form that they cau be stored away in bookshelves. A coat of enamel paint aud a label would make such a mode of preserving one's negatives as neat a one as could possibly be wished.

---

M. Deslandres, the chief of the Spectroscopic Department of the Paris Observatory, confirms Herr Vogel's evidence as to the error in photographs taken by Mr. Fowler at South Kensington of *α Lyræ*, by which this star was made to appear as though it were double. Mr. Fowler's paper, it will be recollected, was read at the Royal Astronomical Society in November, and Herr Vogel's communication was placed before the Society a few weeks ago. M. Deslandres says that a photograph was taken of this star on the same day and at the same hour as that on which Mr. Fowler's photograph was made, and that the line K was thin and single. A Fellow of the Royal Astronomical Society, commenting on the matter, says that the Astronomical Department has, it is understood, achieved photographs of Rigel with certain lines tripled, and it becomes a curious subject of speculation how far they will advance in this direction if the projected railway should pass underneath the building. Perhaps vibration from some cause not suspected gave rise to Mr. Fowler's double effect.

---

In America there seems to be a wider and more general interest taken in astronomy than in England. This is evidenced by the great number of visitors to the Lick Observatory during the summer months. It is open to the public every Saturday night, and, in spite of the great distance from the nearest town (San José, 26 miles), strings of coaches frequently bring up as many as two or three hundred visitors. We are afraid if a proposition were made that the Observatory at Greenwich should be open to the public once a week, a cry of horror would go up from every official, to which the protest made by Sir Joseph Hooker when it was suggested that Kew Gardens might be opened before one o'clock, would be insignificant indeed. Apparently, they manage these things better in America.

---

A visit to the popular places of resort where the itinerant photographer once did most abound discloses the fact that this once popular individual has become very scarce. What may be the reason we cannot say. Perhaps the race is dying out simply for want of renewal from the outside; or it may be that the public no longer care for the pleasures of the ferrotype. In spite of the increase of the number of amateur photographers who are now to be found in almost every class of society, we do not think that the peripatetic operator has suffered from the competition. But whatever the cause may be, the fact remains that the out-door photographic business has of late sadly diminished, and only those firms do a fair amount of trade who possess facilities for taking photographs by artificial illuminants. The novelty of this lends a little attraction, but here it stops, for those who look upon their photographs so taken are not disposed to make a second experiment. The result is frequently too awful.

---

The instructions issued by the Berlin Exhibition authorities in connection with contributions of illustrated books require a little explanation. The invitation to publishers of such works says: "In the case of original work, any kind of reproduction is allowed; in the case of reproductive work, only an artistic form of reproduction is admissible, such as engraving, etching, lithography, and wood-engraving." It will be noticed that photography is conspicuous by its absence. As the instructions stand, they appear to mean that books illustrated by photographic reproductions from original drawings may be exhibited. Other works illustrated by photography are not admissible, because, according to the inference of the wording, photography is not "an artistic form of reproduction." Surely this cannot be intended.

---

The Stereoscopic Company has again paid a five per cent. dividend—not a phenomenal rate of interest on money invested, but, according to Mr. Howard J. Kennard, the chairman of the annual meeting held last week, quite an average one. It is satisfactory to note this, and that the Company's new premises are likely to see an increase in the business. The lift which takes the sitters to the studio has had an exceedingly good effect—a result which is not surprising, as many people, old persons especially, regard the task of mounting four or five flights of stairs an insuperable obstacle. Mr. Kennard says that the new building of the Company, its fittings, decorations, and arrangements, make up "the finest photographic establishment in the world."

---

The necktie camera has received notice at the hands of the *Societé Francaise Photographie*, a paper on M. Block's invention having been read at the last meeting by M. Londe. M. Londe hints at a possible terror in this necktie. He says it has been the reproach of the amateur that he has committed a host of indiscretions with his detective apparatus. With the *photo-cravate* it will be worse, as it will be difficult for the most astute to avoid being caught. As, however, the lens is fixed in the centre of the head of a scarf pin, the only way will be to avoid those persons who wear suspicious looking cravats of this kind.

---

The commencement of the photographic tourist season is foreshadowed by an announcement made at the last meeting of the *Societé Francaise Photographie*, that an enterprising firm had placed at the disposal of the Society labels for attachment to photographic baggage, so as to protect it from the too curious examination of the Custom House officer. The notices contained on these labels are printed in all languages, and all one has to do is to stick them on the place reserved on the sheet of red paper with the black star, which is the design approved by the International Photographic Congress. We presume that such labels are procurable at London photographic establishments; if not, they should be, as their use will save the tourist much trouble. If travellers are wise, however, they will not use their cameras in France. It is quite impossible to know when you are infringing a military regulation.

## THE PHOTOGRAPHIC SCHEME OF THE BODLEIAN LIBRARY.

BY JULIUS F. SACHSE.

Within the last few months renewed attention has been called to the use of photography in the large libraries. All students know the great importance of having valuable manuscripts duplicated photographically. The same applies to important pages of books, rare engravings, portraits, plans, and legal documents, which, by reason of their value, age, or deterioration of texture or fading of the inscription, can be handled or examined only with the greatest care, under the direct supervision of the custodian in charge.

The latest effort in this direction appears to have been made by the management of the Bodleian Library at Oxford, in connection with the University Press. This scheme has been heralded in the daily press far and wide as a solution of the problem, and placing the means within reach of all. But while we agree that it is difficult to estimate the extent to which the usefulness of a library *might* be increased by such arrangements, we cannot refrain from saying that the whole matter as quoted is misleading and impracticable, to say the least, at the ridiculous rates mentioned. Further, the broadcast publication of the matter in the present shape is an injustice and a direct injury to such photographers who make a specialty of that branch of photography, which often requires the highest intelligence in addition to their skill as photographers.

We cannot but think that the parties who formulated the schedule of prices have had but little or no practical experience, either in the line of the average run of library, copying, or in practical photography. We quote the original notice as issued, viz. :—

"The controller of the University Press, Oxford, is prepared to take photographic negatives from MSS., printed books, &c., belonging to the library or deposited there, and to supply prints at the following rates, permission having been first obtained from the librarian :—

| | s. | d. |
|---|---|---|
| For a 10 by 8 negative taken at the library ... | 3 | 0 |
| For a silver print (unmounted) from a 10 by 8 negative ... ... ... ... ... | 0 | 4 |
| For a platinotype print from a 10 by 8 negative (With regard to platinotype prints, the price must vary with cost of the special paper. It will probably increase from time to time.) | 0 | 10 |
| For a carbon print from a 10 by 8 negative ... | 0 | 10 |
| For 20 collotype prints, with clean margins, from one 10 by 8 negative ... ... ... ... | 5 | 6 |
| For 50 collotype prints, with clean margins, from one 10 by 8 negative ... ... ... ... | 9 | 0 |
| For 100 collotype prints, with clean margins, from one 10 by 8 negative ... ... ... | 12 | 0 |

"Estimates for larger sizes or greater numbers may be had on application.

"The sums quoted above are given on the assumption that only *ordinary trouble will be involved* in making the negatives and prints."

If we mistake not, the price for a photographic copy of an ordinary subject in the British Museum and other libraries in England has heretofore been a guinea. In this country the average price has been five dollars—a price which, to an outsider, at first would seem high, but, as will be found in actual practice, it will not pay any competent man to undertake the work for a much less sum.

The writer has probably had as great and varied experience in this line of photography as any one in this section of the country, consequently can speak from experience. Firstly, the work has to be done in the library building, where there are no special provisions for photography, the apparatus having to be sent to the library for the purpose.

Secondly, on account of the great difference in the character of the subjects, often varying from, say, the title of a 24mo. missal to a map 6 by 8 feet, a different apparatus has to be improvised for almost every exposure.

Thirdly, as to the MSS., they require the most careful handling. The parchment is often discoloured and the ink so faded that it is almost impossible to obtain any result suitable for reproduction, the colour values of parchment and writing being almost equal. Then, again, the light is usually a side light, more or less dim, for which allowance must be made. Then, as there are no facilities in the library for development or testing the plates, from two to six plates have often to be exposed on the same subjects in different times, to ensure at least one perfect plate, and prevent the necessity of going over the same ground.

With oil paintings—usually old, cracked, and discoloured—the difficulties are still greater. Assistance is often needed to take down and place into position ; then, again, under the peculiar circumstances, it is often necessary to expose through a colour-filter, thus lengthening the time of exposure from minutes to hours.

The handling of old books—frequently priceless gems, brittle with age and shaky in their bindings—requires the greatest care, and are not to be trusted to anyone with impunity to truss up in front of a camera.

All these little matters mentioned above occur in actual practice. Each subject, it will be found, requires the most careful study and manipulation, which often necessitates a loss of valuable time. In addition, this work requires a degree of judgment and skill which, unfortunately, is not to be found in the composition of every button-presser or amateur-professional who would count himself capable for this branch of photography.

While, at first glance, it would seem to be the easiest matter to photograph the page of a book, the tyro, if he make the attempt with the usual apparatus at the disposal of the average photographer, will soon find that to get the page square upon the plate and properly lit is not near so easy as it seems when we look upon a finished print made by an expert.

It is to be assumed that the authorities in charge of the Bodleian Library have made every provision for development and ordinary copying, securing the best and latest apparatus; but even then they will find that there are many difficulties to be overcome in the practical working of the scheme, not the least of which will be to obtain talent of the order requisite to produce results which will satisfy the patrons of the photographic department, without injury or detriment to the property of the library or museum. Talent of this calibre costs money, and, even without taking into consideration the uncertain demand, and the usual delays from bad weather, which all causes loss, we doubt if they can make the departure a paying success at the formulated rates, unless the management stoop to the questionable plan of assuming that every negative "involves more than ordinary trouble," and then charge accordingly.

## REPORT OF PROGRESS IN SPECTRUM WORK.*

BY PROFESSOR HENRY A. ROWLAND.

DURING the past year or two a great deal of work has been done in the photography of the spectra of elements and the identification of the lines in the solar spectrum, which it will take a long time to work up ready for publication. Hence, I have thought that a short account of what has been done up to the present time might be of interest to workers in the subject. In the prosecution of the work, financial assistance has been received from the Rumford Fund of the American Academy of Arts and Sciences, as well as from the fund given by Miss Bruce to the Harvard Astronomical Observatory for the promotion of research in astronomical physics, and the advanced state of the work is due to such assistance.

The work may be summed up under the following heads:—

1. The spectra of all known elements, with the exception of a few gaseous ones, or those too rare to be yet obtained, have been photographed in connection with the solar spectrum, from the extreme ultra violet down to the D line, and eye observations have been made on many to the limit of the solar spectrum.

2. A measuring engine has been constructed with a screw to fit the above photographs, which, being taken with the concave grating, are all normal spectra, and to the same scale. This engine measures *wave-lengths direct*, so that no multiplication is necessary, but only a slight correction to get figures correct to $\frac{1}{100}$th of a division of Angstrom.

3. A table of standard wave-lengths of the impurities in the carbons, extending to wave-length 2,000, has been constructed to measure wave-lengths beyond the limits of the solar spectrum.

4. Maps of the spectra of some of the elements have been drawn on a large scale ready for publication.

5. The greater part of the lines in the map of the solar spectrum have been identified, and the substance producing them noted.

6. The following rough table of the solar elements has been constructed entirely according to my own observations, although, of course, most of them have been given by others.

I do not know which are the new ones, but call attention to Silicon, Vanadium, Scandium, Yttrium, Zirconium, Glucinum, Germanium, and Erbium, as being possibly new.

Silicon has lines on my map at wave-lengths 3905·7, 4103·1, 5708·7, 5772·3, and 5948·7. That at 3905·7 is the largest and most certain. That at 4103·1 is also claimed by manganese.

These tables are to be accepted as preliminary only, especially the order in the first portion. However, being made with such a powerful instrument, and with such care in the determination of impurities, they must still have a weight superior to most others published.

The substances under the head of "Not in the Solar Spectrum" are often placed there because the elements have few strong lines, or none at all, in the limit of the solar spectrum when the arc spectrum, which I have used, is employed. Thus, boron has only two strong lines at 2497. Again, the lines of bismuth are all compound, and so too diffuse to appear in the solar spectrum; indeed, some good reason generally appears for their absence from the solar spectrum. Of course, this is little evidence of their absence from the sun itself. Indeed, were the whole earth heated to the temperature of the sun, its spectrum would probably resemble that of the sun very closely.

