## University of Maryland Theses

### Early Doctor of Medicine and Doctor of Physic Dissertations with Corrected Tables of Contents

These manuscripts described as either an Inaugural Dissertation or an Inaugural Essay were presented to the University of Maryland for the Degree of Doctor of Medicine and/or Doctor of Physic during the years 1813-1887. The individual dissertations were bound together during the 1940's. The original tables of contents for the bound volumes contained multiple errors in authors' names, titles, and/or years. To address these errors, an additional "Corrected Table of Contents" has been inserted at the beginning of each volume.

The project team who investigated and corrected the tables of contents were Richard J. Behles, Historical Librarian/Preservation Officer; María Milagros Pinkas, Metadata Management Librarian; Angela Cochrane and Carol Harling-Henry, Resources Division; Sarah Hovde, Abra Schnur and Megan Wolff, Services Division.

These dissertations were digitized in 2011-2012 and are available at the UM Digital Archive ([archive.hshsl.umaryland.edu](http://archive.hshsl.umaryland.edu)) and the Internet Archive ([www.archive.org](http://www.archive.org)).

# Dedication.

The gentlemen of the Faculty of Physicians  
of the University of Maryland.  
Gentlemen,

In addition to the gratification which the act affords me, — the highest I can experience, there is a peculiar propriety in my dedicating to you the following lines.

Conscious as I am of the numerous defects of this my first essay on a medical subject, it is with the most profound deference I now lay it at your feet: but I do it encouraged by the reflection that parental connivance at its defects, in you it will only meet: and this consideration alone has, hitherto buoyed up my mind amid those waves of discouragement, with which some of you are aware I have had to contend.

As parents therefore I do and ever shall regard you: & wherever my future lot in life may be cast, rest assured your respective names are indelibly written in my most grateful remembrance.

Venerable men! yours is the angelic task of drying the Widow's tear — of lighting up joy & gladness in the countenance of a fond but fearing father. Grow & prosper. May each of you go down to the grave "in a good old age," as a sheaf of corn cometh in its season." And finally when all the "pains of life shall be o'er" may you together be admitted to that healthful clime where the inhabitant "shall not say I am sick".

So prays

your ever affecte<sup>d</sup> servt.

The Author.

Handwritten text at the top of the page, possibly a title or header, written in a cursive script.

Main body of handwritten text, consisting of several lines of cursive script. The text is dense and appears to be a continuous passage.

Lower section of handwritten text, continuing the cursive script. It appears to be a separate paragraph or a continuation of the text above.

# Phthisis Pulmonalis.

The proposition - "had no sin ever existed, no suffering should ever have been experienced," seems to be just. Hence if argue "a posteriori" i. e. from effect to cause, we must admit that sin has been committed and hence the introduction of suffering, and of the true "Pandora box" into our world. A retributive Providence seems very manifest also in apportioning the magnitude & multitude of the sufferings to the magnitude & multitude of the sins of men. It is conspicuous also, in rendering, very often, the offending, the suffering member.

Altho' the diseases to which mankind are liable are almost innumerable, yet the selection of one for a "Medical Thesis" has been to me matter of much perplexity owing to a consciousness of my inability to do it even common justice.

One excellence however I am resolved it shall possess (and seriously doubt whether it possess any other) - it shall "in toto" be my own. —

In discussing this subject we shall notice in the order mentioned, 1<sup>st</sup> The symptoms; 2<sup>nd</sup> The causes; 3<sup>rd</sup> The treatments; & 4<sup>thly</sup> The Prophylaxis of Phthisis Pulmonalis. If the term  $\phi\theta\iota\sigma\iota\varsigma$  from  $\phi\theta\epsilon\omega$  *Taliesco*, to consume or corrupt, be the origin of the name of this disease it implies its effects rather than its character. The same may be said - if it be derived from,  $\pi\upsilon\epsilon$  *Spuo*, to spit.

This disease makes its attack in the most insidious manner: and from whatever cause its distinguishing sym-

ptoms are ordinarily present. The slight cough is at first but occasional, and as it often for a length of time, yields commonly no alarm. But eventually it becomes more habitual, and becomes associated with a frothy mucus. Now the breathing, especially on exercise, becomes more than ordinarily hurried: and also unusually laborious. Languor, loss of appetite & dejection of spirits, also prevail. At length, emaciation, and an expectoration of blood-streaked mucus yield alarm. Patient lies easiest on one side or perhaps on the back. These symptoms become gradually more & more aggravated, accompanied with two exacerbations daily, the former ordinarily occurring at noon, the latter at midnight. Colligative night sweats and diarrhea now set in & in the course of some time render the Patient "a walking skeleton" But fortunately for him, hope, "the balm of human life," lingers with him even to the last - year until in perhaps a few hours delirium carries him quickly off "the stage of action" or life ebbs out gradually, its last.

Having briefly noticed the symptoms we are now to specify the causes of this disease.

Altho Hemoptysis is not always yet it is frequently the cause of Phthisis. The vessels of the lungs, as of the nose, may heal "by the first intention" as we say, yet we can readily conceive of a quantity of blood remaining & stagnating in the ram-

ifications of the Bronchia, irritating and exciting ulceration - but where this result occurs that the patient has been predisposed is very presumable.

2. Extraneous substances as dust of mills, filings of metals also occasionally induce Phthisis but ordinarily thro' the instrumentality of Asthma.

3. Suppuration as a sequel of Pneumonia is also an occasional cause of this disease. Here an abscess, or as it is commonly termed One or more Pouches are formed, commonly in that part of the Pleura investing the lungs. On the surface of the lungs if tubercles exist they are more exposed to the vicissitudes of the atmospheric air, than those deep seated. Hence it is very probable that where Phthisis results from this cause tubercles had previously existed. Where the constitution is good and free from such predisposition, the pus discharged will be expectorated and the parts healed. Hence it is the journals of the day announce the cures of so many phthisical patients and of the most confirmed kind - in which "pus" had been so "freely expectorated."

4. Catarrh, if frequent or violent is often a cause of Phthisis. But as a mere Catarrh it cannot excite it, it must first form Bronchitis from the inflammation travelling down to the lungs from the -

1.

Schneiderian membrane. Here we are unhappily found  
"at issue" with the justly celebrated Cullen, who we find  
declaring - "it is to me very probable that a cataract is very  
seldom the foundation of Phthisis." That cold is only  
the ordinarily exciting cause of this disease cannot  
be denied: but it may & indeed should be considered  
the sole cause, acting as it does in inducing the fore-  
mentioned causes of Phthisis, first causing pneumonia,  
& thro' pneumonia [occasionally] Phthisis pulmonalis.

To what cause beside, can the dreadful havoc  
made annually in Great-Brittain be ascribed? "In  
that country alone" says Dr. J. Johnson of London,  
"Pulmonary consumption alone is computed to carry  
off fifty-five thousand British subjects annually, or  
cause between one fifth & one sixth of the whole  
mortality." Should it hereunto be objected that "those  
subjects were scrophulous," we confront the assertion  
with the declaration of that Physician "I believe," says he,  
the remote cause to be a scrophulous taint, or nascent  
tubercles of the lungs; but I believe in four cases out  
of five, these tubercles are excited into inflammation  
& suppuration, by the effects of climate & principally  
by oft repeated & neglected colds. If therefore" [he  
continues] "scrophula itself has been called into

3.

action, by climate, the whole class of pulmonary complaints, may then be referred directly or indirectly to atmospherical transitions." Indeed a moment's cool reflection will result in the corroboration of the above-mentioned argument. For the British are, collectively taken, men of the most robust stamina - and expanded thorax: nothing, therefore can account for the above mortality but their cold & ever-varying climate, the atmosphere of which is ever surcharged with hydrometic vapour. A number even of my own school-mates have fallen by this sly snatcher, whose parents altho' now old are yet alive. But even granting that many of the forementioned victims had been predisposed or under the influence of "incipient tubercles" if Dr Johnson's reasoning be correct these tubercles in more equable climates would never have been called into action, & of course ~~the~~ various vicissitudes of atmosphere have been the true causes of that dread mortality - The point "quod erat demonstrandum"

In confirmation of the above the suffrage of our judicious professor of the "Theory & Practice of Medicine" is both full & strong - viz: "Cold is the cause of more cases of consumption than all other causes united."

5<sup>th</sup> But of all the causes yet noticed, Tubercles are confessedly the most frequent.

These are no doubt often congenital; but according to the supposition of some of our best authorities they may also be subsequently acquired. The doctrine of predisposition is, by some, treated with ridicule: but it is indisputably proved by matter of fact. We see almost daily the child possessing not only the same form of person but (what is still more difficult to account for) the same temperament of mind as one or both of its parents. The analogy is very strong in regard to the corporeal appearance especially recognising as we sometimes do the child by its father. If then the father possessed scrophulous lungs we think there is nothing contrary to sound pathology in supposing the son will possess them also.

These tubercles are at first small and indolent: not larger than millet seed & hence called "milliary tubercles". They are, at first colorless; but on excitement they inflame, enlarge and become of a yellow color & of a cheesy consistence. They afterward, together with the adjacent parts, indurate, and where in contact, unite, and if cut, the mass presents a polished surface, which is impervious to the air. These masses or tubercles eventually suppurate, and if seated in

There are no doubt of the composition, but as  
to the supposition of some of our best authors  
may also be substantially answered. The doctrine  
of the nature of the mind, treated with relation to  
intellectual powers by Mr. Locke, is not only  
daily the child of the imagination, but also  
of power, but what is still more difficult to  
for the same comprehension of mind as one  
of its powers. The quality is very strong in  
to the intellect especially in the  
relation to the child by its father, of the  
father's property, and the child's duty we think  
is nothing contrary to nature, but only  
the one will pass them over.  
The children are at first small and simple  
in their nature, and the mind is called into  
it. They are at first white, but as they  
they increase, colour and become of a purple  
of a strong complexion. They are simple, but  
the various parts, interests, and values we  
will not say, but the mind is a  
face, which is superior to the  
or the child's naturally superior, and

in the substance of the lung will discharge itself into the bronchial ramifications. If large in quantity it may induce strangulation and instant death.

But it is ordinarily expectorated; leaving a tubercular cavity behind. In some cases the sides of these cavities have been found united by cellular adhesions or by structure similar to fibro-cartilage which forms a cavity in which different structures often exist. No healthy granulations however are deposited; the parts exhibit the characteristic scrophulous aspect.

Whenever, therefore, the individual possesses a fair skin, blue eyes, thick upper lip, long neck, rosy complexion & flat thorax, there is found the legitimate subject of the forementioned process, or what is technically called—"predisposition"

Many exanthematous diseases and repelled eruptions are also said to be occasional causes of Phthisis: but as these are the result of entirely neglected, or of partially treated, diseases, we shall not take any farther notice of them.

Having specified the most common causes of Phthisis, we now, as was proposed, pass on to their treatment.

Whether it be referable to the present, imperfect state of the healing art, or to the absolutely incurable

ble nature of the disease, is a question, but it is a lamentable fact, that to a great extent, at least, this disease still continues to be classed among those of the "opprobria Medicorum." Even a glance at the ephemeral remedies of the last century, then so extolled now so abandoned, substantiates this lamentable truth. Where is now the fame of Digitalis? of Hydrogen gas? of prussic acid? of tar water? of its vapour, together with that of Nitric acid? They have all alike evaporated into air,—"thin air."

The most natural division of the treatment is perhaps into that in which \*predisposition does not, and that into which it does exist.

When the patient is not scrophulous the disease is much more under the influence of medicine than in the latter case.

I. When excited by pneumonia or reiterated colds, the disease is commonly, especially in the onset, of an inflammatory character, and then the lancet should be freely used: debility at this period should not be so much dreaded as it ordinarily is; every judicious Physician will studiously endeavour to save his patient from inflammation and suppuration of the lungs by taking off the mischievous effects of the "vis a tergo"

The probable cause of the present prejudice that exists against bloodletting in this disease is, the physician is rarely called in till the

For the sake of arrangement I have used the word "predisposition" in a wide sense comprising its ordinary import together with Malconformation.

The nature of the disease is a general, but not  
infectious, one. It is a great relief of heart,  
and continues to be the chief remedy here  
for a long time. There is a stroke at the  
beginning of the last century, and is  
attended, but not by the same  
as now the form of epidemic of  
effusion and of the water? of the  
with that of other and? they have all  
acted with me - then are.

The most natural (and in fact) the best  
remedy is that in which (the patient) is  
and that into which it goes with.  
When the patient is not suffering from the  
must more than the influence of medicine  
in the latter case.

I. When excited by anxiety or  
with the disease is commonly, especially  
that of an inflammatory character, and  
the least likely to be cured by  
this kind of treatment, and to be much  
relieved by; every patient who is  
with anxiety and the patient  
inflammation and effusion of the  
of the inflammatory effect of the  
the inflammatory cause of the  
that inflammatory effect of the  
in the inflammatory state.

The period of bleeding is perhaps forever gone; & suppuration has commenced. It is true blood-letting must be sparing, but generally should be frequent.

The promptings of nature should here, as elsewhere, be carefully marked; she is often a good, tho' never an infallible guide. She should therefore be followed when right and corrected when wrong. It is now justly generally remarked that Hemorrhoids, when of the bleeding kind, together with the "Menses" and "Fistula in Ano" arrest the progress of Phthisis. If so, the "desideratum" is to ascertain the principle on which they act. Their uniformity in voiding blood seems to be that principle. Nature's directions herein should be attended to - & the judicious physician be led to go & do likewise - to use the Lancet moderately & frequently.

The subjects of this species of Phthisis being ordinarily men who are inured to hard labour, they should be kept at that of the most active kind. Riding on horseback and remaining in a dry warm climate especially during the winter season are both very promising. The former especially, if care be taken

---

\* Menstrual discharge tho' destitute of the qualities of pure blood, does certainly lessen the sanguiferous volute.

taken to prevent the vicissitudes of the air to which such persons are necessarily exposed.

If the disease result from mal-conformation of the thorax, sawing wood, or what perhaps has more mechanical effect in expanding the thorax, - using a flail is promising employment.

Seasons Issues are old, but good remedies, their use is now superseded by blisters: when these latter are employed, they should be small & applied to different parts.

Diet should be bland and nutritious. Intemperance in the use of meat and drink studiously avoided: early rising and early retirement are equally important.

Fleecy clothing should be <sup>un</sup>interruptedly worn: for this purpose flannel is, perhaps, the best. Of medicines, those calculated to keep up perspiration, as the antimonials and lessen the heart's action, as Digitalis, are the most promising. —

A host of other means and of other medicines might here be noticed; but they are such as will not justify much reliance, should those mentioned prove unavailing. —

11.  
II. We are now come to notice the treatment of that species of Phthisis which results from predisposition. Here we commonly find the delicate male or female with emaciated body, hectic flush, accelerated pulse, streaked spit &c. Here what is termed active treatment is inadmissible: the abstraction of blood, to any considerable extent would very probably accelerate the patient to a more early death. Gestation on horseback or on foot cannot perhaps be long endured. If so that of a slow-driven carriage on a smooth road will be proper.

But in such a case a voyage to sea and remaining in a mild, equable and warm climate is the most flattering means with which we are yet acquainted. Should it be enquired, how do these means so beneficially act? we reply as follows, Altho' the benefit of sailing has been ascribed to the purity of the air, we are pretty confident it is not just: we conceive it more justly attributable to the following circumstances 1<sup>st</sup> The air is more equable at sea: 2<sup>nd</sup> The nausea it never fails to excite in most persons, acts on the cutaneous exhalents (just as does the abstraction of blood) and there-  
by

The new course to which the treatment of  
specimens of *Phthirus* is directed from  
this we commonly find the effects are  
familiar with ourselves, but, to be sure,  
other parts, besides the head, the whole  
active treatment is indispensable: the whole  
of blood, to any considerable extent, must be  
ably accelerated the patient to a more  
active. Particular attention on the part of  
cannot perhaps be long continued. It is  
a slow, tedious course, on a small  
in paper.

But we find a case a person  
and remaining in a mild, quiet  
state is the most desirable means  
which we are yet acquainted. There  
engaged, how do they mean to  
act, we reply as follows, "While the  
of healing has been awarded to the family  
and we are pretty confident this not  
concerns it, more fully attributable to the  
ing circumstances. If the case is more  
at least, the success of our path is  
in most persons, and on the whole  
just as does the exhibition of this

keeps up a free, insensible perspiration; nor is this so slow, and inefficient a means of lessening arterial action as is commonly supposed; indeed if we are to judge of it by its effects, we must allow it to be a means of considerable efficacy.

3<sup>d</sup>) It is supposed (and I think very conceivably) that a chronic, congested state of the liver by pressure and irritation against the Diaphragm & Lungs, may induce ulceration thereof & consequently pulmonary consumption. In such a case, a sea voyage has been found exceedingly serviceable, by emptying the liver (the source of irritation) by nausea & especially by vomiting.

If practicable patients predisposed should make a permanent residence in a dry, equable climate, or imitate our birds of passage and on their interapproach, flee towards such a place. The "modus operandi" thereof must be similar to the above: In such a climate the cutaneous exhalant vessels are more active and thereby lessen the circulating volume.

• Matter of fact daily shows the power of the mental, and the corporeal faculties, in all voyages and journeys therefore, an amusing, agreeable companion, should, if possible, be obtained.

At this period of the disease and in this species tonic medicines are often indicated. Did the famed Quistly-famed, Peruvian bark or any of its preparations really possess the anti-fetile virtues so univocally everywhere assigned to it, its efficacy here should be very great - but we find it rather injurious than otherwise.

Iodine and its preparations are more promising and so is prussic acid.

The same form of regimen, and directions as to clothing, as those in the former species, are here also to be attended to.

Cold or Warm Baths are doubtful remedies. they are rarely serviceable, and when there is any considerable action in the pulse may be injurious.

Where the disease is of a confined nature, & if especially from predisposition, the above-mentioned remedies and indeed all the medicines of the "Materia Medica" will be found unavailing.

As the "dernier resort" the best is opium.

It is said to alleviate pain, mitigate the cough, moderate the diarrhoea & when hope itself is ready to expire, disarms the Monster of his "terror." To all those appoint-  
-ed

to die" of this disease it may most emphatically be termed the "magnum Dei donum."

In reference to prophylaxis we are now to treat. It has already been asserted that "Piles," "fistula in Ano" "Menses" &c. have pro tempore, arrested the progress of Phthisis: to these we shall add "Marsh Miasmata" Its "modus operandi" seems rather obscure: On it therefore we shall bestow a few remarks. Its influence has been ascribed to the supposed fact, that two different predispositions cannot exist in the system at the same time. This is very questionable: we conceive every organ may have its predisposition, but no organ two predispositions at the same time. Hence it is in this, as in some other forms of disease, that the weaker yields to the stronger affection.

Finally, it is truly lamentable to observe that the whole series of this disease the heartrending sight presented to the parent and the disappointing hopes which to the last spring up in every hectic breast. Whether the delicate organization which predisposes to this disease contributes to amiability of temper and sweetness of disposition is a question: certain however it is that this illusive disease falls, in general, on the best as well as on the loveliest part of the Creation.

Baltimore, March 2<sup>nd</sup> 1833.

An inaugural essay  
upon  
Business Remittances  
by  
J. Buchanan

1827

An inaugural essay  
upon

Bilious Remittent-Fever

By

J. A. Buchanan

Mr. [illegible]

[illegible]

[illegible]

[illegible]

To Ashton Alexander M.D.

Dear Sir,

As a small proof of the high estimation entertained for your medical achievement, as well as of the deep sense of gratitude which I feel, and shall always cherish, for the uniform kindness bestowed, I take the liberty to dedicate to you, this my first essay, whilst fully sensible, as well of the weakness of the effort, as of the many erroneous ideas which it may advance. I flatter myself that the Motive will recommend it to your clemency; in this hope I remain

Dear Sir,

Your grateful pupil,

J. A. Buchanan.

Nothing but an acquiescence with the laws of  
the university could induce me at this early period  
of my medical career to introduce my ideas  
upon a subject which I am fully aware  
requires a masterly hand to treat in  
a manner worthy of its importance, the  
necessity of the case will I hope plead for  
me whilst I endeavour briefly (yet in as  
lucid a manner as my abilities will permit  
to show the Cause and symptoms of Bilious  
Remittent-Fever which I have chosen as the  
theme of my first efforts.

In the sequel of these observations I will  
place the remedies employed in the most  
common and successful practice.

The cause of this disease has been attributed to  
the operation of a certain poison to which has  
been given the name of Miasma, supposed to

originate from the decomposition or putrefaction  
of vegetable matter.

This opinion is strongly supported by the authority  
of some of the most intelligent medical men  
If we consider the season of the year in which  
this disease prevails, the situation of the  
countries in which it most frequently appears, &  
the peculiarity of the climate to which it  
most properly belongs, or if I may be allowed  
the expression, of which it is a native, this  
opinion will be placed almost beyond a doubt  
of the exact nature of the poison we are as  
yet uninformed, but of its operation on  
the system, & its consequences we are permitted  
to say something definite. -

There are I believe but two theories which at  
the present day distract medical men upon  
the modus operandi of this poison on the  
body, one supposes the miasma to be entered  
in the sputa and in the act of deglutition

conveyed to the Stomach where it makes its impregnation and by Sympathy is propagated to every part of the body, the other, that it is inhaled and conveyed to the lungs where it acts, also by Sympathy.

It is the latter of these opinions I shall adopt not only as the one most generally received, but as my opinion, as the most rational, for as this poison is opinioned to be floating in the atmosphere it seems natural to suppose we inspire it with the air we breathe and in which it exists.

In giving the symptoms of this disorder it is not to be expected, I shall enumerate all that appear in the different forms or types it is sufficient to mention the most common those which generally characterize it. A paroxysm, or regular fit of remittent is divided into three stages.

In the first, the most striking symptom is a sense of cold or shivering, it is therefore

called the Cold Stage.

In the second, there is an evident increase of temperature or feeling of heat, it is consequently termed the hot Stage.

In the third and last there is a copious secretion by the skin, this is therefore called the sweat Stage.

At the commencement of the paroxysm the patient is observed to yawn frequently and shiver, a general languor pervades the system, the face assumes a pallid hue and the skin over the body appears constricted as if cold had been applied to it.

The patient is not always sensible of chilliness at the commencement of these symptoms, though his skin feels cold to another person, in a short time however he begins to complain, which he sometimes does from the beginning.

This sensation of cold is in most instances referred at first to the back, a trembling succeeds commencing in the lower jaw, & gradually spreading

over the body -

The pulse during the cold stage is small, frequent & compressible & often irregular, the respiration considerably affected, it is frequent anxious & accompanied with sighing, loss of appetite, nausea, & sometimes vomiting of bilious matter, pain in the stomach and loins, headache, with a sense of stiffness or soreness in the joints and an indisposition to any exertion are the characteristics of this stage.

These symptoms decreasing the second or hot stage commences, the cold after alternating with short fits of heat, gradually abates and more permanent heat is at length diffused over the body; instead of the paleness of the face & constriction of the skin which attend the cold stage, the face becomes red, the skin dry, the patient still suffers from pain in the head, anxiety & restlessness, the respiration continues to be frequent, but fuller & more free

the pulse more regular, hard & full, the tongue is  
purplish and tinged yellow, these symptoms are  
at length succeeded by a profuse sweat  
which forms the last or sweating stage of the  
paroxysm, during which the strength and  
frequency of the pulse are diminished as  
the heating is less.

If the fever be an intermittent the patient is left  
apparently without fever, though not restored to  
health for I believe he is never well until  
a complete crisis is formed.

If a remittent the symptoms of the hot stage,  
though with an evident abatement continue with  
a recurrence of exacerbation which is regulated  
by the type of the fever.

The tendency of intermittents to become continued  
is always unfavourable, on the contrary the prognosis  
is good when they change from a less to a more  
intermittent form.

By the alvine discharges not having the colour when  
the bile always imparts to them when it is secreted in  
proper quantity and in a healthy state; & the symptoms  
of the disorder remaining during the discolouration of

forces and subsiding and at length disappearing  
they return to their natural condition, it is evident  
this disorder there is a deranged action of the secre-  
tory vessels of the liver, in consequence of which the  
secretory vessels is either deficient in quantity or  
vicious in quality."

It appears then, that the liver is the principal seat  
of the disorder, and is generally found in a congested  
state in a phlegmious or infarcted condition.

In a congested state I wish to be understood as alluding  
to the blood vessels & to the vena portarum, particularly  
in congestion of the veins may I think be attributed  
wholly to the infarcted condition of the parenchyma-  
tous substance of the liver and partly to the interrup-  
tion of its secretory vessels.

This opinion I am supported not only by what  
takes place in other parts of the body, but by what  
takes place in the liver itself, on an increased secretory  
action.

If we look at inflammatory affections of the trachea &  
bronchus, to which this state of the liver certainly bears  
analogy, (at least as far as increased secretion has  
a tendency to lessen ingesta & remove congestion) we  
shall find by administering medicines which promote

The secretory action of the vessels of these parts, they are greatly relieved & the inflammation subdued; we then turn our attention to the condition of the liver after an increased vitiated secretion. Cholera Morbus, Drankosa &c we shall I think be disposed to admit depleting effects of secretion & vice versa.

Though this state of the liver resembles an inflammatory affection in some points, yet it differs essentially from it, in many important particulars, for must be remembered in an inflammation of the liver, it is the arterial system that is affected and the secretory function of this organ being called on by a distant clap or order of vessels, partakes secondarily in its effects, whereas, a venous congestion of the liver is produced by an interruption in its secretory action together with an infarcted condition of its parenchymatous substance, the arterial system is consequently affected but in a secondary manner the state of congestion being limited to the *vena portæ* -

To remove these morbid, but dissimilar states, the treatment it is evident must be necessarily different.

The inflammation of the liver must be man-

ed in all respects as an inflammation in any  
other part, from which it differs neither in its cause  
nature: not so in a disordered function of that  
part from the operation of marsh poison  
where the principal object is to remove the in-  
fection and restore healthy secretion  
unless we eradicate the cause effectually we  
make no durable impression, & our patient is  
not secure.

But I should be accused of assuming too much in  
my pathological views on this subject I would  
instance the state of the portal system in cases  
of ascites proceeding from neglected intermitted  
rather remittent fevers as I have already hinted  
there is strictly speaking no intermitted fevers.  
will be found in almost every instance of as-  
cites arising from remittent fevers, or where the  
system has not been sufficiently purged (if the  
suppression be allowed,) the conclusion of that  
case is a state of infarction or congestion  
is not only shown by dissections, but by the  
happy termination of those cases of remittents

in which due attention has been paid to the evacuation of the liver & the beneficial effect of those remedies calculated to remove parasympoma in cases of ascites, from improperly treated remittents -

That it is not a point assumed then, that the liver is in a state of congestion and infarction or has a tendency to this last condition, I am disposed to think will be granted by most impartial men and even if it should not appear that a state of infarction actually exists in remittent fevers, I still contend for a disposition to a congested state of the vessels of the liver & a paralytic condition of its parenchymatous substance, either of which points out a course of treatment & demands our attention

In the treatment of this disease two objects are indicated, the first is to remove the cold stage when present, the second to correct the disordered state of the liver by removing or if you please preserving the infarction

that rescues" with the conjectured state of the Venice  
state.

It is not my intention to enter into a dis-  
cussion on the *modus operandi* of mercury, whether  
has or has not any specific action on the liver.  
It is no great difficulty in admitting it has, if it  
is granted that antimony exerts an influence on  
the skin, Cantharides on the kidneys & bladder, Spe-  
rank on the stomach, aloes on the rectum, why  
should not mercury act on the liver?

The operation in this disease however may be as-  
easily explained without attributing to it any ten-  
dency to act particularly on the liver, when it is  
admitted the power it exerts over the abscess  
& secretion, repels as is demonstrated in  
causing to be removed the pus <sup>in</sup> Hypopyum  
effusion in Leucoma and on the lungs  
& its capability of increasing the action  
the secretory vessels of the skin and kid-  
neys why should it not remove the infected  
state of the liver and increase its secretion

By a general action?

When we bear in mind too that the liver is the  
seat of disorder, <sup>and is the weakest & most irritable part</sup> and from a known law in the  
animal economy is consequently the most  
effected by our remedies, it seems to me to  
require no great effort of the mind to see  
why the liver should be most acted upon,  
(in the same way that a blister may remove a  
inflammation of the lungs though applied to  
the feet) without attributing to the mercury  
any particular disposition to act upon the  
viscus.

I have already declined embarking in any  
speculation on the modus operandi of mercury  
in liver complaints, whether its action be par-  
ticular or general, the high source from which the  
latter opinion emanates & which denies to it  
any particular virtue, though opposed by a  
of equally respectable medical men, would  
me pause before I would ~~venture~~ ~~to~~ ~~venture~~  
to attribute to it virtues which it might or  
not possess; fortunately however in a practice

out of view it is of little importance as the espousers  
both these opinions unite in advocating its  
utility in this disease which is the subject of  
present attention.

administering the different preparations of mercury  
which I believe sub mur Hydraz, is the most eligi-  
ble it is necessary to bear in mind that its proper  
use being to correct the state of the liver, it is  
so usefully employed if given as a purge:  
doses of this medicine should therefore precede  
in hours the employment of any other cathartic  
it appears to be more serviceable when allowed  
to continue in the stomach, & from the observation  
those gentlemen who treat of chronic biliary  
affections & who have had an opportunity of  
examining the operation of this medicine, it seems  
that these diseases are more relieved by means that  
correct the disordered secretion, than by evacua-  
tion from the bowels, for the complaint is often  
more after copious evacuations as it was previous  
on the contrary there is in many cases, a mark

ed improvement after the exhibition of a dose  
the mild muriate before any evacuation  
has taken place; a small dose of this medi-  
cine taken at a proper time proving  
better than any of those remedies that are  
the highest estimation for their anodyne  
and narcotic effects.

I think it however necessary to qualify the  
observations as I believe in all fevers the po-  
-sibility of evacuating the circulating contents  
the bowels is indicated and in no disorder  
more strongly than in those of the head or  
liver, for it may readily be believed that mu-  
-tations and indigested matter in the pri-  
-viae may prove an irritant to the bowels &  
sympathy to other parts; independently of the  
Cathartics promote the discharge of the exha-  
-rteries of the bowels & by taking off the me-  
-cal obstruction of the focus fire this way not  
only permit a free circulation, but dimi-  
-ish plethora.

In ordinary cases a dose of 10 or 15 grains of the sub-

hydrar. every 12 or 15 hours or 4 or 5 grains in com-  
bination with as much pulv. Antim. every two hours for  
first 24 will be sufficient which for the reason  
already assigned, and as the mercury will by  
this time have made its impression, be followed  
an aperient of some of the neutral salts  
stor oil, or a conspersion of Cremor Tartar &  
Laps.

particular attention should be paid to  
appearance of the evacuations either by the  
physician himself or the attendants on the  
patient, for this will greatly assist in forming  
opinion of the state of the liver and the impres-  
sion of our remedies.

All febrile disorders attended with heat & dry-  
ness of the skin diaphoretics of the saline & anti-  
acid kind may be advantageously exhibited  
and when we consider the important function  
of the skin and how great an emunctory we  
easily perceive what an auxiliary it  
may become in reducing febrile action.

Among the most eligible of the febrifuge medicines  
I should clap the Nit Pot. The antimonial prepara-  
-tions, Spiritus Mindereri Carb or Super Carb Sodae  
mixed with lemon juice and taken in a state  
effervescence. Spt. Nit. Dul taken separately  
combined with Vir Antim, or a combination of  
Nitre & Tart Antim. or when there is much ir-  
-ritability and jacitation unaccompanied with  
high arterial action. Pulv Doveri. might be a-  
-to be only exhibited

When the thirst is distressing which it often  
I should by no means inaitate those practitioners  
who withhold drink or allow none but the sta-  
-lating diaphoretic kind on the contrary I look up  
it as calculated to harass the patient. I should  
therefore allow him to drink moderately of lemon  
-toast-water or weak lemonade or any other beverage  
not calculated to excite the action of the head  
On the subject of blood letting in this disease,  
general rule can be laid down as in every case  
certain variations occur which require judgment  
and observation, much therefore must be always

the discretion of the practitioner -  
could appear as a tonic always, fatigues, if we could  
more strength by bleeding & thus lessening the  
ton of the heart, than we lose by the loss of  
& no doubt would arise upon the propriety of  
practice, but we should deceive ourselves by  
reasoning, for if no neural disorganization  
to be apprehended strength never could be  
aid by blood letting as the morbid action is  
a consequence of the condition of the blood  
rather the state of the blood the result of  
aid action -

let us allow for an instant the state of the  
in cause of excitement it would be difficult  
to apply a remedy in as much as we could not  
extract the inquinatum & leave the healthy & by  
extracting both nothing would be gained as  
striking off the support of the system we render  
it incompetent to resist the poison to which  
we justly refer both the excitement of the heart  
state of the fluids - however  
must be always remembered these are organs.

essential to life as the brain and lungs, these by  
the excitement of the heart may become involved  
against which catastrophe it will be prudent to  
guard, and as in gonorrhoea and gonorrhoeal  
ophthalmitis diseases arising from a peculiar  
poison, there is always more or less phlegmonous  
inflammation accompanying them, so in this disease  
as we have reason to apprehend the liver may  
be similarly affected, it will be judicious to observe  
the consequences of high arterial action on the

viscus.

The long contest about the proper period of exhibition  
of tonics among which bark is the best is I believe  
this time settled, & it is now generally admitted  
the most eligible time is during the apyrexia  
or when any marked remission of all symptoms  
of fever shall have taken place. though instances  
do now & then occur of such extreme exhaustion  
it will be found necessary to support over  
with stimulants even though he shall not be in

fever.

These means will I think be found sufficient to

more most attacks of this disease for I am  
inclined to believe "we rather want judgment  
precision in the application of old remedies  
than stand in any need of the introduction  
of new ones & with the poet should say

Be not the first by whom the new is tried,  
Nor yet the last to lay the old aside."

Joseph. Haller. 1789

This is a copy of the original manuscript of the first part of the work, which is now in the possession of the University of Zurich. The original is written in Latin and is in the hand of the author, Joseph Haller. The copy is written in French and is in the hand of the copyist, Joseph Haller. The copy is a faithful reproduction of the original and is of great value to the history of medicine.

## Dissertatio.

Ingenii ostentationi nullum est argumentum  
quod licentiam ampliore[m] praebuit; et eodem  
tempore, nullum obscuritatis labyrinthis plus invo-  
lutum quam mens humana. Philosopho themain-  
vestigationis fertile omnibus aetatibus fuit, Zoroaster,  
Bacon, aliarumque quorum spiritus emanatio-  
nes illuminare hominum animas tum de hac de  
tenebras multum contribuerunt, tempus ingenium  
que in explorandis mysteriis ejus abditis fue-  
runt exercita. Post indagationem operam, etiam  
ad consequentia, ut definita, vulgo accepta, compro-  
bataque perventum est. Ita tanquam multa alia  
mysteria, diu in naturae arcanis involuta, rapidus  
constansque intellectus humani gradus hoc evolvit  
et nostro conspectui exposuit, quod quidem scriptor  
praemium nobillissimae hominis occupationis de-  
nominavit: nempe, scientiam mentis humanae, utpote  
conversae cum structura humanae corporis complicata  
tamen concordanti. Cerebrum, organum tenerum  
et sensu acutissimum, inclusum defensumque ab iis

The first section of the report  
 gives a general view of the  
 progress of the work during  
 the year. It is divided into  
 three parts: the first  
 contains a list of the  
 names of the persons who  
 have been employed in  
 the service of the  
 Government during the  
 year; the second  
 contains a list of the  
 names of the persons who  
 have been employed in  
 the service of the  
 Government during the  
 year; the third  
 contains a list of the  
 names of the persons who  
 have been employed in  
 the service of the  
 Government during the  
 year.

ossibus, vulgo denominatis cranii ossibus, sedem  
esse mentis, nunc conceditur, cui sicut centro com-  
muni omnis sensatio pervenit et ibi percipitur.  
Sic sensuum instrumenta variorum, eas causas ex-  
ternas quas valetudini ministrant, ab iis quas  
nocent et cum sano ratione mentis corporisque  
sunt insociabiles, discernere licet. Inter sensorium  
commune ut dicitur aliasque humani corporis par-  
tes firma existit et interna. Esse aliquod similitudinis  
in formatione non dicere volo, sed medium comuni-  
cationis, facere ea, proscima relatione, participes in hu-  
mani corporis constructione, egregie accommodatum.

Principium hoc, igitur, tractans. hic denomin-  
abo communicationum nervosam, vel sensus trans-  
missionera ad centrum magnum, cerebrum: mutua  
inter se partium fiduciam, perturbationemque in  
qua attesa quom fit morbida attetam involvere  
potest, demonstrabo. nervis tam exquisitus tactus  
sensus est, ut vulnus leve angorem gravissimum  
excitabit. Sed argumentum necesse est assumere,  
de qua speciatim disserere volo.

Sensus omnes nostri, quum morbo percussi, et  
vice versa, vim mortuam vel salubrem, secundum  
impressionem acceptam et pro suâ communicationis  
facilitate vel morbi conditione in parte primum  
affecta, uter de utraque et corpore toto, exercent.  
Partem omnem in una confusione implicari pos-  
se, esse hoc constat. In presentia, tamen, mentis  
actionem in excitando et repellendo impulsum  
nosivum, vel verbis cæteris, ejus effecta in pro-  
creando et medicando morbum, considerabo.

Connexio intima et pene individua inter animum  
materiamque, paucissimorum (patuitate, exempli gratiã  
exceptis, impetum malum ab alio acceptum) am-  
bulans in conditione sana (non existentibus) alteri  
translatum in, clare illustrat. Utroque, utpote æ-  
quitudinis alterius conscium particepsque, ab ea  
primum affecto, onus removere conjuncto canatur.  
Hinc illis etiam fortuito observantibus, sanitatem  
sines necessariam esse ei alterius satis apparet;  
et veritatem accuratam que verborum meorum  
quotidianus usus medici exercitati ~~testari~~ testari

potest. Quoties in ratione vitae vulgari, conditionum  
rerum huic similem spectamus! nonne videmus  
ut impedimenta parva composita, et levia, pecu-  
niaria, exempli gratiâ; quorundam vitam con-  
trahere crebro valent; praecipue si cum his sine  
conjunctae causas noxiae aliae quas pene semper  
gignunt. Haec habeo testimonium certum, principi-  
is accusatis argumentum stare. Et eos ita con-  
siderans, vel sanitate vel morbo, mutuo officii,  
probandi causâ sic se rem habere, documenta  
aliquot proferam.

Hominem vini haustu leniter  
incitatum contemplemur. Stomachi nervos  
primo corripens, illine ab his transmissionis  
chordis per partes corporis omnes peruehitur,  
et ejus affectus cito apparent. Calor lenis tum per-  
sentitur, mens fit exhilarata, et ideae suae clariores  
et multa majis acutae: musculi effectum ad illos  
peruenisse, mentis actione testari possunt. Neque  
vascula sanguinea sunt exempta, sed aequè cum  
caeteris commoventur. Aucto cum impetu sanguis

a cordis latere sinistro propellitur, et ad peragen-  
dum officium constitutum urgetur.

Spentem, in multis conditionibus morboſis corpus in-  
valere poſſe, procul dubio, hoc temporis eſſe  
credo. Si valetudinaria viſamus aliaque loca cu-  
rae et auſilio eorum quas infirmatas ſeu ~~inferas~~  
infortunium invaſit, ſeparata; quot, rebus ſuis  
quaesitis auditisque, invenimus quorum malus praee-  
sens caſus, actioni mentis fortunã infelici la-  
borantis, ſolum, attribuendus eſt. Paſſus inter ſin-  
gulas, perſonae varii, commiſerationem moventes, con-  
ſpectui efferuntur. Hic ſpectantes, faciem palli-  
dam, maceram cadaverasamque unius cuius forma  
macie confecta et titubans caſum miſerabilem  
bene ſatis expoſionit, intuemur: illinc ſpectaculum  
ſevera luctuſum hypochondriacus alia mentis  
morbo laborantis victima, oculos in ſe convertit.  
Haec multis cum aliis quae proferri poſſent doloris  
amplitudinem humani et miſeriae, quae mens pro-  
creare valet, demonſtrare, quamvis imperfecte, ſuffici-  
unt. Quoadcunque, ait Dr. Potter cuius opinione, multum

honoris debetur; debilitatem inducere tendit, tendit  
etiam excitabilitatem augere; aut, verbis aliis, sic  
corpus disponit, ut nocentium activarum causa-  
rum multo facilius reddatur, et necessario id magis obno-  
xium morbi incursui vastationique facit. His pro-  
certis acceptis, et cognitis, quasdam esse mentis  
conditiones quae debilitatem utcumque obliquam  
gignunt, statim constat, quod nemo est qui neget,  
mentem in praesens morbum saepe valere.  
Aliquot morborum, in quibus mens saepe multum  
implicatur, enumerare nunc conabor. Nulla est  
aegritudo, quae, ut mihi videtur, actioni mentis  
est primo inducta tam frequenter, quam Dyspep-  
sia. Longa atque variata notarum turba, quae comi-  
tatur hunc intolerandum praecipue facit morborum  
omnium quibus homo subiectus esse potest. Cum, attamen  
simul cum notis divinis omnibus, quoties testimonium,  
haud dubitandum habuimus maerorem, sollicitudinem  
atque molestationem genuisse — Icterus etiam a mente  
interdum oritur. Post impetum irae vehementem  
flavum colorem super totam corporis superficiem

Faint, illegible text, likely bleed-through from the reverse side of the page.

inducere homines fuerunt inventi: eujus exem-  
pla plura quam unum memoriae sunt prodita.  
Hic, stimulatoris officia in hepate fungi videtur,  
ducens auctam bilis secretionem quae in circu-  
latione, ut ego puto, recepta, tum per cutem totam est  
diffusa. Apoplexis, quoque, toto in catalogo mor-  
borum terribilissimus maximeque letifer, magnis  
subitisque animi perturbationibus, ut gravi et vi-  
violenti irâ, vel, de contrario, laetitia subito impro-  
visoque communicatâ, saepe procreatur. Totum  
stimulatur corpus: Cor, simul cum caeteris sentiens  
impulsum, sanguinem cum impetu iterato, ad  
cerebrum propellit; quod rerum statum ad ~~pro-~~  
generationem hujus horridi periculosi que morbi  
adaptatum facit. De mentis efficacia in pro-  
creandis morbis, plus dici posset; sed exempla  
quae jam dudum prolata fuerunt, probare quod  
in parte prima thesisi proposui, satis esse ju-  
dico: Nunc repellendis, et tenuendis, medicandisque  
morbis potentiam ejus animadvertam.  
Genus humanum periculis impedimentisque

*[The page contains extremely faint, illegible text, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

undique circumdatur. Principia noscia se con-  
stanter exercent, semper parata tanquam hostes  
vigilans, partem infirmismissionam et minime defen-  
sam adoriri. Sed ut obsesi, salutis ansii, ad re-  
pellendum hostem invadentem rationes moliantur,  
sic leges quae animali oeconomiae praesident,  
tempore periculi, sunt ipsae vigiles. Vim repellentem  
intelligo, in corpore inhaerentem, quam vim  
medicatricem hic denominabo, et cui mens quum  
operam conferens firmiter conjuncta esse dicatur.  
Hanc, autem, ut seorsum agentem suisque viribus  
innitentem, tractare malo; et in hoc aspectu  
spectantes potentiam salutarem exercere inveni-  
emus. Mentem cum nasciis principis illis quae  
pandaem memoravi, prospere congressam esse  
ne omnino dubito. Ea in conditione quae causarum  
morbosarum operatione faret, videlicet debilitate,  
aliquid leniter stimulans vires corporis prostra-  
tas supra potestatem illarum Elevaret.

randi facultatem, nemo est quin affirmet.

undique circumdatur. Principia noscia se con-  
stanter exercent, semper parata tanquam hostes  
vigilans, partem infirmissimam et minime defen-  
sam adorsis. Sed ut obsesi, salutis ansii, ad de-  
pellendum hostem invadentem rationes moluntur,  
sic leges quae animali oeconomiae praesident,  
tempore periculi, sunt ipsae vigiles. Vim repellen-  
tem intelligo, in corpore inhaerentem, quam vim  
medicatricem hic denominabo, et cui mens quum  
operam conferens firmiter conjuncta esse dicatur.  
Hanc, autem, ut seorsum agentem suisque viribus  
innitantiem, tractare malo, et in hoc aspectu  
spectantes potentiam salutarem exercere inveni-  
emus. Mentem cum nascis principiis illis quae  
gaudium memoravi, prospere congressam esse  
ne omnino dubito. Ea in conditione quae causarum  
morbosarum operatione faret, videlicet debilitate,  
aliquid leniter stimulans vires corporis prostra-  
tas supra potestatem illarum Elevarit.  
Hoc efficere mens interdum potest, et vi sua  
morbo venienti occurrat. Habere quoque eston-  
vandi facultatem, nemo est quin affirmet.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and cannot be transcribed.]*

In morbis quibus aegrotus esse debilitate multum  
patitur, animum habere quam plurimum erectum,  
optimum semper existimatur: et si non sic  
excitare possimus ut illum stimulet, praeter-  
tere tamen animi maiorem esse quo effectus con-  
trarius perniciosusque oritur, nitimur.

Postremo; mens in medendo morbo multum valet;  
quod ad probando, nullo exemplo clariore opus  
est quam aegroti eius credulitas persuaderi  
potest, et in quem impressio, nostris accommodata  
consiliis facta est: exitus prosperus, ex hoc ortus,  
mirandus est. Fiducia vana medico curanti, seu  
fides fanatica ut potentia gubernantis et sup-  
remi Dei valetudinem rursus renovaret, haec  
ipsum efficit; cum si ille animum despan-  
deret, et imaginatio sua eventum diversum  
concepisset, fortasse e lecto ne omnino assurre-  
isset: quod pristinum proverbium ratum facit,  
Imaginatio et occidere et sanum reddere  
valet.

An essay

on

Cow-pox as a preventive of Small-pox

by

Charles Wesley Parker

of Elkton, Maryland.

The discovery of a remedy for the prevention of so loathsome and fatal a disease as that of small pox, may justly be ranked among the first in any age and in any science. In the preservation of human life, and in the alleviation of human suffering, this discovery stands unrivalled, and is justly entitled to be placed at the head of that long list of discoveries of which the medical profession can boast.

Previous to its being known that Cow pox was a preventive of small pox, the practice of preparing the system and inoculating with the small pox prevailed, but this was but a choice of evils, as the small pox communicated in this way was still a dangerous disease, as will appear on reference to the bills of mortality in any of our large cities previous to the introduction of vaccination. In the Lond. Med. and Surg. Trans. vol. x. p. 326, it is stated that, from 1804 to 1818, twenty three thousand

one hundred and thirty four lives have been saved in London by vaccination, compared with effects of inoculation in the preceding fifteen years."

And in the New York Med. Rep. New Series vol 1 P. 200, it is stated that "formerly two thousand persons died annually in London of small pox; in 1812, such was the effect of vaccination, that the deaths were only seven hundred and fifty, although the population had increased within two years 1810-1812."

It is not certainly known where the practice of inoculation first commenced. It has been ascribed to the Ethiopians who employed it as a means of preserving the beauty of their women. Mungo Park in his travels in the interior of Africa, found that inoculation had been practised on the Guinea Coast.

For the introduction of the practice into England we are, it is believed, indebted to Lady Mary Wortley Montague, whose son was inoculated in Constantinople during her residence there,

The first part of the paper is devoted to a general  
 consideration of the subject, and to a statement of the  
 objects to be attained. It is then divided into three  
 parts, the first of which is devoted to a description of  
 the nature and extent of the disease, and to a  
 statement of the symptoms which attend it. The second  
 part is devoted to a description of the various  
 methods which have been employed for its cure, and  
 to a statement of the success which has attended  
 each of them. The third part is devoted to a  
 statement of the author's own views on the subject,  
 and to a statement of the reasons which induce him  
 to hold those views.

and whose infant daughter was the first who un-  
 derwent the operation in England, about the  
 year 1721; and the Royal Family submitting  
 to the operation in 1726, ~~the~~ <sup>the</sup> practice of in-  
 oculation prevailed <sup>in</sup> from that period to <sup>the</sup> time  
 of the discovery of the preventive power of the  
 Cow pox by Dr Jenner. <sup>The</sup> genuine Cow pox  
 is a disease which appears on the teats of the  
 Cow, in the form of vesicles, of a bluish colour,  
 approaching to livid. <sup>These</sup> vesicles have an  
 elevated margin, and are depressed in the Cen-  
 tre; and are surrounded with an inflamed  
 circle or areola. <sup>The</sup> fluid which they con-  
 tain is limpid. <sup>The</sup> animals appear languid,  
 and feverish; and the secretion of milk  
 is diminished. <sup>The</sup> fluid contained in  
 these vesicles when applied to parts in the hu-  
 man subject destitute of cuticle, or to parts  
 where this covering is abraded, produces a disease  
 possessing the same specific and diagnostic characters,

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

Hence, dairy maids are particularly exposed  
 to it. There is also a spurious Cow pox, or inf-  
 -fective modification of the true Cow pox,  
 incapable of preserving against small pox, which  
 was the source of much ~~unending~~ difficulty to  
 Dr. Jenner, in his researches after the prophylactic  
 powers, of the true disease; nor were his difficulties  
 removed, until he made himself master of  
 the diagnostic characters of the two diseases.  
 In the spurious, the vesicles are less uniformly  
 circular: fluid not limpid, frequently pure-  
 -lent; with little or no central depression.  
 These are the diagnostic symptoms as it ex-  
 -ists in the cow, and are equally applicable  
 when it is transmitted to the human system.  
 In inoculated Cow pox <sup>in</sup> from genuine virus, the  
 progress of the disease as given by Dr. Good  
 in his study of medicine 2<sup>nd</sup> Am. Ed. P 596, is  
 as follows—

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

"The puncture disappears soon after the insertion of the lancet: but on the third day a minute inflamed spot becomes visible. This gradually increases in size, hardens, and produces a small circular tumour, slightly elevated above the level of the skin. About the sixth day, the centre of the tumour shows a discoloured speck, augments in size, and becomes a manifest vesicle, which continues to fill, and to be distended till the tenth day: at which time it displays in perfection the peculiar features which distinguish it from the inoculated variolous pustule. Its shape is circular, sometimes a little oval: but the margin is always well defined, and never rough or jagged; the centre dips instead of being polarised, and is less elevated than the circumference.

