Cuttings of these plants that were inserted in a cold frame or in boxes in September now require attention. If when the cuttings were planted sufficient space was allowed for their development until they are finally planted in the open, all that they will require now is abundance of ventilation in order to induce robust growth. A good plan is to remove the lights whenever the weather is favourable, placing them on again at night-time. Stir the soil between the plants, removing any moss or dead leaves, and keep the plants well supplied with moisture at the roots. Should the plants require more space, the present is a suitable time to shift them. They may be planted in an ordinary cold frame, with a bottom formed of coal-ashes for drainage, placing a layer of about 2 inches in depth of half-decayed horse-manure and some old Mushroom-bed materials, finishing with a layer of sandy compost. The manure affords an excellent medium for the roots, and enables the plants to be lifted with a good ball of earth at planting time. Lift the plants carefully, giving each a space of 3 inches. Afford water with care, and keep the frame closed for some days, and until new growth is made. If large and early-produced flowering-spikes are desired, do not stop the plants by pinching, but allow them to grow uninterruptedly. If, however, more spikes and a later display of flowers are required, then pinch out the point of each plant when it has attained a height of 4 inches.

SWEET PEAS.

Those that were sown during the first week in February are growing sturdily. Should the pots be already full of roots shift the seedlings to larger-sized pots. The plants cannot be grown too vigorously at this stage, presuming they have abundant space to allow of sturdy growth. Pots 6 or 7 inches in diameter will afford ample space for the plants until planting time arrives. A suitable compost is one consisting of two parts fibrous loam, one part half-decayed horse manure, with a dash of bone meal.

When the first tendril appears some support is necessary for the haulm. Twiggy Hazel or Birch shoots 1 foot in length answer the purpose well; indeed nothing is better than pieces of a partly-worn-out Birch-broom. On the whole the seeds have germinated remarkably well this season, showing how well the crop was harvested last summer.

PHLOXES.

The month of March is a suitable time to increase the stock of both early and late-flowering

varieties of herbaceous Phloxes. If growth is not too far advanced, stools that will admit of division should be carefully severed, selecting small portions from the outside of the stools, as these give the best results. Although this type of Phlox succeeds well in the herbaceous border, if extra large flower-trusses are required the plants should be grown in a separate bed where they can be fed liberally with liquid manures. A good method of increasing the stock of these plants is to insert stout cuttings during the first week in April. They should be placed in sandy loam in a cold frame, keeping the frame shaded until roots are formed, after which air should be given freely. When the plants are well furnished with roots, lift them carefully, preserving as much soil about the roots as is possible. Plant them in a triangular manner about 7 inches apart. These will produce during September and October good trusses of flowers, varying in height from 1 foot to a yard, according to the variety. *E. Molyneux, Bishop's Waltham.*

DAHLIAS.

In a recent number of the *Revue d'Horticulture Belge*, is an article by M. Charles Pynaert, and a coloured illustration of some semi-double Dahlias of large size and with flat florets. They were raised by Mr. Hornsveld, of Baarn, and have been introduced into commerce by Messrs. Capyn & Sons, of Utrecht. Some of the varieties were shown at Düsseldorf, and others at Paris, where they received the award of a Gold Medal.

ANOTHER APPLIANCE TO PREVENT "DRIP."

ALTHOUGH we have adopted in recently-erected plant and orchard houses condensation channels in both the principal and ordinary rafters, similar to those shown on p. 155, yet having suffered considerable damage to Orchids and various other plants from drip in previously erected structures, one could not fail to understand the importance of the editorial remark at the end of the paragraph respecting Messrs. Foster & Pearson's sash-bar. As we could hardly strip the roof off houses in good repair in order to insert glazing bars with condensation channels, we adopted the following methods with perfect success and at very slight cost.

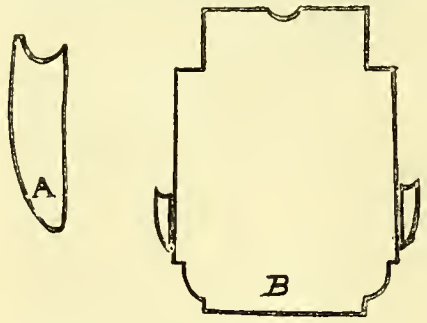

FIG. 81.—APPLIANCE TO PREVENT "DRIP."
A, Section of Pine Moulding (*full size*), with condensation channel.
B, Section of principal Rafter (*one-third actual size*).

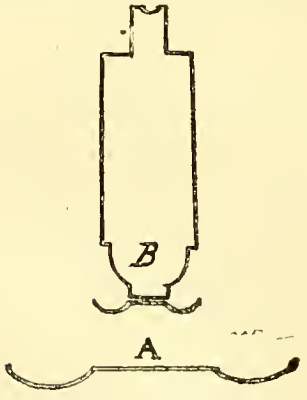

FIG. 82.—APPLIANCE TO PREVENT "DRIP."
A, Section of Zinc Moulding (*fullsize*).
B, Ordinary Glazing Bar (*one-third actual size*).

Anyone adopting this method would naturally vary the form of moulding in keeping with the form of rafter in use, the hollow channel being the important and essential part.

Bearing in mind the importance of obstructing the light as little as possible, we adopted two different devices. To the principal rafters we fastened Pine mouldings (see fig. 81, A). To the ordinary rafters or glazing-bars we fastened zinc mouldings underneath (see fig. 82, A), rolled specially to my design by Messrs. Braby & Co., zinc workers, Euston Road. It is not at all necessary to have the zinc channelling wider than the rafter. The surfaces attached to the bars of both the zinc and the Pine mouldings were heavily coated with thinned white lead, and the whole finished with two coats of paint. *Ralph Godbeer, Rockhurst Gardens, West Hoathly, Sussex.*

GARDEN WALL SHADES.

How frequently it happens that a promise of a good crop of fruit on wall-trees is shattered in one night; yet this might easily be avoided by affording a slight protection, an example of which is shown in fig. 83. A brief description how to make a similar shade will perhaps be useful to those readers of the *Gardeners' Chronicle* who are amateur horticulturists and know just a little of the practice of carpentry. It is not necessary to possess an elaborate collection of tools, and this article is written presuming the reader is not so equipped, the reason being that the man who has the tools generally has the knowledge to use them and would not want suggestions how to make a simple fruit-protector. It is the man who has limited tools and limited experience of woodwork who will, it is hoped, find the instructions given below useful. One can nowadays purchase wood practically finished, *i.e.*, cut to size and machine-planed at but a trifling cost beyond the price of the rough material, this is encouraging to those who have not the facilities for sawing and planing wood in large quantities.

The wall shade shown in fig 83 represents one that measures 8 feet long and 2 feet deep. This is about as long as one part should be made, so that if a greater length is required the shade should be made in two or more parts. If, for example, the shade is required 12 feet long, it is better to make two 6-feet frames rather than one long one, besides which it is very much easier to make them in the shorter lengths and easier to fit them. It is convenient also to have a wall shade detachable, so that for this reason also short lengths are the handier.

The shade is made exactly on the same principle as a light for a cold frame. The top rail, which fits close to the wall, is of 3 by 2 inch quartering of yellow deal, the sides 2 by 2 inch, the bottom or front rail is of 3 by 1 inch stuff, which really means $\frac{7}{8}$-inch thick when planed. This is mortised into the sides, and the sides into the top rail, whilst the intermediate sash-bars, 2 by $1\frac{1}{4}$ inch, are mortised into the top rail, and shouldered on to the bottom one.

This, then, is the theory; the next thing is how to do it. Take the top rail first, which should be cut about 3 inches longer than will ultimately be required; a rebate will have to be cut on the inside edge, as shown in section in fig. 84 at A, the rebate being $\frac{3}{8}$ inch wide and $\frac{5}{8}$ inch deep. The amateur who does not possess the necessary plane to do this can adopt an easier method by nailing a strip on the inside edge, as shown at B, fig. 84, which will answer the same purpose; and the same particulars apply equally for the side rails, although, if adopting the second method, the strips are put on after the frame has been put together, whereas in cutting a rebate out of the solid it is done before making the joints.

Fig. 85 shows how the sides and top rail are put together with mortice and tenon-joint, and also shows the mortice prepared in the side for the front rail. The amateur should note that in the tenon which fits into the top rail the shoulder is deeper on the underside than at the top; this is on account of the rebate, and must be allowed for when cutting the length of the side pieces. If the shoulder or rebate for the glass is fixed on to the frame, the latter can be jointed together by "halving," as illustrated in fig. 84, E. It is of course a much easier way of making the frame; but if the amateur is anything of a carpenter he will naturally prefer to mortise and tenon the parts together.

The intermediate sash-bars should be placed about 15 inches apart. These bars, which are $1\frac{1}{4}$ inch wide and 2 inches deep, are best bought ready prepared; it never pays the amateur to work these up by hand. A section of the sash-bar is shown in fig. 84, C, the dark square representing

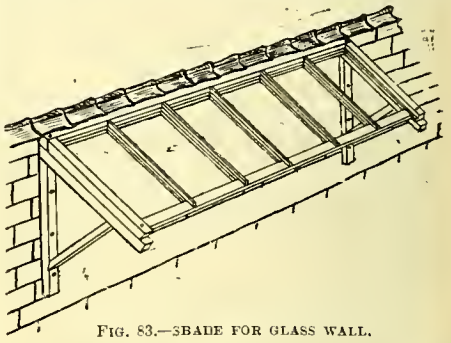

FIG. 83.—SHADE FOR GLASS WALL.

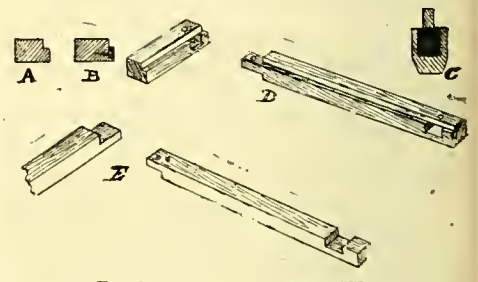

FIG. 84.—SHADE FOR GLASS WALL.
A and B, section of rail; C, section of sash-bar; D, mortice and tenon joint; E, "halving" joints.

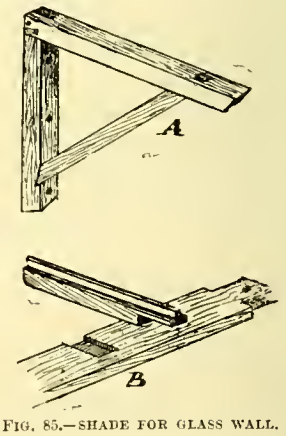

FIG. 85.—SHADE FOR GLASS WALL.
A, wall bracket; B, fitting sash-bars to front rail.

the size of the tenon, which need not go into the top bar more than about 1 inch.

Fig. 85, *b*, shows how the sash-bars are fitted into the front rail, the recess in the latter being ½ inch deep and 2 inches long, the bottom of the rebate when fitted should come flush with the front rail. The tenons on the front rail are 2 inches wide, which means that there is a ½-inch shoulder each side. The bars are fixed to the front rail with a couple of brads or wire pins to each. By carefully following these instructions any length of shading can be made. The shading is fixed at an angle of about 30° to the wall, so that before fixing the frame permanently together the side of the top rail which fits against the wall should be bevelled off with the plane to this angle, then joint-up and secure the tenons to the mortices with ½-inch wooden pegs through them.

To fix the shade to the wall so that at any time it can be taken down, brackets must be made similar in design to those shown in fig. 83, and are of 2-inch-square quartering throughout. The method of putting them together is clearly shown in fig. 85, *a*, so that very little explanation is necessary. The upright is 24 inches long, the top piece 27 inches, which is fixed at an angle of 30° to the upright, and is "halved" to it. The stay is mortised into the top piece, and at the other end fits into a nitch cut in the upright. It is important that these brackets should be firmly fixed, and so the wall must first be plugged where the nails are to come, cutting out a hole for each about 1 inch over and 3 to 4 inches deep with a cold chisel; then drive in a hard wood plug, cutting it off flush with the wall. The shades should be then laid on to the brackets and fixed with screws.

Finally come the painting and glazing. A coat of priming is first required, which is made up of white-lead, dryers, plenty of boiled oil and some red-lead to harden it, and when this has become dry putty up any ill-fitting joints, and then glaze the lights, using 21-oz. glass, which is the cheapest in the end, laying it on a bed of putty at the top and two sides, and after pressing the glass evenly on the putty, scrape off any of the putty appearing above the glass. Put a couple of wire pins to each division into the front rail to prevent the glass slipping down; then proceed to paint with white paint (white-lead, dryers, two-thirds boiled oil and one-third turps), letting the paint just cover the edges of the glass about ⅛ inch at the top and sides. The work should have not less than two coats of paint in addition to the "priming." *S. W. N.*

SEED TRADE.

The Vegetable Crops in Italy.—Advices from Naples state that since the middle of November there has been a succession of hard frosts almost without intermission, and owing to their unusual severity during the past months they have caused great damage even to the less delicate plants.

Cauliflower.—The breadths put out for seed-supply have specially suffered, and it is anticipated that not more than a fourth of the plants will yield seed.

Onion.—English seedsmen are so much dependent upon Italian growers for the Tripoli and Improved Silver-skinned types, that they will regret to learn that the crop will be short all round.

Garden Beans.—Here again will be a great shortage of crop, and no hope of improvement.

Flower Seeds.—The autumn sowing of these has suffered severely, and any quotation of prices which may be made are for prompt orders, but without any guarantee as to the quantities to be supplied. *Pisum.*

ODONTOGLOSSUM × LAWRENCEANUM.

At the meeting of the Royal Horticultural Society on March 14 two hybrid Odontoglossums were exhibited by M. Charles Vuylsteke, of Loochristy, near Ghent, Awards of Merit being recommended in each case. One was named amabile, and was raised from a cross between O. crispum and O. Harryano-crispum; the other, of which an illustration is given at fig. 86, and named Laurenceanum, being from a cross made between O. triumphans and O. Rolfeæ. This latter hybrid is a fine flower, having yellow sepals and petals heavily barred with chestnut-brown colour. The lip is marked with purple over a white ground.

[*From a photograph by Jno. Gregory.*

Award of Merit at Royal Horticultural Society, March 14.

ALPINE GARDEN.

SAXIFRAGA BURSERIANA AND ITS VARIETIES.

Early as the flowering of Burser's Saxifrage usually is, it was much earlier in the present year, and other species appear also to be in advance of their usual time. The only drawback to this exceeding earliness is the possibility of the flowers being cut off suddenly by frost. Where a cold house or frame exists, and these plants can be given shelter for a time, the earlier flowering is appreciated, but where no such shelter is forthcoming the inflorescence loses much of its beauty. I advise shelter for the flowering time only, and for the single purpose of retaining the blooms as long as possible in good condition after they begin to expand. These plants which constantly receive shelter in frames are robbed of much of the early beauty of stem and flower-bud. For this reason the few specimens I now grow are fully exposed, and for a month at least before a single flower opens some kinds are exceedingly beautiful in the colouring of their flower-stems and buds. Of Burser's Saxifrage there are at least three well-marked forms.

S. "Burseriana" (type).—The individual rosettes are small and spiny, leaves greyish, about ½ inch in length. Plant closely tufted, spreading, and of free growth. The flowering-stems are not more than 1 inch long at flowering time. Stems reddish; calyx pale-green, with red tipped segments or lobes. Flowers solitary, white; ovary creamy-yellow. Blooms in February and March.

S. B. major.—This is the finest of the set. In all its parts the plant is fully twice as large as the type. The spiny rosettes of leaves have a heavy glaucous hue, and are rather more irregularly tufted. This is so well marked a characteristic of the plant that the specialist at any season of the year may recognise the variety from all others. The flower-buds and stems are of a pronounced reddish-scarlet, and are conspicuous in the middle of January. Stems 2 to 3 inches long, the alternately-disposed, ovate, acuminate leaves coloured equally dark green and scarlet. Flowers usually solitary, and nearly 1 inch in diameter. This is one of the most valuable of early-flowering alpine plants. A good example of this in a 7-inch pot has given some nine dozen of its glistening pure white flowers.

S. B. macrantha is said to be the largest-flowering variety of this group, and it blooms later. The rosettes are almost wholly green, exceedingly minute, and contracted at the tips, not widely expanded as in the other kinds. A six-year-old plant of this singularly sparse-flowering variety is but one-fourth the size of S. B. major; its lateness to bloom is its chief merit. If potted quite firmly in loam, road-grit, and old mortar-rubble, and the plants divided as often as necessary so soon as flowering is well past, these Saxifrages give but little trouble; but good drainage should be provided, and abundance of water should be afforded throughout the spring and summer.

Saxifraga Grisebachii.

The hirsute, crimson inflorescences of this Macedonian species have proved an attraction for weeks past, from the moment that their coming was signalled by the more mature rosettes assuming the cup form in their centre, and the first touch of blood-crimson was visible, until nearly eight weeks later, when the leafy, hairy stems have become 6 inches high, crowded in the club-shaped form of the upper portion with somewhat fleshy, roundish, crimson bracts. In the growing season of last year for a long time the 3-inch-wide rosettes gave one the idea of a small S. longifolia, but lacking a good deal of the latter's hoary incrustation. Presently, however, S. Grisebachii attempted to separate the large rosette, several plants forming two centres each and producing the distinct inflorescence referred to. Prior to the flowering stage being reached, this dividing of the rosettes robs the plants of much of their beauty, and a growth not unlike that seen in the winter rosettes of Androsace sarmentosa results. It is to this peculiarity, however, that much of its freedom of flowering is due, and arranged among stones on the rockery it is the most picturesque member of the genus in bloom in February. The species grows freely in any sandy soil, and the rosettes will root freely in coal-ashes and similar material. *E. H. Jenkins.*

NOVELTIES.

ARABIS ALPINA.

VARIETY WITH DOUBLE FLOWERS AND VARIEGATED LEAVES.

Among the many novelties brought out this season this is one which will no doubt attain great popularity as, being perfectly hardy, it can be grown successfully by anyone and without much trouble. In 1899, Mons. A. Lenormand, the well-known seed and bulb grower of Caen, was the fortunate raiser of Arabis alpina with double flowers, a form which is now well known wherever hardy plants are grown, for it has been found to possess all the good qualities with which it was credited when it first appeared. An accidentally variegated branch which had been noticed and carefully nursed by Mons. Lenormand was the origin of the entire stock of the novelty now under notice. It may be confidently expected to find a place in every garden on account of its variegated foliage coupled with its conspicuous flowers, which in early spring are produced in great abundance. The flowers are pure white, perfectly double, delicately scented, and in general appearance much resemble those of a double Stock, but as they are borne on long, slender stems, and not set so closely together, they are particularly useful for cut flowers. It may be added that, even when not in bloom this plant still possesses special decorative value on account of the bright colour of its foliage, which in the early stage is quite white, but gradually develops into a regularly and evenly variegated plant. *Geo. Schneider,* 17, *Ifield Road, Fulham Road, S.W.*

[The doubled-flowered Arabis was in cultivation many years ago, but has recently been re-introduced. Ed.]

Spraying.—It has been demonstrated over and over again by nearly every experiment station in the country, says *American Fruits,* that the codling moth can be largely controlled by thorough spraying of the trees with a poison. At least two applications are necessary, the first just after the petals of the blossoms have fallen, and the second a week or ten days later. Use either Paris-green at the rate of 1 lb. to 100 gallons of Bordeaux-mixture, or the arsenate of lead at the rate of 1 lb. in 50 gallons of the fungicide. It is largely a question of thoroughness of the application.

The Week's Work.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Cœlogyne cristata having flowered and been given a rest for a week or two afterwards may now receive attention. Large specimens will retain their vigour for a number of years without much being done to them; but small plants should be potted-on every two years or so. When any large plant needs re-making up, carefully separate the pieces, leaving three or four pseudo-bulbs on each and a short length of rhizome without bulbs for convenience in potting. Use shallow pans of suitable size, and having perforations around the sides. Fill these to within 3 inches of the rims with clean drainage, over which a layer of moss may be placed to prevent the compost being washed into it. The latter may consist of equal parts of fibrous loam and peat, and a fifth part of sphagnum-moss, adding a good sprinkling of coarse silver-sand and small crocks. Commence to rebuild the specimen on a low conical centre, and as the sides are neared so dispose the pieces that the growing points may be directed towards the centre of the specimen. Do not bury the rhizomes or bulbs more than is needed to steady each in the desired position, but work the materials in evenly and press them together moderately firmly. When completed give a good watering to settle the compost, and then for a considerable time afterwards no further supply will be required. As growth proceeds the soil should be kept moist, and when rooting freely a generous overhead supply should be afforded. Place the plants in the coolest and shadiest part of a Cattleya-house, or in one having intermediate conditions, but on no account grow them in a hot humid atmosphere or they will fail to flower well. Should an increase of stock be desired, lay the old back pieces on a moist surface and after a time new growths will appear on some of them. C. cristata alba should be held over till later.

Cœlogyne Massangeana and *tomentosa* are useful when grown in suspended pans or baskets. They need a similar rooting medium to that afforded C. cristata, but should be placed in a warm house. Much water is needed by these species and by C. Dayana only when the plants are growing freely, at other times a very limited supply will keep them healthy. C. Dayana enjoys abundance of heat and moisture during the growing season now commencing. The inflorescences being long and pendulous, it is necessary to raise or suspend the plants well above the stage. Repot or renew the surface materials as the case demands after the flowers have passed and root action is about to commence, using a similar compost to that recommended above. Spray the under sides of the leaves frequently to prevent red-spider.

Cœlogyne pandurata does not usually produce new roots until the young growths are somewhat advanced. As soon as the roots appear give fresh material for the roots to enter. Plants of this species thrive well fixed on a teak-wood raft, with a few large pieces of crock, and equal parts of peat and moss placed between the rhizomes and raft. Starting with a good length of raft, new material may be added as the plant elongates, tying each new rhizome down to the raft when strong enough to bear the strain. Elevate the raft on inverted pots above the stage in a moderately shaded part of an East-Indian-house. Afford water copiously when roots are developing freely, but after the bulbs are made up decrease the supply until during the autumn and winter months, when an occasional dose will suffice.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Wythes, Esq., Copped Hall, Epping, Essex.

Necessity for Promptness.—With the advent of spring the work becomes of such importance that neglect in doing it at the right moment often brings disappointment. From various causes it is sometimes difficult to avoid falling into arrears of work, but the old adage, "Never put off until to-morrow what can be done to-day," is very applicable in gardening, and should be acted upon.

Creepers that were cut back and tied-in early in the year are now making growth, and will require attention. Over-crowding of the young growths should be avoided, and all weakly shoots should be removed. The present is a suitable time to make good any losses, and either of the following species, if planted-out in a warm conservatory, will make an abundance of growth during their first season—Passiflora quadrangularis, Ipomœa Thomsoni, I. paniculata, Aristolochia gigas, A. Sturtevanti, Hexacentris mysorensis, Vitis Voineriana, and Schubertia graveolens.

Cyclamen Seedlings that were potted off into thumb-pots as advised in a previous calendar will be ready for a shift on into a size larger pot. The corms should be kept well above the surface of the soil, and similar compost to that advised for the first potting will again be suitable. The plants should be kept growing for some time in a warm and moist atmosphere, where they can be shaded from the direct rays of the sun.

Bouvardias, Fuchsias, Abutilons, Aloysias, &c., that were placed in heat as advised, will be making growth and roots. If it is desirable to increase the stock, take off cuttings with a heel attached, and insert three or four in small pots filled with old potting soil, plunging them in a bed having considerable bottom-heat. If it is intended to cultivate the old plants again, knock them out of the pots and reduce the soil about the roots, then repot them in pots of a slightly smaller size. Place them in a warm, moist atmosphere, and syringe them frequently until they have made new roots, when they should be afforded another shift into larger pots and be gradually hardened.

Achimenes.—Place a few sprigs of Birch around the sides of the pots to support the growth of the plants; they will then appear much neater than when tied to sticks with raffia.

Aphis.—Keep a sharp look-out for aphis. Houses containing plants should be frequently fumigated with the XL-All Vaporiser at this season.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Border Carnations.—These will soon require to be planted out. They do well in a medium loam inclining to be heavy rather than light. The border will have been prepared some time since by thoroughly mixing with it, two spades deep, a liberal supply of rotten hotbed manure and fresh loam, which should be free from wireworm, adding a good sprinkling of wood-ashes, old lime rubbish, and soot. Let the beds be made about 4 feet wide, and put the plants 12 inches apart. The alleys between the beds may be made 2 feet wide. If two alternate rows of Carnations and Violas of contrasting colour be planted diagonally, the effect will be very good in large borders, especially if the Carnations be supported with spiral wires. Examine Carnations that were planted out last autumn, and make the plants firm in the soil. Fill up any blanks there may be, and apply a dusting of Carnation-manure over the soil, which should be loosened a little with a fork when in a moderately dry condition. Robust-growing varieties, as Duchess of Fife, Viscountess Melville, Mrs. Muir, Dundas, &c., winter well outside. Clove-scented varieties, such as Uriah Pike, are best wintered in pots placed on shelves in a cool well-ventilated house, as they are apt to be affected with "spot" if kept in the open. Queen Alexandra is a fine heliotrope-coloured sport from Uriah Pike.

Calceolarias that were rooted in frames last autumn should now be transplanted into cold pits or temporary structures. Put 6 inches deep of rough leaf-mould in the bottom and 6 inches of fine rich soil on the top. Carefully lift the young plants and plant them 6 inches apart each way. Shade them from bright sunshine until they have become established, then admit air freely; pinch the plants occasionally to keep them dwarf and sturdy. In their summer quarters Calceolarias should be afforded deep loamy soil well enriched with rotten manure, as the plants die away when grown in poor, shallow soils.

Pentstemons and Phloxes that were propagated last summer may now be planted. They require rich and well-prepared soil.

Dactylis glomerata varieties may be divided. Let the bed be enriched with manure, as the plants become rusty on poor soils.

Lamium aureum requires slight shade. The plants may now be divided; also various Sedums, Saxifrages, Polemonium cœruleum var.

Gladiolus.—If these be wanted early they can be forwarded by potting and placing them under glass, planting them out at the end of May. For ordinary planting choose an open situation and rich, sandy soil. Plant the bulbs about 12 inches apart, and cover them with soil 2 or 3 inches deep. G. brenchleyensis has a good effect when springing out from a bed of Gaura Lindheimeri.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Onions [see illustration on p. 203].—The demand for large Onions has increased, and they are now used extensively for culinary purposes. If the seeds were sown early in order to secure large bulbs, and if previous instructions have been followed, the soil must now be made quite ready for the reception of the young plants. Apply a good dressing of soot and wood-ashes, and should the surface be at all uneven as the result of deep cultivation, level it down with a fork to a fine and firm condition. When planting give the plants plenty of room, allowing 18 inches between the rows and 12 inches between the individual plants in the rows. Plant in trenches of sufficient width and depth to freely admit the soil and roots without cramping. Place about 1 inch of the stem below the ground to prevent the plant from being disturbed by high winds. I have sometimes placed a twig of Birch to each plant until it is firmly established. A sprinkling of bone-meal applied in the trenches will favour the growth of the seedlings. The soil round the stems will have to be gradually removed subsequently, and must be entirely cleared away before the bulbs commence to swell. If the weather is dry and warm sprinkle the plants with water in the morning, and again early in the afternoon, and when they are established mulch the soil with specially prepared stable-droppings. These will retain the moisture in the soil, and encourage the roots near to the surface. Quick development in the plants render them less liable to the ravages of the Onion-fly, which gives us very little trouble here.

Potato Planting.—If the soil is in a good and workable condition, push forward the work of planting, carrying it out in the method best suited to the condition of the soil. If this has become well pulverised by early autumn digging (which we find the best), and is of a light and open nature, a Potato dibble may be used. Personally I prefer opening a trench in which the sets are placed at an equal depth and distance apart, according to the variety, to allow full development of top growth. The Potatos when planted in the trench are covered by the soil removed in making the next trench, and so on, leaving a slight ridge to mark the row. In those cases where the ground has not been previously dug, or where the soil is of a heavy nature, plant the tubers as digging proceeds, using the spade to its full depth. As most garden soils will produce good and cleaner crops of Potatos of sufficient size for culinary purposes without the addition of fresh manure, it will be necessary only to apply a good dusting of air-slaked lime as the work proceeds.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Grafting should be commenced as soon as the sap rises freely in the stocks, commencing with Cherries, and proceeding afterwards with Plums, Pears, and Apples. In the case of young stocks, headed down as advised, the process is a simple matter. Level them down to green wood, as a portion of the stock will possibly have died back from the early cut. Dig up the scions carefully, and wash all grit from them; then cut them into 6-inch lengths, using one knife for the rough work, and another for the process of grafting. Tongue (see fig. 88) and rind grafting (see fig. 87) are most suitable for small stocks, and in the former case scions of a size near to that of the stocks should be selected. In cases where the stocks are too large to allow of this, it is important that the bark of scion and stock should meet. The sloping cut made in the scion should not be less than 3 inches long with a reverse cut at the top of the slope to form the tongue. The stock should be cut in a similar manner, with a transverse cut in which the tongue of the scion must be fixed firmly. The

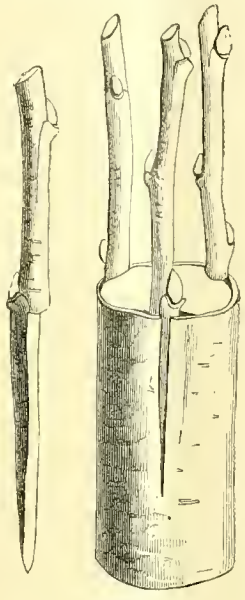

Fig. 87.—Crown or Rind Grafting.

Fig. 88.—Whip or Tongue Grafting.

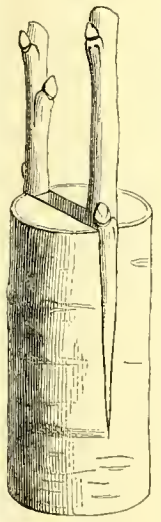

Fig. 89.—Cleft Grafting.

scion should be bound tightly to the stock, sufficiently so that an upward pull would not displace it. Cover the operated part with clay, making all as nearly air-tight as possible, then cover with moss. Grafts made near to the ground level may be banked up with soil, and those so treated often grow away most quickly. If much grafting has to be done use grafting wax, made according to instructions given last week; it is much more convenient than clay. Break off a portion of the wax and warm it in an iron pot; then apply the wax with a half-worn painter's brush. Grafts so treated as a rule do not start so freely into growth as those covered with clay, but success is more certain. Old standard trees which were headed back some time since should now have the wounds trimmed back with a sharp knife or chisel. For the grafting of trees of this description I prefer to use scions of the second year's growth, if they have good dormant wood-buds; failing these, well-ripened growths of the previous year are necessary. For old trees, on which four to six grafts need to be placed on each branch, according to size, I advise wedge grafting, as it produces a better union, and the scions are also better able to withstand strong winds. Whether clay or wax be employed, moss should be used to cover the whole externally, by so doing the scions are kept uniformly moist, and protected from cold winds and hot sunshine.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Early Peaches.—The earliest Peaches will now be stoning and the trees should not be forced severely until the stoning stage is past. Maintain a temperature at night of 55° to 60° and allow a rise of 10° during the day. Patience must be exercised until this trying period is passed. The final thinning of the fruit should then be carried out, and the number to be left on each tree will depend on the vigour of the tree and the condition of its roots. One fruit to each square foot of space upon Peach-trees, allowing Nectarines to be 2 inches closer, may be recommended for healthy trees, and given liberal treatment good average fruits may be expected. Tie down the shoots as they require it and remove any superfluous growths to avoid over-crowding, finally leaving the shoots 6 to 9 inches apart. Stop any shoots that are growing extra strong or remove them altogether in order that there may be an even flow of sap over the whole tree. Afford tepid liquid manure and other stimulants to old trees, also apply a good mulch of short stable manure, care being taken to leave a very little ventilation on at night for the ammonia to escape. Syringe the trees freely twice each day, and close the house early in the afternoon with abundant moisture, occasionally using clear soot-water of moderate strength for damping the surfaces in the house.

Succession Peaches will require daily attention to disbudding and thinning of the fruits as each tree passes out of flower. In some cases a partial thinning of the flowers on the underside of the shoots of weak trees will be beneficial. Disbudding should be deferred for a time on any trees that have been recently removed or root-pruned, and until they are growing freely. A shoot at the base of each piece of last year's wood and a leader are generally enough to furnish the trees with fruit-bearing wood for the following season. As the fruits increase in size these should be further reduced, and do not allow too large a number to remain on the trees for stoning above what are required for the crop, or the object of early thinning will be defeated. Pass the brush over the flowers if the weather be unfavourable for pollination, and fumigate the house moderately should green-fly make its appearance. Do not permit the trees to feel the want of water at the roots or suffer a check from careless ventilation.

Strawberries will become more plentiful during this month, and less forcing will be necessary to swell and ripen the fruit. Later plants will be grown under more favourable conditions, and will set and swell their fruit freely. Ventilation should be increased as the sun gains more power, and the plants will require to be looked over twice daily for the purpose of watering any that require moisture. Syringe the plants freely twice each day except when they are in flower, and apply manure-water liberally until the fruits change colour; then remove the plants to a cooler house, and maintain a constant circulation of warm air. Later plants should be brought in from cold frames as required to keep up a constant supply.

Campanula glomerata.—The *Gartenwelt* of March 4 contains illustrations of a "stemless" form of this pretty species. The stem is so short that the flowers rest only slightly above the rim of the pot in which the plant is growing.

APPOINTMENTS FOR APRIL.

SATURDAY, APR. 1—Société Française d'Horticulture de Londres Meet.
TUESDAY, APRIL 4—Truro Daffodil Show (2 days).
THURSDAY, APR. 6—Linnean Society Meet. Royal Horticultural Society of Ireland Spring Show.
Royal Horticultural Society's Committees Meet. National Rose Society's Committees Meet.
TUESDAY, APR. 11—Devon Daffodil and Spring Flower Show at Plymouth (2 days). Brighton Spring Flower Show (2 days).
WEDNESDAY, APR. 12—Shropshire Horticultural Society's Spring Show. Chester Paxtou Society's Spring Show (2 days).
SATURDAY, APR. 15—Kiddermiuster and District Horticultural Society's Daffodil Show.
TUESDAY, APR. 18—Midland Auricula and Midland Daffodil Society's Show at Birmiogham Botauic Gardeus
WEDNESDAY, APR. 19—Darlington Spring Flower Show. Royal Botanic Society's Flower Show. Glamorgan Spring Flower Show. Croydou Flower Show.
MONDAY, APR. 24—Easter Monday. Bank Holiday.
TUESDAY, APR. 25—Royal Horticultural Society's Committees Meet, and National Auricula and Primula Society's Show combined.
THURSDAY, APR. 27—National Auricula Society's (Northern Section) Show at Manchester (Provisional).
FRIDAY, APR. 28—Royal Botanic Society Meet.

SALES FOR THE WEEK.

WEDNESDAY, NEXT—
Azaleas, Rhododendrons, Palms, Roses, Fruit Trees, Perennials, Border Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Roses, Azaleas, Palms, &c., at Stevens' Rooms, at 12·30.
FRIDAY NEXT—
Herbaceous Plants and Perennials, Liliums, Border Plants, and Bulbs, Azaleas, Roses, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Imported and Established Orchids from various sources, Orchids in Flower and Bud, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.
(*For further particulars see our Advertisement columns.*)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —46·1°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March* 29 (6 P.M.): Max. 56°; Min. 47°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 30 (10 A.M.): Bar., 29·9; Temp., 51°.
Weather—showery, with occasional sunshine.
PROVINCES.—*Wednesday, March* 29 (6 P.M.): Max. 53°, S.E. Coast of England; Min. 49°, West of Scotland.

Do Varieties Degenerate?

THE discussion which took place at the Scientific Committee on Tuesday last on the question of the degeneracy of varieties was very instructive. The subject was introduced by the Chairman, the substance of whose remarks is appended. Mr. A. DEAN opened the discussion with a short paper covering the whole matter at issue, and the speakers included Messrs. PERCEVAL, BAKER, ODELL, WORSLEY, DOUGLAS, GORDON, SHEA, CHITTENDEN, and others, a report of whose remarks will be given in a subsequent issue.

Nothing is more certain than that individuals when no longer in harmony with their surroundings disappear. In the struggle for existence and in the competition with other individuals, the one least well adapted to sustain the onslaught succumbs, or, as the adage has it, the weakest goes to the wall. What is true of individuals must be true of species, which are collections of individuals, and must be equally certain in regard to varieties. But let us suppose that the conditions remain favourable, that no one individual dominates over another, then the balance is maintained —individuals, varieties, species remain as they were.

Although these are truisms, yet every now and again the question is raised—Do varieties degenerate?

Under cultivation every effort is made to maintain the favourable conditions unimpaired, to secure the permanence of the variety, to afford it preferential treatment, and to protect it not only from adverse conditions but from internecine competition.

Hence it is that, on the one hand, certain varieties, such as the Black Hamburgh Grape, the Admiral Curzon and Sportsman Carnations, alluded to by Mr. DOUGLAS in our last issue; the Ashleaf or the Beauty of Hebron Potatos, still retain so much of their pre-eminence that they have not been displaced or supplanted by newer comers.

On the other hand, many varieties appear, have but a short career, and then disappear. Not one of the five hundred varieties of Carnations mentioned in THOMAS HOGG'S catalogue is now in existence, according to Mr. DOUGLAS.

Now what we want to know is, whether a wearing-out process really occurs, independently of external agencies, whether the so-called degeneracy is innate, or whether it is merely apparent, arising from the substitution of some newer variety which is supposed to have, or really does possess, superior qualities.

These are the questions which were discussed at the meeting of the Scientific Committee, and in order to give point to the discussion and to obviate discursiveness, it was judged advisable to confine the discussion, so far as possible, to the question whether varieties propagated by vegetative methods do deteriorate independently of external conditions, and if so, why? For convenience sake, and because Potatos loom largely in the public mind at this time, the illustrations were confined as nearly as might be to the Potato. In other words, Do varieties of Potatos raised from sets and subject to unaltered conditions deteriorate, and if so, why?

LINNEAN SOCIETY.—A meeting will be held on Thursday, April 6, at 8 P.M., when the following papers will be read:—(1) "Intra-axillary Scales of Aquatic Monocotyledons," by Professor R. J. HARVEY GIBSON, F.L.S.; (2) "A Further Communication on the Study of Pelomyxa palustris," by Mrs. VELEY, F.L.S. Exhibition: Pitchers of Nepenthes, with lantern-slides, by Mr. W. BOTTING HEMSLEY, F.R.S., F.L.S.

BEQUEST TO THE ROYAL HORTICULTURAL SOCIETY.—Mrs. JANE BEGLEY, the widow of the late Dr. W. C. BEGLEY, Medical Superintendent of Hanwell, has among numerous other legacies a bequest of £250 to the "Royal Horticultural Society, Chiswick." As the Society has not actually given up possession of Chiswick, the bequest, we presume, holds good.

THE FRUIT INDUSTRY.—The Departmental Committee appointed by Lord ONSLOW held sittings on March 21st to the 24th. The following members were present:—Mr. A. S. T. Griffith-Boscawen, M.P. (Chairman), Colonel Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Hodge, Mr. Vinson, Dr. Somerville, Mr. P. Spencer Pickering, M.A., F.R.S., the Rev. W. Wilks, M.A., and Mr. Ernest Garnsey (Secretary). The Committee had under their consideration the draft Report prepared by the Chairman.

FLOWERS IN SEASON.—From Messrs. PAUL & SON, Cheshunt, we have received specimens of Eucommia ulmoides, a species remarkable for the large quantities of caoutchouc it contains. It has proved hardy at Cheshunt and at High Beech, as also at Kew, so that there is a possibility of having a hardy rubber-tree amongst us. The new Jasminum primulinum and Carpenteria californica have succumbed this winter at Cheshunt, although the latter had previously lived through several seasons.

—— To Messrs. R. VEITCH & SONS, of Exeter, we are indebted for cut specimens of the deciduous Japanese Magnolia Kobus, with large spreading white flowers, richly perfumed.

MECONOPSIS INTEGRIFOLIA.—There is some doubt as to whether the plant introduced from Central China by Messrs. VEITCH, through Mr. WILSON, is of the same species as that which was figured in the *Flora and Sylva*, and which was, we believe, collected in Tibet. The principal difference is in the stigma, which is sessile in WILSON'S plant, whilst in that pourtrayed in the *Flora and Sylva* the stigma is raised on a long style. It is possible, therefore, that we may have more than one species. At any rate the question will soon be decided, for Mr. WILSON has just returned from China, bringing with him seeds not only of this but of various other species of Meconopsis, besides other plants of great interest, of which we shall hear later on.

HALF HOLIDAY AT KEW.—It is reported that from this date the young gardeners at Kew are to have a half holiday on alternate Saturday afternoons, and only sufficient men will remain on duty to attend to the necessary work.

THE ROYAL AGRICULTURAL SOCIETY announce that an Agricultural Education and Forestry Exhibition will again be held in connection with the Society's show to be held at Park Royal from June 27 to 30 next. The Forestry Department will be organised on the same general lines as last year, and offers of exhibits are invited for the following sections:—(1) Seeds and cones of trees and shrubs. (2) Seedling trees and transplants, consisting of specimens and plants suitable for woods, plantations, coverts, shrubberies, &c.; plants suitable for agricultural hedge-rows, with illustrations of planting; and collections of Willow-plants for industrial purposes (cricket-hats, basket-making, &c.). (3) Woods and plantations, chiefly photographs and diagrams, showing systems of treatment as to mixing, thinning, &c. Photographs of historic or specimen trees. (4) Timbers. Planks and hand-specimens of home-grown woods of various species. Specimens of timber, &c., showing the effects of pruning, injuries, &c. Specimens of timber showing the effects of creosoting and of other methods of preservation. Articles in process of manufacture from home-grown timber. (5) Insects and diseases. Specimens of forest insects and of fungi and their ravages. Characteristic examples of the attacks of game, birds, squirrels, voles, &c. (6) Plans, maps, models, &c., illustrating working plans, forest exploitation, manipulation of timber, &c. (7) Forest and nursery tools, instruments and appliances. Any offers of exhibits or enquiries should be addressed to the Secretary of the Society at 13, Hanover Square, London, W.

FORESTS, WILD AND CULTIVATED. — Dr. AUG. HENRY delivered a very interesting lecture on this subject at a meeting of the Horticultural Club on Tuesday last, when the attendance was much larger than usual. Unfortunately the pressure on our space compels us to hold over our notice until next week.

NICOTINE POISON.—Two well-known firms of seedsmen have been fined £1 and costs for selling a poison called nicotine without having complied with the necessary regulations. The bottle, it was stated, contained enough nicotine to kill 100 persons. It is a pity that the dealers do not take the trouble to comply with a law so evidently framed in the public interest.

JAMES GORDON, the "eminent" nurseryman of Mile End, is mentioned frequently by botanical writers. PETER COLLINSON (LYSONS's *Environs of London*, Supplement, p. 417), writing in 1764, describes him as "most celebrated." LYSONS (p. 147) says he first introduced the Sophora japonica into England; and (p. 492) that he had his grounds in the parish of Stratford, Bow, and St. Leonard's, Bromley. He was "well known for his extensive culture of exotic plants." According to the *Annual Register*, he gave his name to the well-known order [genus] of plants called Gordonia about 1776. He is mentioned in RICHARD WESTON's *Critical Remarks on Botanical Writers à propos* of MILLER's *Gardeners' Dictionary*. The *Gentleman's Magazine* of 1781 records the death, at Barking, of Mr. JAMES GORDON, senior, the "ingenious and eminent botanist," January 20. The will of JAMES GORDON, nurseryman, Fountainbridge, Edinburgh, was proved April 6, 1788. "*Notes and Queries*," *February* 11, 1905.

THE SHROPSHIRE HORTICULTURAL SOCIETY will hold a Spring Flower Show on April 14 at Shrewsbury instead of the Chrysanthemum Show usually held in the autumn. The Summer Show will be held on Wednesday and Thursday, August 23, 24, in the Quarry grounds, Shrewsbury. The cash prizes offered in the schedule amount to £1100, and in addition a Silver Challenge Vase of the value of 50 guineas for Grapes is offered. Entries for this show will close on August 16, 1905.

GARDENING IN NEW ZEALAND.—A new work on gardening at the Antipodes has been published by Mr. ELLIOT STOCK, entitled *My New Zealand Garden*, by a Suffolk lady. The work is illustrated by views of nooks and corners and remarkable shrubs and trees in the garden.

"THE TROPICAL AGRICULTURIST."—This Journal, hitherto published by Messrs. A. M. & J. FERGUSON, of Colombo, has secured to itself a large measure of appreciation for the collection and diffusion of information relating to all descriptions of vegetable produce cultivated in the tropics, together with an abundance of details of importance to planters and commercial men. We now learn that the Journal in question is to be amalgamated with the Magazine of the Ceylon Agricultural Society, and that it will in future be edited by Dr. WILLIS, the Director of the Botanic Garden, Peradeniya, with the assistance of some of the old staff. The Journal will be published at the *Observer* office as before. Subscribers to the Ceylon Agricultural Society will receive the *Tropical Agriculturist* every month without extra charge.

"THE TIMBER TRADES JOURNAL" does not believe in the adage that a big book is a great evil. Its number for March 18 is a bulky one richly illustrated and full of matter of interest to its clients. In addition there are articles which appeal to the general reader, such as those on West Africa, Sweden, and British Colombia. Those who desire to gain some idea of the extent and importance of the timber trade and of the sources whence its supplies are obtained, should peruse this valuable production (RIDER & SON, 164, Aldersgate Street).

"HARMSWORTH ENCYCLOPÆDIA."—This is to be published in forty fortnightly parts at a cost of 7*d*. each. With 160 pages of illustrated letterpress per part, this cannot be called expensive. It professes to be a history, geography, doctor, lawyer, and business-guide all in one, and scientific information is also included. Judging by the first part the volume will be very serviceable to general readers, but we wish that the compilers had consulted the article "Accent," and afforded to the uninitiated some idea of the pronunciation of unfamiliar words. For instance Abrus, Alcyonaria, Alchemilla, in fact almost all the troublesome words, are printed with no accent or punctuation to indicate whereon the stress should be laid. Some of the illustrations are disproportionately large; the portrait of a distinguished admiral, for instance, takes up a whole page, whilst maps of Africa do not occupy half the space. A scale of magnitude seems generally deficient in the illustrations. This Encyclopædia (*Everybody's Book of Reference*) is obtainable from the Amalgamated Press, Ltd., or from THOMAS NELSON & SONS, London.

THE SWANLEY HORTICULTURAL COLLEGE: CURE FOR "SPOT" IN CUCUMBERS.—We have received the following communication from the Swanley Horticultural College, where the means described in the letter are believed to be a cure for this disease. The authorities do not ask £1,000 for the recipe, but only that the process may be so named that the cure may be associated with the College:—"On the first appearance of the spot, immediately remove all affected parts and burn them. Then, on the same evening, apply to the pathways of the house through an extra fine rose the following mixture: To every 5 quarts of water add 1 pint of Calvert's carbolic acid (No. 5), and thoroughly mix acid and water together. This done, the preparation is ready for use. Give the pathway a light damping down, and take great care not to allow the mixture to touch either the plants or the border in which they are growing. We intend to carry our experiments further this season, and try if possible to discover a preventive also. Upon this subject we hope to be able to make a few remarks after the year has further advanced. We shall be very pleased to show any gardener round our crops at any time, in order to bear out our statements."

VEGETABLES.

POTATO-PLANTING.

THERE is room for much improvement in the manner Potato-planting is generally practised. In order to secure success, a thorough preparation of the ground, an early selection of suitable "sets," and the adoption of the proper manner of planting, are matters requiring the closest attention. A friable soil and one that is well cultivated undoubtedly greatly facilitates planting; but although many growers complain of their soil being unsuited to Potato cultivation owing to its heavy and retentive nature, it must be crude indeed if it cannot be converted into a more suitable state by proper treatment. Such soils, with time and with the requisite attention, may be made to produce excellent crops of vegetables, including Potatos, the retentive nature of such soils, especially in dry seasons, being more favourable to growth than is the condition of others that are light and porous. The land on which my vegetables are grown is of a heavy nature, and with a view of preparing a site for Potatos it was ridged last autumn, and at the present time the sides of the ridges when disturbed crumble into small particles.

It may not be too late even now for those whose ground intended for late varieties is of a heavy nature to form it into ridges, for even a fortuight's exposure to wind and sun will aid the work of planting and will benefit the crop later. Another advantage in ridging heavy ground for Potatos is that the ridges may be left at the time of planting and thus afford protection to the tender shoots from frost, the soil meanwhile being ameliorated by the exposure it receives, and will fall to a fine state when levelled down as the growth and season advance.

The width of the ridges should be regulated according to the variety of Potato grown; thus for most Ashleaf varieties I allow a width of three good spits, or say 27 inches, while for stronger-growing kinds I give more space in proportion to their requirements. The distance to allow between rows requires consideration. The heaviest crop which I have ever seen of the variety Up-to-Date was from plants afforded a yard space between the rows, and even at this distance the roots practically met. It is no economy to plant Potatos thickly, and in gardens where room is limited a greater distance between the rows will not only result in better crops of Potatos, but allow room for planting such crops as Broccoli, &c., between the rows.

Do not permit the "sets" to remain in bins or heaps until they are required for planting. They should be evenly selected, and stood on end in shallow trays, the latter having little blocks of wood at each corner to allow a current of air to pass between them. The trays when filled may be stacked one upon another in a cool fruit-room or in a light airy shed. In such positions the sprouts which form will be strong and sturdy, and when the time arrives for planting several of the trays may be carried on the hand-barrow to the trenches, and the tubers handled without much damage being done. The trays referred to are most useful in a garden, and are easily made. When cleaned they are useful for storing Apples during winter.

The modes of planting vary, and this is noticeable in different districts. On light soil it is a good plan to dig the ground and plant the tubers at the same time. A trowel is preferable to a dibber for use when planting, for when the latter is used a cavity is often left below the tuber. A strong home-made foot dibber is used in some gardens on large breadths of ground that have been dug, the sets being simply dropped into the holes, and the surface of the soil raked over. This is a quick way of planting; but, as stated above, the sets are not at a uniform depth, which is indicated later by the irregular way in which the shoots come through the ground; the sides and bottom of the hole also present a hard surface, which is not so suitable to the sets as when they are resting on and surrounded with friable soil. *Richard Parker.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

CUCUMBERS WITHOUT FERTILISATION.—I am forwarding by this post two unfertilised Cucumbers. The stigmatic part of flower was cut from the ovary before opening. When growing early Cucumbers I always remove the male flowers so as to increase the fruiting power of the plant, as I have proved on several occasions that fertilisation is only necessary when seeds are required. Why gardeners should encourage male flowers and weaken the plant by fertilisation and the production of seeds when saleable "fruits" only are wanted, I am at a loss to understand. The Cucumbers I am sending were cut from a plant growing in a 6-inch pot. *G. H. H. W.* [The result is strictly analogous to that in the coreless apple. Ed.]

"BLACK STRIPE" IN TOMATOS.—I have read with great interest the letters from Mr. Ward and Mr. Owen Thomas *re* "Spot" on Cucumbers, and in the hope that it may be of service in contending against this disease, I would like to give you my experience on "Black Stripe" in Tomatos. For some years I have been much worried with this pest among my Tomato plants. Starting five ago with three or four plants it gradually spread until in 1903 it affected 300 plants, or a quarter of the number of plants that I grow. Change of seed, soil, &c., made no difference, the disease being worse in each succeeding year. Thinking that the mischief might perhaps lie in the soil, I cleaned out two of the houses to a depth of 3 feet, and filled the pits with ashes. I then put in good fresh loam, mixed with mellow cow manure, but the plants were just as badly affected as those grown in another house where merely the top soil was removed and fresh put in. Things had got to this stage when I remembered my experience on a Manitoba Wheat farm (where I worked for two seasons for Mr.

G. A. Middleton, brother to Mr. Peter Middleton, who was for many years gardener at Wynnstay, where and under whom I served my apprenticeship), and that was the dressing of seed Wheat with bluestone or sulphate of copper. As the Yankee says, I figured it out in this way, "If a dressing of sulphate of copper on seed Wheat would prevent smut when it was in the ear, perhaps it might have a similar effect on Tomatos." So last spring, when I was going to sow my Tomatos, I got a piece of bluestone about the size of a Walnut, powdered it fine, and put it in a pound jam jar half filled with hot water to dissolve the powder more readily. After it had cooled somewhat, I put in the seed, let it remain there for four minutes, then drained the water off, dried the seed, and sowed it. Now, it is remarkable that last year I had not a single plant affected with any kind of disease, although, with the exception just mentioned, the plants were grown under exactly the same conditions as in the previous year. Whether this immunity was due to the dressing of copper sulphate I, of course, cannot be positive, but there is much to favour such an opinion in the fact that the year before dressing the seed there were 300 plants affected, while the year after there was no sign of disease whatever. I am merely writing this as a suggestion, for, as Mr. Ward says, when one has invested one's savings in a business, any suggestion, however simple, that may help to get at the root of the matter, ought to be thankfully received and carefully considered by all who are thus afflicted. *George Appleton.*

MIDLAND DAFFODIL SOCIETY: ALTERATION OF DATE.—Having ascertained the opinion of some fifty of the principal exhibitors, a large majority of whom consider the present a very early season, we have decided to hold our Daffodil exhibition at Birmingham on Tuesday and Wednesday, April 18 and 19, instead of the later date April 27 and 28. *Robert Sydenham.*

MOLES ATTACKING ROOTS.—We send you a few fruit-tree (Paradise) stocks which have been gnawn at the roots by moles. This is the first time we have had experience of their attacking roots. Perhaps you may have heard of such cases before. *Laxton Brothers, Bedford.* [Is it not the work of a vole rather than of a mole? Ed.]

EXOTIC TREES. — I have read with much interest, in your issue of March 25, Mr. A. C. Forbes's observations on the timber value of exotic trees. The warning he gives is timely, and if I venture to make comment upon the subject it is not from any doubt as to its value. Seeing that of the five Coniferous trees which he cites as producing unrivalled timber in this country—Scots, Corsican, Spruce, Silver, and Larch—only the first is indigenous, and the remaining four are exotic, it does not seem to follow that it is vain to expect good results from trees obtained from the American continent. Mr. Forbes speaks disparagingly of Thuya gigantea, but has it ever received a fair chance in this country? Has it ever been grown under proper forestry conditions? Personally, I have only seen it in the form of arboricultural specimens, and none of Mr. Forbes's five chosen Conifers produce good timber results when so grown. I shall not live to judge of the results from seven acres which I planted last year with this Thuya; but I would remind Mr. Forbes that nobody in this country realised the value of Larch as a timber producer until the Duke of Atholl had planted it very extensively at Dunkeld. What is to be desired is that we should abandon the practice of dotting our lawns and pleasure-grounds with isolated specimens of trees, the nature of which is to grow in high forest, and apply ourselves to testing the most promising species in masses. The Douglas Fir has established its reputation as a most valuable timber tree in the few places where it has received proper sylvicultural treatment. Two species which I should like to see submitted to a similar test are Pinus monticola, which is far superior to the Weymouth Pine in maintaining a single leader and in resisting storm; and Picea orientalis, which, though reputed to be of slow growth, responds to a moist climate and cool soil with an annual growth in height of 2 or 3 feet. Abies nobilis also seems to deserve its specific name. One would like more information about the quality of its timber. Cedrus atlantica and libani we never see except as lawn specimens, but the quality of the timber and rapidity with which it is formed are such as to command attention. Abies Nordmanniana I shall deal with no more, it is so peculiarly subject to parasites. I have said no word about deciduous exotics. We can beat all the rest of the temperate-zone timber of that class if we resume right treatment of our woodlands. *Herbert Maxwell.*

MEASUREMENTS OF CEDARS.—At Campsey Ashe, Suffolk, there are eight fine Cedars in the grounds, and five of the finest are in a group too close to the mansion, and have fine clean trunks. The measurements of the three finest are as follows:—

No. 1 at the ground measures 20 feet 6 inches; at 3 feet from ground, 20 feet; at 6 feet from ground, 19 feet 6 inches; at 16 feet from ground, 18 feet 9 inches; with a clean stem of 18 feet from ground without a branch. Total height of tree only about 45 feet.

No. 2, at 3 feet from ground, 18 feet 9 inches; at 6 feet from ground, 16 feet 6 inches. Total height of tree fully 100 feet.

No. 3, at 3 feet from ground, 18 feet 6 inches; at 6 feet from ground, 17 feet 9 inches. Total height of tree fully 90 feet.

The five Cedars in a group are from seedlings, but, alas! the date of their being planted is unknown.

—— At Bayfordbury, Herts, out of many specimens, three have the following dimensions:—

1. Cedar marked No. 7, girth at 1 foot from ground, 27 feet 3 inches.

2. Marked No. 3, at 3 feet, 19 feet 5 inches; at 5 feet, 19 feet 9 inches.

3. Marked No. 8, at 3 feet, 18 feet 11 inches; at 5 feet, 19 feet 3 inches.

All these Cedars average 94 feet in height. They were all planted in 1765, and are therefore 140 years old. The date of planting is marked on a stone ball at the base of each tree. *J. R.* [It is interesting to add that seedling Cedars come up abundantly in the adjoining lawn and paths. Ed.]

CAMELLIAS OUT-OF-DOORS.—We so seldom see good beds of Camellias outside that I thought it would be interesting to mention that at present (March 15) we have some fine plants of C. nobilissima with several beautiful white flowers fully expanded, and a quantity of buds opening on each. Camellia imbricata rubra and C. Donckelaarii are just showing colour, and will soon be covered with flowers. All other varieties are thickly studded with buds, and give promise for a fine show of bloom. Surely this is early for outdoor Camellias? *A. C. Smith, Lydhurst Gardens, Haywards Heath, Sussex.*

RAISING APPLE STOCKS FROM CUTTINGS.—I am sending some pieces of Apple wood for your inspection. You will notice a number of protuberances or aërial roots, which in the early stages closely resemble the galls caused by American blight. It seems only to occur in certain varieties, such as Marlin, Broadlin, Stone Pippin and Green Pippin. I was recently shown some young trees said to be grafted on the French Paradise stock with similar protuberances on the stocks only. Amateurs and cottagers in this district often root pieces of branches from 2 to 3 feet in length cut from varieties producing these protuberances. These cuttings quickly root and form quite strong trees. They are headed back the following winter and used as stocks. Some varieties of Apples, such as Golden Noble and others, do not appear to succeed when grafted on these stocks, but I have seen Warner's King, Bramley's Seedling, Ecklinville, Annie Elizabeth, Beauty of Bath and other varieties doing well and bearing excellent crops. Are the trees producing these protuberances of different variety to the ordinary garden Apple, and would a mild atmosphere be conducive to the formation of these aërial roots? If would be interesting to know if these stocks have been tried with success by any good fruit-grower, and whether found to be of use as such. Nothing interests amateurs and cottagers more than producing their own stocks and grafting their own trees. I should also like to ascertain if trees grafted on these stocks will continue to fruit for any length of time. As far as I can find locally they are a decided success, and the trees last in bearing for a considerable period. I believe Winter Pearmain also produces these protuberances, but I cannot confirm this. *J. O. W.* [The "burr knot." Apples of which you send specimens are not uncommon. Ed.]

APPLE LORD BURGHLEY.—I agree with Mr. Easter concerning its qualities. As a late dessert Apple I think no late variety can approach it for flavour. It also keeps fresher in appearance than any other dessert Apple with which I am acquainted. Court Pendu Plat and Cockle Pippin are also very satisfactory late varieties, but both are very much given to shrivelling. Lord Burghley does very well with us in Cheshire, growing strongly and freely in rather light soil, and it is a good cropper. *J. Thompson, Delamere House Gardens, Cheshire.*

RIPERSIA TERRESTRIS. — In your issue of March 26, 1904, in reply to a question of mine, you state that the insects Ripersia terrestris were first discovered in this country, near London, in the year 1901. From what I can gather it had been known here for some years before that date. I made inquiries, and Mr. Crump, head-gardener here for many years, writes—"I cannot say exactly when the insects were first discovered, but I think quite ten or twelve years ago. It caused me some anxiety when I first discovered them, but as time went on I found no ill-effects to the plants from their being there." *Geo. A. Head, The Gardens, Kingsdon Manor, Taunton, Som.*

MANURE FOR PEACH-TREES.—I am surprised to learn from "A Reader" of injury being done to Peach-trees by the application of farmyard-manure-water. During the so-called resting period the roots are always active, though not to the same extent as when the tree is in full foliage. Root action being slow during the winter months, the better the quality of matter absorbed by the roots the better yield of fruit may be expected in the following summer. Not only that, but by using manure-water for the border the soil is enriched to no small extent, and valuable food is afforded for the roots to seize on and benefit by when the tree is in full crop, and needing something more than "a light gravelly soil" could give to it. I would recommend the frequent use of manure-water all the year round, not only on medium soils, but especially on such a soil as "A Reader" describes. Again, he advises that manure-water should only be given to a tree carrying a full crop. Would it not be better to give a tree unable to carry a full crop special treatment, and so try to build up for it a constitution capable of bearing the strain of a full crop the following year? Of course there is always the possibility of a misuse being made of manure-water. It should not be applied to a border when by repeated applications the soil becomes sodden and soured. One extreme is as bad as the other. *C. W. Muir, The Horticultural College, Swanley.*

—— I have frequently applied liquid-manure during the winter months to Peach and other fruit-trees occupying walls having south, west, and east aspects, in preference to allowing the valuable liquid to overflow from the tank into the river close by, and with the best results in the production of vigorous growth and of heavy crops of fine fruit. When, during wet weather, the drainings from the manure filled the underground cement tanks to overflowing, two or three water-tubs were brought into use, and the dark-brown liquor was carted to the several fruit-trees, and applied at the roots; the Peach and Nectarine-trees receiving an application first, afterwards the Apricots, Green Gage, Plums, &c. Fruit-trees cannot be said to be absolutely at rest during the interval that elapses between the shedding of the leaves in autumn and the buds pushing into growth in spring. They are therefore capable of assimilating to some extent the nutriment thus applied, and benefiting thereby. Moreover the ground in which the roots are growing is considerably enriched by the manurial properties, and this the trees will benefit by as soon as active growth begins. "A Reader" says at p. 139 that

"such" manure-water is too rich in nitrogen for Peach and Nectarine-trees when in a dormant state, that it is apt to harm the fibres, and excite the growth of the tree too much in spring." I do not think there is anything in the way of practical fact to support this supposition, which appears to me to be more imaginary than real. However, as a rule, liquid-manure is scarce in most gardens, and the supply does not admit of its being applied at the roots of Peach-trees until the process of stoning is completed, which is the "time-honoured" period for applying liquid-manure at the roots and onward until the fruits approach ripening. But it does not follow that judicious applications at short intervals from the flowering stage up to as well as after the stoning of the fruit would not result in even heavier crops of larger individual fruits, than from trees which had only been watered with liquid-manure at short intervals after the stoning of the fruit. Any grower of Peach-trees can test the efficacy of this statement for himself by adopting this plan now the trees are in flower. A reader says that "liquid-manure should only be applied after the stoning is completed, and then only if the tree is carrying a full crop of fruit." Why should not a tree carrying only a light crop be given the same encouragement to ripen a satisfactory crop as that accorded to the tree carrying a full one? True, the latter requires generous feeding at the roots to enable it to swell the numerous individual fruits constituting a "full crop"; but the same generous treatment afforded the tree carrying a light crop will result in the production of much larger and finer fruit than would otherwise be secured. I wish it to be distinctly understood that it is only when the liquid-manure, i.e., the drainings from manure-heaps, would be otherwise wasted that I advocate its use on fruit-borders during the late autumn and winter months. Where there is sufficient tank space to store such drainings until the trees are in active growth, by all means reserve the supply of liquid-manure until that period. *H. W. Ward.*

TRANSPLANTING TREES.—During the late autumn, winter, and until quite recently, we have been busy moving trees of sufficient weight to necessitate some ingenuity in the way of labour economy. For a small transplanting machine we improvised the wheels and wood framework of a water-barrel by removing the tub and substituting a piece of strong sacking, which was fastened to the framework at both ends and sides. This formed practically a sort of hammock, in the top of which the plants or trees were placed. During my early period at Combe Abbey there was much transplanting of trees, and for this purpose I had a machine especially constructed. I obtained the idea from a figure by the late Mr. McNab, of the Edinburgh Botanic Gardens. This I showed to a local wheelwright, and asked him if he could construct a machine after that pattern, calculated to lift trees of from 5 to 18 cwt. in weight; this he accomplished most successfully. There was no axle, a pair of strong arms being securely fixed upon the side pieces of the wooden frame, and upon these the wheels worked. The framework at the end next to the handles was permanently fixed, but the tie-piece at the opposite end was made so that it could be removed. Two pairs of portable rollers, each about 5 inches in diameter, were placed on the framework, two at either end. When the tree was ready for removal the two rollers and the portable tie-piece were lifted off and the machine placed so that the tree was within the framework. A couple of strong ropes were carried beneath the bole of the tree and fastened to the rollers at either end. Iron handspikes were next placed in holes provided in the rollers, and the ropes then wound sufficiently to admit of the tree being carried to its new quarters. A machine of this kind is always useful about an estate where heavy weights, such as stone, have often to be shifted. Tree lifters are often required, and ought to form part of every large garden equipment. *W. Miller, Berkswell, Warwickshire.*

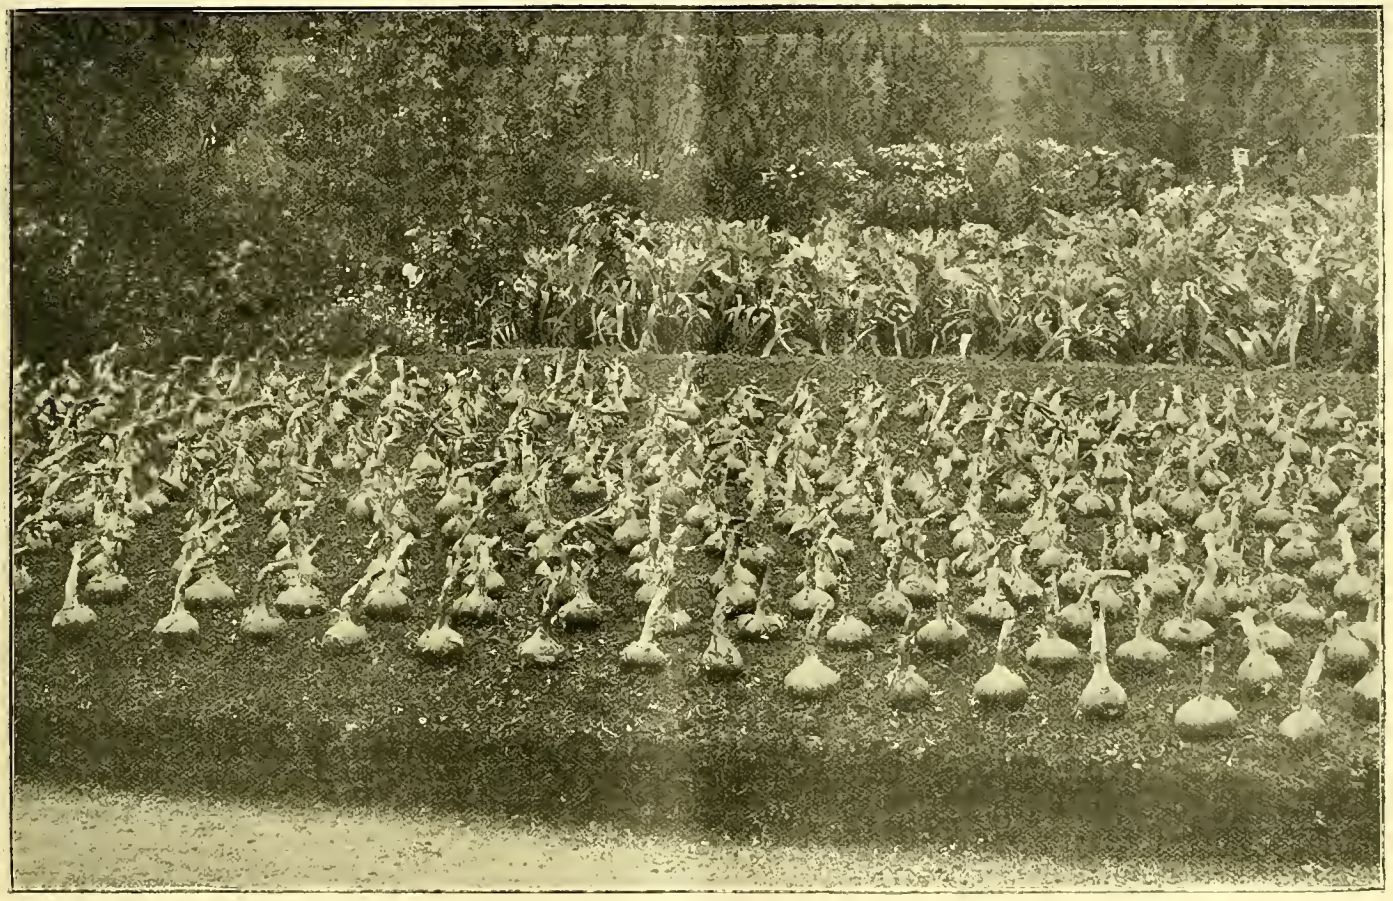

Fig. 90.—Bed of onions grown by Mr. W. Fyfe, Lockinge Gardens, by a system of cultivation described in the Calendar on p. 199.

THE ROSARY.

PRUNING ROSES.

This is an operation thought by the novice to be involved in much mystery. An hour's practical instruction by a competent operator, with a little explanation of the reason why, would show that the mystery is imaginary. Such instruction is not to be had by everybody, and then the best thing for the would-be pruner to do is to endeavour to ascertain from books why so apparently an unnatural a procedure is recommended. In pruning he must remember that the knife is used not for the benefit of the Rose bush, but to serve the purposes of the grower, which are often at variance with the natural requirements of the plant. The National Rose Society has issued an excellent little treatise on the subject, which we strongly commend to amateur rosarians. The illustrations are most serviceable. An alphabetical list of varieties is given, and reference is made in each case to the appropriate time and method of pruning. The "Hand-book on Pruning Roses" is distributed to the members of the National Rose Society. Outsiders must seek the intervention of a member if they desire to secure a copy, as no doubt many will do, and should make application (enclosing 2*s.* 6*d.*) to the Hon. Secretary, E. Mawley, Esq., Rosebank, Berkhampsted.

SOCIETIES.

THE ROYAL HORTICULTURAL.

MARCH 28.—On the occasion of the usual fortnightly meeting held on the above date in the Hall at Vincent Square, Westminster, there was a beautiful display of interesting exhibits.

Orchids again constituted an important feature, and awards recommended by the ORCHID COMMITTEE to novelties included eight Awards of Merit and one Botanical Certificate.

The FLORAL COMMITTEE recommended a First-class Certificate to a supposed new species of Crinum (C. Rattrayii) from Uganda; also three Awards of Merit to other plants.

The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty.

At the SCIENTIFIC COMMITTEE an interesting discussion was held on the question of the degeneration of varieties, a report of which will be given in our next issue. See also p. 200.

In the afternoon a large number of new Fellows were elected to the privileges of the Society, and a paper on "Bananas," by Mr. FRANK PINK, was read by the Secretary, Rev. W. WILKS, M.A.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. Geo. Nicholson, J. Green, C. J. Salter, C. Blick, J. F. McLeod, W. Cuthbertson, C. R. Fielder, Chas. Dixon, W. Bain, H. J. Cutbush, C. E. Pearson, E. H. Jenkins, H. J. Jones, W. G. Baker, Geo. Gordon, W. Howe, J. Jennings, R. Hooper Pearson, R. C. Notcutt, Geo. Paul, R. Wilson Ker, and W. P. Thomson.

A very fine variety of Anthurium Rothschildianum, and named rotundiflorum, was shown by Sir TREVOR LAWRENCE, Bt. (gr., Mr. W. Bain), the spathe being much broader than usual, and very prettily spotted.

From Sir W. PLOWDEN'S garden, Aston Rowant House, Oxfordshire (gr., Mr. W. H. Clarke), were shown flowers of Sweet Peas. These early-flowering sorts have been obtained by crossing varieties received from Algiers with others grown in this country. The early-flowering habit of the varieties from Algiers has been remarked upon in these columns already.

Mr. GEO. MOUNT, Canterbury, Kent, again showed a beautiful display of cut Roses. The group, although more extensive, was similar to those presented by this grower at the two previous exhibitions at the Hall. The varieties staged were Catherine Mermet, Captain Hayward, Mrs. John Laing, and Mrs. C. Sharman Crawford (Silver-gilt Banksian Medal).

Mrs. ROLLES HOARE, West Grinstead Park (gr., Mr. Smith), presented baskets of Violets, one of which had flowers of a pale bronze colour (Bronze Flora Medal).

Messrs. JAS. VEITCH & SONS, Ltd., King's Road, Chelsea, had a wide range of plants. One group contained standard plants of Pyrus Malus Scheideckeri flowering profusely, also Corylopsis spicata, C. paucifolia, Hydrangea Hortensia rosea, &c.; Primula × kewensis, Rhododendron Veitchii, Crowea angustifolia (see Awards), Clerodendron myrmecophilum, a new species, figured in *Gardeners' Chronicle*, April 9, 1904, p. 237, &c.

Messrs. J. AMBROSE & SON, Cheshunt, Herts, showed Carnations, Roses, Narcissus, and other flowers.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, filled a side table with a display of greenhouse plants, Gardenias, Boronias, Roses, Clematis, Ferns, Astilbe (Spiræa), &c. A batch of Rose Crimson Rambler occupied the centre of the display.

Mr. CHAS. TURNER, the Royal Nurseries, Slough, put up a group of pot-plants of "Malmaison" Carnations. There were several named forms—Princess May (of deeper colour than the type), Princess of Wales, Lady Rose, &c.

Messrs. HUGH LOW & Co., Enfield Nurseries, Enfield, exhibited a number of Carnation flowers.

Mr. Kemp, gr. to WILBERFORCE BRYANT, Esq., Stoke Park, Slough, brought half-a-dozen plants of Hippeastrums (Amaryllis).

Messrs. CANNELL & SONS, Swanley, Kent, again showed Zonal Pelargoniums and Cineraria flowers (Silver-gilt Banksian Medal).