ELEMENTS IN THE SUN, ARRANGED ACCORDING TO THE INTENSITY AND THE NUMBER OF LINES IN THE SOLAR SPECTRUM.

| According to Intensity. | According to Number. |
|---|---|
| Calcium. | Iron (2,000 or more). |
| Iron. | Nickel. |
| Hydrogen. | Titanium. |
| Sodium. | Manganese. |
| Nickel. | Chromium. |
| Magnesium. | Cobalt. |
| Cobalt. | Carbon (200 or more). |
| Silicon. | Vanadium. |
| Aluminium. | Zirconium. |
| Titanium. | Cerium. |
| Chromium. | Calcium (75 or more). |
| Manganese. | Scandium. |
| Strontium. | Neodymium. |
| Vanadium. | Lanthanum. |
| Barium. | Yttrium. |
| Carbon. | Niobium. |
| Scandium. | Molybdenum. |
| Yttrium. | Palladium. |
| Zirconium. | Magnesium (20 or more). |
| Molybdenum. | Sodium (11). |
| Lanthanum. | Silicon. |
| Niobium. | Strontium. |
| Palladium. | Barium. |
| Neodymium. | Aluminium (4). |
| Copper. | Cadmium. |
| Zinc. | Rhodium. |
| Cadmium. | Erbium. |
| Cerium. | Zinc. |
| Glucinum. | Copper (2). |
| Germanium. | Silver (2). |
| Rhodium. | Glucinum (2). |
| Silver. | Germanium. |
| Tin. | Tin. |
| Lead. | Lead (1). |

| Arsenic. | Gold. | Selenium. |
| Bismuth. | Indium. | Sulphur. |
| Boron. | Mercury. | Thallium. |
| Nitrogen (vacuum tube). | Phosphorus. | Praseodymium. |

SUBSTANCES NOT YET TRIED.

| | | |
|---|---|---|
| Bromine. | Oxygen. | Holmium. |
| Chlorine. | Tellurium. | Thulium. |
| Iodine. | Gallium. | Terbium, &c. |
| Fluorine. | | |

With the high dispersion here used, the "basic lines" of Lockyer are widely broken up and cease to exist; indeed, it would be difficult to prove anything except accidental coincidences among the lines of the different elements. Accurate investigation generally reveals some slight difference of wave-length or a common impurity. Furthermore, the strength of the lines in the solar spectrum is generally very nearly the same as that in the electric arc, with only a few exceptions—as, for instance, calcium. The cases mentioned by Lockyer are generally those where he mistakes groups of lines for single lines, or even mistakes the character of the line entirely. Altogether, there seems to be very little evidence of the

* *Johns Hopkins University Circulars*, vol. x, No. 85.

breaking up of the elements in the sun, as far as my experiments go.

Even after comparing the solar spectrum with all known elements, there are still many important lines not accounted for. Some of these I have accounted for by silicon, and there are probably many more. Of all known substances, this is the most difficult to bring out the lines in the visible spectrum, although it has a fine ultra-violet one. Possibly iron may account for many more, and all the elements at a higher temperature might develop more.

Then, again, very rare elements, like scandium, vanadium, &c., when they have a strong spectrum, may cause strong solar lines, and thus we may look for new and even rare elements to account for very many more. Indeed, I find many lines accounted for by the rare elements in gadolinite, samarskite, and fergusonite other than yttrium, erbium, scandium, praseodymium, neodymium, lanthanum, and cerium, which I cannot identify yet, and which may be without a name. For this reason, and to discover rare elements, I intend, finally, to try unknown minerals, as my process gives me an easy method of detecting any new substance or analysing minerals, however many elements they may contain.

The research is much indebted to the faithful and careful work of Mr. L. E. Jewell, who has acted as my assistant for several years. Preliminary publications of results will be made in the *Johns Hopkins University Circulars*.

Among the latest results, I may mention the spectroscopic separation of yttrium into three components, and the actual separation into two.

## HYDROQUINONE *VERSUS* EIKONOGEN.

We have noted lately a considerable amount of discussion in the foreign journals about the relative merits of hydroquinone and eikonogen. Two French experimenters, Balagny and Reeb—the former on hydroquinone, the latter on eikonogen—have been making quite a number of tests that are of special interest to the working photographer. Balagny says that he has been using hydroquinone for two years,and has found its reducing power so great that he has not had to abandon it once since he has studied it. But he also says that the first formulæ given when the hydroquinone was introduced caused two difficulties: first, the bath soon became brown and stained the negative; and second, the development with a new bath produced hard negatives. After experimenting on these difficulties, M. Balagny has come to the conclusion that the carbonates of the alkalies are responsible for the colour of the negative, especially sodium carbonate, while the hardness of the results is due to alkaline carbonates generally. To overcome these defects, he recommends the use of caustic potash as an alkali. The formula given consists of two parts, as follows:—

*Solution* No. 1.

| | |
|---|---|
| Sodium sulphite ... ... ... | 250 grammes |
| Water ... ... ... ... | 1,000 c.c. |

Dissolve with heating, and add—

| | |
|---|---|
| Hydroquinone ... ... ... | 20 grammes |

*Solution* No. 2.

| | |
|---|---|
| Potash (by lime or by alcohol) ... | 100 grammes |
| Water ... ... ... ... | 900 c.c. |

After solution is complete, add the following mixture, which is best made with heat:—

| | |
|---|---|
| Potassium ferrocyanide ... ... | 50 grammes |
| Water ... ... ... ... | 100 c.c. |

This last gives softness, and preserves the whites.

It is also well to have on hand a 10 per cent. solution of potassium bromide.

The method of using these solutions is as follows:—For a plate 13 by 18 centimetres (5 by 7 inches) take—

| | |
|---|---|
| Solution No. 1 (hydroquinone) ... ... | 80 c.c. |
| Bromide solution ... ... ... | 1 ,, |
| Water ... ... ... ... ... | 40 ,, |

This constitutes the developing bath for instantaneous exposures.

The above mixture is poured over the plate in the developing dish, and allowed to remain till the film is thoroughly soaked—say thirty seconds. The fluid is now poured out of the dish into another vessel, and 2 c.c. of the potash solution No. 2 are added, and the mixture returned to the plate in the dish. Allow the fluid to act on the plate a few seconds to see if the image will appear. If the image does not appear, add another 2 c.c. of the alkali and wait again for the appearance of the image, adding the solution in this manner until the picture just begins to appear; the development will now proceed without farther additions. As a means of bringing out the last details in the shadows, 2 c.c. of the alkali solution may be added when the development appears complete to the eye.

The bath given above will develop one dozen negatives if care is taken. After use the bath should be returned to the bottle, and the latter carefully closed for exclusion of air. To start the development of a new series of instantaneous exposures, a bath may be made as follows:—

| | |
|---|---|
| Bath already used ... ... ... | 60 c.c. |
| Solution No. 1 ... ... ... ... | 60 ,, |

The addition of bromide is not necessary, as the bath contains enough from the former development; but solution No. 2 must be added with the same care as before, using only 2 c.c. at a time until the high lights begin to appear. This last bath will answer for a new lot of exposures.

For time exposures the bath is made up as follows:—

| | |
|---|---|
| Solution No. 1 (hydroquinone) ... ... | 40 c.c. |
| Bromide solution ... ... ... | 4 ,, |
| Water ... ... ... ... ... | 80 ,, |

The method of using is exactly the same as with instantaneous exposures, always searching for the limit of development, the additions of No. 2 being always 2 c.c. at a time.

Working in a somewhat different line of research, M. Reeb has determined, by a series of careful experiments, the best proportions to mix the hydroquinone with sulphite of sodium and potassic hydrate to give the most satisfactory results in development. For this purpose, he determined the actual reducing power of hydroquinone upon a given quantity of silver oxide, also the best quantities of alkali or alkaline carbonate to use under these conditions, and, at the same time, the quantity of sulphite of sodium for the best working of the developer. Taking silver nitrate as a standard, he found that 0·08 grammes of hydroquinone would reduce 1 gramme of the salt. In the case of sulphite, he found the use of too much was injurious, and finally came to the conclusion that the following proportions are the best to use:—

*Hydroquinone and Potash.*

| | |
|---|---|
| Hydroquinone ... ... ... ... | 1 gramme |
| Potassium hydrate ... ... ... | 1 grammes |
| Sodium sulphite ... ... ... | 7·5 ,, |

*Hydroquinone and Carbonate.*

| | | |
|---|---|---|
| Hydroquinone | ... | 1 gramme |
| Sodium carbonate | ... | 10·5 grammes |
| Sodium sulphite | ... | 5 ,, |

If other alkalies are desired, they may be used in the following proportions:—

| | | |
|---|---|---|
| Sodium hydrate | ... | 2·85 grammes |
| Potassium carbonate | ... | 4·92 ,, |

To be used with 1 gramme of hydroquinone.

Applying the same set of tests to eikonogen, M. Reeb found that 1 gramme of silver nitrate requires 0·33 gramme of this developer to completely reduce it, together with the same quantities of the alkalies found necessary for hydroquinone. As with the last compound, sulphite of sodium affects the development within certain limits. A mixture of sulphite and eikonogen without alkali will have some reducing power, but the action will be slow. Using the sulphite as a preservative of the eikonogen, five parts of the salt are needed for one part of eikonogen. If, on the other hand, an alkali is used, this amount is increased to ten parts.

Commenting on the results obtained in these experiments, M. Reeb comes to the conclusion that hydroquinone is better than eikonogen, and he gives the following formulas for comparison.

To reduce 1 gramme of silver nitrate, using hydroquinone, the following proportions are required:—

| | | |
|---|---|---|
| Hydroquinone | ... | 8 grammes |
| Potassic carbonate | ... | 40 ,, |
| Sodium sulphite | ... | 40 ,, |
| Water | ... | 1,000 ,, |

Using eikonogen, 1 gramme of silver nitrate requires:—

| | | |
|---|---|---|
| Eikonogen | ... | 33 grammes |
| Potassic carbonate | ... | 40 ,, |
| Sodium sulphite | ... | 300 ,, |
| Water | ... | 1,000 ,, |

It will be noted that, in the last formula, there is four times the amount of eikonogen that there is hydroquinone in the first. In the last formula the sulphite is eight times that used in the first.

M. Reeb acknowledges that hydroquinone is slower than eikonogen, but only under the ordinary conditions, and not when used properly. As a rule, its action is retarded by the use of too much sulphite.

Drawing our own conclusions from the above-mentioned results of both experimenters, we should say that the developer of Balagny, with a reduction of the sulphite to 150 grammes, would prove the most desirable to use, and his method of development is one that we can strongly recommend from our own experience. The use of ferrocyanide was advocated by Captain Eugene Himly in the "International Annual" several years ago, and Dr. Eder and Professor Lainer, of Vienna, have confirmed his results quite recently.

When the question of economy is of no importance, a mixture of hydroquinone and eikonogen will be found very effective, but the hydroquinone alone is only a trifle behind it when used with potassic hydrate.

Now is the time for the amateur to experiment with developers, and not wait till the fine weather comes. For him we would strongly recommend an attack on the hydroquinone and eikonogen question on the above lines. —*Anthony's Photographic Bulletin.*

Photographic Club.—The subject for discussion on April 8th will be, "The Development of Instantaneous Exposures"; April 15th, "Printing on Emulsion Papers."

## STEREOSCOPIC PHOTOGRAPHY.

BY EDWARD D. LEDYARD.

I am glad to see that this most beautiful of all the accomplishments of photography is taking a rise and becoming popular again. Personally, I use only a stereoscopic camera. My wife has protested against getting any more frames in our house, and the 8 by 10 camera has been laid on the shelf. She thought perhaps she would henpeck me a little when she issued this mandate, but, on the contrary, she was leading me to greater enjoyment than I had ever had in my "crank" before. I am glad, however, that I began to make 8 by 10 pictures first. The knowledge which I thus gained in the choice of subject and in lighting and expression is invaluable to me in the production of stereoscopic pictures. I give just as much thought and just as much work in the selection of a stereoscopic view as I did with an 8 by 10, and I do not know but what a little bit more. Since my number of negatives has largely increased, I begin to suspect my wife of having a larger knowledge of things, for, to use her own remarks in the matter, she "finds the stereoscopic views very helpful on many occasions."

To begin with, we have two very excellent hand-stereoscopes. If we have children to manage, or if we have company, the hand-stereoscopes are brought out, the views are divided among them, and the parties are kept busy and amused and interested by looking at them. Indeed, I have grown to believe that nothing that photography can produce can give one-half the pleasure that a good stereoscopic view does.

As an amateur, I find or discover qualities or points in my results which I did not dream were there until I saw the prints in the stereoscope. I use a 5×8 plate, from one end of which I can print my lantern slides, or I can print single pictures and mount them on small cards and make them acceptable presents to my friends, when I feel that I have been smart enough to secure a view that is worth diffusing. Of course, this is about as much as an amateur can see in stereoscopic photography, but during the last summer's season I was taught a great deal more from somebody else. I happened to be on the portico of an hotel down on Long Island, when not a book-agent but a seller of stereoscopic views—or, if you choose to call him so, a stereoscopic-view agent—came along. He had a pack of boxes, each one containing a stereoscope, in one hand, and a heavy satchel containing views in the other. He opened his pack on the portico and worked the resorters there for all they were worth. I was surprised to learn that some of the people there had never looked through a stereoscope, not to say owned one. They have ceased to sin in this direction. The young man converted them. They are now the happy possessors not only of a stereoscope, but have made a good beginning toward a collection of views. One of them, who is my neighbour and who leads a leisurely life, has become "insane" on the subject. He says he is "going to have a stereoscopic view of every subject which it is possible to obtain." I know that a few years ago there were many people insane in the same direction. They had large and wonderful collections. I predict that the same thing is coming about again. The stereoscopic view is coming into fashion, and it is coming back to increase. It is to be the future of photography, out of doors as well as in doors. The facilities afforded by the dry plate of to-day enable the photographer to make stereoscopic portraits without number. I have made a few attempts in this direction, and they are perfectly charming. It is almost life to see one of your children, or one of the older members of the family, standing out round and full and life-like, as they do under the magic influence and power of the stereoscope. "By the gods, I never saw anything so fine," was the expression of an enthusiastic veteran friend, one who had travelled over a good portion of the world, as he looked at some of my stereoscopic portraits. Every day I grow more and more of the opinion that the good old chappie was right. If I dared to make another prediction, it would be that stereoscopic portraiture is the direction in which the photographer who is complaining of "bad times" should work. Take pains, use a good stereoscope with prisms sufficiently large to cover the picture, and take my word for it there is money in it.—*Wilson's Photographic Magazine.*

### Specifications Published.

2,034. *Feb. 7th,* 1890.— "Walking-stick Camera Tripods." Archibald Griffin Rider, 11, Jewry Street, Winchester, Hants.