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

About the eighth day, when the vesicle is completely formed, the disease exhibits some thing of a constitutional influence: the arm it is painful, and there is perhaps a slight head ache, shivering, lassitude, loss of appetite, and increase of pulse, this may continue in a greater or less degree, for one or two days, but always subsides spontaneously, without leaving any unpleasant consequence. During the general indisposition the vesicle in the arm becomes surrounded with a circular inflamed halo or areola, about an inch or an inch and a half in diameter, which is the pathognomic proof of constitutional affection, how slightly soever the internal symptoms may shew themselves. After this period, the fluids in the vesicle gradually dries up: the surrounding blush becomes fainter, and in a day or two dies imperceptibly:

1

*[The text on this page is extremely faint and illegible, appearing as ghosting or bleed-through from the reverse side of the paper. It consists of approximately 20 lines of cursive handwriting.]*

so that it is seldom to be distinguished beyond  
the thirteenth <sup>day</sup> from inoculation.

At this time the vesicle hardens into a thick scab,  
of a brown or mahogany colour: and if not separ-  
ated antecedently by violence or accident,  
falls off spontaneously in about a fortnight,  
leaving the skin beneath perfectly sound and un-  
injured. The entire progress of the inoculation  
scarcely opens a door to any medical treatment  
whatever. No preparatory steps are called for,  
as in small pox: and all that can be necessary  
is a dose or two of some aperient medicine if  
the Constitutional indisposition should be severe  
or troublesome." From 1798 untill 1813 or 14, the  
reputation of the Cow pox, as a preventive of small  
pox, steadily and constantly advanced in the es-  
timation of all classes of people, and so firmly  
was it established, that the few cases of small  
pox which did, from time to time, arise in those  
who had been vaccinated, were attributed

The first part of the paper is a list of names  
 of the persons who have been admitted to  
 the office of the Secretary of the  
 Board of Education since the year  
 1850. The names are arranged in  
 alphabetical order, and the date of  
 admission is given for each name.  
 The names are as follows:

Adams, J. M. 1850  
 Allen, W. H. 1851  
 Anderson, C. D. 1852  
 Armstrong, J. B. 1853  
 Baker, R. T. 1854

to the patients not having had the true vaccine disease, and not to any doubt of its perfect and entire prophylactic powers.

We are informed in the Ed: Med. and Surg. Journal, for 1820 <sup>that</sup> Dr Adams of Glasgow in Scotland in 1813-14 observed and described one hundred and fifty cases of small pox presenting some peculiar phenomena, as having occurred after perfect vaccination. It was noticed in the Isle of Man in 1817, and in England and various parts of the Continent in 1818. From the general mildness of most of its symptoms, compared with those of the small pox in the unvaccinated, it was called the varioloid, but it was then believed, as it is now, to be the same disease as it appeared to be in the vaccinated and unvaccinated, differing only in degree, hence the propriety of calling it modified small pox. That it is nothing more than

A modification of small pox, is established by the  
 fact, that the matter taken from the pustules in those  
 who have had the vaccine disease, will produce  
 small pox in those who have not been vaccinated,  
 and the matter taken from the pustules of those  
 who have not had it, will produce the modified  
 form of the disease in those who have been vac-  
 -cinated. These facts are established by Sir  
 Gilbert Blane, and are also noticed in  
 Thomas' Practice. The proportion of those who  
 have had the cow pox, and are afterwards sus-  
 -ceptible of small pox, it is not easy to ascertain  
 of 46,662 persons who have been vaccinated by  
 the English vaccine Establishment, only five of  
 whom are reported to have had small pox in any  
 form." *Ann. Hor. Med.*

Mr Croft of England, who kept a register of cases at  
 Norwich, of whom ninety one had been vaccina-  
 -ted, of which number three only had small pox.

and they the mild form of the disease. Hence it would appear that the proportion of those who are not protected <sup>and</sup> from small pox, even in its modified shape, to those who are, is but small, and that it is not calculated materially to impair ~~materially~~ ~~to impair~~ our belief in the value of vaccination as a preventive of small pox.

Why vaccination should be a preventive in some cases, and not in all, is a problem more easily stated than solved. It is known that small pox itself does not always destroy the susceptibility to a subsequent attack, and it has been asserted that some are obnoxious to it at every successive exposure to its contagion.

As a general rule the vaccine disease should be viewed as constituting a certain and complete exemption, and those cases in which it fails in being so, should be ascribed to the influence of other diseases, or to peculiar habit or constitutional idiosyncrasies.

The first part of the paper is devoted to a general  
 consideration of the subject. It is shown that the  
 results of the experiments are in accordance with  
 the theory. The second part is devoted to a  
 detailed description of the apparatus used in the  
 experiments. The third part is devoted to a  
 discussion of the results. It is shown that the  
 results are in accordance with the theory. The  
 fourth part is devoted to a discussion of the  
 results. It is shown that the results are in  
 accordance with the theory. The fifth part is  
 devoted to a discussion of the results. It is  
 shown that the results are in accordance with  
 the theory. The sixth part is devoted to a  
 discussion of the results. It is shown that the  
 results are in accordance with the theory. The  
 seventh part is devoted to a discussion of the  
 results. It is shown that the results are in  
 accordance with the theory. The eighth part is  
 devoted to a discussion of the results. It is  
 shown that the results are in accordance with  
 the theory. The ninth part is devoted to a  
 discussion of the results. It is shown that the  
 results are in accordance with the theory. The  
 tenth part is devoted to a discussion of the  
 results. It is shown that the results are in  
 accordance with the theory.

modifying and impairing its <sup>own</sup> force. It is an opinion which generally prevails among the people, that the influence of vaccination over the system is impaired by time, and that the insusceptibility to the influence of small pox contagion, is only to be preserved by repeated vaccination; and there being something magical in the number seven, seven years is the period assigned by them, during which it is to be relied on; and consequently that vaccination should be repeated every seven years. The fallacy of this opinion it is hardly necessary to controvert, as I am not aware of its having been sustained by any member of the Faculty. But if it were necessary, facts could be adduced to prove that its preventive influence is not impaired by time - I will, however, having a case in point, give it - My preceptor, who was vaccinated twenty seven years ago, does at this time (having patients with small pox) as he has frequently done before in the discharge of his professional duties, expose

The first part of the paper is devoted to a general  
 description of the country and its resources.  
 It is situated in the western part of the  
 state, and is bounded on the north by  
 the mountains, on the east by the  
 river, and on the south by the  
 sea. The soil is fertile, and the  
 climate is healthy. The principal  
 occupations of the people are  
 agriculture, stock raising, and  
 commerce. The principal cities are  
 and the population is about  
 100,000. The paper concludes with  
 a list of the principal towns and  
 a description of the principal  
 industries.

Himself with impunity to the variolous contagion.

Having pointed out those <sup>or</sup> features in true cow pox, by which it can be distinguished <sup>or</sup> from the infective or spurious kind, I shall now endeavour to give a succinct account of the characteristic symptoms of small pox, as it appears in those who have not undergone the vaccine disease, and in those who have. Small pox commences with the usual signs of a <sup>or</sup> febrile cold. <sup>or</sup> About the third or fourth day an eruption resembling flea bites, appears on the <sup>or</sup> face, neck and breast; and successively over every part of the body. <sup>The face is much more covered than any part of the body,</sup> so much so, that the proportion is reckoned <sup>or</sup> five to one. On the appearance of the eruption there is generally an abatement of the <sup>or</sup> fever. <sup>or</sup> The head, face, and hands gradually swell, and the eye lids are often so much swollen as to close the eyes. The spaces between the pimples are red-dish and the <sup>or</sup> fever is of the inflammatory kind, and suppuration is generally completed about the eighth day.

About the eleventh day the inflammation and pustules begin to abate, and the latter dry away by degrees and scale off by the <sup>fourteenth</sup> ~~or~~ <sup>fifteenth</sup> day. The extent of the eruption is in proportion to the violence of the eruptive fever. The pimples being few in number in those cases where the fever is mild, and numerous where it is violent. The eruption appears on all parts to which the air has access, external and internal; hence the soreness and swelling of the throat, increased secretion of saliva, cough, expectoration and dyspnoea &c. are common in all severe cases, particularly if they partake of the confluent variety. When the swelling of the <sup>face</sup> declines it is common for the hands and feet to swell, which is considered a favourable symptom:

Such is the usual course of the distinct variety of this disease. It would be difficult however to draw the line of separation between the severer cases of the distinct, and the milder cases of the

The first part of the document  
 discusses the general principles  
 of the system and the  
 various methods of  
 application. It is  
 intended to provide a  
 comprehensive overview  
 of the subject matter  
 and to serve as a  
 guide for the reader.  
 The second part of the  
 document contains  
 detailed information  
 regarding the  
 specific aspects of  
 the system. This  
 section is designed to  
 provide a thorough  
 understanding of the  
 various components  
 and their interactions.  
 The third part of the  
 document focuses on  
 the practical application  
 of the system. It  
 includes a series of  
 examples and exercises  
 that illustrate the  
 various methods of  
 application. These  
 examples are intended  
 to help the reader  
 understand the  
 practical aspects of  
 the system and to  
 provide a basis for  
 further study and  
 research.

confluent varieties, running as they sometimes do, into each other by insensible degrees.

In the confluent, the eruptive <sup>fever</sup> is higher, and the eruption at first assumes the appearance of a general efflorescence, without any distinctive points; innumerable pimples make their appearance about the third, being a day or two earlier than in the distinct variety. These soon coalesce, and become <sup>filled</sup> with a yellowish serum, as this variety seldom suppurates regularly.

The <sup>fever</sup> is apt to assume a low type, and instead of subsiding on the appearance of the eruption, as in the distinct variety, very generally increases, attended with comas and deliriums.

The increased secretion of the salivæ and soreness of the mouth and fauces are troublesome.

About the eighth day the pustules break, and extensive dark or brown scabs are <sup>formed</sup>, which are very fetid. About this time too, the fever

undergoes considerable exacerbation, called secondary fever, and is a period of great danger to the patient. If he survive, the swelling of the face, about the tenth or eleventh day, abates, and that of the extremities commences.

It is a disease attended with much danger, and one of hideous aspect. It was formerly one of the greatest scourges of mankind. It is estimated that one in six, of all who take it in the casual way, dies. A mortality scarcely less than that of the plague. There is some slight resemblance between the distinct variety and chicken pox; and in the mildness of the symptoms, a still greater resemblance, perhaps, between modified small pox and chicken pox. There is however, one symptom which would not escape the most casual observer, and is completely characteristic viz- In small pox the pustule invariably presents a depressed centre. The eruption in chicken pox

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side of the page.

is purely vesicular; and if the vesicle be punctured, its sides collapse and fall to a level of the surrounding parts.

When small pox occurs after perfect vaccination, the initiatory symptoms are sometimes pretty severe, and resemble the eruptive fever in symptoms and duration of the common distinct variety of the same disease. But on the appearance of the eruption the fever generally terminates. The eruption runs its course with great rapidity, the pustules rarely exceeding the fifth day before they have begun to turn, and the lymph contained in them appears to dry and fall off without the intervention of pus, leaving the face marked for some time after with small brown spots, but without pits.

All authority on the subject goes to show that it is not only as safe, but as very mild disease; and one of comparatively rare occurrence. But

The first part of the paper is devoted to a general  
 consideration of the subject, and to a statement of the  
 objects to be attained. It is then divided into three  
 parts, the first of which is devoted to a description  
 of the nature and extent of the disease, and to a  
 statement of the symptoms which attend it. The second  
 part is devoted to a description of the nature and  
 extent of the disease, and to a statement of the  
 symptoms which attend it. The third part is devoted  
 to a description of the nature and extent of the  
 disease, and to a statement of the symptoms which  
 attend it.

17-

if it occurred more frequently, or, indeed, if vaccination had no preventive powers whatever, and had no other effect than that of modifying small pox, and disarming it of its malignancy and danger, it would notwithstanding, be an inestimable blessing to mankind. It is one of the established rules in the doctrine of cow pox, that it cannot be ~~repeated~~ communicated to the same individual more than once, but in the present state of our information regarding its diagnostic characters, there appear to be some exceptions to this rule, and they are, perhaps, about as numerous as modified small pox after apparently perfect vaccination. Hence, it appears probable, that the susceptibility of the system to the influence of small pox contagion is not entirely destroyed, except in those cases in which the susceptibility to the influence of cow pox is also destroyed. Should my conjectures prove to be well founded, subsequent vaccination will be the best test of the preventive influence of previous vaccination. I would, therefore, recommend that <sup>can it</sup> in all, be repeated until the system shall be no longer susceptible to its influence. —

— PNEUMONIA is a disease of frequent occurrence, and from the dangerous types it often assumes, the investigation of its history and most proper mode of treatment is of primary importance to the Medical practitioner. It may occur at any season of the year, but it prevails to the greatest extent during the spring months, and during some seasons it rages Epidemically through a large tract of country proving extremely fatal in its effects —

The symptoms of this disease are few in number and though most of them singly are observed to take place in other diseases yet taken collectively they characterize it so strongly that it is almost impossible for the well informed practitioner to mistake it. — Dr. Cullen defines this disease, Pyrexia, dolor in quadam parte thoracis, respiratio difficilis et tussis and places it among the phlegmasia. — The febrile symptoms generally show

*[Faint, illegible handwriting throughout the page, likely bleed-through from the reverse side.]*

themselves before the local ones, but occasional  
the latter are the first experienced. The cold  
stage is generally strongly marked in some instan-  
a severe chill ushers in the hot stage - The state  
the pulse and skin vary according to the character  
the disease, and afford to the practitioner a clue  
its proper treatment. The febrile symptoms if  
preceded or accompanied from their commence-  
ent are soon followed by a short hurried respiration  
suppressed cough and pain in some part of the  
chest. The local symptoms are frequently much aggra-  
ted by particular positions of the body, the patient  
finding ease only from lying on his back. The Cough  
highly characteristic of the disease. It is short and  
suppressed and is made with as little effort on the part  
the patient as possible. The principal diseases with  
which Pneumonia may be confounded are acute Hepatitis  
and inflammation of the intercostal muscles - where the  
disease is accompanied with fever, the diagnosis is some-

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mirrored and difficult to decipher.

is difficult. In Pneumonia when the pain is very  
severe, the difficulty of breathing and the cough are  
proportionate to it, and the accompanying consti-  
tutional irritation is considerable. In inflamma-  
tion of the Intercostal muscles the pain is by far  
the most prominent symptom and the difficulty  
of breathing less in proportion unless a full inspi-  
ration be attempted so as to bring the inflamed  
muscles much into action when it becomes extremely  
acute - The fever is likewise less in proportion to the  
local symptoms and the cough is less troublesome  
except when a full inspiration is attempted.

In acute Hepatitis the pain is generally increased  
by pressure over the region of the Liver, and we  
discover the organ is not performing its functions  
properly, that the stomach is irritable, the bowels  
constipated or the biliary secretion is of a vitiated un-  
healthy appearance. We are frequently assisted in  
arriving at a correct diagnosis by observing a jaundice

ing of the eye, and by the patient's complaining  
of a pain in the region of the acromion process of  
the Scapula — Under the title of Pneumonia is  
imprehended inflammation of the viscera of  
the Thorax and of the pleura and it has hence  
been divided into Pleuritis vera and the peripneu-  
monia; the former denoting inflammation of  
the lining membrane of the Thorax and the lat-  
ter inflammation of the substance of the Lungs.  
This distinction whether correctly founded or not is of  
very little practical use. The treatment is not at all  
changed by it, as inflammation of the Pleura even  
if it should sometimes be proved to exist without the  
Lungs themselves being concerned, still they are so  
contiguous to the inflamed membrane and so  
liable to be affected in the course of the disease that  
the same remedies are required and to the same extent  
if we supposed them to be already involved.  
Besides it is extremely doubtful if we have any

athognomonic symptoms in which this distinction can be founded. A more useful division of this disease in a practical point of view is founded on the character of the accompanying fever. It may be of a low Typhus grade in which the vital powers are prostrated from the commencement or of the character of Synocha. I do not wish to be understood as recommending the above division of the disease strictly scientific - These two different states run insensibly into each other that it is impossible to draw an exact line of demarcation between them. The synocha in a few days frequently runs into the symptoms of Typhus and many cases occurring which from the commencement it is difficult to decide in which division they ought to be ranked. Still, however imperfect the division, it is highly useful in the consideration of the treatment, and the practitioner who treats Pneumonia without reference to this distinction is more worthy the name of an

executioner than a Physician — The difference in the symptoms of these two states is the same as is observed between the Febris Synocha and the Febris Typhus. In the former the pulse is strong, tense and quick, the skin is hot and dry and muscular debility not very great — in the latter the Pulse is frequent, small and weak, the skin is dry but the temperature is not so much increased generally as in the former state. The patient complains of much ~~the~~ muscular debility and frequently unable to stand in a few hours after the invasion of the disease.

The tongue is generally covered with a slimy, white mucus coat which soon becomes brown and dry. Delirium is an early symptom and the patient is restless and desponding. —

The Athletic and those of a plethoric habit are most subject to Pneumonia. No Phlegmasia is more easily renewed in persons who have once laboured under it. Dr Cullen observes it is more apt to occur between the age of 40 and 60, but it does

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

to appear that any age is exempt from it.

The principal causes of the disease are those of general inflammations, such as changes of temperature, exposure to cold and damp weather, sudden exposure to cold particularly when the skin is moist, suppressed excretions, suppressed eruptions and every thing which conduces to plethora — The causes which are peculiar to this disease act immediately upon the lungs, violent exercise propelling the blood rapidly through the Lungs, loud speaking, blowing wind instruments &c.

Pneumonia terminates by Resolution, Effusion, Suppuration & Gangrene.

Resolution is the only favourable termination, which is marked by a copious expectoration of a thick white or yellowish matter, a little streaked with blood and brought up with little exertion, hemorrhage from the Lungs or other evacuation, particularly by the skin which seldom fails to bring relief.

The second termination generally proves fatal by an effusion of red blood or lymph in the cellular substance of the Lungs, so as to impede the circulation and the patient dies from suffocation. The tendency to effusion may be known by the unusual violence of the symptoms, a change in the appearance of the sputa expectorated, the sinking of the pulse, by the restlessness and anxiety, the hurried and laborious expiration. When effusion has taken place, there is an entire cessation of pain, the pulse becomes more feeble and intermitting, the difficulty of breathing increases, the face is pale and shrunk, cold clammy sweats break out, hiccup, facies hippocratica and death finally closes the tragic scene.

When suppuration has taken place, it is manifested by rigors and a sense of fullness in the part, an abatement of pain, by the pulse becoming softer and either slower or more frequent, the cough and dyspnoea continue & are rather augmented and hectic symptoms

in following. We have reason to expect suppuration, the symptoms do not yield to blood letting and the pur remedies and the signs of resolution do not appear in a few days. This disease rarely terminates Gangrene - the symptoms are similar to those of Pusion. — —

The Prognosis in this disease is gathered from the severity and nature of the symptoms, the relief obtained from the use of the remedies, the age, constitution and general habits of the patient and the genius and character of the prevailing Epidemic. With regard to the severity and nature of the symptoms, it is a mark of a dangerous disease, when either the states mentioned in the division of the disease is very strongly marked, but more danger is to be apprehended from the Typhus state, because the remedies applicable to that state have less influence on the local affection. When the Skin is cool in the commencement, attended with delirium

and great impairment of the muscular power, with  
continual restlessness, the case is of the very worst  
character, and should that state continue for several  
days and the skin become covered with a cold  
clammy perspiration recovery is hardly to be expec-  
ted. When the fever runs very high and the state  
the pulse unequivocally calls for the lancet, - should  
free use of it convert a tense strong pulse into a  
relaxed small one and bring no relief to the pain  
and difficulty of breathing, should the expectoration  
still continue scanty and of a thin consistence - dan-  
ger is to be apprehended. On the contrary, should  
the pulse become more soft and less frequent, the cough  
more free and loose, the expectoration of a yellow  
color and of considerable consistence, the pain abate  
and with it a cessation of the febrile symptoms, with  
improvement in the respiration - recovery is con-  
fidently to be looked for.

In considering the prognosis, it may not be

proper to remark, that there is in this disease a  
at amelioration of the symptoms after the use of  
Lancet. So much is the condition of the patient  
improved that he deems himself convalescent,  
but this improvement is frequently but of short  
duration, the fever returns with increased violence  
and all the symptoms appear in an aggravated  
state. In no disease can a judicious prognosis  
be drawn from a few symptoms separately con-  
sidered and in none with so little certainty as in  
this. The Respiration is frequently much hurried  
and the cough oftentimes continues very troublesome  
even after the patient is convalescing.

In considering the favourable and unfavourable  
symptoms in forming a prognosis, due attention  
ought to be paid to those indicating any of the  
peculiar terminations of this disease. When those  
of suppuration or effusion show themselves after  
proper remedies have been assiduously used

a stage of the disease when those terminations are  
to be dreaded, the Prognosis is rather unfavourable,  
the age, constitution and general habits of the patient  
to be carefully considered in forming an opinion  
of the probable issue of this disease. Persons ad-  
vanced in life with a broken down constitution  
are less able to bear the use of those remedies which  
in an inflamed state of the Lungs imperiously  
call for. Should the disease terminate in suppura-  
tion the constitution of the patient is what we  
must principally look to — Should it be strongly  
tainted with scrofula, Phthisis pulmonalis will in  
probability be the consequence — Should it be  
free from any taint of that kind, the contents  
of the abscess may be expectorated and the Ulcer  
heal as in other parts of the body. It must  
be enforced itself on the observation of all  
practitioners who have had an opportunity of  
treating many cases of this disease, that it is

peculiarly fatal to intemperate men, and should  
a disease attack with violence the habitual drunk-  
ard, his recovery is but rare. This disease we have  
marked sometimes prevails Epidemically and  
such useful information relative to the prognosis  
may be obtained from an attentive study of its  
causes or character. In some years it is peculiarly  
fatal, and the cases which ultimately prove so are  
sometimes very similar in the symptoms charac-  
terizing the disease from its commencement to  
a fatal termination -

The treatment of this disease is entirely reg-  
ulated by the type it assumes. The lancet is in  
one the unicum remedium and in others altogether  
inadmissible - and to decide when to dispense  
with its use and when to use it boldly is in many  
cases extremely difficult. When the Pulse is tense  
& strong, the skin hot and dry, the pain severe,  
the breathing difficult, blood should be

ely drawn - No circumstances can well forbid  
loss under those symptoms - and it should be  
allowed to flow until the Pulse becomes softer  
and there is a manifest. In cases of this descrip-  
tion it will often be necessary to repeat the opera-  
tion in the course of a short time, and should  
vascular action have a disposition to increase,  
then as the pulse becomes hard and strong, the  
in difficulty of breathing distressing, we must  
not to the use of the Lancet again and again.  
Cases of this description will require the bowels  
be opened freely - and for this purpose the  
sliding laxatives are most proper - Until the  
hardness of the Pulse and the violence of the  
fever is subdued, the best expectorant we can  
use is the Lancet - after it has been freely employed  
according to the urgency of the symptoms and  
Bowels have been evacuated - We should  
minister every two or three hours nauseating

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

us of Tactar emetic in some mucilaginous diluent  
for the purpose of promoting expectoration  
& determining to the skin. At this crisis of the  
case blistering should be brought to our aid and  
blister should be applied as near to the part af-  
fected as possible. It is of advantage that the blister  
should be large and it should be allowed to remain  
8 or 12 hours, as great advantage may be ex-  
pected from a free discharging raw surface.

Under this treatment we will find that the first  
mentioned type of the disease will generally give way  
to an open skin & free expectoration with a soft  
& slower pulse will announce a speedy con-  
valescence. Should we be disappointed in our  
expectations of relief & although the above men-  
tioned remedies were judiciously & energetically  
used the local affection is still remaining with  
powers of life too much prostrated for further  
meddling - we must rest our dependance on

*[The text on this page is extremely faint and illegible, appearing as ghostly impressions of handwriting.]*

mercury - one or two grains every 6 or 8 hours should  
given in the form of pill to which a little  
ipecac may be added, should the bowels require  
evacuation. Our diaphoretic medicines should now  
be changed - instead of the solution of Tartar Emetic  
may administer an infusion of Serpentina,  
provided the Pulse is soft under its use and cutic-  
ular action is increased by it.

In the treatment of the more aggravated cases of the  
second type of the disease, it is needless to offer any  
arguments to prove the impropriety of  
bloodletting. The sunken visage, the powerless  
pulse and the scarcely perceptible pulse, will  
actually protect the patient from such improper  
treatment, when there is the least judgement  
or discrimination in the Physician. Emetics in  
such cases are often admirable remedies, their  
powerful action on the whole system and par-  
ticularly on the Bronchial glands and cuticular

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and difficult to decipher.]*

effects are followed by the happiest effects.  
Should be our aim immediately after vomiting  
keep up as far as possible those two secretions  
for this purpose we should apply a large  
water to the chest and give some gently stimula-  
g diaphoretic as *Serpentaria*, *virginiana* &c.  
Should perspiration and expectoration follow  
accompanied with an improvement in the Pulse  
Breathing, we are assured that our treatment is  
correct. Sometimes the vital prostration is so con-  
siderable that we are obliged to resort to more pow-  
erful stimulants as wine, whey, toddy &c, but it  
should always be done with extreme caution  
and great vigilance. -

We have now described the two types under which  
the disease may appear & carefully noted the  
appropriate treatment of each - As those two types  
possibly run into each other the treatment  
to be so modified as to suit the particular

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

condition of each case. No general rules can  
be laid down, but must leave much that is  
so important to the life of the patient, to the  
judgement and discrimination of the Physician.  
It is only by keeping the division we have  
pointed out constantly in view, and by cau-  
tiously examining which type has the prepon-  
dance, and modifying the conclusion by  
the age, general habits & constitution of the  
patient, with the general character of the  
prevailing Epidemic, & directing his treatment  
accordingly that he can expect to contend  
successfully against the disease. —

An Inaugural Dissertation

On Dysentery

Submitted to the inspection of the faculty of the  
University of Maryland.

By Arnold E Waters

Nathaniel Potter M. D.

As a slight but most sincere Token of  
Admiration of his genius, respect for his character,  
& gratitude for his friendship,  
his Production is inscribed by his obliged  
& affectionate Student. A. E. W.

1830

## Dysentery

This disease may be with great propriety considered, Dr Sydenham does a fever turned inward on the intestines. This view of it we are led to the most successful mode of treatment; for it carries our views beyond the local affection, to its medical cure. But before I give this disease an accurate description it will be necessary for me to point out some diseases, <sup>with</sup> which it may possibly be confounded viz Colic Cholera and Diarrhea. Although these may at first view appear to be very distinctly combined, yet, I hope I shall be able to show that to the minute observer, it will not be so arduous an undertaking. I mention Cholera as a disease which might be confounded with this, but it may readily be distinguished by its being so rapid in its progress, coming on with frequent vomiting, and purging of bilious matter & great and sudden weakness and languor and by its soon giving away to the proper treatment, such as opium alcohol & other Camphor and such powerful Stimulants.

where as the progress of dysentery is more slow, and generally aggravated after the use of Opium - the beginning; but dysentery after begins more

2  
like a curmen lay and goes on increasing in violence with an uneasy ness at the stomach, a violent pains in the intestines, a tenismus frequent ineffectual effort to go to stool is a most constant in this disease, where as no such thing attends cholera these may be spasm of the stomach proceeding from excessive debility, but these may be readily distinguished from tenismus and their cure is directly opposite or perhaps in dysentery a little mucus or blood serum is discharged where as in diarrhea the discharge is generally copious, without the fruitless straining, and griping, tenismus fevers, for tenismus violent griping pains fevers, are the principle signs by which to distinguish a flux or dysentery from a diarrhea and to these may be added, as the disease advances, the mucous and serous discharges never appear in diarrhea; for it is not accompanied with signs of violent inflammation or irritation in the intestines; but in dysentery these symptoms are always present;

We may likewise judge of the disease by the season of the year, or the diseases which are prevalent, dysenteries mostly appearing in

Autum or the latter part of Summer; but they are not  
confined entirely to this season for they appear also  
the Spring, Diarrhea often proceed from slight Causes  
obstructed perspiration eating much green fruit or  
ly and spicy Food, and are easily overcome by a  
or two of Rhubarb and Laudanum; but in  
dysentery Rhabarb or Laudanum; would be the most  
pernicious Medicines that could be exhibited.

I shall next draw a discrimination between this disease  
and colic; colic is a complaint which generally  
proceeds from hardened faeces or flatus bound up  
the bowels which produces pain and the constant  
symptoms of the disease but there is generally  
fever tenesmus or bloody mucus discharge con-  
sisting it and can generally be cured by a  
charitic or carminative, but it is well known  
every practitioner that a dysentery is not to be  
rid of so easily, I can distinguish this disease  
so from other fevers by a knowledge of the prevalent  
epidemics of the time, and from the violence of the  
symptoms; for although, it is always accompanied  
with feverishness, the dysentery shows it self to be  
a reigning disease, although sometimes they are  
both prevalent at the same time and interchange.

4) from one to the other,

In this case I should suppose the most successful mode of proceeding would be to pay the most attention to the most urgent or prevalent symptoms; and as part of the treatment of one case in this case answers for the other when indications are properly attended to, there is no danger of falling into capital mistakes here. Although the dysentery very frequently begins as a diarrhoea, and goes on increasing in violence from the predisposition of the patient, and exciting causes operating together, yet in some cases, it will not yield to the common remedies of diarrhoeas, and soon demonstrates its nature by the symptoms above mentioned, yet it sometimes appears more suddenly, with feverishness, violent griping pains, sickness at the stomach frequent, but fruitless straining, with great heat and inflammation of the intestines with spasmodic constrictions in different parts of them; this symptom may be increased by the hardened faeces which are pent up, and there more parts absorbed by the heat and inflammation.

exists along the whole course of the alimentary canal  
this costive ness and hardened faeces that I have just  
mentioned as a symptom of dysentery is not universal,  
<sup>sign</sup> but may occur when a high degree of inflammation  
exists which checks and prevents the natural execution  
of the intestines which is calculated to moisten and  
facilitate the passage of the faeces. There is another  
disease of the alimentary canal which I think  
might be commonly founded with dysentery from  
those deceitful appearance, the treatment of which  
might lead to dangerous consequences this disease  
Enteritis. It will be incumbent on me before  
distinguish the symptoms of Enteritis to say  
something of its pathology. Enteritis has been  
generally considered an inflammation of the strong  
muscular coat of the intestines, whereas dysentery  
is an inflammation of the internal mucous  
coat. From taking this view of the case  
I think it will be quite easy to draw a distinction  
between them, for in these different kinds of  
inflammations there is a difference both in the  
cause and sensations of pain. The Enteritis

D) Enteritis being an inflammation of a fibrous texture  
the pulse will be small and hard it has been compared  
by some to the string of a musical instrument the  
pain will be more acute and increased on pressure  
so much so that the patient can scarcely bear  
weight of the bed clothes, this disease requires  
most active antiphlogistic treatment the strict  
use of the lancet and purgatives = There as in dysentery  
the pulse is less hard and quick neither is the pain so very  
active or acute increased or purpure such is the difference as far as I  
conceive between the two diseases, I will now  
need to mention some of the causes of dysentery

### CAUSES

The predisposing causes of dysentery appear  
to act in this manner, during the continuance of  
warm weather, the fluids are invited by heat, and  
relaxation of the vessels on the surface of the  
to flow outwardly and the internal large vessels  
left almost in a state of emptiness and relaxed  
by this means they are weakened and become  
more susceptible of the operation of stimuli applied  
to them; and when cold is applied to the surface  
so as to cause contraction of the extreme vessels  
the blood is thrown upon the internal parts.

to prove a stimulus to them = Which if the body is already  
Kredispred, by the effects of noxious miasmata, having  
preceeded the application of cold, for some space <sup>time</sup> of  
while the heat lasted, a dysentery is commonly the cause  
ence. From the limited Knowledge I have of this  
ease by both reading and a little experience I have  
ever known it to occur in cold climates or in  
that destructive form, in which it appears in  
healthy tropical countries and in hot seasons  
It sometimes follows diarrheas, which are caused  
obstructed perspiration after warm summer  
d in crowded places. There have been many  
causes assigned by different writers, This will  
appear more rational than some of them.

It has the sanction of a variety of authors who  
have written in different parts of the world.  
Indurated fœces have been by some eminent  
practitioners and teachers said to be a very  
general cause of dysentery, but the majority  
that I have seen and read incline me to the contrary  
opinion. That indurated fœces as well as urine  
oily food, or mums may bring on a dysentery, then

(8)

be no doubt, especially in irritable habits of  
and the intestinal canal. But I am confident  
indurated foci are by no means such frequent  
causes of dysenteries as some eminent practitioners  
would lead us to believe; for there are very few  
either of the modern or ancient physicians  
who mention the circumstance; and besides  
does not appear credible that hardened  
foci themselves, could put the whole  
frame into such high fevers as generally  
attends true dysenteries. Therefore there must  
be a spasmodic predisposition to the disease  
existing in the constitution, before any of the  
exciting causes can operate effectually in  
inducing this disease. There are sufficient reasons  
to persuade me, that when the human frame  
is predisposed to the dysentery, by being  
exposed to the foregoing causes very slight  
occasional causes, will excite the disease  
such as alterations of the temperature of  
air, from heat to cold and this is very common

The case at the time when it appears; but especially during weather after great heats are very apt to cause its appearance; and the more both cold and <sup>stump</sup> weather set in together.

For the cold air and dens of the evening, after the heats of the day, are peculiarly apt to cause the dysentery to appear; and they increase it the more certainly, if those who are exposed to them are in an inactive situation sitting out of doors or exposed to the cold in any manner. For then the external surface is chilled by the cold and the small vessels contract and get into an inactive state and the fluids are forced inwards on the large vessels and interior viscera, particularly those of the belly, and from this last structure a stoppage of the circulation through them - the blood upon its return from them having no further way much very little a distance through the peculiar

system of the liver. When we consider this and  
 preceding account we may find sufficient  
 for the disease in question. From the foregoing  
 rations one might suppose that I intended to  
 was no other cause of this disease than that of  
 obstructed perspiration & but I am far  
 it that green fruit may act as a cause if  
 the person is predisposed I am very much inclined  
 to believe from actual observation in this  
 the acid acts as a great stimulus to the deli-  
 ciat of the intestines and in this manner excite  
 an inflammation in them which proves a cause  
 of dysentery - ripe fruit I think is innocent  
 here the Lacharine fermentation has progre-  
 so far as to obviate the violent effect which  
 the green fruit has upon the intestines,  
 from its being considered pernicious I have  
 seen it recommended to those who have  
 it under the disease in some treatise which  
 I have seen =

It appears that in all diseases of the intestines  
 there is a considerable degree of susceptibility  
 stimuli and this is a principle cause of these  
 affections whether, cholera, diarrhoea or dysentery  
 and by what ever means this state of the intestines  
 is induced it may cause these diseases in the  
 manner explained; and it may be attended  
 with inflammatory symptoms in those who are affected.  
 These muzz particularly in the young and robust;  
 yet of the ancients supposed ulcers of the intestine  
 to be a cause of the dysentery, but it has been found  
 that they are rather the effect than a cause the  
 mucus discharge which is a very prominent symptom  
 of dysentery, does not all ways proceed from ulcers  
 but from the inflamed surface of the interior coat,  
 the intestines long before any ulcer can have formed,  
 as we know from actual observation that this  
 discharge takes place in any inflamed mucous  
 membrane without the formation of any ulcer

as in Gonorrhoea, Coma or Catarrh. They begin  
 at first with an increased secretion of the  
 Natural mucus which soon becomes thin  
 acid and thus prove a stimulus to the part  
 and increase that inflammation which they  
 intended to prevent and thus the vessels dilate  
 and suffer serum and red blood to be dis-  
 gested. This is a common cause of dyspepsia  
 and the reason why it attacks the intestines  
 is preference to the lungs or any other part  
 is because they are the most debilitated part.  
 In children there are other causes which are  
 common to adults viz the great irritability  
 their habits the cutting of their teeth which  
 affects their system acts by sympathy and as  
 this age <sup>is</sup> after found of green fruit and  
 indigestible substances and at this time  
 they change the food from fluid to solid  
 certainly must be hard of digestion to break  
 organs from these circumstances I should  
 think <sup>the</sup> more liable to ~~than~~ ~~be~~ ~~affected~~ —

## Treatment-

It is now time that I should come to the cure of  
 the pterygia, in the first place I shall speak of the  
 use of the lancet, but with regard to this remedy  
 there has been such a variety of opinions that  
 will be a difficult matter to lay down any  
 general rules as to its practicability, There are very  
 few practitioners who have not seen cases in  
 which this remedy would be indispensable,  
 and on the contrary cases in which it would  
 be pernicious, under existing circumstances  
 will make a feeble attempt to point out some  
 different stages of a case in which it would  
 be beneficial or otherwise as I think general  
 rules in the practice of the healing art,  
 without proper discrimination, are often  
 hurtful than useful. In the strong and  
 letheric, when the pulse is hard and full  
 and repeated bleeding is absolutely necessary  
 it may be repeated in proportion to the  
 urgency of the symptoms; but that must  
 be left to the practitioners prudence who is to be

guided by his experience and reason - When  
 much fever accompanies the disease with pain  
 the head and burning pain in the stomach  
 But bleeding, must appear to any reason as  
 in the weakly, the aged, and those who are  
 reduced ~~in power~~ previously or overcome  
 other diseases in any situation, but more  
 marshy, low and unhealthy districts of  
 where agues are prevalent; Next to bleed  
 or perhaps before if the state of the alimen  
 tary canal should be taken into consideration

It will generally be necessary in the first place  
 to exhibit an emetic and during its operation  
 to allow the patient to drink freely of warm  
 or warm camomile tea, after this has been  
 effected he should wrap himself close in  
 bed clothes so as to promote a general perspiration  
 And by that universal sympathy between  
 skin and stomach and intestines cause a  
 diversion of the fluids from them to the skin  
 Although emetics are generally proper in  
 this disease there are some cases in which

15

is improper as where there is great irritability about  
the stomach and a diseased liver, this being the  
situation of the patient vomiting would do far more  
harm than good by increasing that irritability of  
stomach which all ready excited and communi-  
cating the same to the liver. In cases of this nature  
would be better to trust to Calomel and other  
mild cathartics as the neutral salts, particularly  
the sulphate of magnesia and sulph. lodur.  
or rochel cuts. as these evacuate the intestinal  
mass without producing any great commotion  
of the parts but are also a sedative and cool  
in nature, and even where emetics are of great  
use these purgatives are absolutely necessary  
to clear the easy off the acrimonious contents  
of the bowels, the oleum Ricini is a very excellent  
purgative when the griping and pain  
is very great it may be made more agreeable  
the taste by the addition of a small portion  
of the compound Tincture of Senna the matters  
which are disagreeable to most people they  
may be made less so by the addition of a little  
of lemon Juice or reversed their cathartic effect.

is increased by adding one grain of Turbith  
to the cure and then given in the usual  
All through the cure a perspiration should  
be promoted by warmth of the bed, and mu-  
diluting drinks and antimonials. The  
practice of allowing patients to throw  
the bed cloths off of them is very pernicious  
because it defeats the very effect that we  
wish to produce (that is perspiration) and  
is calculated to check <sup>it</sup> that this is the  
I am very well aware and I am astonished  
that some practitioners do allow it, the  
antimonials though powerful diaphore-  
tics when the patients are exposed to the  
air they are turned in upon the stomach  
intestines and produce vomiting and grip  
Although ipecacuan is a mild emetic  
in the early stages of dysentery its utility is  
doubtful and upon account of a property  
which is this it was formerly much extolled  
as universally useful in this disease I once  
the astringency which it leaves in the gut  
after its operation is over for any thing of  
astringent nature is to be avoided or per

Antimonial Emetics therefore are preferable  
 at least a grain or two of tartar Emetic should  
 mixed with ten grains of ipecac; for  
 its laxative quality it will prevent the  
 effects of the ipecac when it is used. As to  
 the choice of different preparations of antimony  
 when we wish to produce vomiting we should  
 use the most active and those which  
 are the most soluble such as the tartarized  
 antimony or those which are already in  
 solution as the antimonial wine. But  
 when there is great irritability of the stomach  
 and it becomes necessary to give a febrifuge  
 these preparations would increase it by  
 vomiting, then it would be the better plan  
 to use those which are slower in their  
 operation such as the James powder or the  
 former's mineral or Rush's antimonial powder  
 when exhibited in their proper doses  
 are excellent diaphoretics and are proper  
 remedies in most febrile diseases their effects  
 may be increased by warm diluting drinks and

the mouth of the bed. The Ivers powder  
is highly recommended in this disease by the  
practitioners. I think are very improper  
the first steps particularly their stimulant  
effect is so great that they increase the  
the griping and tenesmus but in the  
stages when the patient is much debilitated  
and also exhausted from want of sleep  
are very beneficial from their anodyne  
effect they also have a slightly febrile  
effect. Whilst the pain and spasm  
continue obstinate laxatives of the nature  
of salts or castor oil which is a medicine  
the greatest importance in this disease  
should be repeated every four or six  
hours. It is not until they have been  
the desired effect, which can be told  
by producing a natural operation. The  
drinking plenty of warm diluting fluids  
as good rice or barley water - fresh bread  
or ~~they~~ are especially useful in the early stages.

The disease and they should be taken  
 frequently. but cold drinks should be avoided  
 though they frequently deserved by patient, in  
 disease; yet until the violence of the malady  
 over the patient should not be permitted to  
 indulge himself in the respect. In some very  
 obstinate and violent cases, it may be ne-  
 cessary to have recourse to Opium or Opium  
 This drug is not to be used in the beginning  
 of this disease without the most judicious  
 caution; for at these times it always leaves bad  
 effects after its use unless care be taken to prevent  
 them by adequate means. for I should suppose the  
 most dangerous consequences would follow from the  
 use of it not only in true dysenteries but in  
 diarrhoeas attended with fevers, and on the  
 same account, it is scarcely necessary to  
 mention that all sorts of stimulant and  
 drastic purgatives, are very improper

as Jalap scarcely ever seems to be  
 although too frequently and even indiscriminately  
 used by the ignorant; as well as some medical  
 who should know better. For as the intestine  
 extremely irritable in this disease these  
 purgatives readily cause violent commo-  
 and increase their action (which are  
 by ever great and by this means increase the  
 rent pain gripping and tenesmus with sp-  
 moid strictures and exertions by their ac-  
 on the very sensible coats of the intestines. &  
 they are seen when in this situation deprived  
 of their native mucous lining or covered; as  
 explained elsewhere; and are therefore un-  
 tended and exposed to the acrimony of the  
 contents. When great symptoms of irritability  
 prevail with restlessness and want of sleep  
 a small opiate may be given at bed time take  
 care at the same time to order a mild cathartic  
 the next morning to clear the intestines of  
 accumulated feces which are collected  
 to produce irritation.

21  
This is neglected the pain and griping with  
turn with increased violence These are to be  
ing also when fever and inflammation is gone  
d the increased secretion is kept by the weak  
and relaxed state of the vessels of the intes-  
s. And even Astringents and Tonics as bark  
extract or decoction of Logwood is even  
um or catechu may be given. but these are  
be used with great caution in the beginning  
here attended with febrile symptoms it should  
treated like any other fever

An  
Inaugural Dissertation

## Dedication,

In the ensuing pages I shall speak  
of the disease called Pneumonia  
Beliosa or Typhoides; this disease  
has attracted much attention and  
there is but little, I shall say on this  
subject; but to exhibit in a concise  
form, most of its most prominent  
features; there will be things omitted  
that might be questioned.

For the unremitting attention which  
the Professors of this Institution  
have manifested towards me I  
cannot omit this opportunity of offer-  
ing my sincere thanks to them

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

## Introductory Discourse

— object of the science of medicine is the  
— reduction, and the cure of diseases,  
— though the noxious agents which which  
— surround us are numerous, yet nature  
— applies, in some measure, the means  
— preventing and curing their bad effects.  
— the exhalations from vegetable and animal  
— produce fevers; and their disagreeable and  
— ribble stench is a sufficient warning to  
— avoid them.

— power of nature alone through great  
— not, however; always sufficient, either  
— discover their noxious agents; or to remove  
— the disease to produce them.

— miasmata produce from the putrefaction  
— vegetable matter, often give no warning  
— their smell, and destroy without its danger  
— being anticipated  
— this is true with regard to many other noxious

quits: Thus sudden exposure to impure air  
descending below the surface of the earth,  
takes away life, and no instinct, none of  
our senses warns us of our danger.  
We therefore require other assistance  
than those of nature alone, in  
avoiding the causes of Disease, and  
it is the province of the science  
of medicine to supply them, by a cau-  
tious examination of the properties  
of those around us.

Though diseases are often relieved  
without the assistance of art, yet  
it is well known that many  
receipts undertaken by nature  
to repair an injury, are often  
too violent, and destroy life, without  
the intervention of art. Hence the  
art of a physician, and in doing so, the  
properties and nature of the

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mostly illegible due to fading and the age of the document.

system, as also those of external  
bodies, must be studied to disco-  
ver their effects upon it, and  
subsequently the process of curing the  
disease excited by them.

The mind and the senses, accord-  
ingly, are the instruments by  
which this end is effected.

In their application for the pur-  
poses of discovery to the world  
around us, great errors have been  
committed, and much useful  
time and labour has been  
lost, in their direction to the  
practical duties of our pro-  
fession,

In the following remarks there-  
fore, as medicine is a science  
which teaches some thing to be

down, and the most correct mode  
of doing it, and as it was natural  
to expect its purposes, we shall  
first consider the nature of the  
causes and effects, in relation  
to the production, and the cure  
of Diseases; and secondly, the  
sources of the art of Medicine  
discovered in the history of its  
past ages

We shall thus be enabled to  
pursue our way upon the  
firm and open road opened  
by Modern discoveries, with  
profit and advantage

Pneumonia Biliosa or Typhoides  
This variety prevails principally in  
marshy districts, and in wet and  
cold seasons, and is produced by  
the joint effects of M. asmetata, and  
alterations of temperature, in-  
temperance &c.

It is called in the southern  
and middle states, when it ap-  
pears usually in the winter and  
spring, Bilious or Bad Pleurisy,  
or cote Pleurisy by some persons,  
and it is properly an inflammation  
of the Lungs or Pleura, combined  
with a remittant fever, exhibiting  
the whole series and varieties in  
grade, from the highly Torrid and  
inflammatory to the Typhoid  
form, In the eastern sections,

In our country, the disease is  
seldom distinctly formed,  
presenting the faint rather  
complicated, with Catarch  
or some of the genus Cyanea.  
The farther south the more this  
disease is disposed to assume  
a Typhoid complication, like the  
ordinary remittent of the summer.  
Adults is more frequently the  
subjects of this disease than  
Children, and woman as they  
are less exposed to the cause, suffer  
less than men, and Negroes ac-  
cording to Professor Potter, are rarely  
affected with this disease. It gene-  
rally comes on like the remittent  
fever, with a shivering and numbness  
of the flesh, Chills, with local pains

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

the jaws, ears, head, arms, and legs  
sometimes with the Nausea, vomiting  
and Diarrhea, accompanied with a  
in some part of the Thorax, some-  
times there is no premonitory  
Symptoms, and appears the ordinary  
remittant Type. Sometimes the extremi-  
ties become exceedingly cold to the touch  
and no reaction follows, the patient  
is then dangerously ill.

The general symptoms are attended with  
all the characters, which characterise the  
ordinary remittant fever, as I have  
before mentioned. of course it is useless  
to enter into a particular description,  
the disease consist of the ordinary fever  
of a Typhoid Type, Combined with a  
determination to the Lungs  
When it attacks the head, Liver, Sto-

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side.

each on Bowdo, the complication of the  
case of the Lungs is frequently over-  
run and the complaint is mistaken  
for inflammation of other organs.

The affection of the Lungs however,  
will easily be discovered by attending  
to the difficulty of Breathing the  
Cough &c.

This disease is often insidious and  
suspicious in its career. The patient  
frequently appears better imme-  
diately before its fatal ter-  
mination.

The breathing however, becomes sud-  
denly laborious, the motions of  
of the Chest more irregular a  
rattling in the throat comes on,  
the extremities become cold and  
death the final termination, by an

fusion taken place into the  
Lungs

Obstinate constipation, particularly  
in the Hepatic Cases, often appears  
as a symptom, sometimes a watery  
punging distinguishes the disease,  
at other the stomach is extremely  
irritable, a black discharge takes  
place from the bowels, and  
the discharge goes off by a gentle  
perspiration

The pulmonary symptoms may  
be alleviated by warm pediluvia  
with stimulating diaphoretics  
and a free use of Diluents

Where the habit is Plethoric Blood  
letting is sometimes useful in  
the forming stage of the disease,  
an Emetic followed by a dose

of Calomel and opium, when  
there is any tendency to a watery  
purging, is also useful.  
When the disease is thoroughly  
formed the treatment should  
consist partly of that which is proper  
in Typhus and Pneumonia conjointly  
and it should be active in pro-  
portion to its character. If Cynosis at  
first the depletion must be more  
considerable; if Typhus from the  
commencement it must be more  
or less stimulating. General bleeding  
in this form commonly impossible,  
excepting in the very first hours of  
attack, even when taken from  
the surface ~~of the~~ Chest by scar-  
ifications may in many instances  
threaten a fatal termination; and

*[Faint, illegible handwriting throughout the page]*

the crease of the system completely  
broken up. This however occurs  
only in extreme cases  
The signs of this state of debility are  
similar to those which have been  
given under the head of the Typhoid  
form of continued fever, Rigor, cold  
extremities pain between the should-  
ers, along the spine and back of the  
head, with much difficulty of  
breathing; cold perspiration; general  
feeling of misery and wretchedness,  
great pain with a sense of tearing  
and burning in the breast. The pulse  
at first small, hard and corded,  
slight retching with a greenish  
fluid running from the mouth,  
the Tongue covered with a Brown  
rust, with the edges and ends smooth

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side of the page.

dry and red, the thirst great, the  
breathing laborious and irregular,  
the skin hot and parched; Urine  
scanty and high coloured; Delirium  
with great prostration of strength  
and spirits, the stools offensive and  
dark, the expectorations with blood.  
in some cases blood may be drawn  
in small quantities, and repeated  
until the pulse is reduced.

If the pulse should be always low  
and it be advisable to take away  
small quantities of Blood I have  
been ~~to~~ of it being taken  
away by Scarification or cupping which  
sometimes may be applied with  
advantage to the chest and  
succeeded by Blisters

The pulse must be narrowly

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side.

watched, and if they flag, de-  
pendance must be placed in  
the first stage upon Emetics of  
Tartrate of Antimony or Ipecacubana  
Together with purges of Calomel and  
Senna or Magnesia, Salts, Castor Oil  
or small doses of Tararizid Rutinony  
frequently repeated, till the stools  
become natural. The skin must  
be kept soft with Nitro Senna  
Tea, and as the system debilitates  
Thin Whey, Camphor and Opium  
and Carb Ammonia may be  
given to keep up an expectora-  
tion, and support the strength  
As the pain in the breast, difficulty  
of Breathing; and other symptoms  
of the Pneumonic affection  
abate, it is necessary to give

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

tonics; The system must also  
be supported by mild nourishing  
food as Tapioca arrow root, sago  
&c administered in small quantities  
and frequently repeated; It is irritating  
by Blisters on the Chest; in the  
mean time should also be kept  
up.