Messrs. JOHN LAING & SON, Forest Hill, London, displayed a number of well-flowered plants of Clivias (Imantophyllums).

Two good displays of Cyclamen were shown, the one by Mr. JOHN MAY, Gordon Nursery, St. Margaret's, Twickenham, and the other by the ST. GEORGE'S NURSERY Co., Hanwell. Mr. May filled two tables in the annexe with well-grown plants carrying a profusion of flowers of good form and of excellent colours (Silver-gilt Flora Medal).

The plants from the ST. GEORGE'S NURSERY COMPANY, Hanwell, was an object-lesson in good culture, the plants being sturdy, freely flowered, and of the best type with regard to colours and form of flowers. A number of the plants represented the "Papilio" strain (Silver Banksian Medal).

FORCED SHRUBS.

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, furnished the concert platform with forced shrubs, interspersed with Palms and Ferns. Included was a white form of Dicentra [Dielytra] spectabilis, also Rhodora canadensis, the latter much resembling an Azalea. Japanese Maples enhanced the effect with their beautiful foliage (Silver Flora Medal).

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., put up an excellent group of forced shrubs, having Lilacs, Gueldres Roses, standard trained plants of Prunus and Pyrus species, &c., using Azaleas as a groundwork. The plants were staged to the best advantage, and the group was much admired for its general effect (Silver-gilt Banksian Medal).

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, put up a group of forced hardy flowering shrubs—Azaleas, Clematis, Lilacs, Viburnum Sieboldi, Gueldres Roses, &c. (Silver Banksian Medal).

Messrs. WM. CUTBUSH & SON, Highgate Nurseries, Highgate, N., displayed a large group of forced shrubs. The effect produced was pleasing, bright, and showy. It included the usual members used for forcing, such as Azaleas, Magnolias, Laburnums, Lilacs, Spiræas, &c. Messrs. CUTBUSH also showed Boronias and Ericas, including types of E. Willmoreana, the best of these being E. W. grandiflora. The same firm also brought Carnations, and an extensive collection of alpine plants similar to those displayed by them at the last meeting (Silver-gilt Flora Medal).

Messrs. PAUL & SON, Old Nurseries, Cheshunt, had a small group containing many interesting plants, such as Actinidia Kolomikta, Corokia buddlioides, Deutzia kalmiæflora, an excellent specimen of Andromeda japonica, plants in flower of Lobelia nicotianæfolia, &c. On one of the centre tables Messrs. PAUL displayed a new Tea Rose named Warrior. The plants were carrying numerous buds, which develop into moderate-sized blooms of a brilliant rose colour, with a darker base to the flower (Silver Banksian Medal).

Messrs. THOS. CRIPPS & SON, Tunbridge Wells Nurseries, Kent, arranged a semicircular group of plants, comprised mainly of fancy Maples. Well-flowered plants of Rondeletia cordata were interspersed throughout the group, which was finished off by an edging of small plants of Hypericum Moserianum tricolor (Bronze Flora Medal).

ALPINE PLANTS.

Mr. G. REUTHE, Keston, Kent, put up a group of alpine and hardy plants, Lathræa purpurea was flowering well in a pan. Tecophilæa cyanocrocus was also noticed in flower, the beautiful blue of the petals reminding us of the Gentians.

E. A. HAMBRO, Esq., Hayes Place, Hayes, Kent (gr., Mr. J. Grandfield), showed a choice collection of alpine plants in pots, most of them being in flower and of exceedingly good growth (Silver Flora Medal).

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, brought alpine plants. Gerbera Jamesoni was noticed in flower, also a good form of Viola cornuta named "Papilio."

Mr. H. C. PULHAM, Elsenham, Essex, set up a small portion of a rock-garden, planting suitable subjects in a natural manner.

Messrs. J. CHEAL & SONS, Crawley, had several boxes of alpine plants, with shrubs, &c., at the back. Included among the latter were several well-flowered plants of Choisya ternata. Daphne Mezereum was also shown well in this exhibit.

The Misses HOPKINS, Mere, Knutford, Cheshire, showed a small collection of alpine plants (Bronze Banksian Medal).

Messrs. G. JACKMAN & SON, Woking Nursery, Surrey, brought many interesting alpine plants, including the curious Arisarum proboscoideum. Double-flowered coloured Primroses were a feature in this collection.

Mr. A. R. UPTON, Guildford Hardy Plant Nursery, Guildford, staged a group of alpine plants. We noticed the beautiful Sanguinaria canadensis in flower. Anemone fulgens was also good in this exhibit (Bronze Flora Medal).

Messrs. J. PEED & SON, West Norwood, London, showed alpine plants in pans and boxes.

Messrs. GILBERT & SON, Dyke, Bourne, Lincolnshire, had a fancy stand filled with Anemones, the display being very fine. The dark scarlet of A. fulgens contrasted strongly with the blue flower of the St. Brigid type; A. Pulsatilla was very fine (Silver Banksian Medal).

Awards.

Crinum Rattrayii.—This supposed new species, closely allied to C. giganteum, was shown in flower by Sir TREVOR LAWRENCE (gr., Mr. Bain). It was introduced from Uganda by Major H. B. Rattray, then of the King's African Rifles at Entebbe, who had bulbs growing in his garden there. In a letter to Mr. James O'Brien, dated November 1, 1902, Major Rattray stated that the species is a garden plant only in the Entebbe district, but that it is indigenous at Lake Albert. The habit of the plant is distinct, as shown on Tuesday, the leaves, which are about 2 feet long and 6 inches across at the widest portion, being much more erect than those of most species of Crinum. The umbel was 2½ to 3 feet high, and consisted of seven pure white flowers with broad segments which recurve very little, if at all, but have a form somewhat like that of a Tulip. The filaments are also pure white, and the anthers of deep brown colour. This inflorescence is the second produced by the plant this season (First-class Certificate).

Crowea angustifolia. — This is an old Rutaceous hard-wooded greenhouse plant from Australia, having sessile, very narrow leaves, and solitary axillary flowers ½-inch across and reddish-pink in colour. Shown by Messrs. JAS. VEITCH & SONS (Award of Merit).

Erica Willmoreana grandiflora.—A variety of this popular hybrid Heath, having much larger flowers than those of the type, but of the same attractive colour. Shown by Messrs. W. CUTBUSH & SONS (Award of Merit).

Tree Carnation "Flamingo."—A variety with deep red-coloured flowers of good form, and possessing non-bursting calyces. Shown by Messrs. AMBROSE & SON (Award of Merit.)

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshay, Francis Wellesley, Jeremiah Colman, R. G. Thwaites, R. Brooman-White, W. Cobb, Harry J. Veitch, W. H. Young, W. Boxall, W. H. White, J. Charlesworth, J. Douglas, T. W. Bond, H. J. Chapman, H. T. Pitt, Harold Morris, H. A. Tracy, N. C. Cookson, H. Ballantine, F. W. Ashton, F. Sander, and W. A. Bilney.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr., Mr. H. Ballantine), was awarded a Silver-gilt Flora Medal for a fine group, the centre of which was composed of rare Odontoglossums, including the purple-blotched O. Pescatorei Veitchianum and O. P. Schroderianum; O. × elegans, the rare O. Schillerianum, O. × Coradinei, O. × Wilckeanum, O. × Adrianæ varieties, and some fine forms of O. crispum. At each end were selections of the best Dendrobiums, including Dendrobium nobile album and the fine D. n. Schröderianum, white tipped with pink, and with claret-coloured centre. Other remarkably well-flowered kinds were forms of D. × splendidissimum, D. × dellense, &c.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), was awarded a Silver-gilt Flora Medal for a group of rare Odontoglossums, three of which secured Awards of Merit (see Awards). Among them were several finely-coloured Odontoglossum × ardentissimum, several grand examples of O. Pescatorei, one being the pure white form; good O. crispum, including the spotted varieties Amy, Sibyl, xanthotes, and teselatum; O. triumphans latisepalum, O. × Coradinei rosefieldiense, and other good Odontoglossums; several hybrid Lælio-Cattleyas, Cypripedium × Schofieldianum superbum, Dendrobium × Sibyl and D. × Cybele Oakwood variety, the latter having purple lines on the lower sepals like D. nobile burfordiense.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. H. T. Thurgood), secured a Silver-gilt Flora Medal for a specially interesting group composed almost entirely of species and fine varieties, with but few hybrids. The large-flowered Cattleyas were well represented by fine forms of C. Trianæ, the best of which was C. T. "Our King," a large and finely shaped rose-coloured flower with claret-coloured front to the lip and a distinct feather of the same colour on the petals. The showy Odontoglossums included good O. crispum, O. Pescatorei, O. Hallii, O. Harryanum, and others. One of

the finest was the pure white O. crispum xanthotes "Snow Queen," having a few orange-coloured spots, and which had previously secured an award. The front of the group was bright with yellow Oncidium concolor and scarlet Sophronitis, and there was a varied selection of good Cypripediums, Miltonia Roezlii, Epiphronitis × Veitchii, &c.

Messrs. Sander & Sons, St. Albans, were awarded a Silver Banksian Medal for a good group, in which were several very fine Odontoglossums, the best being O. crispum Milky Way, a large rose-tinted flower with distinct reddish blotchings on the sepals, the petals having two-thirds of the central area densely spotted with small red-brown spots. Others noted were Odontoglossum × elegans, Cœlogyne speciosa alba, a large specimen of Dendrobium densiflorum, several good hybrid Phaius, finely-coloured Lælio-Cattleya × bletchleyensis, &c.

Messrs. Charlesworth & Co., Heaton, Bradford, were awarded a Silver Banksian Medal for a fine group, principally hybrids. Among the best were Cattleya × Empress Frederick variety aurea, a fine rose-coloured flower, the labellum, except the rose margin, being of a rich orange tint; Lælio-Cattleya × Veronique (L. × cinnabrosa × C. Mendeli), a pretty cream-white flower with rose markings on the lip; L.-C. × Dominiana, L.-C. × Mercia, L.-C. × callistoglossa, L.-C. Haroldiana, some fine forms of Cattleya × Enid, and other hybrids. The Odontoglossums were represented by good O. crispum, one of the most interesting being O. c. Lady Molly, a good white flower with brown blotches on the petals, the bases of each of which displayed yellow ground colour, with dark lines in imitation of the crest of the lip. Among the hybrid Odontoglossums the most interesting was O. × Lairessei Heaton variety (Edwardi × Cervantesii roseum). The branched spike had flowers rather larger than those of O. Edwardi, of a pale rose-pink with heavy markings of dark purple on the inner parts of the segments.

Messrs. Hugh Low & Co., Enfield, staged a group made up of varieties of Cattleya Trianæ, C. Schroderæ, C. Schilleriana, Cypripedium × Winnianum, and other Cypripediums; Miltonia × Bleuana, Dendrobium × Sibyl, D. × rubens, &c.; and a pretty rose-tinted form of Mormodes buccinator.

F. A. Bevan, Esq., Trent Park, Barnet (gr., Mr. Parr), sent Odontoglossum × elegans Trent Park variety, a good, large flower.

Mr. H. A. Tracy, Twickenham, showed Cypripedium × Wormsiæ (Charlesworthii × villosum), a large flower with fine rose-coloured dorsal sepal.

Mr. H. Whateley, Kenilworth, showed Odontoglossum crispum Mabel Whatcley, a remarkably finely-blotched flower which had previously secured an Award of Merit.

M. Chas. Vuylsteke, Loochristy, Ghent, staged a small collection of hybrid Odontoglossums.

Awards of Merit.

Odontoglossum crispum Prince Leopold, from Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman).—A very pretty and distinct variety with French-white flowers beautifully spotted with red-brown, the sepals having large blotches, and the petals clusters of many smaller spots. The flower, which is round and with broad segments, has fringed petals and lip. It was first shown by Messrs. Sander at the Ghent Quinquennial Exhibition.

Odontoglossum × *ardentissimum* "*Doris*," from Norman C. Cookson, Esq.—A fine flower of the same general features as the form originally Certificated, the greater part of the flower being purplish-crimson.

Odontoglossum × *ardentissimum Sibyl*, from Norman C. Cookson, Esq.—Flowers of the largest of its class; white, evenly spotted with conspicuous purplish-crimson spots.

Odontoglossum × *Adriance aureum*, from Baron Schroder, The Dell, Egham (gr., Mr. Ballantine).—A very fine variety with light yellow ground colour, spotted with red-brown.

Calogyne Lawrenceana, from Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White).—A large-flowered species of the group Filiferæ, and allied to C. speciosa and C. Micholitziana. Sepals broad, yellowish, petals narrow, tinged with brown; lip yellowish at the base and side lobes, and bearing ridges of brown papillæ. Front of lip pure white.

Calogyne speciosa alba, from Messrs. Sander & Sons, St. Albans.—In this the brown colour usually seen in the species is suppressed. Sepals and petals yellowish; lip white with a salmon-coloured base.

Dendrobium × *Haywoodiæ* (splendidissimum × Findlayanum), from Mrs. Haywood, Woodhatch, Reigate (gr., Mr. C. J. Salter).—Flowers large like that of D. × splendidissimum, but with a rich orange labellum with chocolate base, and much resembling those of a very large D. × Schneiderianum.

Odontoglossum × *ardentissimum* "*Lamus*," from Messrs. Jas. Veitch & Sons, Chelsea.—A pretty flower, white tinged with purple at the back and heavily marked with purple. Another pretty variety named "Melo" was also shown.

Botanical Certificate.

Dendrobium moniliforme (japonicum), from Messrs. Wm. Cutbush & Sons, Highgate Nurseries. The well-known dwarf Japanese Dendrobium with white flowers. Messrs. Cutbush state that it thrives outdoors as a hardy plant in shady and very sheltered situations.

Narcissus Committee.

Present: Mr. H. B. May (Chairman), and Messrs. G. H. Engleheart, E. Willmott, T. Eugene Bourne, Chas. T. Digby, E. A. Bowles, W. Poupart, Jas. Walker, W. M. Copeland, J. Pope, G. Reuthe, J. D. Pearson, P. R. Barr, R. Sydenham, W. T. Ware, G. S. Titheradge, S. Kingsmill, R. W. Wallace, C. H. Curtis.

What may be regarded as the first exhibition of Narcissi this season brought several good collections from the leading growers, most of the flowers having been grown under glass, excepting probably the collections from Penzance and Ireland.

Messrs. Barr & Sons, Covent Garden, had a representative collection, including such fine varieties as Mdme. de Graaff, Maximus, Gloria Mundi, Dandy Dick, one of the incomparabilis group with richly-coloured cup; M. J. Berkeley, Weardale Perfection, and others. Among the newer kinds were Salmonetta, with salmon-stained crown; Apricot, a trumpet variety with apricot tone; Bridal Veil, a pretty drooping white flower; Brilliant (incomparabilis), with long orange-scarlet cup and crown; Duke of Bedford, a fine bicolor; Maggie May, Lucifer, King Alfred, Peter Barr, White Queen, and others (Silver Flora Medal).

Several handsome vases of a rich yellow self Ajax came from the raiser, Mr. Kendall, Newton Poppleford, Devon. It is a noble sort, fine in colour and suggesting as it were a good ideal for future operations.

Messrs. Amerose & Son, Cheshunt, set up a large group, chiefly of Emperor, Barri conspicuus, Hersefieldi, and others, in market-like bunches and in other ways.

From Ireland came a new exhibitor in the person of Sir J. Gore-Booth, Bt., Lissadale, co. Sligo. Some of the varieties were exhibited in especially good condition. That of Stella superba, for instance, we have never seen so fine. Others were C. J. Backhouse, Minnie Hume (a pretty sort), Seagull (with yellow cup), and Albatross (with richly-coloured orange cup). These two, so beautiful and distinct, came from the same seed-pod. Incomparabilis Beauty, Victoria, M. J. Berkeley (very rich in colour) were shown in excellent form (Silver Flora Medal).

From Birmingham Mr. Robert Sydenham brought examples of Narcissi grown in the cocoa-fibre preparation and in bowls, together with a large array of good varieties. Empress Victoria, Golden Spur were all noted in the fibre preparation, the flowers being good in every way. Catherine Spurrell, Glory of Leiden, Stella superba, King Alfred, and Golden Bell, a rich yellow Ajax kind, were also good. A set of the fragrant polyanthus kinds made a margin to the entire group.

From Rosemorran, Gulval, Penzance, Mr. Chas. Dawson brought many exquisite sorts, arranged, not in the oft-repeated crowded bunches of which one soon tires, but in the much more artistic way of twos or threes, when every flower is seen at its best. We much admired this set of novel and choice varieties. Note was made of Homespun, a refined Sir Watkin with a somewhat similar tone to that of Frank Miles, in which the roundly-ovate segments stood out in perfect form. Red Eagle, with flat, inch-wide, flame-red cup; Mermaid, of the White Queen type; Horace, perhaps the finest poeticus yet seen; Pilgrim, a fine white Leedsii, with a large lemon cup; Phantom, a big improved bicolor grandis; Firebrand, with an intensely coloured cup richly coloured to its very base; Gleam, a good poeticus; and Sea King, a sort of white giant Johnstoni, are some of those in this group (Silver Banksian Medal).

Miss Currie, Lismore, Ireland, had a large array of made-up bunches; the blossoms, obviously from the open ground, had suffered from storms. Michael Foster, Queen Bess, C. J. Backhouse, Sir Watkin, Maximus, the double Cernuus, and King Alfred, were among those noted in this group.

Mr. G. Reuthe, Keston, Kent, also staged Daffodils in many kinds, and we noted Fairy Queen, C. J. Backhouse, Glory of Leiden, Mrs. Walter Ware, &c., among the numerous varieties (Silver Banksian Medal).

Award of Merit.

Narcissus Leedsii Ariadne.—This beautiful variety may be regarded as a much-improved Minnie Hume, with large, somewhat flatter, more spreading crown, which is about 1½ inch across, and prettily frilled near the margin; white, and possessing much elegance. These Leedsii forms are very pleasing when seen without spot or blemish. From Messrs. Barr & Sons.

Fruit and Vegetable Committee.

Present: A. H. Pearson, in the chair; and Messrs. O. Thomas, C. Foster, J. Jaques, J. Willard, F. Q. Lane, H. J. Wright, H. Parr, A. Dean, S. Mortimer, Ed. Beckett, Jos. Cheal, Jno. Lyne, and Geo. Reynolds.

Several seedling varieties of Apples were submitted to the Committee, but none was given an award. "Crawley Reinette," a fruit of rather more than average size and of good appearance, was shown by Messrs. J. Cheal & Sons, Crawley, Sussex, who had also "Buxted Favourite," a very bright-looking Apple, of moderate flavour.

Mr. Robert Fenn, Sulhampstead, Reading, exhibited the variety "Pay the Rent," large yellow-coloured fruits much marked with small russety spots. Fruits of the well-known Sturmer Pippin were shown by Mr. J. Crook, Forde Abbey Gardens, Chard.

English-grown fruits of Newtown Pippin came from H. H. Raschen, Esq., Sidcup, Kent; and American-grown fruits of the same variety from Mr. A. Dean.

Several fruits of "Stone" or Cluster Golden Pippin were shown from Lord Ilchester's garden at Holland House, Kensington (gr., Mr. C. Dixon). These small, exceedingly hard, yellow-coloured fruits, freely marked with russet, were gathered from trees more than 150 years old.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, staged nineteen baskets of Apples. Several of the varieties shown have been distributed by Messrs. Cheal, including Atalanta, Parequet, Armorel, and Crawley Reinette. The last-named variety is said to be a prolific cropper, and is recommended for cultivation for market supply, but the flavour is only moderate (Silver Knightian Medal).

Mr. E. W. Caddick, Caradoc, Ross, Herefordshire (gr., Mr. M. Roe), staged thirty-two dishes of Apples. They were a meritorious lot, and had been kept in an almost perfect condition, the fruit showing scarcely any signs of shrivelling (Silver-gilt Banksian Medal).

Excellent bulbs of Onion Ailsa Craig were shown from Sir Henry Peto's garden, Chedington Court, Crewkerne, Somerset (gr., H. Birkenshaw). The seeds were sown on February 4, 1904, and were planted out-of-doors later in the season, as recommended in the Calendar on p. 199. No liquid or artificial manures were applied.

Lecture on Bananas.

At the afternoon meeting a paper, by Mr. Frank Pink, on "Bananas, from a Commercial Point of View," was read by the Rev. W. Wilks. The lecturer pointed out that until about four years ago the monopoly of the Banana business was held by the Canary Islands. Since that time the West Indian trade in the fruit has been successfully encouraged by the Government's giving a subsidy for a direct line of steamers running to and from Jamaica, and each bringing not fewer than 20,000 bunches every fortnight. Other lines now run steamers specially equipped for this purpose, and without receiving subsidies. Bananas are also imported to England from other West Indian Islands and British Guiana. The lecturer described the different varieties to be seen in British markets, including the "Musa Cavendishii," the "Gros Michael," and the "Claret." Those from the Canary Islands are Musa Cavendishii, which grows from 10 feet to 12 feet high, and has very delicate fruit, although possessing thick skins. The flavour is rich, and the fruit is generally preferred to the Bananas received from Jamaica, &c.

"Gros Michael," from Jamaica, produces longer bunches (hands) and the fruits are less good in flavour. Contrary to those from the Canary Islands,

these fruits, being less delicate and harder, are shipped to this country without having to be packed in crates. The best-flavoured Banana occasionally to be seen on the market has fruits with claret-coloured skins. The "hand" bears very long "fingers," but these are few. The fruits are generally sold at 2*d.* each, and they are well worth the extra price given for them. Bananas produce from 200 to 300 bunches of fruit per acre at a cost of from £4 to £5 per acre: but the cost of freight to this country is four or five times greater than the worth of the fruits in the West Indies. The transit from the Canary Islands occupies from five to seven days, from Barbados six to eight days, from Jamaica twelve to fourteen days, and from Costa Rica fourteen to seventeen days. Specially-constructed steamers are capable of carrying 35,000 to 45,000 bunches of fruit. In Jamaica and Costa Rica the fruit is purchased from the growers by an American Trust, who send the riper fruits to America and the less ripe fruits to England. In British Guiana, Trinidad, and Barbados, the grower packs his own fruits and then hands them over to the Imperial Department.

The methods of collecting, shipping, and transport were described at greater length than is possible to mention here, and special reference was made to the fostering care exercised on the trade by the Imperial Department of Agriculture in the West Indies. The temperature of the "hold" in the vessels has to be maintained between 55° and 70°. If it is desired to determine whether particular fruits have come from the Canary Islands or from the West Indies, examine them, and if the fingers are long, somewhat pointed, and strongly marked at the angles, they are from the West Indies; but if the skins are smoother, more rounded at the ends, with a little cotton-wool adhering, they are Musa Cavendishi, from the Canary Islands.

COLONIAL EXHIBITION.

MARCH 30, 31.—The second exhibition of Colonial-grown fruits and other products, inaugurated by the Royal Horticultural Society, was held on the above dates in the new Hall. A miscellaneous display of subjects resulted, ranging from bags of Cotton to choice fruits, and from native garments to pickled vegetables. There were numbers of tinned, bottled, dried, and other preserved fruits and vegetables; Tobacco and Sugar in both the raw and in the manufactured condition; Corn from Rhodesia, Apples from Nova Scotia, Bananas with red-coloured skins; Yams, Papaws, Eddoes, and a host of other things that are everyday commodities with our Colonial friends. In addition to the above there were grand displays of British-grown Apples and Pears exhibited by some of our leading growers, while splendid examples of home-grown Oranges, Lemons, and other members of the genus Citrus, were also to be seen.

Messrs. JAMES PHILIP & Co., 4, Fenchurch Buildings, E.C., put up an extensive exhibit of West Indian products, somewhat similar to that displayed by them at the show held in last December. Most of the commodities displayed were such as are met with in provision shops, the raw material in most instances being staged with the finished articles (Gold Medal).

THE ROYAL MAIL STEAM PACKET COMPANY staged a large number of West Indian fruit, vegetables, preserves, &c. Bananas, in which the company have a large carrying trade, were made a feature. One variety displayed was claret-coloured, and of excellent flavour (Gold Medal).

THE AGENT-GENERAL FOR NOVA SCOTIA sent forty dishes of Apples. We were struck with the pleasing appearance of those labelled Fallawater, Ben Davis, and Mann (Silver Knightian Medal).

THE BRITISH SOUTH AFRICAN COMPANY, Rhodesia, put up a miscellaneous group, comprising Tobacco, Corn, Cotton, Flax, Rubber, Fruit and other products of the colony (Gold Medal).

SOUTH AFRICA was further represented by the Fruit Exporters' Association of South Africa, whose exhibits from various members of the Association were highly meritorious. Apples, Pears, Peaches, Plums, Nectarines, Grapes, &c., were exhibited in first-class condition, those from the Hex River Company, Cape Colony, being splendid. Some of the varieties, such as Louise Bonne Pears and Blenheim Pippin Apples, were easily recognisable, while others, such as those labelled King Pippin, are entirely different in character. The whole of the produce from the Hex River Company was first-class, and the judges awarded the collection a Gold Medal.

An Apple from South Africa named Jonathan has a most exquisite appearance, such as might be given to a wax model. We were informed that its flavour surpassed, if possible, its appearance.

Messrs. PINK & SON, Portsmouth, staged five bunches of Bananas; and the ARMY AND NAVY STORES, Victoria Street, Westminster, made an extensive display of Colonial fruits and provisions.

As already mentioned, home-grown Oranges, &c., were a feature. Messrs. RIVERS & SON, Sawbridgeworth, staged a collection of Oranges, having fruiting trees in pots and a number of gathered fruits. Messrs. RIVERS also contributed excellent Lemons (Silver-gilt Knightian Medal).

Miss TALBOT, Margam Park, Glamorganshire, showed home-grown Oranges, staging some fine examples of the varieties Embiguo, Exquisite, Dulcissima, and St. Michael (Silver-gilt Knightian Medal).

The Duke of RUTLAND, Belvoir Castle, Grantham (gr., Mr. Divers), showed a meritorious collection of Apples and Pears, and some well-preserved bunches of Black Alicante Grapes (Silver-gilt Knightian Medal).

Exhibits of Apples were also shown by Messrs. BUNYARD & Co., Maidstone, who staged sixty dishes (Silver-gilt Knightian Medal); by Messrs. CANNELL & SONS, Swanley, who had forty dishes of excellent fruits (Silver-gilt Banksian Medal), and by Messrs. CHEAL & SONS, Crawley, who contributed twenty dishes of Apples in season (Silver Knightian Medal).

UITENHAGE HORTICULTURAL SOCIETY, CAPE COLONY.

FEBRUARY 15.—This South African Society held its thirteenth annual show on the above date, as owing to the lateness of the season the show had been postponed from Feb. 1. The entries were nearly 300 more than in the previous year, and amounted to 700. The exhibits of fruits were of very good quality. Flowers were not so good, owing to heavy winds and showers having prevailed during the two days previous to the show. The preserved and bottled fruit was excellent.

Three groups of plants arranged for producing effect were very pretty. Messrs. SMITH BROS. easily won the 1st prize, and Mr. H. FAIRY was 2nd. In the class for specimen plants, Messrs. SMITH BROS. showed some very fine Palms, and won the 1st prize for a plant of Cocos Yatai, which was compact in habit with silvery-coloured leaves. Six specimen Codiæums (Crotons) exhibited by the same firm were well coloured and well grown, though of rather small size. Mr. MAGENIS exhibited a very nice collection of Japanese Plums, but this season generally has not been a favourable one for Plums. The Grape season has been a good one, and some big bunches were shown. Mrs. V. ROBERTS won 1st prize for the largest bunch grown in the district. Messrs. SMITH BROS. had a very good collection of eighteen varieties of Grapes, for which they were awarded 1st prize; Lady Downe's Seedling was very good, the berries large, and bearing plenty of bloom on them.

The Society has been affiliated with the Royal Horticultural Society. Monthly meetings are held, at which points are awarded to the exhibits, also Awards of Merit and First-class Certificates. The winner of the greatest number of points during the year will receive a "Cup." *Interested.*

LINNEAN.

MARCH 16.—Professor W. A. Herdman, F.R.S., President, in the Chair.

The President announced that the Council had appointed a Committee to consider the question of zoological nomenclature discussed at the last meeting; also, in view of the interest displayed at a previous meeting on the subject of Œcology, a discussion had been arranged for May 4 next, to be opened by Mr. A. G. Tansley.

Mrs. D. H. Scott, F.L.S., exhibited photographs of plants taken by the kammatograph, showing the natural movements of the plants accelerated so as to be readily followed by the eye.

The plates shown were:—1 and 2. Sparmannia africana, showing the opening of the flower-buds, the movements of the stamens, and the closing of the flowers at night. 3. Sensitive plant, Mimosa sensitiva, showing the movements of the leaves on stimulation. 4. Fuchsia, showing the opening of two buds into flower during sixteen days, the bursting of the stamens, and the growth of the style between them. 5. Maurandia, showing the circumnutation of the stem and two young petioles twining round the stick. 6. Crocus: development of a bud and the opening and closing movements of the flower. 7. Clivia: opening of the flower-buds. 8. Hippeastrum: growth of stamens and style and development of the stigma. 9. A humble-bee fertilising a Scabious flower.

Mr. Rupert Vallentin, F.L.S., showed a series of thirty lantern-slides, from photographs taken by himself, of bird-life in the Falkland Islands.

Dr. Otto Stapf, F.L.S., presented a paper entitled "Contributions to the Flora of Liberia," being descriptions of three new genera and fifty-six new species, in a collection of about 260 species, collected by Mr. Alexander Whyte in the neighbourhood of Monrovia, in three different localities. The flora shows a specific likeness to that of Sierra Leone, and the new genera are not endemic:—Atroxima, a genus of Polygalaceæ, with three species; Urohotrya, Olacaceæ, also with three species; and Afrodaphne, Lauraceæ, with seventeen species, two being new to science, the others transferred from Beilschmiedia and Cryptocarya. The characters of these genera were illustrated by drawings, and described by the author.

BRITISH GARDENERS' ASSOCIATION.

MARCH 24.—There was a large attendance of members of the Kingston Gardeners' Society and others at the "B.G.A." meeting promoted by the Society, and held at the Fife Hall, Kingston, on the above date, Mr. E. H. Jenkins presiding.

In the course of his address Mr. W. Watson, the secretary of the Association, said that the need for a gardeners' association was universally admitted, and that the lines upon which it was proposed that the "B.G.A." should be worked appeared to be generally approved. Why, then, was there not already an active and powerful Association working in the interest of the gardener, as there was now, he believed, for every other craftsman, with success? It was due to faint-heartedness, and to a far too general disposition to let the other fellow take the initiative and do the work. He reminded the audience that whilst it was impossible for the members of the Committee to themselves bring about reform, he was certain that it lay within the power of gardeners as a body to do so. Although the response to the Committee's appeal for members and for money could not be called great, it had been enough to ensure the launching of the Association upon the projected lines, and the interest in and support given to the Association was steadily increasing. He appealed to those present to form a district branch of the Association.

Mr. Jenkins and Mr. A. Dean having spoken in praise of the objects of the "B.G.A.," and in favour of the formation of a Kingston branch, Mr. J. T. Blencoe (secretary of the Kingston Society) expressed himself aware of the need for a Gardeners' Association, but, on the grounds that gardening was a luxury, he was sceptical about the possibility of gardeners obtaining fairer treatment. The proposal to form a local branch was discussed, and finally it was decided that a second meeting should be held to further consider the matter.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending March 25, 1905.

1905. MARCH 19 TO MARCH 25.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	At 9 A.M. Wet Bulb.	Day. Highest.	Night. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	45	43	55	38	29	48	46	45	Tot 0·23	5 35

THE WEATHER IN WEST HERTS.

Three Weeks of Warm Weather.—The present spell of warm weather has now lasted over three weeks, during which period there has been no unseasonably cold day, and but one cold night. The warmest day occurred during the past week, when the temperature in the thermometer-screen rose to 60°. This, although by no means an exceptionally high reading for the season, is the highest as yet recorded this year. The ground, as might be expected after such a long continuance of genial weather, is unusually warm, being 3° warmer than is seasonable both at 1 and 2 feet deep. Rain fell on four days during the past week, but the total measurement amounted to less than a quarter of an inch. These light falls have not affected the percolation gauges, through neither of which has there passed any measurable quantity of rain-water for several days. The sun shone on an average for 4½ hours a day, or for

about an hour a day longer than is usual. The winds have been variable in direction and of very moderate strength. The mean amount of moisture in the air at 3 P.M. was about 2 per cent in excess of a seasonable quantity. *E. M., Berkhamsted, March* 28, 1905.

[*For actual temperature and condition of barometer at time of going to Press, see p.* 200.]

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 50*s.* to 70*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

REMARKS.—Vegetables in crates have arrived from Bermuda. These comprise Carrots, Beetroot, and Cos Lettuce. These Lettuces are very good and of fresh appearance. The Beet are of small size, round in shape, but will not be likely to prove a commercial success. Cape Plums per case are 4*s.* to 7*s.*; Nectarines, 6*s.* to 8*s.*; Pears, 5*s.* to 10*s.*; Grapes, 5*s.* to 12*s.*; F. Apples, cases containing about 60 lb., are 6*s.* to 9*s.* 6*d.* Apples from Victoria represent numerous varieties.

COVENT GARDEN FLOWER MARKET.

Large supplies of cut flowers and flowering plants are now arriving. Trade is fairly good, but prices are very uncertain, and generally favour the buyers. Among plants, spring-flowering Ericas are very good; I have never seen better plants of E. Willmoreana of the ordinary type; in addition there is a variety with larger flowers named grandiflora; the white variety is also good. Plants of E. candidissima are well flowered, also E. coccinea minor and E. Cavendishi; E. persoluta alba is also worthy of note. Fair prices are maintained. Indian Azaleas continue good, and sell fairly well. Boronia heterophylla and B megastigma are still seen in well-flowered plants. Supplies of Cyclamen are now on the wane, some growers have finished seuding, but the present supply is equal to all demands, and prices are low. Cinerarias are plentiful and good. Hydrangeas are now coming from several growers—the variety Thos. Hogg is most plentiful; good coloured pink (Horteosia) are also seen. Roses in pots are now obtainable; of these the dwarf crimson variety Madame N. Levavasseur is of very good quality, making 18*s.* per dozen. Mignonette is very good; Machet is the favourite variety. Zonal Pelargoniums are now more plentiful. Spiræas are abundant, but vary much in quality and in prices. Genistas are arriving from a number of growers; the mild weather is developing these plants too fast. Marguerites also continue plentiful. Supplies of Hyacinths hold out well. Daffodils in pots are also plentiful. Intermediate Stocks are good, but only the white variety is seen; the crimson variety is generally in the market a fortnight later than the white. Bedding plants are already coming in. Zonal Pelargoniums in 60's with one truss of flowers open on each plant sell well. Marguerites, Fuchsias, Coleus, &c., are also seen. Quantities of various subjects in store boxes are seen:—Stocks, Lobelia, Pyrethrum, Fuchsias, Marguerites, dwarf Marigolds, seedling Tropæolums. Sweet Peas are to be had in small pots. Hardy flower roots in variety and Pansies sell readily.

CUT FLOWERS.

Excessive supplies make it difficult to give definite prices. Roses continue over-plentiful, but prices are not much lower. Carnations are also very abundant; some of the Malmaisons seen are not of the first quality, but the best sell well. Liliums are more plentiful; auratums are good, and the varieties platyphyllum and virginale are extra fine; these make about 4*s.* per bunch. Daffodils and various sorts of Narcissus from the Scilly Islands are fairly good, but the market is glutted with them; best English Daffodils make up to 5*s.* per dozen bunches. Supplies of Gardenias continue to exceed all demands. Eucharis are not plentiful. Double varieties of Tulips are very fine, and there are now some good Darwin varieties. French Ranunculus in various colours are now plentiful and cheap. Anemones include the double pink and double scarlet fulgens and coronaria in variety. Violets, both English and French, are very plentiful; good Parmas can be had at low prices. Lily of the Valley continues over-abundant. Among cut foliage, Asparagus, Smilax, and all ordinary foliage is well supplied; Croton leaves are not so plentiful. *A. H., Covent Garden, March* 29.

ENQUIRIES.

HOT-WATER PIPES.—Will some reader tell me how I can clean hot-water pipes inside and out What is the best way to disconnect old pipes? *R. P.*

ROSES.—Has any reader grown the varieties Madame Cochet and Kaiserinn Augusta Victoria in solid beds in the same house as the varieties Liberty, Bride, Bridesmaid, and found them to succeed together? *H. Y.*

ANSWERS TO CORRESPONDENTS.

ADIANTUM FRONDS IMMATURE: *J. H. S.* Th fronds have in all probability been grown in too much heat, and the continued lack of sufficient light prevents their maturing. Those in the vinery obtain more air, and are perfect.

BLACK CURRANTS AND GOOSEBERRIES: *J. B.* You can only protect the buds from birds by covering the bushes with fish-netting, or by enclosing them in a permanently protected garden enclosed and covered with wire-netting. Why have you sent three stamps?

CANNAS: *J. F.* There is no trace of disease that can be attributed to either fungi or insects. The blackening is due to too slow a process of drying after being lifted.

CARNATION FOLIAGE: *J. A. R.* The blisters on the leaves of Souvenir de la Malmaison Carnation are due to the punctures of mites when the leaves are young. The XL-All or other vaporiser will prevent this if used in time.

COLONIAL COMPANIES: *A Constant Reader.* You should consult the advertising pages of such papers as *The Tropical Agriculturist*, published by A. M. & J. Ferguson, *Ceylon Observer* Office, Colombo. The following addresses may prove useful to you:—Secretary, Ceylon Planters' Association, Kandy, Ceylon; Messrs. J. P. William & Brothers, tropical seed merchants, Henaratgoda, Ceylon; Yataderiya Tea Co. of Ceylon, Ltd.; The Putupaula Tea Estate Co., Ltd.; The Talgaswela Tea Co. of Ceylon, Ltd.; Portmore Tea Co. of Ceylon, Ltd.

CROPPING OF VINES: *C. W. S.* A great deal depends on the age and condition of the Vines and their roots, also upon the present state of the border. If the Vines are in a healthy condition, and assuming that the borders are mulched after thinning has been done, and that occasional sprinklings of Thompson's Vine-manure are applied, also that at other times the roots are afforded diluted liquid-manure or guano-water of the strength of 2 oz. of guano to 1 gallon of water, then 1½ lb. of fruit may be permitted to each foot-run of rod if the Vine has more than one rod, or 2 lb. to healthy single rods. In your case these weights should never be exceeded, as it is better to undercrop than overcrop the Vines, badly-coloured Grapes being never more than second-rate in quality. If the Vines make plenty of healthy foliage, and continue to produce lateral growths during the stoning period, this will prove that the Vines are not overcropped.

CUCUMBERS: *F. W.* You are quite right in supposing the injury to be due to forced growth. Modify the conditions very gradually, and the symptoms may cease.

Deciduous Shrubs for the Midlands: *Yew Tree.* Of deciduous species Forsythia suspensa is one of the most welcome of early-flowering shrubs, especially if a background or a groundwork of evergreens can be provided. Its lovely yellow, bell-shaped flowers appear on long, graceful, leafless shoots in March. Exochorda grandiflora (Pearl Bush) is of upright habit, free in growth, and delightful in blossom; flowers single, white, much after the fashion of a single Rose. The flowers of Pyrus (Cydonia) japonica cardinalis are larger and brighter in colour than those of the type. Berberis Thunbergi is a dainty shrub with tiny reddish-yellow drooping flowers in spring, and the plants are conspicuous in autumn, when its small green leaves assume many shades of orange, red, and yellow. Hypericum Moserianum, a low-growing hybrid St. John's Wort is remarkable for its clear, Buttercup-yellow flowers borne profusely in summer and autumn. The common flowering Currant (Ribes sanguineum) and its improved form atro-sanguineum are of easy culture, and succeed in nearly all positions. There is a host of really good things amongst the Spiræas. The first species to flower out-of-doors is S. Thunbergi, which in mild seasons bears its small white delicately-scented flowers towards the end of February. This is followed by S. arguta, one of the best single white forms, and S. prunifolia fl.-pl., also white. Other good sorts are, S. Bumalda var. Anthony Waterer, S. Douglasi, Lindleyana, and media (confusa). Hydrangea paniculata grandiflora is perfectly hardy, and if cut back to within one or two eyes of the old wood before growth commences in spring will bloom freely; its flowers are white, passing to a reddish hue, borne in terminal panicles about 10 inches in length, and remain attractive for about six weeks in autumn. Of small-growing Plums, Prunus triloba is pre-eminent; in early spring its shoots are wreathed with light pink, double flowers rather bigger than a shilling; obtain plants upon their own roots in preference to "worked" plants. Prunus nanus is a lovely dwarf species with rose-coloured flowers in February, and P. japonica (sinensis) with double flowers is prolific in blossom. Several mock Oranges can be recommended, especially Philadelphus Gordonianus, whose large white flowers appear in July; the trees require plenty of room in which to grow. The Snowball-tree (Viburnum Opulus sterile) and the Japanese Gueldres Rose (V. plicatum) merit attention, and if planted in a sunny position would render a good account of themselves. The Bush Honeysuckles, Weigelas, or Diervillas as they are now called, blossom freely in your locality; good varieties are Abel Carrière (rose-carmine), candida (white), and Eva Rathke (dark purple, late). Rhododendrons (Azaleas) of the mollis and ponticum sections should be included, as the range of flower-colour is extensive and particularly rich. Lilacs are good, those here mentioned representing a few of the best varieties:—Marie Legrange (white), Souvenir de Louis Späth (dark purple), all single-flowered; Madame Lemoine (white), Michael Buchner (pale lilac), La Tour d'Auvergne (mauve shaded rose), double-flowered. For planting near the edge of the pond, no berry-bearing shrub of similar growth is so effective as Hippophae rhamnoides (Sea Buckthorn); but the two sexes should be planted together; the orange-coloured berries remain on the branches throughout the winter; a group of half-a-dozen plants would be ample. The above is a selection (not a collection) of shrubs; but if a few small-growing flowering trees are needed, all those mentioned below are thoroughly hardy and very beautiful:—Almonds, Peaches, Amelanchier canadensis (Snowy mespilus), the double scarlet and single pink Thorns, Cotoneaster frigida and C. affinis, both very handsome during autumn, when laden with clusters of showy berries, a remark that applies to the Mountain Ash, one of the most ornamental of berry-bearing trees in the Midland Counties. The common Laburnum is very effective in April, while the double-flowered white Cherry, Prunus avium, fl. pl., P. pseudocerasus Wateri, Pyrus Scheideckeri, P. floribunda, and P. f. flore-pleno (P. Parkmanui) wreathe their branches with flowers in the months of April and May.

Emigration to Colonies: *G. W. R.* We can only answer your question in very general terms, because in the matter of emigration, as in most others of a similar nature, so much depends upon the capacity of the individual to adapt himself to whatever circumstances may arise. It is a fact however, that of the emigrants to Canada or New Zealand, those are likely to succeed best who have had some training in this country in the work of gardening or farming. A man, if he possesses youth and health, coupled with indomitable perseverance and fondness for work, would be likely to find greater scope for advancement in either of the colonies mentioned than is afforded in this thickly populated island. Before selecting the colony, it would be well to write to the Agent-General for each, and he will send you particulars of the demand for labour existing in the colony he represents.

Freesias: *Verax.* We are not sure that we fully understand what is meant by your question. Freesias being Cape plants, we suppose all newly-introduced stock is obtained from that colony. But perhaps you wish to discriminate between corms actually brought from the Cape and corms that have grown in this country. In that event we should choose corms freshly imported, as they would be likely to possess greater vigour than those which originated during pot culture in England.

Hippeastrums: *Amaryllis.* The temperature you mention will be suitable if you regard it as the maximum. When the bulbs are approaching the completion of growth for the season afford rather less water to the roots, and let the light and sunshine have access to them, that the bulbs will become perfected or "ripened," as it is sometimes called.

Insect: *C. Garratt.* The common white Podurus, Lipura sp. It belongs to the family of "Springtails," but unlike its congeners has no power of leaping. They are often abundant in rich composts, and seem to thrive and multiply among the roots of plants cultivated under glass, but are not generally destructive. Bisulphide of carbon [CAUTION] will destroy them, but we doubt if this agent could be applied to such tender plants as the young Nicotiana.

Latin Names: *J. M.* You will find much of the information required on reference to the Supplement issued with the first edition of Nicholson's *Dictionary of Gardening.*

Legacy: *Cambrian.* If your late employer left legacies in his will to all his domestic servants, and the executors have already paid such legacy to the coachman, then you, as head gardener, are also entitled to benefit under the will. We do not think it fair that the gardener should be regarded at one time as a domestic servant and as something quite different at another time, in order to deprive him of the privileges "menial" servants sometimes enjoy. You should consult a solicitor.

Lily of the Valley Crowns: *W. M.* You will not require to use manure in the forcing of the crowns into flower, and the soil should be of a very light nature, consisting largely of leaf-mould. When the plants are growing in the open beds good cultivation should be afforded in order that the crowns may become sufficiently strong and developed to produce good flowers.

Malay Orchids: *J. H. B.* To take Orchids from England to propagate in the Malay district with a view to returning them at a profit would result in failure. Indigenous Orchids cultivated there would not be profitable, for, among other reasons, cultivated plants suffer more when travelling than freshly-collected specimens from natural habitats. If you export any to England, send the wild specimens.

Names of Fruits: *W. C.* 1, Lord Lennox; 2, Beauty of Kent; 3, French Crab; 4, Flower of Herts; 5, Melon; 6, Castle Major.—*W. Lynos.* 1 & 4, London Pippin; 7 & 2, Bachelor's Glory; 3, Minchull Crab; 5, Tower of Glamis; 6, Prince Albert; 8, Forge.—*A. S. R.* Ross Nonpareil.

Names of Plants: *W. R. C.* A variegated-leaved form of Lamium purpureum, the red Deadnettle.—*R. H. S.* Cosmos sulphureus.—*T. D., Alton.* 1, Arpophyllum giganteum; 2, Dendrobium chrysotoxum (the form of the pseudo-bulb makes no difference); 3 and 4, Cœlogyne lactea.—*A. Y. L.* Dendrobium tetragonum.—*A. B.* 1, Adiantum caudatum; 2, Polypodium vulgare cambricum; 3, Oncidium altissimum; 4, Eria bicolor; 5, Phaius grandifolius; 6, Oncidium cheirophorum.—*M. A. W.* 1, Dracæna ferrea; 2, D. pulcherrima; 3, D. terminalis; 4, D. marginata; 5, D. intermedia; 6, D. congesta.—*J. B., York.* 1, Maranta Massangeana; 2, M. Makoyana; 3, Maranta, possibly a small leaf of Lindeni; 4, M. bella; 5, M. albo-lineata. — *F. B. B.* Forsythia suspensa. — *E. D.* Helleborus, possibly nigra. Send when in flower.—*G. B.* 1, Begonia fuchsioides (a garden form); 2, Cytisus racemosus var. Everestiana.—*W. P. L. & S.* Cornus mas.—*Constant Reader.* Why not number the specimens? The white flower is Jasminum hirsutum. The white leaf is Centaurea gymnocarpa. The small yellow flower, Cornus mas; the larger yellow flower is Forsythia suspensa.—*J. B.* Taxus adpressa, a variety of the common Yew.—*G. N.* 1, Acacia juniperina; 2, A. longissima; 3, A. dealbata; 4, A. longifolia; 5, Cupressus funebris (Retinospora stage).

Odontoglossum Leaves: *J. A. R.* The spotting of your Odontoglossum leaves is not due to lack of water at the root, but to a deposit of moisture on the leaves when the atmospheric temperature of the house is low. If ventilation be employed early in the morning it will check this.

Palms Damaged: *J. T.* The plants were grown under good conditions before being used for conservatory or indoor decoration, and the drier air to which they were removed failed to sustain the tissues formed under more favourable conditions.

Primulas: *W. B. Jeffreys.* The numbers were all disarranged through their not having been made sufficiently secure. All are forms of Primula denticulata, that of pale lilac colour, with pointed bronze-tipped leaves, is the type. Those with golden farina on stems and leaves represent P. cashmiriana, of which there are many varieties. P. Sieboldi is very distinct, with its running rhizome, and the growth appearing at its extremity; but P. Sieboldi in the open will not flower for a month yet.

Romneya Coulteri: *Correspondent.* This plant may be cut back to within a few inches of the ground-level early in spring. Some cultivators only remove the very old wood and shorten less severely the growths that remain; such specimens are apt to become of poor appearance, especially if the pruning is not done with more than ordinary care. The species likes to have its head in the sun and its roots in a moist medium during the growing season, but requires drier conditions in winter. It is a pretty flowering plant, but in most districts succeeds only indifferently.

The Pagoscope: *Various Enquirers.* The maker is M. Bernel-Bourette, Rue de Poitou 36, Paris, but we do not know the price.

Vines: *H. P.* The decayed part in one of the leaves is not due to disease, but has probably been caused by scorching or scalding. The tip of the growing shoot appears to be somewhat stunted, but the specimens are insufficient to prove the presence of a fungus. If the symptoms become worse you had better send us more specimens.

Violets Diseased: *J. L.* Your plants are affected with a fungus, Ascochyta violæ. Spray the plants with a solution of potassium sulphide—1 oz. to 3 gallons of water—every fortnight. When planting new beds select a fresh stock from a distance, and plant on a new site in the garden. See *Gardeners' Chronicle* for November 5, 1904, p. 328.

THE TIMBER VALUE OF EXOTIC TREES.

IT is seldom that I differ in opinion from such an excellent practical forester as Mr. A. C. Forbes, but the very weight of his opinion, which must be admitted by everyone who has read his recent work, induces me to offer a few remarks which I hope will not be looked upon as controversial, as I do not intend to argue the question further here.

Undoubtedly some of the exotic trees which have been recommended by various writers in your columns and elsewhere as having a possible timber-value in England are worthless even for ornament, and others require so much care and trouble in raising them, or are so particular about soil, situation, and climate, that they will only be useful as timber trees in exceptional cases. But the places in which the majority of the newer introductions, and many of the older ones, have been tried under proper conditions, by people having a sufficient knowledge of their requirements, are so few or altogether wanting that I cannot allow the necessity for further trial to stand condemned, even by Mr. Forbes.

Take, for instance, the common Acacia or Locust-tree, which eighty years ago was puffed in such an extravagant way by Cobbett, partly perhaps in his own interest, and partly because, in the prime of his life, Cobbett, with all his virtues, could not write temperately on any subject. Will Mr. Forbes or any other man name to me a native tree or any other tree which, on a warm soil in the South of England, will so quickly produce one of the most useful timbers in the world, if one knows how, when, and where to plant and use it?

Take, again, the Black Walnut. I have seen in Kent trees planted not more than one hundred years for which I should be happy to pay to-day twice as much as for any tree of its age, native or foreign, that I ever saw in England; and yet, such is the ignorance of the average British timber-merchant and consumer, that such a tree might be, and actually has been, sold at firewood price. Of course it is impossible at present to say what the timber of any tree will be worth in the future. It took nearly a century before the value of the Larch (itself an exotic tree), was fully recognised, and so long as the local trade is demoralised by unlimited foreign supplies of all the selected timber in the world, at a price little over the cost of felling and transport, and sometimes not even that, no home-grown timber whose qualities are not known will have a fair chance in the open market. But when Mr. Forbes condemns such a tree as Thuya gigantea as having only arboricultural interest, it only shows how little is known, even by good authorities, of the real value of many trees easy to grow in Great Britain. I do not blame him for not knowing what no man can know until he has studied exotic trees in their own countries as well as in England, remembering that I was myself advised by one of the most distinguished scientific foresters to plant for timber Pinus Banksiana, a tree which, however suitable for the barren Laurentian rocks of Upper Canada, is, even there, known as the "Scrub Pine," and which in England has never grown large enough to make a railway-sleeper, for which purpose alone it is, I believe, used in regions where nothing better can be got.

But there is another aspect of the case which Mr. Forbes seems to have forgotten, though his *British Estate Forestry* has shown that he realises it better perhaps than any previous author has done.

It is that as long as many parts of England continue to be a pleasure-ground for the rich, foreigners as well as Englishmen, it is not so much the actual timber-value on the land which gives it worth as the beauty, interest, and sporting possibilities of the woods and plantations on the estate. And I appeal to any experienced valuer whether, for instance, such places as Dropmore, Tortworth, or Ashampstead Common —I name three places as different in character as possible—would not be, either to let or to sell, of far greater value than a forest of German type on the same land, whilst they afford a constant source of pleasure to their owners and to many others. And considering what large sums are lost annually by the landowners of England by letting their valuable timber stand long after it is mature, and how much is spent on many other pursuits which do not afford so much interest or pleasure as the planting of exotic trees, I hope that his warnings will not be taken too strictly.

Believing, as I do, that we do not know nearly enough about trees, native or exotic, and acting on that belief, I am giving, with the help of Dr. Henry, the best of my knowledge, experience, time, and money to an attempt to describe and illustrate the trees of Great Britain in a manner worthy of so great a subject, in the hope that the knowledge we have both acquired in other countries as well as in Britain may be made useful to others. *H. J. Elwes, Colesborne.*

—— Before and since the recent great conversion from "Arboriculture" to "Sylviculture," a few outsiders have persistently confined the list of useful Conifers to the Douglas Fir, Japanese Larch, Corsican Fir, and one or two others yet on trial; but long as the Corsican has been in this country there are few successful plantations of it in England, and unless it be in some recent cases, I believe there are none at all in Scotland worth calling plantations. Most of the favourable opinions expressed by writers are borrowed from the experience of others. An owner of an estate in Scotland wrote to me not long since about planting the Corsican, and on my suggesting that he should see plantations of it in his neighbourhood, he replied that there were no Corsicans to be seen anywhere in one of the best wooded portions of Perthshire. The planting of the Corsican Pine has been a general failure because it has been carelessly effected at the wrong season, yet there is not an easier tree to plant, and I can show miles of it in proof in different soils and elevations.

As to the Japanese Larch and disease there is only one certified case, the Dumfriesshire twig sent to Kew. The Perthshire case, originally reported by the head forester, was subsequently found to have been based on an error. I was told this by the forester when I went to see the tree. The Cockle Park case, mentioned at p. 178, would be an amusing if unintentional confirmation of the disease-resisting powers of the Japanese variety, seeing the fungus had become common there without producing the blister, if it was not for the fact that the fungus cannot be established on the tree unless it takes root in the tissues, and when it does that the blister is inevitable and early. Something else has quite evidently been taken for the Peziza by your correspondent's informant.

It is not a case of waiting to see whether the Japanese Larch will become liable to the disease or not, because ever since the tree was introduced it has been subjected to the same conditions that produced and spread the disease on the common Larch, and in an aggravated degree too, namely, contagion. It has never been suggested by any competent authority that the common Larch gradually grew susceptible to the disease and then fell a prey. The blister appeared as soon as the fungus had time to travel from its original source to British plantations. It says a good deal for the Japanese variety that although hundreds of thousands, if not millions, of it have been planted, diseased examples are so hard to find, and some of these alleged specimens vanish when sought for.

Another quite unwarranted assumption is that the Japanese Larch at about twenty years of age may take it into its head suddenly to stop growing as fast as it certainly promised to do. Is there any record of forest trees playing such absurd tricks? The "boy is father to the man" in trees as well as in human beings. I have not Veitch's last edition of the *Manual of the Coniferæ* by me, but in it, if I remember rightly, some 40 or

50 feet has been added to the stature of the Japanese variety, which in the first edition was only 30 to 35 feet. Schwappach records a case in which the tree reached a height of 37 feet in nine years. At Stourhead, Dorset, a pure plantation of Japanese Larch was put out last November, the trees averaging over 4 feet, many being about 5½ feet, and these were one-year-old seedlings, 2 or 3 inches high, just two years before. Had they not been checked by the transplanting they would have averaged between 5 and 6 feet. One of the first plantations, if not the first, put out in England I planted near here, at a high elevation, on poor, thin soil, a few years ago, and the trees now run from about 14 to 18 feet, and there is not a speck of disease to be seen, although it has been long in the vicinity.

I may add that I do not neglect the common Larch, but always recommend a proportion of both to be planted as a precaution, and these in a mixed wood of other useful species. I can sell diseased common Larch at a good rent-paying price from 4½ inches quarter girth upwards, and considerably under forty years of age. There are, at the present moment about 10,000 cubic feet of diseased Larch poles lying at a station in Mid-Wales, all sold to one customer near Crewe, at the ordinary district price, which, so far as I know at present, must have amounted to about £65 per acre at forty years of age in land worth for agricultural purposes, 1*s.* 6*d.* per acre. *J. Simpson.*

—— In reference to "The Timber Value of Exotic Trees" (p. 177), by Mr. A. C. Forbes, would it not be much better for landlords, and also for national reasons, to grow timber that is used in quantity in this country? Timber imported from Europe has about three times as much value as home-grown timbers. Is it not very bad forestry to produce soft timber from trees that produce valuable timber if not so rapidly thinned out? I quite agree with Professor Schlich in his last book that the new forestry will lead us to make the same mistakes that Brown did, although Schlich does not say that in so many words. When we can produce timber in quantity from our native trees, then it will be time to turn to exotic trees as timber producers. *Alec. D. Berney, Carlisle.*

LACHENALIA HYBRIDS.

THE genus Lachenalia may be classed amongst those which exhibit comparatively little inherent tendency to variation, and as the number of species possessing bright colours, or which are attractive or showy from a florist's point of view, is small, Lachenalias have not received much attention from gardeners. Further, when intercrossed, the seedlings vary very slightly from the parents, so that it takes a considerable time to get well-marked varieties of merit. The fact that it takes three years to flower seedlings, even under good and careful cultivation, is another potent factor which deters hybridisers from taking this genus in hand.

The first authenticated hybrid was raised by the Rev. John Nelson, in or about 1878, a cross between Lachenalia aurea and L. tricolor luteola, and this is still one of the best hybrids for general cultivation. The same hybridiser also raised L. aureo-reflexa (Baker), also known as Aldborough Beauty, a very distinct plant, which when crossed with L. Nelsoni produced L. Wm. Watson. About ten years later some excellent varieties were raised by the Rev. Theodore H. Marsh, including Rector of Cawston, Cawston Gem, Garnet, &c.; and in recent years additional crosses have been offered by Messrs. Dammann & Co., Naples.

The varieties here illustrated (fig. 91) were obtained by me at the Royal Botanic Gardens, Glasnevin. I commenced raising seedling Lachenalias in 1885, and each year since that date I have raised about half-a-dozen crosses, a very small proportion

FIG. 91.—LACHENALIAS × "BRILLIANT" AND "JEAN ROGERS,"
Which obtained Awards of Merit at a recent meeting of the Royal Horticultural Society.

of which have been worth retaining and naming as showing some distinct advance on their predecessors. At first the parents were limited to L. tricolor and varieties, the best of these being L. t. luteola and L. t. quadricolor maculata, generally known as L. superba, L. aurea, L. Nelsoni, L. Cami, and then the Cawston seedlings. Certain objects were constantly kept in view. I endeavoured to eliminate as far as possible the green tints predominant in the flowers of L. tricolor; to get a good clear yellow; to increase the amount of red in the flowers; to increase the size of the flowers, the strength of scape, and the number of flowers. Most of the parents were defective; the predominating colour in L. tricolor is green, and this green is most persistent, appearing through generations. L. t. quadricolor maculata, although with a much brighter flower than L. tricolor, has a weak, thin scape, the flowers being scattered far apart. L. aurea (fig. 93) is of a good colour, deep yellow, but has a small scape, and is a shy flowerer, so that in effecting crosses all these points had to be kept in view. The advent of L. aurea gigantea was a great help, and seedlings from this at once showed distinct advance. Crossed with the best of existing seedlings, the resultant progeny were better than any previously obtained, and their progress has been continued.

One of the characteristics of the newer varieties is the amount of bright red colour which has been got into the inflorescence, not into the flowers, but into the abortive buds which terminate the scape. These have increased both in number and in intensity of colour.

For many years I have endeavoured to get red colour from Lachenalia pendula (fig. 92) or from L. rubida, but hitherto not one seedling from these crossed with other distinct species has flowered. I have apparently had good seed, but either it has failed to germinate, or else the seedlings have shown no trace whatever of L. pendula or L. rubida, probably proving that the cross had not been effected. However, at the present moment some distinct seedlings give promise of better results.

A glance at the varieties illustrated (fig. 91) will demonstrate the advances made. These seedlings are free-flowering; the colours are bright and attractive, the scapes are strong and erect, the flowers distributed all round them and not hanging to one side, the number of flowers has increased from twelve to twenty, until they are from thirty to forty, the last-named being not an unusual number.

Seed should be sown as soon as ripe. It takes from three to four months to germinate, and if kept in a warm house the seedlings remain green and continue to grow for eighteen months, or for two seasons. After this Lachenalias require very little fire-heat; a cool, airy bright house suits them best, and they should be grown close to the light. It is advisable to repot and divide up the bulbs each year, doing this early in August.

F. W. Moore, Botanic Gardens, Glasnevin.

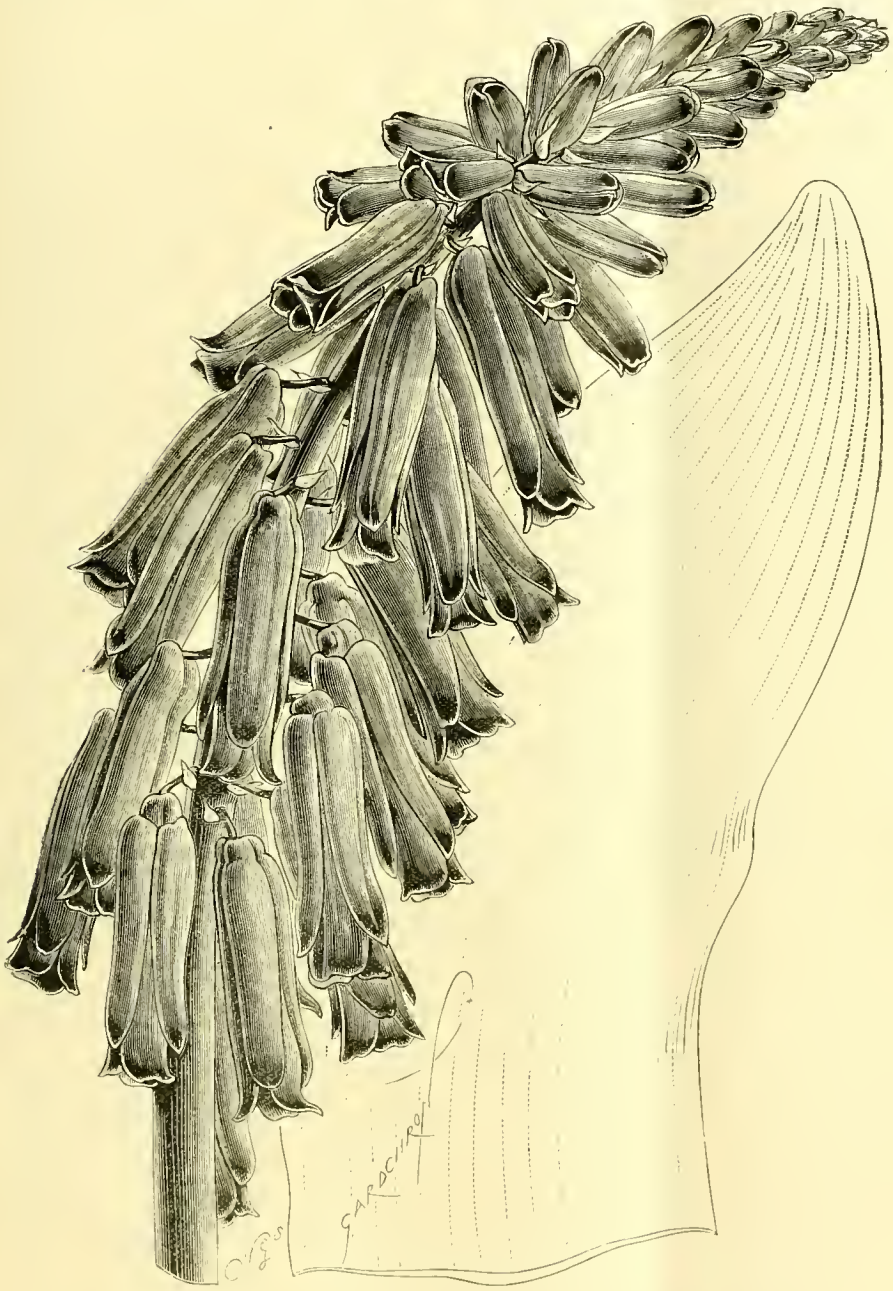

Fig. 92.—Lachenalia pendula aureliana: colour of flowers crimson.

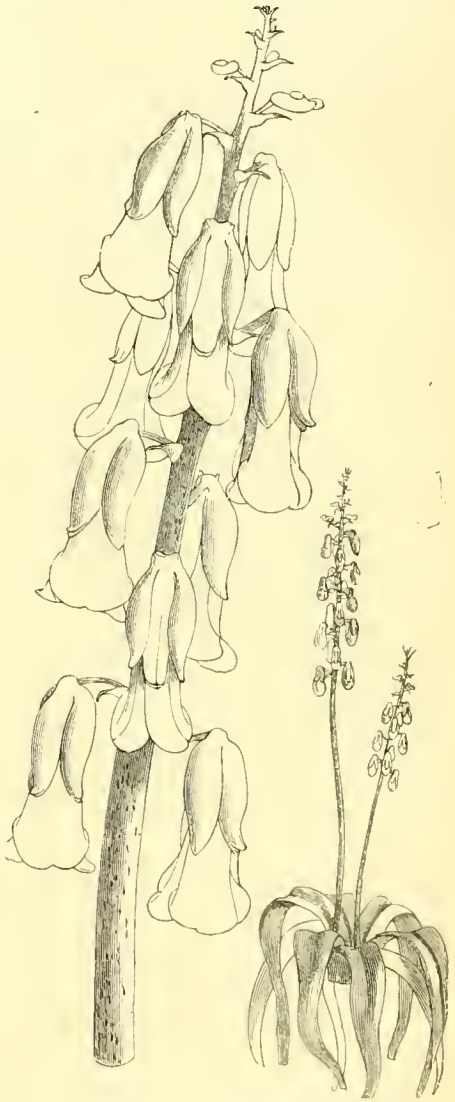

Fig. 93.—Lachenalia aurea: colour of flowers rich apricot or golden-yellow.

[In addition to the illustrations of the new hybrid Lachenalias raised by our valued correspondent Mr. Moore, we take this opportunity to reproduce figures of the species L. aurea, and of L. pendula var. Aureliana, which latter it is stated was found originally growing near to the summit of Mont Esterel, Alpes Maritimes, in the South of France in 1889, a most unlikely position, where, indeed, its presence could only have been accidental. It was shown by Mr. C. G. Van Tubergen, of Haarlem, at a meeting of the Royal Horticultural Society in London, on March 8, 1898. Ed.]

SEED SOWING.

Seeds in many instances, or rather the embryo plants within them, have such vitality that they will struggle into life under the most adverse conditions. But this is not true of all seeds, for many are rendered sterile by the least accident. In raising seedlings, although it is advisable to consider and to imitate natural conditions as far as possible, there are many instances in which these conditions can be improved upon. For instance almost all seeds with hard shells may with advantage be soaked in water before they are sown, provided the water is changed at least once every day. Some seeds (as those of the Acacias) will swell at irregular intervals, although they must be taken out of the water and sown directly they have swollen. It is injurious to seeds to leave them for too long a period in water. At one time I used to soak Cyclamen seed, but I have since found that surfacing the seed-pots with fresh sphagnum-moss chopped very fine, with a little sand added, is sufficient to ensure germination.

The use of sphagnum-moss is recommended for aiding germination in many seeds. Primula seed often germinates badly, but I have always had good results when I have sown the seeds on sphagnum, which retains sufficient moisture for their growth without the risk of the soil becoming sour. Where this practice is adopted it will not be necessary to cover the pots in order to keep the surface moist. Shading and covering of the seed-pans are often overdone. I always prefer standing seed-pots in places where they can be fully exposed to the light, but where the direct sun's rays cannot reach them. I never place seed-pans in a close propagating-pit. I have succeeded best when raising Begonias with pots stood on the open stage, with no covering or shading. The seeds may germinate more readily under heavy shading or in a close atmosphere, but there is great risk of losing the seedlings by damping-off almost before they are large enough to be seen. I have had the best results with many spring-sown seeds when the pots have been stood on a shelf close to the glass. Under these conditions care must be taken to see that the pans do not become dry. A good plan is to stand the pots in saucers containing water, which, if the soil has been well watered before sowing, will supply sufficient moisture until the seeds have germinated.

Conifer-seeds give some trouble in raising, but if they be soaked sufficiently before they are sown, and are only placed just below the surface of the soil, there will be less chance of failure. Those growers who handle Palm-seeds should remember that though of such a hard substance the embryo will perish quickly if exposed to a dry atmosphere. Palm-seeds should be sown as soon as received, or if they must be kept for a time they should be stored in a moist place. I have seen seedling Palms damp off through their not being able to come to the surface of the ground on account of the seeds having been buried too deeply.

Sowing seeds too thickly is an evil which is often practised, especially in the case of very small seeds. I have seen Petunias lost through this error, also Lobelias. Such small seeds as these require no surface covering at all, and may be placed in a light, sunny position as soon as sown.

Aster-seed gives best results when well exposed to the light, and though it may not germinate quite so quickly, the seedlings when they do come through will be short and sturdy. I have never failed with Eucalyptus Globulus, when the seed-pots have been put on a shelf fully exposed to the sun, but in the shade the seedlings almost invariably damp-off soon after they begin to germinate. Seeds of Aralia Sieboldi are also short-lived, and must never be allowed to get quite dry. It is safer to sow these seeds as soon as they are received, but I have kept them for some months by putting them in a tin box and keeping it in a cool place. *A. Hemsley.*

BOOK NOTICE.

"The Book of the Potato."*

Seeing that the Potato has amongst edible vegetables long enjoyed the distinction of being the most fertile source of cultural methods, of literary comment and criticism, and has given rise to a wealth of physical and ameliorative or developing detail in the horticultural and agricultural press, it may well be asked what can there be concerning the Potato that is novel enough to justify the publication of yet another book on the subject. Perhaps the best reason that can be given by Mr. Sanders, the author of this publication, is that whilst so much has been written in the past concerning Potatos, it has been too fragmentary in nature and too widely diffused for the convenience of those who would gladly become more closely acquainted with Potatos and their culture: hence the book before us may be regarded as a compilation of what has been so often previously written about, but which is now presented to readers in more concrete form. The author thinks that the recent "boom" of a few would-be wonders in Potato varieties has done much to call public attention to Potatos. That may be so, but we think the formation of the National Potato Society has done more in that direction, and without doubt, even without Society or boom, the value of the Potato as an important article in our national diet would suffice to make it one of profound interest. The literary matter of the book is rather fragmentary, but seems to cover almost all the ground it is possible to find in relation to the tuber. Its introduction to Europe (an oft-told tale), its general history during the past century down to now; its botanical features, its employment as a profitable crop, soils and their treatment, suitable manures, with details as to experimenta and general methods of propagation by sets of diverse sizes, by cuttings; storing tubers in winter; times and methods of planting, culture on farms and in gardens, or for exhibition, also for forced culture — these features follow each other, and if not always with relevance, at least with full and fair treatment. The rearing of new varieties is also dealt with, as are fungoid and insect pests, and the proper treatment in each case is fully described. That many of these "pests" give, after all, where culture is good, very little trouble, is certain; but then the description of them and illustrations do help to make a book. Some illustrations of what is described as black-scab or wart-disease will assist readers to understand it more fully than will mere descriptions. The disease is happily not common, and may be as a rule remedied by applications of gas-lime. There is also an illustration of what is known as the spindle disease, happily also very uncommon. That is evidenced on the tuber when the eye-buds affected with the fungus endeavour to make shoots, but only succeed in producing mere spindly growths of the size and texture of thread. All such tubers when found can be easily rejected and destroyed.

The proper way to cook Potatos is also explained, and some paragraphs are devoted to the usea to which the tubers may be put in the feeding of poultry and cattle. The book is profusely illustrated with representations of varieties now in commerce—rather too freely, in fact, as very many of these varieties will have passed out of common culture soon. The illustrations of Potato monstrosities might well have been omitted. Finally, the book concludes with a list of some 269 varieties in commerce, which shows how many really inferior varieties have in the past found names.

MARCH FLOWERS IN THE SOUTH-WESTERN COUNTIES.

By mid-March Anemone blanda has been in flower for several weeks, but gives promise of continuing its blooming season until plants of its Apennine sister, now pushing up strongly, are ready to expand their first blooms, and the white form of the Pasque-flower (A. Pulsatilla) is showing numerous buds, while A. fulgens, A. coronaria and its varieties, have brightened the borders for some time past. The common Arabis has been in flower for three weeks, and is now a sheet of white, but its double form has not as yet opened a single blossom. Aubrietias of various shades are commencing to paint the rock-work with soft colour, and the quaint little Dondia (Hacquetia) Epipactis holds aloft dozens of its attractive green-and-gold flower-heads, while the rarely-seen Gagea lutea, sometimes called the English Star of Bethlehem, is freely bearing its yellow flowers. Scilla bifolia and S. sibirica, with their white varieties, have been very beautiful, and the Chionodoxas are still with us. The most effective is certainly C. sardensis, a bed of Tulipa Greigi surfaced with this being now a glorious show of deep blue and scarlet. C. gigantea and C. Alleni appear similar and are unsatisfactory, rarely bearing more than two or three blossoms on a scape. A pretty and rare flower that has been very charming is Romulea pylea. This bears satin-white, starry flowers, about 2 inches across, with yellow throats, and has rush-like foliage. A clump with a dozen or two expanded blossoms glistening in the sun is a lovely sight. The sweetly-scented flowers of Daphne indica are now past their best, but Convolvulus Cneorum is just coming into bloom, and Clianthus puniceus, which ever since Christmas has held two or three expanded blossoms, is becoming slowly redder, though the zenith of its display is still some weeks distant. The Christmas Roses have given place to their Lenten sisters, and a collection of Mr. Archer-Hind's beautiful seedlings, pure white, deep maroon, and white delicately spotted with pink, are in full bloom.