This invention relates to that class of tripod camera stand which is made in the form of a walking-stick for convenience in taking about.

It is composed of preferably three sections or legs, in or upon each of which slides an extension piece, preferably at the top end, in which case the extension pieces are jointed together so as to allow of the legs being extended to secure a firm basis. The plate to which the legs or extension pieces are jointed may be provided with a screwed or other pin upon which the camera may screw direct, or upon which a suitable plate may be screwed for the camera to rest upon.

Any convenient form of sliding arrangement may be provided for the extensions, but I prefer to form a suitable slot in the leg, and shape the extension to the proper curve on the outside, so as to complete the circle of the walking-stick while its inner face is cut at the proper angles, so that when close together the inner faces of the three extensions may fit as required. When the extension passes entirely through the substance of the leg, I prefer to bind the latter with one or more bands, preferably of brass, so as to keep it sufficiently strong, and any suitable form of stop may be provided to prevent the extensions from pulling out altogether, or to return them in their closed-up position. Such a stop may either be a positive stop, as a projection provided upon the extension, or it may be effected by having the inner end of the extension too large to pass the band already mentioned.

The cap which closes all in at the top, and forms an ornamental head or handle to the stick, I prefer to form hollow so as to slip over the joint plate, and arrange it to screw on to the screwed pin previously mentioned.

At the bottom end any suitable form of ferrule may be provided to hold the ends together and protect them, and this may be secured by any suitable form of stop, or, if desired, may be formed into sections, and I prefer to slip a metal ring up the stick, which, being preferably tapered, will provide a bearing for the ring in the proper place.

14,004. *Sept. 5th,* 1890.—"Cameras." Charles Cope Gill, 5, Hornsey Rise, London, Photographer; and James Gentry Evans, 70, Sunnyside Road, Hornsey Rise, London, Builder.

Our invention relates to improvements in photographic cameras of the class known as detective, hand, or box cameras, and has for its chief object mechanism for storing and exposing the sensitised plates.

In carrying our invention into practice, we form our box camera of two parts, or receptacles, hinged together. The front part is divided horizontally in two compartments by a centrally-slotted partition. The upper compartment contains the bellows and lens, and has a flap or shutter at the back moved by a small handle projecting on the side of the front receptacle; this flap or shutter discloses or shuts off the light. The lower compartment is used for storing an additional number of plates or other requisites. The rear receptacle is closed in front by a double-jointed dark slide capable, when withdrawn, of being folded over the back of the said receptacle. The latter contains a sliding case formed of a lower enclosed compartment, and of an upper and open part whereat the exposure takes place. The lower or dark compartment is furnished at each side with an equal number of corresponding guides, between which the sensitised plates can move up and down. These plates are inserted between the inwardly curved and longitudinal edges of metallic plates designed to protect them, at the back. To the end of the rear receptacle is hinged a bar passing through the end of the sliding case, and which, when the said case is pushed back home into the receptacle, it extends over its lower compartment and carries in that position the sensitised plates ready for exposure. When the sliding case is withdrawn from its receptacle, the above bar is likewise drawn back from the dark compartment, when, by reversing the apparatus, the plates are dropped in the upper part of the case, and, by turning the latter back, the bar is moved over the dark compartment, so that when the apparatus is brought back into its original position, these plates rest, as above stated, upon the said bar, when, the two parts of the apparatus being connected, the dark slide raised, and the flap or shutter open, the exposure of the foremost plate can take place.

When this is effected, the sliding case is moved slightly forward so as to drop the exposed plate between the front guides of the dark compartment below. The next plate can now be exposed, the above operation being repeated until all the plates have been exposed. The motion of the sliding case is effected by a rack-and-pinion, the latter being operated from the outside. A dial, indicating the number of exposed plates, is attached to the rear receptacle. The bellows and lens can be moved to and fro by a lever pivoted thereto, the pivot passing through the slot of the partition aforesaid, while the lever passes through another slot formed in the side of the apparatus so as to be operated from the outside.

The apparatus is closed in front by a lid hinged centrally and carrying a finder inside. The camera may be carried in the hand or used on a stand.

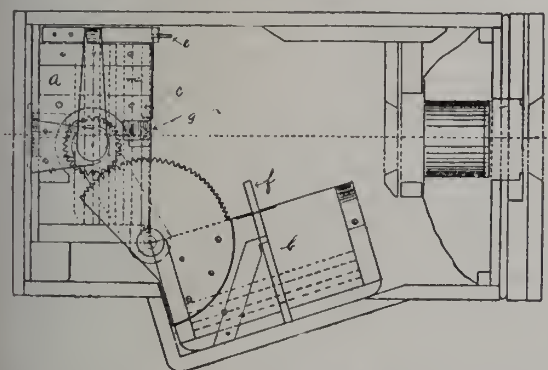
As our improvements are capable of some modifications without departing from the principle thereof, we do not restrict ourselves to material, dimensions, or to the precise form or placement of the several parts thereof.

16,778. *October 24th,* 1889. — "Improvements in Photographic Cameras, and in Apparatus connected therewith." Samuel Dunseith McKellen, 3, Chapman Street, Manchester.

The first part of my invention has for its object an easy means of carrying any convenient number of plates in one storage box, so that they may be exposed one after another, and an easy means of transferring the exposed plate from its position in the storage box into a separate receptacle.

A chamber or magazine is provided at that end of the camera which is opposite to the lens. This chamber is made to contain any convenient number of plates, preferably one or two dozens, the sensitive films being towards the lens. The plates are pressed forward against a frame by suitable springs, which exert sufficient pressure at the back of the plates to ensure that the front one shall be always kept in proper register. The tranferring of the front plate, after exposure, to the receiver may be effected in the following manner:—

The receiver is in the form of a box without a lid, which lies in the bottom of the camera, and is swivelled or hinged by one end or side, close to the front of the magazine, in such a way that it may be closed up against the front of the magazine, the open side of the box being next the magazine. The frame before mentioned, which forms the register, separates the magazine from the box. This closing up may be effected by any suitable mechanical contrivance. The register frame is formed by a rail from top to bottom on each side in front of the magazine. The plates are contained in metallic sheaths, which cover the back, clip the edges, and slightly overlap the film. These sheaths have projections at the sides, two or four or any convenient number. These projections rest upon the rails which stand clear of the sheaths. The rails have gaps cut in, corresponding in number and relative position to, but slightly above or below, the projections on the edges of the sheaths. Now it is clear that if the magazine is turned up so that the front plate faces downwards, and the front plate is slided along until the projections enter the gaps, the plate and its sheath will fall through into the receiver below, and the second plate will assume the position formerly occupied by the first—the projections of its sheath resting upon the solid parts



of the rails. The receiver will then be returned to its normal position on the bottom of the camera. The plates lying face downwards in the receiver are protected from light by the sheaths, and an additional protection can be provided.

The second part of my invention is to provide a cover for cameras of all kinds which have to be carried about. This cover is intended to dispense with the use of a carrying case. For this purpose, I employ any material of which camera cases are usually made. I cover the base-board of the camera with the material, attaching it by means of studs placed in a convenient position, or by any convenient means. I make an opening in the centre of the material corresponding in size to the turntable in my camera, or large enough to allow a triangle to be screwed to the base-board, or with only a small hole through which a base-board screw may pass. I make this material of such size and shape that it will fold over and cover all of the camera when it is folded up. It can then be fastened by buckles, or in any convenient way, so as to appear as if the camera were in a case.

The advantage of this cover is that the camera can be mounted on its legs and, the cover being unfastened, the camera can be opened, leaving the cover still attached to the base-board; the camera, cover, and legs attached can then be carried about when photographing from one point of view to another much more easily, as there is no empty camera case to handle.

# Correspondence.

## THE NEW RAPID IRON PROCESS.

Sir,—It is curiously suggestive of the difficulty that may beset historians, that there should already be a question as to the personality of the originator of the extraordinarily sensitive iron compound which was announced a fortnight since by Mr. Meldola as having been discovered by Mr. F. Varley.

It has already been suggested that—assuming the accuracy of the statements by Mr. Mendola and Mr. Varley that no silver is employed—this invention is the most important that has for many years appeared in photography, and that a process in which the sensitiveness of an iron compound is exalted to that of a silver bromide emulsion, need not be limited to printing, but may be applied to the camera, with possibly an acceleration of even our present exposures. The desirability of settling the origination of the process is therefore obvious enough, and, at this early stage, should not be difficult.

Mr. Meldola, in introducing the discovery, attributed it to Mr. Varley without mentioning any other name. Mr. Varley, who was present and demonstrated the sensitiveness of the compound by exposing under a negative for a second or so to gaslight, and then developing the print, did not contradict Mr. Meldola's statement, with which, too, the report in the Journal of the Society of Arts and other papers is in accordance. The Editor of the Photographic News, however, in last week's issue, speaks of a contemporary, *Nature*, as being in error in attributing the discovery to Mr. Varley, and names Mr. Friese Greene as the originator. Doubtless this exclusive information is not given without good authority, which may be adduced in the interest of photographic history, and perhaps Mr. Varley would wish specifically to disclaim the origination of the process, and explain why this was not done when he was credited with it by Mr. Meldola.

*March 31st.* W. E. Debenham.

## HOUGHTON'S AUTOMATIC HAND-CAMERA.

Sir,—In your notice of our automatic hand-camera exhibited on the 24th inst. at the Photographic Society, there are two errors which we should be glad if you would correct in your next issue.

It is the front plate that is moved to the back by the changing arrangement, and, what is more important still, the extra depth required is scarcely more than $\frac{1}{8}$, instead of $\frac{3}{4}$, as reported. G. Houghton & Son.

89, *High Holborn, London, W.C., March 26th.*

## THE STORM IN THE NATURALISTIC CRATER.

Sir,—When I wrote my book, I did not write it for my own glorification, but purely and simply with the intention of trying to help the photographic world to give the fullest expression to the very limited art that they practised. I was justified in thinking I might help them by the attention which my own photographs had received in the photographic world. I regretted the loss of several months' work which the preparation of the book cost me, but the spirit of the reformer was strong in me, and it had to find expression. I have since learned that in art matters all attempts to bring others to think as you do are hurtful rather than useful. However, to return. I distinctly stated what claims I thought I had to originality. I claimed that I had attempted to reduce naturalistic teachings (which I said were as old as ancient Greece) to *scientific first principles*, and *to apply those teachings to photography*. That was my claim. I still claim and can prove as much, but I am not so greedy for a character for originality as those "who break new ground in the land of Constable."

The study of development and of new scientific discoveries, psychological and physical, obliged me to renounce my former views, and determined me to break a conspiracy I had long watched with amusement—a conspiracy of which I shall one day write a full history, if only as a study of character.

Amid all this turmoil arose a whisper that I had got some of my ideas from a certain book—I refer to "Naturalistic

Painting." As a matter of dates, my first writing on the subject came first ; as a matter of incidental proof, I mentioned the receipt of a letter. Busybodies have now been round trying to make mischief, but they shall not succeed. Mr. Bate shall see the letter, and its author will explain the matter to me and to Mr Bate, and the misunderstanding shall be removed. This is no public matter, but one which concerns us three only. My writings take precedence of those of Mr. Bate by date. The suggestion that Mr. Bate was in any way influenced by me I have already publicly repudiated. Every day that I live and grow to see art matters more clearly, I deeply regret I was ever in any way identified with Naturalism.

P. H. Emerson.

THE FEDERATION SCHEME.

Sir,—I notice in the report of the meeting *re* the proposed federation scheme, held on the 23rd March last, that my name is mentioned as having been elected a member of the committee. As this was done without my knowledge or consent, and not having been present at any of the meetings, I must protest against this irregular proceeding, and decline to recognise the appointment. Moreover, the greatly increased duties caused by the rapid growth of the South London Photographic Society occupy all my spare time and attention. I do not feel justified in accepting any further responsibilities. F. W. Edwards.

*87, Bellenden Road, E. Dulwich, S.E., March 28th.*

# Proceedings of Societies.

London and Provincial Photographic Association.

*March 25th.*—Mr. T. E. Freshwater in the chair.

The report of the delegates appointed to attend the meeting on the subject of the proposed federation of the London and Suburban Photographic Societies was received.