A

My intention in presenting this, is not an attempt to offer any thing new; but merely what I have collected from the opinions & writings of others. — In the first place I shall endeavour to give a correct definition of the disease, & then proceed to the cause & treatment. —

Ascites then, may be defined a preternatural collection of serous like fluid contained within the cavity of the abdomen. — Concerning its immediate cause different opinions are still entertained by medical writers. — Some contend that it arises from two opposite states of the system, viz. a plethoric state & that of debility. — And when arising from the former, the exhalent arteries terminating on the internal surface

of the abdominal cavity, which in their healthy state throw out a halitus to lubricate the contained viscera, have their secretory function completely deranged, & in such a morbid condition, that the fluid poured out is not only changed in quality; but the quantity secreted is more than the absorbents, whose action it is alleged, cannot be increased beyond their healthy standard, are capable of removing — This in my opinion is the most plausible & correct theory of dropsy within the abdomen. — When debility is assigned as the cause, it is said, that the same exhalent arteries from a want of tone become relaxed to such a degree, as to allow a copious exudation of serum to take place, the absorbents being also debilitated are rendered inadequate to perform their duty & thus, is the

*[Faint, illegible handwritten text, likely bleed-through from the reverse side of the page.]*

accumulation, which is gradually increasing, ac-  
 counted for. — With regard to the relaxation of  
 the exhalents & consequent exudation of serum, there  
 exists this unanswerable objection, which is, that the  
 fluid in dropsy is not the serum of the blood, & pos-  
 sessed none of its characteristic properties — the ex-  
 periments, of exposing it to the temperature of 160° of  
 Fahrenheit's scale, or of pouring on it any of the mine-  
 ral acids, will fail in every instance of producing  
 coagulation. — The morbid secretory process of the  
 internal exhalents may occur as well in a system  
 debilitated, as in one of an opposite condition — for  
 any obstacle to the due circulation of venous blood in  
 the abdomen, producing a remora or congestion, will  
 tend to increase the action of the heart, & of the arteries  
 terminating in those veins — the blood, not finding a

ready passage from the arteries to the veins, & from the Vena  
 cava, forced into the extremities of those arteries, which con-  
 sequently becoming enlarged in their calibres, allow not  
 only a greater secretion to take place; but that, of a qual-  
 ity too gross for the absorbents to remove. — Among the  
 causes producing this languid circulation in the veins of  
 the abdomen, maybe enumerated pressure from enlarged  
 viscera or from tumours within the cavity — Enlarge-  
 ment or induration of the liver, from whatever circumstance  
 arising, is one of the principal causes, either by its pressure on  
 the ascending cava or from the diminished capacity of its  
 own vessels, not allowing all the blood of the Vena Porta a ready  
 entrance into them. — Independant of the above causes,  
 suppressed secretions, principally of the perspiration & Urine,  
 increasing the quantity of the circulating fluids, which finding  
 the internal exhalents less resisting than any other part, may  
 force them into the morbid state. — Whether scantiness of Urine &  
 perspiration be one of the causes producing dropsy, or rather

Handwritten text, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher due to the bleed-through effect.

consequence, is uncertain - I am more inclined to the latter  
 opinion. - for the want of perspiration & urine may be only sympto-  
 matic, dependant upon the immense secretion going on rapidly within  
 the abdomen. - Large quantities of fluid taken in as drink  
 said to have occasioned dropsy; but from this opinion I am in-  
 clined to dissent - for whatever fluid is taken into the stomach  
 is expelled very soon by some of the excretories; but it is highly pro-  
 bable, it may increase the disease after it is once formed. -  
 Scites makes its attack insidiously, & not infrequently supervenes  
 on the close of the disease. - When occurring from the  
 latter circumstance, it is for the most part connected with general  
 dropsy. - The symptoms characterizing it are, fever - dry skin  
 with thirst, scarcity of urine, with a pulse round & hard in the  
 commencement, the swelling uniform & tense, somewhat elastic  
 & accompanied with evident fluctuation, the sensation of which  
 can be perceived on applying the fingers of the left hand to one side  
 of the tumour & striking it with the fingers of the right -

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

these symptoms are preceded by an impaired appetite,  
 great languor, indisposition to move about, and <sup>an</sup> almost  
 insupportable drowsiness. — We cannot always dis-  
 tinguish whether the fluid be contained within the pe-  
 toneal sac or not, sometimes it is found in the  
 form of hydatids, & rarely is it situated between  
 the abdominal muscles. — Its complication  
 with anasarca or general dropsy, is of frequent oc-  
 currence. — When it is encysted, the swelling is  
 not uniform, nor is fluctuation so perceptible. —  
 The ovaria are often the seat of dropsy, & when this is  
 the case, the tumour in its forming stage gives consid-  
 erable <sup>pain</sup> & is confined to one side, as it is seldom indeed  
 that both are affected at the same time — the tumour  
 conveys to the patient the sensation, as if loose & mov-  
 able within the abdomen. — And the menstrual  
 discharge is not obstructed, which shews the dis-

The first and most important of the  
principles of the theory of the  
differential calculus is the  
definition of the derivative of a  
function. The derivative of a  
function  $f(x)$  at a point  $x$  is  
defined as the limit of the  
difference quotient as  $h$  approaches  
zero. This is written as  
 $f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$   
The derivative of a function  
represents the instantaneous  
rate of change of the function  
at a given point. It is the  
slope of the tangent line to the  
graph of the function at that  
point. The derivative of a  
function is a function of  $x$ .  
The derivative of a constant  
function is zero. The derivative  
of a linear function is a constant.  
The derivative of a power  
function is a power function.  
The derivative of a product  
of two functions is the sum  
of the product of the  
derivative of one function  
and the other function, plus  
the product of the first  
function and the derivative  
of the second function.  
The derivative of a quotient  
of two functions is the  
quotient of the derivative  
of the numerator and the  
denominator, minus the  
product of the numerator  
and the derivative of the  
denominator, all divided  
by the square of the  
denominator.

Case has not affected the system. — Tympanites & Ascites have sometimes been mistaken for each other; but the absence of fluctuation in the former & every discharge of wind upwards or down affording immediate relief, soon point out the nature of the case. — Pregnancy has also been confounded with Ascites in some of its symptoms, & serious consequences been the result; but the symptoms of the two are widely different. — The enlargement of the mammae & the shooting pains through them, the motion of the child in the uterus, absence of fluctuation & lastly the appearance of the distended abdomen are sufficient to discriminate the state of pregnancy from any disease whatever. —

Ascites may also be distinguished from enlarged viscera, by the swelling being confined only to the region of the diseased organ. —

*[The text on this page is extremely faint and illegible, appearing as ghostly impressions of handwriting.]*

The diagnosis in every case will be found sufficiently plain and evident by careful attention to symptoms. — The prognosis is always doubtful. — It is unfavourable when the disease arises from visceral affections which have long existed. — & the whole system much reduced in consequence. — A favourable termination may result when the constitution is not much impaired, no visceral obstruction existing & the patient has not far advanced life. — When this change for the better takes place, the different secretories resume their healthy functions. Thirst is not so distressing, skin grows moist, & the urine is increased in quantity, appetite returns, & the swelling soon abates. — Its complication with Hydrathorax & anasarca is very unfavourable. — In the treatment of every disease, the first indication is to remove the cause; but allowing this to be practicable, the result in every instance would not be a removal of the effect. — And whatever may have been

*[The page contains approximately 25 lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

cause, we must endeavour to check the further  
progress of the secretion; & if possible by proper medicines,  
cause the fluid to be taken up & thrown from the system  
through some of the excretories of the body. — Abstrac-  
tion of blood, in the forming stage of this disease, by less-  
ening the action of the heart & arteries upon which the  
secretion depends, has proved beneficial in almost every  
instance, & should not be omitted in those cases where the  
pulse is in the least degree tense. — It also allows the  
medicines to exert their proper action. — The blood  
drawn generally shows the buffy appearance, indicating  
the presence of inflammatory action. — Emetics are oc-  
casionally used & are highly serviceable when much  
nausea & vomiting distress the patient — by increas-  
ing the perspiration, the quantity of circulating fluid  
sent to the internal parts is much diminished. —  
They should be given in the earlier stages. — When

*[The page contains approximately 20 lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

As

even after the disease has long existed, the debility occasioned  
by their exhibition serves to render ~~the disease~~ <sup>it</sup> still worse.

In regard to the choice of particular emetics a preference is given to  
Ipec, which after their operation either give tone to the stomach or  
duce but little impairment of its function — Among those maybe  
enumerated the Sulphur Cupri - Sulph. Zinci, Ipecac. & a few others.

A class of medicines recommended in the treatment & considered  
highly important are cathartics — from the great discharge  
which they occasion from the intestinal canal, no doubt can  
be entertained of their efficacy in every species of dropsy. — That  
division of the class of cathartics called Hydragogues are pre-  
ferred, because they eliminate a greater quantity of fluid & there-  
by diminish that morbid secretion from the internal exhalants.

For this purpose the following have been much used, Gamboge,  
Coccyth, Scammony, Neutral salts, & the super tartarite of  
potash, the latter is also given with a view to its operation on  
the kidneys. — ~~Together with these are sometimes~~ frequently

combination with one or other <sup>of the above mentioned</sup> the Mild muriate of

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

Ans.

Mercury is often administered, it renders their operation more certain, & at the same time restrains their too violent action. — Mercury both a purgative & alterative is a sine qua non in the treatment of dropsy arising from diseased viscera — exhibited in every case of this description, experience had always confirmed its happy effects; & restoring in a great measure the different secretions, & the alterative action which it produces in every part of the system — morbid secretions either become changed or suppressed — exhibited under the preparation termed corrosive sublimate do, produce ptyalism, which can easily be effected by giving it such doses as will ~~produce~~ <sup>cause</sup> emesis — the discharge which is occasioned from the salivary glands, when profuse & undoubtedly <sup>tend to</sup> ~~afford~~ diminish the size of the swelling.

Diuretics have long been held in high estimation in the cure of dropsy, & are among the principal remedies demanding our attention. — Among this class Digitalis for some time past claimed the first standing. — Dr. Withering's a periodical publication bestows very high encomiums

*[The page contains approximately 20 lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

As

hon it - his remarks are as follow - "Digitalis or Foxglove  
will not universally act as a diuretic; but <sup>that</sup> it more generally  
produces this effect than any other medicine & often after these  
have been tried in vain; that if it fails there is but little chance  
of any other medicine succeeding; that in proper doses & under  
good management, it is mild in its operation & gives less dis-  
turbance to the system than Squills, or any other active med-  
icine - It may be used in every species of dropsy excepting  
the encysted" - And he further remarks, that it is more  
successful, <sup>when</sup> the system is much debilitated, than  
when there is much excitement. - The form under which it  
is recommended by him, is either the powder, in doses of  
two or three grains during the day, or the infusion in doses  
of ℥ss. - Tobacco is another article of the class which  
is entitled to our consideration - it may be given in  
the form of infusion or tincture - from the unpleasant  
effects it is likely to produce on delicate habits, it is seldom  
prescribed - it induces a plentiful secretion from the

*[The page contains approximately 20 lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

No

inies. — whether ~~the~~ produce the same action on persons habituated  
its use, from the ordinary method of chewing & smoking the plant,  
in my opinion questionable. — I have seen the decoction ad-  
ministered per Anum in a case of strangulated inguinal hernia  
without the least impression being made on the system — this patient  
was in the habit of chewing & smoking the plant to great excess  
the medicines of the same class are frequently employed, but which I  
shall omit mentioning here. — From the constricted state of the skin  
the indication for employing diaphoretics is very evident, &  
since they are most generally with other medicines, but  
either they are of much service, is ~~undoubtedly~~ <sup>doubtful</sup>. — The skin, it had  
become congested, changes in dropsy from the secretory to the absorbent  
state — with this idea a respectable physician, for the sake of ex-  
periment, placed his patient labouring under dropsy into a strong  
coction of oak bark & keeping him in it for some time, in order  
that he should be undressed, as he expressed himself. — It would  
be useless for me to mention the result — as everyone must know  
that chemical agents do not exert the same influence over living

*[The page contains approximately 20 lines of extremely faint, illegible handwriting in cursive script. The text is mirrored across the page, suggesting bleed-through from the reverse side. No specific words or phrases are discernible.]*

vivified bodies, as on dead inert matter. — Blisters are another  
 means resorted to for evacuating the fluid from a dropical pa-  
 tient; but the great excitement which they create in vessels so much  
 debilitated, is apt to throw them into a phagedenic, & hence they  
 are justly fallen into disuse. — After all the medicinal  
 remedies enumerated have been tried & in vain — & the patient  
 on the great accumulation of the water, is rendered unable to  
 move about — then & not before is the operation for paracentesis pro-  
 ceed. — To this delay of the operation may be attributed its frequent  
 failure. — The pressure of such a large collection of fluid must  
 doubtless injure many of the viscera — & also by retarding the circu-  
 lation of blood thro: the ascending aorta, soon produce oedema of the  
 extremities. — The operation is now recommended to be per-  
 formed, the moment fluctuation can be distinctly felt in the tumour,  
 & the medicines which have been exhibited, produced but little  
 effect. — The opinion ~~is~~ <sup>is that</sup> the operation contributes to the cure  
 by accumulating the excitability of the system, thereby allow-  
 ing medicines to act. — Different places are proposed for

*[The page contains approximately 25 lines of extremely faint, illegible handwriting in a cursive script. The text is mirrored across the page, suggesting bleed-through from the reverse side. The ink is very light, and the lines are closely spaced.]*

As

forming the operation - the two most common are 1<sup>st</sup> the midway point between the umbilicus & anterior superior iliac process of the ilium - the 2<sup>d</sup> about two inches below the umbilicus in the linea alba. - the objection to the first is the danger of wounding the epigastric artery - to the second, of a more serious nature, viz the wound, from the low vitality of the part, not closing up, but degenerating into gangrene. - The point selected, is the little cavity around the umbilicus, where there is only skin & cellular substance. - The only instruments required forming the operation, are a lancet, & trochar, with its cannula. A good bandage should be passed around the abdomen, which is to be gradually tightened as the water flows off, in order to prevent syncope, which takes place some times to an alarming extent, from sudden removal of distention. - There are instances on record where it is said, the water of ascites has been discharged from the uterus. - whether it is taken up by the extremities of the fallopian tubes & conveyed by them to the uterus & thence expelled - or according to some opinion, the vessels of the uterus, taking upon themselves a secretory process similar to that of the internal exhalant,

John Revere M.D.

With your  
permission I have taken the liberty of  
dedicating this my maiden epistle  
to you, hoping that it may be  
viewed with less scrutiny  
and severity than  
its merits. —

Your  
Talents and Virtues

both in  
Public and Private life,

have endeared you to numerous friends, among  
which number, for your politeness and  
regard, shown me during my studies  
in your office, I respectfully  
beg leave to subscribe  
the name of the  
Author.

Mr. Green

Dear Sir  
I have taken the liberty  
to send you the enclosed  
which I hope will be  
of some use to you  
I am, Sir, your  
Obedt. Servant

Wm. Pitt

Enclosed are the  
papers which I have  
collected in relation  
to the late  
affair of the  
East India  
Company  
I have also  
enclosed the  
report of the  
committee  
appointed  
to inquire  
into the  
conduct  
of the  
Company  
I am,  
Sir,  
Your  
Obedt.  
Servant

2  
S

My kind and affectionate  
Father

Leonard Trailey Esqr

Who amidst the toils and hardships of a  
laborious profession and the burthensome  
expences of a numerous family still  
extended his love and recollect so  
far as to give me an education  
suitable to studies of an  
honorable profession,

With filial regards - I beg leave to offer my  
grateful thanks, in this my first  
essay, on a branch of the  
profession which I

Have by your assistance and my own exertions  
successfully acquired:

The Author.

11

# — Epilepsia —

Nescius aura fallacis —  
Miseri, quibus intentata nitet; —  
Hor.

I propose in the consideration of this disease, to treat first the History of the disease, second of its Predisposing causes, third of its Exciting causes, fourth of its diagnosis, fifth of Prognosis, and lastly of its Treatment. —

## History.

This disease generally makes its attacks in the form Paroxysms, and consists, in a sudden deprivation of the senses, accompanied with a violent convulsive motion of the body, sometimes more on one side than on the other; if the patient standing, he immediately falls, or with convulsions is presently thrown to the ground; during the convulsion, the facial vessels being alternately relaxed and contracted, the countenance becomes horribly distorted, and the passions, succeeding each other with singular velocity, are often depicted without expression in the face. The muscles of the orbit being affected in the same manner, the eyes are rolled about with avidity, & the dark part being convulsively turned upwards, but the whites, are distinguished between the half

med eyelids; the globes, sometimes, however remain fixed, the wrinkled forehead exhibits the picture of rage; the eyes are closely clenched, and the thumb is violently thrust to the palm of the hand; he foams at the mouth, & thrusts out tongue, which sometimes suffers from the contractions of the sides of the lower jaw, which are often so violent as to break teeth or luxate the Jaw itself; - Rororygmus, cretation, riting, and the involuntary discharge of feces, urine & semen, prove that the internal structures are similarly convulsed.

After a longer or shorter continuance of the convulsions they cease altogether, and leave the patient motionless, still ever in a state of absolute insensibility, and under the appearance of a profound sleep; after some continuance of this kind of sleep, he gradually recovers, having however no recollection of what has occurred: - The vital functions during the paroxysm are also disturbed, - the breathing is laborious & stertorous, and is sometimes performed with sighing & great effort, such as a strong man exhibits when lifting an enormous weight: - From the beginning to the end of the fit, the patient, as before remarked, foams at the mouth & nose, & when the nose has become lacerated, this froth is coloured with blood; the face becomes gradually more livid & sometimes almost black; - In more violent paroxysms, blood is said to flow from

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

mouth and nostrils: after a long continuance of the disease,  
memory becomes imperfect, the senses lose their activity, the  
face becomes pale, and the patient is affected with languor  
dread & fear \* \* \* \* \*

The fit is frequently preceded by pain in the  
side - lassitude - some disturbance of the senses - unquiet  
sleep - unusual dread - noise in the ears - flatulence in the  
stomach and intestines - Spasm of the muscles of the tongue, so  
violent as to draw that organ back into the fauces - Palpitation  
of the heart - coldness of the joints - sensation of a cold air,

Aura epileptica, arising in some part of the extremities,  
gradually creeping upwards, until it reaches the head, when  
the patient is instantly deprived of his senses, and falls as above  
described —

I have here given the usual form of the  
disease, but it is sometimes distinguished by more remarkable  
symptoms as Boerhaave shows in this "there is no gesticulation  
or posture known which is not sometimes exhibited in  
this disease & it imitates on some occasions all the different motions  
running, walking, turning about, prostration & standing up" and  
a singular example is mentioned by a writer on this disease, of a  
patient who on the accession of the fit, "did not fall down, but  
whirled around like an opera dancer".

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

# Predisposing Causes.

Among this class of causes, may be reckoned, great irritability of the nervous system, this is apparent for many of the exciting causes may be applied to many persons without any effect; there exists in some that mobility of minds so analagous and intimately connected with that irritability of the nervous system, that rum et mutabile femina, this is apparent in those who are acted on by slight causes, readily elated by hope, or depressed by fear, & who are easily changed from the one to the other, these minds are constantly waving, between pleasing and displeasable sensations, sometimes pleased and gay, at others sily provoked & peevish; and in no disease is a cause more eminent, than that mobility or irritability in this disease, it is sometimes born with the child, and it dies of it -

Another predisposing cause is sleep - for in many persons are afflicted with the disease, an attack only happens during sleep, or immediately after rising from it - I have myself seen a case, in which the attacks were experienced in the night, or early in the morning, this is owing to this circumstance that during sleep, there is more or less mobility or irritability consequently debility produced -

The last cause of this class, I shall mention is hereditary predisposition, and where this predisposition is

The text on this page is extremely faint and illegible, appearing as a series of light-colored lines and shapes against the aged paper background. It likely contains the main body of the journal's proceedings, but the specific words and sentences cannot be discerned.

difficult, the exciting this disease in one will produce it  
easily in another

## Exciting Causes

Mechanical irritation by substances acting im-  
mediately on the brain; as sharp pointed instruments, which  
perce the cranium & enter the brain; depression of bone  
the substance of that organ; tumours in the same situ-  
tion; fluids lodged in the brain either from rupture,  
tear or effusion, (this is accompanied with mania & Pa-  
lysis) particularly when there is any predisposition to  
disease; - the most important cause is irritation applied  
to the brain, from over-distention of the vessels with blood, this  
distention may be caused; by over eating; too much exercise,  
excess heat; hard drinking and any cause exciting increas-  
ed circulation; - Mental Irritation - The frequent feigning  
paroxysm, called Epilepsia Simulata, will at length  
render the attack real; - the effects of joy & surprize; sudden  
shock and terror; - fits of passion; or any vehement emotion  
affect the mind; - disappointment, this it is said caused the  
case in Julius Caesar and Napoleon Buonaparte, is  
a very powerful cause; - large doses of Narcotics and  
any other poisons taken into the Stomach will, by producing  
direct debility in the brain, cause the disease; - certain odours

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

worms; - dentition; - acute pain; - calculi in the kidneys; -  
action of contagion; - excessive venery; - excessive evacuating  
increasing the excitability, thereby rendering excitement  
more easily produced; - suppression of accustomed dis-  
charges; - tumours pressing on any part of the nervous system;  
sometimes the consequence of a wound of a nerve, this is  
believed by some, but it sometimes takes place, although  
most frequent consequence of such an occurrence is, the  
disease of Tetanus. -

## Diagnosis -

From Convulsions - By its terminating in sound sleep, and  
the total abolition of the Senses. -

From Apoplexy - By the voluntary motions in the one  
case being increased; in the other totally suspended. -

From Hysteria - By the absence of the Globus Hystericus,  
and the presence of the Aura Epileptica; - by the  
convulsive motions in one disease, having the appearance  
of design; in the other, obviously involuntary; by the absence  
of any prominent symptoms of hysteria, such as profuse  
copious urine, alternate laughing & crying &c.

## Prognosis -

Favourable - The disease being sympathetic, occurring  
in the age of puberty, and arising from causes easy of

Stimulus

Propriety

neral; there being no hereditary predisposition; here the disease  
may be easily removed; frequently they recover without the  
use of medicine merely by the gradual development of the  
vires of the body, so that at the age of puberty or a little  
later, the disease leaves them; it has been often removed  
after an intermittent fever, or cutaneous eruption.

Unfavourable — The reverse of the above; when the  
disease comes on after the age of puberty; when it has arisen  
from an hereditary predisposition, or by frequent repetition  
become confirmed, the probability of cure is here slight,  
particularly when the memory & judgement have been impaired.

### Treatment

Notwithstanding the variety of remedies that have  
been used in this disease, it very often baffles the skill  
of the most able Physician, especially when arising from  
hereditary Predisposition; the Indications which would natu-  
rally suggest themselves to the mind are two-fold, first  
to endeavour to abate the violence and shorten the duration  
of the Paroxysm, and second to Prevent its recurrence:  
the first if there be symptoms of determination of blood  
to the head, or if the patient be of a full plethoric habit,  
drawing from the arm, jugular vein, or temporal artery, pro-  
nata; but if on the contrary, the presence of debility is obvious

most powerful antispasmodics; sinapisms to the lower extremities  
anodyne and antispasmodic clysters: - In general little  
can be done during the Paroxysm, than to use the necessary  
cautions to prevent the patient injuring himself in the violence  
of convulsion. - - - - The recurrence of the Paroxysm  
sometimes prevented by the following means: - The disease  
both Symptomatic and Idiopathic; - where it is Symptomatic  
the primary affection, and as a secondary disease it will  
cede, by removing the causes that continue to operate, such  
as worms, dentition &c; a remarkably powerful stimulant  
irritation on the External Surface will often prevent it,  
is for this reason Larrey recommends the Moxa; - Issues  
& Setons have been found useful, by keeping up an action  
weakened vessels, they act in a similar way to blisters  
perhaps these last may be of some service, but they are  
sufficiently powerful; - The Cautey has been used  
the Ancients, and I heard the case of a man related,  
being afflicted with the disease, was seized with a  
paroxysm whilst standing near a large fire, he had not  
time to escape the danger and fell into it, he was rescued  
from by his friends, not however until he had severely  
burned his arm and part of his face; he had no attack  
of the disease until the ulcers had healed although

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

teris paribus he would have had 4 or 5 - Care should  
then to avoid all the exciting causes, as over distention  
the vessels of the head, however induced; fits of passion  
then violent emotions of the mind; and if of a plethoric  
habit, he should be occasionally bled - live abstemious  
use Issues or Setons applied in the neck, & keep low  
frequent purging &c - If the Paroxysm be preceded  
the Aura Epileptica, it has been advised to apply  
isters or caustics to the part from which the sensation  
ies; to destroy the communication with the brain by  
~~trying~~ dividing the nerve; but without resorting to either  
these methods, the simply tying a ligature around the  
ly has been found successful, though the blisters and  
sters may produce a double effect, both by preventing  
advance of the Aura, and at the same time of keeping  
a salutary discharge from the body - If the  
tem be weak and irritable tonics have been suc-  
ful, both vegetable and mineral, the latter however  
more powerful and durable; the former among  
ch the bitters are to be reckoned have sometimes succeed  
the Peruvian Bark &c but they are too weak & transient  
the preparations of Iron, have been used and the Muri-  
et. Ferri with more success than any of the preparations

\*

R

✓

that metal beginning with 10 drops three times a day.  
Preparations of Copper have also been used, and a  
variation of the Cuprum Ammoniacum known by the  
name of Mr Dicks prescription\* has been used, with  
great success;— The preparations of Zinc, have  
also been used and proved successful, the exhibition  
of the sulphate of Zinc, has also been attended with  
great benefit;— those preparations should be given in large  
doses, it is, from the administration of all the remedies, in this  
case in sufficiently large doses, that success is to be an-  
ticipated, and I am disposed to believe that to a neglect  
of this rule of practice is to be attributed in a great mea-  
sure the want of success in the disease, they should  
be given so as to produce some sensible effect on the system  
and this impression kept up;— Arsenic has been used by  
practitioners in Great Britain, & they think with success,  
pulvis stanni, has been successfully used owing not only  
to the small portion, arsenic it contains;— Nitrate of  
Silver, has been used with manifest advantage, I have  
seen its exhibition, in a case which came under the care  
of my worthy preceptor Dr Revere, in which the medicine  
administered, in doses of from 2 to 5 grs, was attended  
with complete success, & the man 30 years of age is

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

now entirely freed from his disagreeable associate.  
Prusic acid will no doubt, become a valuable medicine in this, as well as many other diseases; I have never heard of it, having been administered;—regular exercise, either on horseback, walking, or going to sea,—Cold bathing;—change of climate & new mode of life, also are efficacious;—Instances are on record, where persons have been cured by subjecting themselves to all the hardships and privations of a sea-faring life, & that Julius was cured in his youth with this disease, & cured by the hardships of a military life;—Electricity has been recommended, and its exhibition attended with some advantage.—

Another set of medicines to obviate the mobility of the system, are antispasmodics;—Nusk, Castor, Oiler, cum animale, Opium &c, this last in many cases is a powerful antispasmodic, but the propriety of it has been disputed;—it is certainly liable to injure the patient, when the disease appears to depend on a plethoric state of the vessels, but when it appears to depend on debility, Opium is likely to prove most beneficial. Serian is another of the antispasmodics, which has suffered to lay by forgotten for a long time, it has

The first part of the paper is devoted to a general  
discussion of the subject, and is intended to  
show that the theory of the present is  
not a new discovery, but a revival of an  
old one. The second part is a history of  
the theory, and is intended to show that  
it has been the subject of much  
speculation and discussion since the  
time of the ancients. The third part  
is a history of the theory, and is  
intended to show that it has been  
the subject of much speculation and  
discussion since the time of the  
ancients.

The fourth part of the paper is  
devoted to a general discussion of the  
subject, and is intended to show that  
the theory of the present is not a  
new discovery, but a revival of an  
old one. The fifth part is a history  
of the theory, and is intended to  
show that it has been the subject  
of much speculation and discussion  
since the time of the ancients.

many instances established its claim, to a rank among  
remedies successful in this disease; - When the  
attack can be foreseen by certain well known feelings  
the patient, an emetic given a short time before its ap-  
proach has been known to prevent a paroxysm, a large  
dose of opium or other antispasmodic has produced the same  
effect; - Calomel has been used in this disease, and con-  
cerning its use there is some difference of opinion, I  
was compelled to place some degree of confidence in  
this remedy; - I was afflicted with the disease for nearly  
30 years, during which time, every remedy was tried with  
little success, and until a salivation was induced by  
mercury (a course of treatment I adopted myself,) that  
usually followed tended only to aggravate the disease,  
since the salivation I have not experienced an attack or  
a symptom of the disease, which is now more than  
30 months; - I have frequently averted an attack by the  
administration of an Emetic; but often, owing to the disagreeable  
nature of the remedy, I have deferred it until an attack came.  
Sudden impressions on the mind, if they occupy it en-  
tirely, suspend the disease for a time, but if they become  
intermittent with the stratagem it loses its efficacy - Fear  
& horror, it is to the last passion that numerous super-

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

tious remedies have owed their success. — The viscus  
sericus, has been much celebrated for the Cure of this  
disease, it is given in decoction and may be sometimes of ser-  
vice; but it was principally so in ancient times on account  
of its being an object of Superstition, for in many diseases  
we have to attribute success in a great measure, to the in-  
fluence of the Imagination, it is in this way that rings  
& amulets have been used with success; — Digitalis  
has been used with success, where there is an accelerated  
pulse, it should be then given in doses gradually in-  
creased until the pulse is influenced by it; — Rhuz-  
dicans has occasionally cured Epilepsy, Dupresnoy  
& Hufeland have written much in the praise of this  
remedy; — The carbonate of Potash, is recommended by  
Wiedemann and Michaelis; Oxygen gas has been  
recommended in this disease, and the Gratiola  
officinalis by Sommer. — These are all the remedies  
which I have ever heard or read and all that I  
think worth mentioning; all of which I respectfully submit  
to your judgement and superior abilities. —

Essay  
on  
Bilious Colic.

A large proportion of the human family who are afflicted with this disease, the obstinacy of its symptoms, the fatality which results from its improper treatment, and the ample resources of medicine in preventing its evil consequences, are circumstances calculated to render the investigation of colic highly interesting. —

Although this disease seldom proves fatal when judiciously treated, yet it is attended with a degree of torture and distress which make the most eloquent appeal to the feelings and sympathy of the Physician, and demands the immediate exertion of his skill.

Deeply impressed with this view of the subject I am induced to dedicate the ensuing pages to the consideration of this truly formidable disease. The few remarks that I shall make on the causes, symptoms, and treatment of the disease, are offered as the result

of careful observation during its frequent occurrence in the neighbourhood in which I reside for the last four years. I have adopted the term bilious colic merely in conformity to custom, this being the term by which the disease is usually designated. So far as the term implies a derangement of the hepatic system, I admit its correctness, but in as much as it also implies a redundancy of bile I cannot subscribe to its propriety - I am inclined to believe that hepatic colic would be more appropriate. We shall first describe the symptoms as they manifest themselves in bilious colic. This disease sometimes attacks suddenly, especially those exposed to dampness or night-air during a state of convalescence from a previous attack, and those who have recently suffered from bilious fever.

In the generality of cases, however, this disease makes its approach by gradual and insidious steps. -

The patient complains of a sense of weight and obtuse pain in the region of the stomach, loss of appetite, costiveness, and pain in the inferior extremities for six or eight days previous to the attack of colic.

After sudden transitions from a warm to a cold atmosphere, or the application of cold water to the feet while the perspiration is free, colic suddenly supervenes in many instances. The disease commences with an acute pain in the stomach or intestines, passing with great rapidity from one part of the abdomen to another, generally most severe about the umbilicus, and is alternated with occasional remissions. The pain is frequently so severe as to cause the patient to roll over the bed, and sometimes even the floor, uttering the most plaintive cries, frequently changing the position of the body to seek some respite from suffering. At the onset of the disease pressure on the bowels affords some relief, but in one or two days they become very tender to the touch. The stomach is in an irritable state from the commencement, and after repeated retchings to vomit a quantity of vitiated bilious matter is ejected. Whether the vomiting be spontaneous or produced by medicine it affords temporary relief from the almost intolerable suffering. The bowels are obstinately constipated from the

commencement of the disease. Thirst and furred tongue are manifest early in the disease. In some cases a discharge of the contents of the rectum is the first effect of the spasmodic action of the intestines, a symptom which not unfrequently deceives both patient and Physician by inducing the belief that the state of the bowels is favourable to the operation of cathartics. The pulse varies considerably according to the stage and degree of violence of the disease. In the early stage, especially in mild cases, the pulse is not indicative of any material disorder in the system, but if relief be not speedily afforded it becomes increased in frequency, fullness and force. In some patients the pulse is preternaturally slow, full and tense or hard. In some cases where the spasms are very violent at the commencement the extremities are sometimes cold, and the pulse feeble for a time, but reaction soon occurs, and where much intestinal inflammation exists, as is sometimes the case from neglect of the disease at the beginning, the pulse is quick, small, and hard. A few days prior to an attack of this

disease a yellowness of the skin and tunica adnata is often perceptible, and is a general attendant on the second or third day. If an emetic be given early, followed by the exhibition of prompt cathartic medicines, this bilious suffusion is sometimes prevented. Eructations are very common in the beginning of the disease, and generally afford momentary relief. During the progress of the disease the patient is often extremely harassed by a troublesome singultus. As this last symptom precedes death from this disease it has been considered as affording an unfavourable prognosis, but I have witnessed its occurrence in many cases where the symptoms were removed without much difficulty by the remedies to be mentioned presently. The nervous system is considerably affected in some of the most obstinate cases as is manifested by mental despondency, and convulsive twitchings of the arms. During the autumn of 1824 I witnessed several cases where the whole system was violently convulsed. The urine is generally high coloured, small in quantity, and sometimes voided with diffi-

the second or third day. Of an acute or chronic nature  
followed by the exhibition of prompt cathartic  
drugs, this kind of affection is associated with  
Cerebral and very common in the beginning of  
the disease, and generally affects the brain early  
During the progress of the disease the patient is  
extremely prostrated by a protracted convalescence  
as this last position presents itself from this  
case it has been considered as affecting an  
incurable prognosis, but I have sometimes seen it  
occur in many cases where the prognosis  
was considered to be fatal by the physicians  
to be mortal. The nervous system is  
often affected in some of the most critical cases  
and is by mental depression, and especially  
of the mind. During the continuance of the  
disease the patient is often prostrated by  
the disease. The disease is generally high  
and is often fatal, and sometimes  
is often fatal, and sometimes

culty. The symptoms as detailed above presents the disease in its most aggravated form. It frequently occurs in a milder form, and all the above symptoms are not present. During the periods alluded to above, and in the section of the country, in which I reside, the disease has prevailed most extensively from the autumnal equinox to the middle of winter, though it may ~~occur~~ and has occurred at all seasons of the year. When it occurred in the summer season it was most inflammatory. With regard to the cause of the disease. I have carefully observed that cases of bilious colic were invariably most numerous after a summer remarkable for the prevalence of bilious intermitting and remitting fevers, and indeed the former may be said to follow the latter pretty generally.

From an attention to this circumstance and a consideration of the disease, I have drawn the following conclusion, that marsh miasmata, heat and drought, irregularity, intemperance, and all those agents which produce excessive action in the cutaneous & hepatic secretory vessels, may operate as remote or

x On Tropical climates, art. Dysentery;

predisposing causes of bilious colic. When the cutaneous and biliary vessels are excited from the causes mentioned above, sudden change from a high to a low temperature, exposure to night air, or the application of cold water to the feet, or any other part of the body by suddenly checking their secretions, will be followed by torpor and functional derangement of those vessels too greatly predisposed to such an effect by the previous state of excessive action. The necessary consequences of this torpor and inactivity are, a deficiency in the quantity of fluids secreted, a congestion of the hepatic and portal systems, and with a consequent inequilibrium of excitement in the systems. As an objection to this view of the subject it may be said that the same phenomena take place in other forms of disease. — This I readily admit, and agree with Dr James Johnson<sup>x</sup>, that the "same causes that, applied to one person, will produce bilious fever, will, in a second, give rise to hepatitis; in a third, to most de chiew; and in a fourth, to dysentery"; and I will add in a fifth, to bilious colic &c. according to circumstan

ces and the predisposition of the persons attacked. Amongst the various articles that have been enumerated as the exciting causes of bilious colic in this section of the union are, cider, crude fruit, apple-butter, and acid and all acescent articles of diet. —

### Treatment.

I shall conclude this essay with a few remarks on the treatment of this disease. The exhibition of an emetic as the commencement of the curative plan, is indicated by the spontaneous efforts to vomit, as well as by the quantity of vitiated bile which is frequently discharged. The quantity of bile thus discharged has given birth to, and established an opinion that the disease is invariably attended by a redundancy in the biliary secretion, which is erroneous. The quantity discharged is to be attributed to its accumulation from an obstruction to its exit owing to the constipated state of the bowels, and not to an increased secretion — indeed there might even be a paucity in the secretion. The stomach being very irritable, and the bowels obstinately constipated, what bile is secreted passes into the

stomach, either spontaneously, or by the first efforts at vomiting. The spontaneous vomiting is not sufficient to remove all vitiated matter from the alimentary canal, and hence the necessity of emetics. They promote a free discharge of vitiated matter from the primæ viæ, prepare the stomach for the reception and retention of purgative medicines, emulge the biliary ducts, rouse the torpid action of the cutaneous and hepatic vessels, and, by their nauseating and relaxing effects, they produce a temporary suspension of the spasmodic action of the intestines. In making a selection from the class of emetics the Tartrate of antimony and potash should be preferred on account of the effects it produces on the bowels and skin, effects not so certainly and effectually derived from other emetic medicines. It may be sometimes usefully combined with Calomel, fifteen or twenty grains of the latter with one or two grains of the Tar: Ant: et potasæ. ~~Specaccharum~~ is frequently rejected too soon on account of its unpleasant odour and disagreeable taste. Purg-  
ing constituted an important remedy in the treatment of bilious colic. As respects the choice of a cathartic,

I must give a decided preference to the mild mu-  
riate of mercury. This article will generally lie on the  
stomach, if given in large doses, as  $\text{xx}$  or  $\text{xxx}$  grains, when  
every thing else is rejected. Senna is also a valuable  
cathartic in the disease. The best method to administer  
it is to give it in the form of pill combined with the  
*Sub-muriat hydrargyri mitis*. By giving the Senna in  
substance in this form we avail ourselves of all its ac-  
tive principles, which is not the case when given in  
infusion or decoction, and moreover when given in sub-  
stance it is not so apt to produce tormina. Jalap  
holds the next rank as a purgative. This root, nausea-  
ting and drastic as it is, will often remain on the  
stomach when others are rejected. The *Oleum Ricini*  
will sometimes operate when every other medicine has  
failed to procure an evacuation. The neutral salts are  
sometimes valuable, but the stomach generally rejects  
them. They may, however, often be advantageously used  
in the form of enemata to assist the operation of other  
cathartics. Injections of warm water are sometimes pro-  
ductive of good effects. Considerable advantage is some

X Professor of the theory and practice of medicine in  
the University of Maryland.

times derived from an injection of XV or XX grains of the  
turbate of antimony and potash. A dose of the spirits of  
turpentine will sometimes take off spasm and open the bow-  
els. Warm fomentations to the abdomen frequently afford  
considerable relief. Flannels should be wrung out of hot  
vinegar & water, or hot brandy & laudanum, and applied  
to the abdomen. Rubefacients of the *Semina sinapis* or  
*Cochlearia armoracia* applied to the abdomen are useful  
auxillaries. If symptoms of acidity in the stomach be pre-  
sent Calined Magnesia will be found useful - It com-  
bines with the acid forming a neutral salt, which assists  
the operation of other cathartics. When the stomach is not  
very irritable much advantage may be derived from  
the exhibition of nauseating doses of antimonials. The warm  
bath when judiciously used is a valuable remedy. In  
order to derive advantage from its employment Dr. Potter<sup>x</sup>  
recommends us to "keep the patient in till general re-  
laxation be produced, till the pulse becomes weak, or  
sickness or vomiting be produced, which is the signal  
for removal, and then to use friction with hot brandy  
or spirits." When the constipation is not very obstinate ano-

dynes may sometimes be given, but they should be combined with purgatives. Calomel and opium is a good combination in such a case. The dose should be liberal at first, and continued in small doses. If ptyalism be produced it seldom or never fails to remove the disease. Venesection is often unnecessarily employed in the beginning of this disease to remove spasm. Professor Potter directs "blood letting to be used so as to produce sickness in the first stage when the pulse is hard and strong, the constipation obstinate, and the spasmodic contraction violent." When inflammation supervenes upon colic then blood letting cannot be dispensed with. It should be employed generally and locally in conjunction with the antiphlogistic plan generally. Epispastics are useful after the first use of the lancet. They should be large pads to cover the abdomen - small ones only fret the patient without proving serviceable. Epispastics are sometimes also useful in relieving gastric irritability - They are said to promote the operation of cathartics also when applied to the abdomen in cases of obstinate constipation. The above measures should be persevered in till the

bowels are frequently and copiously evacuated. After the disease is completely removed great care is necessary to prevent a return as there is no disease, I believe, that is more apt to return. The diet should consist of such articles as are easy of digestion, as arrow root, sago, tapioca &c. and exposure to dampness, night air, cold, draughts of cold fluids, and irregularity of diet must be carefully guarded against. Flannel should be worn next the skin, and the bowels kept open by the daily use of the Oleum Ricini or some laxative pills. As the time generally allotted for the production of inaugural essays is short, and as elaborate essays on the subject have preceded this, I have not noticed some other remedies recommended by some, as cold affusion, the exhibition of crude mercury &c. suffice it to say, that no advantage, I think, can be derived from the exhibition of the latter, and the use of the former is hazardous, because if it fail to produce healthy excitement or reaction, it will be productive of mischievous effects.

# Preface

In entering the arena of medical literature, before experience has sanctioned his professional opinions, the author has to urge as his shield, against the rigors of animadversion and criticism, the fact of his having no desire to seek notoriety, nor the no less culpable fault of "seeing his name in print;" but merely a wish to contribute his mite, towards the liquidation of a debt which the medical community, has so long owed the world, namely, that of removing the "shadows, clouds, and darkness," which rest upon pathology.

As no writer has (so far as the author's reading has extended) treated of the unpleasant affection, which

1840

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

results from exposure to the poisonous influence  
of the Rhus Toxicodendron, he has been indu-  
ced to offer this imperfect <sup>account</sup> of it. It is not so much  
the danger or interest, which is attached to the disease,  
as the resemblance some of its features bear to other  
affections of a more important character, which  
has elicited this description of it

As he has had no opportunity of profiting by the ex-  
perience of others in this disease, but writes only from  
his own observations, he hopes the reader will not  
exercise towards this essay, that critical severity  
which perhaps, he would be justified in using towards  
the production of a Cullen, or a Rush.

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

On the poisonous effects of the *Rhus Toxicodendron*  
With a short description of the  
Plants  
Of the *Rhus* Genus

We shall begin by giving a short account of the different species of *Rhus*, the appearance of the plants, the modes of exhibiting them as medicines, and of the diseases in which they have been employed.

The *Rhus glabrum*, *Rhus Radicans*, *Rhus Toxicodendron* and the *Rhus Vernix*, are those to which we shall confine ourselves, as (although numerous) the other plants belonging to this genus are not so well known, or so important in practice, as the four I have mentioned above.

1. The *Rhus glabrum*, does not possess the acrimony of the other species; it is interesting only on account of the excrescences, which adhere to its leaves, and which are said to equal, if not to exceed the Aleppo Galls, in astringency.

Plants

Of the Blue Grass

2. The *Rhus Radicans*, grows upon elevated situations: it may be distinguished from other plants of this species by its, by its attaching itself to trees or other objects, upon which it supports itself, in the manner of a grape vine. It is a very beautiful plant, the leaves being divided into three portions or lobes, which at certain seasons, assume a reddish appearance. "The leaves and bark are astringent to the taste which quality appears to be occasioned by gallic acid, rather than tannin." It also possesses narcotic properties. It has been employed in paralysis, and herpetic eruptions.

It is generally given in substance in the dose of half a grain of the powdered leaves, two or three times a day. There is also a tincture of it which has been sometimes exhibited, and with apparently, good effects.

3. The *Rhus Toxicodendron*, commonly known by the appellations of Swamp Sumach, Poison Oak &c. differs from the preceding in <sup>being</sup> a low shrubby plant, the leaves of which are triobovate, smooth and occasionally heart shaped. It is perhaps, possessed of more virulency than any other plant of the species. The flowers are small and shoot out from the sides of the plant. It has been used by Dr. Alderson, of Scotland, with considerable success in paralysis. He relates seventeen cases, in all of which it was usefully employed. His mode of exhibiting it, was in substance in the doses of half a grain thrice a day, or in the form of extracts, or tincture.

4. The *Rhus Vernix* is generally considered as being more poisonous than any other plant belonging to this class of vegetables. It differs from the *Rhus Radicans*, in delighting in low situations. Although it has been noticed by writers as possessing narcotic properties, we believe it has never been employed as a remedy.

Having given a description of the plants of the *Rhus* Genus, we shall now proceed to a brief account of a singular affection of the skin, resulting from the application of the poison to the external parts of the body.

Though not a dangerous disease, it is one of the most disagreeable affections to which the human body is liable. Producing a very extensive inflammation of the skin, attended by a most insupportable itching and burning, the patient is kept in such agony, as nearly to deprive him of reason, and during the continuance of the disease, to render life itself, almost a burthen. The disease is ~~said~~ never appears except in warm weather; it is said by M. Van Mons. (who appears to have paid considerable attention to the chemical character of the *Rhus*) to be produced by a poisonous exhalation from the shrub; which he affirms is "a carbonated hydrogen gas." Whether any degree of credit is to be attached to this assertion, we are not able to determine; but we are aware that the disease may be produced in other ways, besides the application of the plant.

itself to the skin. Should the patient receive the dew which falls from it upon any part of his body he will as certainly have the disease and in as severe a form, as though he had handled the shrub itself. He will also receive it by standing to leeward of the plant, when there is a strong wind blowing.

Persons are by no means equally obnoxious to the poison of Rhus: there is a complete immunity enjoyed from ~~the~~ by some individuals from the effects of it. The proportion in which they receive it, is perhaps not more than one, in ten or twelve.

What that state of the system is, which renders persons liable to this affection, it is hard to determine. Perhaps it may be accounted for, by supposing the nerves of such subjects to be possessed of a more exquisite sensibility, than those of others, and being thereby rendered more susceptible to the action of the virus. <sup>h</sup>

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

Persons, by age also become less sensible to the effects of the poison; so, that it is seldom or never met with in persons far advanced in years.

We shall now speak more particularly of the symptoms, of the disease; of the character of the inflammation; of the structures, which it attacks; of the time of the appearance of the eruption, after the application of the poison; of some peculiarities which bear an analogy to other diseases of a more important nature; and lastly, of the treatment of the disease.

**Symptoms.** During the first forty eight or seventy two hours after the application of the poison, the following symptoms present themselves. The patient complains of languor or lassitude, great drowsiness and chills; which are succeeded by a hot skin, flushed face, and pain in the head; the eyes are red and watery, there is also great

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

thirst. If the poison has been applied to the face, the patient perceives a sense of roughness in the mouth and fauces of a very disagreeable nature. The Schneiderian membrane of the nose, is also affected, secreting a thin, acid fluid, which excoriates the parts with which it comes in contact. The arterial system is also considerably excited, the pulse being increased both in force and frequency. The urine is secreted in small quantities, and is of a reddish colour. The patient is also generally costive; if he have an evacuation without the aid of medicine, the feces present a firm appearance, and exhale an odour of a very peculiar nature, which can never fail of being recognized by the olfactory nerves of the patient, if he have ever before had the disease.

In about forty eight or seventy two hours ~~after~~ from the appearance of those symptoms, the eruption (if it may be so called) shows itself, presenting the appearance of innumerable small, white, blisters, filled with a serous fluid.

Its appearance is attended by a most disagreeable itching and burning of the skin, which induces the patient to rub the tops off the vesicles, but which, instead of affording him relief, serves only to aggravate the disease. The vesicles are increased both in size and number by whatever determines the blood to the surface of the body; such as exposure to heat, or drinking ardent spirits; while cool weather, light clothing &c. tend greatly to lessen the severity of the disease.

The disease, like small pox, measles, and others of the exanthemata, has a peculiar affinity for the mucous membranes, as well as the skin: it for instance, very frequently attacks the Schneiderian membrane, the mucous membrane of the fauces, and the extremity of the rectum. In general, it begins to decline in about four days. At the expiration of this term, the serum appears to be absorbed from the smaller vesicles; while the larger

become filled with a thick yellowish pus, which, if the disease have extended to the palms of the hands or soles of the feet, where the cuticle is thick, causes great pain. As the disease declines, the cuticle (where it is thin) is separated in large patches, leaving the parts as tender as those of an infant. In other situations where it is of a firmer texture, ulcers are formed, having ragged irregular edges, and a very fetid smell.

In about three or four weeks, the eruption disappears from the whole body, leaving however livid coloured spots, (but no pits) which last a few days longer, but are gradually effaced, and the patient regains his original complexion.

The inflammation, attending this affection is of the erysipelatous character: the seat of the disease is probably the rete mucosum, but the inflammation perhaps may sometimes extend to the cutis vera, beneath.

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

There is one peculiarity attending this disease to which so far as our knowledge extends, there is no analogy, except in syphilis, namely, its occurring, though in a milder form, every year at the approach of warm weather; and that whether he be exposed a second time to the cause or not, until the virus shall have been expelled from the system by mercury.

Upon what pathological principle we are to account for this phenomenon, we are not able to determine; but must content ourselves for the present, with a knowledge of the fact, the truth of which we have had many opportunities of ascertaining.