It may be mentioned that Mr. Archer-Hind has presented to Messrs. Barr & Sons a selection of his best forms, so that these, which are certainly in advance of the named varieties of continental origin, should in course of time be distributed. Of Narcissi, such kinds as obvallaris, princeps, Golden Spur, cernuus pulcher, Santa Maria, the fine trumpet variety M. J. Berkeley, Soleil d'Or, and Victoria have already yielded their flowers, and Sir Watkin is just expanding. The Snake's-head Iria (I. tuberosa) has borne its satin-black and olive-green flowers, I. stylosa is still blossoming, and I. pumila, I. Chamæiris, and some of Mr. Caparne's hybrid Irises are now in bloom; while almost every bulb of the lovely I. tingitana, which often proves an extremely difficult species to flower, is blossoming grandly. Very different is the case however with the dwarf bulbous Irises, such as I. alata, I. persica and its varieties, I. reticulata, I. Histrio, and others, which absolutely refuse to become established whatever compost is employed.

The first flowers of Freesia refracta alba expanded in the open-air on the 18th, and the crowded flower-stems promise profuse bloom. The large Musk Hyacinth, Muscari moschatum major, is bearing numbers of its deliciously-perfumed but rather dingy yellow flowers; and the fine M. latifolium is throwing up strong bloom-spikes, while the curious Fritillaria persica is rapidly perfecting, almost a month before its usual time, one of its tall flower-stems hung with between twenty and thirty wide-mouthed bells, maroon-purple in colour. Hepaticas, blue, white, and red, are flowering in a partially shaded border, where Omphalodes verna and its white form are also blooming well; and the

graceful little Thalictrum anemonoides has produced its fragile white flowers above its delicately-cut foliage. The first blossoms have opened on a large plant of Gazania longiscapa, which has now been in the open unprotected through three winters. Triteleia (Milla) uniflora is blooming lavishly, and the charming little Violet Cress, Ionopsidium acule, self-sown everywhere, is blossoming abundantly; indeed, there is no day in the year when some plants of this may not be found in bloom. The first of the Saxifrages to flower was S. Burseriana, followed by S. Boydii alba; but S. Boydii, the yellow-flowered type, has disappeared. S. Rhei superba is now in bloom, but the type is as yet only in bud. S. apiculata is a mass of pale yellow. S. Wallacei is commencing to flower, as are countless little rosettes of the annual S. cymbalaria, the bright green, ivy-shaped leaves being set with small, deep yellow blossoms. *S. W. Fitzherbert, March 22.*

ORCHID NOTES AND GLEANINGS.

PHAIUS TETRAGONUS, Rchb. f.

A plant of this distinct and interesting species, which has not been recorded as flowering in gardens for many years, has lately been in bloom with Messrs. Charlesworth & Co., Heaton, Bradford, Yorks, who kindly sent a sketch of the plant and a flower. In habit it is very remarkable, its elongated, generally four-angled pseudo-bulbs being furnished with ornamental plicate leaves, from the base of one of which, about half-way up the stem, springs the scape, which is 9 inches in length, and bears at the top four flowers, each rather over 2 inches across. The flowers, which are of the true Phaius form, have the sepals and petals chestnut-red on the face, the sepals bearing three, and the petals one yellow line, the margins of both being yellow, and the reverse side greenish-yellow. The cream-coloured labellum is folded into a tube over the column, having its edges wavy, its interior is decorated with purple lines, and a downy covering around the callus, It was imported from Ceylon as Phaius luridus and it corresponds with that species in Thwaites' *Enum. Pl. Zeyl.*, 300 (1861), but the priority of Phaius tetragonus, Reich. f., in *Bonplandia* (1855), reduces P. luridus to a synonym.

Reichenbach based the species on Pesomeria tetragona (*Botanical Magazine*, t. 4442), a plant said to have been imported from the Isle of Bourbon. The Ceylon habitat is well authenticated, but I cannot find any verification of the Mauritius region record. It seems singular that it should be indigenous to such widely separated localities. The Hon. Walter Rothschild, who has made many discoveries in the eccentric geographical distribution of some animals and insects, and has incidentally learned much about the distribution of plants, informs me that it might have been conveyed from its original native habitat to the other locality by traders, who from the earlier days of maritime communication passed between Mauritius and Ceylon, bringing among other things tortoises to the latter country. Thus if the plant figured as Pesomeria tetragona really came from the Isle of Bourbon it might have been introduced from Ceylon.

The botany of the species seems much confused. The *Index Kewensis* refers the plant figured as Pesomeria tetragona to Phaius villosus, Blume, which in no way resembles it, the plant having rose-coloured flowers with a nearly flat labellum. Epidendrum tetragonum (*Thouars Fl. Iles. Aust. Afr.*, t. 34), is also referred to Phaius tetragonus, but it has little resemblance to that species except in the angular pseudo-bulb.

Phaius tetragonus in Ceylon often develops pseudo-bulbs 3 feet in length, forming with their Palm-like leaves and their three or four spikes of flowers on a bulb very striking objects, as I am informed by a correspondent. None of the other species of Phaius is like it in growth except the Indian Phaius mishmiensis, which has rounder and not angular pseudo-bulbs, and rose-pink flowers. *J. O'B.*

SENECIO AURICULATISSIMUS.

This graceful Groundsel was recently exhibited at one of the Royal Horticultural Society's meetings by Messrs. James Veitch & Sons. It is a native of British Central Africa and was first discovered by Mr. J. T. Last in 1887, near Milangi, and has been sent to this country also from several other localities, where it grows at from 4,000 to 6,000 feet elevation. Plants were raised at Kew from seeds sent in 1898 by Mr. John Mahon, who was then Government Botanist in British Central Africa. The species flowered in the conservatory at Kew in February of 1900, where it climbed one of the pillars and was very attractive. The auricled petiole, the orbicular reniform leaves, and the freely-flowered inflorescence are shown in Mr. Worthington Smith's drawing, which is reproduced at fig. 94. A full description by Sir Joseph Hooker and coloured illustration will be found in the *Botanical Magazine*, t. 7731. The species makes a very decorative pot plant, which will be admired by those who appreciate flowers regardless of their size.

Fig. 94.– SENECIO AURICULATISSIMUS: COLOUR OF FLOWER GOLDEN-YELLOW.

THE ROSARY.

CLIMBING ROSES.

Since the advent of the so-called climbing Roses, which, by the way, do not climb, but must be trained and fastened in some way to the object that supports them, the stiff formality of the old Rose-garden has become obsolete in many country gardens. The favourite methods of displaying the charms of these varieties are by using them as coverings to arches of rustic woodwork, set widely apart or close together so as to form tunnels or arcades, as fancy may dictate to the owner or his gardener. "Pillar" Roses, with or without hanging chains connecting the pillars or posts, have a pretty effect if they are kept abundantly covered with flowering growths; and to have them thus good soil and abundant manuring are points needing annual attention from the gardener who would excel.

Sometimes the simple pillar form is the one adopted, and the effect is good in conjunction with wide borders on each side of a walk of not less than 10 feet in width, the Roses standing at 10 to 12 feet apart and 2 feet distant from the edge of the walk, this space being required in order to carry the growths and wide-flung tresses of blossoms beyond the reach of passers-by, a matter easily

managed by means of long slings of raffia or string dyed of a green colour.

An arbour forms another pleasing mode of utilising Roses that make annual shoots of great length; but although an arbour is planned for affording shade, one that is to be covered with Roses must stand in a sunny aspect, unshaded by shrubs or trees, or the Roses will not succeed.

One of the best varieties for arbour planting is Félicité-et-Perpétue, a most abundantly-flowering plant, throwing perfect sheets of its small white flowers, and a growth of shoots and foliage when in vigour so dense as to form a close pent-house against sunshine. The writer once saw such a plant which was trained over a dome of wire-work 20 feet in diameter, covering it in down to the ground except at the entrance. This was indeed too much of a covering, as it rendered the interior too damp by shutting out the sun entirely. Such Roses as this variety require but a small amount of pruning as the operation is usually understood, but the over-crowded and weaker shoots should be entirely removed, and the remaining ones shortened one-fourth or left at full length according to the wish of the gardener.

It may be said by way of caution that often too much pruning of climbing Roses is carried out, with the result that we miss the fascinating masses produced by less pruned plants.

No arbour of Roses should be without some of the more robust Teas, such as Jaune Desprez, a not too rampant grower, with rather small bronzy-yellow blooms deliciously scented. The climbing Devoniensis is another agreeably tea-scented rose, white and of nice shape like the dwarf variety of the same name; Catherine Mermet, of a tender blush tint and full in form; François Crousse, a pretty tea hybrid, a vigorous variety of a fiery-red tint; Morgenroth, of the same tint; and Reine Marie Henriette, with cherry-red blossoms and vigorous habit. An old favourite climber is the sweet-scented W. A. Richardson, of quick and vigorous growth, the flowers excellent for personal adornment. Madame Desprez is a strong-growing Rose of another section, of a bright-pink colour, the flowers appearing in bunches of a dozen or more. Ruga is a good rambler and abundant bloomer, in tint a shade of pink and in form very full.

The "Wallflower," brought out by Paul & Son Cheshunt, in 1900, is very rich in bloom from the bottom to the topmost shoot, resembling in this respect Crimson Rambler, but of a lighter and more tender shade of colour. Add to the above Carmine Pillar, an earlier introduction of Messrs. Paul & Son, Cheshunt; Coupe d'Hebe, an old and a very charming, good-sized flower of a soft pink tint; Gardeniæflora with small, snow-white, partially full blossoms (this last-named Rose grows and blooms like Crimson Rambler, and may be planted for the sake of the contrast in colour); Mercedes, rosy-blush, a strong grower, flowering in bunches; Prairie Queen, ever blooming, has dark carmine-coloured, very fragrant flowers; Aglaia, one of M. P. Lambert's introductions of 1896, with light greenish-yellow flowers, is valuable from its novelty in colour, and from the fact that the blooms are produced in large pyramidal bunches.

I will finish my list with the names of a few indispensable varieties—viz., the Fellenberg, a Noisette, introduced fifty or more years ago. It possesses flowers of a dark crimson tint, and the buds are carmine before expanding, making, together with the brown-reddish foliage, a charming effect. Hermosa is very free in blooming, and of a tender rose-pink tint. A cross between Hermosa and Reine Marie Henriette has been raised, and is of a red colour, and worthy of a place.

A Rose arbour pure and simple is a summer shelter against the too ardent rays of the sun, and as such it requires neither a fixed roof nor close sides, the growths of the Roses affording the necessary amount of protection; it should, however, be made dry underfoot with tiles, wood blocks, or concrete, raised a few inches above the surrounding level of the garden. *M. F.*

A Hybrid Rose.

M. Maurice de Vilmorin gives a coloured figure and description of a hybrid between Rosa microphylla and R. rugosa in the number of the *Revue Horticole* for March 16. The plant is intermediate in character between its parents, and possesses large depressed-globular fruits of a deep orange-red colour beset with fine prickles.

Rose Fortune's Yellow.

In the spring of 1903 attention was drawn in these columns to this beautiful decorative Rose. At that time some of your correspondents complained of its shyness of flowering and of its habit of shedding the leaves just when the flower-buds were developing. As to the freedom of flowering, the plant under my charge leaves nothing to be desired. It blooms so freely that a very severe thinning of the flowering-shoots is necessary. This I find not only increases the size of the blooms, but there follows a marked improvement in the colour of them. In the case of a sltrong healthy plant, the partial shedding of the eaves is not a serious drawback. The growth made after the flowering season is always satisfactory, and there is generally sufficient foliage retained to "set off" the flowers. *H. P., Bournemouth.* [Our correspondent sent us some flowers of this pretty variety. ED.]

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Potting Cattleyas.—Excepting during the early winter months some Cattleyas, many of the Lælias, and the hybrids therefrom, are continually arriving at that stage when the necessary potting operations should be carried through. To know when and how to do this places the cultivator on the high road to success. There are two periods at which a Cattleya or allied plant may be repotted, and these are just as new growths are developing or immediately before roots are produced on the current season's growth. The latter is probably the better time, for then as the roots enter the new material water may be afforded more freely, and the sphagnum moss preserved in a living state. From a cultural point of view the Cattleyas form themselves into two sections, determined by their season of flowering, thus C. aurea, C. Bowringiana, C. bicolor, C. gigas, C. labiata, C. Schofieldiana, C. Warnerii, and others proceed to flower immediately after developing their new pseudo-bulbs. These then make a new series of roots, and potting or re-surfacing should be done just prior to the latter event. The other section, embracing such specis as C. Mossiæ, C. Mendelii, C. Lawrenciana, C. Percivaliana, C. Trianæ, &c., mature their growths and pass through a season of rest before producing their flowers, and in their case potting may be done when they start to make new growths.

Materials for use in Potting.—Formerly good peat and freshly-gathered sphagnum-moss were the only materials recommended for forming a rooting medium, other than that used for draining the pots, but of late years other ingredients have been introduced, notably leaves. Without entering into the merits or otherwise of the latter, it may be safely asserted that where consistent personal attention cannot be given, leaves should be omitted from the potting material. That we shall have to find a substitute for peat is too evident, as the supply of really good peat is fast failing us; but whilst it is obtainable use it.

Method of Potting.—Pots or pans are better for most of the species, baskets being needed for very few. The drainage must be perfect, and is best obtained by the use of broken pots, the pieces being placed in the pots in as upright a position as possible. The depth of drainage material should be increased in proportion to the size of the receptacle, that is, small pots may have comparatively a greater depth of material than drainage; but in few instances should it exceed 4 inches, even when leaves are introduced. When about to pot a plant whose roots form a network outside as well as inside the receptable, carefully crack the latter in several places, and pick away such pieces as may be removed without injuring the roots, also as much of the old decayed material as possible. Cut off old leafless pseudo-bulbs, insert the plant in a receptacle which will afford space for about two seasons' extension, work in the requisite drainage material, and over this the rooting medium. Use good turfy peat, pressed inwards and not downwards, with patches of sphagnum-moss alternately. The rhizomes must not be covered, but be just on the surface, which should be slightly below the rim at the edge, and slope gently upwards towards the centre. Contrive to have the heads of sphagnum-moss uppermost on the surface, and even with it, and trim off the peat a little to give the whole a neat appearance. Much water should not be afforded newly-potted plants for some weeks afterwards.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Celery Trenches.—Make every effort to prepare Celery trenches in good time. The rows should, if possible, run from north to south, in order that the plants may obtain the full benefit of the sun's rays. The trenches for the earliest crops should be dug 18 inches in width, and should contain one row of plants, allowing 4-feet alleys between the rows. For the main and later crops dig the trenches 2 feet in width, and plant two rows of plants in each trench. The surface soil being the more fertile, remove no more than is necessary to make room for the manure, which should be plentifully applied. Finish the trench just below the general level. At Lockinge late crops planted at the level of the surrounding ground pass through the winter with little injury by reason of being drier than they would otherwise be. But this system cannot be practised on light, dryish soils that receive only a limited supply of water. Celery requires much water until growth is completed. Too early sowing of the seeds, or neglecting the plants in their young stages, will tend to develop the flowering spike prematurely, which is termed "bolting." From seeds sown during the second week in March for the early crop, we are now pricking out the seedlings in boxes filled with fine soil; this is kept well watered, and the plants afforded plenty of light and air to induce strong, sturdy growth. In a few days we shall sow seeds for raising the main crop.

Carrots.—The next ten days will be a suitable time for sowing the main crop of Carrots. The soil for this crop, having been dug in the early autumn, will now be in good condition, and if the ground has already received a dusting with air-slacked lime, then, before the seeds are sown, if a good dressing of soot is applied the insectivorous enemies of the Carrot will be considerably checked. Sow the seeds in shallow drills 12 or 15 inches apart, covering the seed lightly with the soil. Excellent varieties for sowing now are the Red Intermediate, Scarlet Model, and Carter's Blood Red. For cultivating exhibition specimens, bore deep holes and fill them with finely-sifted soil, preferably some old potting soil. Sow a few seeds in every hole, and later remove all the seedlings but one.

Peas.—Draw the soil well up on each side of the row as a protection and a support for the slender stems, and apply stakes directly the tendrils appear. Insert the stakes firmly in the ground each side of the row, at a distance sufficiently far removed to prevent injury to the roots. At Lockinge we place the stakes perpendicularly 12 or 15 inches apart, never interlacing or crossing the stakes at the top. This system

allows the Peas sufficient space to develop between the two lines of stakes, and the work when well done has a good appearance. Small twigs or brushwood are stuck at the base of the sticks to give the Peas a start. Dwarfer varieties that are not usually staked are the better for being afforded short twigs or stakes, which will keep the pods clear of the ground.

Planting.—Although rain fell on twenty days during March (the quantity registered being a little over 4 inches), still on narrow borders, by the use of light planks, we were enabled to plant such vegetables as early Peas, Cauliflower, Lettuce, &c., the wet weather being favourable to the newly-planted plants.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Buds and Grafts. — Examine fruit-tree stocks budded last season, and cut down any in which the buds are not growing and graft them. This will be preferable to waiting until budding time again, as the time so gained amounts to one season. Remove the binding material from "buds" which are growing, and cut the stocks down to within 1 foot of the bud, but not shorter, as this portion of the stock is necessary to afford a means of support to the growth from the bud. This portion of the stock left last season (or twelve months earlier) should now be removed, and such work is termed "snagging." Around the interstices of the bud, under the binding material, American blight often hibernates, and if not destroyed by means previously stated, will kill the buds entirely.

Layering Fruit Trees. — Fruit-trees may be increased by layering in cases where a good strong branch can be spared near to the ground surface. Make a slanting cut about 3 inches in length in such a branch, followed by a second cut to remove a piece of the wood entirely; fix the part so cut firmly into the ground by means of a forked stick or peg, making the soil firm about it, and covering it with soil to the depth of 12 inches. When upon examination it is found that the layered branch has formed roots, it may be partially severed from the parent tree, increasing the degree of severance as the season progresses.

Insect Pests.—If any trees were not given a winter-dressing, this work may be carried out now, and trees which were dressed in the winter may with great advantage be sprayed again, using for this application a solution of Blundell's Paris-green paste; the paste is more easily mixed with water than the powder and is safer to use. Half an ounce dissolved in 12 gallons of water is a safe mixture to apply. In gardens where the use of these arsenical poisons is objected to an excellent insecticide and fungicide will be found in the Bordeaux-mixture, composed of 6 lb. of sulphate of copper and 4 lb. of unslacked lime. Place the sulphate of copper in a bag suspended in a wooden vessel containing sufficient water to dissolve it. Slack the lime in as little water as possible in a separate vessel, afterwards mix the two together, adding water up to 60 gallons. For use through a sprayer the liquid should be carefully strained to take out any residue from the lime. Gooseberry-trees that were badly attacked with caterpillars last year may again suffer this season. As soon as any caterpillars are noticed spray the bushes with Hellebore Tea, which is much more effective than Hellebore powder, and may be more quickly applied.

FRUITS UNDER GLASS.

By F. Jornan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Figs.—The earliest trees grown in pots will soon show signs of swelling their fruits, which will not afterwards be long before ripening. A warm and slightly drier atmosphere will be necessary, also increased ventilation, and full exposure of the fruits to the sun's rays, in order to obtain good colour and high flavour. Remove all weak shoots as they appear, and pinch out the points of others. Afford liberal supplies of warm liquid manure, and apply rich top-dressings of loam and half-decayed manure to the roots of trees which are swelling their fruits. Syringe the trees freely, and do all that is possible to prevent red-spider.

Fig Trees in Borders.—The earliest of the trained trees grown on the extension system of training will require regular attention to thinning, tying down of shoots, and occasional stopping of strong shoots. The roots being in restricted borders should be encouraged to the surface by applications of decayed manure and abundant supplies of warm liquid manure. During the time the trees are in flower the temperature at night should be 58° to 60°, rising 10° higher during the day with fire-heat. Fire-heat should be discontinued early on bright mornings when there is a prospect of the temperature rising; employ a little ventilation when the atmospheric temperature is at 68°. Close the house early in the afternoon, and syringe the trees copiously. The latest trees in cold-houses where no fire-heat is used should be retarded as long as possible by admitting abundance of air to the house until growth commences.

Cucumbers.—The earliest spring-sown plants will now be in full bearing. Do not overcrop them, or it will be impossible to obtain from them a supply lasting over several months. Tie in the growths, and pinch out the points of the shoots at the first leaf beyond the fruits. Should the plants show signs of weakness, a little extra growth may be allowed. Apply light top-dressings of warmed soil as they become necessary, and afford liberal supplies of warm, weak liquid-manure now that the plants are fruiting freely. The temperature at night should be about 68°, and a little air may be admitted when the temperature has risen to 78°, allowing a further rise of 10° or 15° with sun-heat after the house is closed and in conjunction with abundant moisture. Some growers admit no air whatever through the ventilators, but plants so treated make gross growths, produce a heavy crop, but soon become exhausted, and must be replaced with fresh plants, or be allowed a considerable time to regain a satisfactory condition.

Frame Cucumbers should be given a little ventilation early on bright mornings, and the plants be encouraged to grow by syringing them lightly and closing the house early in the day until the plants become established. Do not overfeed the plants in the early stages nor subject the roots to excessive moisture. Place the fruits in glasses or on slates to prevent them from becoming blanched.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Wythes, Esq., Copped Hall, Epping, Essex.

Euphorbia (Poinsettia) pulcherrima.—In order to have a batch of plants in flower early in November, these should be propagated as soon as growths are procurable for use as cuttings. Sufficient stock plants for the purpose should be put in a Cucumber-house or similar structure and plunged in a hot-bed of leaves. Syringe them often, but do not afford much water to the roots. When the growths are about 3 inches in length, detach them from the plants with a good "heel," and insert them singly in thumb-pots in old soil from the potting-shed, with a layer of silver-sand on the surface. Let the pots of soil stand in the house to warm an hour previous to being used, and insert the cuttings direct into them, plunging the pots without delay in cocoanut-fibre in a frame or under bell-glasses.

Euphorbia jacquiniæflora.—For supplying flowers for cutting this plant is invaluable, and when grown under the best conditions it forms a very striking feature grouped amongst foliage plants. If five or six stock plants be placed in heat and treated as advised for Euphorbia pulcherrima, they will yield a quantity of cuttings, and these will flower early in November. In the cultivation of this plant much light, heat and moisture are essential. A 48-size (5-inch) pot will contain all the soil they require, and should not be exceeded unless two or more plants are grown in a pot. This plan I do not advise unless grown for any particular object. The most suitable position for the plants to grow in is one in a low-roofed Cucumber or Melon-house, where as the plants make growth the shoots can be tied to the wires up the roof of the house, and be fully exposed to the sun's rays. They require careful watering at the roots, and should be syringed freely overhead during their season of growth.

Centropogon Lucyanus.—I prefer to propagate this annually, but it is by no means essential, as good flowers may be obtained from specimens several years old; but the plants themselves get out of bounds, and are not useful or handy for grouping; therefore for general purposes it is advisable to propagate a few each year. The plants are now starting into growth, and should be afforded a copious watering; and if to be grown-on should be shaken out of their pots, the old soil reduced, and the plants repotted in a compost of loam and peat in equal proportions, with a little silver-sand and some small charcoal added.

Cinerarias, Primulas, &c.—A few seeds of each of these should be sown now in pans containing finely-sifted soil. Place the pans in a warm, shaded house until the seeds have germinated. Plants that are developing their flowers should be given frequent applications of weak liquid-manure obtained from the soaking of sheep-dung, and they will require to be shaded on hot, sunny days.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Seeds. — Sow on a slight hotbed seeds of Amaranthus caudatus, Acrochiniums, Marvel of Peru, Marigolds, and Zinnias. Prick off seedlings of Antirrhinums into rich soil in frames when large enough to handle, also Nicotianas, Mimulus, &c.

Sweet Peas.—The ground for these should be deeply dug and some good turfy-loam and rotten manure mixed with the soil. Apply a sprinkling of superphosphate of lime and bone-meal. It pays to sow the seeds in pots, as the extra trouble involved reduces the risks of loss from the attacks of slugs and birds. Sweet Peas require much space, overcrowding being fatal to success. It is on record that nearly 500 sprays have been gathered from one plant in a season, and about fifty sprays at one gathering.

Kniphofias that were divided and potted last autumn and have been kept in a cool-house may be planted now. They may also be increased by division in spring. Kniphofias thrive in a warm situation in a deep, rich, but light soil containing liberal supplies of rotten manure and leaf-mould. Do not disturb established clumps, but reduce the winter coverings that have protected these. Amongst the autumn-flowering sorts, K. aloides maxima, K. corallina superba, and K. Pfitzeri are good; K. Tuckii flowers in June, K. caulescens has bluish-grey foliage and flowers early.

Cortaderia argentea.—Now is a good time to plant Pampas grass in a sunny position sheltered from winds, employing a light soil enriched with plenty of stable manure.

Eryngiums require deep sandy soil, and planting should not be delayed after this date. E. Oliverianum superbum is remarkable for the intense glistening blue colour of its stems and flowers. E. giganteum is silvery-white, E. alpinum flowers early, and E. planum late.

Hardy Heaths grow best in peat, but will thrive in most soils that are free from lime. When planting, put leaf-mould or peat obtained from the fells about the roots, to give them a good start. Erica carnea and E. codonodes are flowering well this month. The many varieties of E. vulgaris are all good, particularly alba, alba var. gracilis, Hammondii, Alportii, aurea, and cuprea; the copper-coloured is very distinctive. Other choice varieties of Ericas are E. ciliaris, E. cinerea, E. Tetralix, and E. vagans. If propagated in autumn and kept in a cool frame, then transplanted in due course, Ericas make nice plants in two seasons.

Alpine Plants, &c., of dwarf and spreading growth, suitable for planting about the steps of a rockery: Acæna inermis, Antennaria tomentosa, Arenaria balearica, Dianthus deltoides, Erinus alpinus, Sedums, many varieties, Thymus Serpyllum.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	APR. 10	Birmingham Mutual Improvement Society Meet.
TUESDAY,	APR. 11	Royal Horticultural Society's Committees Meet. National Rose Society's Committee Meet. Devon Daffodil and Spring Flower Show at Plymouth (2 days). Brighton Spring Flower Show (2 days). British Gardeners' Association Meet. at Sutton.
WEDNESDAY,	APR. 12	Shropshire Horticultural Society's Spring Flower Show at Shrewsbury. Chester Paxton Society's Spring Flower Show (2 days).
SATURDAY,	APR. 15	Kidderminster and District Horticultural Society's Daffodil Show.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Japanese Liliums, Fruit Trees, Hardy Border and Herbaceous Plants, Begonias, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
200 Azaleas mollis, Palms, and Plants; 1,000 Fruit Trees, Perennials, Carnations, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Unreserved Sale of Duplicate Plants of the Walton Grange Collection of Orchids, at Walton Grange, Stone, Staffs., by Protheroe & Morris, at 12.30.—Roses, Palms, Azaleas, Gladioli, Lilies, &c., at Stevens' Rooms, at 12.30.

FRIDAY NEXT—
Importation of Vanda Sanderiana and numerous other Imported and Established Orchids, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —47·6°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April* 5 (6 P.M.): Max. 55°; Min. 41°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, April* 6 (10 A.M.): Bar., 30·1; Temp., 44°.
Weather—bright, with cold winds.
PROVINCES.—*Wednesday, April* 5 (6 P.M.): Max 49°, Bournemouth; Min. 45°, W. Coast of Wales.

William Paul. By the death, on March 31 at Waltham Cross, of WILLIAM PAUL British horticulture loses one of its most distingnished representatives. He was in his eighty-third year. Naturally he had for some time past retired from active participation in those duties in the execution of which he had been for so many years zealous beyond measure. Nevertheless, almost to the last his mental powers were keen and his interest in matters horticultural relatively unabated.

So long as the Rose remains an object of attraction, so long will the memory of WILLIAM PAUL be treasured. For it is as a rosarian that he is best known. Few, if any, knew Roses as he did; few could more truly gauge the public taste with regard to them; few could grow them better; few knew better how to display them to advantage. Comparatively early in his career we find him advocating the culture of Roses in pots (then a novelty), and inveighing against the formal ugliness that still characterises the ordinary Rose show. To the last he showed us by many examples the better and more artistic way of exhibiting Roses.

Among the Roses which he raised the following are some of the chief:—

BEAUTY OF WALTHAM	LORD MACAULAY
BOADICEA	MAGNA CHARTA
CLIO	MEDEA
CORALLINA	MORNING GLOW
CROWN PRINCE	PRIDE OF WALTHAM
DUKE OF ALBANY	QUEEN MAB
EARL OF WARWICK	STAR OF WALTHAM
ELLA GORDON	SULPHUREA (Tea)
ENCHANTRESS	WHITE LADY
LITTLE GEM (Moss)	WALTHAM CLIMBER

But Roses did not monopolise Mr. PAUL's attention. Hollyhocks, Hyacinths, Camellias, Hollies, Ivies, Pelargoniums, decorative shrubs, the profitable culture of fruit-trees, these are only a few of what may be called his specialities. His sympathies, in fact, ranged almost over the whole field of horticulture. We say almost, for an exception rises to our minds—we do not recall any saying or writing of his relating to Orchids. With this exception, if it be an exception, WILLIAM PAUL was catholic in his sympathies as regards horticulture.

When, some years after the death of his father, WILLIAM PAUL founded in 1860 the present Royal Nurseries at Waltham Cross, his zeal, energy, and intelligence soon ensured such a measure of success that for many years the nursery has ranked among the foremost in the kingdom.

It is certain that, with such endowments as he possessed, his career would have been equally successful had he chosen literature,

THE LATE WILLIAM PAUL, V.M.H.

art or science as his sphere of work. Circumstances led him into a business career, in which he achieved success; but either literature or art or science was assuredly the loser. We have sufficient proof of this in his *Contributions to Horticultural Literature*, a book published in 1892, wherein he gathered up into a whole a small number of his contributions to the horticultural Press. In their perusal it is easy to appreciate the intelligent grasp of the subject he had in hand, easy to recognise the clear, fluent, sometimes trenchant style in which his writings were couched. He wrote because he had something to say, and what he said he said well.

LOUDON discovered his talents, and for a short time he lent his aid to that industrious and zealous writer, who did so much for the spread of horticultural knowledge. LOUDON died in 1843, and then LINDLEY, ever keen in recognising and utilising ability, availed himself of the services of the young aspirant. As far as we know, WILLIAM PAUL's earliest contribution to the *Gardeners' Chronicle* was in 1843, the subject "Pot Roses." So that up to a few days since we might have claimed WILLIAM PAUL as, if not our oldest living contributor, yet certainly one of the very few who have been associated with the *Chronicle* from its institution in 1841 up to a recent period, when his advancing age deprived us of the help of his ready pen. For some years also he was concerned with the late Dr. HOGG and Mr. THOMAS MOORE in the editorship of *The Florist and Pomologist*.

It was not only in the periodical Press that WILLIAM PAUL made his influence felt. Articles in the Press, however valuable, are more or less ephemeral. Collected in book form they are more persistent and more accessible. Hence *The Rose Garden*, now in its tenth edition, comprises a body of sound information and judicious comment not to be found in equal measure elsewhere. As a richly illustrated book that work is necessarily expensive, but to meet the public demand WILLIAM PAUL issued book after book, edition after edition, adapted to the requirements of those with moderate means. His literary achievements are, however, so well known and appreciated that we need make no further allusion to them.

We have said that had he so chosen he might have made for himself a reputation in science. If the reader will consult Mr. PAUL'S lecture on the "Improvement of Plants," wherein he narrates how he "improved" the common Parsley, the Brussels-Sprouts, the Aster, the Hollyhock, and a host of other flowers, in addition to the Roses which have conferred fame on the Waltham nurseries, and some of which are above alluded to, he will see that the procedures adopted were not merely of a casual, hit-or-miss nature, but were methods based upon accurate observation and careful inference. In these days when so much attention is bestowed on variation and hereditary transmission, this lecture deserves the most careful study. It was read at a "provincial show" held at Manchester in 1869, under the auspices of the Royal Horticultural Society, and happily is reprinted in the *Contributions*, to which we have already alluded. It is one of the most important memoirs in the scientific horticulture of our time, and will prove of great value to those concerned in substantiating or refuting the Mendelian hypothesis, DE VRIES' theory of "mutation," or experimental horticulture generally.

It may here be mentioned incidentally that Mr. PAUL collected a library, in which he took great delight, and which is extraordinarily rich in books on gardening and garden botany.

As to his artistic tendencies we have already alluded to the improvement he introduced in the method of showing Roses. An editorial article in these columns on July 25, 1874, was followed up by an object-lesson by Mr. PAUL at the Royal Botanic Society, which elicited a large meed of approbation. From that time to this the firm has acted on the same plan, and at the last Temple Show the crowning award of the Veitchian Cup, allotted to the best exhibit in the Show, was given to the collection of Roses shown by Messrs. W. PAUL & SON, and arranged artistically in accordance with the principles already mentioned.

Further illustrations of the artistic faculty possessed by Mr. PAUL may be found in his lectures on ornamental trees and their disposition on landscape gardening, the

arrangement of colour, the dressing of florist's flowers—"floricultural millinery" he termed it—and other similar subjects.

We have said enough to justify our contention. For the matter of that nobody who had the pleasure of knowing the man would question it. Naturally, one so full of ideas, so replete with knowledge, so expert in practice, took a prominent part in the public life of horticulture. He was at one time rarely absent from public functions, and as a fluent and eloquent speaker effectively contributed to the promotion of any cause in which he was interested. He was one of the Executive Committee of the famous 1866 Exhibition, and was one of the earliest of those on whom the V.M.H. was conferred. Truly may we say, "There is a great man fallen in Israel!"

Our Supplementary Illustration to the present issue presents a view of part of the rock garden in the Right Hon. Joseph Chamberlain's garden at Highbury, near Birmingham. This particular portion is known as the "spring rock-garden," because the species of plants are those that bloom very early in the season, as Arabis, Aubrietia, &c. Our readers will see that they flower very profusely and give to the path a bright and attractive appearance. We refer to recent numbers for other illustrations and full details relating to this garden.

Royal Horticultural Society. — The next meeting of the Society's Committees will be held in the Hall, Vincent Square, on Tuesday, April 11, when a lecture will be delivered by Mr. T. J. Powell on "Retarded Potatos."

Surveyors' Institution.—The next ordinary General Meeting, being the second of the two afternoon meetings arranged for the convenience of country members, will be held in the Lecture Hall of the Institution on Monday, April 10, 1905, at 4 p.m., when a paper will be read by Mr. H. M. Cautley, A.R.I.B.A., entitled "Farm Buildings."

Potatos.—According to the reports of experiments made at Burgoyne's Farm, under the auspices of the Cambridge University, Department of Agriculture in 1903—1904, the best of the newer main crop varieties was Dobbie's Factor; the best new second early was Findlay's Royal Kidney. The Potatos which resisted disease best were Sutton's Discovery and Findlay's Evergood. Whole tubers rather than cut sets were decidedly best, and tubers weighing nine to ten to the pound, that is about 1½ to 1⅝ inch, were most suitable. However desirable such experiments may be, they are such as could and should be undertaken by the growers themselves. From a University Department we look rather for scientific research than for practical demonstration.

Potatos in 1904.—We extract the following notes from *Agricultural Returns*, 1904, published by the Board of Agriculture:—

The total production of Potatos has only three times previously been exceeded, the greatest crop on record—3,743,203 tons—having been returned in 1884. England and Scotland both had, in 1904, a yield per acre largely above average, the former by 6 cwt., the latter by almost 30 cwt., while an average of over 7 tons per acre, as was secured in Scotland, has never previously been noted in any of the three divisions of Great Britain. Wales was not so fortunate, the 4·84 tons per acre there returned representing about 12 cwt. less than the mean. The best results in England were secured in Lancaster, with nearly 2 tons more than the average; while crops of about a ton over normal were secured in Bucks, Chester, Cumberland, Durham, Norfolk, Northumberland, Salop, Stafford, and Surrey. On the other hand the yield fell below the mean by over a ton in Cambridge and Cornwall. Lincolnshire, the chief Potato-growing county, had a deficit of one-third of a ton per acre. In Scotland, one county only, Dumbarton, fell slightly below the normal. Banff and Kinross had almost 3¼ tons above the average; while Bute, Caithness, Fife, and Forfar were all more than 2 tons to the good. The largest yield recorded in any single county was 9·45 tons on the small area in Clackmannan, while Banff also secured over 9 tons to the acre.

Mr. Dinter, who for the last eight years has been in German S.W. Africa, writes to say that he is about to return for a few months, and that his address from May 10 to September 10 will be—Herr Botaniker Dinter, Bautzen, Saxony.

Diseases of Trees.—We learn that the Board of Agriculture has issued a series of coloured diagrams, prepared at Kew, illustrative of some of the more frequent diseases of trees. Each sheet may be had for 1s., and the whole set, post free, for 9s. 5d. A descriptive account is given, together with an indication of the remedial measures to be taken in each case. Among the nine are illustrations of Apple canker, Larch canker, Peach-leaf curl, &c. Any bookseller can supply them, or direct application may be made to Messrs. Wyman & Sons, Fetter Lane, E.C.

Geo. Monro Concert Committee. — We are informed that the concert held on February 23, realised a profit of £46 14s.; out of this sum donations have been given to trade charities, &c., as follows:—Gardeners' Royal Benevolent Institution, £10 10s.; Wholesale Fruit and Potato Trades Benevolent Society, £5 5s.; Charing Cross Hospital, £5 5s.; Surgical Aid Society, £5 5s.; Royal Ophthalmic Hospital, £2 2s.; Royal Lifeboat Institution, £2 2s.; Geo. Monro, Ltd., Pension Fund, £2 2s.; Geo. Monro, Ltd., Outing Fund, £2 2s, the remainder being placed to the reserve account.

An Impostor.—Gardeners in the neighbourhood of Liverpool are cautioned against a man who states that he is "out of work." His story is plausible, but does not bear investigation, and the police have already received a complaint about him.

Reorganisation of the Buitenzorg Botanic Garden.—The Agricultural Department, Buitenzorg, was instituted by Royal mandate on July 28, 1904, and is now in operation. The establishment consists of gardens, trial-fields, laboratories, museums, &c., in connection with which are special sections, notably those for forestry and veterinary study, and the Government Coffee and Cinchona plantations. It is in name that the establishment is altered; the various sections will be maintained as before. It is proposed to form during the year new laboratories for the study of indigenous products, and for bacteriology and field geology, a maritime zoological station, and several meteorological field stations. Natural sciences, more particularly botany, are placed under the department, which in this matter replaces the Buitenzorg Institute, with instructions to keep up all the traditions. The publication of the *Annales du Jardin Botanique de Buitenzorg* and of the *Icones Bogorienses* is continued with no change of names. The Bulletin will be entitled *Bulletin du Département de l'Agriculture*.

Produce from the Channel Islands and Egypt.—The *Sussex Daily News* for April 3 stated that the average number of boxes of cut flowers received daily at Newhaven from the Channel Islands is about 2,500, and in addition to this there are about 2,000 packages of other produce, made up of Radishes, Green Peas, Kidney Beans, New Potatos, ripe Figs, Tomatos, Melons, Cucumbers, and Asparagus. The bulk of this is for the London markets, and the North, viâ London. There are also large quantities of Onions imported through Dieppe. These are coming from Egypt, and the number of sacks on two days last week was about 6,000—equal to 300 tons. The Guernsey service is a daily one, and two fast steamers are engaged in it.

New Public Garden at Norwich.—By the widening of Bishopbridge Road, Norwich, and through the levelling of the slopes to the river, the people of Norwich have acquired a valuable open space of ground, which has been laid out as a public garden. The slopes themselves—to be known henceforth as "Bishopbridge Garden"—promise to become very beautiful. Mr. J. Ward, the Parks Superintendent, has carried out this portion of the scheme in a very thorough manner. Upon the face of the slopes paths have been cut out and levelled, and beds made for the reception of selected varieties of flowering shrubs.

Publications Received.—Circulars and Agricultural Journal of the Royal Botanic Gardens, Ceylon, Nos. 22, 23, and 24. *Plant Breeding*, by R. H. Lock; *Ground Nuts in Ceylon*, by Herbert Wright; *Varieties of Cacao in the Gardens and Experiment Station at Peradeniya* by R. H. Lock. Nos. 25 and 26, *The Castor Oil Plant in Ceylon*, by Herbert Wright; *Plant Breeding* (Part II.), by R. H. Lock. Nos. 27, 28, and 29, *Plant Breeding* (Part III.), R. H. Lock; *Branch Canker in Tea*, J. B. Carruthers; *Canker (Nectria) of Para Rubber (Hevea Brasiliensis)*, J. B. Carruthers.—*Journal de la Société d'Horticulture du Japon*, December 15, 1904. Contents: Citrus medica et sa Culture, by M. Sasaki; M. Onishi, Choix des Variétés de Pêche; M. Furukawa, Anemones chinensis and cernua; and M. Murakami, Cultnre des Chrysanthèmes.—*Bulletin du Jardin Impérial Botanique de St. Petersbourg*. Tome IV., livraison 6. A new building intended for seed trials and as a phytopathological centre has recently been finished. It is in connection with the botanical museum and biological laboratory. Three large glasshouses and other additions have also been completed lately.—*Lehrbuch des Gartenbaues*, von Max Löbner (verlag von T. Schmidt, Zurich).—*Annalen des K. K. Naturhistorischen Hofmuseums*, von Dr. F. Steindachner (Wien, H. Hölder).—From the U.S. Department of Agriculture, Bureau of Plant Industry, come the following Bulletins:—No. 51, Miscellaneous papers. I. *The Wilt Disease of Tobacco, and its Control*, by R. McKenney; II. *Work of the Community Demonstration Farm at Terrell, Tex.*, by S. A. Knapp; III. *Fruit Trees Frozen in* 1904, M. B. Waite; IV. *Cultivation of Australian Wattle*, D. G. Fairchild; V. *Legal and Customary Weights per Bushel of Seeds*, E. Brown; VI. *Golden Seal (Hydrastis canadensis)*, by Alice Henkel and C. Klugh. Bulletin No. 56—*Nomenclature of the Apple*, compiled by W. H. Ragan. Bulletin No. 66—*Seeds and Plants Imported from September*, 1900, *to December*, 1903, Inventory No. 10.—No. 71, *Soil Inoculation for Legumes*, by G. T. Moore. No 72, Part II., *Salt Water Limits of Wild Rice*, by C. S. Scofield.—*Boletin do Museo Goeldi-Historia Natural e Ethnographia-Pará, Brasil* (1904).—The Royal Society for the Protection of Birds: *Fourteenth Annual Report*, to December 31, 1904. This Society is now incorporated under Royal Charter, and does excellent work in seeking to preserve from reckless destruction all birds, from the peacock of India to the wren of St. Kilda. At the recent annual meeting, Dr. E. A. Wilson, of the Antarctic Expedition, pleaded for protection for penguins.—*Agricultural Experiment Station, University of California, Report from June*, 1903, *to June*, 1904. The number of students having greatly increased, new buildings are necessary; the University Farm also is now too small. Soil Physics and Geology and Agricultural Products are dealt with; also Viticulture, Economic Botany, and Plant Pathology, and there are stations devoted to general culture.—From the New Hampshire College Agricultural Experiment Station, *Sixteenth Annual Report*. Satisfactory progress was made during 1904. Also Bulletin No. 116: *The Inspection of Feeding Stuffs in* 1904.—*Agenda Horticole*, 1905. (Paris: Librairie Horticole, 84 bis, Rue de Grenelle.) A useful notebook and diary full of hints and tables.

KEW NOTES.

Clerodendron myrmecophilum, *Ridley* (see *Gardeners' Chronicle*, April 9, 1904, fig. 98).—A fine group of this handsome and comparatively new species is now the chief feature in the Stove (No. 9). It is quite distinct from all the other members of the genus under cultivation, for they are usually vigorous climbers or well-branched shrubs, whereas C. myrmecophilum has a stout, erect, and generally unbranched stem, plants with more than a single stem being quite exceptional. The opposite leaves are oblong-linear in form, and about 1 foot in length, having a silvery sheen on the upper surface. The plant generally carries about six pairs of leaves at the flowering period. The erect panicle of rather large ochreous-red flowers is usually 1 foot in height, produced on a stem of from 1½ to 2 feet high. The panicle is pyramidal in form, the flowers are very numerous and showy, making a handsome inflorescence. During the development of the flowers the buds gradually move into three distinct positions; when first produced they are erect, and almost at right angles with the pedicel; they then gradually

twist round until the apex of the bud points directly downwards; and eventually, by the time the flowers are ready to expand, they stand out horizontally from the stem.

This species first flowered at Kew in April, 1902 having been sent to the Royal Gardens in 1896 by Mr. H. N. Ridley, who discovered it in the dense forests of Singapore. The plants now in flower are from cuttings rooted nearly twelve months ago. Plenty of heat and moisture are necessary for its successful cultivation.

Chloræa longebracteata, *Lindley.*

A plant of this uncommon terrestrial Orchid is now flowering in the Odontoglossum-house. It is a native of Chile, where it is found growing on the rocky plateaux in great abundance. The species was sent to Kew by Mr. F. W. Burbidge in January, 1903, when it was figured for the *Botanical Magazine* (t. 7909), but failed to flower in the following year. This year it has made a good rosette of leaves, and is carrying a spike about 1 foot in height, having twelve flowers, which are rather more than an inch in diameter. The sepals and petals are white, the two lateral sepals being tipped with a solid, fleshy, green, horn-like tip. The labellum is orange-coloured, with several green crests.

It is a pretty and exceedingly interesting Orchid, though unfortunately it belongs to a genus which is rather difficult to manage under cultivation. The Kew specimen of C. longebracteata was collected by Mr. Warburton, who says of it that "it always seemed to us that the plants grew in what were about the driest places possible, where the ground was so hard that it was difficult to dig them up with a garden trowel." (Syn. with Asarca sinuata, Lindl.) *W.H.*

Cynorchis kewensis

is a very beautiful terrestrial Orchid with rich lilac flowers, now in bloom in the Orchid-house.

Ceanothus thyrsiflorus.

This, which was the subject of a recent illustrated notice, is already showing flower.

Fritillaria aurea.

A batch of this pretty species is very attractive just at present under the wall in the herbaceous ground.

Thlaspi latifolium.

This bright, white-flowered Crucifer is in full bloom in the herbaceous ground, and is so conspicuous that it deserves to be better known. It would be well adapted by its dwarf habit for spring bedding.

Muscari.

It is just the time for these quaint and attractive plants; M. botryoides and M. racemosum, which throw their bold spikes of rich blue flowers well above the foliage, are among the best.

Narcissus Humei,

a large-flowered Daffodil with long, pointed, pale segments, is very conspicuous; so in their way are N. cyclamineus and the yellow Corbularia (Citrinus).

Iris assyriaca

is very distinct with its lax, strap-like decurved foliage and erect spikes of pale blooms. I. orchioides is of dwarfer habit, and has yellow flowers.

Prunus triloba

is one of the loveliest of spring-flowering shrubs, and the botanist likes to get hold of its flowers, for they often show from two to five more or less leafy carpels revealing their presumed ancestral condition.

The Alpine House

is filled with pretty things. Trilliums, Erythroniums, Muscaris, Saxifraga Grisebachii, a most distinct and pretty species with its erect, pink-coloured flower-spike; Anemone ranunculoides, with bright yellow flowers; Saxifraga retusa, a gem with minute foliage and rich rosy-lilac flowers. Androsaces are remarkable for the variation they show in their foliage, the newly-formed leaves being markedly [different from those of the autumn-formed rosettes. There are so many beautiful things in this house that to catalogue them would be irksome; the best thing is to go and see them.

The Greenhouse No. 4 is, as usual, full of colour. Its contents are so diversified that we must necessarily confine ourselves to the statement that this house is, if possible, more attractive than ever.

Magnolia stellata.

A bed of this dwarf deciduous Magnolia is particularly attractive with its conspicuous white flowers.

THE APIARY.

Purchasing Bees.—If it is decided to buy a stock in a skep it is well to do this early in the season before the combs contain much honey, there will then be less liability of the combs breaking down whilst transferring them to their new position. Before buying it will be well to make an examination of the condition of the colony.

How to Examine the Hive.—Give the bees a puff of smoke and wait a minute or two, then give another puff and overturn the skep. This done, scrutinise the combs to see if they are mouldy. Press the combs apart in the centre with a view to finding out whether there is any brood, and in this way you should make certain that there is a queen, and that she is fertile.

How to Move Them.—Tie a piece of cheese-cloth over the mouth of the skep and carry the whole, without any unnecessary jarring, mouth upwards.

Swarms.—One of the best methods of commencing bee-keeping is to purchase a good swarm as early in the season as possible. A really good swarm would weigh about 6 or 7 lb., or about 2 gall. in quantity. If they are bought of a dealer the price would not be less than 3*s.* 6*d.* per lb.; but in this case he would guarantee that the swarm is headed by a young and prolific queen. The above price would not include carriage.

The requisites for a Beginner.—The first thing is a hive well painted and fitted up with good foundation, worker base, and not less than eight sheets to the pound. Make quite certain that the foundation is securely fastened in the frames, or disaster is certain. It would be well to make a bee-veil of coarse black net. This always gives a sense of security; when handling bees, shun gloves of any description. Buy a smoker of good make, sections in the flat, some good worker base foundation (extra thin), some metal separators, and make a section crate.

How to Treat the Swarm when Received.—Take off the covering and shake out the bees in front of the entrance to their new home, which has been previously fitted and made snug. Let this be done in the evening. As their new home is without stores and the weather may not be suitable for the bees to make a flight in search of food, it will be necessary to feed them on syrup for a short period. Disturb the bees as little as possible, and place a good supply of quilts on the top of the frames. *Chloris.*

"Dicks' London Street Guide." — A useful list of London streets arranged in alphabetical order, with indications of the nearest main thoroughfares, and of the nearest railway station. It is amply worth the penny it costs, and may be had from John Dicks, Effingham House, Arundel Street, Strand, London.

Liverpool Botanic Gardens. — There is an excellent display of Hippeastrums in these gardens at the present time, consisting of 200 plants, most of which have two spikes with four, five, and in some cases six flowers on each spike. A similar number of well-grown plants of Cinerarias of a good strain are also in flower, and a large number of other miscellaneous spring-flowering plants. The Hippeastrums were all raised in these gardens several years ago from seed the result of cross-breeding from several plants originally obtained from R. P. Ker & Sons.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

Vitality in Dahlia Tubers.—In the early spring of 1904 we had occasion to pack an order for Dahlia pot-tubers, but received instructions to cancel the order before the goods were dispatched. The roots were left as packed in paper parcels, and the box lay undisturbed until a few days ago [twelve months afterwards], when most of the roots were found to be sound, many of them sprouted and are growing like the one which is now enclosed. It thus appears that Dahlia tubers can be kept alive for a long time under suitable conditions. *Dobbie & Co., Rothesay, March* 29.

Potato Planting.—The method I adopt in planting Potatos is somewhat different to that described by Mr. Richard Parker on p. 201, and to that by Mr. Fyfe on p. 199. For the earliest crops of Potatos undoubtedly "sprouting" has its advantages as the tubers come to maturity sooner. Where the whole Potato crop is grown in the garden and a large quantity of seed Potatos is necessary, it would take a large number of trays and a considerable time to stand all the Potatos on end to sprout. I contend that equally good results are obtained without this trouble. In planting Potatos I use an iron-shod dibber with a cross-handle fixed at the top and an iron tread placed 10 inches from the bottom to allow of its being pressed into the soil by the foot; the tread also regulates the depth of the holes. The planter works a tightly-stretched line, being followed by another person who places the Potatos in the holes. The holes are not filled in with a rake, but with a two-tined "hoe." I find the use of the "dibber" is not detrimental to good cropping, nor is there irregularity in coming up if the work is done when the soil is in good condition. The thorough working of the soil is of much greater importance than are mere methods. *A. Jefferies, Moor Hall Gardens, Harlow, Essex.*

Acacia dealbata. — Having grown and flowered this species in a cool but sunny conservatory, I may say that for several years I have commenced cutting well-developed sprays of blossoms early in January. If "J. N. H. B." intends planting this species, and has sufficient space at his disposal, he should make provision for a border of considerable size. Although growth is satisfactory in a limited root-run, there is the liability of the plant to cast the flower-buds during the autumn months, even if close attention be given to watering and feeding. *H.P., Bournemouth.*

Camellias.—A small display of choice varieties of Camellias was made at a recent meeting of the Royal Horticultural Society by Messrs. W. Paul & Son, Waltham Cross, which found many admirers among the visitors, to whom, owing to the partial disappearance of the Camellia from our gardens in the last thirty years, they appeared in the guise of veritable novelties. Of uncommon varieties mention may be made of Madame Strekeloff, a bloom of a pale rose tint with large petals regularly imbricated. It is of the same shade of colour as Pride of Waltham, but the petals are smaller and less reflexed. Duchess of York is a seedling raised at the Waltham Cross nursery. The colour is a deep shade of crimson. C. imbricata alba, Marchioness of Exeter, and many other old favourites were shown. *F. M.*

Cryptomeria, Araucaria, etc.—Cryptomeria japonica grows, with many other fine specimen Conifers and ornamental trees, in the flower garden here. Its height is 55 feet, and the girth of the main trunk at 5 feet from the ground is 5 feet 11½ inches. The tree has three other limbs,

which come from the main trunk near the ground-line; they are procumbent for about 7 or 8 feet, and then rise spirally, one to the height of 28 feet, one to 27 feet, and one to 18 feet. The largest limb has a girth of 2 feet 8 inches at 5 feet from the main stem; the diameter of the branches at the ground-level is 33 feet. Abies nobilis glauca, near by, has a height of over 52 feet and a girth at 5 feet from the ground of 6 feet 11 inches. Two specimens of Araucaria imbricata, one male and the other female, grow in close proximity to the Cryptomeria. The female specimen is 48 feet high, with a girth of 6 feet 11 inches, and the male specimen is slightly less in girth but about the same height. Two finer specimens of Araucaria that grew near by were completely overturned in a great gale that raged here in November, 1901. At that time, also in the same flower garden, a specimen of Cedrus Deodara, over 50 feet high and of large girth, was destroyed. In this garden is a specimen of Robinia pseud-Acacia over 50 feet high and having a girth of 6 feet 9 inches. *F. Street, Ardwell Gardens, Wigtownshire.*

CUPRESSUS TORULOSA AND THE CEDAR OF GOA.—At page 275 of the *Gardeners' Chronicle* for October 15 last, you kindly inserted a paragraph above my name regarding the difficulty of separating Cupressus torulosa and C. lusitanica in their cultivated forms. To this paragraph an editorial note was added, "C. torulosa is not known in China or near Goa." The purport of this note is not clear. If taken literally it is inaccurate, since C. torulosa, though indigenous to the Himalayas, is widely cultivated in India even on the plains, and would succeed well on the ghauts above Goa. J. S. Gamble, in his classical *Indian Timbers*, states—"It (C. torulosa) grows well and fast at Dehra Dun, Saharanpur, Chikalda, in Berar, and even Calcutta." I can remember its growing in Southern India. There were specimens which grew with particular vigour on the Nilgiris. Then as regards China, in *A General View of the Genus Cupressus*, by Dr. Maxwell T. Masters, we read under C. torulosa var. Corneyana, "E. China vel e Japonia ut existimant auctores allata, specimina indigena hucusque tamen haud offensa," which may be translated "Introduced from China and from Japan as authors believe; indigenous specimens of this (variety) not yet met with." The forest country of the inaccessible mountainous regions of China has been so little explored by Europeans that it is not surprising that indigenous specimens of Cupressus torulosa have not yet come to hand. But it would be somewhat surprising to find that C. torulosa stopped short at the Himalayas while so many other Himalayan trees extend eastwards across the Shan states of Burmah and the mountainous forest country of Yunnan. I am inclined to think that C. sinensis originally came from China, and C. lusitanica from Goa, and that they are both the cultivated forms of Cupressus torulosa. *E. Hutching, Conservator of Forests, Cape Town.* [Of course wild specimens were intended, not such as are cultivated. Our enquiries from Indian botanists and foresters as to the existence of any wild Cypress near Goa have been fruitless. Ed.]

THE CUCUMBER "SPOT."—My object in drawing attention to the ravages committed among Cucumber crops, and the consequent serious loss to growers by this mysterious disease, was that some means for its prevention or extirpation might be found. To some extent that object has been attained, Mr. Ward having contributed some useful suggestions with respect to the probable cause of its visitation, and some practical hints as to how its progress may be arrested. I would not again have occupied your space on this subject were it not for the purpose of clearing up one or two points in my previous letters which seem to have been misunderstood. Mr. Ward gives it as his opinion that the cause of spot appearing on Cucumbers is not to be attributed to the composition and condition of the soil in which the plants are growing under expert management. In my first letter I stated my conviction—a conviction arrived at from recent evidence, which I will not repeat—that the soil in which the plants are grown is not the cause of the disease appearing, therefore we are agreed on this point, as far as practical experience carries us; but this is not to say that science, after all, may not prove by demonstration that a certain chemical treatment of the soil may effect a prevention of the disease. The most likely cause, in Mr. Ward's opinion, for the attack of the disease is to be found in the weak and worn-out condition of the plants after a period of heavy and continuous fruiting, inviting an attack in their more or less enfeebled state. This, I think, is a natural and sound conclusion in relation to the time that plants generally are the most prone to attacks of disease, such as mildew or infestation from insect pests. To my mind, I thought I had proved in my previous letter that this at least was not the only reason likely to cause the disease, because I stated that quite young plants having only three or four leaves, growing in good heat and well isolated from any affected plants, were infested in a garden which I visited last year, and I now hear that the pest has already made its appearance in some gardens at this early date. This, to some extent at least, proves that the cause of the disease is not entirely to be attributed to the proposition Mr. Ward advances. With respect to a preventive or a possible cure, Mr. Ward advises the frequent application of sulphur vapour. No one appreciates better than I do the value of this mode of applying sulphur for the destruction of fungoid diseases, but the recommendation of its application must be qualified by the fact that it cannot be applied without leaving a decided residue behind it on the foliage or fruit it may come in contact with, coating all surfaces with a sort of silvery enamel, which after it sets is difficult to remove without injury to the fruit. For Roses under glass affected with mildew after their season of flowering is over, or for fruit-trees, especially Vines, after the crops are gathered, this is certainly one of the best known remedies, but I venture to say that practitioners generally would hesitate long before applying it to Vines or any other fruit-trees in bearing, or even Cucumbers. Mr. Ward is on firmer ground when he suggests that a contributing cause is to be found in the danger of producing a chill in the plants by the discontinuance of fire-heat at night too soon—say the middle to the end of June. I am quite of his opinion here, and would strongly advocate the continuance of a little fire-heat at night well into the middle of July as calculated to stave off the disease more than anything else. Many growers will be much interested in the statement which appeared in the *Gardeners' Chronicle* of the 25th ult., that [it was reported that] a means had been found for its prevention and cure, and that £1,000 is claimed for the divulgation of the secret. The knowledge if made general would no doubt be cheap at the price, and the wonder is that the fortunate discoverer does not secure his discovery by letters patent, which should be worth much more to him than the price mentioned if the remedy, after independent and searching trial by competent men, proved effective under all conditions. *Owen Thomas.*

SENTIMENT *v.* PROFIT.—I do not often trespass on your space, but I should like to say a few words anent Mr. Douglas's remarks on p. 65 on sunny walls. There is no doubt we shall have to study economics more. It is painful to witness the indifference the average cottager has to anything in the way of progress, even if it would add to his own pleasure and profit. A few years ago I came across a Vine-clad cottage, and as everything seemed favourable for an experiment, the growth of the Vine strong and vigorous, the atmosphere clear, soil and aspect good, with protection from marauders, I got into conversation with the owner (a man of the labouring class), and pointed out to him the possibility of obtaining a crop of fruit next year, and volunteered my services to come at intervals through the season and do what was necessary to attain that object, but as soon as I mentioned that it would mean keeping the laterals short, he scoffed at the idea and said, "Na, na, that woona do; it's a creeper, and meant to hang doon." I immediately transferred the conversation to the village cricket match on the previous day, and found an agreeable companion. *Charles Salvidge.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

March 28.—*Present.*—Dr. M. T. Masters, F.R.S. (in the chair); Prof. Percival; Messrs. Michael, Bowles, Shea, Odell, Gussow, Baker, Drucry, Worsley, Hennessey, Saunders, Nicholson, Gordon, Holmes, Bateson, Douglas, and Chittenden (Hon. Sec.). Visitors: Messrs. L. Sutton, A. Dean, and Foster.

Diseased Amaryllis bulbs.—The bulbs sent to the last meeting by Mr. C. E. Baxter, F.R.H.S., had unhealthy roots marked at their base by a deep red colour, which penetrated right through the root; the red colour in places stained the outer scales of the bulb, and was visible also on the tips of the young leaves, which were hardly an inch in length. Mr. Saunders reported that no mites or other living creatures were present on or in the bulbs. Dr. Cooke wrote: "The dark blotch was caused by a fungus, Botrytis cinerea, apparently the same as described by Prof. Marshall Ward on the Lily. The bulb has been kept in a damp atmosphere for ten days, and has now a fine crop of the mould. Nothing can save a bulb when once attacked.

Galls on Spruce Fir.—Mr. Saunders reported as follows upon these sent to the last meeting:—"The shoots had been attacked by one of the aphides, Chermes abietis. The female lays her eggs in spring at the base of the buds, which she punctures with her proboscis and feeds on the juices; the young Chermes which are hatched from these eggs feed in the same manner. The continued puncturing of the bud causes the leaves to grow in a quite abnormal manner, the result of which is a gall which very much resembles a small Fir-cone. The young insects are gradually quite enclosed in the chambers of the gall. Eventually the chambers open, and the Chermes, which have by this time become winged, fly away. Though this insect is so common, its life-history has not yet been completely made out. In the early summer these galls should be cut off and burnt, so as to destroy them before their tenants escape."

Diseased Spanish Iris.—Plants of several varieties of Spanish Iris were sent to the last meeting, with the note that some had failed to start; some had germinated and grown to some extent, but had then gone off. Dr. Cooke examined them and reported: "After being kept in a damp atmosphere for nearly a fortnight the bulbs exhibit no fungus pest. The bulbs are rotting, and with plenty of the bulb-mite in them, to which their failure must be due." Mr. Massee also writes: "I can find nothing else for it but to attribute the injury to the bulb-mite."

Diseased Richardia.—Mr. W. G. Soper, F.R.H.S., sent some diseased Richardias. The plants grown in his garden had suffered more or less for five years, and dusting the corms with flowers-of-sulphur and soaking them in Bordeaux-mixture had had no effect on the disease. Mr. Odell will report upon them at the next meeting.

Pear Twigs Diseased.—These from the National Fruit Growers' Federation exhibited the well-known signs of canker.

Crinum Ruttrayi.—Mr. Worsley drew attention to the plant shown at the show to-day, and stated that it varied very little from Crinum giganteum. Mr. Nicholson said he had no doubt it was a form of that plant.

Degeneration of Varieties Propagated by Buds.—A discussion on this subject then ensued, opened by a few introductory remarks by Dr. Masters (see *Gardeners' Chronicle*, April 1, 1905, p. 200).

Mr. A. Dean then read a short paper on the subject of deterioration, with special reference to the Potato:—

"Do Potato Stocks Deteriorate?

In dealing with the assumed deterioration of the Potato, it is needful to be clear that not Potatos as edible products are referred to, but as varieties of a species. The assumption is that varieties have lives comparatively short, as compared with other kinds of vegetables. That assumption is by no means proved. One probable cause for the comparatively rapid disappearance of Potato varieties from cultivation is found in the freedom with

which new ones are raised, and the taste for novelties is as great amongst Potato-growers as among any class of persons. That readiness for change is based on a belief that new ones may always be better than older ones. Curiosity to find what may be the characteristics of new varieties is also a prominent factor in the matter. Then it is again a tradition of the Potato trade that varieties wear out, and should often be replaced by newer ones. The trade would no doubt feel hurt were it to be said that such tradition is based on trading interests. In any case it does as a theory without doubt lead to much business.

Now if we turn to some varieties of Potatos long in cultivation, we find that in their cases wearing out is not so evident. There is the Ashleaf Kidney, in cultivation from almost time immemorial, and chiefly recruited from year to year either by selecting tubers for planting from the best plants, or by effecting frequent changes of seed-tubers. The American Beauty of Hebron has been here some thirty years, and seems to be as useful and good cropping a variety as ever. Magnum Bonum has been with us thirty years, and still it is found that tubers from stocks grown in Denmark give as full crops here now as ever the variety did. International Kidney is still found in all parts of the kingdom, giving as fine crops of tubers as ever, and it is grown in the Channel Islands and in France in enormous quantities for the supply of the British markets. Given varieties that newer ones have failed to displace, and there seems to be no lack of endurance in them—tuberous Artichokes in point.

But assuming that the theory of the deterioration of varieties is correct, what may be the predisposing causes to that decay? First, is it not possible that our practice of wintering tubers for future planting in dry places and exposed to air may have a weakening effect? Does Nature require that to be properly progenitive the tuber should remain in the soil all the winter, but preserved from frost. I do not advance this as an absolute necessity; I merely put it forward as a possible cause for the assumed deterioration.

Then we do as a rule—and it is noteworthy that the old Ashleaf Kidney is usually made an exception to the rule—plant small rather than large tubers annually for crop production. In the case of other vegetables, do we not select the very finest roots or plants to produce the seed for the ensuing crops? In everything we grow in gardens or fields it is the rule to select for parentage the finest and best. This is not so with the Potato, and if in its case we depart, as we so commonly do, from an acknowledged rule, what other result can be looked for but that gradual weakening or deterioration of stock must ensue? Conversing recently with an old Scotch Potato grower on the cause of the fine productiveness of Scotch tubers, he said that, apart from Scotch soil and climate, two important factors in that strength or fertility, it was largely the practice to plant large tubers, even though often cut prior to the planting. On that point it may be possible to get further information. Undoubtedly a common cause for real weakness in Potato stocks is found in the storing tubers for planting in pits, tiers, or heaps, in which they sweat or heat, thus speedily causing premature sprouting. That is especially an evil practice in the southern districts, because Potatos ripen early, and as a consequence push growth early. That the result is of the most weakening effect has been demonstrated over and over again. Whilst our crops southwards are ripe often from six to eight weeks earlier than are those in the North, we cannot, because of the prevalence of spring frosts, safely plant much earlier than in the North.

Three hundred years of European cultivation have left the Potato plant as tender as ever it was, and but one sharp spring frost on the plants may kill them to the ground. All good growers hold that boxing seed tubers and wintering in cool sheds away from frost, and where comparative rest is secured, is invariably followed by finer crops than result from tubers that have been pitted and prematurely sprouted, the blanched sprouts being removed. Is it wise to have Potato breadths moulded up, as is commonly done? That it is done chiefly to keep tubers from exposure to sight and air is the case, but it still remains a question how far the practice may be detrimental to plant robustness. The method of propagating Potatos by means of sprouts or cuttings taken from tubers forced into premature growth in warmth under glass, not at all a new practice, but one much revived last year, has led to the declaration that it means ruin to the constitution of the Potato. Absolute proof that such would be the result has not been furnished, and although it may be out of place further to refer to the practice here, yet before such doctrine is accepted more experience must be obtained than now exists. To that end it would be well could a series of experiments be conducted at Wisley on such lines—plants obtained from sprout-cuttings raised and planted out beside others of the same variety raised from ordinarily planted tubers, the progeny in each case being grown-on also side by side for three or four years. Also experiments might be conducted to show the effects of whole large tubers and cut large tubers against those of the customary round tubers that are generally planted, so as to ascertain which progeny would, after some three or four years, the soonest deteriorate. The effects of earthing-up and non-earthing could be tried, also the effects of change of seed from various soils and climates as compared with similar varieties home-grown. These and many other allied experiments might well be conducted at Wisley by a special Potato Committee.

Effect of Soils.—Whatever may be the effects of different soils on Potato-plant growth, it is certain that they do produce very markedly diverse effects on Potato quality in an edible sense. How far deficiency of starch in a tuber may affect its productive capacity when planted as compared with the same capacity of a tuber of similar size that is thoroughly starchy, is a matter which experiment and observation alone can show. It is instructive to find that of the same varieties grown on diverse soils or in diverse localities, that whilst some are really good in an edible sense, cooking dry, mealy, and starchy, from other soils the tubers are watery, close, tasteless, and altogether worthless as food. If such be the effect of soils on tubers, may it not be probable that weakening effects would follow in the plant growth? Here it is evident the analytical chemist is needed to show in what elements the tubers and the soil may be deficient, and what manures are needed to provide them."

Professor Percival said the matter was obviously one of fact, and what was wanted was more evidence. He doubted whether any of those present had lived long enough to settle such a question, especially in the case of long-lived plants such as Vines. The idea of deterioration was no doubt widely spread. When they heard, as in the case of the Potato, that certain varieties had been in cultivation for a long time, it did not touch the point. A large number of varieties might have gone very much more quickly than others which may have had more vitality. Certain it was that some varieties had disappeared, but why was not quite clear. There was evidence that they got weaker and weaker, and that was why they had been discarded for their poorness. A hundred years ago—in fact, in the middle of the 18th century—there was evidence of very great difficulty in rearing Potatos, which in many cases refused to come aboveground. Some such effect was noticed nowadays by growers, and it was no doubt due to a weakening cause. If that were the case, he personally thought it strongly favoured the disappearance of the varieties vegetatively reproduced. To ask why was like asking why old age occurred. We did not know what old age was. Human beings did not live for ever—nor did trees. There seemed to be a distinct life-period for all these things, after which they died down from want of vitality. Everything underwent repair, and he believed the repair was not perfect, and that the life-machinery gradually weakened and vitality was lost. The question would only be settled, if at all, by experiments.

Mr. Odell stated that, after many years of experiments, he had found that Magnum Bonum grown for four years running on a heavy clay loam in Middlesex were completely worn out, and in two years the produce was reduced by 50 per cent.

Dr. Masters: How would it have been on another field?

Mr. Odell said he could not answer that question. In the case he mentioned it was the same soil, but not the same plot.

Mr. Druery: Would that not imply that the soil was not suitable for Potatos, and that would be begging the whole question?

Mr. Worsley said he got some advertised disease-proof Potatos, but at the end of eight years all the Potatos had got disease.

Mr. Douglas recalled how in his young days they had two beautifully flavoured Potatos, Buffs and Dons, but in 1845 they were practically exterminated. The people then took to the white Potato, but they were nothing like the others in quality. It was about that time that guano was introduced, and many farmers thought that was the cause of the disease. He did not know whether there was any truth in that, but he had come to the conclusion that artificial manures favoured the production of disease. In Essex they had Potatos for many years, but the tubers deteriorated. They used to grow 100 acres of Potatos, and it paid to send to Scotland for the seed. He could only grow "Up-to-Date" Potatos now, and after three years it did not pay to grow them. Owing to weakness many of the Potatos never ripened, and degeneration soon followed. He could not say what was the cause of the degeneration, unless it were artificial manures.

Mr. Foster was of opinion that there was no doubt that Potatos did deteriorate after they had been grown in the same soil for a number of years. He exhibited largely some years ago, and he found that he could get much better crops from seed planted late than from tubers planted in the usual way in the spring.

Mr. Gordon remarked the point for them to consider was how to prevent this degeneration. He thought the case of the Potato was wholly different from that of fruit-trees, because so far as he knew no varieties of Apples, Pears, or Plums had degenerated, although they were reproduced vegetatively by grafting. When he was a boy the Ribston Pippin was supposed to be dying out, but now they could see thousands of trees in the country in the most healthy condition, and bearing excellent crops of fruit. They ought to remember that the Potato was an exotic, and was grown in this country under conditions very different from those in its native home, and that was a point to which they should, he thought, pay special attention. Then they ought to consider whether their methods of procedure did not contribute to the degeneration. In his early days they used to cultivate the old Fluke, which was supposed to be dying out, but they used to grow some tons per acre more than their neighbours. Their practice was, instead of keeping the Potatos close in clamps until the time for planting, to spread the tubers in cool sheds protected from frosts. Consequently they did not make long growths, which had to be removed, and the tubers were not exhausted to the same extent. They were thus able to grow the Potatos of that particular variety long after the other growers in the district were able to do so at anything like a profit. There was, therefore, a great deal in their methods. The same could be said of Chrysanthemums. These had been grown for a large number of years, and the plants retained their original vigour until there was a great demand for blooms of the very biggest possible size. Then the forcing system of cultivation was adopted. This brought about weakness of the plant and the particular varieties died out in a very few years. As to the Potato, if they adopted a different method in selecting and saving the seed-tubers, they might be able to retain the vigour of the varieties longer than was the case at present.

Mr. Shea stated that Mr. Gordon had anticipated much that he would have said. They were undoubtedly dealing with an exotic which could not under the best conditions live its perfectly ideal life. Therefore the Potato was in a measure slightly on the down-grade. It was not, however, to be assumed that the Potato was rapidly disappearing for good. It seemed that Scotland had conditions which could maintain a particular variety in better health than could be done in the South. There was great deterioration in all Potatos, due to climatic alteration. It might be extremely slow, but it would be quicker where the soil did not suit it. They could not expect otherwise when their methods produced artificial causes of deterioration which were not inherent in the Potato. They aggravated any inherent weakness there might be by transplanting the plant to strange conditions; and then they found that when new varieties were excessively "boomed" it led to their being introduced to places which were not fit for them, thus leading to the idea that there was deterioration.

Mr. Baker said he had done very well with Potato seed which he got from Scotland, but the second year's crop was best. After the second year, however, rapid deterioration set in. He had found that if the Scotch seeds were put in thoroughly worked soil with plenty of minerals, but which was deficient in nitrates, he got a good crop. He had planted "Snowdrops" on poor soil in which nitrogen was very deficient, and they had never yet fallen victims to disease. Under these conditions he had obtained better crops than from Potatos grown

in richer soils. That was also true of the Chrysanthemum, or any plant. In the case of the Apple, which was not forced to the extent that vegetables were, they did not get deterioration of varieties. That was why the Strawberry did not deteriorate to the same extent as the Potato. The reason was that the grower realised that he must have abundance of minerals and not too rich soil. In other words, he believed that abundance of nitrogenous plant-food caused rapid deterioration, by altering the cell-structure.

Mr. Dean, supplementing his paper, said deterioration resulted from planting small tubers. Large tubers should be planted, as that, he believed, was one of the primary causes of the Scotch seed giving such good results.

Mr. Worsley added that when he said he had produced Potatos on land for eight years he should have stated that he selected large tubers. That was no doubt the reason why he succeeded in growing them well for eight years.