Mr. A. S. Newman read a paper on "The Measurement of the Speed of Shutters." At the conclusion of the paper, replying to various questions form the members, Mr. Newman said one of the plans he had adopted was to photograph a plate pierced with a certain number of slots moving at a known speed backwards and forwards in front of the camera. By this method he had no difficulty in calculating the speed of a shutter up to an exceedingly small fraction of a second. With a shutter working at 200th part of a second, he estimated that $\frac{1}{50}$th of a second was occupied before the shutter attained its maximum speed. He drew a diagram on the black-board of a shutter he had made. It consisted of a circular plate, from which a section had been cut to form an opening, and made to revolve in front of the lens aperture, controlled by a small piston rod. With one inch aperture a speed of the 750th of a second was easily attained.

Reference was made to a method of direct measurement adopted by Mr. A. Haddon, which gave great accuracy, consisting of a bristle attached to a tuning-fork, and allowing it to trace a curve on a smoked glass surface during the time the shutter was moving.

Mr. Newman explained, by the aid of the black-board, a method of measurement he had employed. A pendulum having an arm fixed at right-angles at the top of it, carrying a bristle, is made to swing in front of a piece of smoked glass, travelling in a lateral direction, and a calculation made from a measurement of the curves produced by the bristle.

Putney Amateur Photographic Society.

*Wednesday, March 25th.*—Mr. T. Gilbert in the chair. The members and friends of this Society spent a most enjoyable evening witnessing an exhibition of some 200 slides, the work of the following members :—Messrs. Congreve, Fauckue, Gilbert, Gorni, Macdona, W. and G. E. Martin, Ovey, and Ballard. The lantern was manipulated by Mr. Ovey.

The "Repeater" hand-camera was shown and explained.

The next meeting will be held on April 8th, when the American slides will be shown.

Photographic Society of Ireland.

A technical meeting was held on Thursday, 26th ult., Mr. H. Bewley in the chair.

A paper on "Some Printing Processes" was read by Mr. M. Hedley, who treated the subject exhaustively, and exhibited a large number of prints in silver, gelatino-chloride, ferro-prussiate, platinotype, bromide, and diazotype. Mr. Hedley advocated the use of green glass for printing, as giving a pluckier picture with a greater amount of detail, and stated that it was pre-eminently suited for matt surface paper. In support of his theory, he exhibited some pictures which were equal in every respect to platinotype prints.

North Middlesex Photographic Society.

The first outing took place on Monday to Rickmansworth. The subjects chosen were Moor Park, the beautiful seat of Lord Ebury, with its magnificent trees and herds of deer. The canal at Rickmansworth and adjacent rivers up to Harefield afforded lovely bits for over one hundred plates. Mr. Chang, with his hand-camera, was well to the front.

The Sheffield Camera Club.

A general meeting was held on March 25th, in the Lower Montgomery Hall, the president, Mr. G. T. W. Newsholme, F.C.S., in the chair.

Prof. J. O. Arnold, F.C.S., gave a lecture entitled, "Through North Devon with a Camera," illustrated by slides from negatives taken by himself. Starting from Liverpool to Swansea, thence to Ilfracombe, the tour was graphically described, and many places of interest connected with Kingsley's "Westward Ho!" and Blackmore's "Lorna Doone"—Bideford, Clovelly, Lynmouth, and the famed Doone Valley—were beautifully portrayed, although most of the negatives were taken in heavy rain.

A number of new members were elected, and others nominated.

Bath Photographic Society.

*March 25th.*—Mr. W. Pumphrey in the chair.

Marion's "Radial" hand-camera was shown and explained by the Secretary, and negatives taken that afternoon by its means were on the table. Bain's "Crown" shutter, also sent by Messrs. Marion and Co., was handed round.

Mr. C. Cloakley exhibited half-a-dozen printing frames he had constructed in various ways to secure certain advantages, among them being lightness, ease of manipulation, freedom from shifting the backs during examination, the backs built up of three boards glued up across the grain dowels alternated at fixed points, &c.

Mr. A. G. Bristow showed the hand-camera used by him to secure the pictures awarded the medal at the Liverpool Exhibition. It was a rectangular dark box in which he had fitted an Eastman roll-holder, a Wray lens, and a Caldwell shutter, the latter being released by a pneumatic ball outside the box. Mr. Bristow said vibration was much less marked when a hand-camera was so fixed, than by pressing a spring lever or any such contrivance. A number of prints illustrating the work of the camera were exhibited, including those awarded the medal.

Mr. Pumphrey said he had experimented with the Watkins' exposure meter, which he considered a valuable instrument.

Messrs. Perren, Wilkins, Appleby, and the Secretary also made remarks to the same effect.

Newcastle-on-Tyne and Northern Counties Photographic Association.

A meeting was held on the 24th March in the Mosley Street Café, Newcastle, when Mr. A. S. Stevenson presided.

The honorary secretary, Mr. Edgar G. Lee, read the eleventh annual report of the council, who congratulated the members upon the exceedingly prosperous condition of the Association. The members now numbered upwards of 120. The principal event of the year was the photographic exhibition in the Central Exchange Art Gallery, which was in every respect an unqualified success. About 1,200 frames were hung, representing the work of 110 exhibitors. So far as quality was concerned, it was admitted on all hands that the exhibition had never been surpassed. One practical result was an immediate and, it is to be hoped, permanent large increase in the Association's membership. The main object of the exhibition was to give a stimulus to local photography, and to afford members and the public an opportunity of seeing the work of the best men of the day. The council felt satisfied that this object had been carried out. The Society had acquired an excellent optical lantern.

The financial statement, presented by Mr. J. W. Robson, showed that the Association commenced the year with a balance in hand of £2 13s. 3d. The subscriptions had amounted to £33 0s. 11d.; the expenditure had been £30 10s. 6d.; and there was a balance in hand at the end of the year of £5 13s. 9d.

The Chairman, in moving the adoption of the reports, which was agreed to, congratulated the members upon the healthy condition of the Society. There was a suggestion that they should have a club room, and he would like to see that idea carried out. They who were amateurs must acknowledge their indebtedness to the generous assistance given to them by the professional photographers.

A discussion ensued on "Bromide Printing."

---

### Photographic Society of Philadelphia.

At a meeting held on Wednesday, March 11th, the president, Mr. John G. Bullock, occupied the chair.

A report from the committee on lantern slides was read, relating to the public exhibition held at Association Hall, when one hundred and ninety-one slides were shown by fifty-one members.

Dr. Mitchell opened the subject announced for discussion, "Dark Room Illumination," and exhibited a lantern which he used in his own dark room. The general objection to the illumination of a dark room by means of coloured light, particularly ruby light, was that, in a short time, it generally affected the retina very injuriously, and really produced a form of congestion. It acted very strongly on the eyes of individuals whose retina was a little more sensitive to the colours to which one is limited in the dark room. The light was generally thrown directly in the face of the operator, or very nearly so, so that, while looking at the plate, he received, more or less, the red rays in his face. To develop a plate, an operator did not need the light in his face—he wanted it on his plate; hence, after some consideration, he had had constructed for his own use the lantern now exhibited, in order to concentrate the rays solely upon the plate. The lantern was a square tin box, with the ruby glass inserted in the bottom. The intention was to suspend the lantern above the developing tray, all light thus being shut out directly from the eyes of the operator. The light was furnished from an argand burner. The Doctor stated that he had worked for five or six hours at a stretch with this lantern without feeling any more effect than if he had been reading a book by ordinary lamplight.

For the purpose of overcoming the shadow caused by the lighting apparatus, the President stated that he had used a lantern similar to the one shown by Dr. Mitchell, arranged for the gas to come in from the rear. He used a large fish-tail burner, placed parallel with the glass, and by that means avoided shadow.

Dr. Mitchell suggested that the most perfect thing would be a ten or fifteen candle-power incandescent burner, which one could readily turn on or off, as desired.

Mr. Carbutt next referred to the lamp he used while travelling last summer. It was constructed on the same principle as the one shown by Dr. Mitchell, but in place of glass ruby fabric was used. He found it very convenient, as he could buy a candle almost anywhere.

Mr. Bell said that on his trips he never used a light at all. He closed up his room and changed his plates in the dark.

Referring to the method of development in ordinary light by means of Nuktigonia, a developing fluid, Dr. Mitchell said this was a solution of a very strong orange-coloured aniline dye, and the plate had to be placed in the solution in the dark room, or in some way by which actinic rays could not reach it, but after that development could be conducted without any trouble. Some of the members might be astonished to learn that a plate of ordinary sensitiveness, after development had been pretty well carried on—particularly pyro development—could be taken out in a strong light, and the plate finished.

Mr. Cheyney said there was one fact relative to light which was not often taken into consideration, and that was the operator's distance from it. The lantern he had was very convenient for developing, but the rest of the room was too dark to lay one's hand on a bottle or anything that might be wanted. To obviate this he had a lamp placed about eight feet distant, to which was affixed a ruby chimney. This he found he could burn with impunity and have lots of light. None of his plates had been fogged by it, and he always used as fast plates as he could get.

Mr. Rau described an apparatus made by him for use while travelling in the East with Mr. Wilson. It consisted of a cylinder made by rolling several sheets of Carbutt's ruby paper on a stick. Whenever he desired to change his plates, he stood this cylinder over a light placed in a box lid, and though it lit up the whole room, he never lost or fogged a plate. Of course they did not then use as rapid plates as at the present time. The cylinder did not break, and the same sheets were used during the whole journey—six months probably. The light used was a candle, and the top of the cylinder was turned over.

Mr. Chapman described a method of lighting the dark room from outside, thus avoiding the discomfort from heat and exhausted air. The lamp could be easily placed on the window-sill outside, and the coloured fabric against the glass, made to fit closely to the window frame.

Mr. Ives said he had several dark rooms in use, and wherever he used artificial light, he placed it immediately outside the window of the dark room, so that all the heat was out of the way.

The Secretary suggested that a shelf under the developing table was a very good way to cover up the plate. It was always there when wanted, and saved the trouble of hunting in the dark for covers, which could not be found when most wanted.

Mr. Ives used a hinged lid for this purpose, which he turned down over the developing dish when he desired to cover the plate. He found it very convenient.

Mr. Earle showed an improved form of "diffuser" for flash-light exposure. It was the invention of a Mr. Bridges, of Baltimore, and consisted of a base of tin about 12 by 18, at one end of which was hinged a tin reflector of same dimensions, and at the other a frame holding a thin sheet of white, translucent celluloid. The flash-lamp, of any usual form, was placed in the middle of the base board, the light being reflected through the celluloid, which diffused it in a very perfect manner without materially lessening its actinic power. Everybody predicted that the celluloid would burn up at once, but a very careful test had been made, and they found that the material could even be waved through a gas flame without ignition. It would ignite only when held still in the flame. Considerable heat was necessary to start celluloid to burning. If a little common salt were added to the magnesium it would give a yellow flame, and by the use of an orthochromatic plate very soft effects could be obtained.

---

### The Photographic Society of Japan.

A meeting of the above mentioned Society was held in the rooms of the Geographical Society, Nishikonyacho, Tokyo, on the evening of Friday, 13th inst., Mr. Edmond R. Holmes in the chair. Tnere was a large attendance.

A paper was read by Mr. T. Ichioka on a certain developer that had fallen into his hands. This developer was sold commercially in the form of a bright red solution, needing nothing but dilution with water. It was exceedingly active, and could be used over and over again. It contained a large quantity of sulphite of soda, and some caustic soda, but Mr. Ichioka did not know what was the actual developer.

Mr. C. D. West thought that the actual developer was probably hydrokinone. Either pyro or eikonogen would be detected by the colour, in spite of the fact that some dye, probably an aniline colour, had evidently been added to the solution to make it more difficult to guess what it might be made up of.

Mr. W. K. Burton demonstrated the washing of eikonogen that had turned quite black. By the particular method of washing adopted, the loss of eikonogen was a mere trifle.

Mr. B. Munster showed some tubes of the new eikonogen developing powder. This powder was found to be quite white, and, when dissolved in water, gave a colourless solution. Mr. Munster said that it needed no addition of any kind, and was a most active developer.

A portfolio of prints that had been sent to the Society some time ago by Dr. H. P. Emerson, as examples of "Naturalistic Photography," were handed round for criticism.

Mr. K. Ogawa said that, when he was in America, he had taken every opportunity of studying reproductions of the work of the French artist, Millet, whose pictures he admired greatly. It was evident that Emerson was trying to imitate his work photographically, and, although Emerson's work was far from faultless, it was, Mr. Ogawa considered, a great deal better than what was commonly turned out by photographers, who might study Emerson's work with advantage.

Mr. C. D. West said he thought the greater part of Emerson's work was too black and sooty to be natural.

Mr. J. Milne recognised great artistic merit in Emerson's work, but, speaking not particularly of the specimens shown just now, but of Emerson's work in general, he could not see that it was necessary for a "naturalistic" effect to select, for photography, only such phenomenally hideous figures as were generally to be seen in Emerson's photography. At least half of them would be arrested on suspicion only on account of their faces if they were seen by daylight. He proposed a vote of thanks to Dr. Emerson, which was seconded by Mr. A. J. Hare, and carried unanimously.