The treatment of this disease is sufficiently simple. It may be divided into two stages, *viz.*<sup>two</sup> that before the vesicles have appeared; and that which we are to pursue, after, they have shown themselves

There is one possibility attending this statement  
as far as our knowledge extends there is no  
right in a patient normally its necessary that  
we take from every year of the appearance of  
it, and that whether it be a case of a  
the case is not until the virus is  
which is the system by means  
the what pathological phenomenon are  
the phenomenon, we are not able to  
it must be considered whether the  
number of the fact the truth of which we  
a many of the characteristics of  
the treatment of this virus is  
it may be divided into two stages  
the first is the appearance of  
the second is the appearance of

1. If the patient be plethoric, and febrile symptoms run high, the pain in the head acute, or the <sup>skin</sup> hot and dry, blood must be taken from the arm, to the extent of reducing the pulse. It is impossible to describe the relief it affords in such cases; it relieves the headache, and (by inducing a gentle diaphoresis,) that burning heat of skin, which is so distressing to the patient. It also prevents the disease taking on that severe form it is apt to assume, where the lancet has not been employed.

If the patient is generally costive, purging should be used, in conjunction with bloodletting. The best cathartics in this disease, are the neutral salts; such as the sulphate of magnesia, or the sulphate of soda; or he may take, the sulphate of magnesia, <sup>and the calcined magnesia</sup> in combination

tion, as the mixture operates better, than either of the articles would alone.

The skin being in a hot and dry state, the necessity of diaphoretic medicines, would appear to be indicated.

The antimonials might perhaps, be usefully employed; but we should carefully refrain from using such as are of a stimulating nature.

The diet, should be light, and consist of easily digested articles, such as sago, Indian gruel, milk and bread, rice, &c. thus of a similar nature.

To allay thirst, the patient may drink freely of barley water, toast and water or lemonade.

He should also avoid the heat of the sun, or of a fire, as warmth has a tendency to increase the severity of the disease. The clothing should likewise be light.

The mixture of the  
the world  
this being in a  
of the  
the  
of a  
this, which  
articles such as  
as together  
they think  
is a  
about  
with  
therefore

There have been a great number of articles recommended in domestic practice, as external applications, such as, strong solutions of the muriate of soda, solutions of the corrosive muriate of mercury, and others of a similar character; but in general they are of little service. The best that we have ever employed is a liniment, composed of castile soap, blanched almonds, and loaf sugar, rubbed up with rose water to which a small quantity of tincture of cinnamon should be added. This, which has been dignified with the title of "Balsam of Mecca," by the apothecaries, is very soothing, and may be applied to the parts with a feather, frequently throughout the day.

There have been a great number of persons who  
in the course of their lives have attended  
with an ardent solicitation of the most  
of the various sciences, but in general  
a similar character, but in general  
the sciences, the best that in some  
a treatment, comparison of doubtless, the  
interest and progress, which will  
to which a small quantity of  
can be said to be all that  
connected with the title of "The  
of the sciences in any  
of the sciences with a  
at the day

As the disease declines, we may begin to exhibit mercury in small doses, so as slightly to affect the system, as without this precaution, the disease will certainly reappear the following season, at the approach of warm weather.

*FINIS*

An Inaugural Dissertation  
On the  
Pathology and Treatment of  
Febris Intermittens  
Submitted to the examination of  
Provost  
The Trustees and Medical Faculty  
Of the  
University of Maryland  
- For the  
Degree of Doctor of Medicine  
By  
John H. Riggs of Maryland.

The Principal Lecturer  
in the

Botany and Chemistry of  
the University

of the University of  
Oxford

The Hon. the Vice-Chancellor  
of the

University of London

and the  
Vice-Chancellor of the

University of Cambridge

In setting out, we maintain, that medicine as a modern science has accomplished much for the relief of suffering human nature, but that it has arrived to perfection, no one will admit when he brings to mind the improvements and discoveries, which are daily making in the efficacy of remedial agents, of their varied adaptation to the organization, and grades of disease depending upon that organization.

Without further prefatory remarks, we shall make a feeble attempt to discharge a duty devolving upon us, of inviting the attention of the Faculty, to one of the many diseases, with which we are afflicted, this disease is one which has been called *Febris Intermittens*.

Intermittent Fever, is a disease of low countries, and generally those remarkable for fertility of soil, and mildness of climate, especially where large streams abound it is there the companion of every age and sex, and if disappearing for a time leaving in its subjects, traces of various morbid predispositions. As it is our intention to be brief, we shall not attempt to enumerate those diseases, supervening on Intermittents. It may be sufficient to state that reiterated and prolonged attacks, will eventually break down the constitution of the sufferer, also tend to impair the mental and physical energies, of a greater part of the population, abridging human life and happiness, perpetrating upon an enfeebled offspring, the misfortunes and misery of their progenitors.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and difficult to decipher.]*

Notwithstanding such is truly the condition of a people labouring under this form of disease, such is their delusion and infatuation, that they deem themselves happy, in being subjected to a disease which does not directly destroy, <sup>to</sup> the treatment of which they feel themselves competent, and boast with engorged Livers, and Spleens, tumid abdomens, and impending dropsies, of their independence of Physicians. We are confident it will be conceded, that medicine has not accomplished all, to be wished for, while a disease like this is treated with levity, or regarded with indifference by those modern writers, who occupy high ground in professional reputation, for it is little short of mockery to limit the resources of medicine for its relief, to tonics, and antispasmodics. In casting our eyes (says Dr Good) over the great diversity of medicines that have been employed for Intermittents we shall find innumerable as they are, they may be arranged under two general heads, <sup>tonics and antispasmodics</sup> and yet he says whenever the accession of an Intermittent is violent, be its type what it may, it is sometimes attended with very alarming symptoms, as syncope, apoplexy, and vehement spasms, over the whole body.

Nevertheless, when of the Tertian Type, and not violent, or of long duration, it is <sup>often</sup> pernicious to the general health, and carries off many lurking diseases, of other kinds. We cannot withhold an expression of surprise, that in a work so recent and truly valuable, as Dr

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

Goods, views of the treatment, of Intermittent Fever, should be laid before the medical public, so materially at variance with the best practical authorities.

Dr Cullen's view of Intermittents, as arising from marsh miasma is generally concurred, with in this country, and will probably never be successfully controverted. It places them in their just relation to remittent Fever, and prepares the practitioner to expect in them, all those phenomena which are common to this poison, in its influence over the animal economy, modified generally by type and circumstances. We could but be disappointed therefore, in perceiving that their propagation by sympathy, and contagion, was advocated by Dr Good, admitting however, that marsh effluvia is their most general source.

To those experienced in the treatment of this disease, a caution against the mode prescribed by the learned author in question, (from the supposition of the harmlessness of its character,) would be supererogatory, but it may be necessary to guard against the principles on which that treatment is predicated, for it is generally conceded, that this disease is one of a most serious character, in its autumnal recurrence, its inflexibility without remedial means, and when removed the morbid sympathies which succeed it.

Although these results are proper to it, in the conviction of

all, still from mistaking it, as it not infrequently happens, for a disease of low action, founded and continued in debility, we shall be led to the same course of treatment, as if it were possessed of, the attributes ascribed to it by the author in question.

Intermittents, as well as other fevers, have their seat in the blood vessels, the action of which, under the influence of the heart and arteries, may be that of increased or diminished excitement. At one time the power of the remote cause may <sup>be</sup> such, on the sensorium commune, as wholly to prostrate or destroy the vital functions, again, such will be the recovered power of the heart and arteries, that means the most active are indispensable to the preservation of life.

Causes. So many observations have been made (says Dr Cullen) with respect to marsh miasm, in so many regions of the earth, that there is not any doubt of its being very universally, the cause of Intermittents in all their different forms.

The appearances of this disease occasionally as an epidemic in districts generally exempt from it, is explicable on the principle, generally admitted this side of the Atlantic, that the miasm producing it, is purely of vegetable origin, and liable to be evolved under those circumstances, which combine a luxuriant vegetation, with a humid and heated atmosphere, while sporadic cases may be traced to local accumulations of vegetable filth in the immediate vicinity of dwellings, often in damp cellars, foul yards,

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and cannot be transcribed.]*

and gardens, and in the Pann yards of the Farmer, where vast collections of vegetable matter are pressed into putrefaction, preparatory to the approaching Autumn. In what this poison specifically consists we are unable to state. Chemistry (which has done much) may yet develop its character, and counteract its influence. What homage will not science owe to him, who shall wrest this spoiler's power, who maintains his pestilential empire, with such tyrannical domination over our globe.

The opinion (says Professor Potter) that the remote cause of the miasmatic family of fevers, acts primarily on the stomach, and thence its effects are radiated to all other parts, will scarcely bear the scrutiny of a skilful etiologist. We judge (says the learned Professor) that the first impression is made through the nerves, probably the nerves and lungs, upon the brain, and from this great function of power to other viscera. It is generally admitted, that the poison considered as the remote cause, would generally fail to manifest itself, but for other causes deemed exciting; hence it is found that Intermittents generally supervene upon sudden vicissitudes of temperature, upon exposure to nocturnal damps, or follows close upon the heels of revelry and intemperance, and in short all those causes which exhaust or debilitate body, thereby lessening its power of resistance, against the influence of predisposing causes.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and difficult to decipher.]*

## Symptoms:

The approach of a paroxysm of an Intermittent, is marked by lassitude, disinclination to motion, yawning, shivering, weight and oppression in the epigastric region, coldness of the extremities, paleness of the face, with contraction of features; the heat of the surface becomes generally diminished, the pulse small, breathing anxious, anxiety, and apprehension about the precordia, sensation impaired, mind weak and restless; a chill or rigor now comes on, frequently attended with uneasiness of the head. It now seems impossible to restore heat to the body, the patient's teeth chatter, and his entire system is irresistibly agitated, as if pierced by the cold of winter. We have not noticed a case thus strongly marked of long continuance, the reaction of the system is generally more prompt, than in dumb agues as they are vulgarly called, in which the pulse is slower, with but little apparent disturbance of the system.

The cold stage may be said to last from half an hour to one, after which a sudden transition is experienced, as though the patient were transported in so short a time, from polar ices to the heat of the tropics. This transition is often preceded by bilious vomiting, now anxiety becomes extreme, the respiration hurried, there is throbbing and pain in the temples, the face is flushed, the hands, and feet burn, the skin also is hot and dry, the thirst extreme, with restlessness, often with delirium, and incoherence of ideas, the pulse varying according to the force of the disease, or condition of the system, as bounding, jerking or frequent, with a furred tongue. The febrile stage may be from three to eight hours.

The appearance of a foreigner of an extraordinary height and  
build, and a singular manner of dress, attracted the attention of  
the people in the public square, and a crowd of spectators  
gathered round him, who were all looking at him with  
great curiosity, and some were making signs to him, as if  
they would have liked to see him more closely. He, however,  
did not seem to be in the least embarrassed, and he continued  
to walk on, as if he were perfectly at ease. He was  
observed to be of a very fair complexion, and his hair  
was of a light brown color. He was dressed in a  
simple, but elegant manner, and he carried himself  
with a graceful and easy air. The people who  
surrounded him, were all of various ages and  
sexes, and they all seemed to be very much  
interested in him. He walked on for some  
time, and then he turned round, and he looked  
at the people who were looking at him, and he  
smiled, and he bowed to them, and he continued  
to walk on, as if he were perfectly at ease.

At length a sweat or moisture breaks out over the whole body, and then the febrile symptoms rapidly diminish. The condition of the patient if the paroxysm <sup>has</sup> <sup>been</sup> undisturbed, is never perhaps that of health, he is conscious of the impairment of his functions, his head is disturbed, and he complains of heaviness or dizziness, nausea, or want of appetite, his voluntary powers are feeble, his intestines torpid, and he is apprehensive of another attack.

### Treatment

In the view we have taken, we believe that the symptoms are so many links in morbid association, by which, if any one be abstracted, the disease is rendered less perfect, thereby proportionally preserving the balance of the system, and enabling it more effectually to resist subsequent attacks.

The treatment divides itself into two parts, the treatment during the paroxysm, and that in the intervals. During the paroxysm our object is to hasten its different stages, and relieve violent symptoms, in the intervals to prevent a return, by making such an impression upon the nervous system, as may prevent its development. On the approach of a chill, the patient should be laid in bed, between blankets, warm diluents should be freely administered, warm applications <sup>made</sup> to the sides and extremities, these simple means will generally prove sufficient for the first indication, though not always, the prostration may be such as to require stimulants, as wine, whey, brandy and water, sinapisms &c. We should suggest that it is proper or necessary to distinguish a chill prostration, from that Apoplectic form which Intermittents occasionally assume, requiring active depletion, and where the

exhibition of stimulants would be fatal. When the heart shall have come freely into action, indicated by a rapid pulse, a dry and heated skin, with burning extremities, and other symptoms proper for the febrile stage as already given, we are called to the second indication; This we propose to fulfil by a judicious employment of the lanceet.

Persons seized with Intermittents for the first time, who have been vigorous and athletic, will generally be benefitted by moderate depletion, if the symptoms are rather mild; but the employment of the lanceet is indispensable, where there are evidences of great excitement, as when the head is very painful, there is lethargy, delirium, a full and rapid pulse or small and tense. But if the febrile symptoms do not run so high it may be dispensed with, provided there be a free evacuation of the Stomach and bowels, which may <sup>be done</sup> by giving an Emetic of Tart stutet Pot, if there be a foul tongue, sickness of the stomach, and other symptoms of a foul stomach, without any pain of <sup>or</sup> great determination to the head, followed cathartics, which carry off large bilious dejections, as the submur Heyd, Salafii, Gambog. Rhei. Aloes, and Ol Ricini; the quantity of the evacuation by the lanceet or Cathartics, to be governed by their effects, under the observation of the practitioner. The leading indication of cure is to <sup>be</sup> learned by attending to the Liver and causing it to take on a healthy secretion. We deem the use of the lanceet of so much importance that we cannot forbear giving the words, Professor Potter.

"Bloodletting is often necessary in the hot stage, and in all Intermittents not of very feeble type. the cure is rendered easier by the loss of blood, during the head and back ache of the fit, provided the quantity be regulated by good judgement.

In the cold stage of an inflammatory intermittent bloodletting is not only justifiable, but

*[The text on this page is extremely faint and illegible due to fading or bleed-through from the reverse side. It appears to be a continuous block of handwritten text.]*

highly useful, if a tense and hard pulse indicates, it shortens the paroxysm, renders the next fit milder, and sometimes performs a radical cure.

By the judicious employment of those means we are disposed to believe on the authority of others, and some little experience, that they may be disposed of, with less liability to a second attack, than under the usual mode, or tonics and antispasmodics. To guard against which however we come to consider the means most proper, under the head of —

### Prophylactics.

Under this head we might notice many articles, which have been employed with little or no advantage, which have been said to act specifically and without evacuation, but we will not waste time in controverting these points.

We conceive tonics applicable to Intermittents as to all other affections, indicated under like circumstances, and to be employed with like views; which are likely to prove pernicious in the hands of ignorance and empiricism, and simple as their abstract character may appear, they are productive of far more injury in the hands of the vulgar, than either the lancet or cathartics.

As a tonic we prefer *cinchona lancifolia*, which is most effectual, given during a state of apyrexia, when practicable should be administered in powder, in as large doses as the stomach will bear, When it disagrees with the stomach, or runs off by the bowels, it may be united with an aromatic or opium, or a few grains of roasted rhubarb; the infusion, decoction or extract may also be substituted, or the sulphate of quinine.

Faint, illegible handwriting at the top of the page, possibly a header or introductory text.

Proposition

Text block below the section header, containing several lines of faint handwriting.

Main body of faint, illegible handwriting, consisting of multiple paragraphs of text.

But there are certain states of the system which are found to interfere with the exhibition of bark in any form. The principle of these are, an inflammatory diathesis, a disorder in the primæ viæ, obstructions in the liver and spleen, and others, hence arises the necessity of bloodletting, purgatives, or antimonials, and alteratives, previous to the exhibition of bark.

In extreme cases, where dissolving sweats, or excessive weakness comes on the use of camphor will prove advantageous, with cordials, as wine, also the sulphate of quinine, in doses of from  $\text{i}$  to  $\text{v}$  grs. In these cases, large doses should be given, or it will be so much time lost. There are some auxiliaries, which should not be overlooked, as they are important when the system is prepared, among these we would mention first, solution of arsenic, or what is generally known under the name of Fowler's solution, a very good indigenous article is the *eripatorium perfoliatum*, and in particular cases would seem to be second to none of them, used in the form of infusion.

The sulphate of zinc, has been given with evident advantage, in the dose  $\text{i}$  to  $\text{ii}$  grs. three times a day.

Inaugural Dissertation

on

Cyanische Tracheitis

By

John W. Stout.

of Virginia.

Submitted to The Medical Faculty  
of the University of Maryland.

1833

## Cynanche Trachealis.

An inflammation of the mucous membrane of the Trachea obtained this appellation, It is a disease almost exclusively of infants and children—Some authors say that adults are sometimes the subjects of it, though we have never traced an instance of it in any person above ten years of age, from one or two to ten or twelve years of age appears to be the age at which they are most subject to croup. We do not believe it to be contagious as suggested by some, but it is said to visit epidemically, Cynanche Trachealis appears peculiarly in some families, and a child once having had it will have it excited again by very slight exposure, but probably its after effects are less severe—The robust and healthy appear to suffer more than the thin and delicate.

Cold and moisture are the common causes of Cynanche Trachealis, The disease prevails of course in the fall winter and spring, and particularly in the damp and rainy part of those seasons, It is said to prevail more commonly on the sea coast than in other places—But as cold and moisture are the causes it will prevail in many other places, particu-

George Washington

Faint, illegible handwriting covering the page, likely bleed-through from the reverse side.

only in northern countries. — The attack which  
generally comes on in the night, sometimes succeeds  
the exposure in a few hours. At other times it does not  
come on for several ~~hours~~ days, but under such circum-  
stances the child appears indisposed. Drowsy and  
stupid, the eyes appear heavy — he is troubled with cough  
that shall kind, that always characterizes the  
case. The cough and hoarseness increase, and  
become more troublesome. The face is red and sometimes  
swelled — As the disease advances great difficulty of  
breathing prevails accompanied by a swelling  
of the parts adjacent to the throat.

The head of the child is sometimes <sup>thrown back</sup> in great  
agonny apparently to escape suffocation.

There is also a peculiar sound attending respiration  
in Cynanche Trachealis, compared by some to the  
barking of a small dog or goose.

There is generally no expectoration, but when there  
is any, it is of a purulent character or of a membra-  
nous appearance.

*[Faint, illegible handwriting on lined paper]*

There is great thirst, a continual sensation of heat over the whole body, a disposition to change from place to place, with a frequency of pulse,

Very frequently the symptoms suffer considerable remission and exacerbation, The disease will sometimes almost disappear in the day and return at night with double violence, If it proceed undisturbed the symptoms continue to be aggravated until the child dies.

When the disease proves fatal it generally does so in one or two days, The character of the disease is such, that if the symptoms are not moderated in the first ten or twelve hours, in bad cases it generally proves fatal, Should the child recover <sup>from</sup> what has been called the second stage, the convalescence is generally tedious, and is attended by expectoration of portions of a peculiar membrane of which I shall speak presently,

In milder forms of the disease when the symptoms are not so urgent, the cough and difficulty of breathing are generally much abated on the second day—

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

The skin becomes moist, the fever abates and the voice recovers its natural tone, Doct. Gregory <sup>speaks</sup> of a spasmodic or spurious croup. The existence of this form of croup is positively denied by Doct. A. Potter (Professor of Theory and practice of Physic, in the University of Maryland) Doct. Potter says that the sonorous sound which has been compared to the barking of a small dog or fox is occasioned by the rigidity of the inflamed parts, Should not such authority put such questions completely at rest? We think it should.

We shall now say something of the membrane that we had occasion to speak of formerly - There have been many dissections of infants that have died of croup, and almost constantly there has appeared a preternatural membrane lining the mucous surface of the upper part of the Trachea, and sometimes extending down into its ramifications.

This membrane may according to authors be separated from the proper membrane of the part, It <sup>has</sup> been found separated -

The above is a summary of the first part of the  
report on the subject of the proposed  
amendment to the constitution of the  
State of New York. It is submitted to the  
Legislature for their consideration and  
approval. The report is divided into two  
parts, the first of which contains a  
statement of the facts and circumstances  
connected with the proposed amendment,  
and the second part contains the  
recommendations of the committee.  
The committee believe that the proposed  
amendment is necessary and proper for  
the good government of the State, and  
they recommend its adoption.

The mucous membrane of the trachea is found entire, but with signs of inflammation, and is covered with a matter resembling pus. This substance is sometimes found in the bronchia in considerable quantity.

After the formation of this membrane the child throws his head back so as to put the trachea on the stretch.

This membrane appears to be a secretion of the arteries, of the inflamed part. Children that have once had an attack of croup should expose themselves to the vicissitudes of the weather with great caution, as the disease is liable to be excited by very slight exposures. A common cold in the predisposed will renew the disease or produce croupy symptoms, until the tenth or twelfth year of life. The utmost care should be taken by those who have children predisposed to this formidable malady.

Doct Gregory has suggested the idea that croup is a contagious affection. It is surprising to us that a man who ought to be so well qualified to decide a question of this kind should take up an opinion so inconsistent. If it is contagious, we think it cannot be proved, and

if so should not be admitted, We are of opinion that  
croup is not more contagious than diarrhoea, or catarrh, and  
we believe that the idea of the contagiousness of croup is now  
abandoned by every one whose intelligence has kept  
pace with our science,

Authors have divided croup into two stages. The 1<sup>st</sup> is that  
of inflammatory action, the second being distinguished by  
that peculiar membrane previously described,

In treating this formidable malady when the febrile symp-  
toms run high and the breathing is very difficult, bloodletting  
is one of our principle remedies - In slight attacks  
however emetics assisted by rubefacients to the throat  
will often give a permanent check to the disease,

Whenever therefore vomiting and rubefacients do not af-  
ford speedy and effectual relief recourse <sup>should</sup> be had immedia-  
tely to the lancet and calomel. Blood should be drawn  
untill a decided impression be made on the system,

Doct Faure found bloodletting necessary in all cases, he  
says it is the essential point of cure. If the patient was  
palethoric the difficulty of breathing great, with much restlessness

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the document. The text is mirrored and difficult to decipher.]*

he bled on the second day of disease to fainting.

Bloodletting has a twofold effect in croup. In the first place it is the most speedy, prompt and effectual means of reducing inflammation. in the second place it relieves that cerebral congestion and consequent insupportable and unmanageable state of the stomach, which so often attends this disease.

Some speak of Vomiting as a troublesome symptom in croup, but this is in direct opposition to our experience. We have witnessed many cases of croup, but never found vomiting a troublesome symptom, but on the contrary almost always found difficulty in producing it. And furthermore we can say that we never knew a case to prove fatal after the stomach had been properly excited.

Doct. Eberle says that emetics should be used at intervals until the disease is completely subdued. After the leucit has performed its office, it <sup>may</sup> be necessary to resort to blisters. I say blisters because I think it would be better to apply one on each side of the sides of the neck than one over the trachea. We think the counter irritation produced by the blister when applied over the trachea is too near the

real inflammation, since as such is calculated to defeat the  
very object that we so ardently wish to accomplish,

In the first stage of croup or Tracheitis particularly of a mild  
form the inflammation may be frequently stopped by some  
subsequent to the part, spirits of turpentine answers this purpose  
well, But when the disease is making rapid advances such  
means will not do, and the Physician who depends on such  
remedies will find himself sadly disappointed, for he will  
have to witness the death of his patient, and all the consequent  
disagreeable attendants on such an occasion,

Therefore feeble means should ~~not~~ not be resorted to  
when this formidable malady requires the more energetic, such  
as the lancet, emetics, Blisters, and calomel in large and  
repeated doses, Croup is we think as much under the  
control of medicine as any disease, and furthermore we  
<sup>think</sup> that no child ought to die of croup, if properly treated from  
the commencement, Physicians have been too sparing of  
calomel in this disease, Croup is sometimes a formidable  
complaint, and requires a powerful remedy, and in calomel  
we find it, But blood letting should generally be first permitted,

The first step in the process of writing a book is to choose a subject. The subject should be one that interests you and that you know something about. It should also be one that is not too broad or too narrow. Once you have chosen a subject, you need to do some research. This will help you to understand the subject better and to find out what has already been written about it. You should also think about the audience for your book. Who are you writing for? What do they need to know? These are some of the questions you should ask yourself as you plan your book. The next step is to write a plan or outline. This will help you to organize your thoughts and to know what to write next. It is important to write a plan because it will save you a lot of time and trouble. Once you have a plan, you can start writing. Remember to write regularly and to keep your writing simple and clear. It is also important to take breaks and to read what you have written. This will help you to see if you are on track and to make any necessary changes. Finally, you need to edit your book. This is a very important step because it will help you to make your book as good as possible. You should read your book carefully and look for any mistakes or areas that need improvement. You should also ask someone else to read your book and give you their feedback. This will help you to see if your book is interesting and easy to read. Once you have finished editing, you can publish your book. There are many ways to do this, but the most common is to go to a publisher. You should look for a publisher who specializes in the type of book you are writing. You should also look for a publisher who has a good reputation and who has a good marketing plan. Once you have found a publisher, you can submit your book to them. They will decide if they want to publish your book and if they do, they will handle all the details of the publishing process. This includes finding a printer, designing a cover, and promoting the book. You should be prepared to wait a while before your book is published. This is because the publishing process can take a long time. However, once your book is published, you can start selling it and earning money. This is the goal of writing a book, and it is a very rewarding experience. So, if you are interested in writing a book, start now. Choose a subject, do some research, write a plan, write regularly, edit carefully, and publish your book. You will be on your way to becoming a successful author.

The antiphlogistic regimen should be pursued through-  
-out. The bowels should be kept open with calomel  
introducing occasionally a dose of oil,

Should the bowels be difficult to move it may be  
right to use an injection. The Sulp. Mag. will accomp-  
lish this end with sufficient promptness.

Expectorants when properly selected have a happy and  
desirable effect, considerable caution should be observed  
in their selection. Those of a stimulating character should  
not be used in the inflammatory stage of the disease. They  
may however become admissible in the second.

We should endeavour after proper evacuations to produce a  
determination to the surface, Antimony in small doses will  
accomplish this object better probably than any other remedy-  
particularly when conjoined with an equal quantity of the  
Spiritus Aetheris Nitrosi. experience will we think always determine  
in favour of this compound in the early stage of croup.

By promptly resorting to the means that we have pointed  
out the disease will almost always be effectually checked, but  
by neglecting them and trusting to trifling ones, and thereby

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

suffering the inflammation to proceed, the practitioner wis/say  
the perfect with the death of his patient, which a vigorous and  
proper treatment might have prevented, Doct. Potter recommends  
the use of corrosive sublimate in that insensible state of the  
stomach which so often attends this cynanche Trachealis

The corrosive sublimate is no doubt a potent remedy in this  
complaint and when we fail with the others we  
shoud resort to this immediately, It is asserted by high  
authority, that in that insensible state of the stomach, which  
accompanies croup that it is a safe prompt and efficacious  
=ous emetic, and has arrested the progress of the patient to the  
grave even when he had reached the confines of eternity,

It is recommended in solution. one grain suspended in  
one oz of water, of which a tea spoonfull every half  
=n may be given till vomiting be produced,

One disadvantage attends this medicine it is apt to  
produce salivation, but it is seldom that it is profuse  
when produced in this way

Doct Gregory seems to think unfavourably of calom  
=el in croup, He says that according to his experience

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

it has been much over-rated, We imagine the Doctor never gave it fair trial, He speaks of giving from one to five grains every two hours, It is evident from this that he had never learned the use of calomel in croup, Such doses in desperate cases are of little or no account, and <sup>are</sup> calculated to lull the patient into <sup>apparent</sup> security when he is making rapid strides to his grave.

Calomel appears to be almost a specific in this complaint and when properly administered in conjunction with other means hardly ever fails to effect a cure.

In bad cases the doses should be five or six grains every hour until a change for the better shall take place.

We have said that expectorants are useful and in the latter stage after the inflammatory action shall have been reduced. The Polyzala, Senega is highly recommended Antimonial wine and assafetida are useful; The osyml of squill has been used.

As to the operation we can say but <sup>little</sup> never having seen it performed, Should the means we have recommended fail, without the operation will hardly save the patient,  
Finis.

This disease consists in an inflammation of the serous  
membrane of the intestines, but according to some  
Authors it would probably be going too far to say  
that in every case of the disease there is always  
an inflammatory action of the vessels of the serous membrane  
of the intestines, yet in the majority of cases this certainly  
happens, if not in every case, and an fully certain  
it does in a greater or less degree, and there can it  
wants be no great error in considering the disease as  
all times arising from or strongly tending to such a state.  
The view of the pathology of the disease is born out by  
a consideration of its remote causes, of its symptoms,  
and of the success of a treatment similar to that which  
is adopted in other inflammatory diseases.

Diagnosis clearly points out the pathology of the disease,  
for ulceration and mortification are here caused, not  
as in the inflammations of other parts. The principal seat  
of disease is always in the same membrane of the large  
intestines, for morbid appearances for the most part  
are confined to that part of the disease, or at least  
they extend in proportion to what the disease is confined to.

# Dysentery

This disease consists in an inflammation of the mucous membrane of the intestines; but according to some authors, it would probably be going too far to say, that in mild cases of the disease there is always inflammatory action of the vessels of the mucous membrane of the intestines, yet in the majority of cases this certainly happens, if not in every case, as I am fully convinced it does, in a greater or less degree, and there can at all events be no great error in considering the disease, as at all times arising from, or strongly tending to such a state. This view of the pathology of the disease is borne out by a consideration of its remote causes, of its symptoms, and of the success of a treatment similar to that which is adapted in other inflammatory diseases.

Digestion clearly points out the pathology of the disease, for ulceration and mortification are here commonly met with, as in the inflammations of other parts. The principal seat of disease in dysentery is the inner membrane of the large intestines, for morbid appearances for the most part present themselves in that part of the alimentary canal, though not unfrequently we meet with them in every part of

the alimentary canal. Dysentery is peculiarly a disease of warm climates and seasons: between the tropics it often rages with a degree of violence, of which no adequate idea can be formed from instances of the complaint witnessed in this country. There are three remote causes of this disease, the first being heat, which is the most common and principal one, the second is Marsh Miasma, and the third are certain articles of diet, of which last, putrid meat is the most common; and therefore the disease must require a various treatment; being produced by three different causes. When it is produced by heat or articles of diet, it is accompanied with but little fever, but when it arises from marsh effluvia, the fever is considerable, and it assumes the remittent form. Authors have mentioned a variety of exciting causes, the most frequent of which are, obstructed perspiration from cold, vicissitudes of atmospheric temperature, a cold and moist autumn succeeding a warm and dry summer is peculiarly favourable to the production of dysentery; it is doubtful whether paludal effluvia are of themselves capable of exciting this disease; but their influence in modifying its general character, is frequently very evident in hot and marshy situations, where

It often happens that a person of business of means  
as a subject to see to be done for his business  
the business interests in the country. There are  
these three cases of the business in the country  
and which is the only reason and which is the  
the second is the business and the third is  
business interests of the country and the fourth is  
in the first business and the second the business  
business a business interest being the only  
different cases. When it is business in the  
case of this it is a business interest but the  
but when it is a business interest it is  
business interest it is a business interest. When  
business interest a case of a business interest  
of which are the business interests in the  
business interest a case and the business interest  
a case and the business interest is a business interest  
business interest it is a business interest and the  
business interest a case of a business interest  
business interest a case of a business interest  
business interest a case of a business interest

the disease generally exhibits a mixed character, partaking both of the nature of bilious remitting fever and of pure dysentery. In localities of this kind, it is not uncommon to find intermitting fever and dysenteric symptoms succeed each other in alternation. Dysentery seems indeed very often to be the production of the united influence of marsh-miasma and atmospheric vicissitudes; and hence perhaps, the almost universal presence of torpor of the hepatic and cutaneous functions in this disease. The atmospheric temperature which is necessary to the production of Miasmata, is sufficient also to excite the cutaneous exhalents to inordinate action; whilst both the heat and the Miasmata tend, at the same time, to encrease the biliary secretion. If in this state of predisposition, a sudden reduction in the temperature of the air occurs; or if the body be exposed to the chilling effects of a humid and cool night air, the exhalents of the surface will be rendered torpid, the blood will recede from the external to the internal vessels, and the liver, in common with the other internal organs, becoming engorged with blood, will not only become further disturbed in its functions, but contribute directly to congestion in the portal vessels, and consequently to the rise of intestinal inflammation; and in this state of the disease the liver is always

more or less affected with congestion, and frequently a total suspension of its secretory action. The night dews of hot and marshy countries are therefore particularly to be avoided; but excessive fatigue and long exposure to the direct rays of the sun appear in most cases to have brought it on. Some stress has been laid upon irregularity of diet, (such as eating a bundantly of ripe fruits), as tending to dysentery; but I believe it will not often be produced by such a cause; but eating largely of ~~putrid~~ animal substance, which is putrid, will frequently produce it; cold water drunk in large quantities, and bathing in very cold water when the whole system is raised to a high temperature often excite the disease. This disease formerly was thought to be of a contagious nature, and perhaps it is so when it occurs in crowded camps, and on board of slave-ships, but it never is propagated, by contagion in a well ventilated atmosphere, as has been clearly proven; by injecting the bloody discharges into the rectum of a healthy person, without producing the disease. Dysentery likewise always leaves a predisposition in the system, which is in opposition to the laws of contagion. When persons have lived on salt provision for some time, and then suddenly change it for fresh meat they will have diarrhoea

and very often dysentery. It is sometimes symptomatic of typhus fever; this disease appears in our climate of every grade, and sometimes alternates with others, frequently with ophthalmia, and persons having this latter generally are not subject to the intestinal affection: Africans are more subject to this disease than whites, and in them it is much more difficult to cure. Old women are peculiarly subject to dysentery, which is more fatal among them than any others, and among children next; persons when convalescent from this disease, are peculiarly liable to attacks of Rheumatism: It is sometimes mistaken for hemorrhoids, but in this latter disease, the blood is discharged without mucus, or if mucus be discharged, it is without tenesmus: the blood, also in hemorrhoids is first discharged, and then the feces, whereas in dysentery the feces is first discharged, then the blood and mucus, and griping always attends the evacuations, followed by tenesmus. There are cases of dysentery recorded, in which the intestines have been ulcerated and pus has been discharged instead of mucus, which state almost always indicates a scrofulous habit.

The symptoms of dysentery, are griping pains in the bowels, and a frequent desire to go to stool, the evacuations are small, attended with griping and followed by

The following is a list of the names of the persons who have been appointed to the various offices of the Board of Education for the year 1880-1881. The names are given in the order in which they were appointed, and are followed by the names of the persons who have been appointed to the various offices of the Board of Education for the year 1880-1881. The names are given in the order in which they were appointed, and are followed by the names of the persons who have been appointed to the various offices of the Board of Education for the year 1880-1881.

tenesmus, and a discharge of Mucus mixed with blood, without any admixture of natural faeces: preceding the attack, the bowels are slow and there is much flatulence, there is a loss of appetite, the tongue is not often changed, and the greater the hemorrhage, the less pain attends generally. Patients generally complain of a hard in the intestines, which they endeavour to throw off by violent efforts of straining, and though they feel them to be ineffectual, yet they are unable to resist them. Small lumps called scybala are sometimes passed, but their appearance are not uniform, nor of any particular importance.

This state of disease in the alimentary canal is always accompanied by fever: and in many cases of a highly inflammatory character. The pulse is very frequent, the mouth and fauces dry and clammy. The tongue is coated with a yellow fur at its posterior parts, when the disease assumes the remittent type, or has for its origin the combination powers of marsh-miasma and heat. In severe cases the stomach becomes very irritable, the mildest fluids being rejected, while an unceasing thirst prevails; or that state of sympathetic irritation in the whole tract of the alimentary canal takes place, by which tormina and tenesmus immediately succeed the ~~prostration~~

swallowing of the blindest liquids. The nervous system suffers also severely in some cases. Dysenteric purging appears to weaken the body very much by its irritating effects on the intestines, which is communicated to the stomach, brain, and the whole nervous system; and in very bad cases, hiccup, cramps of the gastrocnemii, and strangury occur; and great exhaustion of power is evinced in the staggering, or quivering, and even syncope, which takes place when the patient is brought into the erect posture.

The typhous form of this disease is attended with all the symptoms of common typhus, such as fainting, stupor, heaviness, ghastly expression, and calm delirium; watchfulness and headache are often the first symptoms; more decided marks of debility appear; the voice becomes weak, the tongue and teeth brown or black; excessively large or very small stools with great pain or none at all in the bowels; the pulse low, threadlike, and intermitting, with other symptoms of typhus fever, as picking of the bed-clothes, cold extremities, hippocratic face and so forth, successively and close the scene.

The duration of this disease is subject to great variety.

Acute dysentery of hot climates often proves fatal in a few days; but in a practical point of view, it is more important

The history of the world is a long and varied one, and it is not possible to do justice to it in a few lines. It is a story of the struggles of the human race for freedom, for knowledge, and for happiness. It is a story of the triumphs of the brave and the just, and of the failures of the weak and the wicked. It is a story of the progress of civilization, and of the growth of the human mind. It is a story of the love of God, and of the love of our fellow-men. It is a story of the hope of a better world, and of the faith in a just God. It is a story of the life of the human race, and of the life of the human soul. It is a story of the life of the world, and of the life of the universe. It is a story of the life of the human race, and of the life of the human soul. It is a story of the life of the world, and of the life of the universe.

to bear in mind the disposition of the disease to assume a chronic form.

Post mortem appearances. — The true pathological character of dysentery was not well understood, until within the last twenty years. Richter was of opinion that dysentery is a rheumatic or catarrhal affection of the intestinal tube. This opinion was indeed, formerly entertained by many pathologists, such as Stoll, Vogel, and others. Some Authors allege the cause of dysentery consists in a vitiated state of the fluids, which stagnate in the alimentary canal; i.e. the bile or the intestinal mucus and the pancreatic juice. Inflammation of the mucous membrane, say they, is not primary in this affection, but secondary, the result of the irritating action of these fluids on the internal membrane of the intestines. Dr. Cullen considered the proximate cause of the disease to be a preternatural constriction of the colon, occasioning those spasmodic efforts which are felt in severe griping, and which efforts, propagated downwards to the rectum occasion the frequent mucous stools and tenesmus. It does not appear that he suspected the existence of mucous inflammation as the essential pathological condition of this affection. Later inquiries have shown, however, that an inflamed state of the mucous membrane of the large intestines is invariably present to a

greater or less degree in this disease. In ~~some~~ some instances inflammation and its consequences are nowhere but in the Colon and rectum; but frequently more or less phlogosis occupies the whole extent of the intestinal tract from the duodenum to the rectum; But even when this is the case, the signs of inflammation and its effects are always most conspicuous in the large intestines. When dysentery terminates in the early or inflammatory stage, fatally, dissection exhibits the inner membrane of the great intestines thickened and formed into small irregular tubercles of a white or yellow appearance, with thickening of the peritoneal and muscular coats. In some instances patches of the membrane have been seen in a state of high inflammation; not unfrequently it is found abraded or extensively ulcerated.

This appearance has been seen to extend to the small intestines. In tropical dysenteries the Colon has sometimes been found decidedly in a state of mortification; and feces have even escaped through the mortified gut into the cavity of the abdomen. With these, which are the true dysenteric appearances, marks of peritoneal inflammation are not unfrequently united. In the bilious form of this disease the liver is sometimes found much enlarged and its whole structure apparently destroyed.

Treatment. The treatment of dysentery is to be regulated by a consideration first of the tendency to inflammation which exists in

attracted my attention, and I was  
much interested in the results  
obtained. It was indeed a  
very interesting and instructive  
study, and I was glad to  
find that the results were  
very similar to those  
obtained in the case of  
the other two cases. I  
was particularly interested  
in the results obtained  
in the case of the  
third case, and I was  
glad to find that the  
results were very similar  
to those obtained in the  
other two cases. I was  
particularly interested  
in the results obtained  
in the case of the  
third case, and I was  
glad to find that the  
results were very similar  
to those obtained in the  
other two cases.

The mucous membrane of the intestines; secondly, of that apparently spasmodic contraction of the muscular fibres in contact with the diseased membrane, by which the feces are retained; and lastly, of that morbid increase of irritability in the whole alimentary canal, which prevails in this as well as other affections of its mucous membrane. If the pain be constant and severe, and the pulse strong, or crag, blood should be taken from the arm, particularly in a case which comes early under treatment. When it is inflammatory, and of the bilious remitting type, it can be cured by the use of the lancet, succeeded by large doses of Calomel. When the disease comes on with nausea and vomiting, with constricted skin, the use of emetics together with the warm bath and friction, will often cut it short. The employment of purgatives constitutes the most important part of the cure of dysentery. They must be steadily persisted in until fecal evacuation have been produced, and that sensation of load in the bowels completely removed, which leads to the effort of straining. Then, and not until then may the practitioner desist from the liberal use of his cathartics. Almost every kind of purgative medicine has been tried, and at different times recommended. Provided a due effect be produced, it does not appear to be of much consequence which of them is selected; but the mild and liquid forms are generally to be preferred. When the disease arises

from heat or animal matters, it is not of a remittent character and in this form, purgatives, tonics or opiates may alleviate the symptoms, but to cure the disease the cause must be removed. No purgative except calomel will cure that species arising from Marsh effluvia; but in the other varieties it is not more valuable than other mild purgatives as salivation has little or no effect. When the pulse is not very frequent, but the skin constricted and dry, the disease may be removed by a slight salivation. It is a great mistake to use Opium in the first stage of dysentery, as nothing is more apt to kill the patient than the constipation thus produced; it has even been known to produce suppuration of the liver. A large dose of Calomel succeeded by a dose of Oil, will always remove the tenesmus; Calomel has this advantage, it will very often remain on the stomach, when no other medicine will; so soon as it comes in contact with the stomach, it causes a secretion to be poured out, and becoming involved in it, does not irritate. In all cases where purgatives are required calomel is perhaps as good as any other; a pill of six or ten grains of calomel, followed immediately by an ounce of the sulphate of magnesia, will commonly be found to answer well, and in some cases the Ol. Ricini may be preferable: if the stomach should reject these medicines, some other form of cathartic is to be chosen.

In dysentery from heat or articles of diet Tartarised Antimony in combination with some neutral salt, makes a good prescription; given in such proportions as to produce both emetic and cathartic effects. There have been a variety of cathartic medicines recommended in this disease; among which are the extract. Colocy. Compos. Sclap, Rheubarb, and even staterium: if they have any peculiar virtues in mastering this disease, it is more than I know I am rather inclined to think they are inadmissible; at all ~~events~~ events, they are, in a highly inflammatory and remittent state; there large doses of Calomel and Alum. Picini are our purgatives. In the treatment of this disease astringents, were formerly much employed. At present however, their use in the early stages of this disease are very justly considered as highly pernicious. Cullen was one of the first who spoke decidedly against their employment in this complaint. Although his objections to their use are unquestionably correct, they were not predicated upon just views concerning the nature of dysentery. He supposed that this disease depends on an increased constriction of a considerable portion of the alimentary canal; and concluded, therefore that astringents must do harm by increasing still more this constricted state of the bowels. The pathology of the disease is, however, better understood at present, it being well established that it is essentially connected with a phlogistic state of the intestinal canal as well

as of the general system. It is on this account that astringents act perniciously in the early stages of the disease. They not only tend to increase the general inflammatory excitement of the system, but their direct action upon the tender and irritated surface of the bowels, is calculated to do much mischief, by increasing the local intestinal inflammation. They are further injurious by confining the vitiated and irritating contents of the bowels. After the inflammatory symptoms have been subdued, and proper evacuations made from the bowels, the employment of mild astringents may, sometimes be resorted to with benefit; In such cases small doses of Rhubarb are among the best astringents. Demulcents are also serviceable, and the best is a decoction of the slippery Elm bark and Gum Arabic combined with Opium. When the inflammation is removed, the intestines are left in a weakened state, requiring the alimentaria to be very carefully managed; and sometimes Opium must be given to remove the remaining irritability of the canal. In low typhus state of dysentery, sometimes prevailing in hospitals and jails, the remedies must be refused and in their effects, or the patient is lost. It must be treated by Opium, wine, bark, volatile alkali, and the warm bath. When patients are convalescent, the bowels may be suffered to remain in a constipated state for four or five days with much inconvenience. The Pulv. Ipecac. compos. either in the dose of ten or fifteen

The present system of management of the  
estate for the term and estate of the  
land is not a subject of a very  
importance. They are the subjects of  
our ordinary conduct of the house. After the  
petition has been taken up and the

grains at bed time, or of six grains every six hours, is well adapted to dysentery when the inflammatory symptoms have been subdued, it promotes perspiration, a proper attention to which is very requisite during the whole course of the complaint. The effect of this medicine will be materially aided by the warm bath. The tincture of Kino combined with toasted Rheubarb is an excellent astringent in this disease, blisters are sometimes serviceable. Chronic dysentery is the sequel of the acute stage, it is sometimes connected with structural derangement, particularly ulceration of the mucous membrane of the Colon, and when this is extensively ulcerated, extreme weakness and emaciation follow, and the patient is at length worn out by the incessant discharge which is kept up. The patient will sometimes linger a long time under circumstances apparently hopeless in such a state, the slightest irregularity of diet or regimen aggravates the symptoms. Ulceration of the intestines has been supposed to heal with difficulty under all circumstances, but it is obvious that the healing process will go on most favourably, when a light, unirritating, and easily digested food is taken. A gentle action should be kept up also in the bowels, so as to prevent accumulation and distension. Hence we may see the propriety of directing an occasional dose of Rheubarb and Calomel, as R<sup>o</sup> Sub. Mur. Hydrar. gr. v. Rhei

Pulv. gr. iiii. m. ℥. Pulv. - or a dose of castor oil when there is any considerable degree of griping pain. Benefit has been derived, in many cases of chronic dysentery attended with ulceration, from the exhibition of a decoction of bark, myrrh, the aromatic confection, balsam of Capaiba, and other stimulant and tonic drugs, as, R. Bal. Capaib. gr. ℥ss. Vitell. Ovi, q. sup. Ag. cinnaur. aq. distillat. āā ℥ss. Stb. lavand. Comp. ℥j. Syrup. ℥i. m. S. haust. ter die sumenda.

When the evacuations are copious, but unattended with pain, and probably kept up by an irritable state of the membrane, astringents, absorbents, and opiates may be required; but in every case their effects are to be watched, and omitted altogether, if they bring on tormina. A mixture composed of chalk ℥j. Oil of pepper mint gr. i. tinct. Opii ℥i. Mucil. G. Arab. ℥viii. take half ounce of this every six hours. Lime water taken freely has an excellent effect, particularly when there is nausea with acidity. The sulphate of Copper in the dose of two grains twice or thrice a day, has been found a useful astringent in chronic dysentery. It not infrequently happens that the patient gradually recovers his strength, appetite, and flesh, during a moderate state of diarrhoea. In some cases it is found, that small doses of Calomel in combination with opiac. contribute to an improved appearance, of the secretions

of the intestines and certainly is a very valuable medicine.

The complication of dysentery with chronic hepatitis, which is occasionally met with, will be an additional motive, for the exhibition of Mercurial alteratives; such are the principles upon which the treatment of chronic dysentery is to be conducted.

They should be well understood, because an injudicious practice may do much harm, though the best regulated may prove ineffectual.

## De Colico dolore.

Quemadmodum luxuriaque elegantia affecta morbos nobis inserunt, sic progressa et continua cultura Medicinae sufficit nobis vires impedire illorum res.

Colicus dolor, ut morbus frequenter occurrens est, uniusque quem ars Medicinalis jam dudum triumphavit, facietur materia conamissis sequentis. Is definitur cruciamentum in ventre comitatum pertinentibus ad Umbilicum terminibusque contractione spastica musculorum abdominis et pertinaci alvi astrictione; non solumque quaecumque in stomacho capitea rejiciuntur; sed etiam in magnis intestinis. Nonnunquam astrictio relaxatioque intestinorum invertuntur

atque actio eorum tam perturbatur ut una pars intestini contracti coacta est in alteram minus contractam: Quod cum ita sit, vocatur Intus susceptio. Cum prorsus motus intestinorum invertitur morbus, vocatus, est Fluxus.

### Causae:

Causae remotae sunt multitudine. Sed quae saepissime obveniunt, tantum numerabo.

Haec sunt videlicet: Certa coactio organorum pepticorum, ac secretionum Hepaticarum, cibi diversae varietates, focum retentionis, exinanitionis repressio consuetae, ac etiam quaedam res metallicae in ventriculo receptae.

Idemque articularis morbi transitivi ab extremis attributus est et creditum.

est intestina esse subjecta Rheumatismo.  
Sed quaecumque causa remota huiusce  
morbi sint, probabiliter proxima est  
eadem in perpetuum, canalis in=  
testinorum motus abnormis.

Ut discernamus Colicum dolorem  
Enteriti, necesse est remenisci priorem  
pyrexia saepe expertum, et praetera  
alteram diagnosticam indicem  
esse, cruciamentum pressu augeri  
in Enterite, cum Colicum dolorem  
ab eodem aliquanto mitigari.

Sunt in Colico dolore intestina  
subjecta phlegmonae ac quum id  
evenit acerbantur indicia omnia.

### Remedia.

Haec propensio phlegmonae prae=  
scribenda est sectione venae. In primis  
exta movenda medicamentum cathe=  
articum adhibiendo.

Sed in nonnullis statibus rerum

et in istis de rebus  
et quomodo causa  
habetur in re

Jalapae Radix commendata fuit  
quoniam stomacho minus ing-  
rata quam cathartorum fort-  
~~ium~~ maxima pars.

Remedium utile et idoneum  
est Oleum Ricini; sed cum non  
sustineant multi patientes.

Saepe aeger inflatione ventris tur-  
batur, ex qua liberetur pro tempo-  
re Aromatibusque stimulis. Posteriora  
darentur in portionibus minutis.  
Ubi peritus purgatus fuit angis-  
portus intestinorum Opium  
adhiberetur si haud ex peris dol-  
oris aegrotus.

Epispasticis Emplastr applicatio  
invenietur utilis spasmos mus-  
culorum abdominisque intestino-  
rum leniendo.

Doct. Johannes Eberle inquit, "Et Submuriæ  
Hydrargyri et Opium dato essent  
in conjunctione commode, ante conatus,  
purgare primas vias faciendatur;  
ac effectus Submuriæ Hydrargyri sus-  
tineretur ab paucorum granorum  
constante administratione in horas  
tres vel quatuor."