Mr. Chittenden said it was the common practice in Essex to get seed from Scotland. He had been informed that it was necessary to change from one district to another. It was not necessary to make a big change in the climate, though that would probably follow there, he thought, from the "lay" of the land.

Several letters on the subject will be published in our next issue.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

March 16.—There was a fine display of plants at the meeting held on this date. A large number of groups were shown, and the principal awards were as follows:—

A Silver-gilt Medal to Messrs. Cypher & Sons for a very fine group of plants, in which good Dendrobiums were prominent.

Messrs. Charlesworth & Co., Bradford, were awarded a Silver Medal for a choice group of hybrids.

M. Vuylsteke, Ghent, was awarded a Silver Medal for Odontoglossums.

Dr. Roberts, Altrincham, made a good display of Dendrobiums, and was awarded a Silver Medal.

A. Warburton, Esq., Haslingden, was voted a Bronze Medal for a group of plants.

Votes of Thanks were passed to Messrs. Wrigley, Sander, Leemann, Keeling, Mitchell, and Stanley & Co., for groups.

First-class Certificates

were awarded to the following plants:—

Odontoglossum × Rolfeæ var. meleagris (W. Thompson, Esq., Stone).

Brasso-Cattleya × Digbyano-Trianæ Heaton var. (Charlesworth & Co.).

Odontoglossum × amabile, O. crispum × O. × crispo-Harryanum (Charlesworth & Co.).

Lælio - Cattleya × luminosa var. Aurora (J. Leeman, Esq.).

Odontoglossum × Lawrenceanum (M. Ch. Vuylsteke).

Awards of Merit.

Odontoglossum × percultum (M. Ch. Vuylsteke).

Cattleya Mendeli var. Diana (Stanley & Co.).

Cypripedium × pulchrum (Stanley & Co.).

Odontoglossum × ardentissimum West Point var. (S. Gratrix, Esq.).

Dendrobium macrophyllum var. album (Dr. Hodgkinson).

At a meeting held on March 30 the following Awards were made:—

First-class Certificates.

Dendrobium × "Queen Alexandra" (S. Gratrix, Esq.).

Odontoglossum crispum "Oakdene Surprise" (E. Rogerson, Esq.).

Odontoglossum × Wilckeanum var. princeps (Charlesworth & Co.).

Award of Merit.

Odontoglossum × Lairessei (Charlesworth & Co.).

Odontoglossum crispum var. Mabel Whateley (Charlesworth & Co.).

Odontoglossum crispum var. "Clio" (W. Thompson, Esq.).

Odontoglossum × Waltonense (W. Thompson, Esq.).

Silver Medals.

Messrs. Charlesworth & Co., and to W. Thompson, Esq., for groups.

Votes of Thanks.

O. O. Wrigley, Esq., for a fine group of Lælia Jongheana, and to Messrs. Sander, Schofield, Low, Cypher, and Keeling, for meritorious groups.

Cultural Certificate.

Mr. S. Allen, for some well-grown plants of Dendrobium nobile. *P. W.*

HORTICULTURAL CLUB.

Forests, Natural and Artificial.

On March 28 the members of the Horticultural Club were treated to an interesting lecture by Dr. Augustine Henry upon the subject, "Forests, Wild and Cultivated." Mr. Harry J. Veitch presided, and the attendance, which was much larger than usual, included Sir Herbert Maxwell, Bt., and other visitors.

The lecture consisted in a large measure of explanations of a number of excellent lantern views, obtained from wild and cultivated forests, and their bearing upon the question of economic forestry. In presenting the first view, which consisted of an imaginary map in which the earth's surface was divided into the three colours, blue, green, and yellow, Dr. Henry said that the blue represented the forest area, the green the grass area, and the yellow the desert. This was shown probably in order to introduce the question of rainfall, to which Dr. Henry referred several times, and in connection with which he insisted that areas of grass land or forest were determined not so much by heat or cold, or by the nature of the soil, as by the amount of rainfall. In all natural forest regions there was a very heavy rainfall, and where it was greatest, said Dr. Henry, the forest trees grew to the extreme height of which they are capable, and evidenced the greatest luxuriance. The differences in the aspect of tropical forests compared with forests in a temperate zone were not only described but graphically illustrated by a magnificent view of a tropical forest. The great roots frequently possessed by tropical trees were illustrated by a view of the immense Ficus growing at the entrance to the Peradeniya Botanical Garden, Ceylon; and the freely branching habit of tropical deciduous trees by a view of a specimen of Bombax growing in Southern China. Temperate-zone trees, like Sycamores, Elms, and Birches, afterwards shown on the screen, afforded a great contrast in the comparatively few branches they possessed.

Passing to the question of shade-bearing trees, a Ficus was shown growing in Yunnan, in which scores of lower branches were heavily shaded by others almost of the same length, upon the same tree, but all remained in a perfectly healthy condition. Of our own trees, it was pointed out that whilst Beech will bear shade, Birch will not do so, and the Lombardy Poplar is so impatient of shade that it is impossible to form a screen with trees of this species, owing to the slight amount of shade that results from the trees being placed in line adjacent to each other. This quality in trees has an important bearing in the planting of forests and of trees generally.

Dr. Henry, then referring to the subject of soil, said that whilst the amount of rainfall decided the question of forests or no forests, the nature of the soil usually determined the kind of tree. Ash or Sycamore required good soil, but Pines, Oak, and Beech, were far less exacting. Birch was described as the one deciduous tree that takes possession of almost "absolutely barren" soil. Pictures were then shown of the remarkable Arbutus forests in Killarney, where the Arbutus form trees of considerable height, though but an under-shrub in France and in the Mediterranean region generally. Reference was made to Alders in Co. Wicklow, and, passing, Dr. Henry reminded his hearers that it was very unsafe to conclude that because a tree was found growing under certain conditions of climate and soil in nature that those conditions were the best possible for that particular species. It was quite possible the tree was there because it could not hold its own amongst other species in better situations. A Silver Fir Dr. Henry recently measured in this country is 145 feet high, Quercus Ilex in Co. Wicklow was 95 feet high, being taller than any known tree of this species in the world; Q. Toza in Co. Wicklow also was taller than the same species in France and Italy. These instances went to show the favourable character of portions of the British Isles for tree growth. A tree of Pinus insignis planted 43 years or so ago is now 98 feet high and has a girth of 6 feet. A Hornbeam in Co. Wicklow is bigger than any specimen of the species recorded elsewhere.

In a natural forest or a properly managed cultivated forest the soil improves year after year; it is enriched by the boughs and leaves that fall from the trees, and which conserve the moisture in the soil, whilst the timber which is taken away from the forest consists of little but carbon, and this is derived largely from the atmosphere. But in order to preserve these conditions, it was necessary that the trees be planted so densely and over such an area that the sun and wind will not affect the soil or accumulated humus. The value of close planting in the production of timber was illustrated by a number of views, one of which showed trees of Scots Fir, which having been planted closely had made straight, long stems, and, casting the branches early, the wounds soon healed over and left but small knots; whilst trees growing at greater distances, by retaining the branches for a longer time, contained such knots that reduced very considerably the value of the timber.

A forest Oak shown on the screen, that measured 90 feet to the first branch, and was 125 feet in height, was a striking testimony to the value of close planting.

Dr. Henry had much to say in praise of French forestry, and many of the slides represented scenes in the forests there. Special reference was made to the forest belonging to the hospitals of Nancy, located at an elevation of 3,000 feet, where the soil is mostly silica and the climate quite ordinary; and Dr. Henry explained that in France the theory was "A forest once, a forest for ever." This led to a description of how the French forests are regenerated without any planting being done. "Natural regeneration," briefly stated, is as follows: The timber trees, when ready for felling, are cut down at different times. First, there are removed as many as may be necessary to allow sufficient sunlight into portions of the forest to cause seedlings to grow, then another season more are felled to allow of the young plants making growth. Finally, all the trees are removed from that particular part of the forest, and it will afterwards assume what is known as the "bush" stage. The foresters then cut out the weeds and undesirable bushes to let the better trees make quick growth, and subsequently after several seasons' growth the 2,000 or so trees there may be to the acre are thinned to perhaps 200 per acre. The thinning is a work of some importance, as the principle of selection has to be applied in each case, so that the species required be kept, and the most promising trees of that species.

Dr. Henry severely criticised the attempts at forestry that have been made in this country, and anathematised the picturesque old Oaks that are prominent features in many of the private parks.

Then followed arguments in favour of the afforestation of waste lands—a matter which, said Dr. Henry, had been regarded as important in every country of Europe, except in England—and Turkey! In spite of the opinion of German foresters that the peat-bog is not reclaimable, Dr. Henry maintained that it is, and related in favour of the contention instances of trees now growing in such places. Among these were that of a Larch 114 feet high in peat moss at Bangor, and Alders 90 feet high in peat in Ireland.

In concluding his lecture Dr. Henry spoke of the different conditions in which Pinus montana was found, and their effect upon the tree's growth. In connection with this subject he said that this Pine and other forest trees in ascending mountain slopes were not stopped by cold as was generally supposed, but always by drought at the roots.

Referring to the artificial forests in France, he said that if it was possible for some one in the planet Mars to look upon the surface of the earth, these forests were the only work of man he would see that is of consideration.

Sir Herbert Maxwell said that such forestry as Dr. Henry recommended was impossible in this country until rabbits, which, like some of the trees, are exotics in this country, are confined into warrens. He did not think we could get much guidance from the State in the matter of forestry, for he found that in the *Returns of His Majesty's Woods and Forests for* 1903—1904, the expenditure was given as £52,000 and the receipts as £28,000 only.

Mr. A. H. Pearson, having raised the question of the difficulty experienced in effecting a sale of the timber when grown, Sir Herbert said that this might be merely a question of supply and demand. In all such matters the purchaser wanted a guarantee of uniform quality and of a regular supply. This the forester had never yet given. On his own estate some years ago it was with difficulty the thinnings could be sold locally for £135, but upon engaging a new forester, who was not satisfied with this price, and therefore advertised the thinnings, they sold for £450.

In reply to a question by Mr. R. C. Notcutt, Dr Henry said that although disease had been found upon the Japanese Larch, for practical purposes it could be regarded as immune in this country up to the present time. "It seems to be a better thing (than the common Larch) at the moment, but none can tell its future."

TORQUAY DISTRICT GARDENERS' ASSOCIATION.

March 30.—The above Association held a most successful spring show in the Bath Saloons, Torquay, on the above date. Quality was generally high, and the classes were, for the most part, well filled. The nurserymen who exhibited added much to the attractiveness of the exhibition by the fine collections of plants and flowers displayed by them.

Messrs. Barr & Sons showed a representative selection of Narcissi, among which were such varieties as Peter Barr, Dandy Dick, Concord, King Alfred, Constellation, Lucifer, Vesuvius, Constance, White Queen, White Lady, Bridal Veil, Salmonetta, Ariadne, Apricot, and others, also a collection of rock plants, as well as Anemones, Scillas, Muscaris, Chionodoxas, Fritillarias, Trilliums, and Tulipa Kolpakowskiana.

The Devon Rosery, Torquay, exhibited a quantity of cut Roses, pot Roses in flower, a brilliant bank of Anthuriums, Lily of the Valley, Staphylea colchica, Petrea volubilis, Boronia heterophylla, Tree Carnations, Lilacs, Ericas, and other plants; while from their Fruit Farm were contributed excellent Apples, Strawberries, Mushrooms, and salads, arranged with a wealth of Violets and Narcissi.

Messrs. Robert Veitch & Son, Exeter, staged

Primula kewensis, P. Isabellina, P. floribunda, Magnolia Kobus, M. Yulan, M. Alexandrina, M. Norberti, M. speciosa, M. Soulangeana, M. rustica, the new Erica Veitchi ×, the single white Camellia devoniensis, C. reticulata, Acacia armata, A. Riceana, A. hybrida, A. ovata, A. Drummondi, Grevillea rosmarinifolia, G. sulphurea, the new Cheiranthus kewensis, and numerous rock-plants.

Messrs. W. B. SMALE & SON, Torquay, showed Cactus Pelargoniums, new hybrid Azaleas, Coleus thyrsoideus, Clivias, Cyclamen, Acalypha Sanderi, Tropæolum tricolorum, Hyacinths, Freesias, and Tulips.

Mr. J. HEATH, Kingskerswell, was responsible for an exhaustive collection of all the best Violets, the white, blue-veined Princesse de Surmonte and the pink Perle Rose attracting considerable attention.

Messrs. W. H. ALLWARD and H. MAYNE, Torquay, staged miscellaneous plants.

The classes for bulbous and other flowering plants were well filled with high-class exhibits, and the competition for flowering and foliage table-plants was very keen. The Silver Cup for a group of miscellaneous plants was won by Miss LAVERS with a fine group tastefully arranged with Caladiums, Palms, Pandanus, and other foliage plants.

The 1st prize for a group of Orchids 10 feet by 3 feet was won by Mrs. TREVOR BARKLY with an excellent collection; Miss LAVERS taking 1st prize for three Orchids, one of the plants being a superb Cœlogyne cristata.

The 1st prize for three distinct flowering plants, won by Miss CONGREVE, brought out a magnificent balloon-trained Clerodendron Balfouri.

The Amaryllis class was good. 1st prize was won by Mrs. TREVOR BARKLY with fine hybrid Hippeastrums; and 2nd prize by Miss LAVERS with the now seldom-seen Jacobea Lily, Sprekelia formosissima, in excellent form.

BRITISH GARDENERS' ASSOCIATION.

APRIL 3.—The second committee meeting of the Birmingham and District branch was held on the above date, when a number of new members were elected, and a resolution adopted having reference to the number of enrolled members of a local branch necessary to ensure representation upon the Executive Council. *W. L. Deedman, Hon. Branch Secretary.*

GARDENERS' DEBATING SOCIETIES.

LEE, BLACKHEATH, LEWISHAM, AND WEST KENT HORTICULTURAL.—At a meeting of the above Society, held on Friday, March 31, Mr Marlow, Superintendent Greenwich Park, gave a lecture on "Summer Bedding for Effect." The lecturer gave the members some useful hints as to effects, and the culture of various bedding plants. *H. T. H.*

REDHILL, REIGATE, AND DISTRICT GARDENERS'.—This Society held its fortnightly meeting on March 14, Mr. W. Seaman presiding. About eighty members were present to hear a paper by Mr. Black, of Streatham, on "Orchids and their Culture." Mr. Black said it was not necessary to give high prices for this particular class of plants, as many useful and beautiful Orchids could be procured for a reasonable sum. Referring to cross-breeding, Mr. Black strongly advised growers to refrain from crossing dark kinds with lighter varieties. Suitable times for repotting the plants and the best potting materials for the various species were given.

——A meeting of the above Society was held on March 28, Mr. W. P. Bound occupying the chair. The lecturer for the evening was Mr. W. Seaman, of The Gardens, Margery Hall, whose subject was "The Cultivation of the Dahlia." Mr. Seaman referred to the introduction of the Dahlia into this country by Lady Bute in the seventeenth century. In dealing with the cultural side of the question, Mr. Seaman advised placing the old stools in moderate heat about the end of February to obtain a supply of cuttings. The first growths should be pinched out, for the later ones will be found to strike more readily. *Frederick C. Legge.*

NORTH FERRIBY AND DISTRICT GARDENERS'.—A meeting of the above Society was held on Wednesday, March 15, Mr. F. Reid presiding. Mr. G. Picker, The Gardens, Hesslewood, gave a paper on "Early Flowering Chrysanthemums for Open Borders." Mr. Picker dealt with the subject in a practical manner, giving chief points of culture, and a list of those varieties he considered most suitable for growing. The essayist exhibited some seedling Clivia flowers, and Mr. C. Jennings a display of spring flowers.

—— The members of the above Society held the last meeting for the season on Wednesday, March 29, Mr. F. Reid presiding. Mr. G. Cottam, Alma Gardens, Cottingham, gave an essay on "Hardy Perennials." The lecturer recommended planting these subjects in clumps, which gives a better effect than when they are planted as dot plants or in rows. He also stated the best season for propagating the different varieties. A discussion followed. It was decided to hold the General Meeting of the Society on April 26. Mr. F. Reid displayed an excellent dish of Canadian Wonder Kidney Beans.

KINGSTON GARDENERS'.—At the meeting of the above Society held on March 17, Mr. J. Smith, of Coombe Court Gardens, Kingston, gave a lecture on "Some Forcing Plants," dealing chiefly with the more valuable flowering shrubs. For earliest forcing a hot-bed is required in a shed or house; 6 inches of leaf-soil is laid on the bed, and the pots are plunged into the material until the buds start, which is in a fortnight. They are next placed in a house with a temperature of 50° for another fortnight, after which the temperature is raised to 60° until the flower-buds burst, when the plants are gradually hardened-off and placed in their flowering quarters. The plants should be pruned immediately flowering is over, and with generous treatment they may be flowered for three or four years in succession. Mr. Smith exhibited a collection of forced flowering shrubs. *J. T. B.*

LOUGHBOROUGH AND DISTRICT GARDENERS'.—At the recent fortnightly meeting at the Town Hall, Mr. J. H. Woolley, The Gardens, Leicester Frith, lectured on "Insect Pests." He referred to the life-history of many of the "aphides," and pointed out the distinction of the lower orders of pests from those of more active life, as centipedes, millipedes, and spiders. Leaves and their functions in the life of plants were fully explained, and it was shown how essential it was that these should be kept in a healthy condition and free from pests. By the aid of limelight views, manipulated by Mr T. Simpson, the lecturer was able to give the complete life-history of a great variety of garden pests, including the green-fly, woolly-aphis, Gooseberry saw-fly, Cabbage-grub, Celery-fly, wire-worms, &c. At the conclusion the lecturer advised constant watchfulness to detect the early appearance of troublesome pests. Good and deep cultivation added much to the vigour of vegetation, and a healthy growth often escaped the ravages of garden pests.

CARDIFF GARDENERS'.—The annual meeting of this Society was held on Tuesday, March 21, at the Sandringham Hotel, Cardiff, when Mr. Tom Clarke presided over the largest meeting ever held in the annals of the Association. The balance-sheet showed a cash balance in favour of the Association. J. Lynn Thomas, Esq., C.B, F.R.C.S., J.P., was unanimously re-elected president, and the whole of the vice-presidents were re-elected (with two exceptions), and three additional names were added. Mr. Robert Mayne was elected chairman, with Mr. C. E. Collier vice-chairman. Mr. Thomas Malpass for the tenth successive time was re-elected hon. treasurer, while Mr. John Julian was unanimously re-elected hon. secretary. The committee was also elected.

BOURNEMOUTH AND DISTRICT GARDENERS'.—At a meeting of the above Society held on Tuesday, March 21, Mr. Dumper, of Hinton Admiral Gardens, Christchurch, read a paper on "Some Injurious Insects." Mr. J. B. Stevenson occupied the chair. The lecturer gave much useful information on the haunts and peculiarities of these garden foes, with hints on the methods of their extermination. Two gentlemen were elected honorary members of the Association at the meeting.

CROYDON AND DISTRICT HORTICULTURAL.—A prize essay by Mr. J. Sugden was read at the meeting held on Tuesday, March 21. The subject was 'Birds of our Garden." The paper was suitably illustrated by the help of a magic-lantern. The exhibits were good, and comprised a pod of the Cotton plant, Cotton seed, and raw Cotton from Mr. F. W. Moore.

BRIXTON, STREATHAM, AND CLAPHAM HORTICULTURAL.—"How I Grow my Chrysanthemums," was the subject of the lecture at the meeting of the above Society on March 31, the lecturer being Mr. W. C. Jones, gardener to Mrs. H. S. Fitter, Okeburn, Streatham High Road. Mr. Jones gave many valuable and original hints in the details of stopping, manuring, &c. He emphasized the importance of having well-ripened wood. A discussion followed the reading of the paper, which was listened to by probably the largest gathering of gardeners ever held in Streatham. Mr. W. Roupell, Vice-President, who presided, made a special appeal to amateurs to join the Society, and said that the large audience present was an appreciation of the advantages offered by the Society.

BATH GARDENERS' SELF-HELP AND DEBATING.—A meeting of the above Society was held on March 27, Mr. T. Parrott presiding over a large attendance of members. There was a good display of plants, flowers, and vegetables at the meeting. Mr. Sparey read a practical paper on "The Culture of Vegetables," which was followed by an instructive discussion. Mr. Sparey exhibited a collection of nineteen varieties of vegetables. It was decided to accept an invitation from Messrs. Sutton & Sons to visit their nurseries at Reading in July next. *O. G. McLaren.*

DEVON AND EXETER GARDENERS'.—The subject under discussion at the closing meeting of the session was "Ornamental Shrubs and Flowering Trees for all Seasons of the Year," Mr. A. W. Luscombe, general foreman at Messrs. Robert Veitch & Son's nursery, Exeter, being the essayist. Mr. Luscombe gave an exhaustive address, illustrating his remarks by a miscellaneous collection of flowering sprays of shrubs, including the deciduous Japanese Magnolia Kobus. The lecturer recommended pruning such subjects as Lilacs, Robinias, Philadelphus, Magnolias, Escallonias, &c., in the resting period. Though peat was most helpful to Rhododendrons it was not absolutely essential, for a rich clay soil with an absence of lime and the addition of fibrous loam would also suit them. Amongst other shrubs Mr. Luscombe strongly recommended Spiræas, Andromedas, Ceanothus, Magnolia stellata, Cistus, Hypericums, Olearias, Weigelas, Brooms, Laburnums, Prunus (for foliage), Clerodendron, Veronicas, Acers, Arbutus, Catalpa, Liquidambar, Rhus Cotinus, the Crataegus family, Almond, and others. *A. H.*

CHESTER PAXTON.—The closing meeting of the present session was held in the Grosvenor Museum, on Saturday, March 18, when Mr. J. Thompson read a paper entitled "Local Fungi, when and where to be found." Mr. Thompson, who is an acknowledged authority on the fungi of the district, described the characteristics of the principal edible and poisonous species, and pointed out that, in addition to Mushrooms, many other species formed really delicious articles of food. An interesting discussion followed.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending April 1, 1905.

1905. March 26 to April 1.	Temperature of the Air. At 9 A.M. Dry Bulb.	Wet Bulb.	Day. Highest.	Night. Lowest.	Lowest Temperature on Grass.	Temperature of the Soil at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	Rainfall.	Sunshine.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	47	44	55	40	34	48	46	46	Tot 0·15	5 25

THE WEATHER IN WEST HERTS.

Over a Month of Warm Weather.—The present term of unseasonably warm weather has now lasted over a month. During the past week the highest reading in the thermometer screen was 59°, and on the one cold night the exposed thermometer registered 6° of frost. The ground, owing to the comparative coldness of the last two days, is not now quite as unseasonably warm as it was at the end of the previous week, but is still 2° warmer than the average, both at 1 and 2 feet deep. Rain fell on two days, but the amounts deposited were insignificant. So that the soil is gradually becoming drier, as is shown by the percolation gauges, through which no measurable quantity of rain-water has passed for ten days. The sun shone on an average for 4½ hours a day, which is about a quarter of an hour a day longer than is usual in the early part of April. Calms and light airs have again prevailed, and the direction of the wind has been again variable. The mean amount of moisture in the air at three o'clock in the afternoon exceeded a seasonable quantity by 1 per cent.

The first swallow of the season was seen on the Watercress-beds at Berkhamsted on March 28, or twelve days earlier than its average date in the previous fourteen years, and eighteen days earlier than last year.

MARCH.

Exceptionally Warm and Wet.—This was an exceptionally warm March. In fact, in the last nineteen years there have been only two other Marches with as high a mean temperature. With the exception of a few cold days at the beginning of the month, the weather remained moderately warm throughout. The highest day temperature, 60°, was nothing unusual, but it is very seldom in March, as was the case last month, that the thermometer exposed on the lawn does not show at some time more than 13° of frost. Rain fell on as many as twenty days, and to the aggregate depth of 3⅛ inches, which is 1⅛ inch in excess of the average for the last forty-nine years, and with three exceptions more than in any previous March during that period. Nearly the whole of the rainfall came through the 2½ feet of soil in the percolation gauges during the month. The sun shone on an average for four hours a day, or nearly half an hour a day longer than is usual. The strength of the wind was, as a rule, about average, and in no hour did the mean velocity exceed 21 miles, direction S.S.E. There were scarcely any easterly winds. Indeed, for only 110 hours, or less than five days, was the direction any point between North and East. The average amount of moisture in the air at 3 P.M. was about seasonable.

OUR UNDERGROUND WATER SUPPLY.

The winter half of the drainage year has now come to an end. The results are as follows. Owing to the heavy rainfall in March the deficiency is not quite so large as at the end of February. Nevertheless, taking the total fall of rain during the six months in question, there is a total deficiency of 1 inches, equivalent to a loss on each acre in this district of 91,170 gallons, or nearly nineteen gallons on each square yard of surface in my garden. *E. M., Berkhamsted, April 4, 1905.*

[*For actual temperature and condition of barometer at time of going to Press, see p. 216.*]

Remarks.—The Bermuda vegetables were a failure. Custard Apples, 5*s.* to 10*s.* per dozen. Cape fruit: Plums, 4*s.* to 7*s.* per case; Peaches, 6*s.* to 10*s.* ditto; Pears, 7*s.* to 10*s.* ditto; Grapes, 10*s.* to 15*s.* for large cases containing about 16 to 17 lbs.; smaller cases, containing about 10 lbs., 5*s.* to 6*s.* Cucumbers are more plentiful. Prices for Onions are much easier. Turnip and Swede tops, 1*s.* per bag. Good Cabbages are arriving. Prices all round are easier, and supplies are plentiful. English Apples: Wellingtons, 5*s.* to 7*s.* per bushel; Hauwell Souring, Norfolk Beefing, and French Crabs, 4*s.* to 5*s.* ditto; other varieties are to be had as low as 2*s.* 6*d.* per bushel. The Vegetable Marrows quoted above are forced.

Potatos.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 50*s.* to 80*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

The market is now open for the sale of plants during each day of the week. There is not much that is fresh among pot plants. Fairly good Pelargoniums, both Show and Regal, are arriving; these sell moderately well at from 12*s.* to 18*s.* per dozen. "Zonals" are now more plentiful, the variety F. V. Raspail realises from 6*s.* to 8*s.* per dozen. Various varieties in 60's, with one good truss of bloom, are in fair demand; these make from 1*s.* 9*d.* to 2*s.* 6*d.* per dozen. Good Crimson Rambler Roses are seen, also General Jacqueminot and other H.P.'s. The dwarf-growing variety, Madame N. Levavasseur, appears to be suitable for market purposes. Ericas are good; 3-yr.-old plants of E. Cavendishi, plentifully flowered, make from 3*s.* 6*d.* to 5*s.* each. E. coccinea minor, E. perspicua nana, and E. Wilmoreana are also seen. Boronias are still of good quality. Azaleas are not so plentiful, but there are more than required. Prices for Genistas are well maintained. Marguerites also sell at good prices. Spiræas vary much in quality and are over plentiful. Good Hyacinths and Tulips in pots are still seen, but another week will see the finish of these plants for the season. Mignonette is well grown. Cyclamen are still obtainable, also Hydrangeas both Hortensia and Thos. Hogg. Among Ferns, Palms, and other foliage plants there is little variation. Ferns sell more readily, especially among country trade. Temperary stands are now erected under the new French Market, and many are already occupied with hardy roots and bedding plants, Violas, Pansies, Daisies, Polyanthus, Primroses, &c. Many tender bedding plants in store boxes are sold: these include Geraniums, Fuchsias, Heliotropes, Petunias, Marguerites, Harrison's Musk, Asters. Stocks, Nicotiana, Lobelia, Marigolds in flower, and other similar subjects. There are many hardy shrubs, climbers, &c., also Roses from the open ground.

Cut Flowers.

Supplies continue excessive, and with the prevailing mild weather and Easter falling late it appears probable that much that usually comes in for that season will, when it arrives, be over. Daffodils from the open are now arriving from many parts. Supplies from the Scilly Islands are almost finished. Many are coming from Holland. Hyacinth bloom is also seen in large quantities. There are still many Tulips in the market. The ordinary "Dutch" will soon be finished, the "Darwins" succeeding them. Spanish Iris will in a few days make a great display. Supplies of Liliums are moderately plentiful. Callas have been a drug, but these may be scarce before Easter. Roses were never so abundant. It must be disappointing to growers, who find it is impossible to sell even the best flowers in sufficient quantities to clear out. At the close of the market this morning many remained unsold. Carnations continue over-plentiful. Orchid bloom is seen in large quantities, but the demand is very limited. Large branches of deciduous flowering shrubs are brought in. Cut foliage is plentiful. Galax leaves from America are now extensively used, especially those with a bronzy red tint. *A. H., Covent Garden, April 5.*

ANSWERS TO CORRESPONDENTS.

Begonia Gloire de Lorraine: *J. F. S., Wolverhampton.* We believe that this popular winter-flowering Begonia was raised by MM. Lemoine & Son, Nancy, France, from a cross between B. Dregei and B. socotrana, the former a Cape species and the latter from Socotra.

Books: *Constant Subscriber. The Book of the Peach*, by H. W. Ward. This may be obtained from our Publishing department, price 2*s.* 9*d.*, post-free.

Cannas and Begonias: *A. R. T.* Put these into boxes containing light soil with much leaf-mould, and they will commence to make growth. When you remove to the new house, the plants may be lifted very carefully and be planted in the ground. The leaf-mould is useful because it will adhere to the roots of the plants at time of moving. In the meanwhile retard the growth of the plants as much as possible by keeping them in cool conditions.

Caterpillars on Fruit Trees: *H. J. C.* The caterpillars are those of the Magpie or Currant Moth (Abraxas grossulariata). You cannot successfully treat the trees while they are in blossom, but you might lessen their numbers considerably by shaking the branches over a tarred tray. As soon as the bloom has set you may spray the trees with Paris-Green (poison) at the rate of 1½ oz. to 20 gallons of water. Keep the water constantly stirred during the process of spraying, and if necessary make a second application about fourteen days afterwards. In winter unnail the trees and dress the wall thoroughly with paraffin, taking care to apply it to all the crevices and under the coping-stones, as it is in such places that the caterpillars hibernate; they may also be found among the branches hidden in bits of dead leaves and in the shreds, so that these will also need attention. As an extra precaution spray the trees next spring with Paris-Green just as the buds begin to open.

Fern: *A. H. Pearce.* Your Fern is Pteris biaurita. We know of several instances in which this has appeared among seedlings in places where it has not previously been grown.

Figs: *J. J. G.* The tree is attacked by the fungus which is so detrimental to Figs, Cercospora Bolleana. Cut the diseased branches away and burn them. Dust the new growths with flowers-of-sulphur.

Fungus on Apple: *G. P.* The Apple is partially covered with the mycelium or vegetative portion of a fungus, probably one of the Agaricus species, of which the common Mushroom is a member. The fungus has not entered into the tissue of the Apple, and its presence is no doubt due to accidental circumstances.

Grapes Spotted: *R. B.* Your berries are attacked by the spot fungus, Glœosporium laticolor. Burn all the diseased bunches, and spray the plants with liver-of-sulphur, in the proportion of ½ oz. of sulphur to 1 gallon of water.

Grevillea robusta: *R. H.* Plants may be raised readily from seeds sown in a slight hotbed in spring, and this is the more general means of propagation. Cuttings from well-ripened wood, however, will make roots if inserted under a bell glass. Use plenty of sand in the compost. Treat the cuttings as you would those of greenhouse species of Cytisus. The diseased Pelargonium leaves are being investigated.

Hyacinth: *G. H. D.* Owing to some reason that could only be ascertained after examination of the soil and the conditions in which the plants have grown, most of the roots have died. At

the same time the flower-spike appears to have been injured by insect bite, which would account for the sudden and absolute collapse. Examine the others for insect punctures.

INSECTS ON FERN ROOTS: *J. B.* The insects are a small species of coccid, closely allied to the mealy-bugs, known to scientists as Ripersia terrestris. In repotting the plants wash the roots thoroughly in clean water, and destroy any bugs that may float upon the surface. Bisulphide of carbon will destroy them, and to apply it make four holes close to the side of the pot with a 4-inch wire nail, and charge each hole with a small quantity of the fluid by means of a glass syringe, at the rate of about two teaspoonfuls to a 6-inch pot. Close the holes after the application has been made, and keep the plants in the shade for a week afterwards. *Caution:* Bisulphide of carbon is highly inflammable and poisonous, and its application should be made in the open, far from any light. It is important that Ferns be watered very carefully.

JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY: *H. P.* Communicate with the Secretary of the Royal Horticultural Society, Vincent Square, Westminster.

LENT LILIES: *H. H.* In order to obtain the best results from bulbs planted in grass it is imperative that the foliage be allowed to remain until it withers away. The leaves perform the work of elaborating the material that is stored up for next season's growth, therefore do not cut them off with the mowing machine, or let them be grazed off by cattle. When all that is practicable has been done, bulbs are not always successful among grass, and they have continually to fight for their existence. But you need not restrict yourself to the variety known as Lenten Lily, but plant any of the commoner varieties, and some will then show themselves to possess a greater degree of adaptability than others.

LOAM: *A. S.* We cannot undertake to analyse samples of soil, but would express an opinion upon its suitableness or otherwise for the purposes you mention. If you are a Fellow of the Royal Horticultural Society, you can have the soil analysed by the Society's analytical chemist for a small fee.

MANGOSTEEN: *R. G. F.* We are unable to point to any garden in these Isles where Garcinia Mangostana fruits satisfactorily. It has fruited at Syon House, Royal Gardens, Kew, and possibly at other places, but it is exceedingly shy, and we are unaware of anyone growing it for the purpose of producing fruits for table use. The tree may grow 10 or 15 feet high here, and the fruit was figured in the *Gardeners' Chronicle*, December 17, 1904, p. 428. We have tasted imported fruits and they have been disagreeable to our palate.

MUSHROOMS: *Zola.* Judging from the information contained in your letter, we think the failure is due to the use of defective spawn, or spawn that has become weakened through long keeping. There should be nothing risked when choosing spawn, and if there is the slightest doubt that it is not so good and vigorous as it might be, let it be discarded and a fresh sample obtained. In order that you may assure yourself that your beds are made properly and the correct temperatures observed, refer to the notes on p. 135 in the *Gardeners' Chronicle* for March 4, and p. 128 in the issue for February 25.

NAMES OF FRUITS: *J. C. W. & Son.* Tyler's Kernel.—*J. Taylor.* 1, Reinette Granville; 2, Galloway Pippin.—*W. Camm.* Pigeon.—*Lady Malcolm.* The largest fruit is Catshead, and the smallest one Cox's Orange Pippin. The other is Whitmore Pippin.—*W. H. S.* 1, Northern Spy; 2, Tower of Glamis; 3, Birmingham Pippin; 4, Calville St. Sauveur; 5, Claygate Pearmain; 6, Ringer.

NAMES OF PLANTS: *T. N.* 1, Forsythia suspensa; 2, Hedera helix var. pedata.—*D. & W. C.* Brunsfelsia (Franciscia) eximia.—*J. J.* Narcissus Telemonius plenus or double Van Sion.—*G. B.* Probably Andromeda calyculata, but the specimen is insufficient.—*E. T.* The variety you send is called in some gardens Cœlogyne cristata intermedia. It is between the variety Lemoiniana and the original form. The yellow colour on the lip varies from one year to another on the same plant, and the difference is not important.—*H. P., Cardiff.* Dendrobium speciosum.—*C. B., Braintree.* The fine form of Lælia flava known as Lælia Cowani.—*J. C.* Odontoglossum crispum, which may be good when established.—*J. Y.* 1, Dendrobium nobile Cooksoni; 2, D. nobile; 3, D. crassinode; 4, D. chrysotoxum; 5, Sophronitis grandiflora; 6, Masdevallia Harryana; 7, Epidendrum selligerum.—*E. B., Worthing.* Albuca caudata of Jacquin.—*G. H. B.* 1, Forsythia suspensa; 2, Erica mediterranea; 3, Anemone Hepatica varieties; 4, Scilla sibirica; 5, Corydalis bulbosa; 6, Muscari botryoides, the Grape Hyacinth.—*D. W.* 1, Codiæum (Croton) angustifolium; 2, C. pictum; 3, C. Weissmani; 4, C. interruptum; 5, C. irregulare; 6, C. angustifolium maculatum.—*V. I.* 1, Eulophia macrostachya; 2, Liparis longipes; 3, Eria bicolor; 4, Adiantum sulphureum.—*C. E. F.* Sprekelia (Amaryllis) formosissima.

NICHOLSON'S DICTIONARY OF GARDENING: *A. K.* We are informed by the publishers that it is the old edition in eight volumes that is sold for £3 8*s.* In order to make this complete it would be necessary to purchase four supplemental volumes at 8*s.* 6*d.* per volume. The edition sold at £4 2*s.* is a complete one.

PEACH SHOOTS DISEASED: *Persica.*—Your tree is affected with the disease known as "Silver leaf." The cause of the disease is not perfectly understood. It has, however, been found that an application of a solution of iron-sulphate applied to the roots of the trees in the proportion of ½ ounce of sulphur to 2 gallons of water is beneficial.

PELARGONIUMS ROTTING: *E. F. C.* The rotting of the stems seems to be due to the plants having been planted too deeply in the first instance, and having received too much water during the winter. The top of the growths is sound, and would afford excellent cuttings for insertion now.

PLANTS FOR BORDER: *J. F. S., Wolverhampton.* Suitable plants that produce yellow or orange-coloured flowers are Zinnias, Gaillardias, Tagetes, Coreopsis Drummondi, Chrysanthemum coronarium, Antirrhinums (selected as to colour), Escholtzias, &c.

ROSE OF SHARON: *R. H.* Hypericum calycinum is generally regarded in gardens as the Rose of Sharon, but the authenticity is doubtful. Some authorities with equal uncertainty give the plant as Althæa frutex (Hibiscus syriacus).

THE FLOWER BEDDING IN LIVERPOOL BOTANIC GARDENS: *W. A. L., Portagela la Prairie, Canada.* The Crocuses and Scillas and Chionodoxas in early spring are followed by about 10,000 Narcissus and 20,000 Tulips, associated with large beds of Wallflowers. The scheme of summer bedding is a large one, and it is remarkably well carried out by Mr. J. Guttridge and his staff. Some thousands of the following plants are required for the work: Pelargoniums, Violas, Marguerites, Lobelias, Calceolarias, Tropæolums, Alyssums, Iresines, ornamental Beet, and Centaurea candidissima, all of which, excepting the two last-named species, are propagated from cuttings. One of the most important features of the flower gardening is the "carpet-bedding," to which sixteen beds, each 16 feet by 4 feet, are devoted. The designs vary each year, and are formed by the aid of the under-mentioned plants: Mesembryanthemum cordifolium variegatum, and varieties of Alternanthera, all of which are propagated from cuttings obtained from stock plants in spring; Mentha Pulegium gibraltarica, Spergula pilifera aurea, Herniaria glabra, Antennaria tomentosa, Arenaria cæspitosa, Ajuga reptans purpurea, Sedum lydium, Sempervivum in variety, Echeveria secunda glauca, Saxifraga hypnoides, Pyrethrum selaginoides, and P. "Golden Moss," a variety of recent introduction. These Pyrethrums are raised from seeds, but most of the other species are increased by division in the spring. The mixed borders contain a large number of herbaceous plants, and the Dahlia borders, in which some thousands of these plants are grown, as well as the botanical beds, in which the plants are arranged in the various natural orders. If you wish to employ similar bedding in the grounds of the General Hospital near Manitoba, you should have little difficulty in acquiring a stock of these plants from the nurserymen. A little pamphlet on the subject of carpet-bedding may be obtained for 6*d.* from Messrs. H. Cannell & Sons, nurserymen, Swanley, England, and there is a more expensive work by Karl Götze, price 15*s.* 6*d.*

THE PAGOSCOPE: *Several Correspondents.* We are informed that this instrument may be obtained from Mr. Phillips, 12, Charterhouse Street, London, E.C. The figures, it should be remembered, are arranged according to the Centigrade system, not the Fahrenheit, which is in common use in English gardens.

TOMATOS: *S. B.* The appearances are like those produced by the "sleepy disease," but we cannot be certain from your specimens. Probably you have grown them on too fast, with not sufficient ventilation.

VINE SHOOTS: *J. G.* From the appearance of the shoots we suspect the presence of a fungus disease called "browning." The disease "browning" is figured in the *Gardeners' Chronicle* for August 19, 1893, p. 217. The disease is caused by a fungus, Plasmodiophora vitis, one that is allied to the fungus causing finger-and-toe in Brassicas. You can do nothing against this disease but remove and burn the affected parts from the Vines.

VINES: *Puzzled.* The pieces of cane received are quite dead, nor do we wonder that this is the case. No plants should be expected to survive when a large portion of the roots has been killed by absolute lack of water, and their canes painted with such a caustic mixture as you have described. There is nothing to be done but to make a new border and plant fresh Vines.—*Geo. H.* The disease is caused by the Vine mildew, Plasmopara viticola. It is as yet in an early stage and could be checked by two or three applications of dilute Bordeaux-mixture at intervals of ten days. If it is not advisable to use Bordeaux-mixture in the house, then a spray consisting of one part by measure of lysol in two thousand parts of water may be used, and is equally effective.—*S. H. T.* The shoots are "fasciated" from overgrowth. They will not be detrimental. Probably you have overcropped the other Vines mentioned and have not sufficiently thinned the bunches.

VIOLETS DISEASED: *F. G.* Your plants are affected with a fungus, Ascochyta violæ, a disease that is troubling growers all over the country. Spray the plants with a solution of potassium sulphide, 1 oz. to 3 gallons of water, every fortnight. When planting season arrives select a fresh site for the beds, and obtain fresh plants from a distance that are free from the disease.

WORMS IN LAWNS: *P. Yule.* (1) Dissolve ½ oz. of corrosive sublimate (POISON) in 15 gallons of water, and apply it over the lawn; and when the worms come to the surface sweep them up. If the fowls eat them they will be poisoned. (2) If you mix a peck of freshly-made quicklime in 40 gallons of water, allowing it to stand until clear, and then apply the liquid from a rose watering-pot, it will also serve to bring the worms to the surface; but in this case they must be picked up by fowls or brushed up at once, as they are not poisoned. (3) You can obtain from Messrs. Cooper, Taber & Co., Ltd., London, a preparation known as "Chinese Worm Soap," or from Messrs. Read Bros., Ltd., Wolverhampton, their "Worm Eradicator."

A FLOWER SHOW IN MENTONE.

UNDER the auspices of the local authorities an excellent collection of plants and flowers was recently exhibited in the Mentone Public Gardens. These public gardens occupy a site immediately over the Carei River, which has been arched over to allow the waters to reach the sea. The gardens are well laid out, and present a very bright appearance. They form a striking feature, leading the eyes to a grand view of the outlying jagged flanks of the Maritime Alps. It is to be regretted that one quarter of the gardens was ruthlessly dug up and levelled in order to make room for the erection of the necessary tents, which cut off the view of a noble vista at a time when the season is at its height.

The tents were about 250 feet in length and 75 feet in breadth. A row of shrubs and Oranges formed a background to the tents, the centre of the roofs of which were raised lantern-wise, and the upper sides being covered with a white material afforded a soft and pleasant light. The remainder was alternately red and white in stripes. The tents were lofty, and, hung with national flags and banners, presented a cheerful appearance that is wanting in our British show-tents; while the gay colour, being elevated, did not "kill" the masses of flowers below. The tents were made in three sections.

Entering at the lower end of the tent, the first object that attracted attention was a grand bed of those bold spiked Stocks which are so largely grown in the Riviera. The centre was raised, and planted with the native yellow Coronilla, broken up by the crimson spikes of Antholyza, thickly set with its opposite flowers. The Stocks were planted in nine wedges of separate colours, among which was one of a conspicuous salmon-rose colour, another of a lovely primrose shade, the rose "Chair de Nice," Mauve de Nice, &c. The whole was surrounded by cut bracts of Bougainvillea, with a parallel line of the dwarf Centaurea candidissima, finished with a nearly oblong margin of fine moss having an appearance similar to grass. Next the gravel was a row of Centaurea, set with four small circles filled with French Giant Ranunculus in various colours, among which were disposed three fine spathes of Arums. A few flowers of Iris florentina (bluish-white) were placed next the centre bed, while dotted in the moss were single flowers of Tropæolums. The effect of the whole was excellent.

The table decorations were not equal to those seen at our own shows, being heavy and crowded, while one fails to appreciate the advantage of draping the falls of the white cloth with wreaths of Smilax, which would be in the way of persons when dining. The tables were set for eight persons, and for effect should have been double the size.

An exhibit from a local villa afforded evidence of the climate of the district, consisting of a magnificent display of cut Palm-leaves, fruit, and flowers, with Oranges, both Mentone and Jaffa, in splendid condition. The most distinct of the Palms were Kentia Fosteriana, with fruit similar in appearance to Olives, green in colour, and with a black eye; Cocos Romanzoffiana, the fruit of which was set close to the main stalk like very green Gooseberries, the points of the mass of stalks being bare of fruit and standing out on all sides, yellow in colour; Livistona sinensis, with loose bunches of fruits like Black Hamburgh Grapes; Phœnix canariensis, with fruit of golden-yellow colour, on very large diffuse stalks; Chamærops excelsa, with branched, compact clusters of rich violet berries; Phœnix senegalensis, with oval, ruby-red-coloured fruit, set on a loose panicle some 2½ feet long, the whole being most striking in appearance; Sabal Adamsoni, with small fruits similar to Black Currants in appearance; Pritchardia filifera, with flowers in an embryo state, and with greenish-yellow Dates; Cocos flexuosa (?), whose flowers look like long ears of Wheat, a branching spike 2 feet in length gracefully curving on all sides (probably staged the wrong way up); Seaforthia elegans, with a bunch of long grey filaments, similar to pack-thread, set with embryo fruits. This grand exhibit was well labelled. The largest leaves formed a background, while in the front was a flower-spike of the still rare Phœnix Robelini.

A trade exhibit by the firm known as "Au Myosotis" was superb. Words can scarcely convey an idea of its beauty and the taste displayed in the arrangement. It occupied four bays, separated by pillars made up with a mossy background, on which were sprays of corky Elm, lightened with long streamers of the wild Asparagus verticillatus, and picked out with superb Carnations, each pillar being of one colour. The Carnations were disposed singly, and were of a size never seen in Britain, except among the Malmaison race.

The bays were arched over; these were also decked with Carnations on a background of Myrtle, and the centre bore a huge device carrying the name in scarlet letters on a groundwork of white Stocks. Benches about 2 feet high and 15 feet deep were carrying very large fancy baskets of Roses on long stalks—Maréchal Niel, Ulrich Brunner, Magna Charta, G. Luizet, one kind only being placed in a basket. Screens and elegant baskets of glorious Carnations on long stalks were also included, the whole having a background of elegant Palms, forced Lilacs, and Snowballs (Gueldres Rose).

The eyes rested on any part of the display with pleasure, the general effect and harmonious arrangement being evidently the work of an artist.

The best Carnations were Fernandi Rondeau, of pale salmon colour freely striped and flaked with red; Elise Perrin, pure white; Olga, rather paler than F. Rondeau; Député Boccard, pale salmon ground with brick-red stripes (extraordinarily good in quality); Roi des Noirs, an enormous "Clove"; La Heliotrope, washy purple; one named Carlo Rodolphi was more curious than beautiful.

Among the most tasteful baskets and drawing-room devices of flowers were the following:—An oblong satin basket, the handle of which was dressed with salmon-coloured ribbon, the base inside being composed of half-opened Gueldres Roses with a suspicion of green in the flowers, above which rose a mass of the palest salmon-coloured Carnations rather to one side of the basket, and circling over the whole were branched sprays of Asparagus. This device was charming. In the same exhibit were grand baskets of Maréchal Niel and pink Roses, with splendid foliage. Among the exhibits of brides' bouquets was one very neat device in the form of a cone, entirely composed of Orange-blossom covered with tulle, and tied with the same material and white satin ribbon. Another with similar "millinery" was made with Druschki Roses, Carnations, white Lilac, and Myrtle. The bouquets were smaller than we make them in this country.

The 1st prize bouquet was accompanied by a shoulder-knot, a 2-feet bridal wreath of loosely set Orange-buds, and a pair of Orange-flower button-holes for the bridegroom, the whole forming a complete wedding set.

I must not omit to mention a superb basket of flowers arranged for a boudoir. It had a tall handle decorated with orange-and-pink satin ribbon completed with bows, and contained a plant of Azalea "Hermode," 2½ feet in diameter, palest salmon with a darker upper petal and creamy-white edge; a pink Hydrangea at each side, and a fine bold plant of Adiantum scutum in the centre—a most *recherché* arrangement. In another instance a harp of white Carnations, with strings of Violets and base of pale blush Carnations, with China rose-coloured satin ribbon, was very choice.

A green basket with handle some 4 feet in height, covered with pink figured ribbon

supplemented with a bow, the handle centre being decorated with fine Phalænopsis sprays; on the right bright Anthuriums and Croton-leaves, and on the left mixed Orchids and paler Anthuriums — a most striking and elegant design. A lyre 4 feet high had the outer sides composed of Étoile d'Or Marguerites, the strings being made of Parma Violets, the whole being in very good taste. Another very beautiful device was a child's cane lounge. The back seat was of Parma Violets, with an arching of splendid Maréchal Niel Roses, and the front formed of more Maréchal Roses, which were remarkable for the size of their flowers and for their excellent foliage. The whole was set off with soft pale-rose ribbon, forming a real work of art. Baskets of Carnations, elegantly set up with tasteful "millinery," not out of place, made these groups, next to the "Myosotis," the most attractive in the show; and our London florists could with advantage take a few ideas from the exhibits.

In the same tent were trade groups of Palms, Araucaria excelsa, forced plants, Rhododendron molle and Belgian Azaleas, mostly staged on the ground, thus showing them off to advantage. A group of plants of standard and dwarf Prunus triloba was superb; while a private grower's group of Lilacs, Roses, Acacias, Magnolias, Wistarias, and Cinerarias was most creditable. Cut flowers in dirty (!) champagne "pints" were shown on long tables. There were glorious Anemones in several varieties, turban Ranunculus, among which the white variety Gloire de France was lovely. Some 1,500 Carnation flowers staged on one table were of the widest possible range of colour, but naturally not of the "quality" one sees in our London shows. The brightest among these were "Cherry Rose," a white Malmaison with a lovely salmon-pink centre and of extra large size; Tamagno," an immense loose white variety; Château Neuf, rose-coloured shaded with palest salmon; Rosa Bonheur, 3 to 4 inches across and striped like Charles I., an extra fine flower; Tonquiere, of a rich brick-red colour; Raynaud, purple-lake, and hundreds of numbered seedlings.

Another table contained magnificent plants of Stocks, the plants being 18 inches tall, branched, and with blossoms 3 inches in diameter; Iris Susiana, Jerusalem Iris, Tulips, and indifferently-grown Narcissi.

The members of the trade and several amateur growers put up a few Orchids and stove plants of small size. Gloxinias were of poor quality, interesting but not striking. One whole tent was filled with a display from the Monte Carlo Casino gardens. This exhibit was artistic in arrangement, the subjects well cultivated, and alone worth a visit, reflecting the greatest credit on the "Chef du Jardin," Mons. Van de Vaele. On entering the tent, a long central bench glowing in colour arrested the attention, while around the sides were arranged banks of plants whose foliage and colour gave a splendid effect. The eyes, dazzled for a few moments, rested satisfied on a group of clean, well-grown stove plants, in the centre of which stood a fine Vanilla plant. In this display were large specimens of Pothos, Asplenium nidus, Acrostichum grande, Nidularia, Codiæums (Crotons) Adiantum farleyense, and other beautiful plants. The central "stream" of colour was formed by blooms of Cyclamen papilio, which, although curious, are not to my fancy; C. latifolium giganteum, arranged in rows across, each batch containing some forty plants; the plants were two-year-old, and were well grown. Next was a mass of a pretty branching dwarf double-yellow Wallflower, Rayon d'Or. A bank of Hoteia japonica had better foliage than spikes of flowers, one hundred freely-flowered specimens of Primula obconica, some carrying blooms of a good purple shade, the whole batch being excellent. At one end of the exhibit was a set of finely-grown 12 to 15-inch plants of blue Hydrangeas, carrying bold heads of flowers, with as many as six to eight inflorescences on a single plant, although they were so dwarf. The foliage of these plants was most perfectly developed. In front of these was a number of plants of Xanthoceras sorbifolia, well flowered, but not more than a foot in height. The whole of this grand bank was edged with a violet form of Viola cornuta, larger than the species, which is of a deep lavender shade of colour. These plants were also used to edge the sides, totalling in all 1,000 plants.

Referring to the outside display, a set of twenty-four Bougainvillea splendens, forming 3 to 4 feet pillars of fiery purple, was superb, the front being toned down with Primula obconica. Plants of white forced Lilacs formed a background to the Bougainvilleas, whilst Phœnix Palms and Spiræa confusa (named Reevesii) alternated round the whole tent as a background.

Double Cinerarias followed a dwarf set of Lilacs (white) and single Cinerarias in every shade of colour, including one of a sweet pale blush. These were splendidly grown, not over 15 inches in height, with inflorescences a foot in diameter, but the flowers lacked the refinement and imbrication of some of our English strains. A fine group of larger plants of Hydrangeas of splendid culture completed the right side of the exhibit. On the left were displayed well-flowered Imantophyllums, Deutzia gracilis (very chaste and freely flowered), Lilac Charles X., well-grown Belgian Azaleas, including Mrs. Mendel, President Walters, and Apollo. A group of pot Roses of old varieties was not remarkable, but a large bank of Fortune's double white Prunus sinensis was grand. A mass of Heaths, backed with white and blue Wistaria, brought us to the end, the whole being completed by a grand bank of large Gueldres Roses, fine in foliage and flower. When it is understood that in some cases 100 plants of a kind were used, some idea of the general effect can be imagined.

The cut Roses in the "trade" groups had apparently been forced too rapidly. The varieties Isabel (a small white H.T.(?)), Rachel, Marie Louise (the latter resembling Gloire Lyonnaise, pretty white blooms, but small), and Druschki were the finest.

The show also included fruit, wine, and agricultural products. The only fruit I saw consisted of a few Reinette du Canada Apples, a so-called Calville Blanc (not the five-sided one we know), a Reinette d'Angleterre after Hollandbury, and forced Strawberries, Dr. Morère, the latter not equal to our variety Royal Sovereign. Green Peas and Beans were included.

Sacks of Rye-grass and of Clovers from Nice were all the agricultural produce noticed. A pretty bower of large branches of Lemon covered Olive-oil and wines of Mentone in bottles. Other exhibits of honey, wax, wines, and liqueurs, completed the show.

Bamboos and Palms made the entrance very taking, while a bed of Aloes and Agaves was a feature My general impression was that we in England are in advance of the French in our cultivation, but lack their taste in arrangement, for the very good reason (as at the Temple) that we have not sufficient space at command to show the exhibits to the best advantage, nor could ground beds be formed where such crowds of people as we are accustomed to see are gathered together. *Geo. Bunyard, Mentone, April* I.

GARDEN PATHS.

These may be roughly divided into those on which there is vehicular traffic, and those confined to pedestrians, or at most to a barrow. In the first are the carriage drive, the cart road to the back premises, and in a large garden the main paths, where a cart is often used to save labour. In laying-out a carriage drive it is desirable to get as easy a sweep as possible, both at the entrance and before the door of the mansion. Right angles are more or less difficult to manage, and particularly so at night, and should be avoided as much as possible in the pleasure grounds. But in the kitchen-garden all paths should be at right angles, as it is very desirable to keep the quarters for the vegetable crops either square or at least with parallel sides, and as the vehicular traffic is confined to slow-going carts, the sharp corners are not objectionable.

The width of the roads must depend on the size of the grounds, but no cart road should be less than 10 feet; 12 feet is better, and they may be made 20 feet with advantage if space allows. When the roads are laid-out they should be levelled when necessary, and for utility the more absolute the level the better, but a long approach to a house may undulate to certain extent, provided that the surface is good. If, however, there should be a very steep pitch, it is better to lower the road and let it run between banks for a time. On an approach never allow a pitch that will try a horse in the least. If the soil is wet or the road passes through damp hollows, a drain must be laid down on one side, and catch pits and traps put in at intervals, to take away the surface-water. In any case, even where a drain is not required, a gully should run down each side of the road with grips cut to carry off surface-water. Nothing ruins a road sooner than water constantly percolating into its foundations. The road should be excavated 2 to 4 feet deep, according to the nature of the soil. At the bottom of the excavation a layer of stones, rubble, clinkers, &c., should be laid to one-third the depth. On this a layer of broken granite, flints, or slag, evenly spread, and the last layer should be of the same materials, but broken so small that it will pass through an inch riddle. It will improve the wearing quality of the road if this last layer is lightly coated with tar before being laid. Pour some tar over a heap of material and turn it till the whole is lightly coated; then lay evenly and roll with a heavy roller. The middle or crown of the road should be slightly, but only very slightly, higher than the sides, just enough to carry off the water. If, as is sometimes the case, it is made very convex, not only is the labour of traffic increased, but the surface of the road is worn unevenly and needs constant repairs Near the house these roads may have an extra coat of gravel or granite chips, but, except for

appearance, they are better as firm and clean as possible, as the labour of keeping them swept and rolled is much lessened when there is no loose material.

Smaller Paths.

The formation of smaller paths is merely a modification of the above. Traffic being lighter, there is no need to excavate so deeply, nor need the upper layer be tarred. As a general rule this upper layer consists of gravel, granite chips, or spar chips put on thickly and rolled. Be careful, however, to see that if gravel is used it is sharp and with a certain amount of sand. Water-worn gravel should never be used, the smooth, rounded stones always remain loose, require constant attention in raking and rolling, and are very uncomfortable to walk on. Ashes from the stokehole make a good surfacing for paths in back premises, but wherever possible asphalt is to be preferred. As usually prepared, asphalt requires the tar to be boiled, but this is not really necessary. A good, cold asphalt, which will last twenty years, is prepared with small, sharp, sandy gravel and tar. Make a heap of the gravel with a hole in the centre, and pour in the tar. Turn the sides into the middle, and mix thoroughly as you would mortar. Let it lie in a heap for two or three days, and then re-turn, adding more sand or tar as may be necessary. It is impossible to give the exact proportions, as some gravel requires more tar than others, but when properly mixed it should not stick to the boot when trodden on. A good test is that when on a heap it should move as a heap of mites does in a cheese. A little lime helps to dry it, but too much causes blisters in the path when laid. The longer it remains in heap the better. Make the foundation of your paths of clinkers or stones, and lay the asphalt 2 or 3 inches thick. A cubic yard of sand will make enough asphalt for 12 to 15 yards of path.

Where there is no wheeled traffic at all, nothing looks better than grass, but it takes a great deal of work to keep it in proper order, and unless so kept is the worst path you can have. For woodlands and rough paths where it will grow, Ling makes a capital path. It must be mown short twice a year, and the young shoots will make a thick elastic carpet very pleasant to walk on. Where Ling cannot be grown, nothing is better for these rough woodland paths than Pine needles. If spread thickly they soon decay, and are always dry and pleasant to walk upon. *J. S. Turnor.*

Fig. 96.—Rosa sorbiflora: a newly-discovered Chinese Rose.
A, flowering spray; B, inflorescence of R. sorbiflora; C, simple inflorescence of R. Banksiæ.

NEW OR NOTEWORTHY PLANTS.

ON A NEW CHINESE ROSE: R. SORBIFLORA, *Focke, n. sp.* (Fig. 96.)

I suggest this name because the inflorescence is like that of Sorbus. Inflorescence at the end of the branches, corymbose (branchlets many-flowered) as in Sorbus or Viburnum (fig. 96, B). Flowers about ½ inch (scarcely 2 cm.) in diameter. The outermost sepals often with filiform or trifid appendices. Styles elongated over the orifice of the receptable; fruits scarcely 5 mm. in diameter. Climber, 6 feet high. West Hupeh (coll. E. H. Wilson, 828).

The new Rose, collected by Mr. E. H. Wilson in Central China, belongs to the section Banksiæ, which has been characterised by Crépin as follows:—

"Styles free included; stigmas forming a sessile head over the orifice of the receptacle; sepals entire, reflexed after flowering, caducous; inflorescence many-flowered, umbellate, with very small caducous bracts; stipules free, subulate, caducous; leaves on the flower-shoots 5 to 7-foliolate; stems sarmentose, prickles hooked, alternate."

This description is founded on R. Banksiæ, R. Br., the only hitherto known species of the group. After the discovery of a second species it must be modified as follows in the characters of styles, sepals, and inflorescence. The two species are closely allied, but they can be easily distinguished when in flower or in fruit.

Rosa Banksiæ, *R. Br.*

Inflorescence at the top of the branches, subumbellate (branchlets one-flowered) (fig. 96, C). Flowers about 1 inch (3—4 cm.) in diameter. Sepals entire or the outermost occasionally with a few scattered small teeth. Styles included, the stigmas covering the orifice of the receptacle; fruits about ¼ inch (8 mm.) in diameter. Hab. Central China. White and yellow-flowering double varieties cultivated in European gardens. *W. O. Focke.*

Cœlogyne Lawrenceana, *Rolfe, n. sp.**

Messrs. Sander & Sons' recent importations from Annam prove to be particularly interesting, the latest novelty being a Cœlogyne of the speciosa group, which was exhibited by Sir Trevor Lawrence, Bart., at the meeting of the Royal Horticultural Society on March 28 last, when it received an Award of Merit by the Orchid Committee. The species of this affinity are not common in gardens, with the exception of C. speciosa itself; but a striking species known as C. Micholitziana is found in a few collections, and C. psittacina is represented at Kew, having been

* *Cœlogyne Lawrenceana, n.sp.*—Pseudo bulbs ovoid-oblong, 2 to 3 inches long, 1 to 1½ inch broad, diphyllous. Leaves broadly lanceolate, accuminate, attenuate at the base into a distinct petiole, 8 to 11 inches long, about 1½ inch broad. Scape arising from the apex of the mature pseudo-bulb, about 7 to 8 inches long, 1-flowered. Bract spathaceous, clasping the rhachis, obtuse, striate, 1½ to 1⅔ inch long. Ovary 14 lines long, with six very prominent angles. Sepals oblong, somewhat narrowed towards the apex and subacute, obtusely keeled behind, and somewhat gibbous at the base, 2 inches long. Petals linear, acute, nearly 2 inches long by rather over a line broad. Lip strongly 3 lobed, 2 inches long, subsaccate at the base; side lobes oblong, rounded at the apex, 1¼ inch long; front lobe broadly ovate, apiculate, somewhat undulate, recurved, 1¼ inch long; disc with three rows of crested keels extending to the base, with an additional pair at the base inside the lateral keels, another at the apex outside the lateral pair, and a few additional teeth on either side nearer the margin; filaments of crest 1½ line long in front, the rest about ½ a line long. Column elavate, incurved, winged in the upper half and at the apex, 1½ inch long. Colour of flower light buff-yellow, with the front lobe of the lip cream-white, and a larger orange blotch at the upper part of the crests; below this and on the upper part of the side lobes the ground colour is irregularly marbled and dotted with light cinnamon, while the base of the lip is bright yellow, and the crests are tipped with cinnamon. Column whitish-green. *R. A. Rolfe.*

lately in flower there. The present species is distinct from all of them, and perhaps most resembles C. Micholitziana in habit, though the flower is nearer to C. speciosa in size, and borne on a taller scape. C. psittacina is of more robust habit, but has smaller flowers of different colour, and the scapes are produced from the young growths, not from the mature bulbs, as in C. Lawrenceana. The latter has light buff-yellow sepals and petals, while the front lobe of the lip is cream-white, and he disc deep orange in front and bright yellow near the base. There are five keels on the disc of the lip in front, which are much fimbriated and tipped with brown, while the inner three extend down to the base. It is a very interesting addition to the group. *R. A. Rolfe.*

PLANT PORTRAITS.

IRIS "PARSAMB" ×. *Flora and Sylva*, March.—A hybrid raised by Sir Michael Foster between I. paradoxa and I sambucina. Flowers purple with gold-coloured streaks on the falls.

MECONOPSIS INTEGRIFOLIA, *Flora and Sylva*, March; see also Supplement to the *Gardeners' Chronicle*, October 1, 1904.

ERICA VEITCHII ×.

THIS is a hybrid raised and exhibited by Messrs. R. Veitch & Sons, of Exeter, between E. codonodes (of which a good illustration was given in our number for February 6, 1904, p. 91) and E. arborea, the arborescent Heath which occurs on the Riviera. Mr. Worthington Smith's illustrations (figs. 97 to 100) suffice to show the character of the plant and the main differences between it and its parents. Artificial hybridisation, owing to the conformation of the flower, must be a difficult matter, though an insect might accomplish the feat. The appendages at the base of the anther as shown in the sections of the flower differ considerably in the two species, those of the hybrid most resemble those of E. arborea in this respect. The pollen-grains, as observed by Mr. Smith, differ slightly in the two parent species, whilst those in the hybrid (fig. 100) are unlike those of either progenitor. The plant is a decided acquisition to the number of our hardy Heaths, and is especially valuable for flowering freely at this early season.

FIG. 97.—ERICA × VEITCHII, FROM A NATURAL CROSS BETWEEN E. LUSITANICA (CODONODES) AND E. ARBOREA.

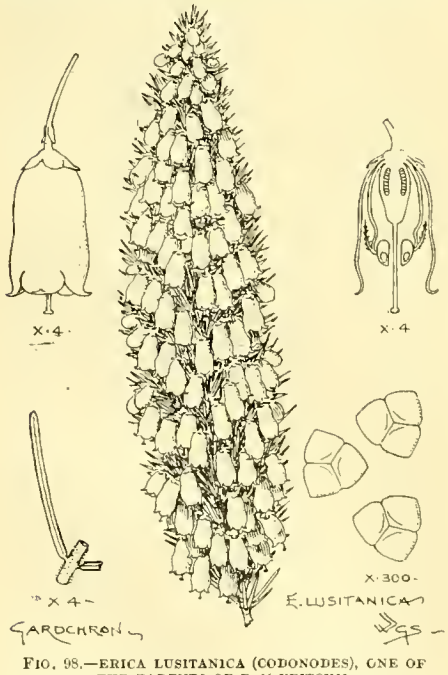

FIG. 98.—ERICA LUSITANICA (CODONODES), ONE OF THE PARENTS OF E. × VEITCHII.
Showing a single leaf, a flower, and a section through a flower, all magn. 4 diam.; pollen-grains magn. 300 diam.

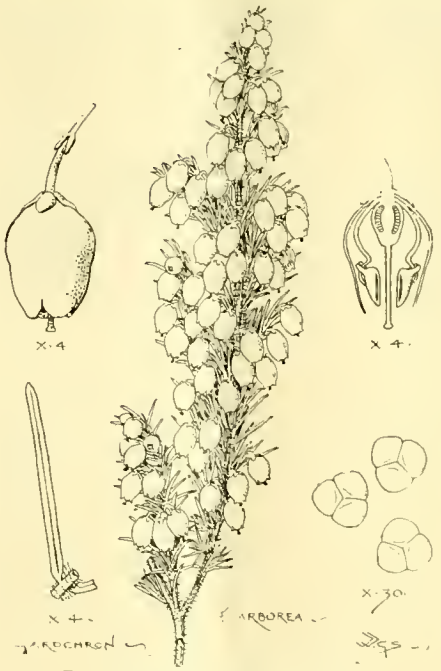

FIG. 99.—ERICA ARBOREA, ONE OF THE PARENTS OF E. × VEITCHII.
(Details as in fig. 98.)

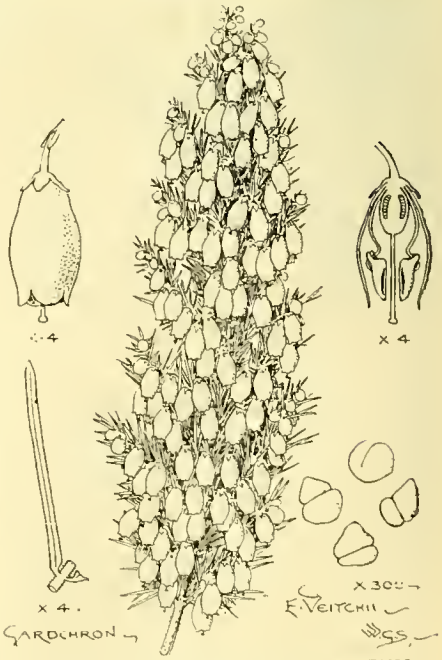

FIG. 100.—FLOWERS AND STRUCTURAL DETAILS OF ERICA × VEITCHII.
(*See Figs. 98, 99; notice the distorted pollen grains of the hybrid.*)

THE FERNERY.

FERN VARIETIES: A PROTEST.

Although I have long been accustomed to see these varieties more or less ignored in botanical literature, and can quite understand that they necessarily occupy a subordinate position with respect to normal species, I nevertheless think it a pity that in a presumably up-to-date work like the *Manual of British Botany*, Babington, ninth edition, edited by Henry and James Groves, varieties should be alluded to in the following out-of-date fashion.

A footnote appended by the editors named to Order C. Filices runs as follows:—

"Dr. Boswell, in *E. B.*, ed. 3, vol. xii., described many varieties of Ferns, and these are enumerated in *Lond. Cat*, ed. 9. We have not, however, thought it desirable to include most of them, as they were no doubt known to Professor Babington and rejected by him as unimportant. The vegetative organs of Ferns are so liable to trivial variations that there is no limit to the number of forms which might be described. *H. & J. G.*"

It will be observed here (1) that reference is only made to what is now ancient literature in the varietal connection, ignoring entirely recent publications by specialists; and (2) that "trivial" variations alone appear to be in the editors' minds. Surely, now that it has been demonstrated so clearly that a great number of variations are by no means trivial but extremely marked, and that some of these moreover have been recognised as scientifically of the highest interest, especially in the reproductive direction —aposporic and apogamic forms to wit—such a reference is inadequate and misleading.

The amusing part of the matter to the varietal specialist is that in such a case as Athyrium filix-fœmina, in which so many extraordinary forms have appeared, we have several so called varieties described, such as A. rLœticum, A. convexum, A. latifolium, A. molle, and A. trifidum, with the appended remark that "there are innumerable sub-varieties," while all these are now regarded as mere sub-varieties, and are indubitably trivial as compared with varieties proper. In Lastrea filix-mas, again, no notice whatever is taken of G. B. Wollaston's undoubtedly justifiable division of this species into three well-defined sub-species, L. pseudo-mas, L. f.-mas, and L. propinqua, nothing later than Newman's book being referred to, though surely the valuable work of succeeding writers and authorities, who knew and know infinitely more than Newman could have known in his day, should have some recognition in a book which purports to be a student's guide.

I fully recognise that the book in question is condensed as much as possible, but this does not justify the lack of contemporary knowledge indicated by references to now ancient authorities who, however much we may revere them as pioneers, have long since been superseded as authorities in this special direction. In Newman's time the capacity of sporting into new and constant types was only just beginning to be recognised, and at first numerous sub or trivial varieties were noted and named by Newman and others, only subsequently to be regarded in their proper light, and relegated to practical oblivion when the really typically distinct "sports" turned up. Nevertheless we find these pioneer forms still persistently chronicled in scientific botanical catalogues and handbooks, while the real varieties subsequently discovered as wild sports, and therefore of botanical interest, morphologically and otherwise, are ignored. This should not be. *Chas. T. Druery, V.M.H., F.L.S.*

PLANT NOTES.

CLEMATIS GRATA.

Two or three years ago, when selecting plants of this species for covering a low wall, I was told that it belonged to the herbaceous section. This has not proved to be the case here in Derbyshire, and I find that last year's growths are quite sound and plump in bud to a height of 6 feet at least. The same thing has occurred during the past two winters, consequently we may, I think, consider that its herbaceous character is non-existent, which is all for the best. In my opinion, it is one of the very best plants that has been introduced for some years past for covering a low wall or similar position. The whitish flowers, tinged on the back of the petals with purple, are borne with great freedom all over the plants, and are succeeded by silvery rosettes, reminding one strongly of the "Old Man's Beard" Clematis of our woods and lanes, so that the plant is beautiful for a long season, beginning in August, and even when in leaf only it has a cheerful and vigorous appearance that is pleasing. Unfortunately, caterpillars seem very fond of the leaves, and if not checked will eat big holes that are disfiguring in them. C. grata is very easily grown and managed, as its growths have no tendency to become tangled as they do in the true climbing forms. *J. C. Tallack, Shipley Hall Gardens, Derby.*

COLONIAL NOTES.

UGANDA AND THE VICTORIA FALLS.

I left Mombasa on October 17, and arrived twenty-four hours later at Nairobi, a place 300 miles up the great Uganda Railway, towards the great lake, after a most interesting journey. It seems hardly credible, and yet it is a fact that from the train one sees thousands of head of game. Buck antelopes, and even zebras (a drove of which actually crossed the line in front of us), and sometimes giraffes and lions are seen. Only recently a rhinoceros charged the train, but the latter came off best, reminding one of George Stephenson's "So much the waur for the coo!"

This place, though only about 120 miles from the equator, is over 5,000 feet above the sea-level, so that though at mid-day the heat is great, the early mornings and late afternoons are nice and cool, with nights naturally always cool—a state of things which differs from the popular conception of equatorial regions. In my carriage I had a gentleman who is a member of a well-known English firm of machine-makers. To-morrow I am completing my explorations of this part by going right on to the Victoria Nyanza and across to Entebbe, the European capital of Uganda, which will be on the very outside boundary of civilisation and quite far enough into Central Africa! But I hope to have time to spare to have a look at Port Florence, the rail terminus, and take the trip across the lake, the source of the mighty Nile.

The Victoria Nyanza.