Mr. I. Isawa showed some excellent micro-photographs, and gave a short description of the means of producing them.

Mr. Kajima Sebi photographed the meeting by flash-light.

During the evening, prints made from negatives exposed on the occasion of the flash-light at Kaga Yashiki, by Messrs. Kajima, West, and Burton, were exhibited.

Production of Silver in the United States.—From a report recently issued by the the director of the United States mint, we learn that the silver output of the United States mines in 1890 approximated 54,500,000 fine ounces, corresponding, at the average price of silver during the year, to 57,225,000 dollars, and, at the coining value of silver, to 70,464,645 dollars, against a production of 50,000,000 fine ounces, of the commercial value of 46,750,000 dollars, and coining value of 64,464,464 dollars in the preceding year, an increase of 4,500,000 fine ounces in the silver production of the United States last year. The silver production of American smelting furnaces and refineries in 1890 was 64,920,927 fine ounces. The total amount of silver offered for sale to the Goverment during the year was 68,130,457 fine ounces, and the amount purchased 37,594,373·75 fine ounces, costing 39,991,840 dollars, 80 cents, the average price per fine ounce being 1 dollar 6 cents. The coinage executed in 1890 by the American Mint aggregated 124,025,365 pieces, of the value of 61,054,882 dollars, 84 cents. There was a marked improvement during the past year in the price of silver, reaching the highest point in 12 years. The fluctuations covered a range of 26 per cent., a wider range by far than in any previous year. At the commencement of 1890, silver was quoted at 96 cents per fine ounce. It reached 1 dollar, 21 cents on August 19th, and closed on December 31st at 1 dollar, 4½ cents. The average price during the year was—in London, 1 dollar, 4·6 cents; in New York, 1 dollar, 5 cents. At the lowest price reached during 1890, the value of the silver contained in the silver dollar was 74·8 cents; at the highest price, 92·6 cents; at the average price 80·9 cents.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

T. Norris.—*Combustible Acetic Acid.* The ingredient referred to under this name in Sir David Brewster's letter of September 10th, 1850, is that now known as *glacial* acetic acid. It is "combustible" from the fact that when heated in a test-tube, the vapour takes fire and burns continuously, which is not the case with the dilute forms of acetate acid. "Azotic acid" is an old name for nitric acid, and would be suitable for coagulating the blood albumen. M. Nièpce de St. Victor probably specified *l'acide azotique*, and so, by a too literal translation, the eminent writer was probably led to adopt the antiquated form of nomenclature.

Old Amateur.—*Bleached Silver Prints.* The mysterious photographs were, as you say, plain silver prints bleached by immersion in a solution of corrosive sublimate, and subsequently washed to remove the excess of mercury salt. Then on treatment with hyposulphite (contained in the blotting paper), the latent image was reproduced. No particular strengths of solutions are imperative, for we have never known the experiment to fail; but the prints must not be gold-toned.

W. T. S. P.—*Photographs of Machinery, &c.* Your programme is rather ambitious, and covers a wide range of requirements. The whole-plate camera and rapid rectilinear or symmetrical lens would be suitable for machinery, but could not be very conveniently taken on your projected pedestrian tour. For the latter purpose one of the kodaks, say "No. 4 folding," with stripping films, ought to answer, and then you might afterwards enlarge your negatives, even up to whole-plate size, if the definition warrants such amplification. The "hire system" is unknown with the better class of cameras.

L. F. (Burton).—*Kallitype Instructions.* The paper is always sent out with full details for working, which we have not space to reproduce in this column. Apply to Messrs. J. Lewis & Co., 100, Gladstone Road, Sparkbrook, Birmingham.

A. M. M.—*Details of Cost.* In the case mentioned we should estimate the wages at £300, and the cost of materials at about the same amount; then rent and taxes, with office charges, at another £100, or probably a little more if advertising is necessary. Much out-door work would add to the expenses, for some of it must be done in the height of the season.

T. S. D.—*Mr. Warnerke's Simplified Process.* The flexible basis described in the official report as "Kent's Patent Vegetable Parchment" should have been *Gaine's* patent parchment, as obtained by immersing thick white blotting-paper in a cooled mixture of two parts by measure of oil of vitriol with one of water.

Exhibitor.—*The Crystal Palace Display.* The course which we indicated a fortnight ago has been acted upon, and we hope it will meet your case.

F. Warren.—*The New Ixol Developer.* The account given in the *Bulletin Belge* by M. René Lacoste-Delpérier, of Le Mans, describes ixol as a new chemical body, the crystals of which are soluble in water. We are not yet acquainted with any such substance. On referring to Watts' "Dictionary of Chemistry," vol. iii., p. 436, we find "ixolite" as the name applied to a fossil resin found in a bed of bituminous coal at Oberhart, near Glogynitz; but this is not likely to be soluble in water, or useful for developing. The word ixol is not mentioned; so, for the present, we cannot help you.

J. Imray.—*The Camera Club Conference* will be held on the 7th and 8th April at the Society of Arts, commencing each day at 2 p.m.

W. H. M. (Hull).—*Persistence of Vision.* The holidays intervening, and the Patent Office closed, we have been prevented from making the search as to the novelty of your suggestion.

Vol. XXXV. No. 1701.—*April* 10, 1891.

CONTENTS.

## AFTER THE STORM.

The letter of Dr. Emerson's which we published last week under the title, "The Storm in the Naturalistic Crater," once more reminds us of the somewhat bitter controversy—now, we are thankful to say, at an end—which for so long a time agitated the minds of many of our leading workers. In looking back upon the history of this discussion, which we have not the slightest desire to renew, we may, perhaps, usefully consider one view of the subject which appears to us to have been lost sight of by both sides. We may fairly assume, to begin with, that the term "naturalistic photography" would never have been invented if a certain school of artists had not first arisen—we refer to painters, not photographers—who worked by methods different to those to which people had become accustomed, and which set at nought, in nearly every respect, the methods adopted in our schools of art. These "impressionists," as they called themselves, broke loose from the established order of things, and painted pictures, in some cases of considerable merit, but which, in others, seemed to represent nature in a way so distorted that the ordinary man could not understand them.

This wandering from the beaten track, instead of being a matter for surprise, should be regarded by the most careless student of human nature as a thing to be expected. Indeed, we have no hesitation in saying that, had it not been for this tendency to stray away which is inherent in human nature, all progress in the world would long ago have ceased. In children this feeling is largely developed, and we suppose that everyone must have felt, at some time in his early years, a yearning to be up and doing, and to break away from the restrictions which encompassed him. If a child find his playground in the meadows surrounding his home, the longing will take the form of a desire to go beyond the boundary line. He will first begin to wonder what lies beyond the visible horizon. "What is there," he will ask himself, "on the other side of the hills?" He will imagine that a more beautiful country awaits him there, and the longing to roam and to find it out will often be strong upon him. When early manhood comes the feeling is not relaxed, but is rather strengthened, only his ideas have expanded, and he begins to dream of fairer lands beyond the sea. If circumstances compel him to stay at home, the longing to break away from established custom will still be strong upon him, and may take the form of change of religion, or some other fancy which his elders will look upon regretfully, and regard as a foolish craze.

It is not strange that artists and students generally, who have the imaginative faculty in a highly developed degree, should, more than any others of their kind, possess this strong tendency to seek fresh fields and pastures new; and the history of all arts tells us that more than once new schools have thus arisen, and have often been productive of good. As a case in point, we may refer to the new German school of music, which, born of the marvellous genius of Wagner, has obtained such a firm footing, although we must admit that certain of his imitators have gone into excesses which bring their works too near to the boundary line which separates harmony from mere noise. A glance at the list of the three hundred or more different "persuasions" or forms of religion which exist in our own country alone, will show that this longing for something different, something better than the world has yet offered, is common even in the more serious phases of human thought.

But returning to art, we find something akin to the present "impressionist" movement in the outbreak of what was called *pre-Raphaelitism* more than forty years ago, and which was thus summarised by a writer of the period:—

"Some three or four artistical aspirants have, within the last four years, exhibited certain pictures distinguished by a peculiar quaintness of conception—a cold, dry, hard, meagre manner, an equalised distinctness of parts, and a laborious and superabundant detail of particulars mistakenly regarded as high finish. In these doings we find great attention paid to little things, and little consideration bestowed on great ones, and, supposing a purpose, the object of the artists seems to be to paint nature as she appears to untutored eyes—

single, separate, unconnected, ungrouped, agreeable with the practice of the earliest, the rudest, and the most unformed aspirants in art; a practice exploded centuries ago, entirely distinct from that adopted by the artists of England or the intelligent of any other country."

The pre-Raphaelite movement would most probably never have claimed the attention which it did had not Ruskin given it his powerful advocacy. He recognised that these young men were really in earnest in what they did, and, possibly, he saw that the new school would, in some measure, infuse new blood and fresh life into the art of the day. Very likely it did so; but who now thinks of painting a picture according to the doctrines then accepted by so many? "The superabundant detail of particulars, mistakenly regarded as high finish," has given place in the impressionist school to an absence of detail altogether, and a blurring of objects which is too often a screen for faulty drawing. Attention to detail was left to the photographer, and the gradual perfection of apparatus has enabled him to do so in a manner which leaves pre-Raphaelitism far behind.

It is, therefore, no matter for wonder that in these days, when photography and art are studied side by side, the new thoughts which have arisen with regard to the one should be applied to the other. Were naturalistic photography to be blindly accepted by all, most surely the reaction would presently come, and a new school would arise which would insist upon microscopic sharpness of definition. So long as human nature is as it is, these fluctuations of thought and taste are bound to occur. It is as much a want of right feeling to treat them with open contempt as it would be to ridicule a man's religion. If there be honesty of purpose allied to any movement, it can hardly be mischievous in its operation, and it is more likely than not to leave behind it influences for good.

Photographic Society of Great Britain.—On April 14th, at 8 p.m., Mr. W. Willis will read a paper on "Platinotype"—a specimen of M. Lippmann's colour photographs will be shown; April 28th, discussion on "Animal Photography"; May 12th, M. Leon Vidal will read a paper on "Photographic Methods of Obtaining Polychromatic Impressions"; May 26th, discussion on "The Influence of Development on Gradation."

To Transfer Photographs.—To transfer a print to wood, metal, glass, or even porcelain, it suffices to well clean the object if it is already polished, and to polish it in the contrary case, and then to spread over the surface a light coating of copal varnish. Then apply the toned and fixed print, still wet, and with a squeegee or printer's roller drive away the air-bubbles and excess of varnish; allow to dry for three or four hours. Then, rubbing gently with a slightly wet sponge, gradually remove the paper, the albumen film containing the image remaining attached to the glass by the varnish. A second coating of varnish will consolidate the whole. The only defect in this process is that it reverses the images. Those who operate on pellicle, or who practise phototype, and detach the gelatine pellicles, can make a reversed print, which, in this case, the process will correct. In this way it is possible to make very beautiful slides for the lantern, which are then to be painted for this particular application. Engravings may also be transferred in the same manner.—*Les Annales Photographiques.*

## THE PORTRAITURE OF THE UNSEEN.

BY JAMES MEW.

"Photography is fertile in useful applications."

This remark has been made so often before that it would seem at first unnecessary to make it again; but, as sermon after sermon is preached on the single subject of Christian obligations Sunday after Sunday, and will probably continue to be preached for some time to come, so the sentence at the commencement of this paper is likely to be again and again repeated, and has as much reason as the sermon for its persistence. Photography, like the sea-god Proteus, is capable of appearing to us in very different forms, and of giving us help in all. It provides for us deftly what we earnestly desire, and could apparently be by no other means provided, as the magic lamp gained for Aladdin, the poor tailor's son, an alliance with his beloved princess, the beautiful Badrulbadur. If we seek its assistance in the domain of the infinitely great, it will register for us volcanic explosions of the sun; if in the infinitely small, it will present us with the three-horned *Triceratium*, or the dissection of the dust on a butterfly's wing.

Some confusion formerly arose between small representations and the representations of small things; in other words, between micro-photography and photo-micrography. The difference between them has been well expressed by Ogilvie, who explains photo-micrography as an art or process of enlarging minute objects by means of the microscope, and projecting the enlarged image on a sensitised collodion film. Micro-photography, on the other hand, is an art or process by which an object is diminished in size, and yet its exact form retained. This latter art or process was of considerable service during the Franco-German war, in conveying intelligence to and from Paris while in a state of siege. But a decade of years before that time micro-photographs were a fruitful source, if not of advantage, at least of amusement.

Among the many delights which please children both of smaller and larger growth at the Crystal Palace, is to be found a delight, born of micro-photography, in the ivory works, wisely thus placarded, "Admission Free." The humble shilling admission fee is now so often quadrupled and quintupled if the visitors desire to see any of the sights advertised to be seen, in our various places of public entertainment, that this notice is as welcome as it is necessary. In these ivory works may be purchased a pen-holder, perforated at the end farthest from the pen. By looking through this little hole, may be seen the Crystal Palace, or Queen Victoria herself in all her glory. This attractive peepshow seems to have originated in the Paris Exhibition of 1859. There a little spy-glass stood in the place of the pen-holder. This *lunette breloque* containing a spot of paper not larger than a pin's head, a lilliputian photograph, showed through a magnifying piece of crown glass to the astonished eye the portraits of the 450 deputies of the French Empire.