Communiter fomenta callida baln-  
eumque tepidum aegro ministrabant  
operis. Per syringam injicere violenter  
aquam tepidam commendatum  
fuit a DeHaen, pro re spasmos discut-  
iendi. Aqua fontana, cum fusca prore-  
nata per corporem, stimularit intes-  
tinos prompte, posteaquam moeli  
alii deficient. Nece est per plures  
dies, exhibendo medicamenta aper-  
ientia mitia oportune, obsistere  
alvi suppressionem.

## Methodus preventionis.

Attendere scrupulose conservandae salutis est omnium, sed maxime illorum, qui colico dolore subjecti sunt. Unus impetus facit hujusce morbi secundo obnoxiosem. Itaque ad hunc propensio, si potest fieri, reprimetur. Efficiatur hoc studiose attendendo victus regimen et excitantes omnes causas vitando. Exercitatio magni momenti. Haec temperata esse atque victa nonnunquam laboris productioni. Deambulatio omnium diversorum exercitiorum sub dio anteferenda; deinde Equitatio. Dieta levisque nutrens que constaret alimenti concoctu facillime. Cum hoc proposito praeponendum est alimentum animale, vegetabili; posteriore patienti magis idoneum fermentum acidum.

Interanea diurno usu a periculis  
nitium patefacta fuissent. Horum  
laudatus fuit magnus numerus  
iterum atque iterum: Ex his nomin-  
entur Gummi Aloe, Tinctura Aloes,  
Radix Rhei, Tinctura composita  
Rhei, Podophyllum peltatum, Oxidum  
Hydrargyri, et caetera.

Supra dictorum Oxidi Hydrargyri  
ac Radicis Rhei conjunctio indicationem  
melius peragit quam aliam quodpiam.  
Aloes pilulamque tinctura saepe uter-  
bantur eventus bono, et interdum  
decuratur utiliter. Sed hoc remedium  
in omnes patientes Hemorrhoidales  
affectiones prohibitum fuisset: Sicut  
est primum ficum exaggerare necnon  
persaepe excitare quod non ante  
extitit.

Persaepe stipatio regula declinatione

# An Inaugural Dissertation on Nitrous Oxide Gas.

In searching through the vast range of Medical science for a suitable subject of a thesis, that which I have chosen, seemed to possess much interest and to promise much advantage in its examination. It was <sup>not</sup> until I had advanced too far to recede, that I found it would require much more time and labour than I could command, to discover and gather any of the fruit which is yet hid in this unexplored field. Many experiments which suggested themselves, could not be executed for want of a suitable apparatus.

I have been therefore obliged to submit a thesis in which there is scarcely any new suggestion or observation. I have consequently principally collected from the

An Improved Digestion

Nitrous Oxide Gas.

On reading through the work of  
of medical science for a number of  
of years, that which I have chosen  
to present to you is much interesting in its  
character. It was <sup>not</sup> until I had  
read it too far to recede, that I  
found it would require more  
time and labor than I could  
command, to discover and  
any of the fruit which is yet  
in this unexplored field. Many  
experiments which I expected  
to be, could not be expected for  
want of a suitable apparatus.  
I have been therefore obliged to  
submit a thesis in which there is  
scarcely any new suggestion or  
observation. I have consequently  
principally collected from the

writings of Sir H Davy, Murray  
and others, materials without which  
I could not have raised a  
sufficient edifice. Gas.

The compounds of oxygen and nitrogen  
form subjects of the greatest interest to the  
enquiring chemist. He perceives one  
combination forming atmospheric air,  
the source and preserver of the life  
of the whole animated world; he sees  
the increased proportion of one of its  
component parts (oxygen), causing this  
mild and almost imperceptible substance  
to be endued with new powers, and exerting  
the highest dominion over both body  
and mind; he beholds another addition  
of this ingredient rendering the compound  
completely unfriendly to life, and a  
fourth extending its controul over the  
hardest substances in nature. Though  
Proteus like in changing its form,  
in ~~all~~ none has it eluded the grasp  
of modern chemistry.

of modern chemistry  
in the more far extended group  
of Proteins like in changing its form  
various substances in nature, these  
forms containing its content over the  
completely inflexible to life, and a  
of this incident rendering the compound  
and must; he holds another solution  
the highest knowledge over both parts  
to be enclosed with hydrogen and oxygen  
mild and almost imperceptible changes  
component parts, oxygen, containing the  
the increased proportion of one of its  
of the inside animal world; the whole  
the water and presence of the elements  
considerable forming atmospheric oxygen  
and mixing element, the presence of  
from subject of the greatest interest to us  
The components of oxygen and nitrogen  
sufficiently simple.

The discovery of nitrous oxide gas, (the most interesting perhaps of these compounds), is one of the numerous obligations which Chemistry owes to the labours of the celebrated Priestley. In conformity with his theory of its formation, he named it Dephlogisticated Nitrous air, and concluded from some indecisive experiments, that it was unfit for respiration. It was farther examined by the associated Dutch chemists, who called it Gaseous Oxide of Azote and apparently confirmed Dr Priestley's conclusion of its being non-respirable. In consequence of the theory of Dr Mitchell of New York, which supposed it to be the principle of contagion, Sir H Davy was induced to examine more minutely its properties and particularly its effects on the animal system. He first obtained it in a state of purity, ascertained that it could be breathed with safety and gave it the more concise appellation of Nitrous Oxide.

nitrous.

Nitrous Oxide cannot be formed by the combination of its constituent parts, but is always procured from the decomposition of Nitrous gas or Nitric acid, by substances which attract oxygen -

Priestley obtained it by exposing nitrous gas to iron filings, moistened with water; the water being decomposed, the hydrogen at the moment of its production, attracts part of the oxygen from the nitrous gas, and reduces it to the state of nitrous oxide.

He also procured it by placing nitrous gas in contact with a humid mixture of iron filings and sulphur, or with the liquid compounds of sulphur with the Alkalis.

Kirwan obtained it by exposing nitrous gas to sulphuretted hydrogen, and the Dutch chemists by subjecting it to the action of chloriate of tin or copper dissolved in ammonia, and by passing it over heated sulphur. In all these cases the changes of the nitrous gas into nitrous oxide, is owing to the partial abstraction of oxygen by the substances to which  
it is

of oxygen by the substance to which  
it is owing to the partial oxidat  
the change of the nitrous gas into nitrous  
was heated up. In all these cases  
and an amount, and the following  
action of chloride of tin or copper  
water chemist by suggesting it to the  
gas to sulphuric acid, and the  
nitrous obtained it by exposing nitrous  
compounds of sulphur with the alkali  
kinds and sulphur, or with the alkali  
in contact with a dilute mixture of nit  
is also observed it by heating nitrous gas  
reduces it to the state of nitrous oxide  
part of the oxygen from the nitrous gas  
at the amount of a proportion of alkali  
water being decomposed, the nitrous  
to now being, instead, with nitrous gas  
greatly obtained it by exposing nitrous gas  
substances which affect oxygen -  
tion of nitrous gas or nitrous acid, by  
is always produced from the decompo-  
combination of its constituent parts, but  
Nitrous oxide cannot be formed by the

it is exposed.

Nitrous oxide is produced too during the solutions of several metals in nitric acid. Priestley observed that it was disengaged during these solutions of tin, zinc and iron, mixed with variable quantities of nitrous gas and nitrogen gas, its production being probably owing to the decomposition of the water of the acid by the metal, the nascent hydrogen of which, presented to the nitrous gas which arises from the decomposition of part of the acid at the same time, partially abstracts its oxygen, and brings it to the state of nitrous oxide. Mr Davy has accordingly remarked, that the metals which when dissolved in a diluted acid, do not decompose water, as mercury, lead and antimony, give out only nitrous gas with portions of nitrogen. Hence also nitrous oxide is produced, as the Dutch chemists remarked, during the solution of iron or zinc in mixed sulphuric and nitric, or muriatic and nitric acids.

Nitrous oxide, when procured by any of these processes, is always rendered impure by small portions of nitrogen and nitrous gases, which cannot be easily removed. The best method of procuring it, for which we are indebted to Berthollet, is by the decomposition of the Citrate of Ammonia. This salt may easily be made by adding to diluted nitric acid, carbonate of ammonia untill all effervescence ceases and evaporating the solution. As this last process proceeds part of the ammonia is driven off, the loss of which must be carefully supplied by the addition, <sup>at intervals</sup> of more of the carbonate, as any excess of acid would materially interfere with the result to be obtained. The salt is different in its appearance and in the quantity of water it contains, according to the degree of heat employed in evaporating the solution. If this be effected at the temperature of  $70^{\circ}$  or  $80^{\circ}$ , it will crystallize in six-sided prisms, terminated by

...nitrogen and nitrous gases, which

by six-sided pyramids. If evaporated at the  $212^{\text{th}}$  degree, the salt will assume a fibrous texture; a heat of  $300^{\circ}$  leaves it in a white compact mass. These varieties are decomposed at different temperatures. The compact, between  $275^{\circ}$  and  $300^{\circ}$  sublimes without decomposition; at  $320^{\circ}$  it becomes fluid and is partly sublimed and partly decomposed; between  $340^{\circ}$  and  $480$  it decomposes with rapidity. The fibrous is not decomposed below  $400^{\circ}$ . Above  $450$  its decomposition takes place. In both cases water and nitrous oxide are the sole products. At higher temperatures other affinities are exerted. At  $600^{\circ}$  the decomposition becomes rapid, a luminous appearance is produced in the retort, and the gases evolved are nitrous gas, nitrous oxide and nitrogen mixed in variable quantities. When the temperature is raised a little higher, as to  $700^{\circ}$  or  $800^{\circ}$ , an explosion takes place and the products are water, nitrous acid, nitrous and nitrogen gases

To procure nitrous oxide gas, then, ~~in~~  
any quantity of nitrate of ammonia,  
either compact or fibrous, (the latter being  
preferred by Mr Davy as sustaining less loss by sub-  
limation before its decomposition commences,) is  
put into a glass retort and is quickly raised to  
the requisite temperature, taking care not to  
exceed  $500^{\circ}$  and in particular not to raise it so  
high as to produce the luminous appearance  
in the retort; this regulation of temperature  
is easily obtained by the heat of an Argand  
lamp. The nitrous oxide and water are dis-  
engaged; the latter is condensed in the neck  
of the retort and the gas is received over water,  
as is it is not immediately much absorbed;  
it is generally turbid from a small portion  
of the salt being volatalized; but this is  
soon dissolved by the water over which the  
gas is received: and when it is for the  
purpose of respiration, it is generally suf-  
fered to remain half an hour in contact with  
water to deposit this as well as a small  
quantity of acid which is generally suspended  
in it. But in order to prevent entirely the  
devel-

to measure, return, order, good, this, -  
any quantity of water of temperature,  
either constant or variable, the latter being  
dependent on the time in which it is  
measured before the temperature is  
not in a state of equilibrium, and it  
the required temperature, taking account of  
specific heat and in particular, not to  
take as a point the maximum expansion  
of the water; the regulation of temperature  
is easily obtained, by the heat of an  
lamp. The water of the hot water  
expands; the latter is contained in the  
of the water and the gas is received, not  
as it is not immediately, and  
it is generally, under a small  
of the water being, but this is  
not affected by the water over  
gas is received, and when it is for  
purpose of expansion, it is generally  
found to remain half an hour at  
water to prevent this as well as a  
quantity of water which is generally  
not, but is now to prevent water, the

development of this acid, (which must arise from an excess of it in the salt,) I would propose the addition of a small piece of carbonate of ammonia, to the nitrate in the retort, which would neutralize the superabundant acid if any were present, and if not, would be volatilized and absorbed by the water through which ~~which~~ the gas passes. It might be necessary to avoid the risk of having carbonic acid gas mixed with the nitrous oxide produced, by permitting the first bubbles of air to escape. As carbonic acid gas is rather lighter than nitrous oxide, we need not apprehend its remaining any time in the retort, even if produced. Care should be taken that the nitrate of ammonia is free from any intermixture of muriate, as this, according to Davy, ~~for~~ causes a formation of oxymuriatic acid. From 100 grains of compact nitrate of ammonia about 85 cubic inches of nitrous oxide gas are obtained. One pound gives 4.25 cubic feet, while one pound of the fibrous salt gives nearly 5 cubic feet or 149 quarts.

The

development of the acid, which must arise  
from an escape of it in the cells, & would  
propose the addition of a small piece of  
carbonate of ammonia, to the water in  
the vessel, which would neutralize the  
superabundant acid of any other process,  
and of nit, would be evaporated, and  
absorbed by the water through which steam  
the gas passes. It might be necessary to vary  
the rate of heating, according to the results  
with the various other processes, to prevent  
the first bubbles of air to escape. As the  
basic acid gas is rather lighter than air, and  
less elastic, the heat not appearing, it  
remains any time in the vessel even  
if produced. Care should be taken that  
the weight of ammonia is five from any  
intermixture of moisture, as this, according  
to Lavoisier, has caused a formation of  
hydrogenetic acid. From 100 grains of  
compact nitrate of ammonia, about 10  
inches of nitrous oxide gas are obtained.  
One pound gives 4.25 cubic feet, while the  
weight of the fibrous salt gives nearly 2 cubic feet.

The theory of the production of this gas by this process, presents a striking instance of a nice adjustment of affinities. Nitric acid is a compound of oxygen and nitrogen; ammonia a compound of hydrogen and nitrogen: the solid salt therefore consists of oxygen, nitrogen and hydrogen; the affinities of which at a moderate temperature are balanced so as to form the binary combinations which constitute the acid and alkali. But when the temperature is considerably elevated, the disposition of these elements to assume the elastic form, subverts these affinities and others are exerted, so as to combine them in different modes and proportions; the hydrogen of the ammonia combines with as much of the oxygen of the acid as saturates it and forms water; and the remaining oxygen of the acid combining with the nitrogen of the acid and the nitrogen of the ammonia, forms nitrous oxide. The proof that this theory is correct, is that none of the simple elements is evolved during

The theory of the formation of the  
fossil, the fossil remains a solid condition  
of a pure substance of crystalline structure  
and is a compound of oxygen and hydrogen  
and is a compound of oxygen and hydrogen  
of oxygen, hydrogen and nitrogen; the  
affinity of carbon at a moderate heat  
hydrogen are retained, as is to form the  
fossil compounds which exist in the  
acid and alkali. But under the influence  
of concentrated sulphuric acid the composition  
of these elements is known for a long  
time, and it is these affinities and other  
are correct, as is to combine them with  
different matter and properties; the  
degree of the ammonia compound is  
more of the oxygen of the acid is not  
water, it and forms water; and the way  
ing oxygen of the acid combining with the  
hydrogen of the acid and the nitrogen  
the ammonia, forms nitrous oxide.  
The proof that this theory is correct, is  
that one of the simple elements is oxygen

during the decomposition; nitrous oxide and water are the only products and the elements of the salt must therefore necessarily have been combined in this manner for their formation. At a higher temperature other forces are exerted. It appears from Davy's experiments, that nitrous oxide is decomposed by the heat of ignition, as by passing it through a red hot glass tube; it is converted into nitrous acid vapour and a gas analogous to atmospheric air or composed of oxygen & nitrogen loosely combined. Hence when the temperature of the nitrate of ammonia is raised near to ignition, nitrous oxide can either not be formed, or if it be, is immediately decomposed and resolved into these or similar products. As nitric acid is also decomposed at a state of high ignition, it is not improbable, that at this temperature water would be resolved into water oxygen and nitrogen.

Nitrous

During the decomposition, nitrogen and water are the only products and the elements of the salt must therefore necessarily have been combined in this manner for their formation. At a higher temperature other forces are exerted, that have been shown by experiments, that nitrogen oxide is decomposed by the heat of ignition, as by passing it through a red hot glass tube; it is converted into nitrous acid vapour and a gas analogous to atmospheric air or composed of oxygen & nitrogen. Lastly, some kinds of these under the temperature of the mixture of ammonium is applied near to ignition, nitrogen oxide can either not be formed, or if it is immediately decomposed and converted into these or similar products. The nitric acid is also decomposed at a state of high ignition. This is not improbable, but at this temperature water would be converted into water oxygen and nitrogen.

Nitrous oxide may be analysed by a process of this kind, by detonating it with hydrogen gas or by exposing it to charcoal at a high temperature. When detonated with hydrogen gas, the products are water and nitrogen gas; the quantity of hydrogen consumed gives the proportion of oxygen derived from the nitrous oxide, and the remaining nitrogen indicates the proportion of it in the nitrous oxide. In a similar manner when exposed to charcoal, the products are carbonic acid and nitrogen, from which the constituent parts may easily be determined. Taking the mean of the most accurate experiments of this kind, Mr Davy determined it to consist of 63.3 nitrogen and 36.7 oxygen, which proportions when reduced to volume give nearly 2 parts of nitrogen to one of ~~hydrogen~~ oxygen.

Nitrous oxide is permanently elastic. Its specific gravity is, according to Davy,  $1\frac{1}{4}$ , atmospheric air being 1000; 100 cubic inches

1014, atmospheric air being 1000; 100 cubic  
ft of specific gravity is, according to  
obtains air is permanent in  
~~the~~ oxygen is

inches weigh 50.1 grains. It is heavier therefore than carbonic acid gas, the specific gravity of this being 1519, or 100 cubic inches weighing 46.7 grains or according to Allen and Pepys 47.26 grains. Its taste is distinctly sweetish which is perceived when it is respired, even by some persons, at the surface of the lungs. Its odour is very faint.

This gas is absorbed by water, the atmospheric air of the water being expelled by it: the water at its mean temperature and atmospheric pressure takes up more than half its bulk, 100 cubic inches absorbing according to Davy 54: on boiling the solution, the gas is given out unchanged. The solution has a sweetish taste and a slight odour, to me very disagreeable, though Davy prefers it to common water: neither it nor the gas changes vegetable colour.

Nitrous oxide gas suffers no diminution of volume nor any change of properties, when mixed with either of the simple gases

... weight 20.1 grains. It is known  
therefore that carbonic acid gas, the  
specific gravity of this being 1.52, is 100  
times more weighing 20.1 grains or ac-  
cording to other authorities 21.0 grains.  
The fact is experimentally ascertained which is  
further confirmed by experiment, even by the  
process of the surface of the lungs. The  
air is very faintly colored by water, the  
color being absorbed by water, the  
atmospheric air of the water being ex-  
posed by it: the water at its surface  
temperature and atmospheric pressure  
takes up more than half its bulk of the water  
under absorbing according to Henry's law: in  
boiling the water, the gas is given out  
undecomposed. The solution has a constant  
limit and weight known, to be nearly  
the same, though Henry's law refers to the  
case when water is heated at not the gas  
changes vegetable colour  
It is known that gas suffers no change  
of volume nor any change of properties  
when mixed with either of the simple

gases. At ignition it detonates with hydrogen gas. It is decomposed ~~at~~ by heat alone, by transmitting the electric spark through it, or by passing it through an ignited earthen tube, it being converted into nitrous acid and oxygen and nitrogen gases.

A property which it possesses in an eminent degree, is that of supporting combustion. A lighted taper burns in it with an enlarged and bright flame, the white inner flame becoming, before its extinction, surrounded with a blue one: phosphorus burns with a dazzling white light, sulphur with a rose coloured flame. The inflammable bodies, however, require to be raised to a higher temperature to burn in nitrous oxide gas, than they do to burn either in oxygen or atmospheric air. If sulphur be burning with a pale blue flame, on introducing it into the gas, it is extinguished; it is only when the temperature has been previously raised, so as to cause it to  
(burn)

... gas. It is decomposed at by heat alone  
by decomposing the electric spark through  
it, or by passing it through an ignited  
eastern tube, it being converted into  
nitrous acid and oxygen and nitrogen  
oxide.  
A property which it possesses in an  
essential degree, is that of supporting  
combustion. A lighted taper burns in  
it with an enlarged and bright flame,  
the white inner flame becoming, before  
it extinguished, surrounded with a blue  
glow. Hydrogen burns with a bagging  
white light, sulphur with a rose color  
flame. The inflammable bodies, however,  
require to be raised to a higher temper-  
ature to burn in nitrogen gas than  
they do in pure oxygen or at-  
mospheric air. Hydrogen the burning  
with a pale blue flame, or colorless  
it into the gas, it is extinguished, it  
is only when the temperature has been  
raised, so as to cause it to

burn with the blue flame and white light, that it continues to burn; phosphorus which burns in atmospheric air at  $100^{\circ}$ , does not burn in nitrous oxide gas but when the temperature is above  $212^{\circ}$ : and charcoal, and the compound inflammables require all of them to be in a state of high ignition for their combustion. During these combustions, a portion of nitrous acid is almost always produced, together with the oxygenation of the combustible body.

Nitrous oxide is capable of forming combinations with the alkalis. They do not ensue when the gas is presented to the alkali either in the dry state or dissolved in water, but only when it is in its nascent state. The following is the process by which Mr Darcy effected this combination. A portion of sulphite of potash, having a quantity of pure potash intimately mixed with it, was exposed over mercury to nitrous gas. The sulphite of potash decomposes the gas by partially

... of water, but the blue flame and white  
light, that it contained to burn; gas  
potassium which burns in a blue flame  
at 100°, does not burn in nitrogen oxide  
gas but when the temperature is above  
212°: and charcoal, and the compound  
inflammable separate all of them to be  
in a state of high ignition for their  
combustion. During these combustions  
a portion of nitrogen acid is almost  
always produced, together with the  
decomposition of the combustible body.  
Nitrogen oxide is capable of forming  
combustions with the alkalis. They  
do not combine when the gas is present  
to the alkali either in the dry state or  
dissolved in water, but only when it  
is in its nascent state. The following is  
the process by which the lamp operates  
in this combustion. A portion of sulphuric  
acid, forming a quantity of pure  
potash, intimately mixed with it, was  
applied over mercury to nitrogen gas. The  
volume of nitrogen decomposed is only

partially attracting its oxygen and thus converts it into nitrous oxide. This in its nascent state is attracted by the excess of potash present; the sulphurous acid by its farther oxygenation, being converted into sulphuric acid, this acid remains united with its portion of potash forming sulphate of potash. This sulphate of potash and the compound of nitrous oxide with potash are in a great measure separated by solution, evaporation and crystallization at a low temperature. The new compound consists, as nearly as Mr Davy could estimate of about 3 parts of alkali and 1 of nitrous oxide by weight. Its taste is caustic; it renders vegetable blues green, and on adding to it nitric, muriatic or even carbonic acid, the nitrous oxide gas is disengaged.

Mr Davy succeeded by a similar process in forming a compound of nitrous oxide and soda; but was unsuc-

partially extracted by boiling and then  
converted into a soluble state. This is  
its natural state in nature and the  
effects of potato, potato, the tubers  
and by its further application, being  
converted into a soluble state, this  
and remains in the state of potato  
of potato forming a soluble state of potato.  
The soluble state of potato and the  
point of nature, state with potato  
are in a great measure inseparable  
nature, composition and quality.  
nature at a low temperature. The  
low compound consists, as a result  
of the long cold estimate of nature  
3 parts of soluble and 1 of insoluble  
by weight. The potato is converted  
nature, vegetable blue green, which  
adding to it water, character is blue  
Carbonic acid, the nature of the  
is dissolved.  
The long succeeded by a number  
process in forming a compound of  
nature, soluble and water; but was

unsuccessful in his attempts to combine it with lime, ammonia and strontites.

Nitrous oxide gas is absorbed by inflammable liquids and in greater quantity than by water. Alcohol at  $32^{\circ}$  absorbs more than its bulk and acquires a sweet taste, but its other physical properties are not altered. The gas is expelled at the temperature of ebullition and likewise by the combination of the impregnated alcohol with water. The absorption by ether and the results of it are similar. The essential oils absorb it in still larger quantity, as do also the fixed oils, and from both it is expelled unaltered by heat.

But by far the most interesting and singular property of this gas, is displayed in its action on the animal system, when respired. It acts as the most powerful stimulant producing a high ~~state~~ of excitement both of body and mind, accompanied with very singular sensations. As before mentioned

mentioned, it had been supposed to be noxious to life. Priestley found that an animal confined in it is soon killed, and the Dutch chemists made similar experiments on birds with the same result, and concluded it to be highly deleterious from a theory they had formed of its agency, that it is incapable of affording oxygen to any substance but hydrogen, and that therefore it is unfit for abstracting the carbon of the blood, the principal object performed by the air in respiration. Mr Davy first observed its singular powers, his attention having been directed to its action, as before observed, in consequence of the theory of Dr Mitchell, who attempted to prove, from some phenomena connected with contagious diseases, that dephlogisticated nitrous gas, which he called oxide of septon, was the principle of contagion, and capable of producing the most terrible effects when respired by animals in the minutest quantities or even when applied to the (skin)

skin or muscular fibre. The following is the description of the effects he experienced from it when he breathed it pure and in sufficient quantity.

" Having previously closed my nostrils and exhausted my lungs, I breathed four quarts of nitrous oxide from and into a silk bag. The first feelings were similar to those produced in the last experiment; but in less than half a minute, the respiration being continued, they diminished gradually, and were succeeded by a sensation analogous to gentle pressure on all the muscles, attended by a highly pleasurable thrilling, particularly in the chest and the extremities. The objects around me became dazzling, and my hearing more acute. Towards the last inspirations, the thrilling increased, the sense of muscular power became greater, and at last an irresistible propensity to action was indulged in; I recollect but indistinctly what followed; I know that my motions were various and violent. These

followed; I know that my audience  
in; I recollect but indistinctly what  
while preparing to act in (was indeed)  
became greater, and at last an exertion  
increased, the sense of muscular power  
towards the last inspiration, the feeling  
dying, and my hearing more acute,  
terminated. The object around me became  
particularly in the chest and the  
held by a highly pleasurable thrilling,  
part to perform on all the muscles, when  
succeeded by a sensation analogous to  
they diminished gradually, and were  
minutes, the respiration being continued,  
experiment, but in less than half a  
similar to those produced in the last  
into a wild dog. The first fatigue was  
of one quart of water given from one  
half and a quarter of an hour, I recollect  
11  
Having previously closed my eyes  
it gave me a sufficient quantity.  
perceived from it when he reached  
is the description of the effects he ex-  
then or muscular fibres. The following

"These effects soon ceased after res-  
piration. In ten minutes I had recovered  
my natural state of mind. The thrilling  
in the extremities continued longer than  
the other sensations. This experiment  
was made in the morning; no languor  
or exhaustion was consequent, my feelings  
throughout the day were as usual, and  
I passed the night in undisturbed  
repose".

At another time, after having taken  
it in smaller quantities, he breathed 20 quarts  
of pure nitrous oxide, of which he thus  
describes the effects. "A thrilling, extending  
from the chest to the extremities was almost  
immediately produced. I felt a sense of  
tangible extension highly pleasurable  
in every limb; my visible were dazzling  
and apparently magnified; I heard  
distinctly every sound in the room  
and was perfectly aware of my situation.  
By degrees as the pleasurable sensations  
increased, I lost all connection with external  
things; trains of visible vivid images rapidly  
passed through my mind and were con-  
nected

These effects were caused after the  
rotation. In the minutes I had recovered  
my natural state of mind. The following  
in the experiments continued longer than  
the other rotations. This experiment  
was made in the morning; no fatigue  
or excitement was consequent, and fatigue  
throughout the day were as usual, and  
I passed the night in usual tranquility.  
"I passed the night in usual tranquility."  
At another time after having taken  
in smaller quantities, he breathed 20 quarts  
of pure nitrous oxide of which he then  
described the effects. "A thrilling expanding  
from the chest to the extremities, was admitted  
immediately produced. I felt a sense of  
enlarged extension rapidly perceived  
in every limb; my vessels were throbbing  
and apparently enlarged; I learned  
distinctly every sound in the system  
but was perfectly aware of my situation  
I passed as the patients were always  
increased, I got all connected with system  
and; terms of oxide were always regular

ned with words in such a manner  
as to produce perceptions perfectly  
novel. I existed in a world of newly  
connected and newly modified ideas.  
I theorised; I imagined that I made  
discoveries. When I was awakened from  
this semi-dilirious trance by Dr Kinglake,  
who took the bag from my mouth, indig-  
nation and pride were the first feelings  
produced by the sight of the persons about  
me. My emotions were enthusiastic and  
sublime; and for a minute, I walked  
round the room perfectly regardless of  
what was said to me. As I recovered  
my former state of mind, I felt an in-  
clination to communicate I had made  
during the experiments, I endeavoured  
to recall the ideas, they were feeble and  
indistinct; one collection of terms, however  
presented itself: and with the most intense  
belief and prophetic manner, I exclaimed  
to Dr Kinglake, Nothing exists but thoughts!  
The universe is composed of impressions  
ideas, pleasures, and pains,

... the universe in comparison of my position  
to the things that, clothing events out thought  
of and further manner, I exclaimed  
essential itself; and with the most intense  
interest; one collection of terms, however  
recall the ideas, they were fresh and  
during the experiment, I discovered  
to communicate I had made  
my former state of mind, I felt an in-  
dication was sent to me. I discovered  
about the room perfectly regardless of  
medicine; and for a minute, I walked  
me. My emotions were extraordinary  
possessed by the sight of the person about  
nature and possible were the first feelings,  
who took the bag from my mouth, and  
the same distance, hence by the things that  
discovered. When I was awakened from  
I discovered; I imagined that I made  
lowered and nearly modified ideas.  
and I expected in a world of things  
to produce perceptions perfectly  
acted with words in such a manner

Southey, the poet, upon breathing this gas exclaimed, "The air of the highest possible of all heavens, must consist of this gas."

Nitrous oxide, when respired produces different effects according to the peculiarities of temperament or situation of the persons, subjected to its influence; in some it produces very unpleasant sensations, especially in hysterical constitutions, while in others no effect is perceptible. But in the generality of cases, when breathed in the proper dose of from 4 to 9 quarts it produces a variety of pleasurable sensations in different persons, which are scarcely describable. I shall only mention a few of those symptoms which ~~often~~ occur most frequently. In about half a minute from the first inhalation, the pulse becomes fuller and exceedingly quick, the pupil is much dilated and a fullness of the head, as if it were swelling to an immense size is often felt, especially on breathing the gas for the first time

Research in breathing the gas for the first  
to an immense size in other parts, in-  
step of the head, as if it were swelling  
to a point in which dilated over a full-  
size becomes fuller and expanding greatly,  
minute from the first inhalation. It  
occurs most frequently, in about half a  
-few of these symptoms which ~~follow~~  
rarely described. I shall only mention  
how often in different persons, which are  
it produces a variety of phenomena  
- the proper dose of from 4 to 9 grains  
But in the general case, when used  
which in other an effect is perceptible  
later, especially in hysterical conditions  
in some it produces very unpleasant ex-  
of the person, subjected to its influence  
peculiarities of temperament or situation  
ness different effects according to the  
- persons of one when required for

time. A feeling of lightness ensues in many instances, in which the slightest exertion seems sufficient to ~~raise the~~ ~~body~~ into the air. A thrilling is felt in the extremities and even throughout the whole body. Ideas succeed each other with great rapidity and an irresistible propensity to action gives occasion to the most violent exertions. These effects suddenly cease in two or three minutes leaving the person in nearly their natural state of mind and body though often in the more susceptible temperaments, a degree of exhilaration is perceived for several hours. — The effect is much greater when the gas is breathed pure, than when diluted with atmospheric air or hydrogen gas. Mr Davy has been able to respire it for  $4\frac{1}{2}$  minutes and some individuals for 5 minutes. The larger warm blooded animals confined in it, die generally in five or six minutes, the smaller in one or two minutes. It previously produces  
in them

in them, (at least frequently) exciting effects; they become convulsed and soon insensible; and in some the insensibility is induced <sup>at</sup> first. They live in general twice as long as in hydrogen gas or under water; the lungs are inflamed the blood of a purple red colour and the muscles irritable. Amphibious animals are effected in a similar manner but live rather longer. Fishes put into water impregnated with it are soon affected and die in fifteen or twenty minutes: - and winged insects soon become motionless in the gas and are killed in no long time.

It is not the least of the singularities of ~~this gas~~ in the operation of this agent that the excitement it produces is not followed by languor or debility. No law with regard to the living system, seems more general and invariable, than that when increased action is excited by any agent, it is always followed by a proportionable degree of lassitude and debility.

(Nitrous)

in the first part of the experiment  
effect; but because generalization  
is not a simple process, and in some  
cases it is not a simple process  
the blood of a purple red colour and  
the muscles, especially the  
muscles are affected in a similar manner  
but not in the same degree. This is  
water evaporated with it and soon after  
the end die in fifteen or twenty minutes  
- and mixed insects look brown  
insects in the jar and are killed  
in a few days.  
It is not the heat of the sun which  
is the cause in the operation of this agent  
but the excitement it produces in the  
organisms by changing or stabilizing the law  
with regard to the living organisms  
more general and universal than that  
which increased action is excited by  
agent, it is always followed by a pro-  
portional degree of resistance and stability.

Nitrous oxide furnishes a striking exception to this. Notwithstanding, the high exhilaration it produces, this is not followed by any marked exhaustion but the system is reduced merely to that state which existed previous to the experiment, even leaving for a time alertness and pleasant feelings. In order to put this to a severe test and to guard against the deception of a single trial, I breathed in quick succession 6 doses of 5 quarts each, without perceiving afterwards the least languor or debility but on the contrary the exhilaration remained for several hours. It must be remarked however, that, though the sensations and excitement were similar and equal in the last doses, to those produced by the first, there was considerable variation in the pulse.

At the beginning of the experiment, it beat 63 times in a minute, but increased to 130 by the first dose: it very soon subsided again to 63 and each succeeding dose produced a lessened increase to its rapidity.

rapidity, the last only raising it to 76. - Sir H Davy, by placing himself in an air-tight box, breathed it mixed with atmospheric air, for an hour and a quarter, and immediately after res-pired 20 quarts in the common manner. The excitement was extreme, <sup>for a short time</sup> but the exhilaration continued two days. He also breathed it daily for two months, without experiencing at any time, the least depression. The gas continued to produce the same excitement in his feelings, but his pulse became gradually almost insensible to its influence. I was not aware that he had remarked this when I made <sup>a</sup> similar observation.

It was probably this gas that produced the exhilaration mentioned by Dr Rush (on the mind. 230) on the authority of a respectable dyer of Philadelphia. He informed <sup>the doctor</sup> that he had often observed the men that were employed in dying scarlet, to be uncommonly cheerful and sometimes to sing  
from

sing from morning till night. The odour which produces this is derived from a mixture of cochineal with a solution of tin in the nitric acid". We know that nitrous oxide is disengaged during the solution of tin in nitric acid; we are therefore more disposed to think the effect was produced by this agent, rather than by any "odour", to which Dr Rush has attributed it.

The great power of this gas and the difference between it and all other stimulants hitherto discovered, in not producing indirect debility, seem at once to mark it as a valuable addition to the Materia Medica. Its first discovery, philanthropists hailed with enthusiasm its introduction into medicine, and saw in prospect, a whole army of diseases retreating at its approach. Physicians finding these extravagant hopes not immediately realized, have deserted them altogether.

Believing

... from measuring the weight. The

Believing, myself, that at some future period, nitrous oxide gas will probably hold equal rank in the materia medica, with even mercury and opium, I shall venture to suggest some few diseases in which it might, even with our present imperfect knowledge of its effects, be productive of much advantage.

Before doing this, however, it will be proper to make some remarks on the *modus operandi* of this powerful agent. Some philosophers have supposed its action to be immediately on the nerves at the surface of the lungs, exciting the brain and whole system by sympathy, in the same manner as alcohol is generally supposed to produce its effect when applied to the stomach. Another and the more probable supposition is, that it is absorbed by the blood communicating to this a specific highly exciting power over the nervous system. The following considerations support this doctrine.

W

...the nervous system, the following  
...the brain communicating to this a  
...that it is associated by  
...the nerve and the nerve fibers  
...produce an effect when applied to the  
...in generally applied to

...the action of the brain  
...to make some remarks on  
...before doing this, however, it will  
...of much advantage  
...of its effect, be  
...in which it might, and with our  
...to suggest some few diseases  
...with some remarks and opinions, I shall  
...total extent of the nervous system  
...part, I shall not expect to be  
...parent, I shall not expect to be  
...determining myself, that at some future

1<sup>st</sup> Sir H Davy, in experimenting on this subject, observed that the hearts of animals killed by being immersed in this gas, always contained blood of a peculiar purple red colour. This same colour he observed to be always produced in venous blood ~~was~~ out of the system, when it was exposed to and absorbed nitrous oxide gas. He describes it as an entirely different hue from that of blood in any other circumstances. Dr Beddoes also saw this colour evident in the wound made by a leech in the arm of a person under the influence of the gas. (Davy's researches pag 545).

2<sup>nd</sup> In accurate experiments made in breathing nitrous oxide by Davy, a large portion always disappeared. As the lungs were brought to the same <sup>degree</sup> state of exhaustion in the beginning as in the end of the experiment, we can account for the diminished quantity of <sup>air</sup> gas in the lungs and airholder, only by supposing some of the gas to have been absorbed by the blood.

3<sup>rd</sup> The

1. The first experiment was made in  
the year 1774, and was conducted by  
the English chemist, Joseph Priestley.  
He discovered that the gas which  
remains after the air has been  
absorbed by plants, is necessary  
to the support of life, and is  
the same as the gas which is  
absorbed by animals, and which  
is necessary to the support of  
life. This gas is called oxygen.  
The experiment was made in  
the year 1774, and was conducted  
by the English chemist, Joseph  
Priestley. He discovered that  
the gas which remains after the  
air has been absorbed by plants,  
is necessary to the support of  
life, and is the same as the  
gas which is absorbed by  
animals, and which is necessary  
to the support of life. This  
gas is called oxygen.

3<sup>d</sup> The time required to produce the effect, being what we might calculate to be necessary for the blood to pass from the lungs to the brain.

4<sup>th</sup> Sir H Davy took into the stomach several ounces of water highly impregnated with nitrous oxide gas, without any effect being produced on the nervous system. This experiment I have repeated, drinking a pint of saturated water, without experiencing the least change in my sensations or pulse.

We cannot then suppose that it acts on the nervous system of the lungs, when it produces no effect on the more sensible nerves of the stomach.

Nitrous oxide has already been proposed as a remedy in several diseases as Paralysis, suspended animation, tetanus, typhus ~~gastric~~, and mania.

In Paralysis it has been tried by Dr Beddoes in many instances with general but only moderate benefit. It is evidently improper where any apoplectic <sup>symptoms</sup>

The time required to produce  
the effect, being what we might calculate  
to be necessary for the blood to pass from  
the lungs to the brain  
In the last part into the stomach  
General causes of water highly impreg-  
nated with nitrous oxide gas, without  
any effect being produced on the nervous  
system. This experiment I have re-  
peated, drinking a pint of water at  
water without experiencing the least  
change in my sensations or pulse.  
The amount then appears that it acts  
on the nervous system of the lungs, when  
it produces no effect on the more sensitive  
nerves of the stomach.  
Nitrous oxide has already been  
proposed as a remedy in several dis-  
eases on Pabst's, and several countries  
tobacco, typhus, and various  
Mr. Pabst's it has been used by  
Dr. Pabst's in many instances with  
general but only moderate benefit. It is

symptoms or those making considerable pressure on the origin of the nerves, are present.

In cases of suspended animation, it seems to be clearly indicated, though the difficulty of suddenly procuring it and the urgency of the case, must always preclude its employment.

In tetanus it seems probable that the power it possesses over the muscular system, may overcome its morbid excitement, according to the law that no two diseases can take place at the same time in the same part. It seems also to coincide with Dr Rush's practice in this disease.

In typhus and coma, a stimulus of greater power than any used in present practice is certainly a desideratum. This stimulus, not inducing indirect debility, seems to render it more proper in this disease, than those commonly used which all belong to the class of narcotics.

In some diseases of the mind, particularly in hypochondriasis, Nitrous oxide

oxide may probably be substituted  
for opium with the highest advantage  
Dr Rush speaking of the use of opium  
in this state of mania ~~explains~~ <sup>says</sup>. "This  
noble medicine, which has been hap-  
pily called the medicine of the mind  
has many advantages over ardent spirits  
as a cordial. It affords more prompt  
relief and a habit of attachment to it  
is more slowly formed and more easily  
broken". In how much greater degree  
have we reason to suppose these terms  
applicable to the ~~remedy~~ now proposed

The probable utility of this gas in  
dropsy, suggested itself to me by an  
observation of Davy's, that, in the ani-  
mals killed by the influence of Nitrous  
Oxide, the bladder was invariably full  
which was not the case with those  
whose death was produced by other  
means. A considerable diuretic effect  
I have observed to be generally im-  
mediately produced by two or three  
doses taken in quick succession.

... in general success

To

Doctor Isaac Cole

Under whose able guidance  
I have prosecuted my Medical Studies this essay  
is respectfully inscribed.

By his Friend and Pupil  
Michael N. Diefenderffer

Philadelphia

To

Doctor Isaac Cole

Dear Sir, I have the honor to acknowledge the receipt of your letter of the 10th inst. in relation to the case of the late Mrs. M. I have been instructed by the Board of Trustees to examine the same and to report thereon to the next meeting of the Board.

I am, Sir, very respectfully,  
Your obedient servant,  
Richard C. Smith

## Introduction.

Among the many difficulties which the Medical Student has to encounter that of preparing an Inaugural Dissertation is not the least trying. The selecting of a subject adapted to his experience, ability and information perplexes him, & when selected he is aware that it must undergo the scrutiny of men whom fame has placed in the first rank of the profession and to whom many of his views must appear false and unfounded, But one reflection is at least encouraging that the Medical Faculty of the University of Maryland are not less characterized by their skill and learning than by their candour and liberality, qualities which will ensure him not only a lenient criticism but if necessary a mild and generous indulgence. Impressed the truth of these remarks I have been induced to offer to the Consideration of the Faculty the following brief remarks on

Hepatitis I do not claim the merit of originality this cannot be expected from a mere pupil in the school of medicine, All that I desire is that the selection I have made of the opinion of others may be found to be judicious and correct —

Hepatitis is defined an inflammation of the Liver and is divided into acute and Chronic This organ as well as any other internal organ is liable to active and accute inflammation, In the more Northern regions the disease generally attacks the lungs and intestines in its most inflammatory form. As other inflammations it is generally ushered in with a chill attended with a paleness of the countenance, small and quick pulse — When inflammation makes its attack suddenly and violently the patient is seized without any premonitory symptoms with great pain in the right Hypochondryum difficulty of sitting with the body bent forwards Sometimes the lungs and liver are at the same time both affected either hereditary or acquired and the pain alternating with the other being accute in one while there is little or more in the other — In the more milder regions the disease comes on more slowly the person feeling but slight pain in the Right Hypocou

The patient is depressed and complains of the  
in fact is depressed with acute and chronic  
is often as well as any other extensive organ  
likely to occur and acute inflammation  
the more the more rapidly the disease  
usually attacks the lungs and sometimes in  
most inflammation from the other inflammation  
is generally, whereas in with a white color  
a with a pale color of the corresponding organs  
the quiet part. These inflammation marks  
attack suddenly and certainly the patient is  
of the patient and in conversation of the  
the first pain in the night the first pain  
of sitting with the first pain  
the first pain and first pain at the same  
one both affected either together or separately  
the pain alternating with the other pain  
with one or other there is little or none  
in the other. In the more moderate forms  
the pain is more or less of the first pain

tyum with slight fever before the disease makes its appearance - a general attendant on Hepatitis is a scalding of the Urine supposed to be produced by the passage of the bile along the Urinary organs, which symptom authors neglect mentioning it is observed that when inflammation attacks the internal surface of the liver the pain is very distressing and heavy but when the ligaments are affected it is obtuse and pungent - — Pressure on the affected side generally increases the pain the patient finding more ease lying on the left side. General Symptoms — — — — —  
ough caused by the liver lying in contact with the Diaphragm pushes the diaphragm against the ~~liver~~ lungs, Nausea, and vomiting, white of the eyes have a yellow cast, Hot and dry skin pulse full and active but this is not always the case sometimes the pulse is hard small and quick. Diarrhea is generally one of the premonitory symptoms of this disease

...the ...  
...the ...

When this is the case the patient is seized with griping like dysentery and the discharges stringy and watery — The most characteristic symptom is pain in the right clavicle supposed by some when under the right clavicle the right lobe of the liver is affected and in the left clavicle the left lobe, the pain in the clavicle is produced through the medium of the diaphragmatic nerve arising from the brachial plexus of nerves the liver becomes enlarged presses against the diaphragm the nerve is included and the pain is caused in the clavicle through its medium, The state of the bowels enables us to judge of the presence of Hepatitis for in almost all cases where the liver is inflamed the bowels are either constipated or affected with dysenteric irritation. Diagnosis —

This disease is generally confounded with other diseases such as the stomach and lungs it is distinguished from a disease of

Stomach by its full and hard pulse pressure  
on the right side whereas pressure on the ep-  
igastric in the disease of the stomach causes  
most pain - from Pneumonia by inspi-  
ration which will not augment the pain  
in Hepatitis as it does in pulmonic in-  
flammation, from a spasm of the biliary  
ducts occasioned by a calculi it may be  
distinguished by its strong febrile excitement

Terminations \_\_\_\_\_ - This disease ter-  
minates in resolution, supuration, and gan-  
gren its termination in gangren is doubt-  
ed ever to have occurred the disease either  
destroying the subject or terminating in  
health before the form of gangren has time  
to appear, but it has been known to have  
occurred though very rare. The termination  
of acute Hepatitis in supuration is not  
uncommon when it takes place the symp-  
toms are clearly marked, hectic flushes re-  
mission of pain, and irregular state of the

bowels, night sweats and throbbing in the liver  
If the abscess points towards the diaphragm  
we will have cough and symptoms of pul-  
monic irritation, if towards the stomach  
there will be great gastric irritability and  
if the matter escapes into the stomach  
death will immediately follow. When  
the abscess bursts in the cavity of thorax  
the contents are sometimes discharged  
by expectoration this form is considered  
to be immediately fatal, but from the  
experience of some celebrated authors this  
discharge has been known to have been  
followed by the complete recovery of the  
patient - but the prognosis is in gen-  
eral very bad

---

There is a case related of an Hepatic  
abscess penetrating through the diaphragm  
into the lungs and giving rise to all the  
symptoms of Phtisis Pulmonalis and  
soon afterwards the matter found a -

oute by the intestinal canal and the pa-  
tient entirely recovered - When the abscess  
points externally it must be opened im-  
mediately to give vent to the pus for if it  
be left to the ~~effort~~ efforts of nature the  
constitution would be ruined before the  
contents could have an exit. Causes  
Marsh effluvia which acts by impairing  
the energy of the nerves through the me-  
dium of the sensorium deranges the  
biliary functions in combination with  
atmospheric heat the liver is morbidly  
excited and therefore vicissitude of wea-  
ther and every exciting cause would very  
soon cause inflammation to be fully de-  
veloped - Any inordinate action on  
the stomach will produce it in this  
case the face will assume a pallid hue,  
emaciation, irregularity of bowels, sallow  
countenance, swollen abdomen, Ardent  
spirits will produce it by causing an in-

creased irritated secretion in the stomach, the irritation of dentition in children, rage-terror, — Heat is clapped as one of the causes. — The effect of heat in the Hepatic system through the medium of the skin is well known, deranging its functions, & predisposing it to inflammation — But I am persuaded to believe that acute Hepatitis owes its existence to the application of cold and my reason for so believing is this, that heat by increasing beyond the natural standard the biliary and cutaneous secretions debilitates the vessels by which these secretions are carried on and the application of cold renders them more easily struck torpid, the consequence of which is the obstruction of the transmission of blood from the portal to the general circulation, which is the whole source of acute Hepatic inflammation — Blows, and external

violence have been known to produce, <sup>it</sup> A case is related of a gentleman who fell from a height of twelve feet and struck his right side against a ladder, after the lapse of a few days acute Hepatitis came on and the symptoms were subdued by the ordinary means, six months after this acute attack, another attack of inflammation came on which terminated in an abscess which burst through the diaphragm in the lungs destroying the patient in nine or ten days from the appearance of matter in the expectoration, There is one cause supposed to be legitimate that is the use of the Narcotics No one will doubt the strong sympathy existing between the biliary secretion and cutaneous exhalents and therefore whatever increases or decreases the action of the cutaneous exhalents causes an increased or decreased secretion of the liver. —

It is well known that the  
height of the water level  
is affected by a number of  
factors. The most important  
of these are the wind, the  
pressure of the atmosphere,  
the temperature of the water,  
and the shape of the basin.  
The wind is the most  
important factor, and it  
is the cause of the waves  
on the surface of the water.  
The pressure of the atmosphere  
is also an important factor,  
and it is the cause of the  
tides. The temperature of  
the water is also an important  
factor, and it is the cause  
of the currents. The shape  
of the basin is also an  
important factor, and it is  
the cause of the eddies and  
whirlpools.