Going aboard the steamship *Sybil*, lying alongside the little landing-stage at Port Florence, it was a surprise to me to find quite a miniature liner of some 600 tons, with commodious two-berth cabins (one of which I had to myself all the time), fitted with mosquito-nets, lit by electric light, and ventilated by electric fans, ample and well-kept decks, with an excellent table. The trip was thus rendered most enjoyable, and it was hard to realise that one was near the interior of Africa on an inland sea. The Victoria Nyanza is some 300 miles or more long and, say, 200 miles wide. We left at noon on Monday, and anchored for the night in a beautiful little bay, and arrived on Tuesday afternoon at Entebbe, a very pretty place, and in which I spent Wednesday and had a good official "look round," lunching with the Superintendent of Works, to whom I was introduced by a fellow-passenger, Dr. Moffat, nephew of the famous missionary and explorer of the same name. We left again on the Wednesday afternoon for Munzonga, on the north-west side of the lake, and two hours distant from Entebbe. The pleasure of the lake trip is enhanced on the northern side, at all events, by the steamer skirting the mainland or islands, the latter being often beautiful. The whole of Thursday being available, a fellow-passenger and myself set off for an 8-mile walk through the Banana groves of "Darkest Africa" to Kampala, the native capital, containing out of about 70,000 inhabitants only some twelve white men! I had an introduction to an official of the Church Missionary Society, and he showed us great hospitality, taking us all over the mission schools, cathedral, &c., and entertaining us at luncheon. It is a real native town, and the first I have seen. Only a few years ago it was the seat of much barbarism and cruelty. In the afternoon we called upon the King of Uganda (Dandi Chwa), a little boy of eight or nine, who received us with his courtiers kneeling around him—a picturesque scene! We finally returned to the boat safely at 7.30 P.M., after a most interesting day in real African surroundings—an experience I would not have missed on any account, and one that I feel lucky to have had, for but few ordinary globe-trotters get up to the great lake as yet.

Leaving Munzonga on Friday morning after a most agreeable trip, ending by our arrival at Port Florence on Saturday, yesterday I commenced my train journey of some 600 miles to the boat, due at Mombasa on November 1. We left Mombasa on Sunday morning by the German boat, and arrived in Zanzibar on the Tuesday, after spending the Monday in Tanga, German East Africa, a pretty, modern town on a fine bay, inhabited almost entirely by German officials.

Zanzibar, &c.

Zanzibar is a most picturesque and old-world town, one of the most famous ports in the world, the shipping of many countries lying in the harbour. Yesterday a French cruiser and four torpedo-boats came in, on the way to Madagascar, and I have had a row round them, taking snapshots. I suppose if it were a French harbour I might be "run in" as a spy!

I left Zanzibar on November 18 by the *Kronprinz*, calling at Dar-es-Salaam at noon the same day. This is a most beautiful town, the capital of German East Africa, situated on an almost land-bound harbour, and surrounded by Cocoa-nut Palms.

From Dar-es-Salaam we had a pleasant trip to Mozambique, where we arrived thirty-six hours later. This is an ancient decayed Portuguese town, with stagnant trade, on an island 3 miles by 1½ mile in area—a singularly uninteresting place, and which we left the following day, calling off Chindi (Zambesi mouth) to tranship passengers for British Central Africa, and arrived at Beira at daybreak on the Thursday morning; leaving two days later for Delagoa Bay *en route* for Salisbury (in Rhodesia) and Bulawayo, thence twenty-four hours' ride by train to the Victoria Falls—one of the World's Wonders.

The Victoria Falls.

It is hopeless to attempt to describe the sublime grandeur of these Falls; they defy all word-pictures, and baffle the most expert photographer. A mile and a quarter wide at that point, the Zambesi drops 400 feet into a sheer chasm only some 200 feet wide, I should say, and then flows out through a comparatively narrow and sharply winding gorge. The force is

so great that the whole chasm is full of foam-spray, which rises hundreds of feet above the summit of the Falls, and forms a smoke-like pall that causes the natives to name the spot Mosi-on-Tunga, or "The Smoke that Sounds." This spray quite obscures the view from time to time as one stands on the edge facing the Falls; but ever and again a whiff of wind sweeps it aside, and the ever-varied glimpses are superb. A beautiful feature is the rainbow, which is constantly to be seen in the spray below, quite circular in shape. On the south bank of the Falls is the "Rain Forest," beautiful timber and Fern growth, kept evergreen and fresh by this soft warm spray falling upon it. Maidenhair Fern especially flourishes. I am sending some specimens from the forest on the edge of the famous Falls, but I am afraid by the time they arrive in England there will not be much, if any, life left in them. The two Ferns are much like our common Fern or Bracken at home, but the bulb I do not know at all; they are from quite a sub-tropical habitat. The famous bridge is not yet completed. In my opinion it will not at all spoil the general view of the Falls, being quite out of range. After four days and nights in a train southward bound I found myself in Cape Town once more on Christmas Eve. *W.*

Heidelberg, Transvaal.

Some of our readers may be interested to know what crops are likely to succeed in this district. We therefore insert the following extract from a private letter :—

"*Heidelberg, Transvaal.*

Green Peas Dr. Maclean are far and away the best that have ever been grown in this country. The pods are from 4½ to 5 inches long, with nine (average) fine Peas. These Peas are at a disadvantage too, as we have no sticks, and have to use wire netting and string. Beets and Carrots are doing first-rate. Cabbages are splendid, sown in the open ground, and were very easy to transplant, as they were all along so firm and solid. Broad Beans have done well—in fact everything is looking as well as it possibly can do. Mignonette is large and bushy and very sweet. The Sweet Peas are very fine, as also is the Ice-plant. I have had splendid luck with Marrows, and we have made some fine jam. When we come to think of the burning dry heat, it is surprising how well things do. The golden Tomatos are looking very healthy and strong, and Lettuces, since I found shade for them (Cos), are doing thoroughly well." The seeds were obtained from Messrs. Sutton & Sons.

TREES AND SHRUBS.

LAURELIA AROMATICA.

Some time since Mr. F. W. Moore, of Glasnevin, kindly drew our attention to this most attractive evergreen. It is hardy, the foliage of a deep rich green colour, and delightfully fragrant. We gave an illustration at p. 401, December 10, 1904, and venture to call attention to it again, as its merits are not known to many. Moreover, Mr. Moore has kindly furnished us with specimens bearing flowers which are of great botanical interest, although not specially decorative. We need only refer to our former note.

Xanthorhiza apiifolia.

This is an interesting shrub evolved apparently for the purpose of puzzling the botanical student, for in spite of its very different external appearance it is really a Ranunculaceous plant. It is a low-growing shrub, sending up suckers from the creeping root-stocks; the foliage is pinnate, arranged on the end of the naked shoots, and with slender axillary spreading loose racemes of small purplish flowers. It is a native of the Eastern States of North America, and is a very old inhabitant of our gardens, though now rarely seen. The name Xantho-rhiza was given in allusion to the yellow colour of the root as seen when cut. The stem is similarly coloured. Our attention has been lately called to it by Sir Herbert Maxwell, who came across it in a wood, where it had been planted probably for game covert. From its presumably poisonous nature it is distasteful to rabbits, and so remains uninjured where no Holly gets "half a chance." It is well adapted for growing in shady places under trees, and affords excellent cover for game.

The Week's Work.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Cool Orchids.—Wherever a varied selection of cool Orchids is grown there should now be a good floral display. Odontoglossum crispum in variety, with hybrids from it and others, O. Pescatorei, O. triumphans, O. Hallii, O. luteo-purpureum, and others of Columbian origin are now in season. Whilst the plants are still growing and developing their flowers, the rooting medium should be kept in a moist condition, but when the spikes have been removed induce the plant to rest by withholding water so long as the pseudo-bulbs retain their plumpness. Mexican Odontoglossums, such as O. Rossii, O. Oerstedii, O. Cervantesii, &c., are now passing out of flower. These thrive well if suspended near to the roof-glass, and require a long period of rest after flowering. The first two species will only need applications of water at rare intervals, but O. Cervantesii should be given a more frequent supply. All growing plants of the different species will derive great benefit from liberal supplies of water at the present time, even if the rooting medium contains leaves, but should any continue to remain wet for a long time without appearing to get dry, something is wrong with the compost or drainage. Many of the Oncidiums will now be approaching their flowering period, such as O. concolor (a species that flowers at the end of its resting season), O. Marshallianum, O. crispum, O. Gardnerianum, O. Mantinii, O. prætextum, &c., which flower simultaneously with the completion of their pseudo-bulbs. The above should be supplied with sufficient water to keep the materials moist so long as root-action is going on, and to prevent undue exhaustion in the pseudo-bulbs, remove the spikes when the apical blooms expand. O. macranthum and allied species are always in a state of more or less growth, and must not be subjected to a lengthened period of rest. As the flower-spikes develop train them round three or more stakes fixed in the pots, and should slugs or snails be suspected place cotton-wool round the spikes near their bases. Many of the small-growing Masdevallias may have new surface materials afforded them, and M. tovarensis, now commencing to grow, may be resurfaced or potted as required. Those of the Chimæra section that need them may have new baskets provided, using shallow ones, without any drainage material other than a stick or two of charcoal laid transversely on the bottom bars. For these and other species use a compost of good sandy peat and sphagnum-moss in equal parts, half filling the receptacles with drainage, and covering this with sphagnum-moss.

Sophronitis grandiflora.—The plants having flowered will almost have reached their limit of growth, after which rest should be induced gradually by giving them less water. From the present time until autumn these should be accommodated on a stage well removed from the roof-glass.

Trichopilia fragrans needs treatment similar to that afforded Odontoglossum crispum, and should have its cultural needs attended to as soon as new growths appear. T. suavis, now flowering, should rest again until growth begins, when the plants may be potted or resurfaced as required. Plants of this species thrive well in well-drained pans suspended at the warmest part of the cool-house during the summer months, giving them a similar place in an intermediate-house on the approach of winter. Much water is only needed when the plants are rooting freely. T. coccinea, T. crispa, and T. marginata are intermediate subjects, and need a good supply of water when growing, with a decided rest afterwards. T. tortilis needs very dry treatment, and thrives best when suspended near the glass.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Withes, Esq., Copped Hall, Epping, Essex.

Chrysanthemums. — The work of potting on Chrysanthemums from the 60-size pots into 32's (6-inch pots) should be pushed forward. For a time, after being repotted, it will be necessary to keep them in an atmosphere somewhat close, afterwards admitting air freely when they commence to root into the new soil. In preparing a suitable compost for them do not employ artificial manures at this stage.

Plumbago coccinea grandiflora is extremely valuable, whether grown for supplying flowers for cutting or for affording plants for grouping. The plants flower in November and December when there is much table decoration, &c., to be done. Cuttings taken now and inserted three or four in small pots filled with sifted peat soil and loam, will make roots quickly if plunged in a propagating-frame. They will make nice plants by the autumn, but plants two and three years old should also be grown for affording a large supply of flowers. These are now starting into growth, and the roots will be shaken out of the pots and some of the soil be got away by means of a pointed stick. The plants will be repotted in a compost consisting of loam and peat in equal parts; a little broken dried cow manure and charcoal, with silver-sand, being added. They will be stood in a house having a warm, moist atmosphere, where shade from the sun's rays can be afforded, and should be syringed frequently to prevent an attack of red-spider, to which the plants are very liable unless grown under these conditions.

Dimorphotheca Eckloni is very suitable for growing in batches for furnishing a cool conservatory. Cuttings are some time before making roots, but grow away quickly when rooted. They require pinching several times to induce a bushy habit. Several cuttings may be placed round the side of a pot. The pots should be plunged to the rims in ashes under a handlight in an intermediate-house in preference to a warm propagating-frame. A little lime-rubble mixed with loam and leaf-soil and silver-sand suits them admirably.

Kalanchoe flammea.—Plants of this useful and bright-flowering plant may be easily raised from seeds or cuttings, and by either of these methods, if carried out at different times, early and late batches of plants may be obtained. Cuttings should be inserted simply in pots and treated as advised for Dimorphotheca Eckloni. Seeds should be raised in considerable bottom-heat. When the plants are making growth they will require to be dipped frequently in "quassia extract."

Souvenir de la Malmaison Carnation.—Several of the varieties are now showing their flower-buds, and will require careful staking. The side-buds should be removed as soon as they can be conveniently handled, and care must be taken not to damage the leading or main bud in doing so. Afford the plants applications of weak liquid-manure from the farm, and occasionally sprinkle over the surface of the soil a little of Clay's Fertiliser or some fish-manure.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Vegetable-Marrows.—Plants that were raised early may now be planted on hot-beds or in portable frames which have been cleared of Asparagus. The soil employed for early plants should not be very rich, nor should it be used in excessive quantities, otherwise there will follow unfruitful growth. Artificial pollination is necessary in the case of very early Marrows. Sow seeds singly in small pots for raising plants to put out in May, but apply no water to the roots until the seedlings appear above ground. A considerable degree of heat may be employed for raising the seedlings, and when the rough leaves have been formed transfer the plants to larger pots. Induce the plants to grow quickly, but gradually harden them off before planting them out.

Turnips.—Sow seeds of the variety Early Snowball once a fortnight in light, rich, and fairly

firm soil. The drills should be made at 1 foot apart, and the seeds should be sown thinly in them. Afford frequent dustings with soot, and as the season advances choose different aspects for sowing the seeds, such as east, west, and north borders. The Turnip fly has been a plague here, and in spite of all remedies applied, until the last season, when by the use of a fine revolving sprayer for a few hours daily they were completely dispersed.

Coleworts are extremely useful in spring, autumn, and winter. Sow seeds now and again in June. A foot or so space between the plants will be quite sufficient, as they produce but small heads. The variety London Rosette is the best.

Winter Greens.—Seeds of varieties of Winter Greens should be sown thinly in drills drawn at distances of 12 inches apart, between which the hoe may be freely used. "Pricking out" of the plants will then be unnecessary. Use a fork when lifting the plants before they are planted in their permanent positions. Amongst the useful and beautiful varieties of Kale, Veitch's Exhibition and Carter's Welsh Kale should be included.

Chicory, Salsafy, and Scorzonera.—The ground prepared for Carrots is well suited for these plants, and seeds should be sown as recommended for Carrots.

Lettuce and Parsley.—Seeds of the Cabbage and Cos varieties having been sown early, and the seedlings pricked off in boxes and frames, plants have now been put out on sheltered borders, where light protection is afforded them. Plantations of Parsley are now being made from plants prepared in the same way. Seeds of Parsley have just been sown in well-prepared ground.

General Cropping.—Plant the garden generally with the object of securing for each crop its special requirements, keeping in view the general effect, and the best possible use to be made of the ground. To produce vegetables of the finest quality where space is limited intercropping has occasionally to be resorted to, and what may be termed a quick and a slow crop should be chosen to occupy the same ground without causing injury to either. For example, when planting Sea-kale or when making young beds of Asparagus, sow thinly between the lines seeds of Cabbage or of Cos Lettuce. The same applies to breadths of French Beans, and upon the ridges between the rows of celery, but in no case must overcrowding be allowed, for by the exclusion of light and air, quality and flavour are adversely affected.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Tuberous-rooted Begonias.—Tubers that have been stored during winter in a temperature of about 50° should now be put into boxes containing light rich soil and be afforded a moderate degree of heat. Young seedlings, whether of tuberous or fibrous-rooting varieties, require a temperature of 65°, and should be transplanted into boxes containing rich soil as soon as the plants require more space.

Hollyhocks, Carnations, &c.—Pots these plants, and place them in a warm frame for a few weeks.

Laying of Turf.—This work should be brought to a finish as soon as possible. Cut the turves of a uniform size and thickness. When they have been laid, work by means of a besom some fine soil into the interstices between the turves, and when the soil is in a suitable condition, beat and roll the whole surface.

Sowing Lawn Grass-seeds.—The ground will have been prepared in winter by removing the top soil, and levelling the rough subsoil to the desired formation. Then spread some finer and richer soil to the depth of about 9 ins. Be careful that the same quality of soil is applied throughout, or a patchy lawn will result. It is advisable to lay a verge of turf to define the edge. Tread and rake the soil to the proper level or slope, and leave it to settle for a short time before sowing the seeds, which should be done on a fine calm day during this month. Use a wooden rake to cover the seeds, and roll the surface afterwards at suitable intervals.

Senecio pulcher is a choice perennial plant bearing rosy-purple flowers. The plants flower late, and the best time to lift them is in autumn, when they should be removed to a cool-house, for planting-out in spring in a favourable situation. Afford the plants liberal treatment, and this may ward off the fungoid disease that attacks them. As this disease may spread from weeds in the vicinity, take care that no weeds are permitted to grow.

Incarvillea Delavayi is of easy culture, and flowers early in summer.

Tigridia pavonia requires a sunny spot sheltered from wind and well-drained, light soil, in which some well-rotted leaf-soil has been mixed. Let the bulbs be planted now, putting them 3 inches deep and 6 inches apart, and covering them with sand.

Cytisus, &c. — The species and varieties of Cytisus are useful plants for cultivation on steep banks and dry, sandy places, and may be easily raised from seeds. For producing immediate effect it is necessary to have a stock established in pots and ready for planting-out now. C. nigricans, C. biflorus, C. capitatus, are excellent; C. albus, C. scoparius, and C. s. Andreanus are all good, and flower in early summer. Genista ætnensis, and G. tinctoria var. elatior blooms later. G. anglica is a dwarf-growing species. Cytisus decumbens (prostrata) is a first-class trailing rockery plant; Spartium junceum (Genista juncea) is a favourite yellow-flowering shrub, and makes a good brave show on hillsides from July onwards; Genista hispanica, the evergreen Spanish Gorse, has conspicuously dense growth; Ulex nanus is also a desirable shrub. All the above species must be protected from rabbits.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Early Melons.—If the earliest plants obtained from seeds sown at the beginning of January have succeeded well, the fruits will shortly begin to change colour. Maintain the temperature at night at 70° or 75°, and close the house early in the afternoon, taking care to obtain plenty of atmospheric moisture until the fruits are actually changing colour, when the atmosphere should be kept slightly drier, with rather more ventilation on warm days. Gradually reduce the supply of water at the roots. Do not syringe the fruits, but do not allow the plants to become so dry as to cause the foliage to flag. Discontinue the use of liquid manures. Pot plants require most care at this stage, because sudden changes must be avoided, or the fruits will be deficient in colour and flavour. Sow seeds at intervals of about three weeks, or according to requirements, so that there will always be young plants in readiness for providing a succession. It is very necessary thoroughly to cleanse the house before setting out young plants and making up the bed, as advised in the Calendar on p. 119 in the issue for February 25. Only the top portion of the soil need be removed if there exists a proper control over the bottom-heat, and this is obtained from hot-water, but if fermenting materials have to be depended upon then fresh beds must be made.

Succession Plants.—Afford support by means of nets to the fruits of succession plants, and attend to the work of pinching and tying of the growths. Three fruits should now be allowed to mature on plants grown as cordons, planted at 1 foot apart, but four fruits may be allowed to plants growing at distances of 2 feet apart. Top-dress later plants after the fruits have set, and afford a light sprinkling of some approved quick-acting manure, also liberal supplies of liquid-manure from the farmyard, which is one of the best of all stimulants for Melon plants.

Melons in Frames.—The present is a good time to make preparations for growing Melons in pits or frames, when the frames have been cleared of early vegetables, &c. Let the hot-beds be composed of leaves and stable-litter about 4 feet deep. If good leaves are plentiful, use two parts of these to one of manure, as the heat will then be more lasting. On these beds make mounds of a compost of moderately heavy loam, wood-ashes, and a little bonemeal. This compost should be pressed firmly, in order to induce short-jointed growths in the plants. Set out one or two plants under each "light" in the frame as soon as the bottom-heat has declined to 85° or 90°. If strong, healthy young plants are not then ready sow seeds in the mounds. Cover the pits with mats at night to economise the heat. Afford a little ventilation early in the day when the weather is favourable. Take care to use slightly warmed water when syringing or watering the plants.

Tomatos.—The first trusses of fruit having set the plants may be treated more liberally by affording them applications of diluted liquid-manure from the farmyard, also an occasional sprinkling of Clay's Fertiliser. From the present time onwards the plants may be grown in any cool pit or house, provided they can be kept from cold and wet. Should white-fly make its appearance, fumigate the house lightly on one or two occasions. Avoid cultivating Tomato-plants in a very rich compost in the early stages, or strong and unfruitful growths will follow.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Strawberry Plantations. — Hoe the surface of the ground between the rows of plants, and remove all weeds. Slugs may be destroyed by applying a dressing of freshly-slaked lime or soot, repeating the application after a time if necessary, and before the beds are covered with litter. If large exhibition fruits are required a dressing of potash should be applied immediately the flower trusses appear, following this with another application when the fruit is swelling. Many of the artificial manures produce luxuriance of foliage only; these should never be given. Forced plants that have already fruited and which are intended for planting into beds for fruiting again in the autumn, should be hardened off in a cold frame, where they may remain until the end of the present month. Many growers use these early forced plants for planting their permanent beds, but a later batch of plants not so weakened by hard forcing is preferable and stronger for this purpose. If the ground has not been already prepared for planting it should be got ready at once by subjecting it to heavy manuring and trenching.

Alpine Strawberries and those of the Hautbois class can be raised from seed sown now, using boxes or pans for the purpose. When sown the seeds should be placed in a moderately warm frame, and as soon as the seedlings are sufficiently large and are considered hardy enough, "prick" them out on a shady border in the open, finally planting them in well-prepared ground. Plants raised from seeds sown last autumn will now be ready for pricking-out either into boxes or in frames. These when large enough should be planted in their permanent quarters, where they will ripen fruits this season. The variety St. Antoine de Padoue should receive a little bone-meal, which should be lightly forked into the surface soil between the rows. Allow but a small number of "runners" to remain on each plant; these will root and develop a crop of fruit this autumn, and be useful later for forming new plantations.

Arrears of Work should be made good without delay. Late-planted trees are best left unpruned until next season. All wall trees should be nailed or tied as the case may be. Old-established trees, which carried a heavy crop of fruit last year and which are now showing abundant blossoms, will be greatly benefited by copious applications of liquid-manure-water from the farmyard, or of diluted soapsuds from the laundry. The latter contain a large amount of potash. Roots growing quite near a wall, especially near those covered with a wide coping, seldom receive too much water. The soil between the trees should be lightly forked, and all parts of the fruit-garden should be made clean and tidy. Do not dig or plant crops at a distance of less than 3 feet from wall-trees, and allow a greater distance from the trees if the ground can be spared. The recent gales will probably have loosened some of the stakes supporting newly-planted trees. Make these firm, and see that none are rubbing the bark of the trees.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, APRIL 17 — Birmingham Mutual Improvement Society Meet.

TUESDAY, APR. 18 — Midland Auricula, and Midland Daffodil Society's Show at Birmingham Botanic Gardens

WEDNESDAY, APR. 19 — Royal Botanic Society's Show, Regent's Park. Glamorgan Spring Flower Show. Darlington Spring Flower Show. Croydon and District Spring Flower Show.

SALES FOR THE WEEK.

MONDAY NEXT—
Hardy Border and Herbaceous Plants, Liliums, Stove and Greenhouse Plants, &c., at 67 and 68, Cheapside, E.C., at 12 o'clock.—440 cases Japanese Liliums, &c., at 3, by Protheroe & Morris.

TUESDAY NEXT—
Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.—Twenty-two acres of Narcissus and 3 acres Herbaceous Plants, at Hammoud's Farm, West Horsley, near Guildford, by Protheroe & Morris, at 1.

WEDNESDAY NEXT—
The beneficial interest in the Lease and Goodwill of the Bedford Nursery, Haverstock Hill, N.W., Raphael *v.* Anderson, at the Mart, Tokenhouse Yard, E.C., by Mr. J. B. Slade (of Messrs. Protheroe & Morris), at 2 o'clock.—Palms, Plants, Roses, Hardy Border and Herbaceous Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Azaleas, Palms, Roses, Lilies, Gladioli, &c., at Stevens' Rooms, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —48·7°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April* 12 (6 P.M.): Max. 61°; Min. 45°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, April* 13 (10 A.M.): Bar., 29·9; Temp., 62°. Dull, with occasional sunshine.
PROVINCES.—*Wednesday, April* 12 (6 P.M.): Max. 49°, Penzance; Min. 40°, N.W. of Ireland.

Dean Hole. "HORTICULTURAL TUESDAY" is a severe tax upon many of those whose business it is to attend the numerous Committee and other meetings which are held on that day in the new Horticultural Hall or elsewhere. The whole day is taken up by a succession of Committees from early morning till evening, and even later; and of these gatherings the ordinary visitor is usually quite ignorant. One of the meetings held on Tuesday last demands a special notice here by reason of its object. This was no other than the discussion of a proposal by the authorities of the National Rose Society to establish in connection with that Society a memorial to the late Dean HOLE, who presided over its destinies from its inception till his death. The proposal is not so belated as it appears to be, for although steps were taken immediately to commemorate the late Dean's services, it was soon felt that the proposals first made were inadequate, and that a larger scheme should be put forward for the acceptance of the Rose-loving public throughout the world. As the matter is still in the committee stage, we forbear from entering into details which may hereafter be modified. Suffice it to say that the Rev. J. H. PEMBERTON has drafted a scheme, the general principles of which were accepted by the Committee, and of which the particulars will soon be made public. The scheme is catholic in its scope. In its purview are included, with one important exception, everything or anything with which the Rose-grower is likely to be concerned. The exception is that whatever prize or prizes be awarded, they shall not be adjudged to any ordinary flower-show exhibit. The desire is to lift the HOLE memorial to a higher plane than that of the exhibition-table.

Dean HOLE'S *Book of the Rose* is, after all, his best memorial, and we, in formulating our scheme, shall do well to bear in mind the broad, human sympathies which have caused that book to be the delight and companion of thousands of people who never visit a Rose show, and never read a gardening book of the ordinary character. An appeal will shortly be made to the rosarians of the world, and we doubt not that a suitable response will be forthcoming.

PELARGONIUM "CLORINDA," which forms the subject of our Supplementary Illustration in this issue, was exhibited by Messrs. CANNELL & SONS at the meeting of the Royal Horticultural Society on February 28, when it attracted considerable attention, and was generally regarded as an acquisition among useful garden plants. The plant, which belongs to the sweet-scented-leaved section, will flower the whole year round, and is as valuable for planting in the borders and beds in summer-time as it is for decorative purposes in the conservatory during the winter. The variety was raised by our old correspondent Dr. BONAVIA, of Worthing, who kindly sends us the following note regarding it:—"I began by pollinating the flowers of several Cape Pelargoniums with different pollens, and carefully ticketed every flower so pollinated with the names of the parents, but I did not obtain a single result. I grew tired of thus ticketing, and commenced to hybridise without making any record. As a result I found a single seed on Pelargonium quercifolium which resulted in this pretty variety "Clorinda"; so that the mother is P. quercifolium, but the father is not known. I was at the time using pollen of some zonal Pelargoniums, but nothing is certain as to the pollen parent. "Clorinda" is an Italian woman's name. This new Pelargonium has one interesting feature in that the flower umbels all open at the same time, and remain in good condition for a fortnight or more, but when cut and placed in water the petals begin to drop off within twenty-four hours. It is a fine trailer and a magnificent bloomer. *E. Bonavia.*"

THE ROYAL HORTICULTURAL SOCIETY.—We regretted to observe among the exhibits at the Royal Horticultural Society on Tuesday last, one completely out of character with a horticultural display, and though in itself unobjectionable yet highly incongruous. Such exhibits if permitted will decidedly vulgarise, lower the tone of the exhibitions, and disgust the legitimate exhibitors, as was, indeed, the case, as we have reason to know.

BOTANICAL MAGAZINE.—The plants figured in the April number are:—

Catasetum Christyanum, t. 8007; Reichenbach, in *Gardeners' Chronicle*, 1882, i., 588; 1895, ii., pp. 617, 618, fig. 104.

Derris albo-rubra, Hemsley, sp. nov., t. 8008.—An evergreen climber from China, belonging to the Leguminosæ. The leaves are unequally pinnate, with glabrous, oblong leaflets and long, axillary, drooping, many-flowered panicles. The short, cup-like calyx is of a red colour; the pea-shaped, fragrant corollas white, 5 to 6 lines long. It flowered profusely in the Palm-house at Kew. *D. Hancei* is also described by the same author under this heading.

Burbidgea schizostyla, t. 8009; Hackett in *Gardeners' Chronicle*, 1904, ii., 301.

Cotoneaster rotundifolia, Wallich, t. 8010.—Remarkable for its large, pear-shaped, pendulous, scarlet pomes. It is spoken of as specially desirable for winter decoration, as at Kew the "berries" survived the severe frosts and destructive fogs of the last season.

Pinanga maculata, Porte, t. 8011.—A low-growing (3½ feet) Palm, with tufted, slender, erect, jointed stems, bearing sheathing leaves near the top; each leaf oblong, deeply two-lobed to beyond the middle, light green marked with darker spots of the same colour. The small, reddish, globular flowers are thinly arranged on long, slender drooping spikes. Kew.

MONSTERA DELICIOSA: AN OFFER.—Our old and valued correspondent, Sir CHARLES STRICKLAND, writes that having a very large plant of this noble and edible fruited Aroid, for which no room can be spared, he would be glad to present portions of the plant to any of our readers who may desire to cultivate it. Sir CHAS. STRICKLAND'S address is Hildenley, Malton.

"CASSELL'S POPULAR GARDENING."—Two volumes of this publication are awaiting our notice. During its appearance as a periodical we have previously mentioned this "illustrated cultural guide for amateur and professional gardeners," to whom it should prove exceedingly useful. Mr. WALTER P. WRIGHT is its Editor, and the letterpress is enlivened with coloured plates and many other illustrations. The publishers are CASSELL & Co., LTD., London, Paris, New York, and Melbourne, who are to be congratulated on the way in which the work has been brought to a completion.

THE FRUIT INDUSTRY.—The Departmental Committee appointed by Lord ONSLOW to enquire into and report upon the Fruit Industry of Great Britain held sittings on the 5th and 6th inst. The Committee had again under their consideration the draft report prepared by the Chairman.

APPLES FROM THE CAPE.—We have received samples of Apples of high quality and in perfect condition, though lacking in colour. The Apples, so far as we can tell, appear to be different from any grown here. The average weight was between 11 and 12 oz., the flesh firm and of good flavour. If our Cape friends can send us Apples as good as these at the period when our own are practically over, they will be able to do good business in the market, for the samples sent were not only better, for the season, than our own, but are equal to the American and Canadian Apples in keeping qualities.

"SCHLICH'S MANUAL OF FORESTRY."—We note the issue (by Messrs. BRADBURY, AGNEW & Co., Ltd., 10, Bouverie Street), of a third revised edition of *Schlich's Manual of Forestry*, Vol. III., "Forest Management." Several additions have been made by the author, and these are duly explained by him in his preface. This is the standard work on the subject, and well worth the most careful study by the trained student.

APPLICATION OF SCIENTIFIC METHODS TO PRACTICE.—We hear so much of the activity of our American cousins as compared with our own inertness that it comes as a surprise to read the following extract from the *Louisiana Planter*—"We are sometimes disposed to think that our British West Indian *confrères* are a little slow in their sugar methods, and yet investigations have always shown that for decades the sugar planters of Barbados led the world so far as excellence in cane-culture was concerned; and the sugar planters of British Guiana led the world so far as excellence in the manufacture of sugar was concerned. If we are to maintain our leadership in the cane sugar industry, so far as its advancement along scientific lines is concerned, we shall need to be especially enterprising in the matter of our experimentation and ascertainment of the merits of seedling canes." The West Indies are under a great obligation to Sir DANIEL MORRIS for his successful efforts to apply scientific principles to practical work.

THE "ECKFORD" TESTIMONIAL—We are informed that upwards of 250 shillings have been received. Further donations are requested, and may be sent to Mr. H. J. WRIGHT, 32, Dault Road, Wandsworth.

Grafted and Ungrafted Vines.—There are considerable differences, according to M. Curtel, in the *Comptes Rendus*, September 12, 1904, between the fruits of grafted and of ungrafted Vines. The bunches of a grafted Vine are larger, have more berries with less thick and less defined skins; the seeds are less numerous but larger. The more abundant juice is usually both more acid and more sugary; less rich in phosphates, more charged with nitrogenous matters, with less tannin and less deep colour; the colouring is also less stable.

Lettuce.—In America it is computed that there are more than 300 varietal names, representing about 100 distinct varieties. Five hundred acres are annually planted in California alone for seed. Mr. Tracy, of the Bureau of Plant Industry of the United States Department of Agriculture, has published a valuable monograph of the Lettuces grown in America. The varieties are classed under the heads of 1, Cos; 2, Buttery; 3, Crisp. Further subdivisions are made according as the leaves are "self-closing" or "open," "cabbage-heading," and "bunching," and also according to size, period of maturity, habit, shape and colour of the individual leaves, colour of the seeds, conformation of the seedling plants, &c. Lists are given of particular varieties suited to different conditions and requirements. Analytical tables are given to facilitate the recognition of the varieties, followed by a detailed description of each admitted variety, with its synonyms; these descriptions are arranged alphabetically. A list of names, also in alphabetical sequence, is given. No fewer than twenty-seven plates are added, each devoted to the illustration of from two to five varieties. The Bulletin affords a good example of the scientific method with which our American cousins are treating all matters relating to commercial horticulture and agriculture. Application for copies should be made to the Bureau of Plant Industry, Washington, D.C.

Looking Back.—The death of Mr. William Paul, writes Mr. R. Dean, recalls the fact that he was the sole surviving member of the large Committee of the National Floricultural Society, which was founded in 1851, and which remained in existence until 1858, when the formation of a Floral Committee by the Royal Horticultural Society rendered the existence of the National Society unnecessary. Mr. Paul was a member of the first Floral Committee of the Royal Horticultural Society, of which Mr. J. Jackson Blandy was chairman; and of the thirty-four gentlemen forming that Committee the only survivors are the Rev. H. H. D'Ombrain, Dr. Masters, and Mr. H. J. Veitch. Mr. Paul was one of the twenty-one original members of the Executive Committee of the International Horticultural Exhibition and Botanical Congress held at South Kensington in 1866, afterwards supplemented by the addition of Mr. Charles Lee and Mr. H. J. Veitch. Of that body only Mr. Edward Easton, Dr. Masters, and Mr. H. J. Veitch survive, with Mr. Richard Dean, the assistant-secretary; and they all appear in the photograph of the Executive Committee which was taken by Mr. Vernon Heath. In the middle of the last century, at the old nurseries at Cheshunt, the Hollyhock was largely grown, and new varieties were raised; while the Rose was extensively cultivated and new varieties produced. I can recall, too, says Mr. Dean, "the sharp competitions with Hyacinths and single Tulips in pots, forty to fifty years ago, between Mr. W. Paul and Messrs. W. Cuthush & Son. Hyacinths *were* grown in those days. One rarely if ever sees them now with the fine development of that remote period."

International Congress of Horticulture at Liége.—We are informed that an international meeting for the discussion of matters of interest to horticulturists, both practical and scientific, will be held under the auspices of the United Horticultural Societies of Belgium at Liége, on the occasion of the Exhibition, May 8, 9, and 10, 1905. Those wishing to take part in same may obtain full particulars from the Secretary, Mons. Chas. Gonthier, 101, Rue de Statte, Huy, Belgium.

Oversea Supplies: March.—The *Board of Trade Returns* for the past month are again of a favourable nature. There is an increase in the value of imports as well as in volume, but a "boom" in exports. The situation is as follows:—Imports for March, £48,983,312: for the same period last year, £48,692,275; difference (increase), £291,037. The exports for the past month are valued at £28,070,823; for the corresponding period last year, £24,251,796—a difference of £3,819,027. Coming to the summary table of classified vegetable imports, we have the following totals:—

Imports: Description of Produce.	1904.	1905.	Difference.
	£	£	£
Class I. — Cereals, and other field crops — Wheat, Barley, Oats, &c.	6,352,359	6,846,996	+494,637
Class II.—All other food cultures — Tea, Coffee, Fruit, &c.	4,813,186	4,322,028	−491,158
Class III.—Used in manufactures — clothing, household goods, &c....	6,305,760	5,700,915	−604,845
Class IV. — Miscellaneous — including seeds, flowers, &c.	1,937,245	1,924,665	−12,580
Values of Produce...	19,408,550	18,794,604	−613,946

In connection with Class II. we have some items affecting Truffle cultivation, pointing to an increased oversea trade in this esculent. The Consul-General at Naples informs us that two Italian botanists (Prof. Mattei and Dr. Serra) have patented a mycelium which is to make the growing of Truffles an easy achievement and profitable. In cut flowers we have to note an increase of £3,377 in value, the figures for March being £50,637 against £47,260 for March, 1904. The influx of fruit from the Antipodes at the present season adds interest to our table of imports for March, as follows:—

Imports—March.	1904.	1905.	Difference.
	£	£	£
Fruits, raw—			
Apples	238,826	156,666	−82,160
Apricots and Peaches	745	491	−254
Bananas	98,128	101,007	+2,879
Grapes	3,791	4,979	+1,188
Lemons...	32,593	31,464	−1,129
Nuts—Almonds ...	31,243	30,059	−1,184
Others used as fruit	42,552	51,996	+9,444
Oranges...	304 273	385,689	+81,416
Pears	2,659	1,254	−1,405
Plums	1,468	1,130	−338
Unenumerated ...	8,265	9,506	+1,241
Vegetables, raw—			
Onions ... ...bush.	100,112	85,286	−14,826
Potatos ... ... cwt.	250,750	27,257	−223,493
Tomatos ... ,,	76,079	102,745	+26,666
Unenumerated ,,	53,789	48,926	−4,863
Totals ...	1,245,273	1,038,455	−206,818

The arrivals of fruit from the Cape during the past month, as forwarded to us by the Union Castle Steamship Company, are as follows:—Plums, 2,913 cases; Pears, 2,098; Grapes, 4,224; Nectarines, 427; Peaches, 402; Tomatos, 14; Pineapples, 5; Apples, 61; Melons, 8; and Apricots, 1 case—a total of 10,183 packages. Of Raisins and Currants imported last month the record is £40,798—a gain of £24,854 over the same period last year.

Forests, Wild and Cultivated. — Dr. Henry, who was unable to see a proof of our report of his lecture at the Horticultural Club, published on p. 221, writes us as follows:—"Tropical trees are characterised by slight branching, which is only carried out to the second or third order. Temperate trees, on the contrary, branch to the fifth, sixth, and seventh order, and show delicate sprays and thin terminal twigs, in great contrast to the coarse terminal twigs of many tropical trees. The exact height of the Quercus Ilex mentioned is 86 feet. The Pinus insignis referred to is 95 feet high, with a girth of stem of 14 feet 4 inches. The biggest specimen of Hornbeam occurs in Co. Kerry. In describing French forestry, 'bush' stage is not the correct term, 'thicket' stage is better, referring to the period when young trees are growing thickly together, and have not begun to 'clean' their stems. The paragraph regarding my criticism on forestry in this country and picturesque old Oaks conveys a wrong impression of what I intended to say. I advocated planting in large masses, not in thin belts, and attention to the forest soil, and I did not consider decaying and diseased old trees, with which there were no historical associations, picturesque in the least. Many old Oaks in sound condition are very picturesque."

Seedsman as High Sheriff.—Many of our readers will be interested to learn that Mr. Edward Webb, of the firm of Edward Webb & Sons, Wordsley, Stourbridge, has been appointed High Sheriff of the County of Worcester.

"Garden-Colour."—We have received from Messrs. Dent & Co. a copy of a work under this title, consisting of water-colour sketches by Miss Margaret Waterfield, with descriptive notes by Mrs. C. W. Earle, E. V. B., Rose Kingsley, and the Hon. Vicary Gibbs, etc., etc., the "etc., etc." including an article on "Rose Culture" by Mr. Mount. We shall take an early opportunity of adverting to this interesting volume. The price of the book is 21*s*.

Spring Flowers at Belvoir Castle.—Our correspondent, Mr. W. H. Divers, informs us that the recent cold weather will delay some of the spring flowers considerably, but has done them no serious injury. Hyacinths, Polyanthus, Aubrietias in variety, Arabis, and many others are commencing to bloom. The best time to see the full display will be during the last week of April and the first week in May. We may add that the flower gardens are open to the public daily without charge.

Publications Received.—*Transactions and Proceedings of the Botanical Society of Edinburgh.* Session 68. Contents: Drosera bulbigena from W. Australia, by Dr. Morrison. Preliminary Report on the Batony of Captain Dowding's Colombian Expedition, by T. Sprague. Botanical Visit to the Balearic Islands, by J. White. Origin of Lenticels (with illustration), by J. A. Terras. Notes from the Royal Botanic Garden, Edinburgh, February.—*History of the Garden and Principal Gardener; Science and Practice of Horticulture, Farmer's Handbook*, by Thomas Jamieson, Director of the Aberdeenshire Agricultural Research Association. A record, fully illustrated, of Experiments and Observations made by the Association from 1875 to 1903. The conclusions, carefully sought and fully verified, seem justly entitled to command the confidence of farmers and to prove of valuable assistance to them.—From Cambridge University Department of Agriculture, Farmers' Bulletin, No. 3: *The Potato Crop.* Report on Experiments conducted at Burgoyne's (Univerity) Farm in 1903 and 1904. The best of the newer main crops was Dobbie's Factor, the best new second early was Findlay's Royal Kidney, the Potatos most disease-resisting were Sutton's Discovery and Findlay's Evergood. The value of a change of seed must depend on the conditions of growth of the particular sets, and no general conclusions are attempted.—From the same University: *The Improvement of Poor Pastures.* Report on an experiment at Cransley, Northamptonshire, 1901 3. Basic slag proved valuable as favouring the growth of Clover. "When the farmer begins improving his land he must think only of the Clovers, and the whole plan of manuring must be designed to encourage them.—Also from Cambridge: *Report on Experiments carried out at Bramford and Saxmundham by the East Suffolk Education Committee.* The experiments dealt with soil improvement and management of pastures.—From the County Council for the County Palatine of Lancaster, Education Committee, Agricultural Department: *An Experiment on Manuring Potatos and on Planting*

Potatos at Different Distances apart. In the latter trials it was found that for large, free-growing and late varieties of Potatos the best distance apart for planting the seed was from 18 to 24 inches.—Technical Instruction under the Worcestershire County Council: *Reports of the Experimental Garden, Droitwich, and the County Instruction Gardens for* 1904.—*Bird Notes and News*, April.—From the Imperial Department of Agriculture for the West Indies: *Seedling and other Canes in the Leeward Islands.*—*The Queensland Agricultural Journal*, February. Contents: Grafting the Mango, by D. O'Connor; Contributions to the Flora of Queensland, F. M. Bailey; General Notes on Stock, &c.—*The Agricultural Gazette of New South Wales*, February. Contents: Myall Creek Estate, Information for Persons desirous of obtaining Land, Orchard, Dairy and Stock Notes, &c.—*The Agricultural Journal of the Cape of Good Hope*, March. Contents: Extra-tropical Forestry (illustrated), by D. E. Hutchins; Irrigation in the N.W.. Destruction of Locusts, by C. W. Mally; Salt Bushes (illustrated), by Dr. Nobbs.—*Annual Report of the Secretary for Agriculture, Nova Scotia*, 9-4. The season was not generally favourable for crops. The growth of agricultural societies and of their work was marvellous. The unfavourable season has not discouraged growers as it succeeded several more prosperous years.—*The Indian Forester*, January. Contents; Forests of Eucalyptus marginata, by Dr. Deils; Lumber Industry of Lake Huron, by Col. G. F. Pearson; Madras Forest Members' Tour in Anantapur; also, on a separate leaflet, Water yielding Plants found in the Thana Forests, by G. M. Ryan.—*The History and Culture of Grafted Roses for Forcing*, by Alexander Montgomery. Reprinted from the *Florists' Review* (Chicago).—College of Agriculture Agricultural Experiment Station, University of California: *Commercial Fertilizers*, by George Roberts.—From the Librairie Horticole, Rue de Grenelle, 84 bis, Paris, come the following useful pamphlets: *Les Peupliers*, Espèces, multiplication, culture, exposition, maladies, ventes, usages, par J. Beaumont.—*Les Plantes Alimentaires Indigènes*, par Georges Gibault; and *Les Plantes Médicinales Indigènes leur utilisation dans la médicine populaire*, par G. Gibault et J. Bouyssous.—*Les Œillets, culture des Œillets à la grand fleur*, par S. Mottet (2od edition).—*L'Ornementation Florale des Jardins*, par Albert Maumené. Revue descriptive et analytique de l'Ornementation estivale des Jardins publics de Paris, en 1904, &c. Avec 65 figures.—*Flore Descriptive et Illustrée de la France*, par l'Abbé H. Coste. Tome 3me., Fasc, 3, avec figures 3159-3343.—*Le Chrysanthème*, March. Contents: Notes on new Chrysanthemums, List of varieties cultivated in France during 1905 (continued), &c.—*Queen-rearing in England, and Notes on a Scent-producing Organ in the Worker Bee; the Honey-Bees of India and Enemies of the Bees in South Africa.* By F. W. Sladen. A useful illustrated pamphlet by a well-known authority.—*Agricultural Bulletin of the Straits and Federated Malay States*, January. Edited by H. N. Ridley. Contents: Planting Para Rubber in Johore, R. W. Burgess; Mangrove Swamps in the Federated States, H. Furnivall; Casuarina equisetifolia, its Cultivation and Treatment, R. D. Hudson, &c.—*Proceedings of the Agri-Horticultural Society of Madras*, October to December, 1904. Contents: Agavo Poling, Agave Fibre Experiments, &c.—*Report of the Conservator of Forests, Natal*, January 1903 to June 1904. The work done includes the entire reconstruction of the Forest Service. Demarcation of 15,904 acres of best forests, and inspection of most of the forests, nursery work, construction of arboretum, &c.—*Bulletin du Jardin Impérial Botanique de St. Petersbourg*, Tome V., Livraison 1. Contents: Lettres de Voyage, M. B. Fedtschenko; Frage des Polymorphismus von Evernia furfuracea, M. Elenkin; Nouvelles espèces de la flore du Turkestan. M. Fedtschenko.—From the Central Experimental Farm, Ottawa, Canada: *Results obtained in* 1904 *from Trial Plots of Grain, Fodder Corn, Field Roots, and Potatos*, by William Saunders and C. E. Saunders (Bulletin No. 48).

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—The remarks of a "A Fellow" in your issue of March 4 in my opinion demand an expression of opinion on the other side, as I cannot help thinking that they are dictated from a very narrow point of view. If it were true that not one Fellow in a thousand is able to read the Journal through, so much the worse for the immense majority implied. I venture to think that the assumption that only eight or nine Fellows in all, for that is the logical deduction, not only study it thoroughly, but appreciate it greatly, is a gross reflection upon the body generally. The Journal represents as far as practicable a record both of "up-to-date" horticultural knowledge and of the proceedings of the Society and its Committees, hence it is bound to deal with many branches, and every specialist is entitled to expect to find his particular cult represented, not merely in a condensed form, but *in extenso* with full details. This need being met, it of course results that outsiders, so to speak, that is, Fellows without any special cult of their own, may find much of the matter uninteresting, but it by no means follows that the Journal should be brought down to their level. It can only be such who object to the Journal on the score of its bulk, while I am sure there are very many of the other class who hold entirely opposite views, and regard it as a rich mine of information of the right kind throughout, and consequently recognise with gratitude the immense amount of labour and pains devoted to its publication by its editor, the Rev. W. Wilks. It is not usual to complain of getting too much for one's money, but this is practically what "A Fellow" does, and I am glad that I am not the only one to enter a protest against his views as expressed, since if they were adopted I and many others would be much the poorer. The cost of the recent issue was naturally increased by its special character as a centennial record, as well as one of nearly a year's work; it is absurd to multiply this by three to estimate the cost of three ordinary issues dealing with shorter periods. Neither does it follow at all that the £1,200 mentioned in the balance-sheet relates to this issue alone. The only point in which I agree to some extent with "A Fellow" is with regard to the uncut issue. Many, I think, in these busy days would prefer a cut one, but as the bibliophile differs from this view for æsthetic reasons, perhaps it might be possible to meet both views by issue of cut (guillotined) copies to such Fellows as expressed a desire for such to the Secretary. *Chas. T. Druery, V.M.H., F.L.S.*

[When some time since we took the opinion of our subscribers on the question of whether our own pages should be issued "cut" or "uncut," an overwhelming majority expressed their opinions in favour of the "guillotine," and this in spite of the greatly superior appearance of the uncut copies. ED.]

ARRANGEMENTS AT THE ROYAL HORTICULTURAL SOCIETY.—In the case of the Hon. J. H. Turner's lecture at a recent meeting of the Royal Horticutural Society I think some of the audience did not show the respect to the lecturer that he deserved for so interesting a lecture and the lantern-slides he exhibited. Almost before he had finished there was a quite a stampede to get out. I think the Chairman should have inquired if anyone wanted to ask any questions, before moving a vote of thanks to the lecturer. Would it not be advisable to have more lights on the stairs from the lecture-room and the lower regions, which were quite in darkness at 3 P.M.? *John Carvile, F.R.H.S.*

[The publication of this letter has been unavoidably delayed, but it is still applicable. It would be an improvement if the lecture table were placed at the opposite end of the room. Those who wish to leave could then do so without disturbing the lecturer. ED.]

ANTI-DRIP APPLIANCES.—We have been greatly interested in this correspondence, and are surprised that so many gardeners adopt a construction that gives them so much trouble. The anti-drip bar adopted in all our constructions, and referred to by more than one of your correspondents, overcomes the disadvantages and inconvenience caused by drip. We agree that its application to existing houses is a difficult matter, but we cannot understand why so many seem to prefer patching-up a defective rafter than the adoption of the right system in the first instance; a good article at the outset is the cheapest in the long run. *Foster & Pearson, Beeston, Notts.*

MANURE FOR PEACH-TREES.—I read with much interest Mr. C. W. Muir's answer to "A Reader" on p. 202. I cannot agree with Mr. Muir in applying manure-water to Peach-trees all the year round. Peach-trees certainly require a period of rest, and the roots are not so active in winter as many gardeners maintain. During the winter months many Peach-borders are made sour and sodden and their value destroyed for the coming season by applying manure-water when there is not enough root action to absorb the same. When the tree is in full growth I should even then be careful when applying manure-water, and would make a close examination of this or that particular tree, and apply the manure-water as my observation would direct. I am a firm believer in the value of manure-water; but I fear there is much harm done in many cases by want of discretion when the liquid is applied. It is a common thing in many gardens to have set days for feeding Peach-houses and Vineries. In the case of a large Peach-house, where there are many trees and also many varieties, the observant gardener will see the necessity of using his discretion when applying the stimulant. Would Mr. Muir apply manure-water to a healthy tree bearing no fruit, in the expectation of building-up a good constitution for obtaining the desired crop in the following year? I am afraid his labour would be in vain. I believe in keeping the surface of Peach borders well forked, and not allowing them to become hard. Of course care must be taken not to destroy the roots in forking. This practice helps to keep the border sweet, and at the same time admits warmth, which is so beneficial to Peach roots. *W. Campbell, Brahan Castle Gardens, Canonbridge.*

PEACH BUD DROPPING.—For a number of years back much has been written on Peach bud dropping, and from the numerous articles that have recently appeared in the *Gardeners' Chronicle* it is clear that the real cause is not yet understood. Many years ago, when the *Scottish Gardener* was in circulation, a gardener of good standing and a frequent writer in the gardening press expressed the opinion that the cause arose from the Peach-house being filled all the autumn with Chrysanthemums, but beyond this he gave little or no further explanation as to how he accounted for the Chrysanthemums affecting the buds in such a way as to cause them to drop. Recently another writer stated that the watering of the plants in the Peach-house with manure-water (the water from the plants getting into the border) was probably the reason. Then another contributor asserted that dryness at the roots was not the cause. Let us consider what goes on outside in nature. To the shrewd and the intelligent this is an acceptable guide to go by in all matters relating to cultivation under glass. We never hear of Peach buds dropping off trees cultivated out-of-doors; and why is this? Just because the trees are fully exposed to all weathers, and when they are at rest and leafless they have most wet both at root and top. This fact of itself should be convincing proof that the course adopted in cultivating Peach-trees under glass is evidently not in accordance with their natural requirements. Dryness at the roots and a dry atmosphere together are the source of this species of bud-dropping. The Peach-house filled with Chrysanthemums all the autumn and well into the winter has to do with it, inasmuch as there are no proper means of getting the borders thoroughly moistened so as to preserve the roots of the trees in that plump fresh state they should be in to keep them all alive and in health. The pipes having to be kept warm to keep a circulation of dry air among the plants to preserve the Chrysanthemum blooms from damping, the soil becomes dry immediately about where the principal feeding roots are, and before this dryness is discovered great injury to the roots may happen. Suppose the surface of the border may seem wet, this is no evidence that the soil is sufficiently wet underneath It should be borne in mind that the fibrous roots, that are so fine that they can scarcely be seen by the naked eye, are the main feeders, absorbing the watery elements from the soil. Now if the soil is dry, this process of absorption cannot go on, hence the whole energies of the tree flag from contraction. It would be rather out of place to syringe Peach trees indoors through the winter; still, to do so, the trees would be getting nothing more in the way of moisture than the trees outside get. The bark of the tree is a breathing organ, and the plump, fresh state of the buds is much impaired by any obstruction to breathing, whether from drought or other cause; and when in this state the buds part readily from their setting in the branches. Hence Peach bud dropping. *Andrew Kemp, Coolhurst Gardens, Horsham.*

POTATO PLANTING.—Mr. Jefferies' statement on p. 218 respecting his somewhat different method of planting Potatos to that recommended by me occasions no surprise, because, roughly speaking, out of something like 200 allotments cultivated by *employés* upon this estate, and within a mile radius of these gardens, I question if ten could be found who do the work of planting with any marked degree of similarity. Yet, like those obtained by Mr. Jefferies and myself, the general results are fairly satisfactory. The use of the dibber, however, has been discontinued in

ninety-nine cases out of the hundred. It is more than thirty years since I used the dibber as described by Mr. Jefferies, and I have no intention of re-introducing that instrument to these gardens. Mr. Jefferies' letter tends to show how astonishingly the Potato can adapt itself to the treatment accorded it. "Trouble" is a wrong word to apply to work done properly. *W. Fyfe.*

CARBOLIC ACID AS A REMEDY FOR "SPOT" IN CUCUMBERS (CERCOSPORA MELONIS).—Carbolic acid (phenol) has valuable germicidal properties, but it is usually believed to be only a mild fungicide. At Swanley Horticultural College the present head gardener is a thoroughly good, practical man, although without any scientific pretensions. His general cultural methods are so excellent that the plants under his care have the best opportunities to resist disease and pests. They are therefore to a great extent immune, and when attacked a somewhat mild preventive or remedy is sufficient to quite turn the balance in their favour. The special remedy or rather preventive [for Cucumber "spot"] is a mixture of the contents of a pint bottle of No. 5 Calvert's carbolic acid with 5 quarts of water. The path of the house is watered with this mixture just before shutting up the house in the evening. Last Wednesday (April 5) a house, 1200 cubic feet, containing Cucumber plants 3 to 4 feet high, was treated with a quarter of a pint of the fluid mixed with one quart of water. I was in this house at 3.30 P.M. on Thursday, and again at 4.30 P.M. on Friday in last week. Even on Friday the odour was very unpleasantly strong, yet no ill effect whatever could be detected on the plants. I was informed that some seedlings which were intentionally placed in contact with the solution had been killed. This damping is done weekly as a preventive, but the mixture is applied at about one-half the strength described above. Some houses have been weekly sprayed with liver-of-sulphur (K_2S), 1 ounce to 2½ galls. of water; but it is believed that the carbolic acid is the better method. Anyhow, since above treatment has been adopted, "spot" has been practically absent. When, however, any indications have appeared, the affected parts have been removed and burned, and the preventive measures adopted. Probably good cultural methods are largely the cause of the immunity from disease, but the treatment is worthy of trial, although nothing can rectify the ill effects of persistent bad culture. *F. J. B.*

—— May I take the opportunity of answering through your columns the numerous enquiries I have received regarding the proper quantity of carbolic acid to use for houses of different cubic capacities. For a house of 4,000 cubic feet I have found ½-pint of carbolic do very well. A stronger dose could only be applied to plants which are very sturdy and robust. After the house has been treated to the first application, if upon a close inspection twenty-four hours later the spot continues to spread, then give another application slightly weaker than the first. This should be continued if the spot has got a firm hold, but if it is taken in time one application should prove sufficient. As a preventive a slightly weaker solution could be used about once a week during the cropping season. On the morning following the application let the plants be syringed vigorously with plain water. *Jas. Lawson, Head Gardener, Swanley Hort. College.*

MARKET GROWERS' DAFFODILS.—What is the use of raising a "Peter Barr" Daffodil when in twenty years' time a coster in the streets of London will sell twelve of its blooms for 2*d.*? The aim of growers and raisers of new sorts should be to try and provide for the public taste, and give the many an early-flowering one. Size does not matter much with the West-end florist if he can give his customer a bloom for 6*d.* in November and December. *An Irish Grower.*

APPLE LORD BURGHLEY.—I have grown this Apple for many years, but beyond its late-keeping qualities there is little to say in its favour. At the time when I read Mr. Easter's note in the *Gardeners' Chronicle* I had just received some very fine specimens of this Apple from a gardener in the Eastern Counties famed for his hardy fruit culture. In view of Mr. Easter's note I took a deep interest in tasting the specimens received. The fruit was of full size, and especially well coloured. I found the flesh hard, and the flavour was comparable to that of uncooked Rhubarb! *E. M., South Hants.*

DISEASED JAPANESE LARCH.—On p. 209 of the *Gardeners' Chronicle* Mr. Simpson made some interesting remarks on the Japanese Larch. While agreeing with Mr. Simpson that diseased examples are difficult to find, still they are to be discovered. Quite recently I was one of a party which had the pleasure of inspecting some of the plantations on the Dunkeld estate of the Duke of Atholl. Among the many interesting objects to be seen was a thriving plantation about ten years old, which, with the exception of half a dozen trees of the common Larch, was entirely composed of the Japanese variety. In one part of this plantation we found a considerable number of diseased trees. I myself counted seven or eight within a radius of 20 yards. This is the first occasion on which I have seen disease on Japanese Larch, but if foresters persist in mixing it with common Larch I fail to see how it can escape. One great objection to the Japanese Larch in this district is the frequency with which it loses its leader. *C. McDonald, Methven, Perth.*

PINUS INSIGNIS.—We have some trees here which were planted eighteen years ago, and they measure 5, 6, and 7 feet round the base of stem. Is this a satisfactory growth? *Ireland.*

LAW NOTE.

PECULIAR POINT UNDER THE MARKET GARDENERS' ACT.

AT Brentford County Court recently, before his Honour Judge Shortt, K.C., an arbitration under the Agricultural Holdings and Market Gardeners' Acts was heard, in which John Smith, of Chiswick, was claimant, and his Grace the Duke of Devonshire respondent.

The matter came before the Court by way of points of law raised in the award of the umpire between the parties. Mr. Bremner, in dealing with the special case, stated that the claimant, since 1888, was a tenant of 235 acres of market-garden land at Chiswick under leases of 1888 and 1899 from the Duke of Devonshire, and he claimed compensation under the Market Gardeners' Act of 1895 in respect of valuable improvements made upon the devised land by planting and setting out of fruit-trees. The leases had some years to run, but the landlord reserved the power to resume possession of the land, and he had exercised that power. The leases provided for certain allowances being made to the tenant, and by a clause in each there was to be no allowance or compensation for improvements. The arbitrator had found certain amounts due to the claimant under the leases, but added that he would be entitled to a great deal more if he could avail himself of the benefits of the Act of 1895. Counsel contended that this Act superseded all prior leases, and there could be no power to contract out of it, that the respondent had not, as he should have done, exercised his power of dissent to any improvements, and that therefore, notwithstanding the leases, the claimant was entitled to come in and receive compensation according to the scale which the enactment granted.

For the respondent it was urged that the claimant could not be paid twice over for compensation. He had already received some under his lease, and he was barred therefore from coming in under the Act.

Mr. Bremner replied that the lease was made under the Agricultural Holdings Act of 1883, but this was over-ridden by the Act of 1895, and any leases were subject to the latter Act.

His Honour reserved judgment. The point, he believed, was an entirely new one under the Act of 1895, and he should have to look very closely into it, because it must have a very important bearing on leases of market-gardens.

On Friday, April 7, the Judge delivered judgment as follows:—

His Honour said that the leases were explicit, and so also was the Act of 1895. But he considered the applicant could not claim under both, and as he had made a claim under the leases and received an award, he could not attempt to come in under the Act. He therefore found for the respondent with costs. As the point was new, he gave leave to appeal if necessary.

SOCIETIES.

THE ROYAL HORTICULTURAL.

APRIL 11.—The usual fortnightly meeting of the Committees was held on the above date in the new Hall in Vincent Square, when a very large display of exhibits was made.

THE ORCHID COMMITTEE recommended two First-class Certificates and five Awards of Merit.

The FLORAL COMMITTEE recommended six Awards of Merit, and among the numerous groups and displays was one by Messrs. CUTBUSH & SONS, of a large rockery planted with Alpine plants. This was carried out on a scale such as is seldom seen at merely temporary exhibitions, and a Gold Medal was appropriately awarded to the exhibitors.

The FRUIT AND VEGETABLE COMMITTEE recommended a First-class Certificate to Potato "Syon House."

The NARCISSUS COMMITTEE recommended one First-class Certificate and two Awards of Merit.

At the meeting of the SCIENTIFIC COMMITTEE some letters were read on the subject of deterioration of Potatos. These are printed below.

At the general meeting of Fellows, a number of candidates were elected as Fellows, and a lecture on "Retarded Potatos" was read by Mr. T. J. POWELL, Park Place Gardens, Henley-on-Thames.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. Jno. Green, W. Bain, R. Hooper Pearson, Jno. Jennings, J. F. McLeod, H. J. Cuthush, J. W. Barr, W. Howe, Chas. Dixon, Chas. Jeffries, R. C. Notcutt, Chas. E. Pearson, W. Cuthbertson, C. E. Shea, W. P. Thomson, E. H. Jenkins, M. J. James, Ed. Mawley, E. T. Cook, R. W. Wallace, and George Paul.

Messrs. WM. CUTBUSH & SONS, Highgate, London, N., showed what appeared to be a large portion of a well-arranged rockery, the representation being admirable, and one of the best displays ever attempted with this class of plants. The background was high, and was furnished with Conifers, hardy flowering shrubs, climbers on rustic branches, Magnolias, &c., while numbers of "pockets" arranged throughout the exhibit were furnished with many kinds of alpine and hardy plants in season. A bog and water-garden found a site near the front portion of the display, furnished with suitable subjects, Marsh Marigolds, Irises, Aponogeton distachyon, &c. Hardy Orchids were a feature in the display, Cypripedium spectabile, C. acaule, C. Calceolus, C. debile, Calanthe discolor, Bletia hyacinthina, &c. Primulas were represented in numerous species, while hardy Ferns were interspersed among the group in many favourable positions. Aubrietias, Anemones, Liliums, Hepaticas, Ranunculus, Saxifrages, Veronicas, and a host of similar subjects were to be seen in flower, and the whole arrangement was executed on a well-designed plan (Gold Medal).

Messrs. CUTBUSH also displayed on an adjacent table a collection of Ericas.

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, put up one of the showiest groups in the Hall in the form of a collection of forced flowered shrubs and other plants. This was a strikingly bright exhibit, and one that was much admired. The group included Lilacs, Wistarias, and species of Ribes, Prunus and Pyrus, Laburnums, Spiræas, Azaleas, &c. A batch of species and varieties of Magnolia in the centre of the display was magnificent. Maples, Ferns, and other foliage plants increased the effect, and the manner of arrangement was all that could be desired (Silver-gilt Flora Medal).

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., displayed a large group of forced shrubs, &c., Azaleas, Lilacs, Ribes, Gueldre Roses, and other

plants that are utilised for early forcing (Silver Banksian Medal).

Sir Trevor Lawrence, Burford, Dorking (gr., Mr. Bain), staged a group of Anthuriums, mainly improved forms of A. Scherzerianum. Many of the spathes were of rich scarlet colour and of large size, varying in shape from linear to ovate. Other plants carried spotted bracts, the groundwork being white with splashes of red. A few plants of A. Andreanum were included in the group (Silver-gilt Flora Medal).

H. L. Bischoffsheim, Esq., Stanmore, Middlesex (gr., Mr. C. J. Ellis), also displayed a number of plants of Anthurium Scherzerianum. The flowers made a pretty display, and were pleasingly set off by Ferns, Panicum plicatum, Palms, &c. (Silver Flora Medal).

Mr. Geo. Mount, The Rose Nurseries, Canterbury, displayed a superb collection of cut Roses. There were large groups of the varieties Frau Karl Druschki, Mrs. John Laing, Catherine Mermet, Ben Cant, and Ulrich Brunner staged in vases and boxes, every flower a specimen, while other boxes contained numerous miscellaneous varieties, all excellently shown (Silver-gilt Flora Medal).

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, contributed an extensive exhibit of Ferns and Begonias. The Ferns were nearly all specimen plants of rare and choice species, while the Begonias were of the Rex type, small plants in 60 pots, and well adapted for decorative purposes (Silver Flora Medal).

Sir F. T. Barry, Bart., M.P., St. Leonard's Hill, Windsor, Berks (gr., Mr. Robert Brown), sent a remarkable collection of Camellia flowers cut from plants growing in the open-air. Many varieties were included (Silver Banksian Medal).

Messrs. H. Cannell & Sons, Swanley, Kent, displayed an extensive collection of Zonal Pelargonium flowers in vases, similar to those staged by them at the two previous meetings. A few "show" varieties were included. Messrs. Cannell also exhibited a choice collection of Cacti, among which Mammillaria Stella-aurata was shown in flower (Silver Flora Medal).

Mr. A. F. Dutton, Iver, Bucks, exhibited vases of cut Carnations, principally of the "Tree" varieties. The flowers were excellent examples, rich in colour, large in size, and of good form, and included some of the best varieties. An imposing batch of the soft blush-coloured variety Enchantress occupied the central position, the flowers being as large as those of the "Malmaison" type. Other varieties included Mrs. Thos. W. Lawson, Flamingo, Lady Bountiful, Fair Maid, Melba, and Harlowarden (see Awards) (Silver-gilt Banksian Medal).

Messrs. Gilbert & Sons, Bourne, Lincolnshire, showed a pretty exhibit of Anemones very similar to their group of these flowers shown at the last meeting. Many types and species were shown, including the lovely A. Pulsatilla, the pleasing St. Brigid varieties in many colours, the delicate A. apennina of the purest blue colour, grand specimens of A. fulgens, &c.

Sir A. Harmsworth, Bart., Sutton Place, Guildford (gr., Mr. J. Goatley), set up a large group of Cinerarias of the "stellata" type. The plants were staged on the floor of the hall, and were arranged so as to slope from the back to the front, which was edged with decorative plants (Silver-gilt Banksian Medal).

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, exhibited a mixed collection of plants—pans containing well-flowered examples of Corydalis Wilsoni (see *Gardeners' Chronicle*, May 14, 1904), also a plant in flower of Tillandsia Lindeni with its rich blue flowers, Crowea angustifolia, Clerodendron myrmecophilum, Pentapterygium (Vaccinium) serpens, and a batch of Gloxinia asminiflora. Messrs. Veitch & Sons also showed a beautiful batch of Xanthoceras sorbifolia, and one of Hydrangea Hortensia, with flowers of a very pronounced blue colour. Adjoining the latter were plants of Azalea (Rhododendron) Yodogama, Amygdalus persica, with double pink flowers; Cerasus pseudo-Cerasus "J. H. Veitch," profusely flowered; the new Senecio auriculatissimus, &c. (Silver Banksian Medal).

Messrs. John Peed & Sons, Roupell Park Nurseries, Roupell Park, exhibited a light-coloured Caladium named Golden King.

F. A. Bevan, Esq., Trent Park, New Barnet (gr., Mr. Parr), staged a batch of a light rosy-coloured Verbena with fragrant flowers, also greenhouse plants, Anthurium Scherzerianum, Begonia Rex, Palms, &c.

Mr. Richard Anker, Addison Nursery, Napier Road, Kensington, brought tiny Ericas and Rhododendrons flowering in miniature pots, &c. The same firm also showed a batch of pot plants of Myrtles.

Messrs. Dobbie & Co., Nurserymen, Rothesay, Scotland, exhibited a collection of Pansy and Viola flowers. The Violas were displayed in vases arranged on a staging, while the Pansies were exhibited on boards and with paper collars. Several new seedling varieties were shown among the Violas: Lizzie Storer (dark purple with upper petals shading to light heliotrope); Mrs. Lindsay (white with a violet edge), Effie (white ground with purple rays and edge). Emmie Bateman is a new Pansy of large size; Mrs. Campbell has an edging of deep rich yellow colour (Silver Banksian Medal).

Mr. Jas. Douglas, Edenside, Great Bookham, Surrey, brought two dozen Auriculas. The plants were of first-class quality, and included several seedlings, to three of which awards were granted.

Mr. John R. Box, West Wickham, Kent, put up an imposing exhibit of plants of Begonia Gloire de Sceaux. The plants were trained as pyramids, and all were carrying a profusion of flowers.

Messrs. R. Wallace & Co., Kilnfield Nurseries, Colchester, exhibited alpine plants, including Fritillaria pudica, F. armena rubra, Trillium sessile, Tulipa Clusiana, &c. (Silver Banksian Medal).

The Misses Hopkins, Mere, Knutsford, Cheshire, displayed a small collection of alpine plants.

Messrs. John Peed & Sons, West Norwood, London, also staged alpine and hardy plants in pans and boxes. Anemone apennina was shown well.

Messrs. Jackman & Son, Woking, in addition to showing flowers of Narcissus, had also alpine and hardy plants in flower. Prominent features were Euphorbia Wulfeni, varieties of Primula Sieboldi, &c.

Messrs. T. S. Ware, Ltd. (1902), had an exhibit, in which Primula Sieboldi was again the most noticeable constituent.

Mr. G. Reuthe, Keston, Kent, showed some excellent flowers of Rhododendron Thompsonianum, cut from the open garden, also flowers of Camellia reticulata; and among plants in pots several species of terrestrial Orchids, Erythoniums, &c.

Messrs. W. & J. Brown, Peterborough and Stamford, exhibited Dimorphotheca Eckloni, Verbena Miss Willmott, Rose Dorothy Perkins, &c., all flowering in pots.

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, exhibited cut flowers of varieties of Carnations, including Coronation, Flamingo, America, Mrs. T. W. Lawson, &c., and varieties of the "Souvenir de la Malmaison" type (Silver Banksian Medal).

Mr. S. Mortimer, Rowledge Nurseries, Farnham, Surrey, exhibited a group of Polyanthus plants that had been lifted from the open ground. They were profusely flowered and extremely varied in colour the strain being one of much merit.

About seventy excellent flowers of Gardenia florida intermedia were shown from the Earl of Clarendon's garden, The Grove, Watford, Herts. (gr. Mr. C. Harris). These were arranged with plenty of good foliage in glass vases, three flowers in each, and the perfume from them was naturally very considerable. The flowers had been cut from pot plants two years old and bearing five or six dozen flowers on each plant (Silver Banksian Medal).

Messrs. W. Paul & Son, Waltham Cross Nurseries, Herts, exhibited a few Rose-plants in pots, the varieties being Étoile de France, Perle des Jaunes, and Celia. The first-named variety is a H.P., which has been described in very appreciative terms, but has too much purple tint in the red flowers to please the majority of Rose-growers. Celia is a new H.T. variety, raised by Messrs. W. Paul & Son; it has pink-coloured flowers, and may prove to be a valuable acquisition. Cut flowers were again shown of the very brightly coloured Rose Warrior. This is of glorious colour, and while resembling Papa Gontier is very much richer in colour than that variety. Plants that were forced early are now flowering for the second time.

Awards of Merit.

Anthurium Scherzerianum burfordiense. — This magnificent variety has been raised in Sir Trevor Lawrence's garden at Burford, Dorking (gr., Mr. Bain). The spathes measure 4½ inches broad and are 5½ inches long, and in colour are of richest scarlet.

Auricula "Daffodil."—This is a bright yellow coloured "self" with white "paste," and possesses good form.

Auricula Favourite.—A purple "self" with white "paste," the flowers being of considerable size and good form.

Auricula Standard Bearer.—This alpine Auricula is of purple colour, which becomes rather paler towards the margin of the petals. The flowers have a white centre, and are good in size and form. All of these varieties and others were shown by Mr. Jas. Douglas, Edenside Nurseries, Great Bookham.

Carnation Harlowarden.—A tree variety with large, rich crimson-coloured flowers, good petals, and a moderate degree of perfume. The petals are fringed, the calyx remains good, and the colour is exceptional. Shown by Messrs. T. S. Ware (1902), Ltd., Feltham, and by Mr. A. F. Dutton (Award of Merit).

Corydalis Wilsoni. — This species was introduced from China by Messrs. Jas. Veitch & Sons through Mr. E. H. Wilson. It was described in the *Gardeners' Chronicle*, 1903, ii., p. 123, and an illustration was published in the issue for May 14, 1904, p. 306. The flowers are racemose, of deep yellow colour keeled with green. Shown by Messrs. Jas. Veitch & Sons.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), W. A. Bilney, R. Brooman-White, De B. Crawshay, N. C. Cookson, J. Douglas, Francis Wellesley, R. G. Thwaites, H. G. Morris, W. H. White, H. T. Pitt, A. A. McBean, G. F. Moore, W. Boxall, W. H. Young, J. W. Potter, W. Cobb, H. Little, H. Ballantine, F. J. Thorne, H. A. Tracy, F. W. Ashton, J. Charlesworth, and H. J. Veitch.

Messrs. Sander & Sons, St. Albans and Bruges, were awarded a Silver Flora Medal for a very showy and interesting group, the principal feature in which consisted in some grand examples of hybrid Odontoglossums raised at Bruges. Specially remarkable were Odontoglossum × Harryano-crispum Jewel, a very beautiful hybrid raised from O. Harryanum (seed-parent) × O. crispum, spotted variety. The reverse cross O. × crispo-Harryanum King Edward, with the spotted O. crispum as seed-parent, was still more remarkable, the large richly-marked flowers inclining in colour to that of O. crispum, even to the toothed edges to the segments, and surpassing most of the blotched O. crispum in colour. Flowers over 5 inches across diagonally, creamy-white, beautifully marked with purple at the back, and heavily marked with rose-purple on the surface. Other fine hybrids were O. × Wilckeanum "Japan" and O. × amœnum Sander's variety. Among showy Cattleyas were good C. Schröderæ, one remarkable form named splendidissima having blush-white flowers, the labellum being white with a glowing mauve-purple blotch with orange disc. Other varieties noted were Eulophia Lubbersiana, with pretty white-and-green leaves and singular flowers; Maxillaria Sanderiana, a fine tuft of the yellow Dendrobium capillipes, good Lycaste Skinneri, hybrid Phaius, &c.