During the Siege of Paris in 1870-1, microscopic photography succeeded in reproducing on a pellicle of collodion, weighing only a few centigrammes, and in size of two or three square centimetres at most, as many as three thousand despatches—in other words, as much as sixteen folio pages in three columns of printed matter. Private or public despatches, containing some 300,000 letters, were reduced to the size of a quarter of an ordinary playing card, and trransferred from paper to collodion films. These microscopic notices were rolled up and placed in a quill about the size of a tooth-pick, constituting a novel kind of letter-box which was fastened to the tail of a pigeon, and this winged postman of the air, undelayed by any amorous solicitation of or cook housemaid, carried them safely to their destination. Each pigeon was able to carry as much matter thus reduced to a minimum of space as might be contained in ten small octavo books of some three hundred pages each. The pellicles, on arriving at their destination, were unrolled by means of ammonia, placed between two glasses, and projected on a screen by the aid of a photo-electric machine or powerful magic lantern. Copyists then transferred the characters on the screen to paper. These pigeon postmen suffered much from inclement atmosphere and aerial pirates known as sparrow hawks; nor, as far as we know, did it occur to the Parisians to imitate the example of the inhabitants of Pekin, who are said to affix whistles of bamboo to their pigeons' tails, which thus make such a noise during their flight through the air as to fill their enemies with alarm.

But it is not with micro-photography, but with photo-micrography, that this article is more nearly concerned. The wonders of the unseen world have attracted interested observation ever since the invention of that well-known optical instrument of enlargement which Dr. Goring, in defiance of the reverence due to age, and in spite of firmly settled precedent, persisted in calling an *engiscope.* This interest has been greatly increased, and the means of observation greatly facilitated, by the happy marriage of the microscope with the camera.

Photo-micrographs—or photographs of microscopic objects—were taken at least forty years ago. In a paper on "The Application of Photography to the Representation of Minute Objects," by Joseph Delves, published in the *Transactions of the Microscopical Society of London* for 1853, positive photographs are shown taken from collodion negatives (1) of the spiracle and trachea of the silkworm magnified sixty diameters, exhibiting the elastic spiral fibre between the layers of the air vessels; and (2) of the proboscis of the common fly magnified one hundred and eighty diameters, showing the divided absorbent tubes. Dr. Woodward, a well-known authority, in a contribution to the *American Journal of Science and Arts* in 1866, expressed his opinion that "henceforward photography is indispensable to the proper representation of microscopic objects, and is adequate to the satisfactory representation of all microscopic objects that do not depend for their value on colours."

Photo-micrography, dealing with pictures enlarged by the microscope, has, by its union with that instrument, become one of the most powerful auxiliaries of investigation in the science of nature. Chemistry, biology, petrology, botany, have alike profited by its welcome support. It lifts the curtain from the infinitely little, and reveals the secrets of the tiniest and most delicate structures in the animal and vegetable world. Insects and infusoria, grains of pollen and potato starch, particles of yeast and tissues of plants—all the wonders of invisible existence unseen by the naked eye, and studied only with fatigue through the microscope, are fixed in the photographic film with a precision unknown to the most scrupulously and minutely exact of Dutch designers. Photographic fleas, male and female—the latter the larger, the stouter, and the more dangerous—old, decrepit fleas, larval infant fleas in youth's first blossom, looking like legless caterpillars; fleas in health and in sickness; fleas of all sorts and conditions, though not good sitters, become, after their frolic activity has been for ever stilled by death's icy fingers, the most favourite subjects of photo-micrographic portraiture. Representations, mathematically exact, of those marvellous organisms, found in numbers not to be calculated by any Walsingham or Cocker, on the surface of weeds on the seashore, and on flints washed by mineral waters; those confervoid algæ, called *Diatomaceæ* by the learned, with their fronds linear or circular, flabelliform or geniculate; perfect plants, and yet ever so much smaller than the smallest prick of the finest needle, are shown by photo-micrography as nature made them. A carte-de-visite of a *coscinodiscus,* that sieve-quoit of the ocean, and fossil deposit of the much-vexed Bermudas, may now be handed round for the inspection of the fashionable guests at a four o'clock tea. That most difficult test-atom, the *Amphipleura pellucida*, by which, we are told, the American, Dr. Woodward, has attained world-wide celebrity—his work in that direction never, perhaps, having been equalled by anyone, and certainly never excelled—is likely soon to become to us as familiar as the face of a household friend.

*(To be continued.)*

## Reviews.

An Easy Walk Through the British Museum, or, How to See it in a Few Hours. By Louis Fagan. (*London: Luzac & Co., 46, Gt. Russell Street, Bloomsbury.*)

This is a book which was sadly needed by the holiday folk who visit our great national collection, for it consists of a short and clear description of the more notable objects contained therein. Commencing with the Roman gallery, it calls attention to the principal busts, such as those of Marcus Aurelius, Hadrian, and our own Julius Cæsar, and gives a short account of their lives and doings. It then takes the reader through the Græco-Roman galleries, and points out why so much interest attaches to the numerous sculptured fragments which are to be seen there. The Egyptian antiquities next come under review, followed by those of Assyria and Babylon. In this manner an interesting tour is made through the building, ending with a description of the wonderful reading room, whose dome is only inferior to that of the Pantheon at Rome by two feet. The book is illustrated liberally with Dallastint blocks, and these are so well executed that the reader at once recognises the particular object described.

Photography in a Nutshell.

This is a second edition of the excellent little hand-book published by Mr. Tylar, of Birmingham. This edition is interleaved with blank pages, so that the owner may make notes of formulæ, &c., as he studies the volume. The book would, however, be much improved by the addition of a title page and table of contents.

Cardiff Photographic Society.—An International Photographic Exhibition, including photographic apparatus and appliances, will be held in the Public Hall, Queen Street, Cardiff, from 12th to 26th August, during the visit of the British Association. The list of classes and awards includes four divisions, viz., open to amateurs and professionals; open to amateurs only; competition between photographic societies; and open to members only. A form, to be filled up and returned not later than 30th June next, may be obtained from the hon. secretaries, G. H. Bedford and T. H. Faulks, 127, Bute Road, Cardiff. All exhibits must be delivered at the Public Hall, Queen Street, Cardiff, on or before Friday, the 7th August.

## THE CAMERA CLUB CONFERENCE.

This Conference opened on Tuesday last at the rooms of the Society of Arts, John Street, Adelphi; there was a fair attendance. and doubtless the numbers would have been greater had they not all known that they would soon have the opportunity of reading the papers for themselves in print. As is customary at this annual meeting, Capt. Abney, the President of the Camera Club, took the chair, and opened the proceedings with the usual presidential address. Capt. Abney began by pointing out how the Camera Club was now a great power for doing good in the photographic world, both by its weekly meetings at the Club House and by this annual Conference in which they had all met to take part. He also pointed out that although the presidential address is usually considered outside discussion, he invited those present to make remarks upon certain of the matters to which he intended to allude.

The first subject which came under review was the suggested standard system of weights and measures, and the questions as to whether such a standard should exist, and what that standard should be, were, he said, most important ones. For his part, he must speak somewhat under reserve, because of the approaching Congress of Photographers at Paris, where he was appointed to act as a delegate from the Photographic Society of Great Britain, in which capacity he would have to deal with this very question. He was certainly of the opinion that a standard should be universally adopted, for the present arrangements led to very great difficulties. Our plate manufacturers, for instance, found that the plates which they made would not fit the apparatus made abroad, and *vice versâ*. With regard to the question as to what standard should be adopted, this had already been discussed before the Photographic Society of Great Britain, and the general opinion seemed to be in favour of taking the 6½ by 4¾ as a basis upon which the standard could be fixed, a size that would correspond very closely with the French size 26 by 18 centimetres. The other sizes would be calculated from multiples of those numbers. The whole-plate would then become 9 by 6½, and would be in this form of far more artistic proportions, in his opinion, than the existing 8½ by 6½. The 12 by 9 would take the place of the existing 12 by 10 or 13 by 9, and the gain in both cases, in artistic effect, would be great. Indeed, he believed that the sizes based upon the method indicated would all be better than the old ones which had been in use in this country for so long. Among the other advantages gained would be the retention of the English inch, which is better than the centimetre. By this means he hoped that a compromise satisfactory to both the Englishman and foreigner would be arrived at.

With regard to the question of weight and volume, he asked, Is a compromise possible here? We, of course, might use the decimal system; and that method was certainly attractive when applied to small incomes, for 2,500 francs certainly looked much more important than £100. But in spite of much that had been said and written upon this question of the adoption of the decimal system, no real impression had yet been made upon existing methods; although chemists used the system almost universally, it is not likely to be used by photographers generally, only a few of whom are chemists. The gramme he looked upon as inconvenient, for it was too large in some cases, and too small in others; and the grain, as generally used by us, is far better. In writing formulæ, he would recommend the adoption of the expression "parts"; thus, a one per cent. solution of pyro would mean one grain in one hundred grains of water; the grain would then become a unit of weight, and the decem a unit of volume. The existing ounce measure would be displaced in favour of the decem.

Captain Abney next alluded to the researches of Messrs. Hurter and Driffield, and he gave these gentlemen every credit for their valuable work. Although there were details on which he differed with them, he might say that recently they had met, and he believed a satisfactory result had been arrived at, which would shortly be published. He had always looked upon this question of measurement of density as a most important one, and he considered that he was justified in publishing his views in full in the *Photographic Journal*, although some had questioned the propriety of doing so.

Photography in natural colours was the next question to which the President turned his hearers' attention. The 'accomplished fact," as some of the newspapers led their readers to suppose, is as old as photography, for the discovery of photography in colours has been made, according to some people, over and over again. Being in Paris a week ago, he had the opportunity of visiting M. Lippmann. He found that gentleman to be a true man of science, with all the modesty of a real investigator. The colour plates about which we have heard so much are due to interference, and not to pigments, and their effect varies according to the angle at which the plate on which they appear is held. Capt. Abney then proceeded to describe how these colours are obtained, by use of a mercury trough, as already detailed in our pages. He pointed out that, to obtain the colours, exposure to a bright spectrum was necessary, and that development must be brought about by alkaline carbonates, and the image intensified with silver. Both exposure and development must be exactly correct, or no colours are apparent, and the best results are gained with dry plates prepared with albumen and collodion. He looks upon the results of M. Lippmann's experiments merely as a verification of Newton's law, and not as a discovery of photography in colour. M. Lippmann has certainly succeeded in fixing interference colours, but the process is clearly one of extreme difficulty. It is a misfortune both for M. Lippmann and his predecessor Dr. Koch, that their experiments should have been dealt with by the ordinary reporters, because these reports have led the general public to expect far more than the experiments in either case justified.

A somewhat desultory discussion followed the reading of Capt. Abney's address, and Messrs. Debenham, Warnerke, and others took part in it.

Mr. Warnerke, who is also a member of the Photographic Commission which is presently to meet at Paris, considered that the half-plate, being a very general size in use, was a convenient basis upon which to found the proposed standard sizes. To introduce plates which could not be used in English cameras would be unreasonable. He considered that Capt. Abney's suggestion to use parts instead of drams and ounces to be a good one, and that if any standards are used, they should be adopted universally. He was in favour of the standard metre being adopted as a measure of length, for every-one understood it. He then made a few remarks with regard to lens diaphragms, and alluded to the system advocated by Mr. Dallmeyer.

The latter gentleman was present, and gave his reasons for adopting the system associated with his name.

Capt. Abney, in closing the discussion, remarked in passing that he had lately ascertained that the original lens used by Niepce was fitted with what is now known as an "Iris diaphragm," and he suggested, therefore, that the name of that form of stop should be changed to the Niepce diaphragm.

The next paper on the list was that by Mr. Lyonel Clark, on the "Use of Uncorrected Lenses." Mr. Clark, in the opening of this paper, alluded to the demands which æsthetic photography had made upon workers with the camera, and pointed out how in the old days photographers used to revel in the amount of detail which they found possible by the use of the instrument; and how afterwards this question of extreme sharpness was condemned. He owned, for his part, that he preferred sharpness to fuzziness, but at the same time he advocated a certain amount of softness. One method by which this result might be obtained was by the use of a pinhole, but this method not only required very long exposures, but it put figure subjects quite out of court. Another method of obtaining the same result was by putting the lens intentionally out of focus. He detailed a number of interesting experiments which he had made with ordinary spectacle lenses, using them both as single lenses, and as doublets of various focal length, and with diaphragms of varying sizes placed in different positions, and with the two lenses separated to a greater or lesser degree. He showed, by means of negatives which were handed round to the audience, what results could be obtained from this simple form of lens, and he owned that he was himself surprised to find how good these results were. He next explained the method by which his tests were made, and showed how he used a large camera with a lens mount in front which could be moved on a vertical axis. The trial lenses he mounted in rings of cork, and then fitted them within the mount, and used an iris diaphragm. He showed a most ingenious method of recording the results given by different lenses on the same plate. This was brought about by placing a sliding shutter arrangement in front of the focussing screen, so that different horizontal strips of the plate could be submitted to the action of the lenses one by one. As a summary of his results, he said that spectacle lenses were no more likely to replace ordinary photographic lenses than were pin-holes. They gave very respectable results for landscape work if well stopped down. On the whole, he considered that opticians need not put up their shutters in consequence of any revelations which his experiment may have made.