The secretion of the capillaries and liver being at the same time stop'd the circulation of the blood through the liver is obstructed an action takes place and congestion being already present affects the system and gives rise to inflammation. The great sympathy existing between the liver and skin is illustrated in the Chronic form of this disease. where there is a dry and rough skin being almost impossible to excite a general perspiration, — Jaundice —

This affection is characterized by a yellow tinge of the skin, a deep brown colour of the urine, clay and pale like appearance of the stools, lassitude, languor, depression of spirits, bitter taste in the mouth, flatulence, indigestion, and generally torpid bowels, The cause of this complaint is considered to be the obstruction of the free passage of bile from the excretory ducts,

The character of the patient is not a  
single but a series of symptoms  
the nature of the blood is not the  
also the character of the patient is  
symptoms being also only present  
symptoms are given and to  
or a third great symptom is  
the liver and other organs  
the chronic form of the  
there are no other organs  
being almost insignificant  
and few characteristic  
this affection is characterized by  
the form of the disease is  
nature of the disease, and  
the character of the  
symptoms of spiritus  
the character of the  
the character of the  
the character of the

of the liver This complaint arises from  
a number of causes, free use of ardent  
spirits, Calculi, &c — Anger will so de-  
range the state of the bile as to produce  
jaundice in a few hours, jealousy,  
grief, there is no doubt that men-  
tal emotions are often the causes, —  
For the cure of this complaint the great  
principle is to remove the obstruction to  
the free egress of bile from the liver to  
the duodenum. the mode of treat-  
ment is according to the nature of the  
cause if it arise from calculi we  
should despair of cure without we  
could get something ~~to~~ in the cir-  
culation to act on the calculi which  
is impossible. — Blood letting warm bath,  
emetics, purgatives. A bath of Nitro Muri-  
atic Acid is very serviceable it effects the  
glands in a peculiar manner, it alters  
the secretions, increases perspiration and

The first thing I observed was a  
number of cases, free case of accident  
in the hospital, the cases were all  
the state of the case, as to produce  
in a few hours, yesterday  
I think there is no doubt that men  
the most are often the cause of  
the case of this complaint the great  
is to remove the obstruction to  
the passage of bile from the liver, to  
the obstruction, the mode of treat-  
ment is according to the nature of the  
cause of it, and from cases the  
most frequent of our visit, the  
most frequent in the case  
to be treated, the cases which  
are frequent in the case of  
the liver, the cases of the liver  
the liver is very remarkable, it affects the  
liver in a peculiar manner, it affects  
the liver in a peculiar manner, it affects

excites a peculiar action in the solids and fluids. this is another proof of the strong sympathy between the liver and skin —

Treatment. Blood letting is the primary remedy in the treatment of acute Hepatitis in order to lessen the momentum of the circulation and remove the congestion so as to prepare the system for the effects of mercury, then the exhibition of Calomel in doses from ten to twenty grains as a cathartic followed by castor oil or senna. Local bleeding is necessary application of leeches to the Hypochondrium it should be carried to the extent of relieving the pain or to enable the patient to bear pressure over the liver, Cupping is better than leeching we can in a shorter time abstract more blood by cupping, Blisters should succeed the local bleeding — It is absolutely necessary to keep up an active purgation throughout the whole course of this dis-

case, Calomel in combination with Opium has been highly recommended used so as to produce moderate ptyalism in doses of from five grains of Calomel with a half a grain of Opium given every four or five hours. In the course of this treatment an occasional use of some mild cathartic is necessary. Frictions of Unguentum Hydrargyrum is used when the mercury is tardy in its operation. Diaphoretics, Pulvis Antimonialis in combination with nitre. In Hepatitis depending on a calculus in the gall ducts we should employ active purging, and the exhibition of alkalis, Warm bath, When suppuration has taken place we should stop the use of Mercury, cupping or the application of leeches near the swelling and warm poultices with a view of promoting the pointing of the abscess the bowels should be gently kept open with the sulphate of Magnesia, Nitric and muriatic acids in

equal parts is administered internally from a dram in a sufficient quantity of water to be taken once every day when given internally it should be given through a quill in order to prevent the acid from injuring the teeth, Nitric Acid in combination with Opium or laudanum is used. Chronic —

Hepatitis — What is meant by chronic hepatitis is sometimes a inflammatory condition of the arteries accompanied by a derangement of the biliary functions and sometimes a congestion of the veins — the venous congestion of the liver is characterized by creeping chills, paleness, of the face, cold feet, when inflammatory action is going on the patient will complain of hot skin, irritability of the pulse light thirst and high coloured urine, these forms appear to alternate with each other the congestion appearing to be the cause of the excitement the cure of the congestive state, therefore these forms constantly alternating

with each other should always be taken in connection —. This form of the disease makes its attack in a slow manner without any symptoms of severe indisposition and it will even run into suppuration or an organic induration before its existence is discovered. Indigestion, nausea, and vomiting slight pain in the abdomen are the most prominent features — The relief which is commonly obtained by purgatives in the expulsion of the fecal accumulations whereby the pressure of the contiguous organ on the liver is taken off contributes to keep up the delusion — a heavy dull pain in the Right Hypochondrium pain on pressure of the affected part — In this form we have the pain under the clavicle in the shoulder joint, and is often continued down the thigh and whole of the leg so as to cause a paralysis of the whole of that side the cause of this disease is supposed to be owing to the acute form of this disease or the

the end other should always be taken in  
connection - The form of the disease is  
often in a slow manner without any  
symptoms of acute inflammation and it will  
be seen with inflammation in an organ  
before its extension is discovered  
in the abdomen and covering light  
part features - the relief which is com-  
monly obtained by purgatives in the epidemic  
is a local accumulation which the purgative  
the acute process is on the brain in fact  
contributes to keep up the disease - a  
my dull pain in the Right Temporal region  
is a symptom of the affected part - the  
form we have the pain under the eye  
in the forehead part, and is often seen -  
next down the right side of the eye  
to cause a paralysis of the whole of that side  
cause of this disease is supposed to be an  
to the acute form of the disease

slow operation of the same causes this latter appears to be the most likely cause — We should believe that Marsh Miasma is the whole cause of this disease upon its long acting upon the system in marshy districts. — In the Post-Mortem appearances of the liver it is found generally to exhibit an ash coloured appearance Abscesses are found and sometimes tubercles scattered throughout the substance of the liver —

Treatment — General bloodletting is hardly necessary in this form of Hepatic inflammation. the application of cups to the epigastric region is found to be very advantageous, Iodo-poultices to the Hypochondrium and a mercurial aperient every night, light and digestible diet a careful avoidance of vicissitudes of weather, blisters, frictions of tartar emetic ointments and counter irritants — Mercury in form of blue pill, exhibition of cathartics as may be deemed necessary as neutral salts, Rhubarb Jalap &c change of air the removal to a warm

## Preface

In the subsequent investigation little else can be expected than to recapitulate in a very imperfect manner some of the opinions of preceding writers.

As there is no pretension to originality in any part of the following essay; as the parts which are extracted from authors; can be easily distinguished by every medical reader, and as I here make particular acknowledgements to those authors. I hope to be excused for omitting minute references to them.

Although I make no pretension to originality, and acknowledge the following essay to be taken from authors, yet it is imperfectly done, and he who would do justice to such a subject, should possess talent, leisure and industry. To a deficiency in the two former points, many of the imperfections of the following essay may be justly ascribed, Instead of some months, or rather weeks, could a few years have been devoted

*[The page contains faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

to its execution, it might have been less imperfect, and consequently less unworthy of the acceptance of the reader.

However, the laws of the University of Maryland, of which I have the honour of being a student, requiring that I should make this attempt, I flatter myself, that your zeal to encourage such an attempt will draw the mantle of forgetfulness over its imperfections. Therefore with great diffidence it is submitted to your inspection.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

# Dysentery

The flux or bloody flux, (from the two Greek words *δυσ*, difficulty, and *εντερα* the bowels.) is a morbid affection of the internal surface of the large intestines, and sometimes of the small, the disease is principally characterized, by frequent mucous or bloody discharges from the intestines, while the proper feces are retained, together with griping, and straining at stool and some fever.

The word dysentery as used by the ancients had no very precise signification but was applied to affections of the bowels in general, for we find Hippocrates using it, not only to signify all ulcerations, but all hemorrhages of the intestines. Neither was Galen more precise in his definition, sometimes defining a dysentery, an ulceration of the bowels, at other times mentioning four species of the disease, all with bloody stools. Celsus more rightly limits the sense of the word, and restricts its meaning to an ulceration of the bowels.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

attended with tormina, tenesmus, and with mucous and bloody stools. Although this notion of the constant ulceration of the bowels in conjunction with dysenteric symptoms, prevailed for a long time; and although it be true, that the bowels are liable to ulcerate in true dysentery, yet it has been fully ascertained by the dissections of the moderns, that ulceration is accidental and not essential, and that instances of fatal dysentery in which the intestines were sound are more numerous than those accompanied with ulceration. For this assertion we have the authority of Morgagni, Cleggorn, and Pringle, and it is now generally understood, that ulceration takes place only in the advanced or chronic state of the disease.

This disease occurs especially in summer and autumn, at the same time as does autumnal intermittent and remittent fevers and with these it is sometimes combined or complicated. Dysentery is a species of enteritis - an inflammation

*[The page contains faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

of the mucous lining of the intestines, chiefly confined to the large ones, and is accompanied either with diminished or increased secretion of mucous. —

In dysentery, I have observed (Says Professor Smith) in one of his medical journals) that the severest cases are not attended with the most copious mucous discharges. This is because the membrane is too intensely inflamed. It is then highly irritable, and the efforts at stool are frequent and ineffectual. — When the mucous is copious and without blood, it indicates a lower degree of inflammation, and the discharge itself is a source of relief, as it depletes the engorged vessels, precisely as catarrh is relieved by copious expectoration.)

The disease sometimes begins, as Sydenham observes, with cold shiverings, heat and other febrile symptoms; but in other cases the feverish symptoms are not felt, but a griping and a pain about the pelvis and loins, with much

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

6  
flatulence, and a constant inclination to go to stool,  
while the belly is tight. Sometimes though more  
rarely, some degree of diarrhoea is the first appearance.  
However in whatever way the disease commences, it  
soon puts on its characteristic appearances. In  
indulging in the disposition, to evacuate the  
intestines which by degrees becomes more frequent  
and urgent, and which the patient is unable to  
resist, but little is voided except, watery, mucous,  
or bloody matter, without any admixture of natural  
faeces, and the tenesmus becomes more considerable,  
This symptom (tenesmus) the most distressing of  
dysentery, arises from the extreme morbid sensitiveness  
of the mucous lining of the intestines, in consequence  
of which it cannot bear the contact even of the  
ordinary contents of the alimentary canal, much  
less of the acid bile, the crude, half digested  
aliments. &c. which result from the general disorder  
produced in the digestive organs, The membrane  
being thus irritated excites, by sympathy, the  
muscles of the bowels, and of the abdomen to

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

repel the cause of irritation. The frequent efforts which result, aggravate the engorgement already existing, and exalt every symptom of the disease. The intestines are made to contract irregularly and convulsively upon their contents, in such a manner as to mould them into scybala, and violently compress them, without, transmitting them along their canal. If a purgative be administered, and operates well, it carries off the scybala, which are apt to continue in the upper part of the alimentary canal, and keep up irritation. When these scybala are voided a remission of all the symptoms supervenes and more especially that of the tenesmus. This state of disease in the alimentary canal is always accompanied with a loss of appetite and frequently sickness; nausea and vomiting also affecting the patient. — At the same time there is always more or less fever, which is often of the remittent kind, and observes a tertian period. In many cases the fever is of a highly inflammatory character. The pulse is very frequent, the

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

mouth and fauces dry and clammy. The tongue is covered with a dark fur in the centre; or when much bile is secreted, with a yellow fur at its posterior part, or it is red and polished. In severe cases the stomach becomes very irritable, the mildest fluids being rejected, while an unceasing thirst prevails: or that state of sympathetic irritation in the whole tract of the alimentary canal takes place, by which tormina and tenesmus immediately succeed the swallowing of the blandest liquids. These febrile states continue to follow the disease through its whole course, especially when it terminates soon, in a fatal manner. In other cases the febrile condition almost entirely disappears, while the proper dysenteric symptoms remain for a long time after.

The nervous system also suffers severely; nothing seems to weaken the body so much as dysenteric purging. In very bad cases, hiccup, cramps of the gastric-muscle, and stranguary occur; and great exhaustion of power is evinced, in the staggering or giddiness,

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

9

and even syncope, when the patient is brought into the erect posture.

It is not the evacuation by cathartics which causes this agitated state, but the effect of the irritable state of the intestines, communicated to the stomach, brain and whole nervous system. The violence of the tenesmus causes universal sympathy, and free purging by medicines, abates or removes the pain and consequent debility. We are aware (says professor Potter) that there is a dysentery, & a low death-like debility, in hospitals, camps, ships, and occasionally in old persons; and that in such a state we cannot employ evacnants. We sometimes succeed by opium, cinchona, wine, and other cordials, but it is the most intractible fever we have had occasion to treat.) Dysentery is a disease subject to great variety, and of various duration in different instances. When the fever attending it is of a violent inflammatory kind, when it is of a putrid nature, the disease often terminates fatally in a very few days,

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

with all the marks of supervening gangrene; but we should bear in mind the disposition of the disease to assume the chronic form. When the febrile state is more moderate, or disappears altogether, the disease is often protracted for weeks, and even for months; but even then, it often terminates fatally. In some cases the disease ceases spontaneously; the frequency of stools, the griping and tenesmus, gradually diminishing, while the natural stools return. In other cases the disease with moderate symptoms, continues long, and ends in a diarrhoea, sometimes accompanied with henteric symptoms. The symptoms of dysentery vary according as it is of the inflammatory, the remittent or typhous type. In the inflammatory form the symptoms are more intense; there is a more fixed and violent pain in the abdomen, with great heat in the integuments, and skin generally; the evacuations consist of blood and mucus, or bloody serum, and great desire for the coldest water, a white and furrowed tongue,

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side of the page.

11  
the pulse febrile and quick, or full and bounding.  
It sometimes proves fatal in a few days. In the  
intermittent form, nausea, bitter taste in the mouth  
with bilious evacuations, distinguish it.

In the typhoid form, fainting, stupor, heaviness,  
ghastly expression, and calm delirium, with dis-  
charges from the mouth of green bile; watchfulness  
and headache, are often the first symptoms,  
more decided marks of debility appear, the voice  
becomes weak, the tongue and teeth brown or  
black; excessively copious or very slight stools  
with great pain or none at all in the bowels.  
The stools are of various colours: dark, green, or  
black; mucous watery, or serous. The pulse  
low, thread like, and intermitting, with the  
other symptoms of typhoid fever, as picking of the  
bed clothes, cold extremities &c.

Dysentery is distinguished from diarrhoea  
by the tenesmus, bloody stools, and general  
fever which characterise it; from hemorrhoids, by  
the blood being discharged first. in hemorrhoids

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

and faces last.

In the progress, it is the indicative of a dangerous case; when the disorder of the stomach is obstinate; when the countenance alters much; when the pulse sinks, and intermits, when the patient is restless without complaining of gripes. In the beginning a hiccup is little to be dreaded; but in the low, and advanced state, if obstinate, it is commonly a sign of mortification.

Hippocrates says in his aphorisms. Si a dysenteria detento, vellet carunculae ceciderint, lethale est. Also In longis dysenteris appetitus prostratus, malum: et cum febre peris. The disease when fatal ends in a prostration of strength, a sore throat or aphthæ; involuntary, and cadaverous stools. The morbid appearances, in very severe and protracted dysenteris, exhibit, by dissection, the inner membrane of the great intestines thickened, and formed into small irregular tubercles of a white or yellowish colour, and occasionally large dark coloured patches with thickening of the part.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

peritoneal and muscular coats. Abrasions or extensive ulcerations are not unrequent. In tropical dysenteria, the colon has sometimes been found decidedly in a state of mortification, and feces have even escaped through the mortified intestine. In dysentery the ilio caecal valve and commencement of the colon are the parts principally affected, the sigmoid flexure and rectum more slightly. The mesenteric glands corresponding to the inflamed parts are often found red and tumefied. With these, which are the true dysenteric appearances, there are not unrequently united marks of peritoneal inflammation.

The causes of dysentery seem to be various; by some authors it is said to be produced by strictures in the intestines; by some it is said to be produced by contagion; by some it is said to be hepatitis in disguise; and by others it is said to be produced by a sudden check of perspiration, which appears to be the most common exciting cause. Excessive

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side of the page.

fatigue and long exposure to the direct rays of the sun, appear in some cases to have brought it on.

It is sometimes brought on by improper articles of diet; as putrid animal and vegetable food, unripe fruit, acid and accecent substances, ardent drinks, and ripe fruit, when taken in too large quantities will produce it, in debilitated habits, and in children. Cold water drank largely has produced it. Dysentery is often a form of Bilious Remittent fever, complicated with disordered liver, and is produced by the exhalations from vegetable and animal decomposition, the effects of which are brought into action, by the cold air of the evening, sudden vicissitudes of temperature &c.

In every case of dysentery (says Dr. Johnson) that has come within the range of my observation two functions were invariably disordered from the very onset, and soon drew other derangements in their train. These were the functions of the skin and liver, or perspiration, and biliary secretion. Agreeably to Dr. Johnson, therefore

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

whenever can, by any means restore those two functions to their natural state, will cure the disorder. The intimate relation which constantly exist between the skin and mucous membrane is known by every one. When the circulation of the skin has been for some time active, and a greater quantity of blood than usual has been contained in it, a sudden impression of cold repels the circulating fluid from the surface, to the heart, great vessels and glandular organs; these not being able to accommodate themselves immediately to the quantity the fluids are rejected, and thrown upon a membranous tissue nearest like that of the skin, as the pulmonary mucous membrane, the mucous membrane of the stomach, the small or large intestines and when upon the latter dysentery is the result. The causes mentioned above may cooperate to effect this state of things. — The expelled excitement may be invited to the mucous surface of the large intestines, by any thing which irritates it.

Faint, illegible handwriting on aged paper, likely bleed-through from the reverse side of the page.

frequently also indicates bleeding, if it be plethoric, young and robust, also if the patient have laid high, and if it be a cold season, bleeding will be required, as the disease may be expected to be inflammatory; If the symptoms run high it should be drawn freely, even to fainting. Some diaphoretic should now be taken by the patient with copious draught of some mild <sup>liberally</sup> as mucilage of gum arabic, barley water, flax seed or bran tea, or cream of tartar water in order to restore the cutaneous excitement. Warm fomentations to the abdomen will be of great use. If leeches can be obtained it will be more effectual to take blood from the surface of the belly, by them, than general bleeding. As often as the pains return, bleeding should be repeated, till the inflammation is completely subdued, then emetics and purgatives may be used, and not before; in the inflammatory form, the patient should be kept at rest, as long as the inflammatory

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

diathesis continues, All stimulating, astringent, and heating substances, as opium, kino &c must be avoided. The employment of purgatives and drastringetics constitute the most important part of the cure of dysentery. Purgatives must be steadily persisted in until fecal evacuations have been produced, and that sensation of load in the bowels, which leads to the effort of straining is completely removed. Almost every kind of purgative medicine has been used, and at different times recommended. Calomel with the addition of tartar emetic or ipecacuanha, is commonly found to answer best. Dr Johnson in his work on tropical climates, says if he can produce a gentle ptyalism in the disease there is no danger. If the object is, as he says, to produce a natural state of perspiration and biliary secretion; Calomel and opium combined with antimonials, seems to answer the purpose, as Opium modifies the action of the calomel, allays the irritation of the

bulbs, and increases the diaphoretic disposition  
 of the antimonial. When the stomach is very  
 irritable, some other cathartic with opium  
 should be chosen as, Extract: colocynth: cum:  
 ℞. V. Hydrargyr: Sublimat: gr. V. opii gr. ʒ,  
 Mij, and let it be made into two pills for a  
 dose. The opium being added to allay irritation.  
 Between the purgatives, however, proper ~~diap-~~  
 horetics should be interposed, and by that  
 means the skin may be kept constantly soft.  
 When the surface generally, is below the  
 natural temperature, and, at the same time  
 the skin dry, the immersion of the body in  
 the warm bath will be found of eminent  
 advantage.

Various diaphoretics have been  
 used, and every one seems to have a favorite;  
 but tart: Antim: in small doses with a  
 large quantity of water is the one most  
 frequently used and is much celebrated by  
 Senac, it may be given in the dose of a grain

*[The page contains faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

dissolved in a pound of water taking a wine glass  
 full every hour, or in doses sufficient to keep up  
 a slight nausea of the stomach. Bad cases of  
 dysentery, it is said, have been cured with this  
 and no other medicine. The vitium cicutum  
 antimonii is much praised, particularly by  
 Sir John Pingle, it being not so liable to  
 irritate the stomach as do the ordinary pre-  
 parations of that metal; the dose is 3 or 4  
 grains gradually increased to eight.

The action which is excited, by these means,  
 on the surface of the body, should be carefully  
 sustained, and the surface of the body should  
 be very carefully protected from the sudden im-  
 pression of cold air, while we at the same  
 time avoid keeping it too hot.

After proper faecal evacuations have been  
 procured, it will be proper to continue  
 the use of some mild purgative for a  
 short time after us;

*[The page contains faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

℞. Infus: ros: comp: ----- ʒx.

A. Dissertation  
On the Physical effects of heat, and cold,  
on the Human System.

By William S. Mapwell  
" " " "

1830

The Physical effects of Heat and Cold —  
and their reciprocal changes on the human System.

---

The succession of diseases, with the course of the seasons, has commonly been noticed by practical Doctors, but we would observe, that these are rarely the simple, or, uncombined, effects of the changes of temperature alone — but in conjunction, with these, we have to regard the effects produced, by various, miasmata and effluvia, together with specific infections —

There is some difficulty in separating these concomitant causes of disease, which arise from various sources, from those of a more simple origin —

It is necessary therefore that we examine the different causes of disease, in various situations and under different circumstances, in order to discriminate them with more accuracy —

In pursuing this subject, we will first, attend to the simple effects of a warm atmosphere with its consequences, separate from the impregnation, which it often undergoes from adventitious causes —

Singular as it may appear there is very little infor-

mation to be had from the older writers in investigations of this kind - but it is equally true, that much has been done during the last centuries in ascertaining the principles, operations and laws of nature -

Hippocrates paid much attention to the vicissitudes of the seasons, but the physical knowledge of nature, was so little understood in his time, that although his diligence was great and his sagacious attention to what ever fell under his own observation, so accurate, as to appear wonderful - yet when we consider that there was scarce any thing written on the subject, before him - very little to be found in the few Grecian philosophers, who preceded him - we are not to expect from him, what the times could not afford. -

Had a rational attention been paid to the effects of heat, we should not have had the medical faculty themselves, differing in opinion concerning it, down to the close of the 13. Century - one contending for its stimulant, another for its sedative property - This would appear singular, and inconsistent, did we not consider, that on all subjects of importance, there are men of various opinions, and talents, whose diligence and information, differ in proportion to their acquirements, each holding himself to be in the right, and his opponent in the wrong -

- Besides many men of abilities often have an apathy

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

to inquiry, believing assertions, rather than seeking for proof  
among the annals of literature, and following others rather  
than thinking for themselves —

The immediate effects of heat upon the human system  
appear to be stimulant; and of all the agents in nature we  
know there is none more directly and certainly so — but  
like all other stimuli it destroys the vital principle by  
excess — in moderate quantity it is necessary to life and  
health — its total privation is known to extinguish life  
in the warm-blooded animals — to cause a torpor in the  
cold-blooded —

The stimulant effects of heat are very similar to those  
produced by other stimulus — on its first application, when mod-  
erate, it enlivens and exhilarates the animal spirits — sets  
the latent and vital energies into action — having an effect  
similar, though in an inferior degree to the different Alco-  
holic preparations; — but if suddenly and strongly applied  
it exhausts the vital energy too soon, destroys its sensibility  
if too long continued — causing weakness, depression and pro-  
stration; — thus we see an inhabitant of a cold northern  
country, on his first removal to a warm climate lively and  
cheerful — full of animation and flushed with buoyancy of  
feeling — but after a series of years residence in such a cli-  
mate, he loses much of this disposition, particularly if  
his employment be sedentary; and his mind seldom re-  
tains that natural vigour and strength, with endurance  
of that intellectual labour, which in his native climate,

he is so capable of supporting:—The imagination being the  
stronger attribute of the mind, he becomes volatile, or sinks  
into hypochondriasis if he has made too free use of Spirit-  
uous drinks,—for a long residence in very warm countries,  
with the additional Stimuli of strong liquors, debilitates  
in an extraordinary manner the corporeal man and also  
depresses the mental faculties,—particularly if the mind  
has been in an anticipating-solicitous state—Persons in such  
conditions are subject to fevers and hepatic affections  
from slight causes—and we believe that diseases of the  
liver are the more frequent cause of hypochondriac, and  
other similar affections, after the energy of the system  
is destroyed by heat and excess of dissipation.—Being ful-  
ly convinced of the stimulant effects of heat—so also are  
we of the sedative effects of cold to a certain extent—  
Heat increases the action of the vessels, and the other "moving  
vital parts" Cold abates and allays this action—but it  
is only on the surface that either of them can act directly,  
though many of the internal parts are involved from  
sympathy—So we know that the temperature of the blood  
and other internal parts are not perceptibly changed by  
the external temperature—so that the effects of these two  
impressions are produced on the surface, and the sym-  
pathies to which they give origin,—but even these produce  
great changes on the system—

In consequence of the sedative effects of Cold on the  
surface of the body, the vital energy is accumulated—  
the strength increased—and an agreeable glow of feeling,

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

experienced. - This is when the first impression has not been too strong to prevent reaction - nor acted on a weak and infirm habit in too decided a manner, having thereby the effect, of a permanent sedative -

The inhabitant of a warm climate, on removing to a cold country, is commonly attacked with Catarrhal affections, obstruction of the viscera, etc; deprived of the external Stimulus to which he has been accustomed - and if in the advance of age and <sup>having been</sup> long a resident in a warm climate, he is more strongly affected in this manner - than any person can be on a accession of winter, after the warmest summer -

Heat as we have before observed, when applied in a moderate degree is necessary to life and health, but an excess destroys and wears out - by keeping up too great an irritation on the surface, and other sympathising parts; - an excess of Cold acts diametrically opposite - on its application to any part of the body, if it <sup>does</sup> not deprive it of its vitality, on coming into a warmer atmosphere, a temporary inflammation succeeds, from the vital energy being accumulated during the action of Cold: - but by heat this vital energy is exhausted, and the body weakened - The alternate changes of heat and cold, if we consult our own feelings are rather agreeable than otherwise; for there is an innate fondness for variety implanted in the human mind; and when they do not go to excess, they cause a pleasing anxiety, which we have every reason to conclude contributes to the preservation of health - for as Sydenham observes -

The changes preserve a balance. Pursuing this consideration, we may also suggest, that an over great uniformity in any of the articles of regimen are to be avoided, by those who wish to pursue the strictest prophylactic course, and enjoy the most uninterrupted health. "for neither food, nor drink, air nor exercise should be too uniform, for they thus engender too great a susceptibility of body - predispose it to be acted on by every variation of atmosphere or regimen - weakens the mind as well as the body, and deprives us of true health" -

But continual heat sets other causes in action, by hastening the putrefaction and decomposition of vegetable and other matters, - it also predisposes the body to be more susceptible of morbid impressions. - It is a remarkable difference which exists, between an atmosphere with moisture simply diffuse through it, as in high and healthy countries - and that which exhales from stagnant water, swamps and marshes - the former is seldom hurtful, the latter often pernicious - we shall endeavour to attend to this latter, in our remaining remarks - drawn from observations, made in regard to this subject -

"The heat of the atmosphere being confined very near the common level of the surface of the Ocean in all climates" appears to be the cause of the heats being so great in low countries - particularly in warm climates, and consequently of the noxious exhalations of which heat

- is always an active agent; - the temperature of any part appears to be affected by various circumstances - but we would presume that it is commonly in proportion to the number of rays of the sun, which fall in a given space of time, as may be proved by a lens or mirror - therefore, where they approach nearest a perpendicular they are the strongest - and when the air is clear they act on the earth with the greater force -

"But though the light comes from the sun, the heat does not, the rays of light extricating it from the earth.. This theory is ingeniously supported by Mr Millar of Perth. the author of a modern work entitled "Physical and Metaphysical Inquiries" he imagines that caloric is not transmitted from the sun, but that it is a subtle fluid originally belonging to our earth - the arguments he uses in support of this opinion are clear and convincing - we will barely make an extract from a work before us, containing this theory - having neither time nor disposition to follow the subject through." This view of the nature of Caloric" says the author above alluded to - "is more correspondent with the general character of matter, than those generally entertained - It still regards the sun as the great agent in the production of heat, without supposing it an enormous mass of fire - we have only to consider the sun as the great storehouse of light, a power indeed the most active in nature - but no way destructive - It shows

5  
that light produces heat merely by exciting an insensible action between caloric and the particles of matter contained in bodies - It accounts for the want of heat in the upper regions of the atmosphere, by the want of sufficient matter to produce the action of Caloric - It shows that caloric is not an exception to all other kinds of matter, but that like its fellows, it exists in other characters besides that of sensible heat - These being some of the prominent propositions of the theory - we have thought fit thus to allude to them, as having a collateral bearing on the subject before us, without entering further into its merits or demerits -

We proceed now more directly with the effects of this matter however produced. Great heats when accompanied by moisture & obataine many substances, which more temperate weather will not affect, but vegetable decomposition on the exposure of a moist surface in the time of frost, does not change the properties of the air - for frosty weather is equally healthy in all parts of the world - the air being of all known substances the most necessary to life, and its variations so generally affecting our health, it deserves our most serious attention as physicians -

The atmosphere contains in general about three fourths of its quantity of air, which is neither a supporter of life nor Combustion - this has been named the mephitic, or Nitrogen - the other is the pure vital air - the *abulum vita* - the oxygen, - but the absence of this pure

principle does not render it so hurtful to life as the presence of fixed or inflammable air, which are commonly extricated by the decomposition of water or vegetable substances - It is this pure part of the air which imparts the beautiful scarlet colour to the blood - the circulating fluid is of a modena, purple colour when it arrives at the lungs - but having there thrown off hydrogen and Carbon - it imbibes <sup>the</sup> oxygen and nitrogen of the atmosphere which changes its dark colour to a brilliant red, rendering it the excitant to the heart and arteries - the source of animal heat - the cause of sensibility, irritability and motion -

"The internal surface of the lungs or air vessels in man is said to be equal to the external surface of the whole body" - it is on this extended surface that the blood is exposed through the medium of a thin pellicle, to the influence of the inspired air - "By the elevation of the chest and the descent of the diaphragm room is afforded for 22 cubic inches of atmospheric air at every natural and easy inspiration" - or according to the experiments of others the quantity of fresh air necessary to support life and health is about one gallon a minute, or near the same quantity which a "common candle consumes" -

By the experiments of Dr Crawford it appears that when the body is immersed in warm water or warm air, the venous blood returns, but little darker coloured than the arterial - this would appear to influence

6

somewhat the idea "that heat alone is not the cause of the dark colour when the rays of the sun are excluded from the body - but it appears to act through the intermedium of other substances" -

The inflammable air contained in the venous blood being the substance, which principally attracts the vital air, when this is deficient, less of the vital air mixes with the blood in the lungs, and consequently less heat is extricated - this appears to be the only explanation we can give, why the interior of the body is no warmer in hot than in cold climates or seasons -

We must say a word as regards the supply of pure air, to its consumption by the respiration of animals and combustion of vegetable matter - the vegetation of vegetable substances afford it in great abundance - the action of the sun on them causes the absorption of inflammable air as part of their nutriment - this appears to be the design of the Creator in their formation - The evaporation of water also affords pure air - the moisture it infuses is in fact a necessary part of the composition of common air, for when deprived of it - as in the Arabian winds - it becomes destructive - we find by experience however, that whenever warm or cold air is overloaded with moisture it is disagreeable to our feelings, and injurious to health - here experience goes counter to what we might expect a priori - From chemical analysis

but this is not the only instance in which chemistry fails of demonstrating the effects which physical substances produce on animal life, there is no state of the air more disagreeable to our feelings than the one much impregnated with moisture, either in a warm or cold atmosphere - we are weakened and dispirited in the most evident manner when the air is warm - The cutaneous surface becomes relaxed and both mind and body assume a state of languor by its continuance - from these reflections we are led to believe, that moist air does not perform its office so salutary in the lungs, as air moderately impregnated - whether this happens from its not uniting the pure principle sufficiently - together with heat; from its not extricating the fixed or inflammable air from the blood - we are not prepared to say. - Cold and moisture appear to obstruct perspiration by rendering the surface quiescent as it were, and lessening the action of the capillary vessels of the skin - hence we have Catarrhal affections; - and in warm moist air, in consequence of the relaxation it produces, the system is liable to suffer from the least change, under cholera, dysenteries, or bilious remittents - But a pure dry air induces strength and vigor, as we experience in frosty weather, - we thus feel more elasticity and buoyance, and are more capable of resisting future impressions, - pneumonic affections are sometimes a consequent of its long continuance -

In consulting practical authors a regard should be paid to the difference of climate under which they write - for this reason a correct knowledge of geography and topography is essentially necessary to an intelligent physician - The most prevailing winds, the nature of the soil over which they pass, their moisture or dryness, heat or Cold - forms a most important consideration in medical science -

Hippocrates appears to have paid much attention to these subjects in his observations upon the air, waters, and locations of particular districts - but after his time it appears to have been much neglected -

The writers who have attended to subjects of this kind do not sufficiently mark the effect of miasma, from those of heat and cold - so as to exhibit their effects separately with their causes, and means of prevention - By pursuing investigations of this kind we trace out the external source of disease, but as for their internal causes we must have recourse to the state of the human system itself.

Local situations whether elevated or low, marshy, or dry - covered with vegetables or bare - all have their particular influence -

The air of Cities and large towns is known to be both unhealthy and disagreeable in the warm season even in middle latitudes - they are consequently exposed to diseases from which the country is exempt - but they are free from them again - Heat and moisture are the great antagonists -

onists to health in the country - As fermentation will not take place unless the exposed fluid be in a state of rest, and acted on by a certain degree of heat - so also the putrefactive decomposition will not take place in marshy grounds, unless the moisture be in a state of stagnation - But pure water in a state of stagnation will not undergo any change in consequence of heat and rest, unless it is impregnated with vegetable matter, consequently will not vitiate the atmosphere -

The effects produced by breathing an impure atmosphere, is sensibly perceived, by persons of much nervous sensibility - Close, ill ventilated apartments have the effect to produce in those susceptible habits, lowness and depression of spirits, with an uneasy erythematic state - and obtuse head aches, for the relief of which nothing more is necessary than a free circulation of air - persons have also perceived a slight riga or chill, accompanied with head ache, from walking about marshy situations -

And yet it is highly probable that no chemical or other physical means could detect any impurities in this air - though the olfactory nerves sometimes can - or it is apparent that there may be noxious substances afloat in the atmosphere, or conveyed by contact, which we have no sense appropriated to detect, although the smell is certainly the one most to be depended on, for we often perceive infectious diseases by their smell - particularly if we are well acquainted with them -

for example, the peculiar atmosphere which pervades a syphilitic ward may always enable the scientific practitioner to detect this disease, wherever met with, either in the public Almshouse, or the more secluded walks of private life. - But we must remember that the properties of animal life, are not to be explained either chemically or mechanically, though often attempted -

The inhabitants of dry, hilly and mountainous countries, are generally endowed with greater mental capacities, as well as activity and strength of body, than those of low, flat, countries, for as the native character is imprinted in early youth, so there is no doubt that the mind, as well as the body, receives lasting impressions from ~~early~~ surrounding objects -

The influence of local situations on the physical nature of Mankind, is too obvious to escape any observer who will use his judgment and reflection, so that we cannot <sup>but</sup> wonder, that even the Speculator should deny it: - but observation and reason must and will ultimately prevail in this as well as similar contests, only by turning mens attention to them,

In taking our leave of the subject, we would state that on a synoptical view of the catalogue of diseases, there are ~~of~~ <sup>many</sup> which do not appear dependant for their ~~their~~ origin either

directly or indirectly on the "matter" of heat or cold -  
We respectfully submit these desultory remarks;  
under a full conviction that the gentlemen before  
whose perusal they have to pass, will, as the teachers  
of youth, make very due and candid allowance  
with these considerations they are cheerfully resigned  
to their inspection -

No. 10

Doctor Williams' Pink Pills for Pale People  
This is a bottle of Doctor Williams' Pink Pills for Pale People  
which will cure all the ailments of the blood  
and make the system strong and healthy  
The price is 50 cents per bottle  
of the doctor

The term which has been employed to designate this affection was not only instituted at an early period of medical science, but was doubtless restricted in its application to denote some derangement or misaffection of the Uterus and its appendages; Though we are far from denying that in very <sup>many</sup> instances, Hysteria is intimately blended with a morbid condition of the uterine functions, yet it would be conceivably hazardous too much to say, that it never exists independently of such a state; Indeed the many, and well authenticated instances of its having occurred in men of enervated fibre, debilitated constitution, and highly nervous temperament, may be adduced in confirmation of the truth of this assertion. But there are those who contend that this disease when met with in men should be denominated Hypochondriasis, nothing however is more absurd or more completely fraught with error, than the maintenance of such an opinion, that they have symptoms in common is not denied but that these are those which peculiarly characterize Dyspepsia is alike undeniable. They are separate and operating strictly distinct affections, and capable of being distinguished by symptoms not only inseparable from each other, but which at the same time

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

of purgative injections, it is said, there is no advantage, but rather mischief, as they irritate the diseased portion of the canal, without reaching that part in which the faeces are observed to linger. Therefore they are not much resorted to. When dysentery is united with diseased liver, which may be known by a bilious aspect of the countenance, tenderness and tumefaction in the region of the liver, dark bilious evacuations &c. salivation will be found most valuable; it has also been recommended, as an effectual method of putting a check to the advances of the disease in hot climates; in the inflammatory and remittent varieties, the depleting and purging plan with diaphoretics and diluents, and fermentations and blisters, to the abdomen will generally be found sufficient. In the treatment of the typhous form ventilation, and cleanliness should be observed, and every thing that debilitates

Faint, illegible handwriting, likely bleed-through from the reverse side of the page.

should be avoided; the bowels are to be kept open, by gentle purgatives, followed by tonics; after every operation sudorifics will be useful. The evacuations should be sufficiently free to discharge any unnatural collection of matter from the bowels, at the same time guarding against much purging.

The system should be supported by ~~simple~~ panada, &c. The volatile alkali, and urine whey, camphor in small doses, are valuable stimulants, astringents are indispensable when the stools are copious. In the last stages blisters applied to the legs are often useful. The convalescence should be managed by gentle purgatives, combined with tonics.

In dysentery the diet should be light and digestible, as rice water, barley water, the yolks of eggs, arrow root, tapioca, sago &c. with a little aromatic powder as ginger or nutmeg to render it more

*[Faint, illegible handwriting on aged paper]*

palatable.

Flesh of all kinds, broths, oily substances as fat and butter, the white of eggs, and spirituous liquors or malt, should be avoided. Exposure to cold damp air, and indigestible food, produce relapses. In the treatment of the disease cold water should be taken with caution, as it generally suppresses perspiration which it is our object to preserve, with the utmost care, as its suppression is attended with almost instant aggravation of the unpleasant symptoms. However, it seems sometimes to be beneficial. If we find on trial, that while it is grateful it is also beneficial, we may allow it to be taken in small quantities.

During convalescence, the patient should wear flannel next the skin; in order to carefully protect the surface of the body from all vicissitudes of temperature; and take gentle exercise.

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

Conscious of the imperfect manner, in which,  
I have treated this subject, I must conclude  
rather than do it farther injustice, but  
before I take a final adieu of you, illustrious  
professors, permit me, in this humble  
manner, to return you my most sincere  
thanks, for the inestimable principles,  
which I have received from each and all  
of you in the science of medicine: And  
that each of you, gentlemen, may long enjoy  
that honor and happiness, which you so  
deservedly merit, from your indefatigable  
exertions, in the promotion of useful  
knowledge, is my most fervent wish.

An Inaugural

Dissertation

On Pneumonia Vera.

by Hammond Stewart  
of Maryland

---

1828

75<sup>h</sup>  
A Treatise on Pneumonia Vera.

It is with peculiar diffidence that I attempt to write on a subject which has been treated of so often and by men so far superior to myself both in mental acquirements and in experience of the diseases to which we all are subject that I feel confident, that it will not be expected that I can advance any thing new upon this disease. I shall therefore merely enumerate the symptoms, secondly its causes and thirdly and lastly the cure of pleurisy.

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

## Pneumonia Vera.

This term is applied to every acute inflammation which affects either the viscera of the thorax or the pleura which lines that cavity, though the principal seat of the disease are the pleura, the mucous membrane of the bronchia, and also that part which lines the air cells of the lungs &c.

Pleurisy may always be known to be present by the presence of a fever, a pain in the side, difficult breathing, and a cough though this last symptom enumerated is not

but is various, for sometimes it is felt under the sternum and in the back between the shoulders, though the most frequent place for it to be felt is either the middle or a little more forwards of the sixth or seventh rib. Sometimes it does not remain stationary but shoots from the side to the scapula, or to the sternum or clavicle, the cough which is hard and short very much increases the pain so that it is stifled as much as possible by the patient at first it is dry or without any expectoration and the whole is acc

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

5  
-ompanied with a fever which is  
urgent; and there is a frequent,  
strong and hard pulse, the tongue  
is foul or loaded with a thick fur,  
the skin is hot, <sup>and</sup> the patient very rest-  
less and complains of great thirst;  
the urine is scanty and of a high  
colour.

This disease sometimes makes  
its attack in a very insidious way and  
at other times and indeed most  
always comes on suddenly.

A slight degree of inflammation  
may sometimes exist in the lungs

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

for a considerable time without  
producing any serious consequence,  
and at other times the same degree  
of inflammation cannot exist but  
for a very short time without occasioning  
fatal effects.

This disease terminates most frequently  
by resolution, sometimes by expectoration which  
is frequently tinged with blood; it may also  
terminate by suppuration and gangrene,  
and by an effusion of serous fluid into  
the air cells of the lungs, this takes  
place more frequently when the inflam

... in ...  
... of ...  
... of the ...  
... of the ...  
... of the ...

found on a post mortem exam-  
ination floating loose in the  
cavity of the thorax, forming  
what is called empyema.

Sometimes in this disease as  
well as in peripneumony there  
are to be found one or more  
abscesses formed which are  
called emicai.

The internal surfaces of the  
pleura frequently adhere to each  
other; and in this state the

breathing is not very materially affected by it.

Pneumonia differs from all other inflammatory affections by its occurring with equal frequency at every period of life and variety of habit. Its exciting cause is cold and sudden transitions of the weather from heat to cold.

It frequently succeeds to other diseases, such as the Measles, Small Pox, Catarrh &c.

A disposition is given to this disease by long continued speaking, by severe exercise of the body and by its having affected the person before. It is also frequently produced by frequent intoxication, and by drinking cold water when a person is very much heated and particularly when he is perspiring freely.

It occurs most always in the winter and spring seasons

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

of the year.

The treatment of this disease consists in bleeding in the early stage of the disease, and to be as often repeated as the urgency of the symptoms require. And the orifice should be made large, so as to admit a large quantity of blood to flow in a short time; the blood should be allowed to run until some impression is made upon the system. Tartar Emetic has been very successfully employed in the doses of from six to fifteen grains dissolved in six ounces of water to be drunk in the course

of the year.

*[Faint, illegible handwriting throughout the page, likely bleed-through from the reverse side.]*

of the mag. gentle laxatives are to be given at  
the same time, purging with the neutral  
salts is to be employed, and refrigerants  
such as nitre are to be used. diaphoretic  
-es particularly the *asclepias tuberosa*  
and the *asclepias decumbens* are highly  
recommended in the form of infusion in  
the dose of a tea cupfull every two hours  
the best expectorants are *Spicacuanha* and  
antimony. Opium is never to be used during  
the high inflammatory stage of the disease  
and it should be used with the utmost

caution when it is more advanced as it  
will otherwise check the expectoration, the  
steams of warm water and vinegar is highly  
advantageous when inhaled so as to promote  
expectoration.

Blisters are of great service but are  
inadmissible as long as the pulse conti-  
nues hard, and the inflammation has  
been subdued by venesection. when the blis-  
ter begins to draw half a pint of barley  
water with a scruple of nitre dissolved in  
- should be drank by the patient every hour

till the blister has completely drawn. It

should be kept running as long as any pain

is experienced. If the disease has terminated

by suppuration advantage will be derived by small

and frequent bleedings and the tincture of digitalis

is particularly if the difficulty of breathing

is very distressing. The diet must be light and

easy of digestion. The patient's strength must

be supported by light and nutritious food

Paracentesis Thoracis is to be performed if

occasions require it.

Hesperia.

designate the space or real nature of the disease, the convulsive  
struggling paroxysm, the variable and inconstant temper, the sen-  
sation of a ball which threatens suffocation, the copious discharge  
of limpid urine, characteristically belong to Hysteria, and  
are never seen in Hypochondriasis when it is strictly idiopathic,  
while on the other hand, the sad and dejected countenance, the  
spirit of despondency which infuses itself into the actions, the mel-  
ancholy gloom which sorrow and anon awaits the ill-fated sufferer  
pathognomically belong to Hypochondriasis are not necessarily  
connected with Hysteria and indeed are rarely if ever seen in it.

A disease assuming as this not unfrequently does every variety  
of form, exhibiting a collection of symptoms various and conflicting,  
assimilating itself to diseases at once unlike in complexion, and  
diversified in character, has not only proved an abundant theme  
for nosological disputation, but affords ample grounds for predica-  
ting the belief that there exists no inconsiderable disarray of the  
mind, as well as the vital functions. — Though deemed of little  
importance by medical writers, it is nevertheless the most difficult  
in its treatment of all the nervous affections, rendered so perhaps  
by its frequent connection and intimate association with other  
affections.

The different temperaments have been too little regarded, and indeed (as we conceive) misnamed by authors, we trust it is with becoming deference, that we endeavour to combat a theory which has so long obtained and been considered orthodox among us; That which has been familiarly recognised as Sanguine should, if we regard the facts exhibited by anatomical research have received the appellation of Nervous, and that denominated the melancholic, the appellation of Sanguine, the nerves being proportionally larger than the blood vessels in the former, & vice versa in the latter.

In accordance with all chronic affections, Hysteria develops itself in persons of mobile, irritable, and highly nervous temperament, and those thus predisposed are liable to its invasion, at the age of puberty, more especially if by the intervention of any untoward circumstance, the menstrual evacuation, be prolonged or obstructed. — Phenomena of the paroxysm: It sometimes takes place suddenly, unaccompanied by previous warning, or any ostensible excitement, (more especially does this happen) should the patient have been the subject of repeated attacks: frequently however it is ushered in by some premonitory signs, such as great depression of spirits, anxiety of mind, palpitation of the heart, a sense of nausea, flatulency, difficulty of breathing, sudden effusion of tears:

But it more frequently happens that a pain is felt about  
the flexure of the colon, gradually passing with a sense of disten-  
sion upwards towards the stomach, thence to the upper part of the  
pharynx, occasioning by its pressure great annoyance, this has been  
called "Glofus hystericus" the fit ensues with coldness and shivering  
sometimes with stupor and insensibility. the body is mitted  
backwards and forwards with violent agitation, gnashing of teeth,  
inability to swallow, a frothy saliva is discharged, the muscles of the  
trachea are violently and variously affected, giving rise to laughing  
which alternates with crying incoherent expressions, and temporary  
delirium: - the limbs are violently agitated, fists firmly clenched  
so much so indeed that no force which you can employ is sufficient  
to open them, the sphincter vaginae and sphincter ani muscles  
are liable to the invasion of spasms of so spastic a character indeed  
to forbid the introduction of a clyster pipe - The violence and con-  
sequence of the convulsive struggle seems to depend on the degree of mor-  
tality present in the constitution, in some it is feeble the person lying  
tranquilly in profound sleep without sensation or motion, whilst in  
others it is exceedingly violent, exhibiting contractions as rigid as  
those of Tetanus. A Ricough of the most obstinate and distressing  
character not unfrequently attends this disease, it being the most

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

prominent, nay, almost the only symptom, its duration is uncertain, frequently, subsiding after a short period, again continuing for several days, threatening, by the exhaustion it engenders the life of the Patient, the equal degree of uncertainty characterizing the continuance of the paroxysm, terminating occasionally in an hour, sometimes however it is protracted to twenty four or even forty eight hours:— when at length the paroxysm has subsided the patient is seemingly, almost exhausted, lies in a stupified and apparently lifeless condition, during this comatose state there is often a temporary typhoid or elastic distension of the stomach and bowels which leaves them in a very sensitive condition. The exercise of sense and motion gradually returns without any consciousness of what has transpired save only a vague and indistinct recollection of some of the accompanying circumstances.

**Prognosis:** However formidable and alarming the symptoms of an hysterical fit may seem, the immediate danger arising, is often very inconsiderable; but should it develop itself in those in whom there exists a strongly marked hysterical habit or temperament, and its recurrence become frequent, then or under other circumstances, we could not but feel some degree of solicitude or anxiety lest it should assume the Epileptic character and indeed completely merge itself into Epilepsy and thereby become incurable. — **Diagnosis:** Hysteria is capable of counterfeiting with most astonishing accuracy with limited or perhaps little exception

almost all of the diseases which are incident to the human family, the mention of a few however is deemed sufficient to show the correctness or prove the validity of the position. A counterfeit canine madness with its accompanying symptom Hydrophobia. Sometimes there will be a smart pain in the throat unaccompanied by inflammation or even redness which is nothing more than Neuralgia, occasionally there will be an hysterical cough counterfeiting Diphtheria: Sometimes it concentrates its force upon the teeth in which case it is not removed by the extraction of the tooth; it unfrequently develops itself in the form of nervous headache in the forehead, a hot spot and a cold one. The muscles are subject to its invasion with acute pain assimilating itself to, or counterfeiting Rheumatism but there will be no excitement of the vascular system. Asphyxia sometimes takes place which has vulgarly been called a "trance". There is almost every variety of pulse, in many cases it is natural, often however it is weak, frequent, quick or slow, which last circumstance does not generally denote an affection of the brain, but when slow, tense and hard the brain is implicated. The lungs are frequently with much difficulty expanded, the abdominal muscles drawn towards the spine as in the or last stage of Cholera. Having mentioned only the more prominent distinguishing characters of Hysterical Chondriasis and Hysteria it may be necessary to contrast them

further or speak of them a little more in detail. Hysteria manifests itself for the most part in the sanguine and irritable, making its invasion about the age of puberty, its attack often sudden and sometimes violent, accompanied with globus hystericus and frequently much spasmodic affection; Hypochondriasis on the contrary attacks the sluggish and melancholic, makes its appearance about the thirty fifth year, a period at which hysteria is either manifestly declining or has totally subsided - its advances are slow and almost imperceptible - tedious in its duration and difficult to eradicate; Hysteria is for the most part a corporeal, Hypochondriasis a mental disease the former an affection of the irritative, the latter of the sensitive fibres. From syncope it may be distinguished by a careful analysis of its symptoms there is for the most part a total cessation of pulse, distorted or contracted face ghastly countenance without any respiratory motion of the chest whatever; whereas in Hysteria the face is more distended or expanded and a pulse though weak and languid and this condition may and not unfrequently lasts ~~several~~ <sup>several</sup> days for a day or two which never happens in syncope. There is an essential difference existing between Hysteria and Apoplexy in addition to the deprivation of sense and motion the breathing is uniformly laborious and oppressed, accompanied by stertor, which does not

occur in Hysteria. That very peculiar and much remarkable pre-  
monitory symptom which characterizes Epilepsy, and which has re-  
ceived the appellation of Aura may be regarded as one of the most  
striking criteria between these affections. In Epilepsy too the mus-  
cular power is generally less extensively affected, while the intellect-  
ual is much more so, in consequence of the very great distension of  
the vessels of the Brain producing Coma: In Hysteria the nerves are  
primarily affected, the brain secondarily, whereas in Epilepsy the brain  
is the seat of the disease, the nervous system becomes implicated con-  
sequently. ... Cause. Though Hysteria is in many instances a truly  
nervous affection, even in its incipient stage, yet a disease the phenom-  
ena of which exhibit such a concatenation of symptoms, a train at  
once so varied, and complicated that our attention should with equal  
propriety be directed to the stomach - alimentary canal, as also to the  
uterine functions. This affection is rarely seen except in those whose  
nervous system is peculiarly irritable and whose constitution exhibits  
great mobility of the nervous system, the *varium et semper mutabile*.  
Those thus constituted are liable to have it called into action by  
the slightest and most transient causes; as grief, excitement, an-  
xiety, passion and indeed any unusual impression as fright, acrimo-  
nies of the stomach and bowels, plethora, mental emotions, and more

especially a turgescence of the uterine functions operate as the occasional cause of the emulsions, which arise in this disease and which manifest more or less of the spastic character, in proportion as the powers of the constitution are more or less vigorous; Great debility from any cause, as suckling fatigue, bad air &c. inducing a languid circulation, the arteries performing their functions feebly, and thereby producing congestion in the venous system, will give rise to this disease. As the exciting causes among men may be enumerated, retention of the Urine, the presence of tough phlegm in the primæ viæ, worms, septicæ affections of the lower viscera &c. Indeed any thing which makes an impaction upon the uniform current (so to speak) of the nervous fluid, will prove a powerful provocateur. Attacks, more particularly the unmenstruated and barren, and is for the most incident to all irregularities of the menstrual discharge.