Messrs. Charlesworth & Co., Heaton, Bradford, were awarded a Silver Flora Medal for an important group containing a good selection of Odontoglossum crispum. In the centre of the group was a number of the showy orange-and-crimson-coloured Lælio-Cattleya × Cappei, and at intervals good forms of Cattleya × Empress Frederick, C. × Enid, several Brasso-Cattleyas, including the clear white B.-C. Dighyano-Mossiæ Queen Alexandra. Several forms of Lælio-Cattleya × Mercia, L.-C. × Myra, L.-C. × Wellsiana, Masdevallia Schroderiana, good Odontoglossum × Harryano-crispum, a fine specimen of Coryanthes speciosa with three large buds, the rare clear yellow Odontoglossum Lindeni, two good examples of the fine Brassia brachiata, Dendrobium × Apollo album, and other Dendrobiums and Cypripediums.

H. S. Goodson, Esq., Fairlawn, Putney (gr., Mr. G. E. Day), obtained a Silver Flora Medal for a group, in which good forms of Cattleya Schröderæ C. Trianæ, C. Mendeli, and Odontoglossum crispum were the feature. Grouped with them were two specimens of Cymbidium Lowianum, several good specimens of different varieties of Phaius × Norman, P. Sanderianus, a large and peculiarly-marked light form of Cattleya Warscewiczii; the white C. intermedia nivea, a specimen of the white Chysis bractescens, Cypripedium Argus, C. tonsum, and other Cypripediums; Epidendrum × elegantulum, Oncidium concolor, Dendrobium atro-violaceum, &c.

Messrs. Hugh Low & Co., Enfield, were awarded a Silver Banksian Medal for a group comprising varieties of Cattleya Trianæ and Odontoglossum crispum, one of which was effectively spotted. Also Cattleya Lawrenceana with twelve flowers, C. × Lawre-Mossiæ, Cypripedium × vexillarum, C. × Olivia, C. Lawrenceanum Hyeanum Vanner's variety, Angræcum citratum, Eria ohesa with many spikes, Oncidium

barbatum, Trichopilia suavis, and Dendrobium Falconeri giganteum.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), staged a very interesting group, in the centre of which was a superbly-grown plant of Odontoglossum ramosissimum Burford variety (see Awards). With it were the rare and singular Masdevallia deorsa, with long drooping leaves and pretty yellow-and-purple flower; the elegant little Pleurothallis astrophora, and P. Grobyi; a very rich yellow-and-crimson coloured Lælio-Cattleya × Myra, Tetramicra bicolor, the rich scarlet Epidendrum × O'Brienianum superbum, and E. Schomburgkii; the orange-yellow E. × radico-xanthina, the rose-coloured E. × Ellisianum, E. evectum, E. Linkianum, Miltonia × Bleuana nobilior, and the singular Epicattleya × Gaskello-Parkinsoni.

Jeremiah Coleman, Esq., Gatton Park (gr. Mr. W. P. Bound), showed a group of Epidendrum × Boundii, the plants together bearing over sixty heads of bright-yellow flowers tinted with scarlet. The specimens had been in bloom since October last, and some after cutting the original spikes produced fresh heads of bloom. A very pretty, useful and floriferous hybrid.

Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Cattleya amethystoglossa Westfield variety, dwarf in habit and bearing good blush-white flowers spotted with purple.

Messrs. Cutbush & Son, Highgate Nurseries, sent Calanthe discolor aurea, a hardy Japanese species with greenish-yellow flowers.

Awards.

First-class Certificate.

Odontoglossum ramosissimum Burford variety, from Sir Trevor Lawrence, Bart.—A very fine form with branched spike bearing about eighty pure white flowers spotted with purple on the inner halves of the segments, which were much broader than in the type, and wavy at the edges.

Odontoglossum × *Wiganianum* (× Wilckeanum × Rolfeæ), from Sir Frederick Wigan, Bart. (gr., Mr. W. H. Young).—A very fine hybrid with the large, flat labellum and fine shape which O. Pescatorei imparts to all hybrids in which it is an agent. Sepals and petals bright canary-yellow, the sepals bearing several large dark red-brown blotches, and the petals with many smaller spots on the inner area. Lip broadly ovate oblong, apiculate, white at the base, primrose-yellow in front, and bearing in the middle a few purple spots. It is derived from hybrids on both sides, O. Pescatorei, O. Harryanum, O. crispum, and O. luteo-purpureum entering into its composition, and the result is highly satisfactory.

Awards of Merit.

Odontoglossum × *amanum Sander's variety* (Pescatorei × luteo-purpureum sceptrum), from Messrs. Sander & Sons.—A great improvement raised at their Bruges establishment. Flowers of fine substance, creamy-white, prettily marked with dark purple-brown.

Zygopetalum discolor atro-caruleum, from Messrs. Sander & Sons.—A large-flowered form with creamy-white sepals and petals, the latter being tinged with violet. Lip broad, violet-blue, with a divided white crest at the base.

Odontoglossum crispum Britain's Queen, from H. T. Pitt, Esq., Stamford Hill (gr., Mr. Thurgood).—A fine flower, with broad, fringed segments heavily tinged with purple at the back. Sepals and petals equally blotched with rose-purple and tinged with lilac.

Epidendrum × *Boundii* (radicans × Burtoni [O'Brienianum × Ibaguense]), from Jeremiah Colman, Esq. (gr., Mr. W. P. Bound).—Stems ascending, 2 to 4 feet. Flowers in almost globose terminal heads, bright yellow tinged with scarlet, and varying somewhat in tint with the age of the flowers. A most floriferous, almost perpetual-blooming hybrid.

Dendrobium fimbriatum oculatum Westonbirt variety, from Captain G. L. Holford, C.I.E., Westonbirt (gr., Mr. Alexander).—A major form of the fine old species, and fully one-third larger than any previously known. The finely-grown specimen had many drooping racemes of large rich yellow flowers, with dark maroon disc to the fringed labellum.

Narcissus Committee.

Present: Mr. H. B. May (Chairman), and Messrs. A. R. Goodwin, W. P. M. Copeland, J. T. Bennett-Poe, Jas. Walker, W. Poupart, E. A. Bowles, P. R. Barr, W. W. Foster, A. Kingsmill, W. T. Ware, W. A. Milner, R. Sydenham, Miss E. Willmott, Chas. T. Digby, J. D. Pearson, G. H. Engleheart, J. Pope, G. Reuthe, R. Wallace, Chas. H. Curtis.

Messrs. Pope & Son, King's Norton, Birmingham, showed some good varieties. Among others were Southern Star, White Queen, Torch (with rich flamed cup), Pope's Surprise (a good yellow), Ajax, Excelsior (yellow self), White Lady, &c. There were also some good seedlings in this display, one named King's Norton having a large trumpet (see Awards) (Silver Banksian Medal).

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, exhibited a small group of choice Narcissus, in addition to several well-known varieties (Silver Banksian Medal).

Mr. G. Reuthe, Keston, Kent, contributed such kinds as Victoria, Incomparabilis Beauty, Lucifer, Fairy Queen, and others.

Miss Willmott, Warley Place, Great Warley, brought a number of the yellow Hoop-Petticoat kinds, Narcissus Bulbocodium, to show the variation in bulbs collected in various localities.

Mr. Chas. Dawson, Gulval, Penzance, exhibited a choice assortment of good and novel kinds. The quality of the flowers shown was of the highest standard. We noticed Homespun, Viking, a large, drooping flower resembling N. grandis; Bernardino, colour pale apricot and orange; Peveril and Cavalier, both with richly coloured crowns; Dawn, a flat-crowned flower of the Engleheartii type, with two and sometimes three flowers in a scape (Silver Flora Medal).

Miss F. W. Currie, Lismore, Ireland, put up a large exhibit, having such good things as Duke of Bedford, Maggie May, King Alfred, White Queen, Flamingo, Goldeye, Lady Margaret Boscawen, &c. (Silver-gilt Flora Medal).

Mrs. Backhouse, Sutton Court, Hereford, had, in addition to Lord Kitchener (see Awards), Dewdrop, a most exquisite flower with a biscuit-hued, orange-tipped crown. Also Snowdon, and Zingara, a Leedsii variety with a scarlet-orange cup (Bronze Flora Medal).

The Rev. G. H. Engleheart, Dinton, Salisbury, had many choice kinds—Will Scarlet, Electra, an incomparabilis of pale lemon colour; Glitter, an improved Barri conspicua; Hector, a big bicolor; Charlemagne, with spreading, open segments; Chaucer, a fine flower of the Poeticus type, and others (Silver Flora Medal).

Messrs. R. H. Bath, Ltd., had a large and good exhibit. Kings Norton was seen in plenty, while Duke of Bedford, White Queen, King Alfred, Lady Margaret Boscawen, Silver Spur, Flambeau, Argent, and others gave ample evidence of the up-to-date character of this fine lot (Silver-gilt Flora Medal).

Messrs. Barr & Sons, Covent Garden, contributed a choice collection—Peter Barr, Monarch, Cleopatra, Big Ben (fine yellow), Queen Isobelle, Isolde (a big bicolor), Apricot, Peach, Lucifer, Weardale Perfection, &c. (Silver Flora Medal).

Messrs. Hogg & Robertson staged a very fine lot of flowers, in which White Wings, Flambeau, Lady Arnott, Lady Margaret Boscawen, Duke of Bedford, Brigadier, and others were seen to advantage (Silver Flora Medal).

Messrs. Wm. Bull & Sons, Chelsea, staged an assortment of well-known commercial kinds in bunches.

Awards.

Narcissus King's Norton.—A giant yellow Ajax variety of great proportions. The large spreading crown or trumpet represented, we believe, the largest yet known in these flowers. From Messrs. Pope & Sons, King's Norton, Birmingham (First-class Certificate).

Narcissus Lord Kitchener.—This is a fine bicolor of the Sir Watkin type, the prettily-goffered crown being of large size, and varying in colour from lemon to palest sulphur. It is a most beautiful and very distinct sort. From Mrs. Backhouse, Sutton Court, Hereford (Award of Merit).

Narcissus Alice Knight.—This is a white Ajax, the much reflexed trumpet passing from sulphur to creamy-buff colour. It is quite intermediate in size, and does not appear to be an improved type or variety. From Messrs. Barr & Sons, Covent Garden (Award of Merit).

Fruit and Vegetable Committee.

Present: Joseph Cheal, Esq., in the chair; and Messrs. J. McIndoe, W. Bates, S. Mortimer, A. Dean, W. Pope, W. Parr, Geo. Kelf, H. J. Wright, H. Markham, Jno. Lyne, Geo. Reynolds, F. Q. Lane, Geo. Norman, Owen Thomas, Geo. Wythes, and Rev. W. Wilks.

Messrs. Robert Veitch & Son, Royal Nursery, Exeter, exhibited a so-called coreless Apple, but the fruit we cut through had a distinct but small core, although no seeds were present (Vote of Thanks).

Mr. John Garland, Broadclyst, Exeter, exhibited a seedling Apple.

Some excellent fruits of Royal Sovereign Strawberry were shown by Mr. H. J. Dover, Langley Fruit Gardens, Slough (Cultural Commendation).

Mr. F. Collis, Bollo Lane, Chiswick, exhibited a bundle of Rhubarb, with a very dark-coloured petiole, named "Collis Ruby." It was recommended that plants be sent to Wisley for trial and comparison with existing varieties.

Awards.

Potato "Syon House Prolific."—This well-known Potato was raised by Mr. Geo. Wythes, gardener to the Duke of Northumberland, and received an Award of Merit as far back as September 10, 1895. The tuber is rough-skinned and of oval shape. In consideration of its good qualities the Committee has now awarded the variety a First-class Certificate.

Excellent tubers were shown in twelve baskets by Mr. J. B. Joel, Potter's Bar (Silver Banksian Medal).

Lecture on Retarded Potatos.

The lecture was by Mr. Powell, gardener to Mrs. Noble, Park Place, Henley-on-Thames. It consisted of an explanation of the methods by which a supply of New Potato tubers is obtained from September until February or even March. The procedure, briefly stated, is as follows: The tubers are selected when lifting is done in August or October, according to the season of the variety. These tubers are then stored in a dry place in a temperature of 45°, and when any growths appear they are rubbed off before they have had time seriously to reduce the amount of nutriment and moisture in the old tubers. In the following July early varieties like Windsor Castle, having been hindered from making growth for so long a time, cease the attempt, and in place of this, in August, they produce fresh tubers, apparently as another and final effort made by the tubers to reproduce themselves. Mr. Powell said that it was not necessary to keep the tubers in a lower temperature than 45°, but it was extremely important that the growth they make previous to the following August be removed very early. At Park Place by repeated experiments this method of Potato cultivation has been reduced to a proper system, and by this means, and forcing in spring, new tubers are now obtained in every month of the year. The old tubers are treated in various ways when they are about to produce fresh tubers; some are put out-of-doors, others indoors, and are covered with a little dry earth or leaf-mould. The variety Windsor Castle is the best to begin with.

Mr. Powell showed new tubers on Tuesday from old tubers which are now seventeen months old, but they have been produced some little time and would not "scrape." They had been saved for the purpose of illustrating the lecture. Cooked samples were pronounced to be of excellent flavour. Tubers seventeen months old were also shown, but had now ceased to produce new ones.

Mr. Arthur W. Sutton said he had watched the experiments at Park Place for several years. He was sure that the system would become more widely practised, the only hindrance to this being apparently its very simplicity. A member of the audience suggested that the variety "Challenge," owing to its compact habit of growth, &c., would make a very suitable variety for such treatment, and said he had used it in this way.

Scientific Committee.

Do Potato Stocks Deteriorate?

April 11.—Dr. Masters, F.R.S., in the chair, and a numerous attendance. The following communications, of which time did not permit the consideration at the former meeting, were read on this occasion:—

Mr. Burbidge.—This is a wide question and has been discussed ever since the late Thos. Andrew Knight, Esq., wrote his *Treatise on the Apple and Pear*, in 1797. It was, I believe, Knight's first book, a small octavo, and is now rather rare. It is a common belief amongst gardeners that varieties do deteriorate or go back in gardens. This I myself do not believe is true if they are well, wisely, and properly cultivated. Deterioration is very often, even if not always, the result of bad culture, senility, or neglect. It is, moreover, due in many cases to growing the same variety too long on the same soil, and to the use of too much manure.

With Potatos this is especially the case; but no Potato as a variety deteriorates on good soils if the seed or sets are changed, or obtained from a different soil and climate every year. The old Ashleaf Kidney Potato is as old as most Potatos, and is still one of the best. The craze for novelty and competition in the trade often lead to good old varieties being superseded by new seedlings or selections, or by old kinds of known excellence being again sent out under new names. Varieties may deteriorate locally, i.e., when badly grown on unsuitable soils or under adverse conditions, but no one can prove that varieties like the Black Hamburgh Grape, Royal George Peach, Moor Park Apricot, Ne Plus Ultra Pea, General Jacqueminot Rose, Old Clove Carnation, ever deteriorate as varieties all over the area of their cultivation. Did anyone ever hear of any variety of Banana, Pine-apple or seedless Grape ever wearing out? Do Osier Willows ever wear out? Varieties may be neglected and weakened by being planted too constantly on the same soil or in unsuitable localities; they may also be renamed or superseded by novel kinds being "boomed" over their heads, so to say; but no variety fairly well grown on fresh and suitable soil ever dies out. No one variety grows or is as productive on all soils alike; but the best varieties are very adaptive, and their produce averages out well on all soils.

Most of the Figs, Mulberries and Grapes grown to-day are practically those known for centuries. Brown Turkey or White Ischia Figs, the Zante Currant Grape, Black Monukka Grape, Bananas, Pine-Apples and other seedless fruits increased vegetatively are as healthy and productive to-day as they have ever been. Of course, the words "a variety" often means that we are dealing with a group of distinct individuals and not with a multitude of individuals precisely alike. Good culture, continual change of soil and rigid selection are all necessary to keep at their best "varieties" so called, and under such conditions I do not admit that the deterioration or wearing out of varieties ever takes place in either gardens or in the fields. In Professor Hugo De Vries work, *Species and Varieties: Their Origin by Mutation*, in which book some aspects of this subject are ably dealt with, it is shown that any crop of either corn or roots, consists of individuals of varying vitality or productiveness. This makes selection possible. There are certain individuals in every crop, as in every flock or herd, that can either utilise more food than others, or that in any case are more productive than are others under the same conditions. The simple art of selection enables the gardener or farmer to improve the best varieties or strains by continual selection. Some individuals in any variety or strain may show a retrograde tendency, and these are eliminated, so as to give added opportunity to the best and most productive individuals, and in this manner the variety is improved and its life ensured. In a word, varieties are constant or ever improving only under the best conditions of cultivation. By the same token they will deteriorate only if neglected and grown under bad conditions. *F. W. Burbidge, Dublin.*

Mr. Clarke: It is a fact that the Potato does deteriorate. It is not wise to grow the same stock for more than two years. We find in this district that the further north we get our seed from the better it is. It is generally considered that the second years' crop gives better results, but at any rate it is not wise to grow the same variety more than two years on one farm. I should not say that after being grown, say, here two years and then moved some miles away, that it would increase in vigour. It might probably grow as well for two seasons and then it would be exhausted. It is a good change from this country on to the black soils, but will not do to come from there to here again, and I think that where the tubers have been grown on black land the better plan is to use the seed for cattle or pigs and get a fresh stock. My experience is that the worn-out stocks take the disease more quickly than others. I am afraid that we shall find that the newer varieties are very tender. I am still a great believer in the spray when properly applied. I think I was one of the first to take it up, and I well remember the opposition encountered. I was in Bedfordshire just putting them in the way how to employ the spray—I think in 1894—when an old gentleman came up to me and said: "Mr. Clarke, I think you are trifling with Providence." That was one instance. Now spraying is general, but it is not half done—hence a good deal of disappointment. *Westmère, Sutton Bridge.*

Mr. Fraser: It has always been reckoned good practice in this district to change "seed" Potatos after a few years, getting seed from a different class of soil if not from another locality. Soil seems to have as much to do with degeneration as climate, or more, and round here we have a great variety of soils—clay that in some seasons is almost unworkable, various gradations and combinations of loam, sand, and gravel, besides black, mouldy soils and peaty soils. We have also within this small county wide differences of climate, including rainfall. Thus, without going far from home, we can have a decided change of locality. It is considered desirable to get seed from a higher district, which means a moister as well as a colder and later climate. Thus, we had British Queen from an up-country farm, say, 600 feet above sea level, planted last season on light gravelly soil on this farm at between 80 and 90 feet. The variety did exceptionally well, but it was from a good farm and was a fine sample to begin with. Potatos from a dry soil are not looked on with favour for "seed," and in the case of such soils it seems to be necessary to change frequently, every two or three years at least, otherwise the leaves grow curly and stunted, and the plant does not properly develop.

Seed from Ross-shire has been found to do well in Morayshire, but so also has seed from Forfarshire. Ross-shire has a considerably moister climate than Morayshire, but not much colder, if at all, at the same elevation. The soil of Ross-shire is, I should think, the richer in general. Forfarshire is agriculturally one of the finest counties in Scotland.

Certain varieties of Potatos seem more liable to degenerate than others. A gardener of some experience tells me that he has grown Snowdrop (or Snowflake perhaps he meant) for ten years, and that he has them still as good as at first.

As a matter of common experience Potatos seem to degenerate by continuous planting in the same class of soil, but there may be contributory causes, such as selecting "seed" from the dressings of the marketed Potatos. I heard just lately of a farmer near here who has stuck to the same stock for I do not know how many years—say fifteen to twenty—with the result that his Potatos are now like "marbles," and this on one of the finest farms in the county.

The Victoria, which became common in this district in the seventies, when the sorts formerly grown suffered badly from disease, was very successful for a number of years, but degenerated in time both as a cropper and in disease-resisting power, and has long been out of cultivation. The Magnum Bonum, which was introduced somewhat later, so far as I remember, kept up better as a cropper, and continued comparatively free from disease, but it was never a favourite on the table at home unless for use in spring, not being "dry" enough. It sold comparatively well, probably on account of its shape and keeping qualities. The Bruce took the place of the Magnum, being somewhat similar in character, but I do not think it was ever so good a cropper, and it has now given place to newer varieties. The Up-to-Date seems to have something of the character of these two last, and does not appear to have degenerated as yet.

As to whether a variety that had lost some of its vigour would regain it by being transferred from the South of England to Scotland, I do not know of the experiment having been tried. I should think there is at least a probability of improvement if soil and locality be properly chosen. The duration of a variety depends largely on its power to resist disease and its place on the market, along with its capabilities as a cropper. For disease-resisting power it has been found necessary from time to time to obtain new varieties, and when new varieties have found favour on the market, they have naturally displaced the old on that account alone. *Alex. Fraser, Lecky Hill, Forres.*

Prof. Henslow: Whether Potatos "deteriorate" in value is a question of trade; but that they vary according to the soil and climate of the localities where a particular variety is grown is well established. Prof. Bailey has given a good example in the case of the Newtown Pippin (*The Survival of the Unlike*, p. 99): "It originated upon Long Island, N.Y., and has been widely disseminated by grafting. In Virginia it has varied into a form known as Albemarle Pippin, and a New York Apple exporter tells me that it is a poorer shipper than the northern Newtown, and is not so long-keeping. In the extreme north-western States . . . it is markedly unlike the eastern fruit. . . . In New South Wales it is called the Five-crowned Pippin," &c. Conversely with the Chilian Strawberry: "Within two years this plant, growing in my garden, varied from its wild type so widely as to be indistinguishable from the common garden Strawberry . . . an instructive case of sexless evolution." Professor Bailey then adds: "Any plant which is widely distributed by man by means of cuttings or other vegetative parts may be expected to vary in the same manner."

The above seems to me to answer the question. In many cases by departing from the typical characters the variety might be said to "deteriorate"; but there is also the chance of its acquiring something new, which might balance its value. There does not appear to be any evidence of a variety "dying out" in any other sense. *Geo. Henslow.*

Prof. Scott Elliot: There are two cases in which there is distinct evidence of deterioration in vegetatively reproduced plants. First, the Sugar-cane, which has until the last few years been invariably propagated by non-sexual methods. Its culture dates back to a period so distant that the priests in India had had time to produce an "observed" law—viz, that "if any cultivator saw a cane in flower he would die within the year, his house would be reduced to beggary, and his entire fortune be destroyed." The cultivation has been carried on in very distant parts of the earth, under totally distinct methods, and in widely varying conditions of soil, climate, and exposure. Yet deterioration has been complained of in every part where its cultivation is of importance. And the West Indian Agricultural Conference of 1905 seems to agree that it is to be remedied by using seedling canes.

Another example is the Canadian weed, Elodea canadensis, which escaped from a botanical garden in Germany, and at once spread by vegetative reproduction only all over temperate Europe. For many years it was a curse to all canals, ponds, lakes, &c., and involved very expensive cleaning; but of recent years, though it is by no means extinct, it is certainly not so serious an evil. In small enclosed ponds, after having been a perfect pest for some years, it suddenly begins to dwindle, and may almost totally disappear. A case of this sort came under my own observation in a small pond at the Glasgow Botanical Gardens, where it is now almost extinct, though some five or six years ago it choked the whole of the rest of the vegetation. This case is specially interesting as it is not a cultivated plant, and is one of that hardy band of freshwater plants which are more widely distributed than any other class of plants known to me.

A very strong argument in favour of deterioration is the general statistical evidence. Out of some 700,000 flowering plants described, there is not one single case known to me of a plant which does not endeavour to reproduce by seed, although arrangements for vegetative reproduction are exceedingly common. Many plants which we do not, as a rule, look upon as vegetative reproducers habitually form underground stolons, rhizomes, &c., and are much more rarely formed from seed.

The answer to the second part of the question is probably a very simple one—Old Age. However much the method of vegetative reproduction varies, the new plant is merely a part of the old one. A Potato grown from a tuber is not a new individual but a part of the original individual. A close examination of bulbs, corms, rhizomes, suckers, stolons, &c., reveals essentially similar methods of branching, which are made different by the different parts in which the food-store is laid up. The differences, such as they are, have been made much more difficult to understand by the misdirected labours of conscientious botanists.

That old age is the primary cause I have personally no doubt at all. We know on good evidence (see Bonnier *Traité du Botanique*) of trees 2,000 years old, not to speak of one kind only, but belonging to several genera. It is not necessary to cite the American Mammoth tree of 3,300 years, or the Canary Island Dragon tree of 10,000 years, and which was probably the original of the Greek myth.

The number of years during which any species can be shown to have been always propagated vegetatively cannot surely attain 2,000 years except possibly the Sugar-cane and the Vine, and in both these cases deterioration has set in. Old age is the reason generally given in both these cases.

Of course, all cultivated plants are grown under quite unnatural conditions. The brilliant sunshine and long, dry season of Chile are quite different from our insular climate. Cultivation under exceptionally favourable conditions must inevitably weaken the

constitution of man, beast, or vegetable, unless all our evolutionary theories are hopelessly wrong. Most cultivated plants must suffer from the absence of a struggle for existence and from one-sided selection. It might be possible to delay the deterioration by severe treatment, by change of soil and climate, and other methods. The survivors after such a treatment should be more vigorous than any selected at random for propagation.

A plant has an organised, correlated body, and reacts distinctly to change of climate. This reaction involves a one-sided development. I fail to see how a flowering plant can escape the common enemy—old age. Where are the Potatos of thirty years ago? *G. F. Scott Elliot.*

DETERIORATION OF VARIETIES OF POTATOS.

At the meeting of the Scientific Committee on Tuesday, March 28, I seem to have been understood to have stated that as good yield of Potatos can be obtained without abundance of nitrate nitrogen as with. There can be no doubt that a well-balanced manure, containing abundance of available (nitrate) nitrogen as well as phosphates, potash, &c., is essential for a heavy yield, but I wished to show that disease was frequently more abundant in these forced crops. A slight deficiency of nitrate nitrogen, with an abundance of phosphates, potash and lime, although materially decreasing the yield, conduces to stamina and partial immunity from disease and less deterioration, and tubers grown thus are much more suitable for seed purposes. I can produce considerable evidence to this effect. I shall be glad to know others are honestly trying to verify or disprove this statement. *F. J. Baker.*

THE CORNWALL DAFFODIL AND SPRING FLOWER.

April 4.—This Society opened a most successful show in the Market Hall, Truro, on the above date. Since the Society's inception nine years ago each show has marked an improvement on that preceding it, and in the one now under notice the number of seedling Narcissi not in commerce that were exhibited, many of which were of high order of merit, was remarkable. The arrangements, thanks to the indefatigable zeal of the honorary secretary the Hon. John Boscawen, left no loophole for complaint on the part either of exhibitors or public.

Twenty-two classes were devoted to Narcissus. In twelve no limit was placed on the price of the bulbs, and in these some specially fine flowers were staged. In the unrestricted classes the results were as follows.

In the best collection of not fewer than thirty or more than forty varieties of Daffodils, the 1st prize was awarded to Mr. J. C. Williams, with twenty-eight unnamed seedlings, and Monarch, Incognita, White Queen, Armorel, White Lady, Pilgrim and King Alfred. Many of the seedlings were very fine.

Six varieties Magni-coronati: 1st prize, Mr. P. D. Williams, with Homespun (a beautiful clear yellow of perfect form), Ringdove, White Lady, Peregrine, Lucifer (hard to beat), and Miss Mary.

Three varieties Leedsii: 1st prize, Mr P. D. Williams, with Tern, Seagull, and White Queen.

Six varieties Parvi-coronati: 1st prize, Mr. P. D. Williams, with Incognita, Horace, Dawn, Blood Orange, Circlet, and Oriflamme, a very bright stand.

Finest bloom of Magni-coronati in commerce: 1st prize, Rev. A. T. Boscawen, with King Alfred; 2nd prize, Mr. C. Dawson, with Mme. de Graaff; 3rd prize, Mr. P. D. Williams, with N. maximus.

Finest bloom of Medio-coronati in commerce: 1st prize, Mr. P. D. Williams, with Homespun; 2nd prize, Mr. C. Dawson, with the same; 3rd prize, Mr. H. G. Hawker, with Lucifer.

Finest bloom of Parvi-coronati in commerce: 1st prize, Mr. P. D. Williams. All the prizes in this class were won with Horace, the finest of the Poeticus section.

Finest bloom of Magni-coronati not in commerce: 1st prize, Mr. P. D. Williams, with Averil, a seedling from Victoria, a well-shaped flower with white perianth and pale-yellow trumpet. Mr. P. D. Williams also showed Spoonbill, a very large flower with white perianth and spreading trumpet 2½ inches across.

Finest bloom of Medio-coronati not in commerce: 1st prize, Mr. P. D. Williams, with Peregrine, a flower of perfect form with white perianth and sulphur cup; 2nd prize, Mr. J. C. Williams, with a rich yellow self. 3rd prize, Mr. P. D. Williams, with a pretty flower having a white perianth and fawn-coloured cup.

Finest bloom of Parvi-coronati not in commerce: 1st prize, Mr. J. Williams, with a fine Poeticus with circular perianth and scarlet crown. 2nd prize, Mr. J. C. Williams, with another Poeticus, having a spreading yellow crown margined with scarlet. 3rd prize, Mr. J. C. Williams, with White Star, a most beautiful flower, by some thought the gem of the show, with a shapely white perianth over 4 inches across, and a flat yellow crown 1¼ inch in diameter.

In eight classes, which were filled, the price of the bulbs was limited to 10s., and in one for children to 1s.

Lady Margaret Boscawen's 1st prize stand of Poppy Anemones was particularly fine. Anemone fulgens, Polyanthus and Primroses were largely shown.

Mr. P. D. Williams was awarded the 1st prize for a collection of hardy herbaceous flowers; and the Rev. A. T. Boscawen the 1st prize for a collection of hardy bulbous flowers, his stand containing Watsonia coccinea, brilliant in colour, and three good Fritillarias.

Violets were splendidly shown, Mrs. J. C. Williams receiving a Cultural Commendation for enormous La France, which took the 1st prize in the class for one variety of singles.

Rhododendrons, as usual at Truro, contributed much to the brightness of the show. In the class for the best group of blooms, Mr. D. H. Shilson easily took 1st prize with an excellent collection, including R. Griffithianum (very early), Duke of Cornwall, eximium, Thomsoni, barbatum, Shilsoni, grande, and many arboreum varieties.

Mr. Shilson also won the 1st prize in the classes for six trusses of outdoor Rhododendrons, and for six trusses of greenhouse Rhododendrons.

For the finest truss of outdoor Rhododendron Mr. R. Fox won the 1st prize with Glory of Penjerrick; Mr. Jonathan Rashleigh taking 2nd prize with R. barbatum.

Mr. J. C. Daubuz took 1st prize for the best truss of greenhouse Rhododendron.

For six varieties of Camellias, Mrs. John Williams won the 1st prize.

Four entries were staged for the finest cut bloom of Camellia, all the exhibitors showing C. reticulata. The 1st prize was won by Rev. A. T. Boscawen with a splendid flower over 7 inches across.

The two classes for outdoor, hard-wood flowering shrubs produced a wonderful display that few not acquainted with the possibilities of Cornwall would have deemed possible in the first week of April. Among the specimens shown were Embothrium coccineum, Boronia megastigma, Acacia longifolia, A. floribunda, A. cordifolia, Eriostemon neriifolium, Polygala myrtifolia, Cestrum elegans, C. fasciculatum, Viburnum rugosum, Grevillea sulphurea, G. rosmarinifolia, Clianthus puniceus, Cytisus racemosus, Clematis indivisa lobata, Melianthus major, Xanthoceras sorbifolia, and several Magnolias.

In the class for twenty varieties of these the 1st prize was awarded to Sir A. Pendarves Vivian.

An Award of Merit was given to the Hon. John Boscawen for Primrose Evelyn Arkwright; and a Cultural Commendation to Mr. A. Blenkinsop for three remarkably fine flowers of Narcissus Homer.

Col. Tremayne, Carclew, contributed (not for competition) a fine group of flowering shrubs, and two plants of the beautiful Rhododendron Nuttalli in full bloom. Mr. P. J. Kendall showed six vases of King Alfred Narcissus; and Mr. C. Dawson, Rosemorran, Gulval, a number of splendid examples of the fine poeticus Horace.

Nurserymen.

Messrs. Robert Veitch & Son, Exeter; the Devon Rosery, Torquay; Messrs. Wallace & Co., Colchester; Messrs. Barr & Sons, and Mr. G. Reuthe, Keston, contributed attractive stands, and all were awarded the Society's Certificate of Merit.

Messrs. R. Veitch & Son showed Rehmannia angulata, said to be hardy in the south-west; Kalanchoe flammea, K. kewensis, Gnidia carinata, Jasminum primulinum, Calceolaria Burbidgei, Primula floribunda, P. Isabellina, P. kewensis ×, P. verticillata, a fine collection of Magnolia species and varieties, of which M. Kobus, a native of Japan, where it grows to a height of 60 or 70 feet, was given an Award of Merit. The flowers of this plant are pure white, about 4 inches across, and sweetly scented.

The Devon Rosery staged a fine collection of pot Roses in bloom, some hundreds of cut Roses, Carnations, Azaleas, and other plants.

Messrs. Wallace & Co. exhibited Gerbera Jamesoni, the perpetual-flowering Viola calcarata Papilio, Fritillaria aurea, Tulipa Kaufmanniana, T. Kolpakowskiana, Sisyrinchium grandiflorum, Shortia galacifolia, Iris sindjarensis, I. sindpers, and divers alpines.

Messrs. Barr & Sons set up a representative collection of Narcissi, among which were many not generally known, such as Henry de Vilmorin, Agnes Harvey, Mountain Maid, Amazon, Lady Godiva, Peter Barr, Admiral Makaroff, Lord Roberts, Loveliness, Cleopatra, Constellation, Vivid, Janet, Image, Lady James Jodrell, Lucifer, Salmonetta and others.

Mr. G. Reuthe showed Iris Mariæ, I. Eggeri, I. stylosa, Daphne Blagayana, Cypripedium spectabile, C. fasciculatum, Dendromecon rigidum, Epigæa repens, Polemonium confertum, a very fine pan of Tecophilea cyanocrocus, Artemisia frigida, Erythronium Hendersoni, and many Saxifragas, Androsaces, Primulas and other rock plants.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

This Society having removed from the Caledonian Hotel, held its monthly Committee meeting on Monday evening last at its new quarters, viz., the Royal Horticultural Hall, Vincent Square, Westminster, S.W. Mr. C. H. Curtis presided. Eleven new members were elected, making an addition of seventy-four since January last. Sixteen members were reported on the sick list at the present time. The amount of sick pay for the month was £46 7s. Two members were allowed to transfer from the lower to the higher scale. The quinquennial valuation of the Society will be placed in the hands of Mr. Thos. G. Ackland. The usual quarterly grants from the Benevolent Fund were passed. The Committee hope that the removal of its headquarters to the Royal Horticultural Hall will be an incentive for many young gardeners to join the Society.

GARDENERS' DEBATING SOCIETIES.

Beckenham Horticultural.—At the last meeting of the above Society for the session 1904—1905, Mr. W. A. Cook read a paper on "Forced Vegetables," which contained much useful information. A number of questions were put to the lecturer, evoking a good discussion. Mr. M. Webster exhibited a fine lot of Rhubarb, "The Sutton."

Liverpool Horticultural Association.—The nineteenth spring show of the above Association was held in St. George's Hall, Liverpool, on March 29 and 30. The quality of the exhibits has never been surpassed in previous years. The 1st prize for a group of miscellaneous foliage and flowering plants fell to Alderman W. H. Watts (gr., J. Bracegirdle); the 2nd prize being awarded to Dr. J. A. Cooke (gr., G. Osborne). For ten pots of hardy herbaceous or bulbous plants, W. Todd, Esq. (gr., G. Heaton), was 1st. The most tastefully-arranged dinner-table was set up by Mr. J. Stone, gr. to F. H. Gossage, Esq. Good exhibits were staged by the following nurserymen:—Messrs. R. P. Kerr & Sons, Mr. H. Middlehurst, Messrs. Cowan & Co., Gateacre; Mr. T. Davis, Mr. C. Young. Messrs. Hogg & Robertson, and Messrs. Charlesworth & Rowlands. *J. P.*

Isle of Wight Horticultural.—A meeting of the above Association was held at Warburton's Hotel, Newport, on Saturday, April 8; Dr. Groves, J.P., presided. Mr. G. Grey, gardener to Mrs. Morgan, Woolmerton Manor, St. Lawrence, gave a paper on "Hardy Bulbous Plants." The essayist, in the course of his paper, made a great point of "naturalisation." The Crocus readily lends itself to this treatment. Anemones represent a wide range of colour, and their flowering season extends over several weeks. Irises were dealt with at considerable length; also Narcissi, which are probably more effective in the wild garden than any other bulbous plants. Bulbs planted in the grass should be allowed to retain their foliage until it shows signs of "ripening," this being most essential. A good discussion followed.

Croydon and District Horticultural.—The subject for Tuesday, April 4, was "Hardy Herbaceous Plants," by Mr. E. H. Jenkins, Queen's Road Nursery, Hampton Hill, who is known to be an expert in this branch of horticulture. The Helleborus, Phloxes, Michaelmas Daisies, Pyrethrums, Delphiniums, and Lathyrus were, amongst others, amply described. In each variety he advised the most suitable situation for their reception, and mentioned the time of year and the method of propagation.

SCHEDULES RECEIVED.

Addlestone, Chertsey, and Ottershaw Gardeners' Association Autumn Show, to be held at the Village Hall, Addlestone, on Thursday, November 9, 1905.

Croydon Horticultural Society's thirty-eighth Annual Summer Show, to be held on Wednesday, July 5, 1905.

Sutton and District Rose Society's Exhibition, to be held in the Public Hall, Sutton, on Tuesday, July 4, 1905.

Croydon Chrysanthemum Society's Autumn Show to be held on Tuesday and Wednesday, November 7 and 8, 1905, in the Public Halls, George Street, Croydon.

Hanley Horticultural Fete, to be held in the Hanley Park on Wednesday and Thursday, July 5 and 6, 1905.

Paisley Horticultural Society's Grand Autumn Exhibition, to be held in the George A. Clark Hall, Paisley, on Thursday and Friday, September 7, 8, 1905.

Windsor, Eton, and District Rose and Horticultural Society's Annual Exhibition in The Slopes, Windsor Castle, on Saturday, July 1, 1905.

London Dahlia Union's Exhibition in the Prince's Hall, Earl's Court Exhibition on Tuesday and Wednesday, September 19 and 20, 1905.

Lee, Blackheath, Lewisham and West Kent Horticultural Society's Summer Exhibition in the grounds of The Cedars, Belmont Hill, Lee, on Wednesday and Thursday, July 12 and 13, 1905.

Darlington Horticultural Society's Spring Flower Show, to be held in the Drill Hall, Darlington, on Wednesday, April 19, 1905.

Croydon and District Horticultural Society's fifth Annual Spring Flower Show, to be held in the Art Galleries, Park Lane, Croydon, on Wednesday, April 19, 1905.

Hawick Horticultural Society's Flower Show, to be held in the Exchange Hall, Hawick, on Saturday, August 26, 1905.

Obituary.

JAMES WILSON, ST. ANDREWS.—The ancient city on the east coast of Scotland has earned fame as the seat of the oldest of the Scottish universities and as the Mecca of golf. It is not altogether unknown, however, as a centre of horticultural enterprise. Most visitors to the city are familiar with the compact and attractive florist's establishment which has been conducted there for forty years by the late Mr. James Wilson.

Mr. Wilson served an apprenticeship to gardening in St. Andrews, and he was a fine example of the old school of gardeners. When an apprentice he made a herbarium of the plants of the district, and thus laid the foundation of an extensive and exact knowledge of plants both wild and cultivated. He was familiar with every branch of gardening and a keen student of horticultural literature. No branch of his profession, however, appealed to him more than that of landscape gardening. To skill in plan-drawing he added ingenuity in carrying out the work and a thorough knowledge of the plants required for effect. He was instrumental in adding to the charms of St. Andrews. Such works of his as the planting of the fine trees in the main thoroughfare, the laying-out of the new cemetery, and the remodelling of the extensive grounds of the St. Leonards school for girls, may be mentioned.

Mr. Wilson took an enthusiastic interest in the experiments in hybridisation carried out by his second son, Dr. John H. Wilson, Lecturer in Agriculture in St. Andrews University. As a result the visitor to Greenside Nursery finds many interesting novelties, which before long may prove to be of value to both gardeners and farmers. It is satisfactory to learn that the business falls into the hands of the eldest son, Mr. James Wilson, who for many years has ably assisted his father. Mr. Wilson died suddenly on the 7th inst. He was 70 years of age.

J. BURRELL.—We greatly regret to hear of the death of this gentleman, on the 31st ult., at Cambridge. Mr. Burrell, of Howe House Nurseries, was not only admired for his horticultural achievements, but was held in the highest respect for his sterling qualities as a man. His collections of Cactus Dahlias, Roses and Gladioli shown at the meetings of the Royal Horticultural Society, the National Chrysanthemum Society and other shows, were always remarkable for their good cultivation and choice varieties.

MR. REW.—There has just passed away in the person of Mr. Rew, at Caledon, Co. Tyrone, an old Syon [House] man. He was an apprentice there in 1827, and afterwards went to Tor Abbey, thence to Tredegar Park, and finally to Caledon Castle, Co. Tyrone, where for fifty years he was Head Gardener to two Earls of Caledon, retiring on a well earned pension in 1893. Mr. Rew was born in 1813, and was therefore in his 93rd year. All who had the good fortune to know Mr. Rew will regret his death. He was a kindly, courteous man, whose ripe experience was at the disposal of all. I, who succeeded him at Caledon, owe him a deep debt of gratitude for his sound advice and kind counsel. *W. B. Jeffreys.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ANEMONE: *A.* The Anemone is affected with Æcidium punctatum. The Crocus leaves appear to have started rapidly into growth, and then suffered a check.

BEGONIAS WINTER CHEER, MRS. HEAL, ENSIGN, &c: *W. C. L.* These plants may be afforded water about once a week or less frequently at the present time, and there are probably some growths appearing in the axils of the leaves which may be employed as cuttings for propagating purposes. The culture in February and March and even now should be such as will induce the plants to swell and mature the tubers. In June the plants should be cut down to within 2 inches of the base, and no potting need be done until then. We refer you to a note which appeared in these pages March 7, 1903, p. 146.

BOOKS: *J. I.* The edition you mention has little if any value.

CATALOGUES OF LONDON HORTICULTURAL SOCIETY: *N. O. B., New York.* Your letter has been forwarded to the Secretary of the Royal Horticultural Society.

CHRYSANTHEMUMS: *W. H. C.* We see no disease in your plants, and should expect that they will, if properly treated, start well into growth later on.

CHRYSANTHEMUM-LEAVES: *Puzzled.* The leaves are injured by the punctures of aphides. Isolate the other variety, and fumigate the infected plants with an insecticide.

EMPLOYMENT AS SEEDSMAN'S CLERK: *M. E. L.* In such circumstances as yours we cannot pretend to offer advice.

GLOXINIAS: *J. S.* Found dead. You should know better than we do what is the reason. Perhaps over-watering. We find no fungus or insect.

MUSHROOM-SPAWN: *R. S.* All sorts of things come up occasionally even when the best Mushroom spawn has been employed. The fungus in this case is that known as Xylaria vaporaria, figured in *Gardeners' Chronicle*, April 16, 1904.

NAMES OF PLANTS: *D. M. L.* 1, Mimulus (Diplacus) glutinosus; 2, send when in flower.—*Y. D.* Cornus mas.—*H. M.* Ceanothus rigidus.—*H. S.* Spiræa Thunbergii; Daphne Mezereum.—*E. A. H.*—Ipomœa hederacea.—*Sir A. B. H.* Euphorbia aleppica.—*T. H. S.* The yellow-and-brown flower with branched spike is Odontoglossum gloriosum; the creamy-white with a few spots, a natural hybrid of it and O. crispum, a form of O. × Andersonianum sometimes called O. baphicanthum.—*A. J. R.* Please inform us of the habit of the plant of which you send flowers. Send rough sketch if possible. Thanks for contribution to Gardeners' Orphan Fund.—*F. L.* 1, Chlorophytum elatum variegatum; 2, Dactylis glomerata elegantissima; 3, Curculigo recurvata; 4, Ceratonia siliqua, Carob-tree (Locust-tree of Scripture); 5, Davallia hirta cristata; 6, Begonia ascotiensis.—*R. S. P.* Dolichos sinensis, widely grown and known at the Cape as Kaffir Bean.—*A. S.* Tricopilia fragrans.—*J. O.* 1, Andromeda calyculata; 2, Skimmia japonica; 3, Muscari neglectum majus.—*R. C. Canon L.* Muscari moschatum; the bulb apparently got in with others by accident.—*F. McD.* 1, Chlorophytum elatum; 2, Cornus mas.—*F. J. P.* Rubus spectabilis—the Salmon-berry.—*J. R.* 1, Mesembryanthemum spectabile; 2, Spiræa Thunbergii; 3, Berberis dulcis; 4, B. Wallichiana.—*W. J.* 1, Athyrium filix-fœmina; 2, Onychium lucidum; 3, Anemia Phyllitidis; 4, Panicum plicatum; 5, Nephrodium molle; 6, Aspidium (Polystichum) angulare; 7, Adiantum Pacoti; 8, Blechnum orientale; 9, Chlorophytum elatum variegatum; 10, Lonicera brachypoda variegata; 11, Pteris hastata macrophylla. You send double the number of specimens you should do, and moreover they are miserable scraps, badly labelled. You should have more consideration for us, as our time is valuable and the interests of our subscribers paramount.

OSTROWSKIA MAGNIFICA: *G. A. M.* This handsome plant is quite hardy, and will flourish in any good and well-drained garden soil, but it prefers a rich sandy loam, and one that is deep enough to allow its long roots to strike downwards in the soil. The seedlings do not bloom until about their third or fourth season. This probably accounts for the fact of your plants not having flowered up to the present time.

PEACH: *G. G.* The leaves have suffered a check from some cause or other. The fungus will be reported on in another issue.

PEACH FLOWERS DROPPING: *C. R.* The tree probably suffered too severe a check when you root-pruned it last autumn. If this is the case the tree can only develop a small crop of fruit this year, and is endeavouring to attain this by shedding most of its blossoms. Another season should see the tree benefiting from the new soil, &c., given when the root-pruning was performed. Numerous letters on the dropping of Peach-buds have appeared in our columns quite recently.

PEACH-SHOOTS DISEASED: *J. E.* The black patches are the result of a fungus, a species of Botrytis. The disease most frequently appears on imperfectly ripened shoots, or on those that have received a chill. All diseased shoots should be cut off and burned, otherwise the disease will spread. After pruning spray the trees with a rose-red solution of permanganate of potash.

PEACH-TRAINING: *G. H.* In well-appointed gardens it is considered the correct practice to train the young shoots beneath the wires, and not to leave them growing untrained until the trees are fastened again the next season. When the Peaches are ripening all the shoots should be fastened down to the trellis, in order to allow sunlight and air the better to reach the fruits.

PELARGONIUMS AND BLACK VARNISH: *J. S.* The effect would be much the same whether caused by the black varnish or tar. It is best to employ as much ventilation as practicable after using either in plant-houses, until the varnish or tar has become dry.

PHASEOLUS CARACALLA: *Correspondent.* This species is from India, and requires stove treatment. Let the growth have plenty of light, and when the plant has made a considerable quantity of roots it will be likely to flower.

SALE OF BOX PLANTS: *Box.* We are not dealers, and therefore are unable to answer your question. An advertisement would probably elicit the information you require.

SHAMROCK: *H. T.* It is entirely a matter of opinion. What you send is Trifolium minus. The subject was treated exhaustively by Mr. Worthington-Smith in our issue for April 7, 1900, p. 222.

STONE PINE: *G. M. R.* The seeds may be liberated by knocking the cones with a hammer or mallet, or by placing them in water hot enough to soften the turpentine which keeps the scales together; then take out the seeds by means of a knife. The scales will also come asunder if the cones are placed in a warm oven. It is not really necessary to break the hard outer shells of the seeds previous to sowing, but if you do break them be very careful not to injure the embryo plant. Germination will be facilitated if they are soaked in water. The present is a suitable time for sowing the seed either in pans or shallow boxes, which should be placed near to the glass in a warm frame. No special soil is necessary so long as it is sweet, and ample drainage is provided. When the seedlings attain to a height of about 2 inches they should be transferred to small pots and returned to the frame, watered carefully overhead, and shaded during the hottest part of the day. It will be advisable to keep them in a cold frame for about two years, because they are rather delicate during the early stages of growth.

VINE LEAVES: *J. C.* Powdery mildew is present on the leaves received. Spray at intervals of six days with a solution of 1 oz. of sulphide of potassium dissolved in 3 gallons of water. This method is more effectual and much safer than treating the leaves with flowers-of-sulphur.

COMMUNICATIONS RECEIVED.—S. Palmer.—W. B. B. We appreciate your comments very highly.—G. R. S.—National Dahlia Society—T. M.—James Veitch & Sons—F. J. ILLUSTRATIONS.

THE PITCHERS OF NEPENTHES.

At the meeting of the Linnean Society on April 6, Mr. W. B. Hemsley, F.R.S., the Keeper of the Herbarium of the Royal Gardens, Kew, exhibited a series of lantern-slides prepared by Mr. Farmar illustrative of the structure of the pitcher in various species of Nepenthes. Mention was also made of a new species, N. Macfarlanei. The following notes include an abstract of Mr. Hemsley's remarks, for which we are indebted to the author:—

Among the many works of the veteran Sir Joseph Hooker there is perhaps none that is more attractive to a large number of readers than his Address on Carnivorous Plants to the Department of Botany and Zoology of the British Association at Belfast in 1874. I refer to this essay because Darwin designates Hooker as the discoverer of the carnivorous nature of the pitchers of Nepenthes, and because Hooker's nomenclature of the different parts has been generally adopted by subsequent English writers.

There are glands of various kinds on nearly all parts of Nepenthes plants—on the stem, on the leaves, on the tendrils, on all parts of the pitchers, on the pedicels, and on the flowers. There may be few or none or many on a given organ; they may be conspicuous or inconspicuous, and of very diverse structure or shape; but they may all be referred to two classes, according as their function is "attractive" or "digestive."

Attractive glands of all kinds exude a sweet juice, and may be called honey-glands. They are generally distributed over the plant, excepting on the inside of the pitchers, and serve to attract insects and other creatures towards the pitchers and to their own destruction. Digestive glands occur only on the inside of the pitchers. In an early stage, while the lid of the pitcher is still closed over the mouth, the digestive glands secrete a fluid and discharge it copiously into the cavity of the pitcher, sometimes half filling it. At first the fluid is of a pleasant taste, but later it changes in character and is able to dissolve organic substances and render them available as food for the plant. It has been compared to the gastric juice, as it exercises practically the same function. Honey-glands and digestive glands are alike in structure, and very similar to simple animal glands.

The pitcher (ascidium) consists of the tubular or inflated body, with or without two longitudinal wings (alæ) in front, a longitudinal rib (costa) at the back, terminating in a spur (calcar) near the hinge of the lid; the collar or rim (peristomium) and the lid (operculum), which is sometimes smaller than the mouth (os) of the pitcher.

All the parts of the pitcher present great variety, and specific distinctions are drawn more often from the pitchers than from either the leaves or the flowers. In adult plants the pitchers usually have an attractive, a conductive, and a secretive surface. The attractive surface is the underside of the lid and the collar, which usually abound in honey-glands. Below the collar is a zone of variable breadth, of very smooth surface, affording no foothold to insects and usually opaque and glaucous. This is the conductive surface. The rest of the surface of the pitcher is more or less thickly beset with glands, forming the digestive and detentive surface. The relative size of the areas of the conductive and glandular zones differs very much, and sometimes the whole surface is glandular.

Professor Macfarlane, formerly of Edinburgh and now in Philadelphia, who has long made a special study of the Nepenthaceæ and Sarraceniaceæ, and who has published several important papers on the subject in the *Annals of Botany*, when at Kew last year called my attention to a specimen of a curious new species of Nepenthes which he came upon when he was on the very point of leaving. It consists of one small pitcher and three or four small leaves, and comes from Gunong Bubo in the Malay Peninsula, from an altitude of about 5,000 feet. I agreed to examine and describe it, and drawings had been made for Hooker's *Icones Plantarum*, and I proposed naming it N. Macfarlanei.

Having reached this stage, I showed what I had to Dr. Prain, the Superintendent of the Calcutta Botanic Garden. He at once very generously offered to have the whole of the Calcutta Nepenthes sent to Kew to aid me in my studies. Fortunately the collection arrived a week ago, and it contains upwards of a dozen specimens of this remarkable new species from the same locality, so that I am now in a position to give you an almost complete description of it. A further consignment received this week included female flowers, which were previously unknown to me. However, there is nothing remarkable in the flowers of either sex.

This new species differs from all previously described species, except N. Lowii, in having numerous, rather stiff bristles interspersed with the large honey-glands on the under surface of the lid. In all other respects it is very different from N. Lowii. It is of climbing habit, the stems attaining as much as 15 feet in length. Like most if not all other species of Nepenthes, it bears two kinds of pitcher, independently of the rudimentary ones of young seedlings, both of which I will briefly describe. The lower ones are much the smaller, being only about a third the size of the largest, the dimensions of which I will give you presently. The honey-glands are very prominent, oval or circular in outline, surrounded by a raised rim, and from one-fiftieth to one-twelfth of an inch in diameter. The function of the bristles on the underside of the lid is not obvious, but it would appear to be preventive, so far as flying insects and the honey-glands are concerned. On the other hand, ants might creep in amongst them and obtain the honey. The lids of the pitchers of some species of Sarracenia are furnished with similar though weaker hairs.

The wings of the pitcher are slightly developed and not fringed, and the collar is very simple and narrow. The whole of the interior surface, except a very narrow belt close under the collar, is thickly studded with digestive glands, which become gradually smaller from the base of the pitcher upwards, and vary in number from about 2,000 to 5,000 in a square inch. The digestive glands are many-celled, ovoid or spherical in shape, and, in consequence of the unequal growth of the tissue in which they are embedded, they are more or less over-arched, the opening of the arch looking downwards. The surface is hard and polished, quite smooth to the finger moving in a downward direction, but rough to the finger from the sharp edges of the arches moving in an upward direction.

Coming to the larger pitchers, I have one which measures 12 inches from the base to the apex of the erect lid. It is borne on a tendril 18 inches long, and the sessile blade of the leaf is several inches long, making a total length of 37 inches. Pressed flat, the body of the pitcher is nearly 4 inches in its greatest diameter. The collar is half an inch wide, and the finely pectinate inner border has solitary, immersed honey-glands between the teeth. The lid is 2 inches across, and the longest bristles are half an inch. The interior is very different from that of the smaller pitcher, as it has a broad, glaucous conductive zone.

The pitchers of *N. Lowii* are larger, thicker and stronger, and remarkably constricted in the middle. The bristles on the lid are larger and stiffer and more of the nature of prickles, whilst the honey-glands are perithecioid, in other words immersed in and covered by the surrounding tissue, with the exception of a very small pore, through which the honey is exuded. The glands are relatively very large, sometimes as much as $\frac{1}{5}$ inch in diameter, and there is a large lumen or empty space between the top of the gland and the excretory pore.

The collar of the pitcher is the simplest in the genus, having no embellishments beyond a ring of prominent honey-glands. These honey-glands are immersed and protected by a very hard, shining, overhanging tissue with a pore-like opening, looking downwards. In time the glands decay and disappear, leaving the hard empty sockets, which accounts for the glands having been overlooked by some writers, and the sockets described as perforated tubercles. The under or outer surface of the collar is thickly beset with small honey-glands. Inside, the pitcher is wholly covered with digestive glands. Those near the top are small and over-arched, but the size increases downwards, and in the lower half the glands are about half a line ($\frac{1}{12}$ inch) in diameter and pentagonal to heptagonal in shape, with a raised, hard rim all round, giving the surface the appearance of being irregularly tesselated. The dried specimen shows this very distinctly.

In striking contrast to N. Lowii the huge pitcher of *N. Rajah* is most elaborately ornamented. It has broad, fringed wings, and the broad, plaited, slippery collar has a strong, comb-like, incurved inner margin. The mouth of the pitcher is very oblique, and the collar is split and

elongated at the point where the lid is attached, and the teeth of the opposite margins overlap each other and are continued up to the hinge of lid. Between the teeth of the comb-like margin are solitary pores, visible to the naked eye, which are the openings of excretory ducts leading to the deeply-seated honey-glands. The enormous lid is covered with honey-glands, which are quite different from those of N. Macfarlanei, being perithecioid and similar to those of N. Lowii. The honey-glands of the lid of the cultivated specimen of N. Rajah have much larger pores than those of the big wild one. Inside, the pitcher is covered with glands, of which there are about 4,000 to the square inch, and as the pitchers sometimes have a capacity of two quarts it may be imagined how enormous the total number of glands must be. This species has the largest pitcher of any of the genus. The wild one exhibited has a leaf-blade 20 inches by 7 inches; a tendril 20 inches long, peltately attached 2 inches within the margin of the blade; a pitcher 12 inches by 7 inches, with a lid 10 inches by 8 inches. This gives from the base of the leaf to the top of the upraised lid a total length of 5 feet 2 inches. In addition to beetles, ants, and other insects, some of these big, strong pitchers catch other creatures. A drowned rat has been found in a pitcher of a plant of N. Rajah growing wild.

N. Edwardsiana has a pitcher of a totally different type. Compared with that of N. Rajah it is narrow, but a specimen nearly 2 feet long is on record. It is wingless, but the collar is very elaborate, being furnished with thin, broad, transverse rings at right angles to its circumference. The conductive surface occupies nearly three-quarters of the inside of the pitcher; the glandular part has a very glittering surface, and the glands are very small.

The pitcher of *N. echinostoma*, as its name denotes, has a spiny mouth, the collar being furnished with about four series of flattened spines projecting inwards and downwards into the cavity of the pitcher. Each spine has an apical pore, which is the mouth of an excretory duct leading to a deeply-seated cylindrical honey-gland. In all the other species I have examined the glands are between the teeth. The conductive zone of the pitcher extends about a third of the way down, and the rest of the surface is densely covered with peptic or digestive glands, which are completely overarched or at the bottom of inverted pockets, and hidden from view. In the upper part there are about 15,000 to the square inch, and they are almost as small and as thickly set down to the very bottom of the pitcher.

I may mention that this and other computations have been checked by one or more of my colleagues. In several instances I obtained independent estimates, because my figures are so much higher than any I have found on record. For example, Prof. Macfarlane's highest is 5,000 to 7,000 on the square inch, in the pitchers of N. bicalcarata. *W. B. Hemsley.*

(To be continued.)

FIG. 101.—CROWEA ANGUSTIFOLIA, A HARD-WOODED GREENHOUSE PLANT: COLOUR OF FLOWERS REDDISH-PINK.

CROWEA ANGUSTIFOLIA.

THE genus Crowea is closely allied to Eriostemon. The members of both these genera are natives of South Australia, and they brighten the greenhouse with a profusion of flowers at a season when greenhouse flowering subjects are few. Crowea angustifolia (fig. 101) is an old garden species, having been described as long ago as 1849. It produces its reddish-pink flowers freely in the axils of its narrow leaves, so freely indeed that the plants become quite studded with their star-shaped flowers. When shown at a recent meeting of the Royal Horticultural Society by Messrs Jas. Veitch & Sons, Chelsea, the Floral Committee recommended a First-class Certificate for this species. Our illustration has been prepared from specimens supplied us by Messrs. Veitch. Though hardy wooded plants, Croweas may be propagated easily by cuttings if inserted in sand, and then placed under a bell-glass over a moderate degree of bottom-heat.

PLANT PORTRAIT.

RHODODENDRON PERLE DE LEDEBERG.—A derivative from R. ponticum, with large trusses of pink flowers heavily spotted on the uppermost petal. Highly recommended for forcing purposes.—*Revue de l'Horticulture Belge*, April.

NEW OR NOTEWORTHY PLANTS.

CYMBIDIUM SCHRÖDERI, Rolfe, n.sp.*

The appearance of the Chinese Cymbidium Wilsoni about a year ago showed that novelties in the C. giganteum and C. Lowianum group were not exhausted, and now another new species of this group has appeared among Messrs. Sander's Annam importation, and has just flowered in the fine collection of Baron Sir Henry Schröder, at The Dell, Egham. At the first glance it recalls both the species named, having the very hairy lip and strongly striped side lobes of C. grandiflorum, and a median line and zone of red-brown on the front lobe, much resembling C. Lowianum, but narrower and lighter in colour. The flowers are, however, smaller, and the petals narrower than in the latter, while the segments are somewhat lined and minutely dotted with red-brown. On the whole the species is most allied to the North Indian C. giganteum, but the inflorescence is more arcuate, the flower rather smaller, the lip less hairy, and the markings on the front lobe not disposed in blotches, as in that. From the shortness of the inflorescence, as compared with the allied species, and its appearance generally, it is believed that this first inflorescence is not fully developed, but when the plant has had time to become established, we shall be better able to judge of its real character. C. Wilsoni is a smaller plant, with much narrower leaves, but a near ally of the present novelty. *R. A. Rolfe.*

THE GIANT WILLOW APHIS (LACHNUS VIMINALIS).

Amongst the Willow aphides, of which there are several species, two stand out very prominently, namely, the Red-legged Willow Aphis (Melanoxanthus salicis, Linnæus) and the Giant Willow Aphis (Lachnus viminalis, Fonscolombe). These are the two largest species, and consequently are readily noticed. The former I have never known to do any damage, but the latter is frequently very destructive.

Although not common, the Giant Willow Aphis is widely distributed. It is usually noticed where it occurs for several seasons: first, its great size attracts attention; secondly, on account of the large size of the colonies; and thirdly, the great damage it so often does to the foliage. It appears in large colonies on the stems and twigs, and never attacks the leaves. These colonies are often a foot in length and from 1 to 3 inches wide. In one colony I have counted as many as 700 individuals, so densely packed together that they all touched one another, not only at the sides but in front and behind.

As a rule, many colonies are found on one tree. A small Goat Willow in my own garden had in October last no fewer than six large colonies and several smaller ones, the large ones from 6 to 8 inches long. The tree is only 9 feet high.

Each colony starts by a single-winged viviparous female, who crawls from a neighbouring mass of the aphides and at once commences to deposit living young. The rate of growth of a colony is rapid. During rather wet and damp weather one was noticed to increase from 5 to 8 inches long in four days, and during that period very many winged females had flown away from it.

In all attacks that I have observed the insects are grouped together side by side, with their heads pointing upwards, not, as stated by Buckton* and quoted by myself† with all their

Fig. 102.—Giant Willow Aphis.

heads turned downwards. I have frequently watched colonies start, and they always commence with their heads in the same position as when they are in large groups. Now and again a stray specimen may be in the reverse position. These large aphides are always attended at the close of the season by numbers of wasps. The wasps, as noticed by a correspondent, Miss J. Borroughs Norgate,‡ at Enfield, feed off the honeydew, which drops down on to the leaves beneath the insects. William Curtis also noticed this phenomenon, and also that beetles totally disregarded the honey-dew. Recently I have found that ants will not touch it, as they do the honeydew of other plant-lice; nor will bees feed upon it. The flow of this gummy matter is very copious at certain times, especially in warm weather, but even in dull and rainy weather a considerable quantity is excreted. The flow of this sweet substance is so great that Curtis suggested that "their secretion might be gathered, and by purification converted into the choicest sugar or sugar-candy." This, of course would not be dreamt of at the present day.

The honey-dew soon kills the leaves upon which it falls, not only the leaves of the Willows and Osiers upon which the Lachnus feeds, but those of any other trees, bushes, or plants growing beneath them.

The leaves assume a yellow-and-black appearance and soon become very noticeable even at a distance. Thus the Giant Willow Lachnus do much damage not only to their food plants but to any other plants growing beneath them. This honey-dew frequently coats the ground with a shiny mass. The effects of this pest upon the Willow and Osier are very strange. At one time they seem to do no harm, save indirectly by causing the leaves to fall from the effects of their excretions. At other times, or even at the same time, a neighbouring Willow will be killed outright by the actual sucking of the aphides at the stems and branches. Death of the affected trees when they are small is very frequent if the attack is a persistent one. Buckton records a case where this Lachnus swarmed in such numbers at Carshalton that trees 30 and 40 feet high had been killed by their poisonous influence! But he mentions that a resident horticulturist in Nottinghamshire states that the harm they do the trees is not at all marked. Probably the strange difference in the results seen in their working is due to the condition of the sap, and also the kind of Willow or Osier affected.

Wherever the insects puncture the bark the spot is marked by a reddish-brown stain; these marks may and frequently do occur in rows forming more or less prominent brown streaks on the rind. I have found this Lachnus from June until November, but by far the greatest numbers seem to occur in September and October, when a large quantity of winged females make their appearance. The winged female is very large, often measuring three-fifths of a inch in expanse of wing; the body is about one-fifth to one-fourth of an inch long. In colour the thorax is dark-brown, the abdomen dusky greyish-brown with rows of dark spots, one large one being central. This large dark spot is supposed to be the representative of the curious tubercle seen in the wingless female. The antennæ are short and dark-brown, with the base of the third segment reddish. Legs dark-brown, the base of the fore femora, mid femora, and most of the hind femora bright reddish-brown to almost red; base of the fore and hind tibiæ also reddish; claw double; coxæ or base of the legs black. The proboscis is dark, and reaches to the base of the third coxæ; venter of abdomen ashy-grey with a black spot at the junction of each segment. The cornicles are dark, and very short and conical. The wings are very large, the stigma bronze, the base of the insertion and the cubitus orange-yellow.

The wings in all I have seen are carried pent-wise. Mr. Buckton says they sometimes carry them horizontally. When first hatched the wings of the female are opaque, milky-white, and become transparent.

The apterous viviparous female is very marked; it varies from one-sixth to nearly one-fourth of an inch long, and is globular in form, with long legs; the colour is brown with a pile of fine silky grey hairs. The antennæ are short and slender, with reddish base. The abdomen has a row of large black spots, and a large black median tubercle, which projects prominently from the surface. The cornicles are short, black, and stumpy. The legs are long, particularly the hind pair, and similar in colour to the former, but the red bases of the femora are broader. There are also black marks on the thorax, which may or may not be prominent. In certain lights

* *Cymbidium Schröderi, n. sp.*—Pseudo-bulbs oblong, sub-compressed, with numerous rings representing the base of the leaf sheaths, up to 6 inches long by over an inch broad. Leaves elongate-linear, rounded or obtuse at the apex, subcoriaceous, up to 2 feet long by 9 lines broad. Scape arcuate, a foot long and bearing five flowers, but apparently not fully developed. Lower bract lanceolate-oblong acuminate, 1½ inch long; the others triangular, acute, and 2 to 3 lines long. Pedicels ¾ to 1¼ inch long. Sepals lanceolate-oblong, acute, obscurely carinate, the dorsal somewhat concave, about 1¾ inch long, 6 lines broad. Petals lanceolate, acute, subfalcate, as long as the sepals, 4 lines broad. Lip strongly three-lobed, recurved, 1¼ inch long; side lobes erect, oblong, with a broadly triangular subobtuse apex, an inch long; front lobe recurved, ovate, acute, slightly undulate, 6 to 8 lines long; whole inner surface of lip pubescent or shortly hirsute; disc bearing a pair of fleshy, nearly parallel keels, very prominent in front and hairy throughout. Column clavate, arcuate, with acute margins, over an inch long. Colour of sepals and petals green, somewhat lined and minutely dotted with red-brown. Lip light yellow, with five or six strong red-brown stripes on the side lobes, and the front lobe bearing a narrow median line, and a zone of red-brown in front, similar to that of C. Lowianum, but narrower and lighter in colour; disc bearing a few red-brown spots. Column yellowish-green, lined and dotted with red-brown on the face, and suffused with dark red-purple at the apex. *R. A. Rolfe.*

* *Monograph of British Aphides*, p. 55, vol. iii., 1880, Buckton.

† *First Report on Economic Zoology*, p. 116, 1903, Theobald.

‡ Ibid, p 111.

especially when the sun is shining on them, they present a metallic, bronzy appearance. The pupæ are more elongate than the adults, and have very large dorsal tubercles and bright brown wing-cases. The wings when they first moult their skin are like small milky-white projections, very noticeable amongst a colony of the dark-coloured larvæ, pupæ and adults.

The winged females remain a little while with the colonies, and then crawl away, and now and then fly off in numbers. Some observers have recorded that the wingless females may migrate *en masse* from one tree to another. They frequently move from one side of a tree to another to get shelter from the wind. The winged females do not always follow the example of the wingless forms, for some may be settled in a colony with their heads downwards, others upwards, the latter being the favourite position.

Unfortunately, I have no description of the oviparous females that occur in the late autumn. I have found what may be their eggs in great masses on the rind of the smaller branches and twigs.

The use of the conical tubercle on the back is not known. The apex has several very minute pores, but is nevertheless apparently blind. It is thought to be an odoriferous gland.

The Giant Willow Aphis, like most others, has been described under several names. The following may be mentioned for reference:—Aphis saligna Walker, Aphis salicis Curtis, and Aphis viminalis Boyer de Fonscolombe.

During last summer I had sent me a number of large Lachnus from Abies pectinata. They cannot be named. The sender said they always leave the Abies at a certain time, and occur again the following year. They bear such a strong resemblance to the Giant Willow Aphis, I cannot help thinking they are one of its stages.

As long ago as the appearance of the sixth volume of the *Linnean Transactions*, we find reference to this insect as being "nearly a quarter of an inch long, one of the largest species." Curtis, the writer of the article says, "towards the end of September multitudes of full-grown insects, winged and otherwise, desert the Willows on which they feed and ramble over every neighbouring object in such a manner that we can handle nothing in the vicinity without crushing some of them."

These large Lachni when crushed give out a rich red stain, which dyes silks pink, and which can easily be extracted, but is never likely to be of any economic value in these days of cheap aniline dyes.

Very strange is the behaviour of this and other species of Lachnus when frightened. If we shake the bough that they are on or touch them with any object however lightly, they stand on their heads and wave their hind legs in the air. These strange acrobatic movements are evidently for frightening off chalcid flies and other enemies when they come to lay their eggs in them or to attack them. These weird movements are still more pronounced in the Black Pine Lachnus (Lachnus fuliginosus), which look like pigmy millers standing on their heads and waving their limbs in the air.

Prevention and Treatment.

Obviously there can be no means of preventing the attack of such creatures, which are winged and capable not only of flight but of flying a considerable distance. As they are very noticeable, and as we do not know what effect they may have on a tree, it is just as well always to assume that they are going to do damage, for they only too frequently do so, and destroy them at once.

In low Willows spraying is not necessary. The best way is to rub the colonies off with a gloved hand. Larger trees must be sprayed with strong soft-soap wash, at least 12 lb. of soft-soap to every 100 gallons of soft water. Quassia improves the wash for destroying this aphis as it does that for the Cherry Black Fly, as it cleans the gummy leaves more readily than does plain soft-soap. Number of apterous forms fall off when the spray reaches them if applied with any force, and so the ground must be well wetted with the wash or thickly sprinkled with lime. *Fred. V. Theobald, Wye College.*

CEROPEGIA WOODI.

We had occasion to illustrate this interesting little species at the time of its first introduction from Natal, when we saw it in the nurseries of Mr. William Bull, at Chelsea. It was named in honour of Mr. Medley Wood, who has done such good service in making known the botanical resources of Natal, and in introducing to the mother country many of the most interesting and beautiful of the plants of that colony.

The fruit which we now illustrate (fig. 103) from a specimen kindly forwarded by Mr. Greenwood Pim, is what botanists would call a double follicle, consisting of a pair of slender elongated pods bursting along one edge only, and revealing within a number of closely and beautifully packed

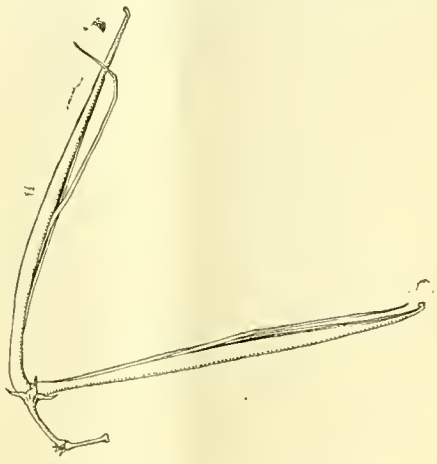

Fig. 103.—Seed-pod of Ceropegia woodi.

seeds provided with glistening silky hairs. All this is in accordance with Asclepiads in general; but it is desirable to complete the history of this particular species by the representation of its fruit. The construction of the flower of Asclepiads is complicated, and of such a nature that the agency of insects is required to ensure fertilisation. What particular insect it was that was so obliging in this case we do not know.

CULTURAL MEMORANDA.

THE WATERING OF PLANTS IN POTS.

Watering is one of the most important operations in the successful cultivation of plants in pots. It is a regrettable fact that it is difficult to find young gardeners exercising the necessary care and judgment, and studying or knowing the needs of the various plants under their care. Many evergreen plants, such as Crotons, Carnations, Humeas, &c., are more often injured through receiving insufficient water and nourishment at the roots than from all other causes put together. How often does one see a collection of Crotons losing their leaves through being infested with red-spider and thrips during the winter, and all because of dryness and starvation at the roots! Careless watering is responsible for many of the diseased and unhealthy collections of Carnations seen. Humeas are often ruined by being kept too dry at the root. A mistaken idea prevails largely among inexperienced growers that stimulants should not be applied until the plants have thoroughly exhausted the soil in which they are growing. To ascertain if the plants require watering, the pots should be tapped smartly with the knuckles or with a stick. If the soil is dry and requires water, a clear sound will be heard; but if the soil is at all wet a dull sound will result. Should there be any doubt, a good plan is to lift the pot (if the size permits), when one can easily tell by the weight whether the soil is dry or wet. Avoid top watering only, and fill up the pots with water to the rim, especially in the case of those plants that are potted firmly. It has often been said that gardeners have much to learn from trade-growers in the watering and feeding of plants. These growers rely more on the proper watering and feeding of the plants than on fanciful and elaborate mixtures of soil. *John Fleming, Wexham Park, Slough.*

Violet Culture.