Mr. W. E. Debenham said that although, for occasional purposes, it might be desirable to lose sharp definition, yet, generally speaking, he thought a photograph should be as well defined as possible. The objection to definition had, he thought, very much arisen from the different meaning of the word sharpness as employed by artists and by photographers. Photographers, by sharpness, understood fine detail, whereas when painters spoke of being too sharp, they referred to harsh or cutting lines. He had known painters condemn harsh, under-exposed photographs as being too sharp when, photographically, they were not sharp at all. On the other hand, a photograph might be sharp in the photographic sense of being exquisitely defined, and soft at the same time. With regard to Mr. Lyonel Clark's statement that lenses made of one kind of glass only could be achromatic or have the chemical and visual foci, he would like to have some proof offered. As to the Zentmayer lens, he had, at the time that a claim for coincidence of focus was made, shown that apparent coincidence was managed by directing the operator to focus with a large diaphragm, and then insert one of a calculated smaller size for the exposure. For lenses having spherical aberration, the alteration of diaphragm practically alters the length of focus, and, by regulating the sizes of the diaphragms, this could be done to just the extent required. He had published this explanation at the time in the *British Journal of Photography*, and shown the editor a lens of his own construction in which these conditions were fulfilled. It had been claimed for uncorrected lenses—not in this paper, but by Mr. J. H. Dallmeyer and Mr. T. R. Dallmeyer—that, by introducing spherical aberration, and sacrificing definition at the focal plane, the focus of other planes was improved. The true view he held to be that expressed by Petzval, Burton, and others, and was that when definition was sacrificed at the focus, the other planes, not having a sharp one to contrast with, did not obtrude their want of sharpness so much. In the report of the last Camera Club Conference held here, is a paper by Mr. T. R. Dallmeyer, illustrated by photographs, professing to show the advantage of spherical aberration in giving definition on out-of-focus planes. This was supposed to be proved by photographs taken at a so-called "best focus," and at certain distances therefrom. On examining the photographs, however (which were here handed to the president), it will be seen that plate xvi., which is stated to be taken half an inch from the best focus, is actually in better focus than plate xv., which is said to be in the best focus. A similar thing, though not to the same extent, is noticeable in plates viii. and ix., where the one said to be removed from the best focus is in a little better focus than that in the so-called best focus. In a more recent endeavour to meet this objection, Mr. Dallmeyer says that the visual effect on the screen is not the same as in the fully-developed negative. If this were so, and it had any bearing on the subject, it would just go to show that, independent of other drawbacks, the introduction of spherical aberration would necessitate shifting the position of the plate after focussing, as with lenses not properly achromatised. If the difference in sharpness, say in plate xv. (the so-called best focus) and xvi. (the one said to be half an inch removed from the best focus), had been less glaring; if the real best focus had been somewhere half-way, so that the one stated to be in best focus were not manifestly in the worst, the fact that the demonstration had not been performed in the manner stated respecting it might have escaped detection. As it is, the professed proof is too much overdone, and a cause which requires to be supported in such a way stands sufficiently condemned.

After a few words from Mr. Dallmeyer and from Mr. Traill Taylor, Capt. Abney closed the discussion. He owned that he preferred sharpness in a photograph to fuzziness; that he had himself tried spectacle lenses in a great many different ways, and he believed that many of the cheap cameras are furnished with two simple lenses of this character, with a diaphragm between. One which he had lately examined certainly had that construction, and with such an arrangement a very decent image was producible. A combination of this kind was perhaps useful in teaching beginners their first steps, and in leading them to wish for better results by the use of more perfect optical arrangements.

Next in order was Mr. Pennell's promised paper, entitled, "Photography as a Hindrance and a Help to Art." The author being, unfortunately, absent, the reading of this paper was entrusted to Major Nott. Mr. Pennell begins his paper by asserting his belief that it was the custom at these conferences for members of the Camera Club to lure some unsuspecting artist to the meeting, to get him to state his opinions upon his art in relation to photography, and then to fall upon him and pulverise him. But he was prepared to make a very good fight for himself. Photography he considered to be a thing which is not a fine art, and which never can be. It employs an unintelligent machine to obtain results which really depend for their artistic value upon human intelligence and highly developed technical ability. The nearer a machine-made photograph seeks to approach artistically produced art, the more glaring are its defects, and the more are its shortcomings. Comparing a photograph with an etching, both representing the same scene, or the same figure, the etching may be a great work of art, while the photograph causes amusement for a moment, and may then become food for the paper-mill. If six artists were to render the same object, each of their renderings would be entirely different; but if six cameras were used, the results would be so similar that there would be no choice between them. Photography has not helped to make artists more accurate; all that photography has done is to prove things which were well known before. No object other than a perfectly flat one, which can be placed directly in the front of the middle of a lens, is rendered by the camera with entire truth. Truth of light, shade, colour, and tone no photograph has ever recorded, or will record, although it is claimed for photography that it renders detail in such a wonderful way. He did not find anything in it as faithful to detail as the drawings of Albert Durer and others. Mr. Pennell next points out how photography hinders artists, and as a proof of what he advanced, he stated that some years ago he obtained a number of photographs in order to help him in making some drawings of certain cathedrals. He carried the photographs down to one of the cathedrals, and after comparing them with the building he tore them all up. He maintained that these photographs were altogether worthless, both because the proportions were wrong, and the distance was absurdly reduced by what he would call "photographic perspective." He maintained that although the photographic view may be correct, artistically it is absurd, and it removes all feeling of size, impressiveness, and dignity. He also said that many of the features, such as distant turrets, and even towers, were completely ignored in the photograph, although visible to the eye. Passing on to instantaneous photographs, he said that it was frequently asserted that these were of great value to artists. He admitted that they were useful as suggestions and hints in the case of swift motion, and saved a great deal of trouble; but the man who depends upon them will become a photographer, or he will be of no value as an artist. Results remarkably near being artistic have certainly been obtained by a few workers with cameras, either because they used artistic methods, or by successful flukes. He then asked the question: "Of what use is photography to artists, and why did they practise it?" They took it up because it was an interesting and fascinating study, apart from their work, and because the photograph furnished them with details which often they have no time to draw. He then recorded his own experience with a detective camera in France. On one occasion he endeavoured to take some photographs of a number of people dancing. He sent his exposures to London to be developed, for he admitted that he was unphotographic enough to merely "pull the string." As a result, he had six good pictures and thirty-two failures, and he had to wait nearly two months before these results were obtainable. He would have done very much better if he had dispensed with the camera, and kept his eyes wide open, and his pencil at work. Photography is certainly beneficial to the illustrator, and more or less to the painter in other ways; especially is it useful in photographing drawings on to wood or other material, or reproduction, and it was grievous to think how, before this method was adopted, our works of art utterly disappeared under the hands of the engravers—referring here, of course, to the destruction of the original drawing on the wood block by the action of the graving tool. After a few remarks on wood engraving *versus* process blocks, he said that many artists feared that the improvement of these processes, especially that of reproducing wash drawings, will injure wood engraving. He is of opinion that it cannot injure the best wood engraving, and in art certainly it must be a case of the survival of the fittest.

As may be imagined, this paper, which was so plain-spoken in its contempt for photography, gave rise to a somewhat animated discussion.

Mr. Maskell answered the paper point by point, and his remarks were frequently applauded.

Mr. Robinson thought it should be taken as a huge joke, and that its reading should have been received in solemn silence.

Mr. Davidson pointed out that the principal statements were unsupported assertions, and showed the entire ignorance and innocence of the author of photography. He combated the extraordinary statement that detail is better rendered by draughtsmen than by the camera, and, as a proof of his contention, he called attention to Mr. Stevens's beautiful lantern slides of flower subjects, which contained detail which would be quite impossible for any draughtsman to reproduce; but he believed that we ought not to take Mr. Pennell's remarks too seriously, as possibly he only meant to amuse the meeting. It was a pity, if his remarks are to be taken seriously, that he did not support his contentions with some kind of proofs. His paper showed ignorance of photographic resources, and he had probably gained his experience only from the use of short focus lenses. Were he to study the works of our leading photographers, the pictures of Robinson, Emerson, and others, he felt certain his notions would be modified.

Major Nott followed by saying that it was evident Mr. Pennell did not know good photographs from bad ones; that artists in France now acknowledged that photography had made fresh demands upon them, and realistic scenes are now produced by them, which before the time of photography were undreamt of. Major Nott concluded his remarks by referring to Muybridge's photographs of animals in motion.

Mr. Valentine Blanchard pointed out that Mr. Pennell had probably written in haste; that, in spite of himself, he has been, and always must be to a certain extent, under the influence of photography. As a proof of what he meant, he referred to an old book on cathedrals (Winkle's), published before photography got to be a power, and he invited Mr. Pennell to compare pictures in this old book with his own work of to-day. The first was false in every way, and some of the pictures were, indeed, truly offensive to the eye; in fact, he maintains that photography has, in a measure, taught the eye to see.

Capt. Abney, alluding to Mr. Robinson's opinion that the paper should have been received in silence, said that, on the contrary, photographers should be glad of any criticism. Mr. Pennell had evidently not been quite so successful in photography as he had been in drawing. With regard to his remarks upon photographic perspective, he himself only recognised one kind of perspective, and that shown in a good photograph is quite as good as any in an artist's picture, and often much better. Mr. Muybridge's photographs of animals in motion had done much to add to our knowledge, but he, for his own part, felt glad that artists had had the good sense not to make use of the somewhat grotesque attitude shown in their works.

The last paper on the list was entitled, "A Note on the Physiological Aspect of some Problems in Art," and as the meeting had been somewhat prolonged, this was taken as read. The meeting closed with the usual votes of thanks to the readers of the papers.

---

The Camera Club Conference was re-opened on Wednesday by the reading of Major Nott's promised paper on "Photography as Applied to Illustrated Journalism." The writer pointed out that the recording of current events by pictorial means was one of the most noticeable features of the past decade, and it was evident to all, from the profuse way in which literature was now illustrated, and the way in which journals—not necessarily illustrated journals—were inserting pictures constantly in their pages, that there was a demand for this kind of work on the part of the public. Pictures, too, were now used to a greater extent than ever they were for advertising purposes. In these matters, the public taste has had to be educated from very early examples up to the present. But time would not admit of showing how this has taken place. He might refer to the Egyptian Hieroglyphics, to the Bayeux tapestry of far later date, and other pictorial records which appeared long before the development of the printing press. Up to quite recent times this mode of illustrating for press purposes has been in the hands of a few artists who worked with the pencil, but such pictures were only valuable in an artistic sense. For his part, he believes that accuracy of detail is the thing to be preferred. Artists will often sacrifice this accuracy to their ideas of what is artistic, and they have often been led by this feeling into absurdities—witness, for instance, the libels on animals, which have been so common, from the pencils of artists.

Major Nott next went on to point out the technical methods necessary in obtaining illustrations for a public journal by means of photography. With regard to the camera to be used, he had no hesitation in saying that the hand-camera was the essential form of instrument. Some of these cameras, however, were quite unsuitable for the work. The prime essentials were lightness of weight, and a ready means of using the shutter and removing the exposed plates, any delicate mechanism likely to get out of order being quite out of place. Another point in using these hand-cameras was, that the manipulation must not be such as to claim any great attention on the part of the operator. His whole attention must be concentrated upon the scene before him, and the rest must, to a great extent, take care of itself. Such a camera should be provided with a shutter which will work either slowly or quickly as required, and the lens should be one of long focus, and such as will work with the largest possible aperture. This last provision is an important one, because, with lenses of small apertures, pictures cannot be taken on dark or foggy days. With the lens which he himself has used he has been able to obtain pictures actually in a November fog—although he does not by this term allude to a "London particular." With such a lens, too, it would not be impossible to obtain pictures, should occasion arise, in well-lighted interiors.

With regard to the diaphragms, he would suggest that only three stops are necessary, and they may for convenience sake be marked "dark," "bright," and "sun"; meaning that the first one is the slowest of the series, and would be suitable for dark situations; the second would be a stop of medium aperture, which could be used for the generality of subjects; and the third one would be used with the quickest exposures for seascapes. It would be much better to label the stops in this manner than that the operator should have to bother his head about "*f*" this or "*f*" that. The plates must be of the best—if plates be used—but, for his part, he looks upon the roll-holder and the celluloid film as perfection for this class of work, and by the use of such a film the great nuisance of resorting to the dark room continually is avoided. Another advantage in using films is that the pictures can be produced at great speed, and this is often a *sine quâ non* in journalistic work. A long strip of pictures can be developed by one operation, and can be taken from the fixing bath while wet, and speedily printed from. It must not be thought that these pictures can be taken by an unskilled hand. The operator must be able to distinguish between what can and what cannot be done; in other words, he must understand the limitations of the instrument. He cannot, like an artist, alter the position of the figures before him at will, but if he only have the virtue of patience, these figures will sooner or later arrange themselves, and give him an opportunity of taking his picture. The camera must be level, and should be furnished with a view-finder of large size, so that the artist can watch the image on the ground glass screen, up to the moment that he touches the trigger. He must, of course, before this last operation is arrived at, take care that his pictures compose well, and do not offend any of the principal canons of art.