Treatment, The indications are first to lessen the violence of the paroxysm, and secondly to obviate or prevent the return, by the exhibition of proper remedies during the intervals. In those cases in which the attack is severe and of long duration occurring in a patient young and plethoric with full pulse a liberal abstraction of blood may be made especially should

There exist a suppression of menstrual evacuation, pungent applications may be made to the nostrils, while at the same time the temples should be bathed with ether, face and neck may be sprinkled with cold water; and warmish together with friction be applied to the extremities. The peristaltic action of the bowels should be encouraged by the administration of stimulating and astringent injections. Should there be no reason to apprehend that the disease has arisen from a disordered state of the stomach from crude or indigestible substances, the exhibition of an emetic will be of essential service frequently in cutting short the progress. Of the utility of emetics in a variety of spasmodic diseases, we have the concurring testimony of many of the most eminent practitioners, <sup>ancient</sup> as well as modern. comparatively few however have recommended their employment, in this affection, in a form of which they are eminently useful. A total suspension of the animal functions characterizing the form here alluded to; the heart beats apparently in profound sleep, respiration is performed slow and without any ostensible effort. countenance pale, eyes sunk and contracted; these symptoms are doubtless referrible to a laceration, in the circulatory system, causing congestion of the thoracic & abdominal viscera which is speedily removed by the exhibition of an emetic.

In the milder forms of the convulsive fits, Asafoetida, Galbannum  
Castor, musk, camphor, valerian &c. will be found serviceable. In  
those however of a more violent and spastic character, we should  
employ stimulants the most powerful and efficient, as Opium, brandy,  
ether, ammonia &c. put them into a warm bath and bleed if the pulse  
be hard. It sometimes happens that Hysteria even in its incipient  
stage is characterised by a high degree of action, arterial as well as  
muscular, and the nervous system is so wrought up, that nothing  
but blood-letting will avail, by the neglect of which, the life of the  
patient would be greatly endangered in the convulsion which would  
ensue. The fact too that it not unfrequently degenerates into Epilepsy  
and even Apoplexy furnishes an additional argument for the ab-  
straction of blood. Sometimes there is violent pain in the back ex-  
tending to the sternum, occasioning by its severity, pale, gassy coun-  
tenance, and a pulse scarcely to be felt, under these circumstances  
we should employ opium and other stimulants; but this affection  
of the back when accompanied by fever, with hard pulse the womb is  
inflamed, and we should have recourse to the lancet and other  
antiphlogistic means. - Symptoms of Dyspepsia often accompany and  
sometimes produce this disease such, as cardialgia, acidity with a burning  
sensation in the stomach which may be removed by an emetic or Alkaline medicine.

It is to the intervals however that our attention should be directed; all  
robustive measures, are we conceive of the greatest importance: indeed  
the advantages arising from a strict observance of the means of prevention  
are incalculable, and he who fails to avail himself of these resources is  
not only guilty of direct and palpable negligence, but is at the same time  
withholding that which promises to afford one of the best sources of  
relief for the eradication of this disease. Our attention should pri-  
marily be directed to the state of the patient's mind, sedulously endeavor-  
ing to preserve that equanimity upon which depends in a very  
essential degree, the permanency of the cure. We should avoid exciting  
curiosity, awakening a passion, or calling into exercise any solici-  
tude, anxiety or desire, which cannot be gratified, and thus guard a-  
gainst all predisposing and exciting causes. In a full plethoric  
state we should obviate the excitability of the system by the lancet, exer-  
cise, and the occasional exhibition of purgatives. A generous diet  
has been recommended, to this however we cannot but object as nothing  
better calculated to engender venous plethora, which, so far from  
preventing would doubtless give rise to this affection, a spare  
diet conjoined with the performance of more labour than they  
have been accustomed to will accomplish much in the preven-  
tion of this disease. In languid and relaxed constitutions.

<sup>20</sup>tonics, are obviously indicated, such as the preparations of Iron  
Steel, bark and many of the warmer sedatives and antispas-  
modics, Asafoetida Camphor &c. with regular hours, exercise on  
horse-back: if there be present a morbid condition of the men-  
strual function, it should receive immediate attention - The  
practice of ~~early~~<sup>rising</sup>, as also of retiring early should be rigidly en-  
forced. The custom of sleeping on feather beds cannot be too high-  
ly deprecated, and consequently its indulgence, should by all  
means be prohibited, in winter as well as summer: Exercise before  
breakfast, except in bad wet weather is of great importance. Water-  
ing places not infrequently exert a very beneficial effect, because  
of the novelty and pleasure they afford - The cold bath in  
summer and the warm in winter is a valuable prophylactic.  
Laziness should carefully be guarded against as it will some-  
times give rise to this disease, and can only be removed by  
the employment of drastic purgatives. When they are subject  
to cramp or spasm of the legs, they should immediately jump  
out of bed, this will frequently remove it, should it not remove  
ligatures may be employed though disagreeable they are of con-  
siderable advantage, immersing the feet in warm water and the  
employment of friction previously to going to bed will effectually

Remove it. When however the cramp or spasm manifests itself  
in the stomach, we should have recourse to stimulants the most  
powerful, and efficient, as Opium ether, ammonia &c. Should  
there be present any old or chronic affection of the Spleen, Liver  
or stomach, it should be removed by exciting a slight Mercuri-  
al Ictericism. Where it occurs in early life, and the accompa-  
nying circumstances justify the belief that there exists too in-  
ordinate a degree of morbid salacity, we should unhesitatingly  
commend a speedy marriage as best calculated to afford  
the surest remedy.

# Preface

If it were not known, I should think it proper to acknowledge, that in writing a dissertation on the subject I have selected, I can have no claim whatsoever, to originality, in the greater, by far greater part of it. Indeed the title of original, can only be granted to a few remarks, I have inserted in different places; inserted, in the true sense of the word, as in all instances, they are made, from theoretical views, but these I have endeavored to establish upon the firm principles of medicine, though in one instance they have led me contrary to what, has been said to be the result of experience.

To Dr. Potters lectures, Dr. Charles late work on the practice of medicine, and Dr. Johnsons treatise on diseases of the digestive organs, I am principally indebted for assistance in writing this dissertation. I have selected from all, indiscriminately, often without mentioning the author.

The seeming presumption there may be in the attempted criticism on a part of the practice of Dr. Keble, it is expected with considerable confidence, will be removed or extenuated, from the consideration of the necessity and demand for some animadversion, which necessity and demand, it is hoped, are supplied in some degree, by the remarks that have been made.

# Cholera.

The Cholera of adults, commonly called Cholera Morbus, though universally acknowledged as one of the most dangerous <sup>diseases</sup> to which the human body is subject, if left to itself, is the easiest cured if properly treated. It has been but a few years since the pathology of this disease was understood, and as a false theory will always lead to inefficient or injurious practice, Cholera was as badly treated, as its pathology was misunderstood. The disease had been considered as dependent on a redundant secretion of bile, till Dr Johnson exposed this pathological error, and pointed out the true cause of the disease, which immediately caused a change in the practice, the success of which proves, that the pathology of the disease is now well understood. Dr Johnson remarks that authors from the days of Hippocrates, down to those of Saunders, were led to the conclusion that Cholera depended on a redundant secretion of bile, by keeping an eye, rather on effects, than on causes. They totally passed over the several links in the morbid chain, preceding the discharge of bile, and thereby confounded a salutary effect, with a proximate cause. Dr Eberle describes this disease more fully, and satisfactorily than any other author. Cholera Morbus most frequently makes its attack very suddenly, the first symptoms are pain, and a sense of tension in the epigastrium, which are soon followed by violent colic pains about the umbilical region accompanied with exceedingly distressing nausea. In a few moments, vomiting and purging com-

monce with great violence, sometimes the vomiting continues an hour or so before purging takes place, but often both the vomiting, and purging commence at the same time and continue with but little intermission, until the system is exhausted, if speedy relief be not obtained. During the intervals between the attacks of vomiting, the patient is usually harassed with continual nausea, and an indescribable feeling of distress in the epigastrium. The alvine discharges, and the fluid ejected from the stomach, are at first without any admixture of bile, the stools at first are thin and watery, as in common diarrhoea. After the disease has continued an hour or so, however, the bile begins to make its appearance pretty copiously in the evacuations, and towards the conclusion of the disease, the fluid discharged consists in many instances, almost entirely of bilious matter. Severe tormina and cramps in the abdominal parietes, and extremities, attack with the vomiting and purging, and become more and more severe and continual, as the disease advances, and the purging and retching become almost incessant. One of the most distressing affections belonging to this disease is the extremely painful cramps, which in severe cases, occur in the abdominal muscles, & in those of the inferior extremities. In cases of less violence the cramps are confined to the muscles of the leg, but in very severe attacks, the muscles of the trunk, with the upper and lower extremities are alike affected in this way. There is usually great thirst, but every thing received into the stomach is almost immediately thrown up again.

Sometimes there is severe headache, in consequence of the sympathy of the head with the stomach. The patient complains of great heat in the stomach and of a burning sensation in the rectum, produced by the acrimonious bile. As soon as the disease is completely developed, the pulse is small, feeble, irregular and intermittent. - the hands and feet become cold, - the countenance pale, shrunk and expressive of great distress. A great degree of languor, debility, and faintness, amounting sometimes to syncope suddenly comes on, sometimes attended with colligative sweats, and other symptoms, which often destroy the patient in twenty-four hours, - frequently patients die in the course of two or three hours, and sometimes in a shorter period. In the Cholera of India, which is the most extremely fatal variety, the patient is suddenly seized with great prostration, - a scarcely perceptible pulse, - cramps in every part of the body, and all the symptoms of the milder forms of Cholera, highly aggravated. If the first stage of the disease is survived, which is not common, the liver begins to pour out a large quantity of bile, thick and highly vitiated, which may be regarded as a favourable indication in the disease. It cannot be wondered that a superabundance of vitiated bile in the stomach, and intestines, was formerly, and by some is yet, regarded, as the immediate cause of Cholera; When the discharge of bile from the stomach and bowels, is the most prominent feature in the disease, - but by these pathologists, what is considered the first stage of this disease, is overlooked, and one of the consequences, the morbid se-

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

erection of bile, is taken as the cause. From the description of Cholera as given by Sydenham, and other authors, we learn that the stools at first are without admixture of bile. - nor is the bile discharged from the stomach till the disease has continued some time. At length, however, a great quantity of vitiated bile appears, and it is accused of being the cause of all the mischief. The remote or predisposing cause of Cholera is manifestly high atmospheric temperature. It is much more frequent during the months of August and September, when cool nights, alternate with hot days, tho' as Sydenham observes, that both in hot climates, and in hot seasons, of mild climates, occasional falls of rain have been particularly followed by epidemic Cholera. This circumstance tends to elucidate and confirm the pathology of the disease, now generally received. Heat predisposed to cholera by inordinately exciting the cutaneous and hepatic functions, thus inducing a state of indirect debility, and when from exposure to cool and damp night air, the perspiration is checked, and the hepatic secretion through sympathy, the blood retreats from the surface to the internal vessels, when the liver and portal circulation, the stomach and capillaries of the mucous membrane of the intestines, become engorged; which congestion it may be presumed produces the morbid irritability of the two latter organs, and consequently the characteristic phenomena of the disease. Miasmata has nothing to do in producing this disease, except incidentally: but if the system be under the influence of miasma, which as a powerful agent in deranging the functions of the liver, is well known, and the person is exposed to heat, the predisposition to Cholera, will be enhanced very considerably, and

if the disease be excited, when the system is then under the combined operation of miasma, and high atmospheric temperature, no doubt but it will be of a more dangerous character, and the treatment after the first symptoms are subdued, would have to be modified.

Cholera is excited by other causes besides cold applied to the surface of the body, viz. by drinking cold liquors, - taking indigestible and irritating articles of food. - All articles of food to which the stomach is not accustomed, and also such articles as excite the stomach in different ways, as drinking milk after eating fresh fish, will most certainly excite cholera, but causes of this kind never produce the disease unless the system is predisposed to it, by a debilitated state of the digestion organs, or by general prostration of the system from the influence of high atmospheric temperature. Dr. Eberle gives the most satisfactory explanation of the extreme irritability of the stomach and bowels, and the incessant vomiting and purging: he ascribes it to hepatic torpor, and congestion in the portal system of vessels give rise to this morbid condition of the alimentary canal? or are we to consider this state of the liver, and the general engorgement of the portal vessels only as concomitant phenomena, and in no way causative of the characteristic gastric and intestinal affections? The fact that the symptoms begin to abate almost always as soon as the liver resumes its function, and pours out a copious flood of bile, strongly favours the opinion, that hepatic torpor and congestion have no small share in the production of the gastro-intestinal disorder. In the malignant grades of bilious fever, the vomiting during the first stage is often incessant, and extremely distressing; and the fluid ejected is generally wholly free from bilious matter.

If death takes place in this stage, the liver and the vessels

of the stomach are always found exceedingly engorged with blood, but when large evacuations of bile take place, an abatement of the symptoms usually ensues.

In the Cholera of India, in subjects who die in the first stage, and in Cholera infantum, the liver and mucous membrane of the intestines are found upon dissection to be greatly engorged with blood.

Treatment. If vomiting alone is present, an injection will be proper; and if purging only exists, an emetic will effect a cure. — These remedies can only be employed in slight cases, they may excite both symptoms, but the disease will be mild, and it will require a much smaller quantity of opium to effect a perfect cure. But in the perfectly formed Cholera, nothing but Opium in some form is to be relied on. The first and principal indications in the treatment of the Cholera of adults, are, to allay, as speedily as possible, the morbid irritability of the stomach and bowels, — to check the inordinate secretion of bile and determine the circulation from the internal to the external parts. These indications are fulfilled by giving large doses of Laudanum, till the vomiting and purging are stopped, assisted by a sinapism laid over the epigastrium; or what is better than the sinapism for equalizing the circulation by inviting to the surface, the application of cloths wrung out in hot water, to the stomach and extremities. The sinapism to the epigastrium, and hot cloths to the extremities might easily be used conjointly, and undoubtedly with more benefit than either remedy alone. The sinapism would aid more the Laudanum in allaying the irritability of the stomach, and the hot cloths would communicate warmth to the cold extremities.

and thus produce general reversion to the surface.  
In the September number of the Journal of Medicine &  
Surgery, edited by Dr Smith, external warmth is highly  
extolled in the treatment of Cholera Morbus. In this  
Journal I first saw external warmth as particularly  
and forcibly recommended, as it appears to deserve. Tho'  
it is mentioned by most authors, but in such a vague  
and undecided manner, that it will scarcely catch the  
eye of the reader, as a remedy at all relied on, or used  
in the treatment of the disease. The writer in this Jour-  
-nal says "there is no remedy employed in the treatment  
of Cholera, to which he ascribes more importance than  
to external warmth; he has rarely seen the disease  
yield till the surface became warm, and as rarely saw  
it continue, when warmth had once been established.  
He plunges the feet and legs of his patient in warm water,  
applies cloths wrung out in hot water to the stomach and  
around the abdomen. A mode of applying warmth and  
moisture more generally to the surface is recommend-  
-ed; which consists in plunging billets of wood into hot  
water. These are to be wrapped in cloths and applied  
around the body. When warm water alone does not  
seem sufficient to stimulate the surface to its nat-  
-ural action, salt and mustard are added to the water  
in which the feet are plunged.

In violent cases, it is useful to give less than ʒss of  
Laudanum at the first dose, and the same quantity  
mixed with a small portion of warm water thrown  
into the rectum. If vomiting occurs soon after the first  
dose is taken, the Laudanum should be repeated in doses  
of ʒss or ʒss every fifteen minutes, until its influence  
on the system be fully obtained. We want neither calo-  
-mel, nor emetics, we want nothing to wash out the

stomach, such as chamomile tea, balm tea, or warm water in the treatment of this stage of the disease.

Dr. Syde speaks highly in favour of minute and frequent doses of Calomel in Cholera, but such treatment cannot be depended on. After the violent symptoms are subdued by Laudanum and the other means, if there remains pain in the side, and the narcotic and constipating effects of opium are manifested, a few grains, or half grain dose, of Calomel, or a few grains of blue pill, with a grain of Spicacuanha, should be taken every evening upon going to bed; or by rubbing the side with a little mercurial ointment, will soon relieve those symptoms, by stimulating the action of the liver to a regular secretion. Emetics above all remedies should be forbidden; there can be no objection to them, when there is not a perfectly formed Cholera, when purging alone exists, but in the completely formed Cholera they are almost certain death. When the laudanum is immediately rejected by the stomach and it cannot be made to operate on the system, either through the stomach, or by injections, we may obtain its effects by external application, with almost the same promptitude and certainty as if it were retained by the stomach. For this purpose the cuticle should be removed from the epigastrium; which may be speedily done by means of nitric acid; two parts of this acid diluted with one of water, is to be applied with a sponge upon the region of the stomach, and as soon as the patient feels considerable pain, the part is to be washed with a solution of the Carb. Potassae. The cuticle may now be easily detached, and upon the raw cutis from ten to twelve grains of morphia may be applied, either in the form of plaster, or by sprinkling the powder on the part, and covering it with a piece of lint thickly spread with

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

simple evacu. By this procedure we obtain the advantage of a powerful counterirritating application, and the full influence of the Opium. Instead of sinapisms to the epigastrium, we may use strong rubefacient embrocations, & when exhaustion is great, and cramps of the extremities seen much benefit will result from rubefacient frictions, particularly with a strong tincture of Capsicum. Brandy may be given in the last stages of the disease, when the pulse sinks, and the extremities become cold. The patient should be wrapped in flannels, soaked in hot brandy. recourse also must be had to diffusible stimuli. Dr. Clarke recommends a solution of Camphor in vitriolic ether, as one of the best articles of this kind. - of a solution of Camphor in Ether ʒj - a tea spoon full should be given occasionally till reaction is brought on.

After the disease is subdued the patient should take light and nourishing diet. - wear a flannel roller round the abdomen, and if the digestive powers remain weak, some bitter infusions with a few grains of Carb. Ammoniac should be taken three or four times daily. Dr. Potter remarks in his lectures, that there is no case of Cholera Morbus, while the pulse is perceptible, that cannot be cured if a sufficient quantity of Laudanum is administered. - to an adult he never gives less than ʒss the first dose, and directs it to be given without weight or measure, only directed and governed by its effects. Dr. Potter gave to one patient an ounce and a half of Laudanum, before he could subdue the disease, but his patient was well and at his usual business the next day. Dr. P. has never found it necessary to resort to the external application of morphia, but has had the disease to yield in a short time to large doses of Laudanum.

Addendum.

Does not the Spts. Turpentina have just claim to the attention of Physicians, in the treatment of this dangerous malady, from its known & acknowledged virtues in various diseases which resemble in some important respects this disease? Not to speak of all the diseases it has been used in, every one knows of Dr. Physic's practice of giving it to check the violent vomiting in yellow fever, and of its almost universal use in all spasmodic affections. In the malignant form of bilious fever, or yellow fever, the vomiting in the first stage is often violent, but the fluid thrown up is free from bile; if the patient dies in this state, the liver and vessels of the stomach are found greatly enlarged with blood. It was in this prostrated state of yellow fever Dr. Physic used the turpentine, and we see the resemblance of the symptoms and the perfect resemblance of the post-mortem appearances in the first stage of Cholera ~~Roux~~ ~~Roux~~ this form of yellow fever, to the symptoms and appearances in the first stage of Cholera ~~Morbus~~, tho. in the two diseases they are produced by very different causes. The practice of using the in any variety of yellow fever is very justly condemned by the best Physicians of the present day, but as its forbidden on account of the fear of consequent fever, that objection does not exist in its application to this disease. The turpentine would be particularly worthy of a trial, when the stomach will not retain the Laudanum long enough, for it to produce its effects, or when there is an idiosyncrasy forbidding its use. In such cases the use of turpentine largely, internally and externally, would appear to hold out high hopes of relief. —

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

# Cholera Infantum

The cholera of Infants, differs in several important respects from Cholera Morbus. It comes on very gradually, and frequently more or less diarrhoea continues for several days before vomiting supervenes. — it is liable to assume a chronic form, which is never the case in the Cholera of adults, and is always attended with cerebral affection. In the majority of cases of Cholera infantum Dr. Potter remarks, there cannot be said to be fever unless the heat of the abdomen and head is called for. The liver is as inactive in this, as in the preceding form of Cholera in the first stage. If the disease does not end fatally in a few days, the patient begins to emaciate, the pulse becomes small, frequent, and irritated, sometimes incalculably frequent. Twenty or thirty stools will sometimes be passed daily, and often contain articles taken into the stomach pass off unchanged. The face frequently colourless showing the torpid state of the liver; the thirst is very great, children who can talk, sometimes say the faces burn them, the extremities become cold; the abdomen hard and swelled, the head and abdomen extremely hot, so much so, that the whole heat of the body appears to be centred in those parts, the skin is dry and harsh, the eyes dull and sunk, or glassy, the countenance pale and sunk, the child sleeps with the eyes but half closed, rolls about his head when awake, and if the disease is not subdued by proper remedies, the little sufferer sinks into a state of insensibility and coma, and at last dies under symptoms resembling those of hydrocephalus. When Cholera infantum is produced by moderate heat, it changes

The object of this paper is to present a summary of the results of the experiments conducted during the past few months. It is intended to serve as a guide to the student in his studies, and to show the progress of the work. The paper is divided into three parts: the first part contains a description of the apparatus used; the second part contains a description of the experiments; and the third part contains a summary of the results. The first part is divided into two sections: the first section describes the apparatus used in the experiments, and the second section describes the apparatus used in the experiments. The second part is divided into two sections: the first section describes the experiments conducted during the past few months, and the second section describes the experiments conducted during the past few months. The third part is divided into two sections: the first section contains a summary of the results of the experiments, and the second section contains a summary of the results of the experiments.

of weather, it is more inflammatory than when heat is great and constant heat producing greater ability. In the latter case, the power of the system being more prostrated, and reaction not taking place to the same degree, the disease is more difficult to treat. It is said, when the disease is protracted in its course, aphthae appear on the tongue, and inside of the cheeks, the face acquires an œdematous appearance, the alvine discharges become so acid as to excoriate the rectum; and towards the fatal conclusion spots of blood under the cuticle sometimes appear on various parts of the surface. The duration of Cholera infantum is very variable, it may prove fatal in five or six hours, or continue for weeks, and even for months, until the child is a mere skeleton, and yet the case terminate favourably. When the disease does end fatally, death takes place in the majority of cases before the end of the fourth day. If death takes place early in the disease, the vessels of the liver and mucous membrane of the alimentary canal are engorged with blood, and when the disease has continued for some length of time before death, ulceration and even abrasion of the lining membrane of the stomach and bowels are discovered. Heat is the principal predisposing cause of both the Cholera of infants and of adults; still by the symptoms, the duration, and the chronic form of Cholera infantum, it is shown to differ very much from Cholera morbus. This difference I should think is produced by other causes & circumstances besides the irritation of dentition, and the contaminated air of crowded cities; that dentition and contaminated air assist in producing the disease is proved by its occurring almost exclusively during the period of primary den-

tion, and being much more prevalent in large and crowded cities, than in the country. The difference is caused by children not being exposed so directly and suddenly, neither to heat, nor to the exciting causes of the disease. In adults the system is suddenly exposed to a great degree of heat, and generally exercise being taken at the same time amidst the high degree of temperature in bringing on a state of prostration and indirect debility. During this state of great debility, the system is also exposed more suddenly to higher degrees of the exciting causes, such as cool and damp night air, or by taking large draughts of cold fluid, or indigestible articles of food, the exciting causes become more powerful than those that act on infants. From the great violence of the causes operating on adults, the reaction of the system is almost entirely prevented. The only symptom of reaction in Cholera Morbus is the increased secretion of the liver, but in Cholera infantum there are almost always distinctly febrile symptoms, the extreme hotness of the abdomen and hard evidencing reaction; but the flowing of bile which alone shows reaction in Cholera Morbus, is entirely absent in Cholera infantum. In both varieties of Cholera the stomach and alimentary canal, primarily manifest the symptoms of disease, though in both the liver is more dangerously disordered & to it we have to direct our remedies principally. In the second stage of the Cholera of adults, from the enormous secretion of bile, which is constantly irritating the extremely irritable stomach and bowels, aggravating the vomiting and purging, we are compelled to give in large doses such articles as will stop the secretion, and when this is done, the opposite course is pursued, such articles must be given as will gently excite the liver to its securing process.

The first part of the paper is devoted to a general  
discussion of the subject, and is intended to  
show that the theory of the origin of life  
is a subject of great importance, and one  
which has attracted the attention of the  
public mind in a very unusual degree.  
The second part of the paper is devoted  
to a description of the various forms of  
life which have been discovered, and to  
a discussion of the evidence in favor of  
the theory of evolution. The third part  
of the paper is devoted to a discussion  
of the evidence in favor of the theory  
of the origin of life, and to a  
conclusion that the theory of evolution  
is the most reasonable one.

But in Cholera infantum, a similar course of treatment cannot be pursued for several reasons, - first, because of the greater general reaction, the higher fibrile excitement, secondly - because of the peculiar cerebral affection, which forbids altogether the use of the article decidedly the most valuable, and almost the only remedy in the Cholera of adults; as it is well known that the effects of opium in all its forms are particularly determined to the brain, and lastly because of the torpor of the liver, which opium would apparently serve to increase. Therefore in Cholera infantum opium is never used to restore the functions of the liver and skin, and to obviate irritation and congestion in the brain. Heat acts in the same way in predisposing to Cholera infantum, as it does in Cholera Morbus. The functions of the skin and liver being highly excited thus bringing on a state of indirect debility. If the child be now exposed to the damp night air, or damp clothes are put on it, or acid is taken into the stomach, such as the unripe acid fruits, or anything that disturbs the stomach, the disease will be excited. If the child has worms, or the mother's milk disagrees with the child's stomach, (which it will do by the mother eating acid fruits or pickles) the disease will be very apt to be produced. Children not weaned, are not so apt to have the disease, therefore children should not be weaned in a large city, between the months of June and October. In this as in the other variety of Cholera, there is always great congestion of the liver, and of the vessels of the mucous membrane of the stomach and bowels. High atmospheric temperature - the irritation of dentition, - and the impure air of cities are the principal remote causes of Cholera infantum.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

The latter cause must have considerable share in producing this disease, as well as, the great heat of cities. Miasm of fluxion has nothing to do in producing this disease, this is proved by the disease never assuming a remittent form, nor is it ever preceded by a chill, and further by its prevailing in June and July, before the diseases of miasma make their appearance, and disappearing at the time they commence, and by its prevailing in countries where miasma is known not to exist. The prophylactics, are clean linens in dress and bed, washing the child in cold water, the use of flannel gowns, ~~as the bed clothes are apt to be thrown off~~; it is the cold mornings before day, after having been exposed to the heat of the previous day, which most frequently excites the disease. Abstinence from all fruit, and indigestible food should be, by all means, attended to. The reason that children are more subject to this disease just after they are weaned, is, the practice of giving them animal food, and that which is not easily digested by their delicate stomachs.

**Treatment.** It appears that torpor of the liver and脾, in connexion with cerebral irritation, constitutes the immediate cause of the excessive irritability of the stomach and bowels. Our principal object must be, therefore, to restore these two functions, and to decidedly obviate irritation and congestion in the brain. To answer these purposes Dr. Pott's practice is to administer very small doses of calomel. To a child two years, he gives  $\frac{1}{2}$  ℥ Calomel two or three times a day, and when younger,  $\frac{1}{4}$  ℥ is sufficient, given the same number of times. If the Calomel is given in large doses, it

prostrates the little strength the child has left, but in small doses, it alters the secretions; the watery evacuations will soon become of greater consistence, and the vomiting and purging cease. Dr. Potter observes that other articles may be given with calomel to assist its operation, but that nothing without calomel can cure the disease; he has used the  $\frac{1}{8}$  ℥ dose, three times a day, and thinks no case requires more than  $\frac{1}{2}$  ℥. He forbids the use of opium as the smallest doses produce such stupor, that the child never recovers from it, but recommends in cases of total failure of the appetite, milk boiled with red oak bark, or black berry root tea, or tinct. Kino; Sometimes one of these will lay on the stomach when the others will not. When acid is on the stomach it is necessary to give a little magnesia before the calomel, this makes the calomel operate sooner and better. Blisters have been recommended, in the last stages but Dr. P. thinks it improper in the first stage; in the last stages blisters may be used to excite the system while tonics are given. Dr. P. remarks, that a patient should never be discontinued of, while the least action of the pulse can be perceived, he says, he never lost a patient in Cholera infantum during his whole practice of thirty five years. The practice of Dr. Eberle, as seen in his late work on the Practice of Medicine, is similar to the preceding in administering minute doses of calomel, but some additional means are advised. He commences his treatment by applying ten or twelve leeches to the temples, the exhibition of small doses of calomel and the acacia, and a large stimulating poultice over the abdomen. He says he is fully persuaded that great benefit will result from local depletion from the

head, as well as, from the application of Usters on the  
back of the neck, or behind the ears. Dr E. gives from  
6 to 4 grs of Calomel in union with half a grain of Ipe-  
cacuanha, every hour or two, and continues this treat-  
ment till the evacuations become mixed with bilious  
matter: he observes that it should be borne in mind  
that as long as the liver remains torpid, the disease  
should be regarded as possessing all its violence, what-  
ever temporary abatement may occur in the vomiting  
and purging, this is a most useful and important  
observation. The appearance of bile whether green  
or dark, is always favourable. Dr E. holds the  
Ipecacuanha in small doses a most excellent antid-  
-oisy to the Calomel, its tendency to counteract the  
inordinat action of the bowels, when given in small  
doses, is well known. When from a tumid, and  
tense state of the abdomen, there is reason to believe the  
bowels are loaded with fecal matter, Dr E. directs  
the quantity of Calomel at each dose, to be increased  
so as to procure its purgative operation; or a dose  
of castor oil to be given. Dr E. also employs exter-  
-nal revulsive applications to the abdomen; rubi-  
-facient and resicating, - but he fortunately remarks,  
that when the habit is phlogistic, and the pulse man-  
-ifestly febrile, leeching both from the head and region  
of the liver are important preliminaries to the em-  
-ployment of resicatives. He also says, the warm  
bath is especially necessary, when the skin is dry &  
harsh, and the pulse quick and tense.

With due respect to the character, and deference to  
the opinion, of Dr E. as a physician of high stand-  
-ing, I think some parts of his practice in this disease,  
may, and should be, subjected to criticism.

That part of his practice, which appears decidedly faulty, and indeed would be positively injurious, is the application of stimulating poultices, or blisters to the abdomen in the commencement of the disease, and particularly, the use of the warm bath, which he especially recommends in that stage of the disease when the skin is dry and harsh, and the pulse quick and tense. The most constant and indeed the essential symptoms of Cholera Infantum, are coldness of the extremities, - extreme hotness of the abdomen and head, and most generally the pulse is frequent and hard, resisting pressure; but in some cases where very high atmospheric temperature has so prostrated the powers of life, that general reaction does not take place, the pulse then is small, frequent & feeble, not resisting pressure; in this case, the head and abdomen may, or may not be hot, but never to the same degree as in the former case.

It is one of the most important, necessary, and at the present time, indisputable precepts in the practice of medicine, that in all diseases, where febrile symptoms of a decided character exist, neither blisters, stimulating embrocations, nor the warm bath, can be employed without doing more injury, by exciting and increasing the circulation, than benefit, by the revulsion and counterirritation produced. If such then be the fact, it is obvious, that the stimulating poultices, blisters, or warm bath, should not be employed, where and when Dr. Keble advises. Leeching at the temples, or behind the ears, will no doubt afford great relief and advantage to the patient; but if the excitant remedies have a place at all in the treatment of Cholera infantum, it can only be during the last stage, when they may be used, to excite the system, while tonics are given, or in the prostra-

-ted, exhausted state of the system, whose reaction has not come on. This last state Dr Eule speaks of, and shows the inconsistency of the practice recommended in the febrile state of the disease, by using in this, the same external stimulating means: he thus remarks, that when from the violence and rapidity of the disease, or its long continuance, the exhaustion becomes very great; - the extremities cold, and the pulse very small and feeble, internal as well as external stimulants, become necessary. Under such circumstances, stimulating frictions, together with the internal use of wine whay, milk punch, or a weak solution of Carb. Ammoniac, are indispensable, to support the sinking energies of the system.

In the febrile state, instead of applying blisters behind the ears, or stimulating poultices to the abdomen, I think it would accord more with the sound principles of practice, to endeavour to equalize the circulation, by applying to the abdomen and head, which are preternaturally hot, cloths wet with cold water, while to the extremities, which are morbidly cold, cloths wrung out in hot water, should be applied.

When the disease <sup>becomes</sup> chronic, attended with great debility and relaxation, the employment of unstimulating tonics are much better calculated to afford relief, than astringents, and absorbents. To relieve the colic pains which occur in the chronic state of this disease, from flatulent distention, a few drops of the oil of Turpentine, or oil of Juniper, have been advised. Particular attention must be paid to the proper regulation of the diet, throughout the whole course of the disease. If the child is weak nothing but the mildest fluid articles of food should be allowed. Articles which most nearly resemble the mother's milk, should be used: boiled milk and water

sweetened, the jelly of hartshorn shavings being added, make a mixture approaching nearest to the nature of human milk. The liquid preparations of arrowroot, tapioca, rice, or sago; thin oat meal gruel, barley decoction, beef tea, or weak chicken broth are proper. Dr. Ferri observes, that he has known the two latter articles, to produce a favourable change on the state of the stomach and bowels. We should be careful in prescribing milk, to direct, that it be used before the cream separates; as the milk, if the cream be separated, will form tenacious coagula on the stomach, which will be very difficult of digestion, as is proved by these coagula passing off entire, with the alvine discharges. The practice of giving what is called pap (which is boiled flour sweetened) is a most injurious one, as the flour forms a heavy, tough, tenacious mass, which is very difficult of digestion.

# Diarrhoea

Diarrhoea is an affection of the bowels  
characterized by frequent and unobscured  
and liquid stools of a feculent character,  
attended with griping pains of the bowels  
owing to the irritability of the intestines  
without tumours, and generally accompa-  
nied with fever.

Dr. Cullen says diarrhoea has for its proxi-  
mate cause an increased persistence and  
action of the intestines. In every case of  
diarrhoea the proximate action of the intestines  
is increased, and this depends of it does  
not seem to point out the true pathology  
of the disease. For in some cases the irritability  
of the intestines may be an idiosyncrasy of the  
individual, in which case a much stronger cause would  
be required to produce diarrhoea than in  
other persons, or it may be excited by an  
irritability of the intestines, arising from  
some other cause, the diarrhoea being a consequence

# Diarrhoea

Diarrhoea is an affection of the bowels characterized by frequent and unusually copious liquid stools of a feculent character, attended with griping more or less severe according to the sensibility of the intestines, without tenesmus, and generally unattended with fever.

Dr Cullen says diarrhoea has for its proximate cause an increased peristaltic action of the intestines. In every case of diarrhoea the peristaltic action of the intestines is increased; but this definition of it does not seem to point out the true pathology of the disease; for in <sup>one</sup> case, the irritability of the intestines may be in a natural state, in which case a much stronger cause would be required to produce diarrhoea, than if they were p<sup>er</sup>ternaturally irritable. In another case the irritability of the intestines may be below the natural standard, then a cause

which would act effectually in the pro-  
duction of diarrhoea in the natural state  
of affairs, would in this last have no effect  
It therefore seems more reasonable to say that  
irritation is the proximate cause of diarrhoea  
and the increased peristaltic action of the  
intestines, together with the increased secre-  
tions are the consequences of irritation.

Diarrhoea is an affection nearly akin to Dys-  
entery; indeed it may be said to be the first  
grade of Dysentery; for if it be suffered to  
run on for a considerable length of time, or if  
from any cause it should become aggravated  
it cannot easily be distinguished from that  
disease. The ~~point~~ point of distinction between the  
two, consists in the appearance of the evacua-  
tions; in Diarrhoea the evacuations are of a  
feculent character, whereas in Dysentery they  
consist of mucus and Blood. ~~When~~  
Whenever diarrhoea assumes this character

amely, mucus or bloody evacuations attend  
it with tenesmus, it may with propriety  
be called dysentery.

Cause, many of the causes which produce  
diarrhoea in no, will produce dysentery in  
another, catarrh in a third, and Rheumatism  
in a fourth. Diarrhoea may properly be call-  
ed a catarrh of the intestines

diarrhoea may be produced by cause acting  
directly on the mucous membrane, or indis-  
rectly, through the system. A very common cause  
of diarrhoea is some indigestible article of  
food, such as the skin of vegetables, or  
that of some of the meats not prepared so as  
to be acted on by the gastric juice.

More than this article may be submitted to  
the stomach for digestion, which are diges-  
tible but in account of the ~~immense~~ quanti-  
ty which is sometimes taken in, the stomach  
is unable to dispose of all of it, consequently

That part which has not undergone the di-  
gestive process be suffered to pass along the  
intestinal canal, it will act as a foreign  
substance and diarrhoea will be the ne-  
cessary result. in this case the undigested  
food will generally carry along with it its own  
curd; but may we not suppose that a consi-  
derable quantity of the chyle is frequently  
carried along with it; for we think it pro-  
bable that the irritation may commence in  
the superior part of the alimentary canal  
as well as in any other part of it; if so a  
portion of chyle must necessarily be carri-  
ed off. <sup>perhaps</sup> This may account in part for the  
debility which so often attends diarrhoea  
acting in some manner like the abstraction  
of blood - for as the blood derives its nutri-  
tive qualities from the chyle so the abstrac-  
tion of chyle lessens the quantity of nu-

that part which has not undergone the  
the part to be suffered to pass  
distant as can be, it will not be a  
distant as can be, it will not be a  
of any weight in this case the  
good will generally carry along with it  
but may in not sufficient to  
the old quantity of the ship's rigging  
carried along with it for in that  
all that the contractor may  
the superior part of the  
as well as in any other part of it  
part of it must be kept  
of it in any account  
ability which is often  
of blood for as the blood  
the quantity for the ship's  
of the ship's rigging

tion, which would otherwise be assimilated to the animal machine  
As an undue proportion of food in a healthy stomach may produce diarrhoea so in a weakened stomach a small quantity of food if not of that kind and quantity which the stomach requires, will produce the same effect in this instance  
As a superficial examination we might be led to suppose that the primary defect was seated in the intestines but if attention be paid to the dejections, it will be seen that the stomach is the sole seat of the disease & for ~~the~~ some portion of the ~~stomach~~ ~~will~~ pass off undigested clearly showing that the stomach is in a weakened condition

Diarrhoea Certain kinds of water emetics produce it more especially that of sulphur

tion which would otherwise be necessary  
to the animal's existence  
in a number of parts of food in which  
the stomach may be found to be  
in a weakened state a small quantity  
of food is not of that kind and  
quantity which the stomach requires will  
produce the same effect as the quantity  
as a sufficient examination will  
lead to suppose that the primary  
effect was to act in the stomach  
attention be paid to the symptoms, it was  
to find that the stomach is the  
of the disease for symptoms of  
the first part of the symptoms to be  
by showing that the stomach is  
in a weakened state  
Certain kinds of food  
from produce the same effect as the

ated with lime and salt. cedar which has  
not undergone the process of fermentation.  
unripe fruits, vitiated secretion from the  
liver, and many other irritating causes  
which it is unnecessary to mention.  
It sometimes attends the latter stage of infla-  
matory diseases. It also occurs as symptom  
atic of other diseases occasionally.  
Most of the causes which act directly on  
the mucous membranes of the intestines in  
the production of diarrhoea generally carry  
along with them their own cure, nevertheless  
if the intestines have been in a previous  
labile condition, or the patient be la-  
bouring under some organic visceral dis-  
ease, then causes though apparently trivi-  
al ~~trivial~~, may aid much in the devel-  
opment of a disease not as yet comple-  
tely formed, as well as add speed to that

to be well known on the spot. When the  
the map of the country of Pennsylvania  
the first part, but that it is not  
it is not a very interesting  
which it is necessary to mention  
the same thing. The latter steps of the  
history also seem to be seen in  
the of the disease occasionally  
out of the case which is usually  
the more numerous of the  
the character of the disease  
along with the first was  
if the intention has been  
of suitable conditions for  
having made some progress  
and the second part of  
all these may be made in the  
of a disease not as yet  
fully formed, or well as also

already formed. Amongst the causes  
which which act ~~through~~ the system  
in producing diarrhoea may be mentioned  
heat and Cold: Cold seems to act much  
more effectually in the production of dia-  
rhoea as well as in some other diseases if  
it be conjoined with moisture  
Moisten seems to evaporate the heat ~~from~~ <sup>from</sup> the  
surface, and Cold determines the Blood  
to the deep seated viscera, in consequence  
of which the several organs receive a pro-  
portionate quantity of Blood. The secre-  
tion from the liver as well as <sup>from</sup> the other vis-  
cera becomes increased in quantity, and  
diarrhoea speedily follows.

Diarrhoea prevails epidemically during a sta-  
tion in state of the atmosphere, ~~at~~ <sup>at</sup> towards aequi-  
no when the days are still hot, and the  
nights beginning to be cold with copious

dews, diarrhoea prevails to a considerable extent. Fear sometimes produces diarrhoea  
Progress - Though diarrhoea is not of its  
self a dangerous disease yet there are many  
circumstances which sometimes make it  
formidable, and very often requiring our  
utmost efforts to arrest it

The progress in diarrhoea is deduced  
from the nature of the disease, whether sym-  
ptomatic or otherwise, the age, constitution,  
habits of the individual, the length of  
time it has existed &

if no great irritability, or no organic visceral  
disease exist, diarrhoea resulting from indiges-  
tion, acridities, or irritating doings, consisting of  
feculent matters with vitiated secretions may  
be easily checked, but if great irritability, or  
some of the viscera be diseased it may be  
but the commencement of a troublesome  
disease

Diarrhoea depending on a disturbance of  
the whole system, returning frequently after  
it has been effectually stopped, may even-  
tually prove fatal by producing general debi-  
litude, great debility with loss of appetite &  
When from a dry state of the skin a mois-  
ture supervenes, if the discharges become  
fewer, if the fever disappears as well as the  
grimacing and no increase of debility the  
symptoms are favourable

Treatment The means for the cure of di-  
arrhoea, are first the removal of the cause  
secondly, the allaying of the irritation  
which follows. For removing the cause there  
~~measures are to be used~~, which are least  
likely to produce irritation; very often simply  
by removing the cause will be sufficient to  
effect a cure; if this do not have the desired  
effect it is presumable that the disease is

kept up by irritation to allay this the  
usual means which are used to allay ir-  
ritation must be put in execution  
Diarrhoea produced by indigestible articles  
may be cured by a dose of Castor oil  
That which is produced by improper articles  
of food must be treated by paying atten-  
tion to diet, and submitting to the stern  
ach for digestion the proper kind as well  
as quantity: " <sup>of food</sup> Symptomatic diarrhoea is  
treated on the same general principle namely  
by the removal of the first affection if this  
can be done The consequences which <sup>result</sup> follow  
will most commonly cease without the aid  
of medicine. But there are some symptoma-  
tic diarrhoeas which it would be impos-  
sible to arrest, that which very frequ-  
ently attends the period of dentition may  
be mentioned. In this instance it

seems to counteract the determination of  
Blood to the head, which is want to take  
place during this period, in such a case  
it would be improper to assist it, unless  
it be for the comfort as well as for the ben-  
efit of the patient

Diarrhoea which is caused by the applica-  
tion of cold must be treated on the same  
principles. As in this case the equilibrium  
of the circulation is destroyed, with too  
great an accumulation of Blood in the sever-  
al viscera, it becomes necessary in the first  
place to restore the equilibrium, and treat  
the consequences as circumstances require  
for restoring the equilibrium a powder compos-  
ed of Opium and Opium & Calomel will  
most commonly be sufficient to effect a cure  
Diarrhoea resulting from vitiated secretions from  
the Liver must be cured by removing the cause  
which produced the vitiated secretions

for this purpose The Blue pill may be used  
to diarrhoea exist long it is apt to assume  
the Dysenteric symptoms then it must be  
treated as Dysentery

# Introduction

In compliance with a law of this University which makes it obligatory on every student to write a dissertation, it necessarily becomes a duty with which I cannot dispense, although I feel my insufficiency to do justice to any subject, and in looking around for a suitable subject that of Opium presents itself to my consideration as an article of the Materia Medica than which few are of more importance to a physician in a practical point of view, and which has been perhaps more abused than any article of the Materia Medica with which I am acquainted. It is by the ignorant administered without any regard to the condition of the system or state of disease, and from this circumstance it has lost much of its deserved celebrity. In diseases of children it is a very common remedy and is frequently prescribed by nurses and mothers whenever the child seems unwell and in consequence of its

anodyne quality it often gives the little sufferer ease without  
contributing in the least to the cure of the disease.

But this should not detract from its value, for when  
given in well regulated doses and in a proper condition of  
the system, I think it is not surpassed in point of value  
by any article in the *Materia Medica*.

# Opium

As to the history and preparations of opium I deem it unnecessary to say any thing, as they may be found in nearly all the works on the materia medica.

I shall therefore proceed in the first place to take a cursory view of its effects and *modus operandi*. Secondly speak of its practical application in the cure of diseases, and thirdly say something of the bad consequences arising from an improper use of this article.

<sup>1<sup>st</sup></sup> First of its effects and *modus operandi*. The question whether Opium, is to be regarded as a sedative or stimulant, has been much agitated. I believe the most prudent opinion at present is that it is unequivocally a stimulant. The effects vary greatly according to the quantity given

In small doses the effects are excitement of the nervous and vascular systems, the cerebral functions in particular are rendered more active and energetic, volition is stronger and

more prompt. and a temporary vigour is felt in all the voluntary exertions of the body, and in short a feeling is excited which bids defiance to the ills of life.

If the dose be increased its narcotic effect becomes more developed, a species of ebriety ensues, the blood becomes congested in the vessels of the brain, voluntary motion is diminished, sensibility is lessened, vision is much impaired and finally if the dose be sufficiently large the brain ceases to exercise its control over the animal functions and profound and heavy sleep weighs down every conscious faculty.

If the dose have been very large the sleep becomes more and more lethargic, respiration is imperfectly performed, the blood is imperfectly decarbonised, which tends further to diminish the cerebral functions, until they finally stop with all the other movements of the animal system, such are the immediate effects of a large dose of Opium. there are other consequences however which follow its long continued or accustomed use demonstrating

5

with equal force the deadly influence of this article upon the living body when improperly used, of these we shall say something in another place.

The primary effect of Opium is an action on the sensitive extremities of the part to which it is applied, it is then conveyed to the brain through the medium of the nerves, and from the brain through the same medium to the general system.

In a small or regular dose Opium increases the force and frequency of the pulse. When given in a large dose however its excitant operation is extremely transient and the pulse almost immediately becomes slower and fuller. It lessens irritability and the peristaltic action of the intestinal canal, It sometimes occasions a difficulty and pain in passing urine. It lessens many of the secretions while it increases some others. It diminishes the secretion of the gastric and pancreatic juices. The mucous of the nose bronchia and bowels and likewise the secretion of bile

we shall say something in the paper  
the primary effect of Opium is an action on the  
the excitement of the part to which it is applied  
is then conveyed to the brain through the medium of  
the nerves and from the brain through the same  
to the general system  
for a small or regular use Opium increases the  
and frequency of the pulse. When given in a large  
dose its excitant operation is continued, however  
the pulse is at first irregular, becomes slow and falls  
It depresses vitality and its further action of the  
that case, it sometimes causes a difficulty and  
in passing urine. It depresses many of the secretions  
it increases some others. It diminishes the strength of  
genital and prostatic fluids. The causes of the  
debility and disease and likewise the nature of

6  
air said to be diminished by the action of Opium.

The serous secretions and especially that of the skin are considerably increased. and the aqueous exhalations from the lungs are likewise said by some to be increased.

It at first excites but afterwards diminishes the action of the sensorial powers, hence its applicability in all cases where there is pain and nervous irritability not attended with an inflammatory condition of the system.

From idiosyncrasy there are some individuals who cannot take Opium in consequence of the distressing nausea and headache which it produces, in such cases we may resort to some of its preparations with advantage, there are also a few cases in which it acts as an opient independent of its relaxing effect.

According to our arrangement we shall now proceed to speak of the practical application of Opium in the cure of diseases.

In advanced stages of Typhus when there is much

7

watchfulness and a small frequent and weak pulse attended with delirium, weak convulsive motions and other symptoms of nervous irritation, Opium is one of our best remedies, Where there is local inflammation Opium combined with Camphor and a small quantity of Antim. Tart. often proves beneficial.

Opium has been recommended in every stage of Intermittent fever, we think this is not a safe mode of practice, but after the patient has been sufficiently evacuated and the disease continues we may then resort to this article with advantage. A full dose of Opium an hour or half hour before the expected paroxysm exhilarates the spirits and produces an agreeable glow over the whole surface and will often remove or mitigate the paroxysm.

In the inflammatory form of Rheumatism Opium is improper it may be given however in the subacute form with advantage. In cases of this kind it should be given

Other symptoms of acute vesicular eruptions is an  
of our best remedies, these are in fact infectious  
of acute eruptions with vesicles and a small quantity  
of acute eruptions of the face superficial  
of acute eruptions has been recommended in every stage of the  
mild form, we think this is not a safe mode of  
practice, but after the patient has had sufficient  
rest and the disease continues running its course  
to the acute with advantage. A full dose of Opium  
is not so safe, but before the eruption of vesicles  
and the skin are formed an equal quantity of  
which surface are well often cause a rupture of the  
vesicles.  
In the treatment of Acute eruptions of the face  
it may be given freely in the mild form  
with advantage. In any of the kind it should be given

with a view to its diaphoretic effect and to ensure this it is best given in the form of Pulv. Ipecac. Comp.