To grow these flowers successfully, annual transplanting is necessary. The month of April is the best period for shifting the plants, except in the extreme North, where early May is soon enough. In the South it is advisable to get the plants in before the hot weather arrives, or much labour will be entailed in watering. As a rule, in those places where Strawberries succeed, Violets are also a success, both enjoying a deep, well-cultivated soil. If the soil is at all light in character, it should receive a liberal dressing of fairly-well-decayed stable or farm-yard manure, which will be better applied if dug in during the early months of the year, and the ground afterwards allowed to settle before planting. With retentive soils nothing is more suitable than partially-decayed, flaky leaf-soil, wood-ashes, or exhausted Mushroom-bed manure, well mixed together. Soot is also a capital fertiliser, and this can either be strewed over the ground previous to forking it back for planting, or a moderate dressing may be applied between the plants in June and the three succeeding months and hoed in. This will also help to ward off red-spider, one of the worst enemies of the Violet plant. The easiest mode of increase is by division of the root, discarding the centre growth and selecting the offshoots with attached roots. This mode of increase is not favoured by some growers, who prefer propagating by cuttings inserted in September, either in boxes or dibbling them in a shady open border. This involves much unnecessary labour, especially where several thousand plants are grown. I have adopted the former plan for a number of years with satisfactory results, and have no hesitation in recommending it to others. The Violet thrives best in the summer months in partial shade, but for successful winter-flowering it is better to allow the plants a position where the sun can reach them. For this reason either a south-east or south-west border should be chosen. If necessary the plants could be shifted in September to a sheltered position facing south. With regard to planting, the single-flowered varieties should be placed 15 to 18 inches apart each way, while 12 inches each way would be sufficient space for double varieties. The plants require frequent attention during the season, especially in dry weather, when a thorough watering should be applied once a week towards evening. Syringing with water after a hot day is extremely beneficial to the plants. Runners must be early removed or the crowns will be small, while the ground should be frequently hoed in order to promote growth.

Varieties of Violets are now numerous, and the flowers are much larger than they were some twenty years ago. The variety Princess of Wales is most extensively grown, and has large, fragrant flowers with long stalks. La France is slightly darker in colour than the former, and

is quite as sweet-smelling; Admiral Avellon is strong in growth, very hardy, and with the nearest approach to red flowers. With us this variety is shy in pushing up its flowers until March; California is an old variety, very prolific, with the flowers borne on long stems; Baroness de Rothschild is considered the largest single-flowered variety yet introduced, and is spoken of highly. Wellsiana is still grown by many; it is certainly very free and highly fragrant. Among doubles Marie Louise is still the best; De Parme, which somewhat resembles the old Neapolitan, is very free, as is also the variety Mrs. J. J. Astor, of pink and heliotrope colour. Lady H. Campbell affords beautiful pale lavender flowers, larger than those of either De Parme or Neapolitan, and is a good, compact grower. Comte de Brazza is the best double white, but a trifle shy in producing flowers until the new year is in. All the double varieties succeed better if given glass accommodation from early in October, although during the past winter I have gathered large quantities of flowers out-of-doors, De Parme and Mrs. J. J. Astor producing the best results. *James Mayne, Bicton, Devon.*

ALPINE PLANTS IN POTS.

Our illustration at fig. 104 has been reproduced from a photograph taken in the Alpine-house at West Down Gardens, near Haslemere. The species of plants represented, we are informed by the gardener, Mr. Eavis, are as follows: Saxifraga apiculata, growing in three pans, each 12 inches in diameter. These are shown in the centre of the picture, and each pan contained about 300 flowers. S. Burseriana major is placed on the right of the picture bearing flowers which measured 3 inches across. The plants are cultivated in pans measuring 8 inches across and 4 inches deep, and containing a compost of loam and sand and limestone chippings. On the left of the picture is S. Boydii alba, growing in pans. They are given similar treatment to that afforded S. Burseriana major. Saxifraga oppositifolia major may be seen just showing between the plants of Veronica buxifolia and V. cupressoides.

A house of Alpine plants cultivated in pots and pans, as are those at West Down, affords much enjoyment to the plant lover early in spring.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM × ARGO-MASTERSIANUM.

A very interesting and distinct cross between C. Argus and C. Mastersianum has flowered with the Rev. A. H. Upcher, Baconsthorpe Rectory, Holt, Norfolk. In the flower received the features of both parents are readily seen, the long flower-stalk and soft tints being derived from C. Mastersianum, and the conspicuous blackish-purple spotting on the petals and the general form of the flower plainly indicating the influence of C. Argus. The upper sepal is greenish-white, with about twenty emerald-green lines ascending from the base. The petals are emerald-green on the inner halves and tinged with rose-colour on the outer portions, the inner parts bearing numerous warted blackish-purple spots, the marginal ones being ciliate. The lip is whitish tinged with dull rose colour, and the staminode is veined with green.

Brassia brachiata.

This species, which was pronounced by Dr. Lindley to be the finest of the genus, is often confused with the best form of Brassia verucosa, but the two are very distinct from each other, and B. brachiata is much the finer. An inflorescence is sent by Mr. Geo. Ellwood, gr. to W. H. Myers, Esq., M.P., Swanmore, Bishop's Waltham, who states that the specimen bore three spikes each with eight flowers. The flowers received have greenish-white sepals 6 inches in length and spotted with chocolate colour at the base. The petals, which are about half as long as the sepals, are similar in colour, but have smaller and more numerous spots. The labellum, which is over an inch and a quarter at the widest part, is primrose colour, and has a brighter yellow tint in the centre, which is studded with more or less warted spots of purplish olive-green. *J. O'B.*

Dendrobium Wardianum under Cool Treatment.

I am induced to send you a few stems with flowers of Dendrobium Wardianum, to show the effect of much cooler treatment than has generally been recommended for this species. About Easter last season I had fifty plants in flower at the same time, and being anxious to prolong the bloom on the plants as long as possible, I removed about half the number of plants to a cool, low, span-roofed greenhouse. Here they remained, suspended near the glass, till their flowering period was over. Observing that the young growths were making satisfactory progress, I decided to leave the plants in this position, the result being that they made strong, plump stems, and retained their leaves till a late period, the stems ripening to a beautiful golden colour. During the winter months the flower-buds gradually developed, and are now in full flower without having been forced. During the summer the plants were not shaded, except by the rafters, &c., and were allowed free circulation of air night and day; they were never syringed, the house being also occupied with show Pelargoniums and tuberous Begonias. The portion of the plants left in the warm-house made long, attenuated growths, and kept losing their bottom leaves. They were removed to the cool-house in the autumn, and now neither the flowers nor the young growths are so far advanced as those grown in the cool-house during last summer. *William Higgie, gr. to her Grace the Dowager Duchess of Northumberland.* [The flowers sent were excellent examples of this popular species. Ed.]

Lælio-Cattleya × Dominiana.

A flower of a large, richly-coloured and fragrant form of this fine hybrid is sent by Eustace F. Clark, Esq., Chamonix, Teignmouth, who states that he bought the plant as a small seedling nine years ago from Messrs. Charlesworth & Co., whose small batch of the same raising has been productive in fine forms. The original type was raised by Messrs. Jas. Veitch & Sons between Lælia purpurata and typical Cattleya Dowiana. Those more recently raised by Messrs. Charlesworth were between Lælia purpurata var. formosa and Cattleya Dowiana var. aurea. The flower sent is equal to the best of hybrid Lælio-Cattleyas. Sepals and petals bright purplish-rose finely veined, the broad petals being nearly 4 inches in length. Lip 2¼ inches wide, very dark in colour, which is a blending of crimson, purple, and maroon, the base being striped with yellow.

Fig. 104.—Group of Alpine plants in pots.

FORESTRY.

TIMBER VALUE OF EXOTIC TREES.

When, a quarter of a century ago, I raised the question of the naturalisation of exotic trees in Germany, I said that the following points must be considered:—

1. Whether the tree furnishes better wood than the native species of the same family; or

2. Whether it will produce in a shorter time larger quantities of wood, even if of less value; or

3. Whether, even if its wood production be the same or inferior in quantity and quality, it excels the native timber either in its slight demands on the soil, in its value as a nurse, in its resistance to climatic conditions, or in some other particular quality.

This system of experiment having been adopted officially, I am now going to illustrate this method with a few examples. To No. 1 belong such trees as Black Walnut, the Caryas, Prunus serotina, the Douglas Fir, and others. As to No. 2, I only mention the American Red Oaks, giving in a shorter time a greater quantity of lesser value than our Oak.

Instead of many instances for No. 3, I only name the Tideland Spruce, Picea sitchensis (Menziesii), which luxuriates in moist, wet, moorish soils where our Spruce perishes.

The article of Mr. Forbes illustrates clearly the old adage, that half the world does not know what is going on in the other half. So I may be allowed to state that the Locust has proved to be the only tree to succeed in the kingdom of Hungary, where vast plains, formerly treeless, are now brought under forest. I quite agree with Mr. Elwes that the Locust is one of the most useful trees in the world, a quick grower on the worst soils, ameliorating these with their roots, giving, after thirty or forty years' growth, large quantities of capital, elastic timber highly valued for many purposes.

The Robinia was introduced into England, according to Aiton, *Hortus Kewensis*, in the year 1640! A hundred years later a member of the Academy in Paris asked if the Government should not begin to study the question of introducing these foreign trees into the forests?

If after another hundred years the Locust could come to the knowledge of William Cobbett, so that he might be able to compare the superior quality of this tree in 1825, which was then hardly known in England, with its condition after two hundred years which have elapsed since its introduction, I very well understand that a man of his character did not write "temperately," as Mr. Elwes says. And though he did not express himself over this novelty of 200 years in a quiet way, he was still right in praising the merits of the Locust; and the blame falls upon the English, not upon Cobbett, if this tree is little planted in Great Britain.

As with the Locust so it is with the Black Walnut, which Mr. Elwes mentions. Compton, Bishop of London, planted at Fulham numerous exotics from North-east America. One of the remnants of that period, which I inspected several times, is a Black Walnut, introduced in 1663 (*Hortus Kewensis*), and planted at Fulham to my knowledge in 1688—217 years ago. Large trees, according to Professor Sargent, begin to be looked for.

We Germans introduced, according to the statistics of the Chamber of Commerce of Hamburgh, during the period of 1893 to 1897 [timber to the amount of] £1,124,067; Mahogany, Cedars, &c., £242,046. We imported more Walnut timber (which we *can* grow) than all the timber used for cabinet work (which we *cannot* grow).

Michaux, who lived for more than thirty years in North America a hundred years ago, directed the attention of the French to Prunus serotina, which is quite hardy, grows on any soil, is highly prized for its rose colour, and is used for the finest cabinet work. It bears beautiful foliage like that of the Portugal Laurel, and produces plentiful berries, which are eagerly sought after by birds.

Monsieur Berger, the late General Inspector for Forests at Brussels, writing a monograph some years ago, addressed his countrymen in the following way: "If you had followed the advice given by Michaux 100 years ago, and planted Prunus serotina, to-day you would be able to pay for the ships of Wheat with the timber of Prunus serotina." In America it is very scarce. And how very few ever heard the name of this tree!

Another common tree, also an introduction of hundreds of years, is Populus canadensis and several species of this genus. A most interesting book on this group was published last year in Paris (*Le Peuplier*), and there we are told that the annual consumption in France of Poplar wood amounts to 250 to 300 million francs (ten to twelve million pounds sterling).

How is it that the nation at large goes on in this [un]happy ignorance, regardless of the treasures which we could grow for ourselves? But instead of planting these valuable trees, introduced some hundred years ago, we read articles about the value of exotic timber; and it would be in this case not so much "exotic" as "indigenous" timber. A good many scientific and practical foresters demonstrated at the last Paris exhibition the insufficiency of the timber supply for Europe (England alone imports annually timber to the value of twenty-five million pounds), and a wood famine is sure to come. Nobody can say when this will happen.

We should do a little more for Forestry. For thirty years I have been a member of the Royal Scottish Arboricultural Society, and for an equal period of time we have humbly asked for a "School of Forestry," and if I look for the actual progress we have made in this quarter of a century, I must confess there is little or none!

John Booth, Corresponding Member of the Royal Horticultural Society, Gross-Lichterfelde, nr. Berlin.

The Week's Work.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Cornet, Impney Hall Gardens, Droitwich.

The Orchard House.—The earliest Peach and Nectarine trees will now require attention twice daily in the matter of watering; they should also be given occasionally liberal supplies of liquid-manure, and be further encouraged to develop by the frequent application of a top-dressing of a rich, well-mixed compost, composed of fibrous loam, horse-droppings, and bone meal. Trees that were moved into larger pots, or any that are making too much growth, will not require these manurial applications. The fruits should be thinned to the requisite number as soon as the stoning period is passed; at the same time keep the lateral shoots closely pinched. Red spider should be prevented from making its appearance by vigorously syringing the trees twice daily when the weather is favourable, and continuing until the fruits show signs of ripening. As the fruits develop expose them to the light as much as possible, and gradually increase the amount of ventilation during the night, closing the ventilators in the morning until the temperature rises to 68° or 70°, when air should be again admitted, and regulated according to the temperature of the house. The latest trees to develop and which are grown in unheated houses should be fumigated as soon as they pass out of the flower stage, or when the first signs of green fly appear. Dishud the trees according as they require it and remove any shoots which were overlooked at the time of pruning. Pinch out the points of the strongest shoots at the fifth or sixth leaf from their base, allowing the weakest shoots a little more time before stopping. If the houses are unheated, let all the damping and syringing of the trees be carried out during the early part of the day in order to allow the foliage to become dry before night-time, until all danger from cold nights is passed. Give careful attention to the ventilation of the house and to the watering of the trees.

Pears and Apples.—As soon as it can be seen which fruits are swelling and which are likely to take the lead, they should be thinned in number, and when finally thinning allow but one fruit to remain on each spur. Caution must be exercised in not finally thinning the fruits too soon, for in some cases, and when least expected, the fruits drop off without any apparent reason. After the fruit is set the same care and attention are necessary when watering the trees and when ventilating the houses as in the case of Peaches. Keep down green-fly by fumigating, and examine any curled leaves for grub, which will otherwise soon do a lot of mischief.

Plums and Cherries.—The latter fruit will develop more quickly than the Plums after the stoning stage is passed, and after the fruits are ripe should, if grown in pots, be removed to a cooler and drier atmosphere, where the berries will hang for some considerable time. Pinch out the points of the shoots as often as they need it, and keep a watchful eye for curled leaves. Black-fly often attacks Cherry-trees; this pest is difficult to get rid of unless taken in time. It can be eradicated if the points of the shoots are dipped in some approved insecticide, or if the trees be fumigated twice with XL-All Insecticide. This fumigating must be done before the fruits change colour.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Vanda Sanderiana.—An importation of this grand Orchid having recently been sold by auction, a few hints on its cultivation may be of service. Newly-imported plants should not be fully exposed to the light or much heat and moisture during the first few weeks, or excessive shrivelling and early loss of many of the lower leaves may result. Place the plants upright in a position where extra shading may be afforded them in a house having an intermediate temperature, and as the leaves regain their rigidity, utilise the extra shading only during the brightest part of the day. In course of time the plants will make roots, and should then be fixed in their receptacles by tying some of the old roots to the bars of the baskets, which should be provided with wires for suspending. Almost fill the baskets with drainage material, and surface with fresh sphagnum-moss. Suspend the plants on the shadier side of the East Indian-house, encouraging the sphagnum-moss to grow, first with partial waterings, and afterwards, as root-action increases, afford a frequent and plentiful supply. In the autumn, when the roots begin to seal at the ends, decrease the supply of water, and continue this practice until the winter, when very infrequent supplies will be sufficient to keep the leaves from shrivelling.

Vanda cærulea.—Some excellent consignments of this plant have also come to hand this season, and if a little extra care be given them, the plants should yield excellent flowers during several succeeding seasons. Newly-imported plants may be fixed in pots filled almost to the rims with pots-herds, and be placed on a stage in an intermediate-house where extra shade can be afforded. Provided the conditions of the house are suitable, no direct watering will be needed until root-action occurs, but the stage should be kept moistened. When the roots have become active, place a 2-inch layer of freshly gathered sphagnum-moss on the drainage material, and remove the plants to a lighter and better ventilated position in the house, keeping the sphagnum-moss and surroundings in a moist condition. Decrease the water supply as soon as root-action declines, and during the winter months very infrequent doses will be sufficient. The majority of the Vanda-like plants that were afforded fresh sphagnum-moss early in last month will now need sufficient waterings to keep the sphagnum-moss in a growing condition, and should any of the moss have failed to start into growth, let it be picked out and fresh substituted for it.

Lælia majalis is now becoming active again, and therefore requires generous treatment. It

may be grown on blocks, rafts, or in baskets, but whichever method is employed a very small quantity of material should be laid about its roots. The plants thrive best when suspended in an intermediate-house near to the upper ventilators, and as soon as a new series of roots appear liberal supplies of water will be needed. If the plants are suspended where they can be syringed several times each day without fear of causing injury to other plants, it will be to their advantage. Growth is very rapid, flowers, leaves and pseudo-bulbs developing together, and by the time the blooms are over the limit of growth is reached. The plants will need copious supplies of water until the autumn, but little or none afterwards, until just before growth commences in the following season.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Seed Sowing, &c.—Seeds should now be sown of Helichrysums, Grasses, Sunflowers, Lavatera, annual Chrysanthemums, and Coreopsis. Afford the seed-bed a slight protection from severe weather. Seedlings of Asters, Carnations, Alonsoas, &c., should be "pricked off" when they are large enough to handle. Make preparations for placing Pelargoniums and other bedding-plants into cold frames where they may become hardy. If these plants have been growing in a shady position or a long distance from the glass, they will need shading from bright sunshine for some days to prevent their being scorched.

The Wild Garden.—Proceed with the planting of hardy plants. Cimicifugas are stately subjects, and are suitable for planting in sunny or shady positions. C. cordifolia has dark-coloured stems, grows 3 to 4 feet in height, and flowers from August to October. The plant thrives in a damp situation. C. simplex is also a fine plant. Other good varieties are C. racemosa and C. davurica. Lythrum virgatum var. Rose Queen is the finest of the Loosestrifes. It makes a brilliant display in a wet situation from July to September. Lysimachia clethroides is a good white-flowering plant, in flower during July. Monarda didyma revels in a sunny, damp situation, as do also Ourisia coccinea and Podophyllum Emodi. Cuttings of Galega officinalis compacta Snowdrift that were inserted during last autumn in a cold frame will be ready to be transplanted to their permanent quarters. The plant is very effective in masses. G. o. Hartlandii is also a desirable plant. Michauxia campanuloides should now be planted in a warm sheltered position. The present is a suitable time to sow seeds of this plant.

The Rock Garden.—Species of Cistus are useful subjects for planting on dry banks and on tops of walls. Cuttings of these that were inserted in a cold frame during last autumn should now be suitably rooted and ready for planting. They will thrive and grow into bushy plants if simply dibbled into the soil of steep banks. When planted in rich soil these plants soon succumb to the influence of frost. The flowers are mostly of diurnal duration, but being freely produced they make a fine show in early summer. C. florentinus is one of the best and most easily grown; C. laurifolius is a hardy and perfectly distinct species; C. crispus forms a compact bush, and produces flowers of a deep rose colour 1½ inch across; its newly-opened crinkled blooms attract much attention. C. algarvensis has bright yellow-coloured flowers. Other good kinds are C. hirsutus, C. ladaniferus, C. lusitanicus, and C. salviæfolius.

Helianthemums require much the same treatment as the above. Rooted cuttings planted now will soon make a bright show.

Gypsophila paniculata is a useful plant for indoor adornment; plants are easily raised from seed. The double variety is a welcome addition to borders. G. p. Steveni is also a good variety. G. repens monstrosa is useful for draping over rockwork. G. repens rosea is a charming rock plant.

Hypericums will thrive in any ordinary garden soil. Plants propagated in a cold frame last autumn will now be sturdy. H. reptans is a good rock-garden plant, its growth quickly covering large stones; H. repens is a smaller-growing species; H. Moserianum makes a fine bush, growing from 2 to 3 feet high, and produces flowers freely; H. M. tricolor is a choice variety, and when planted in a sunny nook the colour of the flower develops well; H. Androsæmum is showy, and the old favourite H. calycinum is useful for planting under trees.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Withes, Esq., Copped Hall, Epping, Essex.

Carnations for Flowering in Winter.—Cuttings that were propagated early in January should now be sturdy young plants ready for putting into 6-inch pots. Previous to being potted the plants should be closely examined for aphis or red spider, any traces of which must be removed by syringing the plants with Quassia extract or immersing them in the liquid. It is essential to success that the plants be kept quite free from insect pests. The potting at this stage is the final one, and the compost should be carefully prepared. Where good yellow fibrous loam is procurable it is undoubtedly the best material for Carnations, but where this is not obtainable, the best must be made of that which is available. Very stiff and heavy soil should have a quantity of road grit or scrapings incorporated with it to bring it to a degree of lightness and porosity which is needful for Carnations. It will also be necessary to add leaf-soil, and a proportionate amount of silver sand. Sufficient of Thomson's Plant Manure to fill a 6-inch pot may be added to each barrow load of soil, but beyond this no artificial manure should be used because better results will be got from judicious feeding before the flowering stage than if the soil were overdone with manures at the time of potting. Let the plants be kept for a time in a cool frame with only a moderate degree of ventilation, but as growth develops and the weather becomes warmer the light may be removed entirely from them, except during heavy rain. The plants will require stopping occasionally to induce a bushy habit, but in the case of those required to yield a supply of flowers in October this operation must cease after the second week in June.

General Propagation.—If the propagation of indoor plants has been carried out as previously advised, most of them are now well rooted, and should receive the attention they require. Economy of space is an important matter in most gardens, and great advantage is gained by selecting the number of plants that can be properly cultivated, so that those that are not wanted may be thrown away, as their retention for an indefinite time would impart an appearance of neglect to the houses.

Begonias Gloire de Lorraine and Turnford Hall.—A batch of cuttings for general use should now be inserted. They will make roots readily in cocoa-nut fibre or in soil in a warm atmosphere. Select growths from the base of the plants for the making of cuttings.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Apricot-trees.—Examine the trees, and in cases where the fruits have "set" several together in clusters, thin them out, removing those which would be likely to get crushed against the wall or between the shoots. The degree to which they should be thinned will depend upon the purpose for which the fruits are required, also upon the variety. If fruits of the largest size are required from such large-fruiting varieties as Luizet, St. Ambroise, Grosse Pêche, and Royal, only one fruit should be left to every 6 square inches of space. Smaller fruiting varieties, including Breda, Powell's Late, and Musch-Musch need not be thinned so severely. The fruits removed at the final thinning will be useful for bottling purposes. Let the thinning be done slowly and at several operations. Any shoot which is much stronger and more vigorous than the others may be cropped more heavily. Although Apricot-trees seem already to have set good crops of fruit, the protection should be kept available for use for some time longer, as there may yet be frost or cold winds which would injure the fruits. The work of disbudding the shoots may also be proceeded with, and by reserving only those buds which are necessary to produce shoots or spurs, a considerable amount of labour, and the detrimental use of the knife subsequently, will be prevented. This work should be extended over a period of two weeks. Do not expose the young fruits severely at the first operation. Shoots growing straight out at right angles to the wall, and termed "forerights," are generally useless and should be rubbed off. Clusters of shoots proceeding from the terminal end of the spurs should be thinned. If a growth can be retained at the base of a long, barren spur, this should be done, removing the spur down to the growth by means of a sharp knife. If a number of spurs are treated in this way annually, the trees will contain more young bearing wood than they would otherwise do. Spurs removed at this season of the year are not so liable to be attacked by canker as if done earlier. Young trees should have their leading shoots continued, and along the growth made last season leave two or three shoots for furnishing the wall-space. Retain also sufficient buds to form fruit-spurs, which should be pinched at the third leaf, removing fore-right and badly-placed buds. The presence of maggots may be detected by the twisted appearance of several leaves together, and if any are found they should be crushed between finger and thumb.

Cherry-trees on Walls.—Trees which bear an abundance of bloom-buds may with safety have a quantity of them removed, thereby strengthening those that remain. Apply a sprinkling of muriate of potash about the roots during showery weather to strengthen the flowers, and thus help in obtaining a good "set."

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Mushrooms.—The material for forming the beds should be spread out thinly in an open-sided structure where the manure will not be exposed to rains. Let each consignment from the stables be treated in this way until the quantity considered necessary to form the bed has been collected. When this has been done, and in order to allow some of the moisture to escape, and to prevent an undue degree of heat arising afterwards, form the manure into a conical-shaped heap, and turn it over at intervals of a few days. Do not be too exacting in the removal of all the litter, nor in allowing too much of the moisture to escape, because the presence of a certain amount is much to be preferred to the other extreme when water has to be added. Close attention must be given in order to have the material in that intermediate stage between a wet and dry condition. The removal of successful and unsuccessful beds affords good object-lessons. The material from beds which have been productive will be found bright in colour, moderately dry, and freely interspersed with a network of white threads with little signs of decay. Although the Mushroom, like many other fungi, is supposed only to exist upon decaying matter, yet in successful cultivation decomposition must not be of a too rapid nature. Therefore it is necessary to avoid excess of heat and moisture. Only the best spawn in a fresh condition is worth utilising. From this season onwards choose for beds out-of-doors, positions that are cool, though provided with shelter and shade.

Beetroot—Sow seeds of the variety Dell's Crimson, and ten days later make a sowing of Blood Red, Perfection and Pragnell's Exhibition. Allow distances of 18 inches between the lines, not with the idea of producing large roots, which are seldom appreciated, but with the object of securing thorough maturity and colour in roots of medium size. Sow the seeds a little deeper in the ground than advised for Carrots, but in other respects the practice should be the same.

Spring Cabbage.—The general appearance of this important crop is all that could be desired. Ellams's Early Dwarf is the variety relied upon here, and at present we are cutting nice little compact "heads," with full and hard centres. In the early batch of between two and three thousand plants I have not been able to detect a dozen plants that have run to seed.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, APR. 24—Easter Monday. Bank Holiday.

TUESDAY, APR. 25—Royal Horticultural Society's Committees Meet, and National Auricula and Primula Society's Show combined.

FRIDAY, APR. 28—Royal Botanic Society Meet.

SALES FOR THE WEEK.

WEDNESDAY NEXT—
Hardy Border and Herbaceous Plants, Roses, Palms, Plants, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 o'clock.

FRIDAY NEXT—
Trade Sales of imported Orchids; also 6,500 O. crispum, 1,200 O. Pescatorei, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12 30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —49·7.

ACTUAL TEMPERATURES:—
LONDON.—*Tuesday, April* 18 (6 P.M.): Max. 47°; Min. 37°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Wednesday, Apr.* 19 (10 A.M.): Bar., 29·9; Temp., 44°. Hailstorms.
PROVINCES.—*Tuesday, April* 18 (6 P.M.): Max. 48°, S. Devon; Min. 40°, N.E. Scotland.

Jonathan Rashleigh.

THE death, at the age of eighty-five, removes another of our oldest and most valued contributors. Mr. RASHLEIGH, who died at Menabilly, Cornwall, on the 12th inst., was an enthusiast in gardening matters and the possessor of one of the most interesting gardens in the county. He was born on January 7, 1820, and was one of the best-known men in Cornwall. He was educated at Harrow and at Balliol College, Oxford. Among his closest friends were Archbishop TEMPLE, Lord IDDESLEIGH, Lord COLERIDGE, Sir THOMAS ACLAND, and the Hon. and Rev. J. TOWNSEND BOSCAWEN, all of whom predeceased him. Mr. RASHLEIGH took an active part in Cornwall county affairs, and had been High Sheriff. He was twice married, and leaves several children. Whilst a lover of plants in general, he was a specialist so far as Conifers, Bamboos, and Eucalypti are concerned, and his garden is specially rich in species, which he collected with great pains and judgment. The favourable climatal conditions of that part of Cornwall enabled him to grow many species which are tender in other parts of the country, or are even unable to withstand a ruder climate of other counties. His communications to this journal were frequent, the last note being one in his own handwriting quite recently published relating to the measurements of certain Cedars, especially those in the gardens of his old friend the late Mr. BAKER, of Bayfordbury, Herts.

Illustrations of Palms, Eucalypti, Tree-Ferns, Dracænas, Mexican and other Pines, growing at Menabilly have often been given in our columns. Mr. RASHLEIGH was a representative of a type which, in spite of the greatly extended interest in gardening generally, unfortunately does not increase in proportion. We allude to those who are not only "fond of flowers," but are not satisfied till they know something about them.

GERMAN SOUTH-WEST AFRICA (see Supplementary Illustration).—Public attention has lately been attracted to this corner of the globe on account of the difficulties which the German colonists have had to encounter with the natives. The district lies to the north-west of our Cape Colony, between it and the Portuguese possessions on the west coast. The German Government are doing their best to develop the resources of the Colony, and to encourage, where the conditions are favourable, afforestation and the culture of useful plants. Our valued correspondent, Herr DINTER, who was formerly at La Mortola, holds a high position in the Forest Department, and, as we have previously announced, will shortly return for a short time to Germany. His address will be Bautzen, Saxony. To him we are indebted for the characteristic photographs now reproduced. They show that however sterile the soil may be in some places, it is rich enough to support the growth of fine species of Ficus, Acacia and other trees. Other photographs, not reproduced, show the extraordinarily rapid growth of some young trees planted out under Mr. DINTER'S care. To the botanist this district will always have a special interest as the home of the Welwitschia, that uncouth-looking plant, which looks as if it might be a denizen of another world, very different from this, and the interest attaching to which, great as it was on its first discovery, has not subsided even now.

LINNEAN SOCIETY.—The next general meeting of the Society will be held on Thursday, May 4, 1905, at 8 P.M. Papers:—Mr. A. G. TANSLEY, M.A., F.Z.S.: "Ecology, its Present Position and Probable Development." Mr. R. N. RUDMORE BROWN: "The Flora of Gough Island" (communicated by Mr. W. BOTTING HEMSLEY, F.R.S., F.L.S.).

THE LONDON GEOLOGICAL FIELD CLASS, conducted by Professor SEELEY, F.R.S., begins its twentieth year's season on Saturday, April 29, with a visit to the North Downs at Betchworth. The Field Class, which is carried on continuously on the Saturday afternoons in May, June and July, affords practical teaching in Geology by studying direct from Nature the structure and modes of occurrence of the rocks in the basin of the Thames and adjacent country. Further particulars may be obtained from the Secretary, J. W. JARVIS, F.G.S., St. Mark's College, Chelsea, London, S.W.

THE ELDER.—There is a saying that when the Elder is in bloom the summer is half over. As we gathered a few days since fully-expanded flowers of the Golden Elder, we trust the saying does not apply to this particular species. Near by were clusters of the common Elder, advanced indeed, but not more than sufficiently so to indicate that summer is approaching. By the way, we may remind the reader that the Golden Elder is a variety of the Canadian species Sambucus, and not of the common European species. The inflorescence of the latter is a flat-topped, spreading, much-branched cyme, whilst in the Canadian Elder the flowers are arranged in elongated panicled cymes. To ensure the full colouration of the leaves it is necessary to cut the bush hard back in late autumn or early spring.

THE BOARD OF AGRICULTURE.—The activity displayed in recent years by the Board of Agriculture is most praiseworthy. Following in the wake of the marvellous United States Department of Agriculture, our own authorities, by means of leaflets and other publications, now circulate information of great value to farmers and gardeners. Although that information has been and is to a large extent supplied through the class-journals, yet it is quite clear either that those periodicals do not reach the great body of agriculturists, or that the cultivators pay little heed to what is put before them, even when the subject is of the utmost moment to them in the conduct of their business. Improved methods of education are gradually working a reform in this matter. In the meantime the Government Agricultural Department is, as we have said, doing good work by diffusing as widely as possible serviceable information. As an example of this we may mention a series of coloured diagrams illustrating some of the more common diseases of trees in this country, together with sheets of explanatory letterpress. The illustrations before us represent the external appearance of several of the more common fungi, whilst the text is not only explanatory, but it furnishes in a concise form directions for the prevention and if not for the cure of the disease, at least for the palliation of its effects. As a matter of minor importance it may be incidentally mentioned that the arrangement of the scales of the cones in the various conifers figured is peculiar. We hope the Board will quickly follow up this series with others of a similar character.

NATIONAL DAHLIA SOCIETY.—We have received a supplement to the Official Catalogue of this Society, which brings the list of varieties up to date by including all the newer introductions and those which will be sent out into commerce for the first time in 1905.

THE NURSERYMEN, MARKET GARDENERS' AND GENERAL HAILSTORM INSURANCE CORPORATION, LTD.—The tenth annual general meeting of this company was held at the registered offices, 41 and 42, King Street, Covent Garden, W.C., on Friday the 7th inst., when Mr. HARRY J. VEITCH presided. The progress of the Company has been continued, the income for the year having increased to £2964 8s. 1d. The assets of the company now amount to £20,229 15s. 4d., and the reserve fund now stands at £9,000. The usual dividend of 5 per cent. and bonus of 2½ per cent. was agreed to. It was noted that the company still had the same chairman, directors and secretary as at its formation.

MR. T. W. BRISCOE, who for some time past has had charge of the collection of Orchids in the Royal Gardens, Kew, has been appointed by Messrs. JAS. VEITCH & SONS, Ltd., to undertake the management of the Orchids at Langley in succession to Mr. SEDEN.

ARMSTRONG COLLEGE, NEWCASTLE-UPON-TYNE.—With a view of obtaining accurate records of the growth and development of ordinary forest trees in the north of England, an attempt is being made by the Forestry Lecturer in this College to arrange for the careful measurement and observation, at suitable intervals, of small sample plots in Estate Woodlands which illustrate the growth of Oak, Beech, Ash, Larch, Scotch Pine, Spruce and other forest trees of economic importance. It is hoped by such means to arrive at definite conclusions as to the value of the various species of timber trees grown in the north of England and the volume of timber which can be produced per acre on different soils and situations by various methods of thinning and under the influence of the varying climatic conditions prevailing on the eastern and western sides of the four northern counties. The size of individual areas suggested as suitable for the purpose are not less than one quarter or more than an acre in extent, the exact size being determined in each case by the crop on the ground, conditions of growth, &c. In the event of a sample plot being laid out it will be necessary for the following conditions to be carefully observed:—(1) The preservation of the crop or sample plot in the same condition in which it existed at the time of measurement, by allowing all trees to stand until mature, with the exception of necessary thinnings which may be advised from time to time for the benefit of the main crop. (2) The retention of all trees standing round the edges of the sample plot until the latter is ripe, so that sudden isolation may not cause damage by wind. (3) The notifying of all deaths or windfalls occurring on the

sample plots to the Forestry Expert of the College, and the granting of necessary facilities for its inspection. Several woodland proprietors have already given their support to the above scheme, full particulars of which may be obtained from Mr. A. C. Forbes, Lecturer on Forestry, Armstrong College, Newcastle-upon-Tyne, and to whom those willing to assist in the work should apply.

Presentation to Mr. Samuel Arnott.—Our readers will be interested to learn that our correspondent, Mr. Samuel Arnott, has been presented by his fellow-townsman of Carsethorn, in which place he has resided during the past twenty-one years, with a handsome gold watch, together with an elegant silver tea-kettle and heating-lamp for Mrs. Arnott. Mr. Arnott, who is removing to Maxwelltown, was the guest of his friends and neighbours at a public dinner held in Kirkbean School on Friday, April 7, on which occasion the presentation was made.

Grouse Disease.—The President of the Board of Agriculture and Fisheries has appointed a Committee to enquire into the nature and causes of Grouse disease, and to report whether any, and if so what, preventive or remedial measures can with advantage be taken with respect to it. The Committee will be constituted as follows:—The Marquis of Tullibardine, M.V.O., D.S.O., Earl de Grey, K.C.V.O., Lord Henry Montague Douglas-Scott, the Lord Lovat, C.V.O., C.B., D.S.O., Mr. W. Dudley W. Drummond, Mr. James Graham, The Mackintosh of Mackintosh, Mr. Ronald Craufurd Munro-Ferguson, M.P., Mr. Reginald Henry Rimington-Wilson, Dr. William Somerville, an assistant-secretary to the Board of Agriculture and Fisheries. The Chairman of the Committee will be Lord Lovat, and Mr. A. S. Leslie, Secretary. The cost of the enquiry will be defrayed by subscription, and it is guaranteed that no charge in respect of it will fall upon public funds.

Grafting and its Effects.—In the older text-books it was laid down that grafting produced no perceptible change in either stock or scion. If this were the case the reasons for grafting would be comparatively slight. More recent investigations have shown, as might have been expected, both physiological and structural changes. M. Colin has lately been examining the structural changes in the stalk bearing the bunch in some grapes grown for wine-making and finds a difference in the size, number and distribution of the fibro-vascular strands and of the liber-cells.

Publications Received.—*Memoirs of the Royal Caledonian Horticultural Society.* This is the first part of a new series. The contents include Alpine Plants, by R. Lindsay; Hybridisation, by Dr. Wilson; Roses, by the late Hugh Dickson, &c.—*Meteorological Notes and Remarks for* 1904, by Jas. Whitton. These are from records kept at Queen's Park, Glasgow. The rainfall was slightly under average; with regard to the temperature the averages were slightly higher than those of the preceding year. *The Estate Magazine*, supplement to the *Country Gentlemen's Estate Book*, April. Contents: The Ellesmere Estates, with portrait of the Earl of Ellesmere; Japanese Larch and Larch Diseases, by J. Simpson; and Notes on Gardening and Agriculture.—*Bulletin of the Department of Agriculture, Jamaica.* March. Contents: Citronella Grass in Ceylon, Half-way Tree, Jamaica; Diseases of Cocoanuts, Experiments with Sugar-cane, and Culture of Ornamental Shrubs and Climbers. — *Western Australian Year-Book for* 1902—4. By Malcolm Fraser. This should be studied by all interested in the Colony, as it gives an excellent hint of its past history and present conditions. The flora and forest resources are duly considered. — From the Ontario Agricultural College: Bulletin 139, *An Experimental Shipment of Fruit to Winnipeg*, by J. B. Reynolds, and 140, *The Results of Field Experiments with Farm Crops*, by C. A. Zavitz.—*Journal de la Société d'Horticulture du Japon*; January and February. This periodical contains short notes printed in French, and longer articles in Japanese.—From the New York Agricultural Experiment Station: Bulletin No. 246, *Seed Selection According to Specific Gravity*, by V. A. Clark. — *Journal d'Horticulture de Culture Maraichère et de Viticulture de la Suisse Romande.* A monthly paper published by the professors of the École d'Horticulture, certain amateurs and professionals, and l'Association des anciens Élèves de l'École. —*Nuovo Giornale Botanico Italiano.* Vol. xii., No. 1.—*Bulletino della Società Botanica Italiana.* December, 1904, and January and February, 1905.

NOTICES OF BOOKS.

The Cultivation and Preparation of Para Rubber. By W. H. Johnson, F.L.S., F.R.H.S., Director of Agriculture, Gold Coast Colony, West Africa. Illustrated. (Crosby Lockwood & Co.) 8vo, pp. 99, 7*s.* 6*d.* net.

Anything calculated to extend the cultivation of the best rubber-producing plants and to increase the supplies of a substance which has been for many years, and is still, increasing in demand for the thousand-and-one uses to which rubber is now put, is to be welcomed as a contribution towards allaying some of the anxiety that has long been felt as to the prospect of future supplies, or the discovery of a real substitute. No substitutes, however, can ever be expected to approach in value and usefulness that particular kind of rubber upon which the reputation of the article was originally founded; consequently the book before us is all the more welcome as it deals only with the Para Rubber-plant. From this tree (Hevea) the best quality of rubber is still obtained to-day, as it was on the introduction of the substance into this country in 1770, when a square half-inch of Para rubber was sold at 3*s*, and was to be had at one place only in London, its wonderful property being that of "wiping from paper the marks of a black-lead pencil."

That Para rubber still rules the market, and this because of its very durable quality, which defies not only substitutes but even competitors, is proved by Mr. Johnson's quotation of prices from London experts, where, on p. 9, he shows that Para rubber, obtained from cultivated plants grown in Ceylon, had so recently as September, 1904, realised the record price of 5*s.* 6*d.* per lb., and further, from various samples submitted for valuation at different dates from July, 1902, to January, 1903, fine Ceylon-grown Para fetched on an average 6*d.* per lb. more than hard-cured fine Para prepared in its native country. These are facts of considerable interest both to the planter as well as to the broker and manufacturer. The great drawback to the introduction of the Para plant (Hevea brasiliensis) into British Colonies or possessions hitherto has been the difficulty of raising plants from seeds owing to the oil contained in them, which, turning rancid, has prevented germination; and, further, the Hevea being a large tree, some years must of necessity elapse before any return could be obtained from the yield of rubber. So far back as 1873 the first experiments were made in transmitting seeds and cuttings of Hevea rubber plants from Kew to India, and about three years later a large consignment was sent to Ceylon, 90 per cent. of the plants reaching their destination in excellent condition. From these plants, which grew well, forming handsome spreading trees, large quantities of cuttings were struck and distributed.

Mr. Johnson tell us, "as the result of this introduction, an important agricultural industry has developed in the Malay Peninsula and Ceylon. . . . It is estimated that there are now about 12,000 acres planted with this tree in Ceylon, while in the Malay Peninsula there is a still larger area under Para rubber cultivation. The small amount of cultural skill required to successfully cultivate the Para rubber tree, coupled with the high prices paid for the rubber which the cultivated trees produce in comparison with that paid for other grades of rubber, has no doubt largely influenced planters in selecting the Para tree in preference to other rubber-producing plants."

It is satisfactory to know, on the authority of Mr. Johnson, that "in the Gold Coast, West Africa, this tree, grown in experimental plots in the Botanic Garden, Aburi, which is situated 1,500 feet above sea-level, and where the average mean temperature is about 81·5° Fahr., and the annual average rainfall 47 inches, promises better results than any other rubber-producing plant, indigenous or exotic." Moreover, to sum up this part of the question, Mr. Johnson further says: "The manner in which this tree has adapted itself to the various climatic conditions obtaining in the different countries mentioned is almost unique in tropical cultivation," the countries referred to besides the Gold Coast being India, Jamaica, Dominica, St. Vincent, Grenada, Trinidad, Zanzibar, Uganda Protectorate, and Mozambique.

In the third chapter of the book, which is devoted to the cultivation of the tree, we find some interesting notes on propagation, in which the merits and demerits of seeds *versus* cuttings are discussed, and information is afforded as to the proper site for a plantation, the distance apart to plant the trees, and the methods of transplanting.

The next chapter, which is very brief, is devoted to insect pests and fungoid diseases, the brevity being fortunately indicative of the scarcity of these pests, for we are informed that notwithstanding that certain insects and fungi are found on the plants, "no disease has up to the present time been discovered seriously to affect this tree under cultivation."

The succeeding chapters, which are devoted respectively to the collection of the rubber, the preparation of the rubber from the latex, and the yield from cultivated trees, will be especially useful to those who contemplate embarking in this important branch of culture; as will also the succeeding chapter, on the "Establishment and Maintenance of a Para Rubber Plantation." The concluding chapter, on the "Commercial Value of the Oil in Hevea Seeds," is interesting; and though it is stated that the oil might be used for the various purposes to which Linseed oil is now applied, and the residue of the seeds used as cattle food, it would seem to us that with the numerous oil-seeds now in the market, and owing to the presumably purgative character of the oil of Euphorbiaceous seeds, as shown in the Castor-oil, Croton-oil, Jatropha, and other allied plants, it would be some time before the seeds of the Hevea cleared themselves from the evil reputation of its allies.

In everything connected with Gold Coast plants, especially those having any economic value or interest, Mr. Johnson speaks with considerable weight, as he has had a very long experience in Tropical Africa, and holds the position of Director of Agriculture in the Gold Coast Colony, besides which, in 1902, he was, as stated on the title-page, commissioned by Government to visit Ceylon to study the methods employed there in the cultivation and preparation of Para rubber and other agricultural staples for market, with a view to introduce them into West Africa. The outcome of this visit is embodied in the book before us.

Pictorial, Practical Tree and Shrub Culture. By Walter Wright and W. Dallimore. (Cassell & Co.). 1*s.*

The title-page further states that this is a "practical manual giving directions for propagating, planting, and pruning trees and shrubs, and selections for various purposes," and the contents amply justify the title. In the preface we are told that the letterpress is wholly the work of Mr. W. Dallimore. We congratulate him and the editor on the production of an admirable little book. Its size does not admit of much elaboration, but the information supplied is, so far as it goes, excellent and accurate, and furnishes a marked contrast to the paste-and-scissors compilations sometimes palmed off upon a too confidin; public. The practical details supply just what is

wanted, and what we may add is often difficult to find. The selections of shrubs intended for different purposes are judicious, and the plants are properly named. The illustrations, though rather coarsely executed, do really illustrate the text, and a table of contents and an index facilitate consultation. There are some omissions which we should be glad to see filled, such as Laurelia aromatica, Berberis Thunbergii, the golden-leaved Oak, Quercus Concordia, &c., and a fuller description of Vitis Coignetiæ and its allies is desirable. Picea is included in the index, but it is not to be found at the page indicated, but at p. 147. But it is clear that compression rather than expansion was necessary, and the wonder is that the author has been enabled to pack so much into 150 pages. The work is so good that we should like to see a fuller treatise on the subject from his pen.

TREES AND SHRUBS.

THE MAGNOLIAS.

MAGNOLIAS succeed best in warm positions and in a moderately rich soil, which should be of a free, open texture, and great care should be taken in transplanting them that no fibrous roots be broken off, as the shrubs are somewhat impatient of root disturbance; judgment should also be exercised with a newly-planted bed as regards protection from frost. This is easily afforded by covering the top with a good coating of stable-manure, and by wrapping the trunks round with a mat, transplanting being done in October. Magnolia glauca and some others grow best in a peat soil in a moist situation. They are generally increased by layers put down in the spring or autumn or by seeds. When the layers are first taken off they should be potted in a mixture of loam and peat placed in a close frame till they have made fresh roots; none of the leaves should be taken off or their tops shortened, as they will not succeed so well, for the more branches and leaves are on them the sooner they will strike roots. Some cultivators cut off many of the leaves and shoots from the layers when they are first taken off, thinking that the roots will not have so much to nourish, which is the very reason they often lose great parts of their crops. Layers of any kind of shrub when first taken off should not have a single leaf removed until they have made fresh root. Even if their tops flag ever so much, so long as there is life the leaves will draw up the sap and help the plant to root afresh. The Chinese kinds are often inarched or budded on M. obovata, and take readily. Veneering and side-cleft grafting are also practised in July and August, the stocks operated upon being placed in a close frame until union is effected.

The greenhouse kinds thrive best in a mixture of peat and loam, and are also increased on M. obovata, one of the readiest-growing kinds. M. fuscata or Michelia fuscata, and any of the weak species, may be increased with facility from cuttings taken off as soon as ripe and planted in a pot of sand under a glass. The seeds of the North American species are received annually from that country when ripe, and should be sown as soon as possible after their arrival, and kept moist until they germinate in pots of light, rich earth, covering them half an inch deep. These may be placed either in a hotbed or in a warm, sheltered situation, or they may be sown in the open ground, and when the plants are of sufficient size they should be planted out singly into pots and sheltered till they have taken fresh roots, and should be protected from the frost by a frame for two or three successive winters, giving them the benefit of the open-air in mild weather. *C. S.*

INTERGRAFTING BRANCHES.

WHILE living at Watsonville, California, U.S.A., I noticed a large orchard of Apple-trees, all of which were grafted as seen in the sketch (fig. 105). I thought it somewhat of a novelty, so made it my business to call on Mr. M. Tuttle, the owner of the orchard, and chatted with him about his Apple-trees. He said it occurred to him that by grafting from one main branch to another it would save placing "props" to the trees, allow more room in fruit-gathering time, and prevent the branches from breaking owing to the weight of the crop. The twigs were bent toward each other, and twisted round. When I saw them the grafts were from 1½ to 2 inches in thickness, the trees having been planted about twelve years. Another thing I noticed was that all the best fruit grows in the orchards where the ground is ploughed and harrowed or, as they term it, cultivated. The trees are planted

FIG. 105.—MUTUAL SUPPORT AFFORDED BY INTER-GRAFTING BRANCHES.

in straight rows seen from whichever way they are looked at, the rows being 25 to 30 feet apart, according to the variety of Apple-tree planted. *G. Osborn, Dunstable.*

KEW NOTES.

LISSOCHILUS MAHONI, *Rolfe.*—This is a very handsome and noble new species now flowering in the Victoria-house. Mr. Rolfe has named it in honour of M. J. Mahon, of the Imperial Institute, and late Curator of the Botanical Gardens, Entebbe, Uganda. Mr. Mahon sent the tuberous roots to Kew from Uganda in the latter half of the year 1902; since which time they have been grown under stove conditions, being potted in a compost of three-parts fibrous yellow loam and one-part of leaf-soil, with a considerable addition of silver-sand. It has grown vigorously under this treatment, and now fully occupies a 10-inch pot with its fleshy roots. L. Mahoni is of the same giant proportions as L. giganteus, which was flowered by Sir Trevor Lawrence in May, 1888, and was figured in the *Gardeners' Chronicle* for May 19 of that year. The species now flowering has very stout, Phaius-like growth, the linear-lanceolate leaves measuring 6 feet in length and 3 to 4 inches in breadth. The stout, erect peduncle (which has been about six weeks developing) is 8 feet in height, and will probably grow another foot by the time it is fully developed. At the present time there are fourteen fully-expanded flowers, and about an equal number of buds. The sepals are partly reflexed, about 1 inch long by ½ inch broad, light brown in colour marked with darker brown. The petals are 1½ inch long, and almost as broad, being curved slightly towards the lip; they are a beautiful shade of pink slightly tinged with violet colour, shading to nearly white at the base. The labellum is very large and handsome, the side lobes are deep green, with broad dark-brown markings, and the apex of the lip of bright violet colour. Running for two-thirds the length of the labellum is a dense straw-coloured crest, which is a very prominent and distinctive feature. When the petals are flattened the flowers have a diameter of fully 3 inches. *W. H.*

FLORISTS' FLOWERS.

SOME NEW GREEN-EDGED SHOW AURICULAS.

NOTEWORTHY additions are being made to the green-edged section of the Show Auricula. The florist places this section at the head of the group. The edge is a very highly-prized "property," in the Auricula, and years of patient toil must have been spent in developing it. The pure, rich green on the edge of a finely-formed, stout and flat pip is considered to be one of rare beauty and value; next to this comes the zone of black body colour, which in a perfect flower should not strike through to the edge of the segments. Enclosed in this the paste, which is a circle of brilliant white meal, smooth, dense, and circular in a good flower; and then the golden tube, waxy in substance and circular in outline when at its best; and round the mouth the anthers, not too prominent, dusted with gold, and hiding from view the stigma, which is at a lower level in the tube. A perfect green-edged Auricula is still an ideal flower. Approximate perfection is of very slow development, but progress is being made, and that is matter for congratulation.

The veteran Ben Simonite of Sheffield is now the principal raiser and distributor of new varieties. He is this season offering two new green-edged Auriculas, having obtained sufficient stock. They are Henry Wilson, paste dense, sparkling and smooth, body colour black, edge pure green, tube golden, and pip of perfect form. It was shown in such fine character at the Midland Auricula show at Birmingham in 1903 that it was selected as the premier flower. From appearance it is a vigorous grower. Dr. Hardy has also been seen on the exhibition table, and it has on a few occasions been selected as the premier bloom at the shows held in London and Manchester. In its best character it worthily commemorates that old-time Lancashire florist after whom it was named. It has a bright green edge, golden tube, solid paste, black body colour, and fine form. It should be remembered that a new Auricula may be exhibited by the raiser half-dozen or more years before it can be put into commerce, so slowly do some yield increase in the form of offsets.

Gladiator is another of the veteran's seedlings he describes it as a flower of the finest quality, with pure green edge, black body colour, clear solid paste, golden tube, and the pip of fine shape. Shirley Hibberd, also one of Simonite's raising, appears to improve in cultivation, and Mr. James Douglas describes it as "a very fine Auricula—I think even superior to Abbé Liszt.; it has a beautiful gold tube, white paste, black body colour, and a fine green edge." It has been shown in good character during the past two or three years, and was distributed five years ago; it has been selected as premier, and awarded a First-class Certificate of Merit. Mr. Simonite is also distributing Diomed, which he describes favourably; but the name of the raiser is not given; it is probably one of Mr. Horner's raising. A

new green-edged Auricula which is becoming popular, and which has been well illustrated at Auricula shows, is Abraham Barker, raised, I believe, and distributed by Mr. Thomas Lord, of Todmorden; the edge is of a distinct olive-green, the various parts well proportioned, a vigorous grower, and an extremely useful variety.

I have seen in Mr. James Douglas's collection a variety raised by Mr. B. Simonite, bearing the name of Chloe, though I do not think it has been formally put into commerce. It produces refined pips, the edge of an unusually lovely green, with a zone of black body colour; but I fancy it is lacking in constitutional vigour. Mr. Douglas has a new variety named Greenfinch, a bright and attractive flower of good properties, but the stock appears to be limited.

Of the standard sorts, some of which still command a high price, there are Abbé Liszt (Douglas), which is generally shown in excellent character; James Hannaford (Simonite), which, when first shown promised well, but has not maintained its early character, and Mrs. Henwood, an excellent variety in addition to being a good grower. Page's Champion, Leigh's Colonel Taylor, and Booth's Freedom, which fifty years ago were the "cracks" of the green-edged section, are now rarely met with. The red F. D. Horner, Snitherfield Green, Talisman, John Garratt, &c., represent a group of cheaper sorts, with which the new beginner in Auricula culture may commence operations, and test his ability to grow the more expensive sorts.

For not one of the foregoing can perfection be claimed, but they are as so many stepping-stones lying in the path of progress, and an examination of their striking pips, when seen in their best character, seems to impart strength to the confident belief that they are but as prophecies of higher forms. *R. D.*

THE APIARY.

MAKING NOTE OF FAILURES.

We may often learn more by taking note of failures than from recording successes. During the present year keep a strict account of all lack of success, and next year will be one of the most successful you have ever known, all other things being equal.

The Skep Beekeepers.

Most of us commenced by keeping bees in skeps. I well remember how much I learned of bees and their ways by closely observing them going in and out of that first skep. To reap the full reward of bee-keeping bar frame hives must replace the skeps, but how to get the bees from one to the other is the difficulty.

Driving Bees.

The best way is to drive the bees from the skep in the following manner. Give the bees to be transferred a puff of smoke through the entrance, and wait two or three minutes. This allows them every opportunity to gorge themselves with honey. Having allowed the time to elapse, give them another puff, overturn the stock, and puff again. Place the overturned skep in a bucket, and put an empty skep on the stock, so that the sides coincide. Drum the sides of the hive containing the stock gently, and the bees will soon be in the top skep. Take the combs containing brood and tie them in the frames with two pieces of tape, taking care that the combs touch the tops of the frames. Fit the remaining frames with full sheets of brood foundation (sheets eight to the pound). Shake the bees on the frames, drive them down with smoke, put on the quilt and feeder, wrap up warmly, and success is almost certain. Some people simply place the stock above frames, and allow the bees to transfer themselves; but the process is a slow one, and far from economical. *Chloris.*

BAY TREES.

By no means the least remarkable feature of Messrs. Sanders' Nursery at Bruges, is the collection of Bay trees (Laurus nobilis). There are tens of thousands of them, ranging from plants a few inches in height to stately bushes 12 feet and upwards, ranged avenue-wise on either side of one of the walks. In so vast a collection variations in form are noticeable. The one we illustrate (fig. 106) shows a tree of peculiarly marked conical form, doubtless aided by a little timely pinching.

Fig. 106.—STANDARD PYRAMIDAL BAY AND AZALEAS IN MESSRS. SANDERS' NURSERY AT BRUGES.

Some of the trees are veterans, sending up in abundance suckers, by means of which they can be propagated; and, as we have said, there is a perfect army of juveniles destined to succeed their forbears. Handsome and fragrant as is the Bay, there are other shrubs which might be used for the sake of variety. In particular we would mention Laurelia aromatica, to which we refer on p. 252. It is true that we do not know at present how far that shrub is amenable to propagation, but every effort should be made to multiply so desirable a hardy shrub when it would prove a formidable rival to the Bay.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE CUCUMBER "SPOT" DISEASE.—On p. 219 in the issue for April 8, Mr. Thomas says: "The most likely cause, in Mr. Ward's opinion, for the attack of the disease is to be found in the weak and worn-out condition of the plants after a period of heavy and continuous fruiting, inviting attack in their more or less enfeebled state." By reference to my letter on p. 150, and to that on p. 188, he will find that he has misrepresented me, unwittingly, no doubt, inasmuch as I did not express the opinion which he ascribes to me. I simply attributed the cause of "spot" in Cucumber leaves to unfavourable external as well as internal conditions occurring after the fire-heat has been dispensed with, merely mentioning that the then nearly-exhausted plants would be more susceptible to the disease than young vigorous plants just coming into bearing would be. Mr. Thomas says that as far as practical experience goes he is in agreement with me that the composition and condition of the soil under expert management have nothing to do with the appearance of the "spot," adding, "but this is not to say that science, after all, may not provide by demonstration that a certain chemical

treatment of the soil may effect a prevention of the disease." We might as well infer that a chemical treatment of the soil in which Vines, Peach-trees, and Roses are growing will effectually prevent mildew appearing on the foliage growing under unfavourable atmospheric conditions. The cause of "spot" appearing on Cucumber-leaves, and mildew on the foliage of Vines, Roses, &c., is to be attributed to the atmospheric conditions of the houses in which the respective plants are growing [which favour the development of the fungus]. A low temperature with a humid atmosphere will cause mildew to appear on the foliage of Roses and Vines, and if the same conditions are present in Cucumber-houses they will also induce [the growth of the fungus which produces] "spot" in Cucumbers. The best preventive of the disease is to maintain a minimum temperature of between 65° to 70°, distributing in the afternoon only sufficient moisture for promoting and maintaining a healthy growth in the plants, and applying the moisture sufficiently early to admit of the pathways, &c., becoming fairly dry before sunset. Avoid opening the doors more than is necessary during the winter and spring months, especially those farthest from the heating apparatus during the presence of north and east winds and rain. When wheeling in the compost for top-dressing, it is a good plan to hang a couple of mats or similar material on either side the door and close up to the wall, as a means of preventing currents of cold air coming in contact with the plants. With this object in view the door should be opened and closed as quickly as possible, selecting if possible a calm, warm day for the work. In short, while a good brisk heat is maintained in the entire length of the pipes, and a buoyant atmosphere is secured day and night, "spot" is not likely to put in an appearance on the foliage of strong, free-growing, well-cared-for plants. Some will say, "Why dispense with fire-heat at all?" The answer to this question is obviously to lessen the cost of production in, say, midsummer, when climatic conditions appear to be favourable to this being reasonably done with safety. As stated in my two previous letters, it is at this critical point that the danger from "spot" is most to be feared and guarded against, and when, in my opinion, vaporising the houses with sulphur with Campbell's Vaporising Machines will prove effective as a preventive if not a cure for "spot." May I here ask if Mr. Thomas has ever had any personal experience of the vaporiser indicated? If not, I feel sure that the result of a trial of one would cause him to modify his views as regards the efficacy of the sulphur vapour so applied, and at the same time to relegate to thin air the drawbacks which he associates with the application of the sulphur vapour as a preventive, if not a cure, for "spot" on Cucumber leaves. The Swanley College prescription (see p. 201) I am inclined to think favourably of. Whatever good may result from the application of this mixture to the pathways must be attributed to the fact that the carbolic acid vapour having been diffused in the atmosphere of the house is inhaled by the plants through the leaves. I am quite convinced that whatever cure or preventive may be found for "spot" in Cucumber leaves it must be applied atmospherically, and certainly not to the soil in which the plants are growing. In conclusion, I should like to know the opinion of any mycologist and plant disease specialist on this very important subject of "spot" on Cucumber leaves, and so learn what reasonable ground there is or can be for supposing that the chemical treatment of a perfectly suitable and root-inviting compost may, as suggested by Mr. Thomas, effect a prevention of the disease—"spot." *H. W. Ward, Rayleigh.*

DO POTATOS DETERIORATE?—It is obvious that the question as to Potato deterioration can only be settled by practical experiment and observation, and not by mere discussion. Could the matter be determined by experience, extending over a series of years, on a plot set apart for such work at Wisley, and placed under the control of a special committee, useful results might eventually be obtained. Whilst, on the one hand, it is asserted that varieties grown on the same soil for several years in succession soon wear out, there are, on the other hand, cases like that furnished by the veteran raiser Robert Fenn, who has not only kept tight hold of the stocks he raised some forty years ago, but for fully thirty years has been growing them in the same garden ground, and still finds the varieties as good as ever they were. There seems to be no reason why the Wisley soil, once it is deeply worked and rendered suitable, should not do well for Potatos, and enable real tests of constitution to be conducted. When Professor Perceval referred to the unsatisfactory results which followed from attempting to propagate old trees by means of cuttings taken from the weak spray of old branches, he did but accentuate the argument that if deterioration does occur in Potato varieties, it may be due to the practice of using small tubers for "seed" instead of large ones. In trees, as in budding or grafting, no deterioration follows if the parts so employed, or if cuttings, be taken from robust, healthy growths. Mr. Foster's plea that to retain robustness of constitution later planting for seed-tuber production so as to secure quite late-ripening tubers should be adopted serves to show, assuming it to be correct practice, why it is that the late-planted and late-ripening Scotch-grown potatos do so well when planted in the South; but it should also serve as an argument in favour of sprout or cutting propagation, as such created plants form tubers later than do those raised from planted sets. Last year Messrs. Sutton & Son's breadth of Discovery raised from sprouts was not lifted until November, and such tubers should naturally give this year exceptionally strong growth. Discovery tubers seem to be of all varieties, even from planted sets, the latest to push growth, beating in that respect tubers from Scotland or Ireland. Evidently Potatos do in many cases seem to need certain elements which all soils do not contain, hence it is that we see from some soils tubers of the greatest excellence, whilst the same varieties grown on other soils are watery, soapy, and worthless. Such soils may soon induce deterioration; but if the essential ingredients the Potato needs were supplied, tubers of great excellence and robust constitution might well result. *A. Dean.*

LAURELIA AROMATICA. — Has anyone succeeded in propagating this delightfully-scented shrub, which was noticed on p. 230? Mr. Burbidge kindly gave me a leaf of it in August, 1901, and it still smells sweetly, after nearly four years' drying. It is, I believe, hardy in Co. Wicklow. Perhaps Mr. Moore's plant will produce seed, as it appears to have flowered; its scent is one of the sweetest I have yet known, and I have been looking for plants ever since I first saw the plant. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

FRENCH TIMBER CROPS.—I have read with interest Dr. Henry's practical address at the Horticultural Club published on p. 221, but I would like to ask if the statement that French foresters leave only about 200 trees to the acre, finally, is not an error? In Bagneris's *Elements of Sylviculture*, p. 40, he says, "the forest can never be too full"; and a reference to his definitions of "thicket," "low pole," "high pole," and "old high forest" will show what he means by density. Speaking of high Oak forest, p. 67, he says the Oak should never be grown by itself, and in giving 200 to 250 Oak trees to the acre, "well distributed," he is, speaking of a forest containing Beech and Hornbeam in addition. All Beech trees, he says, that immediately overtop the Oak must be got rid of, and Beech that are overtopped by the Oak must be preserved. The latter, it is added, must be commenced early, because if any length of time elapses after the pole stage is reached the Beech will die. Two hundred trees to the acre means nearly 15 feet apart, which is incompatible with Bagneris's degree of density, and more than the Oak needs. I believe Bagneris to be mistaken, however, about the Oak smothering the Beech, if that is what he means. The Beech kills every light-demanding species speedily, but in the thickest woods it itself survives. In almost every old wood in England Beech trees, affording quite as good examples of shade-enduring power as the Yunnan Ficus mentioned by Dr. Henry, may be found, not only with tier above tier of leafy branches, but where the Beech is also hemmed in by other trees, no light reaching the lower branches of the Beech except what filters through the thick overhead canopy. From what I have seen and read, I do not think French forestry is as good as the German. *J. Simpson.*

—— In reply to Mr. Simpson's question as to the number of Oak trees to the acre in a good French forest, when the timber is mature, I may quote official figures of one section of the Forest of Bercé, where the trees were 192 years old. This plot, twenty-one hectares, i.e., fifty-two acres, in extent, contained, according to a careful inventory:—

	Cubic Feet.
6,052 Oaks, measuring	565,000
530 Beeches ,, ...	17,000
6 582 Trees ,, ...	582,000

or 116 Oaks and 10 Beeches standing on each acre. The trees stood, therefore, 18½ feet apart. They averaged probably 120 feet in height, and there was complete canopy. I do not see how trees of that size could grow closer together. *Augustine Henry, Kew, April* 14, 1905.

POTATO-PLANTING.—The plan recommended by Mr. Parker on p. 201, of placing the tubers on end in trays, is an excellent one, and one of which I can speak from experience, gained while living at Goodwood Gardens with Mr. Parker. The trays can be stacked to almost any height until the tubers are ready to be taken to the ground for planting. A large number of Potatos can be prepared by three or four men on a wet day, thus saving valuable time in fine weather. The iron-shod dibber is known, I should think, in all country places, but although so well-known, it is not necessarily the best implement for use, for unless the shoe is round at the bottom there must be a cavity left under the Potato. A Potato tuber will start into quick growth if the soil is closely packed round it, which can be better accomplished by planting in a trench or by the use of a trowel. *John Beams, Kensington and Chelsea Schools, Banstead, Surrey.*

SEED-SOWING.—I was much interested in Mr. A. Hemsley's article on this subject, which appeared in the issue for April 8, and would like to support that gentleman's statements respecting the shading and covering of seed-pans. Writers and teachers have so persistently advised the practice of covering all seeds to the exclusion of light, that it has with many become as much a matter of course to do this as to provide crocks for drainage. Were growers to make the simple experiment of sowing two batches of any sample of seed, affording the same treatment to each, except that one shall be darkened and the other left exposed, I am confident it would soon be seen that the practice of darkening has nothing to recommend it. Dr. Pouchet, in his interesting book *The Universe*, says: "Following Ingenhouz and Sennebier, men have long taught that light was opposed to germination. This is an error, as Saussure noticed. Nevertheless, all the coloured rays of light are not favourable to it; the chemical and the calorific rays have an opposite action upon this phenomenon. The former, which are the blue and violet rays, clearly increase its activity; the latter, the red and yellow rays, are hurtful to it." It would appear from this that if, instead of totally excluding light, we could exclude the calorific rays only, germination would be appreciably hastened, and if that be the case, it would surely be good policy to place seeds of such plants as are difficult and slow of germination under handlights of blue-stained glass. The same authority (Pouchet) says, "If we pass an electric current beneath a sown surface, the seed develops much more quickly than in a part which has not been submitted to electricity." One wonders whether such treatment would tend to impair the constitution of the young seedlings; if not, it would probably be a useful method to adopt when handling seeds of such subjects as are stubborn and difficult to start. The greatest difficulty to contend with when seeds are fully exposed arises from the necessity for repeated watering. Not only is this a question of labour, but a necessity which involves dangers such as washing out,

souring soil, rotting of seeds, and facilitating the growth of moss and fungus on the surface of the soil which so often spells disaster. If, however, care is taken in the choice of composts and of situation for the seeds, the necessity for constant watering may be mimimised. Too high a temperature is frequently the primary cause of failure in raising seedlings. *Heather Bell.*

NURSERY NOTES.

DAFFODIL SEASON AT MESSRS. BARR'S SURBITON NURSERIES.

The popular names of some of our oldest and most beautiful flowers are almost as beautiful as the flowers themselves, and are oft-times singularly appropriate. How better could the Narcissus be described than as Lent Lilies, for at this season the Daffodils are at their best, at any rate, they are at Messrs. Barr & Sons' nursery at Ditton Hill, which it was our pleasure to visit a few days since? A sight such as is afforded at "Daffodil time" in these nurseries, where acres of these bulbous flowers are to be seen at a stretch, is one not readily forgotten.

This is not to be wondered at when it is remembered that the firm of Messrs. Barr & Sons is among those pioneers who have taken the Daffodil in hand, and have given to us so many of those beautiful and improved forms with which we are acquainted. The different types and species represented in the genus Narcissus have afforded material to the hybridist and cultivator in plenty. Here at Ditton may be seen the very "acme" of all that is best and novel among these popular flowers. The work of improvement still goes on, evidenced by the many fine seedlings yet unnamed brought to our notice, and by the order overheard given to the hybridist to take advantage of the morning to pollinate.

As we enter the Narcissus fields—for such they can only be described—we pass through a rockery which is full of patches of colour. A drapery of Aubrietia hangs in a mass over a huge boulder; another stone is hidden by tresses of Arabis albida; a patch of Muscari "Heavenly Blue" forms a delightful groundwork to a bed of that rare find of Mr. Peter Barr, Narcissus Queen of Spain; Cydonias in many shades of colour are worked in here and there, while Magnolia stellata is still in full beauty. But we pass on past breadths of coloured Primroses and Cowslips to our objective—the beds of Daffodils. To enumerate the whole of the varieties seen would necessitate the compilation of nothing short of a bulky catalogue, so we must be content to notice a few only of the choicer and newer varieties. The variety "Ariadne," that was recently given an Award of Merit by the Royal Horticultural Society, is of most perfect form, with a perianth of the purest white, surrounding a corona of pale sulphur-yellow, with a crenated margin. Admiral Togo, as its name would suggest, is new, and resembles a big Emperor. Its rival, Admiral Makaroff, is also of the trumpet section, with a glorious yellow corona. Beatrice, one of the Leedsii section, is an almost pure white flower, with perianth of the best form. James Bateman, a small Incomparabilis, carries a pure white perianth surrounding a yellow chalice. J. B. Camm deserves a word of notice; it is still one of the finest light-coloured trumpet Daffodils. Beauty is a large Incomparabilis, the corona being tipped with orange.

A bed of "Barrii conspicuus" in full beauty could not fail to attract attention, while near by were such fine things as Duchess of Westminster, Weardale Perfection, and White Lady. Willie Barr has a lovely perianth of the softest shade of yellow and fimbriated margins; near by is Madame de Graaff, hardly surpassed as a white trumpet Daffodil for its size, colour, and symmetry of form. Vesuvius, Mars, and Lucifer, all of the Incomparabilis type, differ principally in the degrees of colour in the corona. Sunset may be noted for its umbel of fragrant flowers, each crowned with an orange-red cup; as well as Mercedes, a new Burbidgei, which hangs its twisted perianth and bright red cup in quite a modest manner. Varieties still appeal to us, but limited space compels us to but mention such fine things as Rowena, Rev. D. R. Williamson, Salmonetta, Peter Barr, Peach (Leedsii), Mrs. Geo. Barr, Lobster, King Alfred, Hon. Mrs. Jocelyn (new), Loveliness, &c. Among the Poet's Narcissus, one of the finest varieties is Glory, having large snowy-white petals and an exquisite "eye."

The breadths apportioned to seedlings were well furnished, and many promising things were noticed. One labelled 115, a seedling bicolor, reminded us of a large J. M. B. Camm; another, 663, is a fine lemon-yellow-coloured bicolor; its neighbour, 664, carried a fine yellow trumpet, and was the result of a cross between Madame Plemp and Lord Roberts; No. 68 resembles Weardale Perfection, but with a lighter trumpet and a white perianth; Pharaoh is a bold flower with sturdy trumpet of rich sulphur-yellow; No. 660 is a fine white Ajax with curved petals and creamy perianth. The giant trumpet of Milky Way is of the palest yellow, while the flower is of excellent form; Mrs. Batteridge is new, with the trumpet almost white, spreading and crenated at the margin. Mrs. Henry Buckley, a new seedling of the Incomparabilis type, has a large, rich corona and a well-shaped flower; Blackwell, another Incomparabilis, although not new, is one of the best of this type, its beautiful chalice being stained with orange-scarlet; the flower stands well above the foliage. A bed of Cleopatra (trumpet) was in full beauty, while in contrast was the dwarf-growing yet sturdy Phil May, whose trumpet is of large proportions. The list is incomplete, but we must pass on, and as we do so notice some of the other occupants of the nurseries, for—

> "Here Hyacinths in purple sweetness rise,
> And Tulips tinged with beauty's fairest dyes."

The Tulips are not quite forward enough to be seen at their best, although several beds of "English" Tulips are now in flower; while a collection of "the flaunting red" Duc van Thol was most conspicuous, although perhaps somewhat past their prime. Muscari "Heavenly Blue" was observable from almost any position in the nursery, broad patches of it having been planted in various parts of the grounds.

We also noticed some fine forms of coloured Primroses, Irises, Polyanthus, Myosotis, Ornithogalum, &c. The persistent character of this last-named was observable in the many "rogues" of this plant which appeared among the Daffodils, &c.

A NOVEL CARPET BED.

Our illustration (fig. 107) is that of a flower-bed, 30 feet long by 12 feet wide, in the Public Park at Preston, intended last season to represent the armorial devices of England, Ireland, Scotland, and Wales. The arrangement of the planting was as follows:—The symbol of England occupied the central portion. The crown was outlined with Echeveria secunda glauca, dotted with E. Peacockii and Pachyphytum bracteosum, with a line of E. Peacockii along the underside; above was Kleinia repens and Alternanthera magnifica. The feathers were represented by Pyrethrum Golden Ball, with Lobelia Newport Model for groundwork; above was Alternanthera magnifica and Lysimachia nummularia aurea, while the Maltese cross was planted with P. Golden Ball. The representations of Roses were formed with Alternanthera magnifica, and the Rose-leaves with a very compact-growing Sempervivum. The groundwork of England was planted with Sedum glaucum dotted with Pachyphytum bracteosum.