The one dominating idea must be that the picture shall tell its own tale, and care must be taken that the culminating or central object in it shall occupy the principal place. For example, let us suppose that there is a Royal ceremony—say the unveiling of a public monument. The first thing to do is for the photographer to fix upon the position where the light will avail him the most, then he may take the picture of the reception by the troops, and, if this is done well, anyone looking at such a picture will in a minute understand the situation, and will almost be able to hear the strains of the National Anthem. Then, with regard to the unveiling of the monument itself, he must choose the exact moment when the string attached to the veil covering the sculpture is released, and at that moment the button of the apparatus must be pressed. Photographs of historical scenes of this kind must have a value far beyond the pictures due to draughtsmen, on account of their undoubted accuracy. How priceless, for example, would be photographs of events which occurred in the reign of good Queen Bess, supposing that such pictures were in existence.

In conclusion, Major Nott explained that his object in calling attention to this subject was, that photographers generally should understand the conditions on which photographs intended for illustrated journalism ought to be produced. The journals now relied greatly on photographs or sketches sent in by outsiders for acceptance. Everyone now uses the Kodak or similar instrument, and if his remarks had tended to assist anyone in his work in this direction he would be amply rewarded. They should remember that haphazard photographs are, as a rule, perfectly valueless, and that care and attention to details are required in the work.

Capt. Abney, in opening the discussion upon this interesting paper, regretted that Major Nott had given no information about the transfer of photographs to wood blocks, and he called upon Mr. Carmichael Thomas, the art director of the *Graphic*, to favor them with a few remarks upon the general subject.

Mr. Thomas said that he had come to the meeting quite unprepared for any speech-making, but he wished to acknowledge to this club of photographers how much the paper which he represented was indebted to photography for many of the pictures which they published. Indeed, in many cases, he said, it was quite unnecessary to send a special artist to scenes of popular interest, as the manager of the *Graphic* was aware that they could rely upon plenty of photographs being sent in to the office by strangers and outsiders.

Mr. Hepworth said that he had been so long connected with the *Graphic* that he knew something about this subject of illustrated journalism, and the various modes adopted for turning pictures into printing blocks; but the ground had been so well covered by Major Nott's remarks, that he merely rose in response to the remark of Captain Abney with reference to the transfer of the photographic image to the engraving block. Some years ago he had made a number of experiments with different modes of doing the work. He had tried the collodion film, collodio-bromide emulsion, the albumen, and various other processes, but he thought, perhaps, that he had worked in a new direction by adapting gelatino-chloride emulsion to this purpose. The method he adopted was to make a chloride emulsion with a very small proportion of gelatine in it, and to rub the paste thus formed on to the surface of the wooden block with the finger; the block so treated was dried, exposed under a negative, and developed by the usual means. The process gave satisfactory results, as far as the speaker was concerned, but on submitting the block to a wood engraver, the latter complained that the surface of the wood block had been, to a certain extent, hardened by the chemical process, and made difficult to cut with the graver. He thereupon altered the emulsion in different ways, with the result that the hardness disappeared, but the engraver now contended that the surface of the wood had been made too spongy and soft. As it seemed impossible to hit a happy medium between these two extremes, Mr. Hepworth had ceased his experiments.

Mr. W. E. Debenham had hoped to hear something of the process blocks which were coming so much into use for illustrated periodical literature of the higher class. In this department there were two directions in which great advances had been made: the one was in the improvement of block processes, and the other in improved machinery by means of which alone blocks could be properly rendered. Until recently it was considered that rotary machines, such as were necessary for rapid newspaper work, could not be made to act with sufficient nicety for process blocks; but the work of the Marinoni rotary machines had dispelled this idea.

Mr. Warnerke advocated, for the treatment of wood blocks, the transfer of an image in greasy ink direct from the gelatine film—that is to say, a collotype transfer; and Capt. Abney, in bringing the discussion to a conclusion, considered that though Mr. Hepworth's experiments were interesting, the last-named method was, on the whole, best to pursue, probably for the reasons that it involved no wetting of the wood-block, and no film to interfere with the graver.

The next paper read was not on the list, but it proved to be one of great interest. The subject was a new method of producing process blocks, by Mr. H. Sutton. This method consisted in obtaining a direct electrotype from a gelatino-bromide plate, the result being a half-tone block, resembling, in all essential features, that produced by the Meisenbach process. Mr. Sutton, unfortunately, was not very well heard in the body of the room, but we understood his process to be as follows, although here we can only give a mere outline of it.

After exposing an ordinary gelatine plate beneath a positive on glass, or an ordinary print on albumen paper together with the negative of a line screen, the plate is developed with alkaline pyro or hydrokinone, and fixed in strong hypo. The plate is then washed, care being taken that the image does not absorb too much water during this necessary operation. Next, the plate is heated on an iron horizontal surface very gradually by a Bunsen burner, and, while this heating is proceeding, a curious change can be observed extending over the surface of the gelatine. The little dots formed by the line screen remain perfectly insoluble, but the gelatine which has been unexposed between those dots melts to a certain extent, and leaves the exposed dots standing up in high relief; in other words, the image engraves itself by means of heat. The plate is next dried, and, after being dusted over with graphite to give it a conducting surface, is at once placed in a copper solution in connection either with a battery or with a dynamo machine, as in the ordinary electrotyping process, and a metal block is the ultimate result. The copper solution causes the gelatine to swell to a very slight extent, but not enough to blur the image which it bears. Two plates were handed round for inspection. together with proofs pulled from them in an ordinary press. These were certainly of very fair quality, considering the simplicity of the process employed, and they raise hopes that, as the method comes to be experimented with—as it most surely will be—that it will be found capable of far finer work.

Capt. Abney said that the Conference must be congratulated on having this process brought before it for the first time. Although he was pretty familiar with most of these processes, this one certainly bore the stamp of novelty. He might say, in passing, that on one occasion, when he had dried a gelatine plate in the sun, he found that it gave exactly the same results in the partial melting of the unexposed parts as explained in Mr. Sutton's paper.

Mr. W. E. Debenham thought the utilisation of the quality of gelatine, of agglomerating under the exposed portions when heated, was very ingenious. The process might be expected, with further experiment, to be of great service from the rapidity and simplicity of the manipulations employed.

Mr. Bolas also spoke, and said that he was under the impression that the suggestion to use a gelatine plate for direct production of electrotypes came originally from Mr. Swan. He knew that Mr. Warnerke had also worked in the same direction, and, possibly, that gentleman might have something to say on the subject.

Mr. Warnerke remarked that unfortunately—possibly owing to the acoustic properties of the room—he had been unable to catch a great deal of what the lecturer had said, and therefore it would not be fair—indeed, not possible—for him to criticise the paper.

Professor Minchin's paper, entitled "A Review of Photo-Electricity," was the next in order. He gave a detailed account of a number of very interesting experiments which he had made with regard to the action of light upon plates of different metals which had been rendered sensitive to light, and with regard to the electric currents which accompanied exposure of such plates. We have not space to explain in detail the nature of these experiments, nor is it necessary that we should do so, as the author read a paper on the same subject a short time ago before the Physical Society. Prof. Minchin explained that he took up this subject in the year 1877, not knowing, at that time, of Becquerel's experiments in the same direction. A greater photographic interest was attached to certain experiments which he described, in which an electric current was passed through a plate prepared with sensitive emulsion. He showed how the plate was immersed in a solution of bromide of potassium, and, together with another plate, was connected with a bichromate battery cell. This was done in the dark; but when light was allowed to fall upon the arrangement, the result was that the plate connected with the carbon pole—which, by the way, was only half immersed in the liquid—was at once blackened, but no effect was apparent on the plate which had been in connection with the zinc pole of the battery. There was, however, a distinct blackening in the immersed portion of this latter plate when it was subjected to development. Very interesting, too, was an experiment in which two clean silver plates were immersed in a solution of phosphorescent eosene; their upper ends being attached by wires to a galvanometer. When such an arrangement is prepared in a darkened room, and allowed to settle down for some hours, an extraordinary result occurs on exposing the cell to light. There is an immediate deflection of the galvanometer needle in one direction, but this is only momentary, and the needle then becomes permanently deflected in the reverse direction. If the light is then shut off suddenly by a screen, the current, curiously enough, is increased, but this movement, too, is only momentary, for the needle slowly goes back to zero. If diffused daylight or direct sunlight are used alternately, every variation is noted by a movement of the galvanometer needle. When a taper is used, the impulsive sudden action is not apparent, and there is a steady deflection showing that the electric action is due to rays of light which are not present in the flame of the taper. The author explained that he had not yet had time to repeat these experiments with other fluorescent liquids, but he expected that they would give him similar results. He compared the electric action to induction, the current in one wire inducing a reversed current in another wire placed near it. In most electric cells, the currents thus afforded are very feeble in character, but he showed how it was possible to make special cells, which give very much stronger effects. Tin and its salts were, he found, the best elements to use, associated with liquids such as alcohol, which offered great resistance. He then showed how, by special treatment, a strip of tin-foil could be sensitised, and he also proceeded to explain, by means of diagrams, that when such a strip was coupled up with a galvanometer, some very wonderful results could be produced. When such a strip had been in use for some hours it became insensitive to light; but, by using an electric machine in the same room with it—but which, at the same time, was at a distance of twenty feet or more from the strip—a spark having been allowed to pass between the terminals of the machine—the distant strip suddenly becomes once more sensitive to light. This is not caused by any light from the spark itself, for the same result is brought about if the electric machine be shut up in a dark box. He has gained this astonishing result when the plate has been from eighty to ninety feet distant from the electric machine employed. He has also found that the sensitiveness can be restored to an exhausted plate of this character by simple mechanical means. Thus, a tap with any hard substance on such a plate will, it appears, disturb the molecular arrangement in some way, and so cause the plate to be once more sensitive to light.

This paper, which was listened to with great interest, was followed by one by Professor Boys on "An Application of Photography," and by one by Mr. Elder. Want of space compels us to postpone a review of these until a future occasion

The Camera Club dinner took place in the evening at the Criterion, and the company assembled filled one of the largest rooms. There were only four toasts: "The Queen," "The Camera Club," "The Press," and "The Visitors." The toast of the Camera Club was proposed by Capt. Abney, and responded to by Prof. Boys. That of the Press was proposed by Mr. Davison, who called upon Mr. Blane, of the *Times*, to respond for the general press, and upon Mr. Hepworth for the photographic press.

---

ENFIELD CAMERA CLUB.—At a meeting held on the 1st inst., Mr. S. H. Fry gave an interesting demonstration on "Bromide Enlargements"; he also developed two opals successfully, and showed a simple apparatus to be used for enlarging.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION, Champion Hotel, Aldersgate Street.—April 16th, Lantern Polariscope demonstration, Mr. J. J. Briginshaw; April 23rd, demonstration on "Light," Mr. W. E. Debenham.

THE Astronomers' Congress held a meeting at Paris on the 1st instant, the sitting being devoted entirely to the discussion of technical details connected with the proposed photographic mapping of the heavens. Among those who took a prominent part in this discussion was Mr. Gill, of the Cape of Good Hope Observatory. Admiral Mouchez acted as president.

PHOTOGRAPHY IN RUSSIA.—Though the Photographic Exhibition now being held in St. Petersburg is confined to the Russian Empire, the best exhibits, writes the *Daily News* correspondent, are of English goods. This is notably the case with cameras and apparatus. One interesting exhibit is a large series of views taken by the brothers Groum Greshemailo in their recent journey in the Thian Shan and in Chinese Turkestan, and alongside is the camera by which they were taken, and it is of London manufacture. As for the views, enlargements, and transparencies, they are fully up to the standard of such exhibits in England.

## Notes.

Mr. T. C. Hepworth, F.C.S., begs to announce that he is now the Proprietor and Editor of the Photographic News. He has also the pleasure of informing his readers that, commencing with next week's issue, the price of the paper will be reduced to twopence.

The river-side walk at Richmond-on-Thames is one of the finest of the kind in the kingdom, and, as it is within easy reach of the metropolis, where country walks are so fast being blotted out by the brick and mortar fiend, every effort should be made to keep its beauty unsullied. But the Richmond Main Drainage Board think differently, and apparently fancy that the general aspect of the riverside promenade will be much improved by the erection of sewer ventilators at regular intervals along the path. The exact shape which these ventilators will take has not yet been decided upon, or, at any rate, the design has as yet been kept from an expectant public. But probably the vertical brick-chimney shaft common to our manufacturing towns will be the form adopted, so that the sewer gases may fiud vent at a sufficient altitude to be innocuous, unless, indeed, the board should think it advantageous to offend the smell as well as the sight by shortening the dimensions of the hideous excrescences. Are there no photographers who will lift up their voices iu common with the other aggrieved ones to put a stop to this threatened blur on the beauties of Richmond?