In chronic Catarrh or in recent cases unattended by any phlogistic diathesis Opium is a remedy of great value, It is particularly useful in long, standing catarrhs of old persons where there is a profuse secretion of mucus in the bronchia. Where the expectoration is scanty it is best given in combination with some expectorant for this purpose the syrup Squills with Tra. Opic. Camph. is perhaps as useful a combination as we possess.

In the last stage of Phthisis Pulmonalis, it is of all articles the most valuable, it allays pain, relieves the cough, lessens diarrhoea, and for a time supports the sinking powers of life, and when all other remedies have been given up and hope itself is ready to expire, it soothes the passage of the sufferer to the grave. It is to those therefore whose lot it is

9

to suffer with Consumption and other such lingering diseases that it proves to be the most valuable of all medicines.

In the commencement of Dysentery when the febrile symptoms run high, Opium is improper, but after the inflammatory symptoms have been subdued by proper or depleting measures it may be given with advantage. In the chronic form of this disease it may be given with advantage, in combination with Calomel and Speccauka. In distending tenesmus a solution of Opium in some mucilaginous fluid in the form of an enema will be highly servicable.

In chronic Diarrhoea Opium in combination with small doses of Calomel constitutes one of the most important remedies we possess in the treatment of such cases.

In Cholera Opium is our principal remedy and unless given in large doses little benefit

will result from the use of it.

In the Cholera of Infants it is a doubtful remedy, but if the system should become irritable Opium may be used in combination with Calomel with advantage.

For the relief of those distressing pains of the stomach, which frequently attend Dyspepsia, small doses of Opium is our principal remedy, but in the exhibition of this medicine in such cases we should be guarded against a habit being formed by the patient which would ultimately prove highly pernicious to his welfare, and one from which he could not easily break himself.

In Hemorrhage it may be laid down as a general rule, that the use of Opium is improper where there is much vascular excitement, but in Hemoptysis and Uterine Hemorrhage attended with an irritable state of the system and a small contracted

of the system which become alike to the  
be used in combination with others with some  
page  
For the relief of those suffering from the  
marks, which frequently attend the  
use of Opium, as our principal remedy, but in  
the exhibition of this medicine in such cases  
should be guarded against a habit being formed  
the patient which would ultimately prove inju-  
rious to his health, and our plan should  
and not easily break himself.  
In consequence it may be said as a general  
rule, that the use of Opium is improper and  
there is much to be desired. but in other  
cases and in the treatment of others, it will be  
the state of the system and a more correct

11  
pulses it is a valuable remedy.

In Colica. Pictorium. Opium is a valuable remedy if it should come on without fever Opium may be given in the first stage, but if there should be fever we should first bleed and then give a dose of Calomel and Opium and repeat as often as necessary.

In Mania. A Potu. when it depends upon an abstraction of stimuli Opium is a valuable medicine and should be given in large doses but if given in the inflammatory state it would be apt to produce Apoplexy.

In Tetanus. Opium is one of the most valuable articles we possess. In this disease it should be given in large doses and repeated until it produces some sensible effect on the system.

After using large doses of opium it should not be suspended suddenly for fear of producing great irritability of the system.

if it should come on a sudden from opening my  
gown on the first step. but if there should be  
no such fall then and then give a view of the  
and opening and repeat as often as necessary.  
Dr. William C. Cotes writes to explain after a  
abstraction of the mind of the mind as a result of  
one and a half for given and large class of  
given in the system of the mind and the  
to further study.  
Dr. William C. Cotes as one of the most  
the articles in paper. In the course of the  
the given in large class and repeated in all  
see some more to effect in the system.  
after a long time of opening the door and  
repeatedly writing for fear of forgetting and  
state of the system.

12

When injuries have been inflicted and there are any symptoms of approaching Tetanus the system should be kept under the influence of Opium until the symptoms disappear.

In Hysteria when the convulsions are violent and obstinate, and the patient suffers great pain, as is chiefly the case when the disease manifests itself chiefly in the abdominal viscera Opium may be used with great advantage in combination with some antispasmodic; During the intermission of the convulsions if the pain should be violent we may use Opium in the form of an enema with advantage.

In the second stage of Hydrophobia where there is great irritation Opium may be used as freely as in Tetanus (we think it would be more likely to succeed in this disease if given in combination with Calomel).

In cholera if the spasms are very violent Opium may be used in the first stage in combination with a

suitable cathartic, and if the pain should continue after we have well evacuated the intestines Opium is our principal remedy.

In the Colic of Infants, laudnum may be often used with benefit in doses of half a drop or a drop and increased according to circumstances. But as before said it should be used with caution and never unless prescribed by some person who understands the proper time for its administration.

In <sup>sp</sup>asms. occasioned by drinking or bathing in cold water, when the system is heated or the weather is very warm, Opium and its preparations say Dr. Rush given in large doses is the only medicine on which we can rely with safety, laudnum in such cases is preferable to hard Opium

The Vinum Opii. or a watery solution of Opium says Mr. Ware is a valuable remedy in Ophthalmia connected with local vascular aetiology

In Chronic Syphilis attended with violent pains in

Principal Secretary.  
In the Office of the Principal Secretary  
with the highest number of staff in a single  
according to circumstances. But in reference to this  
and with the content and more useful knowledge of the  
and minister the functions for the administration  
In the various occasions of consulting or holding an  
order, under the system in fact with the  
very many Opium and its preparation capital  
given in the past as the only measure or method  
can be made with safety and security in  
to the Opium

reports the price in a regular way in the  
market with the best possible maintenance  
In the Office of the Principal Secretary

214

the bones and irritable painful ulcers Opium has often been found useful.

If the system should be very irritable under the use of Mercury at any time Opium may be used with benefit.

A watery solution of Opium is very useful as an injection in Gonorrhoea where there is chordee or great pain in the parts.

In Hernia. Hemoroides where the pain is violent Opium may be used with advantage; It is likewise a valuable article in spasmodic strictures. diseases of the Prostate, in Strangulated Hernia from spasms and in all spasmodic affections where there is not too much vascular action Opium is our sheet anchor (In strangulated hernia the operation should not be performed until after we have tried the effects of Opium).

As an antispasmodic and anodyne Opium is often a valuable medicine in Nephritis Calculosa, it is likewise

resorted to with the same advantage in the passage of gall stones; and to allay the pain which frequently occurs from the presence of a stone in the bladder Opium is a valuable article.

In that species of Mortification which occurs in old people, beginning at the extremity of one of the toes Mr. Pott says Opium is a valuable remedy and with it he is convinced; he has saved toes which otherwise would have been lost.

We shall now proceed to enumerate some of the evils arising from an improper use of Opium; and in the first place we shall speak of the habitual Opium taker: who unless he is under the immediate stimulant effect of this powerful narcotic; shows all the symptoms of bodily and mental imbecility. He is fearful, low spirited and has a pallid countenance; he is tormented with burning sensations, he is unfit for both mental and bodily exertions, he is fretful and feels pain in different

parts of his body. his extremities are cold, he is tormented with Dyspepsia. he cannot sleep, soundly in consequence of the morbid irritability of the system and the tormenting objects which are frequently presented to his imagination. he often suspects his most intimate friends to be his enemies. and that they are constantly devising schemes to deprive him of his property, reputation or life, and in consequence of this often forsakes his friends and seeks an asylum among strangers; thus leading a life which is miserable in the extreme

If these were the only bad effects arising from an improper use of Opium they are sufficient to entitle it to our consideration; For we frequently see men who were it not for the use of Opium might be ornaments to society.

In consequence of the anodyne quality of Opium it is often given, improperly in painful inflammatory diseases when the lancet should be our principal remedy

## Cynanche Trachealis

It is of great importance to form an accurate opinion respecting the treatment of this disease which is very short in its duration and ended with extreme danger. I shall now describe the practice which is taught by the learned Professor of the theory and practice of Medicine in the University of Maryland and which I myself have invariably found to succeed. Symptoms if the child be accurately noticed some days before the appearance of the disease (drousy, the eyes are somewhat suffused and blood shot the complexion somewhat muddy and livid there is some degree of cough which resembles that attending a common cold but sometimes has sometimes a peculiar shrill sound from the commencement, this cough in the course of 2 or 3 days becomes violent and

of great importance to form an accurate  
 and complete the treatment of this disease  
 is very short in its duration and  
 with extreme danger. In the  
 the first, the patient must be  
 of the common symptoms of the  
 are treated of children in the  
 of other cases and which may  
 of those in which it is necessary  
 of the child is treated with  
 the appearance of the  
 the disease is necessary to be  
 the symptoms are common to  
 the disease is necessary to be  
 the symptoms are common to  
 the disease is necessary to be

unpleasant it is then necessary to watch  
the patient with great attention the den-  
tious attack is made sometime during  
the night sometimes immediately after the  
child is put to bed but most frequen-  
tly about mid night the cough on the  
onset of danger, has a shrill barking  
sound which has been likened to the  
elping of a fox the cough returns  
in redoubled fits the first of which  
turns with redoubled fits the first  
which though very violent is suc-  
ceeded in a few minutes by a second  
longer and yet more violent. every  
fit of coughing agitates the patient  
to an extreme degree the face is  
red and flushed the eyes are pro-  
truded; a general tremor takes  
place and there is a kind of convul-  
sive struggle to renew respiration  
at the close of each fit. there is

expectoration at the this period of the  
disease; as the complaints increases are  
sometimes more troublesome, sometimes  
they become less frequent: but as ineffectual  
efforts of breathing come, or accompanied  
with a swelling of the throat  
about the place of the larynx: the head  
thrown back, in the agony of attempting  
to escape suffocation, as the extensors  
of the trunk, and of the legs, are some-  
times brought into action, to assist  
the effort, so that the whole body is  
erect backwards as in tetanus; in  
this effort and in this attitude the  
patient expires: There is not an un-  
usual sound produced by the cough  
something between the yelping and howling  
of a dog, which it is impossible  
to describe, but respiration is perform-  
ed with a hissing noise, as if the  
trachea was closed up by some tight

hony body. the eruption of the countenance is also appropriate and will denote the disease to any one who has seen it. there is much distention of the bowels of the cheeks is much heightened the eyes are swelled up watery and exhibit great marks of sufficiency. the trembling hands, and restless legs, though accompanied with heavy sleep proceed to an excessive degree. the diseased arteries, and the heart and arteries, are thrown into violent palpitations, respiration becomes more tumultuous, is repeated with greater exertions and at longer efforts until it ceases entirely such are the ordinary course of the symptoms and course of this disease, much diversity however of opinion exists in relation to the violence of this disease and the phenomena which it exhibits

in some instances not more than a  
or hours elapse between the commence-  
ment and termination of this disease  
in other cases the symptoms proceed  
slowly to their acme, and the disease  
protracted for many days or occa-  
sionally for weeks assuming a chronic  
character without perhaps having at  
any time manifested any very alarm-  
ing degree of violence. The ordin-  
ary period occupied by this disease is  
from 12 to 5 days Causes Cinanche In-  
fluenza is one of those ~~predispositions~~ in  
clamitory affections for which a  
predisposition appears not infrequ-  
ently congenital, it is a fact un-  
satisfactorily ascertained that chil-  
dren in some families are particu-  
larly predisposed to the disease  
while in others it never makes its  
appearance, in what this predisposi-  
tion

consists we can not tell we may say  
depends on a peculiar organization  
the Mucous Membrane of the Larynx  
& Trachea may be correct but what  
new organic peculiarities are it  
would be in vain to enquire besides  
this original or natural predispo-  
sition there is a rather aged  
Pneumot Tracheolitis is a disease all  
most peculiar to children but  
not entirely confined to that class  
of persons for it sometimes occurs  
to adults and in usual to persons  
in advanced age but these instances  
occur but seldom we may therefore  
expect to find it occurring in  
children from 4 to 5 years the  
principle exciting cause is cold or  
violent vicissitudes of atmosphere  
in particular here its greater prevalence  
during the damp cold season of autumn

Pathology, untill the time of Boerhaave  
one thought this disease an inflam-  
matory one, although some Physicians before  
his time used the antiphlogistic plan  
is strictly a pleysnasial disease con-  
sisting entirely in an inflamed condition  
the mucous membrane of the superior  
portion respiratory tube the consequence  
this pathology is confirmed not only by  
its well known exciting cause but espe-  
cially also by the more direct evidence  
the symptoms of the disease and the  
appearance discovered on post mortem  
examination; the inflammation is not con-  
fined to the larynx and trachea but  
frequently communicated to the lungs  
muscles of the neighbouring parts and ind-  
eed it sometimes pursues its course  
to the lungs and in proportion as it  
extends does the danger of the disease  
increase owing its propensity to metast

Warts — Treatment, the symptoms point  
to the proper treatment to be pursued  
in the management of this fright-  
ful disease; for they indicate the  
highest state of inflammation which  
alone can be subdued by the most <sup>strict</sup> an-  
tiphlogistic plan; such as blood-let-  
ting, Emetics, purgatives, blisters, and the  
like. In the first place blood-letting  
lessens that highly exciting action of  
the lungs lessens the determination of  
blood to the brain, takes off that dis-  
position of the muscles supposed to be  
spasmodic action and prepares the system  
for other remedies — The next indication  
is to throw off the phlegm and mucus  
which have collected in the trachea  
for this purpose Emetics are to be resor-  
ted to without hesitation — and the  
Physician who turns a deaf ear to these  
indications will find himself overcome

with difficulty nor will he have much  
use to congratulate himself on the  
success of his practice - but the stomach  
sometimes in such a torpid condition  
this disease that is with difficulty  
can get the ordinary medicines to act  
it we should then have recourse to  
corrosive sublimate which Masfies  
introduced in the management of this  
disease by Dr Albert of  
Maryland and to these of it many objections  
have been started on account of its  
producing pain in the stomach nausea  
vomiting and the like; these inconveniences  
may be remedied by brandy and water  
- brandy too by the manner in which it is  
administered is to put ʒij of the sublimate  
- ʒij of water giving a tea spoon full  
till free emesis is produced. Purgatives  
are also useful auxiliaries in the treatment  
of this disease the mention of this step of

The object of this paper is to show the  
importance of the subject, and to  
show that it is not a trifling matter.  
It is a subject that is of the highest  
importance, and one that is of the  
greatest interest to all who are  
concerned in the management of the  
affairs of the State. It is a subject  
of the highest importance, and one  
that is of the greatest interest to  
all who are concerned in the  
management of the affairs of the  
State. It is a subject of the highest  
importance, and one that is of the  
greatest interest to all who are  
concerned in the management of the  
affairs of the State.

Medicines brings me to speak of Colamel  
the medicine which as a single remedy  
more power in subduing this forma-  
ble disease than any other with which  
I am acquainted the small doses in  
which it has been given has in some  
cases brought it in disrepute but  
the experience of Dr Potter and my own  
observations have led me irresistably  
to the conclusion that a proper com-  
bination of Colamel and tartar Emetic  
viz (30grs of the former to 10 of the latter  
- 3j) of water ~~in a~~ spoon full to be  
taken every 15 minutes untill free emesis  
takes place) will cure any case of Cholera  
if taken in time unless in its highest  
state of inflammation. Many object to the  
use of this medicine on account of the  
heat which it produces on the salivary  
glands Dr Potter says that in many hun-  
dred cases which he has seen he has

o. Opera Met with one of salivation  
sometimes makes the mouth run a little  
that soon disappears - in a torpid state  
the bowels and stomach it more  
perfect than any other medicine in ac-  
milately diminished excitability  
The warm bath is also a useful auxiliary  
in the treatment of this disease after  
the reduction of the inflammatory action  
more particularly so after the skin  
is raw brought by producing perspiration  
on and assisting the action of other  
medicines - Seneca has been considered  
a specific in this disease it is  
without doubt a medicine of very con-  
siderable powers but by no means poss-  
ed of the virtues which have been as-  
cribed to it by Archer and some others  
The beginning of the disease it is objection-  
able on account of its stimulating  
properties but after the subsidence

inflammation it is a valuable remedy  
for the relief of the dry cough and  
difficulty of breathing after the disease  
has been subdued no medicine is more  
effective it has been recommended  
after all the usual means have  
been used without success that one  
could resort to an operation which  
is called ~~Tracheotomy~~<sup>tracheotomy</sup> it consists in  
cutting down between the cricoid and  
thyroid cartilages in this manner prevent  
the patient from suffocation

---

Would you explore the secret haunts  
of Omnipotence, and find for the intel-  
-lect its widest horizon, seek the ex-  
-alted regions of Chemistry, —

No one who has ever duly dwelt on the stupendous  
works of the Divine Author of the Universe, and con-  
templated as they successively presented themselves to his  
intellectual vision, the various laws by which the dif-  
ferent parts of this immense system are preserved  
in constant harmony, but must have recognised  
in a variety of the grandest phenomena the element  
which is about to fall under our consideration —  
and when he has traced it through some of its  
operations, marking it now in the fiery jet  
and terrific roar of the convulsed volcano,  
now starting all nature from her hybernal

*[Faint, illegible handwriting at the top of the page]*

*[The main body of the page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

slumber, stepping off the narrow platform that had  
protected her from the deadly blast, magically  
to locate her in the splendor of her vernal  
assurances, and now imparting health and ac-  
tivity to the animated world, ~~her~~ must at once  
be struck with its interest and importance. Still,  
though by these vast and imposing processes, we  
are forcibly and fully impressed with the exis-  
tence and power of this useful agent in creation,  
there are other more familiar cases, in which its  
properties are made known, and exhibited to us. But  
with these properties we are made acquainted only by  
its action upon matter in general; we have scarcely  
an idea of its specific character, which is so elusive  
and intangible, that the deepest investigations and  
utmost scientific scrutiny have resulted in a  
theory which though ingenious, fascinating, and

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

persuasive, is by no means conclusive. At this  
we cannot marvel, when we reflect that it is  
only one of our five senses, with which the  
matter of Heat has made direct acquaintance,  
viz. that of touch. To all the others it is entirely  
unknown, and never comes under their cognizance  
except mediately, by impressions received from ma-  
terial objects subjected to its influence. The eye  
for example can detect the presence of heat in a  
mass of ice, and discover to us one of its attributes,  
that of opposition to the attraction of aggregation,  
only by observing the liquifaction of that ice,  
yet even this is a kind of second hand informa-  
tion, which could not have been communicated  
by the eye had not the sense of touch been  
first consulted. It is clear then, that our  
first ideas, imperfect as they may be in regard  
to air subject, are excited either by touching

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

4

those bodies that may be changed with it, or  
by experiencing the sensation of heat direct from  
its invisible self - by which ever of these means  
we are apprised of its presence, we in common  
language convey our sensations by the terms, heat  
and hot, as for example, "in the sun there is  
much heat," "the season is excessively hot." But it is  
evident that these expressions refer to nothing but  
sensation, without in the slightest manner directing  
the mind to the cause of those sensations which  
have been allegorically adverted to. In order then to  
have as clear an understanding as possible, and  
facilitate the investigation of this abstruse subject,  
Chemists, after adapting and rejecting various phra-  
ses at different periods, have agreed to call that  
invisible and subtle principle to which are ascri-  
bed all the phenomena expressed by the terms  
Heat and hot, with all the chemical changes  
attributed to the action of heat, - Caloric.

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side of the page.

In future therefore, we will understand by Caloric  
a thin, invisible, and penetrating fluid, pervading  
animal nature, and producing all those effects,  
physical, chemical, and vital, which are commonly  
referred to heat — But although Caloric is ac-  
cordingly more conformable to the language of philoso-  
phy than the phrase heat, the latter though not  
used with the same acceptation, is in much more  
general favor, we will therefore attach to it the  
same idea contained in the former, and employ  
them indiscriminately throughout the following  
sheets.

When we follow the element Caloric  
through all its diversified actions and associations,  
we discover what, doubtless, could little have been  
expected, that it is not always in the same con-  
dition, but exists in connection with bodies, not  
only concealed from our senses, but differently

6

disposed under this concealment - we would decline  
ourselves greatly for example, if upon touching a  
cold body we should pronounce it destitute  
of Caloric; hence it became necessary to the unity  
of conveyance and easy comprehension of our sentiments,  
upon the subject, that to Caloric should be ap-  
plied different appellations, or that the term  
should be variously modified, according as it  
was found in the one or the other of these con-  
ditions; we consequently meet with "Heat of  
Temperature," "Latent Heat," "Specific Heat,"  
"Absolute Heat," and "Combined Heat."

As it is our design to treat of but two  
of these, the "Heat of Temperature," and "Latent  
Heat," it would here be superfluous to give  
each its definition. - When we view the almost  
immeasurable field presented by these different  
points for investigation, - a field not untraced

Faint, illegible handwriting on aged, yellowed paper. The text is mostly obscured by bleed-through from the reverse side of the page. There are several small brown spots (foxing) scattered across the surface.

But upon which minds matured by age, and strengthened by experience, have gattered and paused, and to the vast expanse of which some of the brightest stars that ever ascended the horizon of science have been like such lights in the midnight firmament; we feel that independent of any other consideration, two divisions of the subject, the Nature of Caloric, and Spontaneous Evaporation, will be a sufficient task for our feeble powers:—

## Nature of Caloric.

In relation to this point, the question upon which a spirited contest has long revolved, is, whether the cause of all the phenomena proper to heat be material, or whether they be effects consequent to a mere motion among the particles of matter?

*[Faint, illegible handwriting throughout the page, possibly bleed-through from the reverse side.]*

Among the most conspicuous of those philosophers  
 who maintained that heat was an effect of intestine  
 motion among the particles of bodies, were, Bacon,  
 Newton, and Rumford, with the former of whom  
 this chimera originated. We cannot withhold  
 the expression of our regret, that the name of  
 Davy claims a place among the proselytes  
 of Bacon, and perhaps we could not offer a more  
 faithful or clearer expose of this idea, than by  
 transcribing his own language. "It seems  
 possible to account for all the phenomena of heat,  
 if it be supposed that in solids that the particles  
 are in a constant state of vibratory motion, the  
 particles of the hardest body moving with the  
 greatest velocity, and through the greatest  
 spaces, that in fluids and elastic fluids, be-  
 sides the vibratory motion, which must be  
 conceived greater in the last, the particles

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

7  
have a motion round their own axes, with dif-  
ferent velocities, the particles of elastic fluids mov-  
ing with the greatest quickness, and that in ethereal  
substances the particles move round their own  
axes, and separate from each other, penetrating  
in right lines through space!—Temperature may  
be conceived to depend upon the velocities of  
the vibrations, increase of capacity on the mo-  
tion being performed in greater space, and  
the diminution of temperature during the con-  
version of solids into fluids or gases, may be  
explained on the idea of the loss of vibratory  
motion, in consequence of the rotation of par-  
ticles round their axes, at the moment when  
the body becomes fluid, or aeriform, or from  
the loss of rapidity of vibration in consequence  
of the motion of particles through greater  
space!!!

So far as Sir Humphrey Davy  
speaks of motion, which is the basis of the  
experiment, we comprehend him; but when he

comes to modify this motion in order to account  
for the various ways in which caloric is associated  
with bodies, his language, to us, is vague in the  
extreme and has the appearance of those efforts, men  
feel themselves sometimes constrained to make, in defence  
of an opinion they have espoused they know not why.  
But let us examine how much of philosophy there is  
in this idea, and try whether we can reconcile it  
with the laws of motion.

Amongst all the collaries that have been  
deduced from close study and accurate experiments  
relative to the motion of bodies, no one is better  
established, or can be more clearly demonstrated,  
than this "that upon the collision of two perfectly  
elastic bodies, action and reaction, are equal."

One out of many other proofs of this we find in  
the experiment with the ivory balls, which being  
suspended so that they exactly touch, if one of  
the extreme balls be raised, and then let fall, it  
strikes the one next to it, and remains at rest to-  
gether with all the others, except that at the

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

opposite extreme, which immediately flies out, and describes an arc so nearly equal to that of the ball which gave the impulse, that the difference is not appreciable.

Our atmosphere is a fluid constituted of particles immeasurably minute, this fluid is elastic, consequently its particles are elastic. Hence any motion imparted to one stratum of the atmosphere, ought to be communicated to another tho' far distant, which in case of sound we find to be the fact - but this transmission of impulse ought to be instantaneous, and so it would be were not the atmosphere imperfectly elastic. We will now see how far the phenomena of heat come under this law?

Suppose an observer standing at one end of a confined apartment, where the air is perfectly quiescent, if a plate of iron red hot, should be presented at the opposite extremity, he would be sensible of that effect usually as-

*[The page contains several paragraphs of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

erated to Caloric. Now according to Bacon's  
Theory, which Sir M. Huxley seems disposed to in-  
dicate, this sheet suffered a violent vibration among  
its particles, causing in it what we term heat; this  
vibration was communicated to the particles of the  
intervening air, arranged in an infinite number of  
lines, resembling the row of ivory balls, which pro-  
pagating it to the observer, caused in him the  
sensation of heat. Granting the fundamental  
proposition of Lord Bacon, that the particles  
of hot bodies vibrate, and viewing the atmospherical  
particles as possessed of perfect elasticity, the trans-  
mission of impulse ought to be not only instantane-  
ous, as demonstrated by the balls, but its force  
should be entirely preserved.

Mr. Leslie in the prosecution of his ex-  
periments on Radiant heat, observed that there  
was no interval of time between the removal  
of a screen placed before a hot body

*[The text on this page is extremely faint and illegible due to fading or bleed-through from the reverse side. It appears to be a continuous paragraph of handwritten text.]*

and the use of a thermometer in the focus of  
an opposed mirror, and therefore we perceive  
that the communication is instantaneous -  
But this fact could only prove the correct-  
ness of Bacon's views upon two assumptions,  
first, that the particles of hot bodies vibrate,  
and secondly that the air is perfectly elastic.  
The former of which is altogether gratuitous,  
and the latter is not the fact - It is therefore  
to be passed over without further notice

It is the second of the two abovementioned laws of elastic bodies that bears with more importance upon our subject according to this law the vibrations of those particles of air immediately adjacent to the body of the observer ought to be nearly as rapid as those of the stratum of air contiguous to the hot plate, and then consistently with the opinion of Sir H. Davy,

14  
"That the particles of the hottest bodies move  
with the greatest velocity." or in other words,  
Heat is directly proportionate to velocity of  
vibration. The effects of heat should be as  
apparent at the distance of twenty feet from  
the plate, as at ten, which we know is not  
the case, for ~~though~~ above though it may  
be perfectly sensible at ten feet, would at  
the distance of twenty scarcely make us  
conscious that a heated body was present.

In objection to our argument it may per-  
haps be urged, that the primary impulse  
would be preserved undiminished, and that  
the temperature would be found in regions  
far distant from the source of heat, equally  
high with that in its immediate neigh-  
borhood, were it not for the imperfection  
of the atmosphere's elasticity, which causes  
a loss of motion.

That the atmosphere is not a perfectly elastic  
fluid, every philosopher is aware, if from no other  
circumstance than the interval between the flash  
of distant lightning, and its consequent thun-  
der; but when we consider the rapidity with  
which eliminated heat is diminished in tra-  
versing even a limited portion of air, and  
compare it with the variance of the atmosphere  
from complete elasticity, we shall be convinced  
that they are by no means commensurate;  
and agree that any attempt to invalidate  
what we have here advanced, upon such grounds,  
must amount to nothing, more than sophistry  
the most abject; leaving us freely to pass on  
to the fair and legitimate conclusion, that  
the opinion of Lord Bacon and his followers  
upon this subject, being altogether incompatible  
with the laws of motion, is not only unphilos-  
ophical, but essentially wrong; yet should  
not this discover sufficiently, (we must say)  
the absurdity of such an idea, a more di-

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

not appeal to experience well.

Almost every one is acquainted with the double convex lens; and has observed that if it be presented with its plain parallel to the sun's disk, when unobscured by clouds, a point may be found somewhere in its inferior axis, so extremely hot as to fuse the greater part of combustibles, - How shall we explain this?

Lord B. would say that the caloric vibrations of the sun were imparted to its ethereal regions; from these they passed to our atmosphere, from which, being caught by the surface of the lens, they were transmitted to the air beneath it, and thence to the combustible, causing the phenomena of combustion!!!

Now, even were we to admit that this accounts for the appearance of heat, beneath the lens, it does not explain its accumulation - it does not tell us why no such

heated point can be found above the lens - How  
then is the concentration effected? we surely cannot  
not be so blind to philosophy as to say that  
the inferior surface of the lens occasioned a con-  
vergence of vibrations; on the contrary, bodies  
when put in motion take the direction of the  
impelling force, continuing in such direction  
until opposed by some resisting body - Suppose  
the whole surface of the lens to be in a state  
of vibration, it is evident that whatever impulse  
it might give to the contiguous atmospheric  
particles, would be in lines perpendicular to  
its curve, and these would all be not towards  
a focus, but divergent - Again - we will  
go further, and for a moment grant that  
the sun is no more than an immense  
vibrating something - causing a series of vi-  
brations through ether, atmosphere, and lens,  
by the latter of which they are collected to

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

18  
a focus; a second look will detect an  
objection still more formidable and unanswer-  
able than any yet advanced.

It is motion among the particles of bodies,  
say these enemies to Caloric, which occasions the  
phenomena of Heat; we should therefore expect  
that whatever body is capable of giving to another  
the property of causing these phenomena, has its  
particles in a state of motion - the integral  
parts of the lens must of consequence vibrate -  
but then it would be excessively hot - whereas  
the thermometer tells us that its temperature is  
in perfect equilibrium with the surrounding me-  
dium!! - Thus we see, the chain of vibrations  
is broken - where shall we find the connecting  
link?

But we have before stated, that in  
opposition to these views, another theory has  
been established; which is embraced and  
supported by the majority of scientific men.

It concludes that "the cause of all the effects attributed to heat, is a specific kind of matter, existing in the form of an extremely subtle fluid, first named by Lavoisier, Caloric, which by associating itself in a variety of ways with all matter, gives rise to the phenomena of heat."

As might be expected, those who advocated the doctrine of vibration, by an immediate to envelop the merits of this theory, and among the most conspicuous were Pictet and Count Rumford. The latter of these gentlemen, having observed that a given portion of water, was soon raised from the ordinary temperature of the atmosphere, up to boiling heat, when the process of boring a cylinder of brass was conducted in it, concluded that nothing but motion could cause such an effect, "because," says he, "any thing which an insulated body or system of bodies can furnish without limitation, cannot possibly be a material substance."

20  
How futile this objection is, we may perceive at a glance, as it is plain that whatever force it might have, depends entirely upon a position which we cannot accede to; because it is not only presumptuous in the first instance, but it has been invalidated both by observation and experiment.

Dr. Black, for example, while engaged in his researches upon Latent Heat, observing a Blacksmith light his match with the heat produced by the rapid percussion of a piece of iron, had some conversation with the man, and among other things learned from him that after hammering it for awhile, all the persons and in the world not keep it hot or raise its temperature again, unless it were first put into the fire and permitted to cool, when the operation could be repeated with equal success.

Concurrent with this observation, and very conclusive in their character,

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mostly obscured by the paper's texture and color.

now some experiments conducted with great mi-  
 cety, and caution, by Berthollet and others, with  
 the view of ascertaining the comparative rise  
 of temperature upon submitting different pieces  
 of metals to percussion - this is not the question  
 with us however, we are only desirous to know  
 what in any wise may relate to the ques-  
 " will friction or percussion cause an indefinite  
 extrication of Caloric? - or does the temperature  
 of a piece of metal under this operation fall,  
 rise, or remain stationary, upon the contin-  
 uance of the process - the metals employed, need  
 Gold, Silver, and Copper, and the blows  
 were given by a coining machine - it is  
 unnecessary to examine the case of each metal,  
 one is sufficient for our purpose, - we will  
 therefore be content to remark the effects  
 upon Copper. -

*[Faint, illegible handwriting in cursive script, likely bleed-through from the reverse side of the page.]*

Upon the first blow the temperature of a piece of this metal was elevated  $17.44^{\circ}$  the second blow raised it but  $7.00^{\circ}$  and the third only  $1.45^{\circ}$ , proving that the evolution of caloric diminishes in a ratio so rapid, that it would soon reduce it to nothing, when there would certainly be a diminution rather than an increment of heat. Hence we conceive that the very basis of Count Rumford's objection being proved fallacious, no confidence should be given it.

But the theory of Caloric has not resigned without being assailed in another way which we here notice an account of its whimsical character, if for nothing else. authors however have given the exception a place in their works, and it has engaged the minds of students; upon this score therefore it claims an attention:—

If the cause of heat be material, said the opponents to our theory, bodies ought to become heavier or lighter according as they gain or lose caloric, and in order to put this to the test, experiments were instituted by De Luc, Hordyce, and others; these we consider useful, because they furnish a striking commentary upon the enterprising spirit of man, of which we will be sensible when we consider that they were nothing more nor less than attempts to weigh Caloric! One will serve as a sample.

This experiment made by Hordyce, was brought forward with pretensions to prove not only that bodies lost no weight upon reduction of temperature, but that they actually became heavier! - it consisted in putting into a glass globe three inches in diameter and of a given weight, a known weight of water, and hermetically sealing the globe, which

was dried as perfectly as possible - its weight  
 was noted at the temperature of 89° - the whole  
 of the water being then frozen by frigorific  
 mixtures, it was found to weigh  $\frac{3}{10}$  of a grain  
 more than when fluid, though its temperature  
 was down to 10°.

Now, though I by no means approve  
 of that meagre kind of argument which  
 in every instance amounts to nothing more  
 than a wily subterfuge, so scrupulous have  
 been the enemies of the theory of Caloric  
 that we must meet them upon their own  
 grounds; we would therefore remind them  
 that, heat has been proven an antagonist  
 of cohesive attraction - that cohesive attrac-  
tion and gravitation are only modifica-  
 tions of the same law - consequently that

Heat opposes gravitation - therefore the result of Torricelli's experiment is no more than what we might have expected, since the water, in being cooled, parted with a power that lessened its tendency to the earth - beside it should be recollected that even now the atmosphere at 32° the globe being at 10° was 22° degrees colder, which cooling the atmosphere immediately around it, caused it to deposit, tho' invisibly, a portion of the hygrometric vapor contained at all temperatures, and this could very easily amount to  $\frac{3}{10}$  of a grain, if not more.

But it is likewise objected that the reverse of the experiment tends equally to prove the immutability of the cause of heat - that the heating of bodies, or the addition of caloric to them makes no attraction in their weight - whereas it ought to be augmented.

A little impartial reflection, we think, will make the subtility of this argument equally apparent with that of the other. We

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

will for a time discard the idea that Caloric  
is immaterial attraction, and look upon it as  
a material fluid; still when we meditate upon  
its extreme tenacity, all cause of surprise at these  
results disappears; moreover we will address a  
case under common observation, which must make  
them quite reconcilable to an unprejudiced mind.

If into a large apartment a pound of Camphor  
be suddenly introduced, and the air agitated, in  
a very short time its odor would be perceptible  
in any part of the room. This odor is con-  
spicuously and demonstrably owing to the volatiliza-  
tion of the camphor itself, which being dis-  
persed through the air, is detected by the olfac-  
tory nerves; the pound of camphor must there-  
fore have lost something; nevertheless, the  
nicest balance that human ingenuity could  
ever devise, we will assume for it, could  
not show us the loss - and yet were all

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side.

all the camphor vapor contained in the apartment, collected and condensed into a solid body, the size of a musket ball, and naturally without smell, there cannot be a doubt that it would require the power of producing an effect in regard to odor, correspondent to the rise of temperature upon the addition of Caloric -

How then, consistently with reason, could we expect a body to become more ponderous, so incomparably subtle, as is Caloric, which permeating the densest matter in creation, makes its way through every barrier, while the exhalation from camphor may be easily corked up in a bottle?

Thus far upon this point we have been engaged, we will not say have successfully, in combatting the attempts to undermine the theory of Caloric, our efforts therefore, could afford it but a negative support. It

The most of a man's life is spent in a state of  
ignorance and error. It is only in the  
last few years of his life that he begins to  
see the truth. He is then in a state of  
wisdom and knowledge. He is then in a state of  
peace and happiness. He is then in a state of  
enjoyment and contentment. He is then in a state of  
fulfillment and satisfaction. He is then in a state of  
bliss and glory. He is then in a state of  
eternity and immortality. He is then in a state of  
perfection and holiness. He is then in a state of  
divinity and godliness. He is then in a state of  
heaven and glory. He is then in a state of  
eternity and immortality. He is then in a state of  
perfection and holiness. He is then in a state of  
divinity and godliness. He is then in a state of  
heaven and glory.

now remains to review some of those arguments which more positively and directly demonstrate its soundness, and which in our mind, whether taken collectively or individually, will ever prove to its opponents an impenetrable barrier.

In the first place then, we know nothing except by its properties - which so invariably establish the character and distinctive marks of different kinds of matter, that we are often compelled to admit the existence of substances, giving them name and description, merely on observing their effects on other bodies, although they are completely veiled from direct perception - for example, we conclude that oxygen Gas is present, because the introduction of Nitric Oxide, occasions the formation of nitrous acid vapor, which appears in red fumes -

Concluding that all are sufficiently familiar with the above truth, we conceive that to establish the materiality of Caloric we have only

27  
to demonstrate its obedience to the acknowledged  
laws of matter; this therefore shall be the purport  
of what follows.

A formidable body of observations, experiments  
and arguments are in array for the accomplish-  
ment of our design, but so determinate is the  
character of the majority, that it would be re-  
dundant to adduce more than one or two, which  
we select upon account of their superior validity.

Herschel, that companion of the planets, in  
the course of his astronomical observations, re-  
marked that whenever his glasses were so deeply  
colored as to arrest the progress of the solar  
rays, they cracked and fell into pieces - suspecting,  
we presume, that this proceeded from some pecu-  
liar relation between light and heat, he made  
experiments to ascertain the heating power in  
each ray of the prismatic spectrum - the result  
of which was, that the violet ray was the  
least caloufic, the red ray the most so - from

which we deduce the corollary, that refrangibility  
and the power of heating are inversely proportionate  
to each other the latter diminishing as the for-  
mer increases - and as the strongest illuminating  
rays are in the centre of the spectrum, where the  
heat is trifling in comparison with the red ray,  
we have abundant evidence that light and the  
cause of heat observed any different laws, or are  
at any rate affected by the same law in dissimilar  
ways - But what is most interesting to us is, the  
fact that the greatest heat exists about an inch  
beyond the spectrum, where no color is to be  
found, and continues to affect the thermometer  
an Inch further.

In relation to this effect, there have  
been entertained two views at least, which de-  
mand our attention. According to one, Light,  
in passing through the prism and all other  
diaphanous bodies, suffers not only refraction,  
but likewise a peculiar change by which it

is somehow or other endowed with the power  
of causing the phenomena proper to Heat - the  
other idea is, that the solar beam is composed  
of light and heat - that Heat of course is  
emanated by the sun in rays which are less  
refrangible than light or rather of its compo-  
nents, and that the prism in decomposing the  
luminous beam therefore exhibits the greatest  
Heat in connection with and a short distance  
from the least refrangible ray, the red.

Whatever may be thought of these two ex-  
planations, certain it is that neither of them  
 militate in the least against the materiality of  
Caloric, but on the contrary both suppose it  
to be a subtle fluid - It is not questioned  
how Caloric is formed - whether from a modi-  
fication of light, atmosphere, or any thing  
else - we only insist that it is a species of  
matter, which so long as it meets the name

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

32

of Caloric, paper properties altogether foreign  
to those of light.

But the idea that Caloric is merely a modification of Light, opposes the belief that it is an original and distinct species of matter - It has occurred to us however, that it is directly contrary to reason, and harshly dissonant to sound logic - that it looks more like Hypothesis than Philosophy, and for these reasons: -

To the unfortunate being shown Nature has granted but a semi-existence by denying him the joys of vision, Light is equally incomprehensible and inconceivable; it is consequently only known by its impression upon the retina of the eye - When the thermometer is passed by and the red ray, bent in a line with the spectrum, the mercury rises, yet the cause of such rise is wholly invisible, upon what grounds then, but those purely hypothetical, is it believed that light is

*[Faint, illegible handwriting on aged paper]*

concerned in the case? We surely have no  
evidence that Light is present - the effects of  
Heat alone are ~~present~~ observable - but is said  
that this Heat was once light upon which the prism  
has worked a metamorphosis. Let us see how this  
will stand the test of experiment.

In the process of Mr. Leslie's researches into  
the laws of Radiant Caloric, he was desirous  
of ascertaining how it was affected in its passage  
through different media, - to this end, a body  
emitting both light and heat was placed in the  
axis of a concave parabolic mirror, while the  
bulb of a thermometer occupied its focus, and gave  
evidence that Caloric was received - things being  
thus conditioned, a sheet of very transparent  
glass was interposed between the hot body and  
the mirror, when the Mercury instantly fell  
many degrees, which effect increased as the  
screen was approximated to the mirror, till

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side.

every sign of heat in the focus disappeared.  
Was this owing to the interception of Light? Most  
positively not for though the thermometer did  
not escape the presence of Caloric, its bulb  
was as brilliantly illuminated as ever. In addi-  
tion to this, M. De La Roche has shown, "that  
a thick glass though as much or more perme-  
able to light than a thin glass of more quality,  
allows a much smaller quantity of radiant heat  
to pass" - How comes this? - The glass screen has  
evidently caused a disappearance of Caloric from  
the focus of the Mirror, yet if the heat in the  
focus proceeded from nothing but a transmis-  
sion of the light, effected by the surface of the  
Mirror, the thermometer should have remained  
unaltered; for even if we allow that the glass  
retained half of the light, the mirror had still  
some to work upon. Why then did it not  
convert it into heat?

*[Faint, illegible handwriting on aged paper]*

From these considerations, and others of equal force, we are compelled to reject the idea of the essential identity of Light and Caloric, and to adopt the opinion that Light in every instance at least where it is emanated in consequence of the elevation of temperature, is compounded with Caloric, a distinct fluid; and that when Light passes through any medium, if the effects of Caloric manifest themselves separately from those of Light, it is owing to a disunion effected by that medium. But the question returns, what evidence have we that Caloric is material?

Certain it is that the foregoing remarks have no direct tendency to the conclusion demanded; yet is equally certain that we have our hands full in the transmission of something through a material medium. In other words, all that has been said rests upon that point in Dioptrics, termed the refraction of light.

an effect from the rationale of which we  
are to derive our deductions in regard to Caloric?  
So few, if any, are they who now pretend to dis-  
pute the materiality of light, that we are not  
afraid of error when we assert it to be univer-  
sally believed. ~~we~~ Laws than seen from the ex-  
periments of Leslie, Herschel, De La Roche, &c.  
that Caloric obeys <sup>exactly</sup> the same Laws that  
prevail over the motions of Light - yet were we simply  
to say that Caloric is material, because it thus  
resembles Light, which is known to be material,  
reason would be unsatisfied, and the inqui-  
ring mind would immediately ask, wherefore is Light  
considered material? To answer this interrogatory  
we are compelled to wander into Optics, and we do  
not hesitate at the digression, as it must be allowed  
that, if Caloric is operated upon by ponderable  
matter in a manner exactly resembling nearly  
all the changes produced upon Light, and

*[Faint, illegible handwriting on aged paper]*

the materiality of light being an inference flowing  
from arguments based upon such changes, we have  
only to display these arguments, prove the proposition  
in relation to light, and Caloric irresistibly takes  
its place under the lead of matter.

Light is admitted on all hands to be some-  
thing radiated in all directions and in right lines  
from every lucid body, which is evidenced by  
its rigid observance of a law in Projectiles, viz.  
that of reflection, a circumstance not only  
arguing its process in right lines, but with  
its other modifications, refraction, and reflection,  
giving ample illustration of its materiality; and  
this by virtue of a corollary, drawn from the  
accepted rationale of these particular effects:-  
the integrity of which rationale is to be found  
in the well-established, as I might say, self-

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

evident proposition, that "Matter can act upon matter alone" - for the idea of attraction took its rise from matter, and would vanish with its extinction - but in what do these effects upon Light consist?

1st. When the Sun's light is transmitted through a small hole, into a dark apartment, and impinges on a horizontal plain mirror, it is "reflected," i.e. changed from a descending to an ascending direction, making exactly the same angle as would an ivory ball projected in the same original direction, against a marble surface - this reflection is caused by an impulse of the mirror upward upon the pencil of light that strikes it, which must, according to the first position, be material.

2d. - When a ray of Light passes from one

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mostly illegible due to fading and the cursive style.

medium into another of greater density, it suffers  
"refraction". For example, if the mirror in the  
above instance were destroyed, by removing the  
amalgam that coated the lower surface, and  
thus rendered transparent, the light would, in-  
stead of being reflected, pass through, though  
not without a change in its direction. It  
would be bent downward, or towards a line per-  
pendicular to the plain at the point of inci-  
dence. Now, it is impossible to conceive how  
this refraction could be effected, unless by attrac-  
tion, which must be excited by the denser me-  
dium, in lines perpendicular to its surface. But  
upon what is this power exercised?— Surely  
not upon immateriality, for we have seen that  
"matter can attract and act upon matter alone"  
hence we have the legitimate inference that

"Light is material."— There is yet another case, similar to the latter, but if possible, more striking. Whenever a ray of light passes a tangent to the surface of any species of matter, it is directed from its cause towards the attracting body— this is termed the "refraction" of Light. We have a familiar example of this— when the sun's rays pass through a chink between two planks of a fence or door, the line of light that falls upon a surface opposite, is invariably broader than the opening through which it passed; proving that the rays were diverged by the attraction of the mass.

Again, there are in nature, and produced by art, many bodies both solid and fluid, possessing the property of absorbing

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side.

or luminating light, according to circumstan-  
ces - of these, Nature furnishes the Diamonds,  
not all the solar pyrophori.

Thus, being of opinion that the materiality  
of Light is placed beyond dispute, it will be  
sufficient for our ultimate purpose, to mention  
that there is a multitude of experiments and  
Natural phenomena, to demonstrate, that Caloric,  
when exposed to the same causes, undergoes the  
very changes, that constitute the basis of those  
arguments urged in proof of the materiality  
of light - that Caloric, though it has not  
been decomposed, is absorbed by bodies, and  
again rejected by radiation and conduction -  
that it suffers reflection, refraction, and  
inflection, observing precisely the same laws  
as prevail over similar changes of light,

i. e. its angle of reflection equals that of incidence. It is refracted when penetrating a denser medium, toward the perpendicular, and its inflection is toward the body it touches.

Hence, we consider ourselves warranted in asserting it to be perfectly consonant with unsophisticated philosophy and sound logic to conclude that "Caloric is a fluid of inconceivable subtlety, possessed in different proportions by, and obedient to all the laws of Matter."

This brings us to the close of our remarks upon the nature of Caloric - and now, when we look back upon the steep we have attempted to mount, and contemplate the bold and craggy course over which we have lent lamely & lamely - though its misty summit is yet far above us, we tremble at

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

our enterprise - But Science has not deserted  
her votary in time of danger, for on a nearer  
view, we find ourselves firm upon the rock of  
Truth, upheld by the tutelary Land of Experience.

Yet as the eye of the Traveller, when he reaches  
some favorite site upon the mountain's slope,  
is enabled to discern beauties before shrouded  
in that distance which now "lends en-  
chantment to the view" - so from our pres-  
ent position, - after having unfolded the  
nature of Caloric, we are prepared to look  
into the more occult character of all those  
natural processes which depend upon its ex-  
istence, - but this, the circumscribed limits of  
our inaugural thesis forbid, compelling us to  
confine our examination to some one of  
them; therefore, as it constitutes one of

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

47  
The most interesting, and important parts in the  
Grand concert of Nature, we shall select,

## Spontaneous Evaporation.

Amongst all the laws that preside over and  
direct the countless processes eternally going on  
in the Grand Laboratory of Nature, there is no  
one, perhaps, to which is assigned a more im-  
portant and extensive office than Caloric or  
Heat—But upon attempting a survey of its  
multifarious effects, we know of none in which  
it appears in a more interesting light than  
that of Spontaneous Evaporation—Before en-  
tering at large, however, upon an examination  
of its use in the economy of Nature, it is  
proper to mention that this term has been  
adapted in contradistinction to Vaporization

Westmoreland Corporation

The undersigned do hereby certify that the above named  
Westmoreland Corporation is a corporation organized under the  
laws of the State of Pennsylvania and is duly qualified to  
do business in this State. This certificate is given in  
accordance with the provisions of the Act in that behalf  
passed by the General Assembly of the State of Pennsylvania  
on the 22nd day of March 1862, and is given in full  
faith and belief that the said Corporation is a corporation  
organized under the laws of the State of Pennsylvania  
and is duly qualified to do business in this State.

and Simple Evaporation - The two latter usually signifying an effect consequent to the artificial application of Heat, while the former is always a Natural process.

Water, for example, under the medium pressure of the Atmosphere, at the temperature of  $212^{\circ}$  always undergoes ebullition, rapidly assuming at the same time, the form of vapor - This is called Evaporation - Evaporation is its conversion into vapor by the application of inferior degrees of heat - But by Spontaneous Evaporation, we are to understand, that process by which almost every liquid, but especially the whole mass of water on the Globe, is perpetually rising insensibly into the air, unaided by art, and seemingly uninterrupted by the lowest temperatures.

To the mind of Philosophy's votary, ac-

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

customed to lift the curtain of Nature's sub-  
lime drama, and explore her secret springs, the  
subject that at present engages our attention,  
is familiar under many forms - yet to one who  
has never viewed the varied beauties of Creation,  
but with the eye of superficial observation, it  
will be necessary to introduce it by experiment.  
Let some water then, be placed in any vessel cal-  
culated to contain it, and exposed unobscured to  
the atmosphere, provided the vessel be rather broad,  
and permitted to stand undisturbed, but a short  
time will elapse before the entire disappearance of  
the water - Now, as in every instance where an effect  
is perceived, the cause is immediately sought for,  
in this we are led to the inquiry, by what  
agency and law is this phenomenon accomplish-  
ed? - The answer to which will consist of nearly

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

all we have to say upon the subject.

It has already been hinted that expansion is one of the effects attributable to Caloric. It now remains to be observed, that the infinite variety in the physical conditions of matter is wholly dependent upon its existence. For Philosophers have agreed (and upon good grounds too) that the attraction of aggregation stands as an invariable - a fixed and inflexible law, extending its dominion over all matter, with a constant tendency to consolidate it into one, unvaried, solid, and infinitely hard mass, which must inevitably take place, had not the wisdom of Omnipotence given it an inseparable associate, Caloric, evermore its antagonist, repelling and modifying its energies, and according to its intensity, giving us the

and