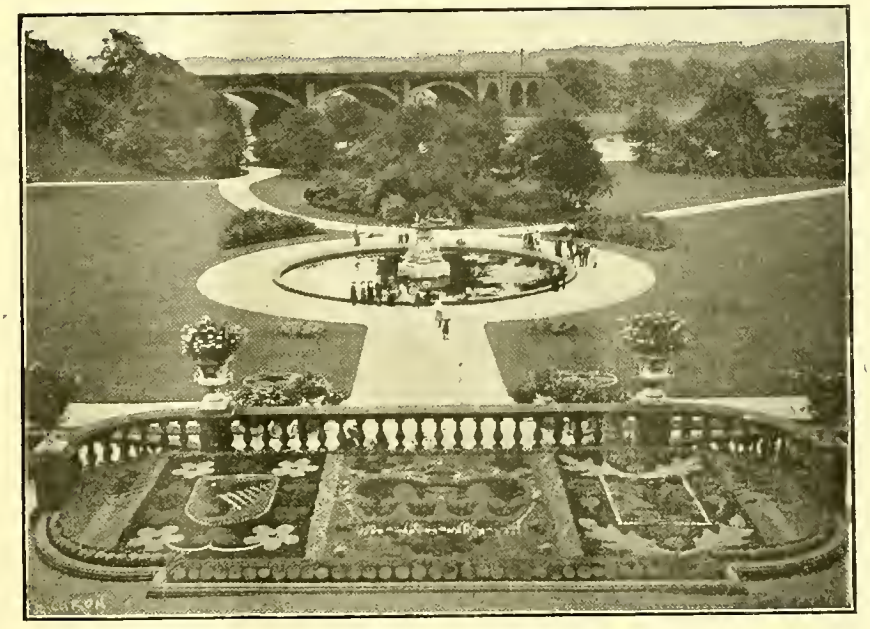

Fig. 107.—A NOVEL CARPET BED.

Scotland is represented to the right, and in this symbol the central figure was planted with Alternanthera magnifica, with a groundwork of Lamium maculatum aureum, the four corners being planted with Iresine Lindeni with a line of Echeveria secunda glauca. The Thistle flowers were formed with Lobelia pumila compacta and Kleinia repens, while the leaves of the Thistles were formed with E. secunda glauca and Antennaria tomentosa. Veronica repens was used as a groundwork for the whole.

To the left Ireland is represented by the "Harp," planted with Alternanthera magnifica,

and having strings of blue Lobelia and Echeveria, and a groundwork of Pyrethrum Golden Ball with a line of Kleinia repens. The Shamrock flowers were formed with E. secunda glauca and Antennaria tomentosa, while the leaves were formed with the same Sempervivum as were the Rose leaves in England's portion. The groundwork here was planted with Sedum.

To the extreme right and left of the bed Wales is represented by the Leek. This was designed with Antennaria tomentosa and Draba aizoides, with a groundwork of Mesembryanthemum cordifolium variegatum. Unfortunately the designer had not sufficient space to represent Wales so fully as he wished.

The dividing lines of the symbols were planted with Echeveria and Mesembryanthemum. Along the front of the bed was a row of Sempervivum tabulæforme, to the right and left E. metallica glauca, with a row of Lobelia pumila compacta running entirely round the bed. The bed was greatly admired by all those who saw it. *C. Ings.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

April 11.—*Present:* Dr. M. T. Masters, F.R.S. (in the Chair); Dr. M. C. Cooke, Rev. W. Wilks, Messrs. Saunders, Shea, Odell, Baker, A. Sutton, Worsdell, Massee, Douglas, and Chittenden (Hon. Sec.).

Deterioration of Vegetatively Reproduced Varieties.—Letters upon this subject from several gentlemen were read (see p. 237), mostly pointing to the conclusion that varieties do deteriorate. Mr. Sutton said that in his experience deterioration of Potatos does take place sooner or later, the only well-marked exception to this rule being the Early Ashleaf, which is now apparently as vigorous as it has ever been. Potatos raised from seed show marked variation on every point, some deteriorating within five or six years, others not until the passage of a much longer period. [A further communication from Mr. Sutton will appear in our next issue. Ed.] Mr. Lindsay, of Murrayfield, Midlothian, sent tubers of Maincrop Potatos and of Solanum etuberosum raised from tubers planted out in ordinary, unmanured, garden soil in 1899, the plants having remained in the open ground unprotected and undisturbed, except for moving once in September, 1902. The plants had not suffered from any kind of disease nor from frost, and do not appear to have deteriorated in any way. The question of the influence of the moister Scotch climate on the Potato was raised, and the effect of flower and seed production on the vigour of the tubers produced was discussed.

Rust on Rose.—Dr. Cooke reported as follows on this well-known trouble:—"This rust was known half a century ago as Uredo pinguis, but afterwards as Coleosporium pingue, and was then considered to be an independent fungus. In more recent times it has been found that most of these parasites exist under three forms; or pass through three stages, viz.—(1) Æcidium, (2) Uredo, (3) Teleutospore. In the present instance (1) the æcidium form is Coleosporium pingue, (2) the uredo form is Lecythea rosæ, and (3) the teleutospore form Phragmidium subcorticatum. The Coleosporium is the first form to appear in the spring, on the twigs and peduncles chiefly; near midsummer the uredo spores appear on the leaves; in autumn the teleutospores appear as black tufts on the under surface of the leaves. As an endophyte this pervades the tissue of the entire plant, and is very difficult to combat. It is recommended that all the affected spots be cut off as soon as they are recognised, and burnt, so as to prevent the dispersal of the spores. Before the buds expand in the spring, bushes that have been attacked the previous year should be well syringed with Bordeaux-mixture. Leaves should be watched carefully through the summer, and when the uredo appears thereon, or later the teleutospores, the leaves should be picked off and burned, because when the teleutospores germinate they are able to infect healthy Roses, and produce the Coleosporium in the following spring. Occasional syringing with Bordeaux-mixture checks both the first and second stages." (See *Gardeners' Chronicle*, 1886, p. 76.)

Diseased Arums.—Mr. Saunders reported that he was able to find only a few springtails and two very minute worms in the tubers, and he thought that neither was sufficient to cause the decay which had gone on to the depth of ¼ inch at the base of the tuber. The two smaller plants had healthy tubers so far as could be seen. Mr. Odell had also examined them and reported: "The decay at the base of the tubers was not unlike in appearance the yellow root-rot of the Hyacinth. I could not find anything to account for decay beyond a few springtails, and these I think would not cause so much injury. In the decayed portion there was evidence of bacteria due rather to the decayed matter than contributing to the cause of the decay, as I could not trace any bacteria high up in the tuber. I have isolated the plant, and shall attempt to grow it on for farther examination, when I will submit it to the Committee. From the growers' remarks drastic measures have been taken to remedy the trouble. I would suggest destroying the stock, taking care that the soil in which the plants have been grown be burnt or treated with lime, and that the pots be washed with a strong carbolic solution."

Vine Leaves Spotted.—Leaves of Vine were received from Roehampton having a large number of small blackish spots upon them. It was thought that the trouble was due to the lack of sufficient ventilation. Dr. Cooke took some to examine farther.

Horse-Chestnut Twigs Damaged.—Twigs from which the bark had been removed on one side near the beginning of last season's growth curiously twisted and bent were received from Wymondham. Mr. Saunders undertook to report upon them at the next meeting.

Fasciation.—Mr. Chittenden showed an example of this in the terminal flower of the Hyacinth, and Mr. Worsdell showed fasciated aërial roots of Ivy reaching half an inch in breadth in some cases. He considered the fasciation was brought about by a dichotomy of the growing point, and it was suggested that this might be due to injury by insects, &c. Dr. Masters mentioned that a similar thing was sometimes seen in Orchid roots and in roots of some of the Cactaceæ.

Narcissus Fly.—Mr. Chittenden showed specimens of this fly, Merodon, which he had bred, showing considerable variation in colour from a foxy-red throughout to the commoner form with blackish bands.

Witch's Broom on Hornbeam.—Mr. Odell showed specimens of this similar in appearance to those commonly seen on Birch, caused by a mite (Eriophyes).

Geographical Forms of Narcissus Bulbocodium.—Miss Willmott, V.M.H., exhibited a collection of N. Bulbocodium from all the known habitats of that species, showing a very large amount of variation both in foliage and flower.

Malformed Iris. Mr. Worsley showed flowers of Iris bulbosa in which the stamens were branched, so that there were six or more anthers in each flower. Dr. Masters undertook to examine them.

DEVON DAFFODIL AND SPRING FLOWER.

April 11.—This Society opened its second annual exhibition at the Guildhall, Plymouth, on the above date. The show was a great advance upon that of the preceding year, the endeavours of the committee having met such success in the county that about 40,000 cut Narcissi were staged in the hall. In the open classes many excellent stands were contributed by Cornish growers, Mr. J. C. Williams's collection of seedlings not in commerce attracting universal admiration, while in the section restricted to the county of Devon, competition in the classes for cut Daffodils was particularly keen, thirteen exhibitors entering for the premier class for fifteen distinct varieties, and many of the other classes attracting ten or more entries. The show of hard-wooded flowering shrubs grown in the open was unique, for probably such an assortment has never before been seen in England early in April as that contained in the eight stands of twenty varieties that competed for the Silver Cup. The most striking specimen in all the collections was Correa cardinalis, in splendid flower in the 1st prize stand of the Earl of Mount-Edgcumbe; while in Rev. A. T. Boscawen's 2nd prize stand were Boronia megastigma, Diosma gracilis, Polygala grandis, Clianthus puniceus albus, and a large flower-panicle of Brachyglottis repanda; and in the equal 3rd-prize stands of Sir A. Pendarves Vivian and Mrs. Coryton, of Pentillie Castle, were Embothrium coccineum and Neviusia alabamensis, rarely seen nowadays. The regulation in this class that none of the flower-sprays should exceed 2 feet in length was not strictly adhered to in all cases, and this caused loss of points to some exhibitors and undoubtedly affected the awards.

Rev. A. T. Boscawen's 1st prize stand for twelve distinct varieties of hardy spring flowers was particularly good, containing Antholyza coccinea, Myosotidium nobile, Fritillaria reticulata alba, F. imperialis, with immense flowers; Echium callithyrsum, and Erythronium Johnstoni, with five flowers on a stem and 18 inches in height. Pot plants were well shown—Cinerarias, zonal Pelargoniums, Freesias, Lilies of the Valley, Cyclamen, Hyacinths, Tulips, Daffodils, &c., being of high merit; while six wonderful plants of Mignonette, exhibited by Mrs. Bainbridge, obtained an Award of Merit. Violets were poor owing to the lateness of the show, but Primroses, Polyanthi, and Auriculas were good.

Of nurserymen, Messrs. R. Veitch & Sons, Exeter, who were awarded the Society's Silver-gilt Medal, had a fine collection of hardy flowering shrubs and other plants, comprising Lilacs, Azaleas, Rhododendrons, Grevillea sulphurea, Diosma linariifolia, Magnolia fuscata, and many other Magnoliss, Acacias, Ericas, rock plants, including Androsace carnea, A. sempervivoides, A. arachnoidea, Saxifraga Boydii, S. Guildford Seedling, S. Griesebachii, S. Rhei superba, and Primula kewensis ×. The Devon Rosery, Torquay, staged a large collection of pot Roses in full flower, Carnations, and other flowers, and received a Silver Medal. Messrs. T. Chalice & Son, Plympton, had a pretty stand with tall specimens of Cytisus purpureus pendulus, Andromedas, Magnolias, Rehmannia angulata, Cotoneaster angustifolia and Jasminum primulinum (Silver Medal).

Messrs. Barr & Sons staged a large collection of Daffodils, for which they were awarded a Silver Medal; and Messrs. Saunders & Biss, horticultural builders, Exeter, had numerous photographs and specimens of their work.

Among the prizes awarded mention may be made of the following:—

Collection of forty variety of Daffodils: 1st prize, Rev. A. T. Boscawen, whose stand contained a fine selection of highly-coloured flowers, amongst which the glowing-cupped Will Scarlet appeared.

Twenty varieties: 1st prize, Mr. E. H. Williams.

Twelve varieties: equal, 1st prize, Hon. John Boscawen and Mrs. W. Tyacke.

Group of Daffodil seedlings not in commeree: 1st prize, Mr. J. C. Williams.

Twelve Magni-coronati: 1st prize, Rev. A. T. Boscawen.

Twelve Medio-coronati: 1st prize, Rev. A. T. Boscawen.

Six blooms out-door Camellias: 1st prize. Mrs. J. Williams.

Finest Camellia bloom: 1st prize, Miss R. Williams.

Six bunches Anemone fulgens: 1st prize, Miss A. Williams.

Group of twenty varieties of hard-wooded flowering shrubs grown in the open: Silver Cup, the Earl of Mount-Edgcumbe.

Fourteen classes for cut Narcissi were restricted to residents in the county of Devon.

MIDLAND AURICULA.

April 18.—The sixth annual exhibition of this Society was held in conjunction with that of the Midland Daffodil Society, in the Edgbaston Botanical Gardens, Birmingham. A month ago it was thought that Auriculas would be early in flower, but the weather having been very variable since that time, and particularly cold a week ago, the prospects of having a good show were not good. In these circumstances the Secretary, Mr. Richard Holding, and his committee, may be congratulated upon the display that was made, which was slightly less in extent and in quality than that of last year.

Show Auriculas.—There were five exhibits in this class, and the one awarded 1st prize was shown by Mr. W. Smith, Bishop's Stortford. The varieties were Cleopatra, Mrs. E. Osmond, and Mrs. Phillips (selfs), Rachael and a seedling (grey-edged), and Abbé Liszt (green-edged).

Mr. W. Smith was also winner of 1st prize in the class for four plants, his varieties being Cleopatra and Mikado (selfs), Abbé Liszt (g.e.), and Geo. Rudd (g.e.).

The best exhibit of two plants came from Mr. J. W. Bentley, Middleton, who had Abraham Barker (g.e.), and Favourite, a self with white centre.

Single Plants.

The best green-edged variety was Mrs. Henwood, from Mr. F. T. Poulson, Stafford; the best grey-edged variety, George Rudd, from Mr. W. Shipman; the best white-edged variety, Acme, from Mr. J. Collier, Dinham; and the best self, Mrs. A. Potts, from Mr. C. J. Fox, Sparkbill.

Alpine Auriculas.—Mr. J. W. Bentley won 1st

prize for six plants with the following varieties:—Godiva, Cynthia, Dr. Pegge, Aglaia, Rosie, and Pluto. 2nd, Mr. J. Stokes, Harborne.

Mr. J. W. Bentley had also the 1st prize for four plants, showing Bunthorne, Dr. Kenshaw, Blue Bell, and Jessie. 2nd, Mr. C. Winn, Selly Hill.

Mr. F. T. Poulson won 1st prize for two plants with the varieties Thetis and Joachim.

The best single plant of a gold-centred variety was one of the variety Richard Dean; and the best light-centre was Thetis, shown by Mr. F. Poulson, Stafford.

There were a few additional classes for Auriculas from local growers, two for gold-laced Polyanthus, and one for a group of alpine plants. The last-named prize was won by Messrs. Pope & Sons.

The premier alpine variety was Dr. Pegge, shown by Mr. J. W. Bentley; and the premier show variety, Acme, shown by Mr. J. Collier.

Certificates of Merit

were awarded to a new show variety named Mrs. E. Osmond (violet self), from Mr. W. Smith, Bishops Stortford, and to a new alpine variety "Dr. Pegge," raised by the exhibitor, Mr. J. W. Bentley.

The Misses Hopkins, Mere, Knutsford, Cheshire, exhibited mounds of Primroses, double Daisies, Fritillarias, &c.

MIDLAND DAFFODIL.

EXHIBITION AT BIRMINGHAM.

April 18, 19.—Birmingham is fast becoming known as the locality in which one of the finest exhibitions of Narcissus is held in this country. The Midland Daffodil Society, though scarcely seven years old, has not only succeeded in establishing fine exhibitions of the flower in the Botanical Gardens at Edgbaston, two miles or so out of Birmingham, but it brings together a very large number of Narcissus cultivators and admirers. On Tuesday last, as may be seen from the details given below, there were exhibitors from many of the English counties, and quite a considerable number from Ireland, whilst the visitors to the show included Mr. F. W. Burbidge, Dublin; the Rev. G. H. Engleheart, Hampshire; Miss Willmott, Essex, and other well-known Narcissus specialists.

A fortnight ago the indications of the season seemed to be that the Narcissus would flower very early, and the Midland Committee was induced to put the date of this show forward, it having been first arranged to hold it next week. The weather, however, since that time has been cold, and the plants have not flowered quite so early as was expected. But for this circumstance the display would have been rather more extensive, as Mr. Crossfield, Wrexham, and possibly other growers, were unable to exhibit, although Mr. Engleheart informed us that most of his flowers will be past by Tuesday in next week.

The show was a very good one, and quite early in the morning the scene in the large exhibition-house was one of activity and of attractiveness, as the exhibitors (ladies and gentlemen) were engaged in arranging their flowers.

Narcissus exhibitions serve to remind us of the great development that has taken place in this flower, and illustrates how the classification of the varieties into magni-coronati, medio-coronati, and parvi-coronati, is being undermined by numbers of new varieties that have arisen from crosses effected between parents of dissimilar types.

The chief workers at Birmingham, such as Mr. Robert Sydenham, Mr. Pope, and Mr. Herbert Smith, are to be congratulated upon the show of 1905, though it was rather less in extent than the previous one.

Competitive Classes.

The 1st prize in the largest open class, which was one for fifty varieties representing each of the three sections, was very well won by Messrs. Pope & Sons, Kings Norton. The flowers in this exhibit were superb, for such varieties as Kings Norton, Boniface, Olympus, Mrs. Galton, King Alfred, Mme. de Graaff (all of the Ajax type), and in other sections the brilliant Will Scarlet, Flamingo, Orangeman, Clarissa, Linda Pope, Firebrand, Marnia, C. J. Backhouse, Barbara Holmes, &c., were splendid examples of the development that has taken place in the flower.

One of the most important of the classes for amateurs was that for twenty-five varieties, selected to represent the three leading sections or types. There were three collections staged, and the 1st prize was won by H. B. Young, Esq., Metheringham, Lincoln. We cannot, of course, enumerate here the varieties shown, but may point to the Ajax varieties Glory of Leiden, Madame de Graaff, Captain Nelson, the Incomparabilis section represented by Lulworth, Gloria Mundi, and Vesuvius; the bicolor group including Mrs. J. B. M. Camm, the Barrii "conspicuus," and the Poeticus ornatus and Præcox grandiflorus as being among the best. The collection from W. A. Watts, Esq., Bronwylfa, St. Asaph, and another from Mr. J. Mallender, Hodsock Priory Gardens, Worksop, were awarded 2nd and 3rd prizes respectively.

A class for twelve varieties of Daffodil seedlings that have not been in commerce four years was won by Mr. Berkeley, Spetchley Park, Worcester, the varieties shown being as follows: Sihon, Great Warley, Noble, Chas. Wolley Dod (all Ajax varieties with yellow trumpet and white or tinted perianth), Robert Berkeley (sulphur coloured), Sir Francis Drake (yellow Ajax), Countess Grey, Incognita, Eleanor Berkeley, Earl Grey, and Poeticus aurora, and Rymster. The 2nd prize was obtained by P. D. Williams, Esq., Lanarth, Cornwall.

In a similar class for six varieties Messrs. Pope & Sons were awarded the 1st prize among several competitors.

Ajax or Trumpet Varieties.

The best dozen varieties of trumpet Daffodils were shown by Messrs. Pope & Sons, who won with Olympus, Glory of Leiden, Emperor, King's Norton, Waverin's Giant, Weardale Perfection, Madame de Graaff, Rembrandt, Mrs. Camm, Mrs. Batteridge, Glory of Noordwijk, and a seedling. Among three other exhibitors the Rev. G. F. Eyre, Far Forest Vicarage, Worcester, obtained the 2nd prize.

A similar class for six varieties was restricted to amateurs, and the most successful among these was Mr. J. Mallender, Worksop. The varieties Victoria, Madame Plemp, and Hodsock's Pride were included in this exhibit.

Incomparabilis Type.

In the class for twelve varieties of the section medio-coronati, the winner of the 1st prize was Mr. H. B. Young, whose collection was an admirable one, the varieties Gloria Mundi, Lucifer, and Crown Prince being very effective. The Rev. G. F. Eyre and Messrs. Pope & Sons were awarded 2nd and 3rd prize respectively, but we think the awards should in this case have been reversed.

In the class for six varieties (amateurs), Arthur R. Goodwin, Esq., The Elms, Kidderminster, obtained the 1st prize; and Mr. C. L. Branson, Coleshill Park Gardens, Coleshill, 3rd prize.

Though less conspicuous than the larger varieties, the flower of the parvi-coronati section are interesting and attractive. The 1st prize for six varieties was won by Messrs. Pope & Sons, the varieties being as follows—Southern Star, Oriflamme, Picotee, Bullfinch, Linda Pope, and C. J. Backhouse. 2nd, H. B. Young, Esq., Metheringham.

The best collection of six distinct varieties of true Poeticus was shown by H. B. Young, Esq. The varieties being Cassandra, ornatus, Homer, Almira, grandiflorus præcox, and grandiflorus.

Miscellaneous Classes.

H. B. Young, Esq., won 1st prize in a class in which the varieties with orange-coloured crowns or cups were selected in collections of twelves. These were effective and illustrated a characteristic of the newer varieties.

In Classes 14 and 15 there were collections of twelve and six varieties respectively, none of which cost more than ten shillings per dozen bulbs, and though the exhibits were not so good as many of the novelties, they were sufficient to inform the public of the fact that very good Narcissus can be obtained at reasonable prices. In Class 16 the same idea was carried a little further, as the varieties shown may be purchased at five shillings per dozen or less. Mr. Sydenham had a further class for bulbs purchased at three shillings per dozen.

There were several classes for Narcissus and Tulips shown growing in pots. Of these the polyanthus varieties were the much more effective, and the best were shown by R. Chatwin Cartwright, Esq., King's Norton, his collection embracing six varieties.

Tulips.

A class for flowers of nine distinct varieties of Tulips was won by Mr. A. E. Campbell, 11, Kempock Street, Gourock, with the following varieties:—Murillo, Pottebakker White, Rose Gustelin, Prince of Austria, Proserpine, Pink Beauty, Mon Trésor, L'Unique, and Jost van Vondel. There were several good exhibits in this class.

Excellent Tulips were shown growing in pots, and the best were from the garden of J. A. Kenrick, Esq., Berrow Court, Edgbaston.

Narcissus Flowers Arranged for Decoration.

A number of exhibits were designed to afford illustrations of the appropriateness of Narcissus for use as cut flowers in decoration; of these the groups of flowers arranged in epergnes and other receptacles, each exhibit being disposed on a separate round-table covered with an ornamental cloth, were the most noteworthy. The 1st prize was awarded to Messrs. F. Impey & Sons, Midland Spring Gardens, Northfield, who employed a rustic flower-stand, silvered over, one variety of incomparabilis Narcissus only, and Asparagus Sprengeri. They were disposed over a cloth with green centre and gold-coloured band. The exhibit was very tastefully executed, and the only criticism that occurred to us was respecting the golden-yellow colour of the cloth, which should have been much paler, because the "cup" of the flowers was only lemon-coloured, and therefore suffered from comparison with the other. When it is stated that there were nine of these tables, and that they were disposed in a manner that the public could easily walk around each, it may be imagined that they contributed one of the prettiest features of the exhibition.

The Premier Flowers

of the different sections were as follows:—Of magni-coronati, King Alfred, shown by Messrs. Barr & Sons; of medio-coronati, White Queen, shown by Messrs. Pope & Sons; and of parvi-coronati, Beacon, shown by P. D. Williams, Esq.

Certificates and Awards of Merit

were recommended as follows:

Anemone "*King of Scarlets.*"—From Messrs. Gilbert & Son (Award of Merit).

Carnation "*The Belle,*" a tree variety with white flowers.—From Mr. A. F. Dutton, Bexley Heath, Kent (Award of Merit).

Narcissus Warleyensis.—A very fine yellow Ajax variety, with particularly large perianth and broad imbricating segments. From Miss Willmott, Great Warley (Award of Merit).

N. "*Lady of the Snows.*"—An Ajax variety with very long trumpet, perianth white, trumpet pale lemon coloured. Shown by Miss F. Currey, Lismore, Ireland (Award of Merit),

N. odorus rugulosus maximus.—A very large and handsome variety of the type. Shown by Messrs. Barr & Sons (First-class Certificate).

Non-Competitive Exhibits.

Messrs. Barr & Sons, King Street, Covent Garden, London, had a very extensive exhibit of choice and rare varieties of Narcissus. Conspicuous among the trumpet sorts were Lord Roberts, Monarch, King Alfred, C. H. Curtis (a yellow variety with a widely expanded trumpet), Big Ben, Weardale Perfection, Pyramus, &c. Of the Incomparabilis type, the varieties Maggie May, Dorothy York, Lulworth, Duchess of Westminster, Peach, &c., were all pretty; and there were numerous varieties of the Poeticus type, and sections nearly allied to it (Gold Medal).

Miss F. W. Currey, The Warren Gardens, Lismore, Ireland, had upwards of 100 vases containing most sections of Narcissus flowers. Some of the white trumpet varieties, like that of "Lady of the Snows," Madame de Graaff, White Knight, &c., were excellent: also the yellow trumpet King Alfred, and many varieties of the medio and parvi-coronati types (Silver-gilt Medal).

Messrs. Reamsbottom's "St. Brigid" Anemones from the Alderborough Nurseries, Geashill, King's County, Ireland, were as brilliant as ever. The shades of colour vary so much that in scarlet, pink, and blue, some are intensely bright, others subdued "delicate," and all are attractive. Particularly prominent was a large single flower with a band of white round the centre, and the remaining part of the segments vivid scarlet colour (Large Silver Medal).

From Messrs. Hogg & Robertson's Bulb Farm, Rush, Co. Dublin, came a collection of varieties of Narcissus and a few Tulips and Muscari, making together a brilliant exhibit (Large Silver Medal).

Another exhibit from Ireland was a collection of Narcissus from Sir Josslyn Gore-Booth's Bulb Farm, at Lissadell, Co. Sligo, the varieties in which appeared to us to represent chiefly the pale-coloured sections, white and lemon tinted yellow being the more frequent (Large Silver Medal).

Mr. S. Mortimer, Rowledge Nurseries, Farnham, Surrey, brought some abundantly flowered plants of a good strain of Polyanthus and Primrose (Bronze Medal).

Messrs. Dicksons, Chester, made a good display of Narcissus, in which the smaller trumpet and cup varieties were well represented (Small Silver Medal).

One of the best collections of Narcissus came from Messrs. J. R. Pearson & Sons, Chilwell Nurseries, Lowdham, Notts. The varieties had evidently been selected to represent the different sections, and from this point of view, and from that of good cultivation, the exhibit was excellent. The white trumpet variety Lowdham Beauty, the bicolor Lady Margaret Boscawen, and the yellow Glory of Leiden were conspicuous (Silver-gilt Medal).

Zonal Pelargoniums asserted their claim to effective colouring, even in the presence of the bright Anemones, for a collection of flowers from Mr. Vincent Slade, Staplegrove Nurseries, Taunton, Somerset, was specially well provided with varieties of scarlet, crimson, and rich pink colours (Large Silver Medal).

The hybrid and seedling Narcissi, staged by the Rev. G. H. Engleheart, Dinton, near Salisbury, was as usual the centre of great attraction, because all the flowers shown represented some new development or some fresh admixture of the characteristics formerly existing in separate individuals. The most wonderful were the varieties with crowns or very small cups, but

many of these were only designated by numbers. There were, however, "Acme" (a beautiful flower with white, handsome perianth and broad, flattened crown of deep colour), Delicata Waterwitch, &c., that were excellent (Silver-gilt Medal).

A very choice collection of seedling varieties was also shown by Mrs. BACKHOUSE, Sutton Court, Herefordshire, of which we may mention Dewdrop, Ardea, Czarina and Silver Mist (Large Silver Medal).

Another exhibit of seedling varieties was shown by Mr. J. MALLENDER, Worksop (Bronze Medal).

Messrs. GILBERT & SON, Anemone Nurseries, Dyke, Bourne, Lincolnshire, showed a collection of Anemones, in which their double-flowered variety King of Scarlets was well shown in considerable quantity. Another double-flowered variety is Queen of Roses (Large Silver Medal).

Messrs. FELTON & SONS, 7, 9, and 9, Hanover Square, London, W., showed magnificent Roses on long stems, and arranged in stands in which the merits of the flower were well displayed (Large Silver Medal).

Mr. W. A. WATTS, St. Asaph, North Wales, showed a collection of flowers of a good strain of coloured Primroses and Polyanthus (Bronze Medal).

LOCAL EXHIBITORS.

Messrs. BAKERS, Wolverhampton and Codsall, exhibited coloured Primroses and a very pretty little rockery planted with alpine plants in flower, among which the Aubrietias and Phloxes were exceedingly bright (Small Gold Medal).

Messrs. GUNN & SONS, Olton, near Birmingham, showed a bank of alpine and other hardy flowering plants in bloom, among which the gayest plants were several sorts of Auriculas, and other species of Primula (Large Silver Medal).

Messrs. HEWITT & Co., Solihull, near Birmingham, arranged a group of flowering greenhouse plants and forced shrubs, as Lilacs, Viburnum, &c.; also excellent flowers of such Carnations as Enchantress, Floriana, Prosperity, Queen Louise, &c. (Silver gilt Medal).

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, exhibited Narcissus, Tulips, Lilium Harrisi, &c., growing in moss-fibre, which it was obvious is very suitable for these plants and exceedingly convenient in use (Large Silver Medal and Cultural Commendation).

Messrs. W. H. SIMPSON & SONS, Birmingham, exhibited a large collection of Narcissus as plants growing in pots, and cut flowers (Large Silver Medal).

THE DINNER.

In the evening, Mr. Robert Sydenham and Mr. John Pope entertained the principal exhibitors, judges, and a large number of visitors at dinner at the Old Royal Hotel. Mr. John Pope presided, and in addition to the speeches connected with the toast list, there were discussions on several subjects relating to the popularisation and cultivation of Daffodils.

ROYAL.

APRIL 6.—"Further Experiments and Histological Investigations on Intumescences, with some Observations on Nuclear Division in Pathological Tissues," by Miss Elizabeth Dale (communicated by Professor H. Marshall Ward, F.R.S. Read April 6, 1905).—This paper is the third of a series on intumescences. The first was mainly anatomical, the second chiefly experimental, and both related to one species, viz., Hibiscus vitifolius. The present paper contains (1) an account of further experiments with different plants, chiefly with Solanum tuberosum and Populus tremula. On the Potato plant intumescences were obtained experimentally in about twenty-four hours, either on a complete and uninjured plant, or on single leaves, or on small fragments of leaves. As in the case of Hibiscus vitifolius, the effect of varying degrees of temperature and illumination were investigated, and also the influence of nutritive solutions on floating leaves—the constant factor being a saturated atmosphere. A close connection was established on experimental, developmental, and cytological grounds between intumescences and wound-callus.

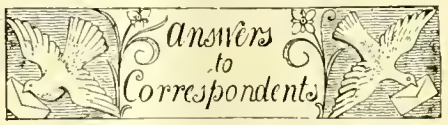
(2) Additional anatomical observations were made, and a classification of various types of intumescences, based on development and anatomical characters, has been drawn up. The cell contents of intumescences on various plants have been examined and compared with a view to discovering the osmotic substance which causes the initial accumulation of water in the formation of intumescences.

(3) In this connection experiments were made to determine whether the relative amounts of acids and salts, respectively, differed in plants with intumescences as compared with healthy individuals.

(4) These observations and experiments, taken in connection with various theoretical considerations, led to the conclusion that the actively osmotic substance is an acid, probably oxalic acid. They further, as do the experiments with fragments of leaves, show conclusively that the internal causes of the formation of intumescences are extremely local, and that root pressure is in no way concerned with the process.

The results obtained confirm and extend the conclusions reached by the earlier work with Hibiscus vitifolius, viz., that moist air, heat, light, and generally oxygen, are the necessary external factors. But the more recent investigations bring out the importance of certain internal or biological factors, namely, irritability and either active powers of assimilation or abundance of stored food material.

(5) Finally, the nuclear phenomena were investigated and compared, and were found to be in every respect identical in various intumescences and in wound-calli. Pathological tissues in certain plants and animals are also compared, and a strong resemblance is seen to exist between certain rapidly formed outgrowths in plants and animals, caused not by any parasitic organism, but simply by the influence of some stimulus, probably always external, acting upon a plant or animal in such a condition of irritability that it is able to respond. A similar resemblance occurs between regenerative wound tissues in certain plants and animals, the formation of which is in all cases accompanied exclusively by the more rapid form of nuclear division known as amitotic or direct.



ABIES NORDMANNIANA: *F. M.* The gall is due to a chermes. It is so destructive to this Fir as seriously to impair its use as a timber. Spraying with petroleum emulsion might be tried on small trees.

APPLYING INSECTICIDES: *L. F.* If the operation of spraying is an extensive one, you cannot do better than purchase one of the many spraying-machines that are on the market. For small operations a syringe works extremely well, but it requires some amount of practice and skill to adjust the proper pressure to the plunger, and one finger to the nozzle in such a manner that a suitable spray will result. It can, however, be done quite easily after a time.

BACK NUMBERS: *H. P.* A small advertisement would give you a better idea of the demand for them.

DOUBLE GRAFTING: *W. B.* This process, as its name implies, consists of placing a second graft upon one which has already been united to a stock. It is practised principally among Pear-trees, for it has been noticed that some varieties of this tree will not succeed upon the Quince stock, and this led to the introduction of intermediate stocks or double grafting. A variety of Pear which grows freely on the Quince is budded or grafted on that stock, and allowed to grow for at least two years; this is then cut back to within a few inches of the Quince stem, and the variety which is desired for fruiting is then grafted upon the intermediate stock.

FUNGOID DISEASES: *C. J. D.* The best plan is to send a sample to the Superintendent of the Royal Horticultural Society's Garden at Wisley, near Weybridge, for trial; or to one or more of the large growers for market.

GRAFTING CLEMATIS: *S. P.* We should say that the Clematis might possibly be grafted outside, but it would not be attended with sufficient success to make it worth while to adopt that method. The only really successful method is one adopted by nurserymen, viz., of working the soft shoots on roots of C. vitalba or allied species. Attempts with hard-wood have usually proved failures. Hence, as soft-wood is the only suitable wood, the necessity for indoor grafting. If you try the outdoor experiment, select showery weather for carrying out the operation, and use clay to cover the union.

MUSHROOMS DISEASED: *L. L., Grantham.* Your Mushrooms are affected by a disease which is, unfortunately, not uncommon to cultivated Mushrooms. It cannot be attributed to the "spawn," but is a mould, which is apparently to be traced to the manure. It has recently been called Mycogone perniciosa, which is undoubtedly another name for Mycogone alba. There is no remedy, when it once attacks a bed, but to clear it all out and thoroughly disinfect the house. *M. C. C.*

NAMES OF FRUITS: *C. E. D.* 1, Ross Nonpareil; 2, Syke House Russet.—*W. H. B.* 1, Gravenstein; 2, not recognised, send earlier in the season; 3, Rosemary Russet.

NAMES OF PLANTS: *F. E. S.* 1, Omphalodes verna; 2, Amygdalus nana; 3, not recognised, send when in flower.—*S. S.* Agathæa cœlestis.—*A. B. H.* Sisyrinchium grandiflorum.—*R. T. & Sons.* The flowers of A. fulgens appear to be of the variety known as annulata.—*Gardener.* Juniperus communis, the common Juniper.—*T. H. H.* Amelanchier canadensis. Other names are of necessity held over till next week.

NARCISSUS: *Derwydd.* The bulbs will probably come right another season. The variety is N. Telamonius plenus.

PEACH-TREES: *G. G.* The foliage shows no trace of fungi, and the condition of the trees, according to your description, seems to indicate mischief at the roots, as there is no organic disease. The Agaric which you declare is "growing rampant on the borders" was so much crushed that it could not be identified; but the very fact of an Agaric growing rampant in the soil indicates that it is so full of mycelium that it cannot be fit for fruit-trees to be planted in. We should advise you to see to the roots, and replace the soil during next autumn.

PLANTS FOR EXHIBITION: *Perplexed.* So much depends upon the character of the exhibition, the opinions of judges, and the means of cultivation you can command, that we are unable to answer your list of questions in a manner that would be conclusive.

POTATOS: *Perplexed.* The land being so poor as you describe it, should have been manured last autumn. As this was not done, there is no choice but to apply a good dressing of well-rotted farmyard manure before planting the tubers. In other circumstances we should not advise applications of manure to land intended for Potatos, for in a large garden it is generally possible to select a site for this crop where the soil having been heavily manured in the previous year is still in good condition, and tubers grown in such soil are generally better in flavour and have cleaner skins than when manure is applied at the time of planting.

ROOT CROPS: *Perplexed.* See the notes appearing week after week in the Calendar, under the heading "Kitchen Garden."

ROSES: *W. D.* The buds have been checked in their growth, perhaps by cold draught. There is no insect nor fungus visible.

ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY: *W. H. C.* Any Fellow can gain admittance to these Gardens on showing his ticket, or a visitor on presentation of a Fellow's transferable ticket, each of which will admit three persons. The Gardens are open for inspection on Bank Holidays and ordinary week days from 9 A.M. until sunset, but are closed on Sundays, Good Friday, and Christmas Day. Our issues for January 23 and March 19, 1904, contain particulars of the best routes to Wisley.

VINE-LEAVES: *A. B.* The leaves you have sent us are very thin in texture, and appear to be ill-nourished. Perhaps you are subjecting them to rather more heat than is essential. Ventilate the house more freely during calm weather. Blisters on the leaves usually arise from unsuitable atmospheric conditions, when the temperature is high and the atmosphere humid and close through lack of sufficient ventilation.

WIREWORM IN SOIL: *Subscriber.* The best remedy for these pests is an application of gas-lime in a caustic state, but it must be applied when the land is free from crops, as it kills all it comes in contact with, whether animal or vegetable life, although this effect goes off after some time has elapsed. Encourage such birds as rooks, starlings, and plovers. Fowls will eat the grubs if they are allowed on the land.

TYLNEY HALL,

THE seat of Lionel Phillips, Esq., is pleasantly situated on a commanding eminence 2 miles from Hook Station on the London and South-Western Railway line from Waterloo to Southampton, and 6 miles from Basingstoke. The mansion is a large and stately building of red brick and white stone, erected by Mr. Phillips five years since. In 1879 a house was rebuilt on the old site by Mr. Charles Edward Harris, who planted most of the trees with which the grounds are now furnished, for a previous owner had cut down all the principal timber on the estate; thus there is now a scarcity of desirable trees in the park and elsewhere. The park has been extended recently, and now covers a considerable area of ground. The soil is a mixture of clay, sand, and gravel, on a clay subsoil. Extensive carriage-drives have been formed, and the older ones altered to suit the more modern styles of arrangement. That leading to Hook station is about a mile long, and passes through an avenue of recently-planted Chestnuts. Another one that leads to the village of Rotherwick, in a northerly direction, is a trifle shorter, and passes through an avenue of Limes that was planted about twenty-five years ago. On the western side there is a delightful grass glade some 40 yards wide, well furnished with Sequoia gigantea [Wellingtonia] and Pseudotsuga Douglasi [Douglas Fir], 40 feet high; Abies grandis, 60 feet; Cedrus atlantica, Cupressus nootkatensis, &c. These are growing grandly, and will soon require more space.

On the east side or carriage-entrance a good view is obtained over Hazley Heath and Winchfield. An avenue of Limes, 600 yards long on that side, is effective on the grass. On the site of a former carriage-drive, Douglas Fir, Cedrus atlantica, Abies concolor, and A. Nordmanniana have been planted extensively.

The pleasure-grounds are charmingly undulated north-west of the dwelling-house, and much planting has been done with Rhododendrons and Bamboos under the existing forest-trees. There are also bold groups of such subjects as Spiræa Thunbergii, Ribes, Olearia Hastii, Andromedas, Skimmias, Golden Privet, and Forsythia suspensa, on a broad winding border, backed up with a Laurel screen. Bulbs have been naturalised under trees and in the grass, including the finer examples of Narcissus, such as Emperor and Sir Watkin, also Sternbergias, Colchicums, and Anemones. A winding, woodland path has been formed under forest trees and is planted with bold groups of Iris, Cotoneaster, Gaultheria Shallon, Bamboos, Kniphofias (Tritomas), and Anemone japonica.

The terrace-garden, so well illustrated at fig. 109, has a distinctly imposing appearance on the north-western side of the house, and is bright in summer with the beds containing well-grown flowering plants. The beds are surrounded with grass, and have Box edgings.

Roses are cultivated extensively, and all the best of the new varieties are obtained as they appear. A hedge on each side of a broad carriage-drive 200 yards long is composed entirely of climbing varieties, such as Euphrosyne, Crimson Rambler, Waltham Rambler, &c. That charming free-flowering variety, Pink Roamer, covers the low south wall of the plant-stoves. Near the house is a large square planted with Tea and H.-T. varieties, and in the grounds a circular plot 40 yards wide encircled with a Yew edge contains hybrid perpetuals, with Crimson Rambler trailing over the central arches.

The yellow Banksian Rose is luxuriating on the walls of the house, while other climbing varieties are growing freely over a Larch-constructed pergola leading up to the gardener's house in the fruit-garden. At the base of the pergola are planted herbaceous and bulbous plants, including a choice collection of Peonies.

[From a photograph by F. Mason Good.

FIG. 108.—ANCIENT WELL-HEAD IN TYLNEY HALL GARDENS.

Much attention is given to hardy herbaceous flowering plants. In the fruit-garden of eight acres two grass paths 12 feet wide are formed with proportionately-sized borders on each side and backed up with bush-grown Apple-trees. The herbaceous flowering plants in these borders are grouped in bold masses of one kind.

On the north side of a pond near to a glass-house, the passing road is protected by a steep rockery wall down to the water's edge. A fine effect in colour is obtained from Aubrietias, double white Arabis, Arenaria balearica, Primula viscosa, Phloxes, Achillea umbellata, and other plants.

Hardy fruit trees are grown against walls facing to the south, east, and north respectively. Standard Apple and Pear trees

growing in grass promise well for good crops, and there are breadths of Gooseberry and Currant bushes and of Strawberry plants.

Fruit and Plant Houses.

The vineries are not upon an ideal site, for some of them have a westerly aspect. In all cases the vines have been planted six years, and abundant room was given for extension of growth. Spaces of 4 feet 6 inches are allowed between the rods, and all are trained on the single rod and spur principle. The back walls are furnished with Vines too, which as yet have furnished good crops. One house is devoted to the variety Muscat of Alexandria, another to Black Hamburgh, one to Lady Downes and Gros Colmar, another contains Madresfield Court, Mrs. Pearson, Mrs. Pince, Black Alicante, and Gros Maroc. Such varieties as Black Alicante, Diamond Jubilee, Duke of Buccleuch, and Canon Hall Muscat furnish the back walls.

The Peach-houses are light structures, but perhaps a little too lofty. They occupy south and western aspects. In the early house the varieties Crimson Galande, Hale's Early, and Bellegarde, with Dryden and Elruge Nectarines, are cultivated. In succession-houses the varieties Marquis of Downshire and Alexander Noblesse, with Stanwick Elruge and Précoce de Croncels Nectarines are the leading sorts. In all cases the trees are remarkably healthy, and carry full crops of promising fruits.

Apples and Pear trees in pots are a feature; the trees are thickly set with fruit. Melons are cultivated in low span-roofed houses exactly suited for their culture. The varieties Best-of-All, Superlative, and Ringleader are most appreciated. Tomatos are required in considerable quantities, Sutton's A 1 being a popular variety for its free-bearing habit.

One of the principal uses of the plant-houses is for the cultivation of suitable plants and flowers for decorating the dwelling-house. Begonia Gloire de Lorraine has been extremely fine, a few specimens were fully a yard in diameter and as much in height. The plants were raised from leaf cuttings inserted in November. Schizanthus wisetonensis was effective in small pots. Carnations of the Souvenir de la Malmaison type receive a large share of attention, the health of the plants being all that could be desired. One thousand five hundred plants of Chrysanthemums are grown, and look well. Celsia Arcturus, Francoas, Liliums, especially of the L. speciosum type, Plumbago rosea, Hydrangeas, and Heliotropes in considerable numbers are pictures of good cultivation. A light, well-constructed house is occupied mainly with Codiæums (Crotons). A collection of Orchids is being gradually acquired, such useful kinds as Odontoglossums, Cattleyas, and Oncidiums, with Calanthes, are promising. A small yet effective rockery and fernery are interesting features, and there is a grand specimen of Cibotium Schiedei. A number of exceedingly fine standard and pyramidally-trained Bay-trees, with grand specimen plants of Hydrangea Hortensia, are employed with good effect in suitable positions outside the dwelling-house.

The offices, tool-sheds, fruit-room, bothy, &c., have been built with all modern conveniences, being efficient and durable. Since Mr. Phillips came into possession of the place seven years ago, improvements have been carried out to the advantage of the immediate neighbourhood. The garden is under the management of Mr. Foster, who was an apt pupil of Mr. McHattie when at Strathfieldsaye, and it promises to become one of the best gardens in the county for horticultural interest and good "keep." The *employés* on the estate have their athletic tastes catered for liberally—a capital cricket and football ground is provided, and in order that the gardeners may practise these games they are given a half-holiday on Saturdays. *A Wanderer.*

THE ALLEGED DETERIORATION OF POTATOS.

The special question under consideration is how far, if at all, varieties of Potatos deteriorate in quality or productiveness during the years which follow their first introduction. From the report of the meeting of the Scientific Committee of the Royal Horticultural Society on March 28, published in the *Gardeners' Chronicle* on April 8, it appears that opinion was then very much divided as to whether any such deterioration occurred or not, and this divergence of opinion was also apparent in the letters read to the Committee on the 11th inst. One writer, I think, even went so far as to say that because varieties of Vines, such as Black Hamburgh, or varieties of Bananas, &c., never vary or deteriorate from year to year, therefore no deterioration could take place in other plants, such as Potatos. Another expressed the opinion that because certain varieties of Potatos, such as the Ashleaf, may be as good now as when first introduced, this in itself proved that the same was true of all other Potatos.

It was even suggested that one reason why the deterioration of Potatos was so much spoken of was in order to create a demand for newly-introduced varieties at much higher prices than the older sorts, which, according to the writer (or speaker), would have been as good now as they were at first if they had received the same careful and liberal treatment always accorded to high-priced novelties. It is not conceivable that any merchant whose reputation depended upon the introduction of Potatos of sterling merit would discard a sort which continued to maintain its original quality and productiveness in view of the fact that many seedlings do certainly deteriorate rapidly. There are, however, noteworthy exceptions. The Ashleaf is certainly one that has "come to stay," and the "Early Rose" is perhaps more widely grown in Europe now than at any period of its existence. "Magnum Bonum" has also a record almost unequalled, and under certain aliases may have continued longer in general cultivation than has been supposed. The old "Redskin Flourball" is another notable case of long-continued productiveness; the "Maincrop" Potato, a beautifully formed white kidney, raised by Mr. James Clark, of Christchurch, Hants, about thirty years ago, still is one of the most profitable Potatos grown in the east of Scotland for the London market. The "Maincrop" does not yield, and never has yielded, so heavily as some varieties, but the quality is uniformly good. The "Langworthy" very closely resembles "Maincrop" in these and other characteristics. Sutton's Early Regent and Sutton's Ringleader, both raised by Mr. Robert Fenn, have been widely grown for more than twenty years, and show little, if any, signs of deterioration. Sutton's Discovery so far has not shown any sign of deterioration, no single case of a diseased tuber having yet been recorded, so far as I am aware, in England.

I have nevertheless no hesitation whatever in affirming that all who have had much experience in raising and introducing seedling Potatos know perfectly well that it is not a question whether Potatos do or do not deteriorate; the great question in introducing a seedling Potato is whether it possesses such a constitutional vigour as will enable it to maintain its productiveness and "quality" for a reasonable number of years. A Potato seed-berry may contain from two to three hundred fertile seeds, and no two of these are likely to produce plants exactly identical. As great variation will be seen in the shape of the tubers, the colour of the skin, the depth of the eyes, the colour of the flesh, the colour, form, character, and height of the foliage; the time of maturity, whether medium, early, or late; and the degree of productiveness. It is equally true that a similar variation exists as to the extent to which the several seedlings will be able to maintain their original productiveness and quality. Seedling Potatos are not as a rule put into commerce until the fifth or sixth year; and it often happens that those which show the greatest promise in their second or third year have been entirely surpassed in the fifth or sixth year by seedlings which gave little or no promise in the first, second, or third year. I remember the case of three or four out of a large batch of seedlings which gave extraordinary promise, and these were grown on to produce stock, but by the sixth year they had manifested such marked signs of deterioration that they were not put into commerce at all; whereas others which showed little or no promise at the beginning became very popular varieties.

Then as regards disease, many seedlings are very often quite free for four or five years, and in the sixth or seventh year succumb to attack. If all this be true of seedling Potatos before they are distributed, it naturally follows to a greater or less extent the same tendency to deteriorate will be seen during the succeeding years the introduction into commerce. Those who have facilities for raising and testing simultaneously several hundreds of seedlings can, nevertheless, form a fairly accurate opinion by the fifth, sixth, or seventh year as to which out of so many seedlings is most likely to maintain its original vigour for a period sufficiently long. Where a comparatively small number of seedlings are raised year by year, it must, in a great measure be guess-work as to what the future has in store for the seedlings. Undoubtedly pedigree in crossing is of great value, but even when the Potatos raised are the result of distinct cross-fertilization, very few of the seedlings will exhibit the distinctive characteristics of either parent, although the qualities of both may be combined in many of the seedlings. I am, of course, only speaking of Potato crosses and Potato seedlings.

On the other hand, a "natural seedling," i.e., a Potato raised from the seed-berry of a plant without cross-fertilization, will often bear a very close resemblance to its parent, in some cases so close as to be scarcely distinguishable, but the experience of twenty-five or thirty years would certainly lead me to say that such "natural seedlings" are far more likely to deteriorate than those obtained by cross-fertilization.

It must not be forgotten that it is extremely difficult to secure exactly the parentage which Potato-raisers often desire, in the first place because many Potatos produce few, if any, flowers, and some others which do flower produce little or no pollen, and also where pollen is produced it may not be available exactly at the right moment. But for these difficulties the judicious selection of parents might have a still greater effect upon the seedling Potatos introduced into commerce.

A great deal has been said and written as to the necessity of rigorous selection in order to prevent or postpone deterioration. Mr. Burbidge,

on page 238 of the *Gardeners' Chronicle*, quotes (but I believe inaccurately) Professor Hugo de Vries in support of selection as a means of both improving any variety of Potato and of preventing its deterioration.

Professor De Vries, whose experimental work will be closely followed by horticulturists, even though they may be unable to adopt the "Mutation theory" for the origin of species, very truly shows that any crop of corn or roots consists of individuals of varying vitality and productiveness, and that this makes selection possible and desirable. I cannot think that Professor De Vries would for a moment include Potatos as roots in this connection, and without a precise reference to De Vries' work, I cannot verify the quotation. Though the several plants in a corn or root crop are all separate individuals, as De Vries says, it is entirely otherwise with Potatos. In the case of Potatos, we all know that, if the crop is not mixed, only one "individual" is represented in a crop, even if the field should be 50 or 100 acres in extent. Each plant is but a portion, in a semi-dormant state, of the plant which flourished in the previous season, and no selection in the world can make the plants of one year vary or differ from those of the previous year, of which they are integral parts. This can be proved by anyone who can devote the necessary time and ground to careful experiments, but I am aware that there is a common prejudice against this very obvious fact.

Had Professor De Vries been speaking of the selection of Potatos he would of course have referred us, not to a crop of any one variety, each plant the same as the other, but to the "nursery bed" where the seedling plants were first raised from seed. It is here, and here alone, that we can say truly that a crop of Potatos "consists of individuals of varying vitality and productiveness." It is here alone that selection can be and is usefully employed by Potato raisers, and during the following years when the "individuals" in groups, propagated directly from the original seedling plant, are grown side by side for the purpose of eliminating the least promising and retaining only those which are superior to others. Any selection after the first year is of course applied, not to single tubers nor to single plants, but to the several groups of plants representing each original seedling.

It has been stated that the selection of small tubers for planting leads prematurely to deterioration, but provided each tuber be fully matured, the size of the "set" planted does not greatly affect the crop, although the result of long-continued experiments points to medium-sized "sets," uncut, as giving the best return.

The fact that some varieties produce seed very readily and others do not, has been referred to as a possible explananion of deterioration; but the "Ashleaf" is one which produces seed-berries quite as freely as any other variety, and it is the leading example of a Potato which shows little or no deterioration.

The method of storing "seed Potatos" during the winter certainly has great influence on the succeeding crop. "Sets" which are allowed to shrivel and exhaust themselves by throwing out long sprouts, which are rubbed off before planting, are naturally greatly inferior to those which have been well kept from the time of raising the crop in the previous autumn.

Deterioration can certainly be postponed by a frequent change of seed from another district, and experience points to Scotland as the source from which such a change of seed is likely to give the best result. The reason why this is so has not been fully shown. It is thought by many that the moister and cooler soils of Scotland prolong the period of growth, and thus prevent premature ripening of the tubers. It is very interesting to note that even in Forres, N.B., Mr. Fraser obtains the best results by getting his change of seed from a higher, colder, and later district, and that the worst results are from the dryer and warmer soils.

It may be interesting to note that in the first two or three years of a seedling's existence there often are very many more fibrous rootlets produced than in subsequent years, and this naturally may account for greater vigour and robustness. In the fourth, fifth, or sixth year these fibrous rootlets often decrease in number, but a Potato which retains such a habit of growth may also conceivably be less liable to degeneration.

It is sometimes considered that Potatos improve in quality after they have been put into commerce, and there are instances which seem to prove this to be the case. It may consequently be true that vigour of growth and "quality," or flavour, are rarely found united in one variety—in other words, that improvement in "quality" has been accompanied by loss of productiveness.

Certainly it is the case that the one thing market dealers are now demanding more than anything else is "quality" and flavour, and no one can well dispute the fact that few, if any, of the Potatos in commerce to-day either equal or surpass in flavour the old Dunbar Regent. If this be so, nothing but deterioration or degeneration can possibly account for the total disappearance of this Potato from commerce at the present day.

In my opinion the best safeguard against premature degeneration will be found in the exercise by raisers of greater caution in the introduction

From a photograph by F. Mason Good.

Fig. 109.—Tylney Hall: view from the west terrace.
(see p. 257.)

of new varieties; by growing a larger number of seedlings side by side under precisely similar conditions, and by subjecting them to a far more critical comparison with the best varieties already in commerce, so that only those which show very marked superiority and constitutional vigour may be chosen for introducing to the public. *Arthur W. Sutton.* (*Letter to Dr. Masters, read to the Scientific Committee on April 25.*)

THE PITCHERS OF NEPENTHES.

(*Concluded from p. 242.*)

The collar of the pitcher of *N. Veitchii* fully deserves the name. It is of the turned-down type, broad and frilled, and brilliantly coloured. Its interior margin is like a comb with very sharp teeth, and the deeply-seated glands are in this species between the teeth, instead of in the teeth, as in N. echinostoma. The pore-openings of the excretory ducts are so large as to be visible to the naked eye. The lid is relatively small, and furnished with thousands of honey-glands, about $\frac{1}{50}$th of an inch in diameter, with a few large ones at the point opposite the hinge, oblong or ovoid in shape, and sometimes as much as $\frac{1}{12}$th of an inch long. The wings are highly developed and elegantly fringed. With the exception of a very narrow zone immediately under the collar, the whole of the interior of the pitcher is covered with digestive glands, which are only partially over-arched. I estimate that there are upwards of half a million glands in a medium-size pitcher of this species.

N. Northiana is one of the handsomest species of the genus, and our slide was prepared from the late Miss North's original drawing as it appeared in the *Gardeners' Chronicle*. The pitchers were upwards of a foot in length, and green spotted with purple. The mouth is very oblique, with a collar similar to that of N. Veitchii, and the lid is remarkable in having two prominent ribs with a central band of honey-glands from base to apex.

The pitcher of *N. bicalcarata* has, in addition to the usual spur outside by the hinge of the deeply cordate lid, two other strong, curved spurs under the lid, projecting from the top of the long neck forward over the mouth of the pitcher. These so-called spurs are strong, sharp spines, and so placed that they would prevent the egress but not the ingress of small birds or mice. The frilling of the collar is very fine, and the interior surface of the pitcher is wholly glandular, the glands being the smallest I have examined, numbering from 15,000 to 20,000 to the square inch, as deduced from numerous careful computations. This species is also remarkable for the perithecioid glands, a tenth of an inch or more in diameter, on the thickened tendril, near the base of the pitcher.

N. celebica differs from all the others I have examined in having a horn-like appendage projecting from a notch in the lid on the distal side, or that farthest from the hinge. There is also a remarkable development of a knee-like intrusion on the under side of the lid.

Both Mr. Moore, of Glasnevin, and Mr. Tivey, grower for Messrs. James Veitch & Sons, inform me that the pitchers of the two sexes often differ, the female being the more attractive. N. Burkei is an instance; N. Burkei excellens being the female. N. Curtisii and N. C. superba bear the same relations to each other. The tendril of the female is no longer than the pitcher, whereas it is at least twice the length in the male. Mr. Farmar tells me he has noticed this in other species. Another peculiarity in N. Burkei is the reversed position of the pitcher in relation to the tendril in both sexes.

N. ampullaria is remarkable for the smallness of its lid, which is turned back, away from the mouth of the pitcher, and has no honey-glands on its under surface; but there are stomates, which is, I believe, quite exceptional.

N. Reinwardtiana is distinguished by having two eye-like spots near the top on the inside of the pitcher. This species has perhaps the narrowest collar of any, and the transverse rings or plaits are exceedingly thin. The contrast in the colour of the smooth and glandular zones is very striking. I have not investigated the nature or cause of the spots, but they appear to be constant.

N. Khasiana has an exceedingly neat, narrow collar, with very numerous narrow transverse rings. On the underside the lid is uniformly covered with honey-glands. But it is the conductive zone of the interior of this pitcher which is specially attractive. It occupies nearly two-thirds of the space, and is of a bright red colour, contrasting well with the yellow glandular zone, in which the glands appear as dark dots, distant from each other from one to three of their own diameters. The dark appearance is due to the greater part of the glands themselves being visible. A dried specimen shows well the colouring of the interior of the pitcher. This species is of historical interest, from having been the second cultivated in this country, and the first figured from a cultivated plant. It was first represented in Loddiges' *Botanical Cabinet*, vol. xi. (1825), t. 1017. From the first it was cultivated under the name of N. distillatoria, and the name still lingers in gardens for this species; so difficult is it to get rid of a name under which a plant is first introduced into gardens.

In all the various structures, the arrangements are such as to facilitate the ingress and to hinder the egress of such insects and other creatures as are tempted within the reach of the various influences. I may add that plants in captivity, otherwise in cultivation, are often very active in the capture and consumption of insects, though it is not necessary for their existence. But a certain wily kind of ant has succeeded in obtaining the liquid from the pitcher of *N. bicalcarata* without risk, by boring a hole in the tendril near the base of the pitcher, when the liquid oozes out out for the benefit of the ingenious creature. Mr. Burbidge, Curator of the Trinity College Botanic Garden, Dublin, discovered this trick during his travels in Borneo. The tendril at this point is abnormally thickened, and the same thickening takes place in the cultivated plant, although it is not perforated.

In relation to the carnivorous nature of Nepenthes, certain species seem to be more attractive to insects than others, or perhaps the fact of their entrapping more insects may be accidental and due to their position. I am speaking of plants under cultivation. In some pitchers I found only ants; in others, various beetles and cockroaches and ants intermixed. A plant of *N. bicalcarata* in a pot partly immersed in the water of the tank in the Victoria-house, had its pitchers half filled with insects, chiefly beetles in various stages of decomposition. Professor Macfarlane mentions that a pitcher of N. Hookeri under observation caught seventy-three cockroaches within a fortnight, having been emptied three times during that period. A valuable plant, indeed, in a house infested with those destructive insects.

Those desirous of knowing more of the anatomy of the pitchers of Nepenthes and the process of digestion that goes on in them, should consult the writings of Prof. Macfarlane and of Dr. Vines, in the third, seventh, and eleventh volumes of the *Annals of Botany*. The geographical distribution, floral structure, and relationships of Nepenthes are dealt with in the seventh volume of the publication named. A more popular and comprehensive illustrated account of the genus, by Mr. Harry Veitch, appeared in the twenty-first volume of the new series of the *Journal of the Royal Horticultural Society* in 1897. The literature of the subject in other languages is voluminous. A large proportion of the most noteworthy species, varieties, and hybrids have been figured and described from time to time in the *Gardeners' Chronicle*, the first being N. lævis, Lindl., 1848, p. 655. *W. B. Hemsley.*

MANURE-WATER AND PEACH-TREES.

To my mind the reasons given by Mr. C. W. Muir and your old correspondent, Mr. H. W. Ward, do not carry conviction as regards the need of stone-fruits for so much manuring as these cultivators recommended in the issue for April 1. In loamy, naturally fertile soils, and in well-made borders consisting of turfy loam, even when the staple is light, sandy, and shallow, if the borders are dressed annually with light, well-rotted stable-manure, but little more is required than to afford plain water several times during periods of drought in the months of July, August, and September; and we sometimes experience wet summers when even these applications are better withheld. I have in my mind only open-air culture, for under glass the conditions are very different, and heavy applications of water more frequently afforded may be called for to assist the growth of shoots and give greater size to the fruit if the crop be an abundant one.

I hold that if fruits be of the normal size for the variety, there is a great loss of flavour if the size is increased to any great degree, and this is scarcely ever desirable when the fruit is for home consumption, fine, full flavour being considered by good judges preferable to mere size. That a Peach border should be maintained in an uniformly moist condition by artificial watering from March to the middle of the month of September is an axiom with most intelligent gardeners, and they endeavour to carry it as far as their means will allow. I have had to do with the Peach, Apricot, Plum, Pear and other fruits for many years on a variety of soils and in different parts of England, and have rarely known much need for the application of water, the natural rain and snowfall being all-sufficient in the majority of years, a thin mulch of half-decayed litter applied after June was out meeting all needs.

If a Peach-tree is lightly cropped, as will sometimes occur from loss of bloom by frost, from removal, transplantation, or over-severe root-pruning, and the prospect of a sufficiently vigorous growth of shoots appears good, applications of manure-water in the summer months are more likely to do more harm than good by unduly increasing the strength of the year's shoots and hindering their maturing. Better thin well-ripened shoots than willowy gross ones that never ripen except at their bases. Trees which bear well every year may need a little more assistance than the soil can supply and I have indicated, but no more should be afforded than will bring the fruits to perfection and furnish fruitful wood.

Climate and local conditions as regards rainfall are matters every gardener must take note of, or he will have to record more failures than successes in the cultivation of the Peach, Nectarine, and Apricot. Of much importance are the rainfall, nature of the soil, the width of the border, its condition as regards drainage, and the depth of the roots below the surface. A good many years ago the writer took charge of a large garden in a southern maritime county. The rainfall (local) was heavy, and during the summer months sea-fogs would fill the valley in which the garden was situated for a week or longer at a time, and under these conditions no artificial applications of water were ever necessary. Splendid Peach and Nectarine-trees covered two south walls, the gross shoots well trained, and foliage as healthy as could be desired. The owner informed me despondingly that these fine trees seldom carried a fruit. Gardeners at that time were just acquiring a knowledge of the benefits derived from the root-pruning of fruit-trees, but the gardener I superseded either knew nothing of this, or he had not put it into practice, and contented himself by trying to check the exuberance of growth by hard pruning. I could at once perceive the trees could be restored to fruitfulness

by lifting and replanting them in a wider border, keeping the roots near the surface, and preventing them entering the cropped ground in the area beyond the tree-border. Replanting was carried out during the same year, and two years later the trees bore more fruits than could be consumed by the family.

Instead of following the advice of your two correspondents, if gardeners with overflowing manure-water tanks would apply their contents to gross-feeding vegetables—as Celery, Asparagus, Cabbages, Cauliflowers, and the like, to aged Pear and Apple-trees, especially to such as may be growing in grassed orchards and worn-out lawns—much good might be done. It will be found that good results follow the severe thinning of all kinds of stone fruits on walls and bush trees when the set has been more abundant than usual, and applying manure-water only to palpably infertile, thin, or gravelly soils. *F. Moore.*

ALPINE GARDEN.

ANEMONE HEPATICA "TORCH."

The variety of Anemone Hepatica known as "Torch" is the best of the Hepaticas, being brighter even than that fine crimson or rather almost magenta form of Anemone Hepatica called splendens, while the flowers are considerably larger in size. It was raised by Mr. James Allen, of Shepton Mallet. The flowers are as large as those of the different forms of Anemone (Hepatica) angulosa, and look exceedingly bright in the garden in March and April.

Veronica filifolia.

Numerous as are the dwarf and other Speedwells in our gardens at the present time, the little Veronica filifolia should be grown where possible, as it is not only very distinct, but also very beautiful indeed to those who can appreciate modest alpine flowers. It is still far from plentiful, and is a plant which I lost about two years ago through some want of care; but from my experience of it for three years I believe it to be quite hardy, and I attribute its loss to the want of a top-dressing one spring remaining unsupplied. I have not seen it mentioned in British catalogues, but I observe that seeds are now being offered by Messrs. Thompson & Morgan, of Ipswich. It came to me from France, and I considered it one of my prettiest alpine flowers. Its character is well indicated by the specific name of filifolia, as the foliage is extremely narrow and linear. The flowers are white with little markings of blue, and the whole effect of the plant is delightful in the extreme. The plants grow only about 6 inches high, and have a trailing habit. I grew my plant on a terraced rockwork with an exposure almost north-east, and well shaded from the sun except when it was about the meridian. The soil was sandy peat, and the plant was watered in dry weather. Until I lost the plant it seemed to thrive well under such conditions, and I look forward to growing it again.

Pulmonaria arvernensis alba.

This is a pretty little early-flowering Lungwort which has not yet been generally seen by cultivators. It never reaches more than from 4 to 6 inches in height here, and has rather dull, green leaves, and bears a number of neat white flowers. The plant appears to thrive perfectly well in shade, and it is not fastidious as to soil. The Auvergne Lungwort was, I believe, introduced some years ago by Messrs. James Backhouse & Sons, of York, but is now in the hands of a few other nurserymen. I have had it in my garden for four or five years, and find it perfectly hardy. Though not among the choicest spring flowers, it is a little plant which ought to meet with some recognition. *S. Arnott, Carsethorn-by-Dumfries, N.B*

NEW OR NOTEWORTHY PLANTS.

CYRTANTHUS INÆQUALIS, *n. sp.**

In January, 1904, there flowered in the nurseries of Messrs. Wm. Cutbush & Son at Barnet a Cyrtanthus, three bulbs of which had been collected by the Messrs. Cutbush's sister in the neighbourhood of Georgetown, Cape Colony. More than one expert in Amaryllideæ mistook it for Cyrtanthus angustifolius grandiflorus (Baker), but on the inflorescence being submitted to me I at once pronounced it to be a new species, its chief distinguishing features being the more or less erect habit of the flowers, the larger perianth-segments, and especially the

Fig. 110.

(1) Inflorescence, leaf, and single flower of Cyrtanthus inæqualis, a new species: colour of flowers coral-red.

(2) Inflorescence and leaf of C. angustifolius grandiflorus: colour of flowers scarlet-red.

(Drawn from living specimens by Alice L. O'Brien, and much reduced.)

peculiar manner in which the upper three associate and form a pent-house over the stigma and anthers, which are not protruded, as in most members of the Monella section of Cyrtanthus. I sent a drawing of the inflorescence to a friend in S. Africa, who fell into the same error as others had done, and taking it for C. angustifolius grandiflorus, sent to the Tulbagh district of Cape Colony, on the opposite side to that in which the specimen in question had been collected, and obtained for me a few bulbs of C. angustifolius grandiflorus (Baker)—the first to arrive in England, I believe. My daughter had previously made a drawing of Cyrtanthus inæqualis (fig. 110 [1]), and we were enabled to include one of the true C. angustifolius grandiflorus (fig. 110 [2]). Reference to the illustration shows many differences. C. angustifolius grandiflorus, which is a very fine plant, is the largest form of C. angustifolius. The mature bulbs are as large as those of Vallota purpurea, and the leaves in the early stage often three-quarters of an inch across. When in flower the inflorescence is about a foot in height, and the leaves about the same, but when seeding the peduncle elongates, and the leaves also. Flowers scarlet-red.

Examination of the illustration of Cyrtanthus inæqualis (fig. 110 [1]) will show on comparison that there is very little resemblance to C. angustifolius var. grandiflorus; it differs at all points from the bulb to the flower. Indeed, it is in no danger of being confounded with any other species. The regrettable point is that the exact spot where it was collected cannot be ascertained. Perhaps some reader of the *Gardeners' Chronicle* in Cape Colony may be able to give further information on the subject. *J. O'Brien.*

* *Cyrtanthus inæqualis*, n. sp.—Bulb globose, 1½ inch in diameter, prolonged into a neck 1 inch in length. Leaves 2–3 contemporary with the flowers, 1 foot or more in length, linear, narrowest at the base, where they are almost triangular, keeled on the under side, channelled above, green tinged with purple at the base. Peduncle erect, 1 foot high, cylindrical, slightly compressed, hollow, green tinged with purple. Spathe-valves four, two large and two small, lanceolate. Flowers four in an umbel (in the specimen seen), more or less erect, curved; pedicels ½ to ¾ inch; ovary ovoid. Perianth 2½ to 3 inches long, tubular in the basal half, the other half having free segments, the lower one decurved, the lateral two spreading, the upper three inclined forward over the style, that peculiar character being very pronounced when the flowers are mature. Stamens biseriate, three of them reaching nearly to the tips of the segments. Style filiform, stigma tricuspidate, not protruded. Colour of the flower bright coral-red. *James O'Brien.*

KEW NOTES.

Hechtia argentea, Baker.—This is by far the most handsome species in a rather small genus belonging to the order Bromeliaceæ. It is extremely rare in cultivation, the Kew plant being probably the only one in this country. It has been grown in the Succulent-house (No. 5) for nearly forty years, first flowering in 1870, again in 1895, and after a lapse of ten years it is once more in flower, carrying two inflorescences, the strongest of which is 4 feet 6 inches in height. This plant is one of the most effective and conspicuous of the many rarities contained in this house. It has about 150 leaves, forming a large dense rosette. They vary in length from 2 to 3 feet, and are 1½ inch broad at the base, gradually tapering to a long slender point. In texture they are very fleshy and rigid, with large curved horny prickles on the margins. Both surfaces of the leaves are a beautiful silvery colour. The flowers are small and white, being developed in dense sub-globose heads towards the top of the peduncle. There are about two dozen heads on each inflorescence. The species was figured in *Botanical Magazine*, t. 7460.

Ansellia africana, *Lindl.*

The genus Ansellia is little favoured by Orchid cultivators generally, yet the plants may be easily grown. They generally flower freely, and when not in bloom are good "furnishing" plants, and may be grown into fine specimens. These characteristics are well marked in the species A. africana, now flowering in the warm Orchid-house. The plant has stout, upright, Dendrobium-like growths 3 to 4 feet in height, each growth having generally about a dozen leathery arching leaves 1 foot to 18 inches in length, and 1 to 1½ inch broad, the inflorescence being a large branched terminal spike. The specimen has six of these inflorescences, the largest of which is composed of ten spikelets with a total of 130 flowers, each having a diameter of 2 inches; the flowers remain fresh for about six weeks. The oblong sepals and petals are light yellow in colour, and heavily barred with chocolate-brown; the side lobes of the lip and the column are marked with light brown colour, the middle lobe being light yellow, and fleshy in texture. It is a native of Western Tropical Africa. The dwarfer plants A. congoensis and A. nilotica are also flowering in the same house. *W. H.*

TREES AND SHRUBS.

THE CHINESE CHERRY.

THE variety known in gardens as Cerasus sinensis rosea var. pendula is one of the earliest to flower of ornamental Cherries, and at the present time is most beautiful. The individual flowers are small, but they are produced in such profusion as to hide all the twigs and branches. Being of weeping habit, the plants should be procured on stems at least 8 feet high. As an isolated specimen planted on the grass or lawn the pale rosy-coloured flowers, together with the general contour of the tree, make it a very cheerful and pleasing addition for large or small gardens. *W. H. Clarke, Aston Rowant, Oxon, April* 17.

NURSERY NOTES.

HIPPEASTRUMS AND OTHER PLANTS AT MESSRS. J. VEITCH & SON'S.

THE span-roofed house containing the Hippeastrums presented a gay aspect recently, and the beds, numbering two, instead of three, as in the old structure now demolished, exhibit the flowers in a more telling fashion. The marked characteristics of H. Leopoldi, employed many years ago—viz., large size of segments, and regularity of form, as opposed to the older stellate type imparted by the now discarded H. pardinum—were recognisable in most of the flowers open at the time of our visit. Among seedlings flowering for the first or second time were the following varieties. Mrs. Bilney has bold, finely-shaped flowers, with a white ground and cerise-coloured flame; Rosalie, also white with delicate pink flame, a crumpled margin and warted surface to the segments, is novel both in this respect and in the markings; Orion, a bright scarlet self; Ivanhoe, a scarlet-coloured flower with green-and-white bands running from the margin to the base of the flower; Cyrus, a white flower sparsely lined with red; Scopas, of large size, a fine-looking and striking red flower; Cythera, a smallish crimson self; Vesta, a large white bloom having markings of a shade of cerise; and Iverno, having a flame of dark crimson, and edging to each segment of the same tint.

In one of the flower-houses some new Cinerarias of considerable promise were noted. They will be useful as decorative subjects for conservatories and large greenhouses, in which the more compact low-growing varieties are of lesser value. Of these there were numbers of plants of Feltham Bouquet, large-growing, much branched in habit, and having flowers of a light purple tint. The florets are broader than those of C. stellata, and as the flowers do not form seeds they are the more enduring. The plants are propagated from offsets. C. "Fantasy" somewhat resembles the foregoing, but the florets are convolute and of a bright purple colour. The habit is branching and strong. This plant is capable of forming seeds. Some nicely-flowered plants of Viburnum plicatum, a species not often grown in pots, were noticed. The globular inflorescences resemble those of V. Opulus, but the foliage is different. Plants of Senecio auriculatissimus, illustrated in our issue for April 8 last, were noted in flower, as also were plants of Corydalis Wilsoni, making pleasing dwarf masses of yellow-coloured flowers; and Kalanchoe felthamensis, which flowers earlier than the better-known K. flammea.

In the warm-houses there were remarked some handsome plants of Sanchezia nobilis, with beautiful green-and-yellow foliage; Heliconia illustris, Phyllotænium Lindeni, Dieffenbachia Fourneri, and the yellow-flowered Gomphia oliviformis, a flower of much beauty.

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pot Vines.—The earliest of these will have made rapid progress during this month, and as the fruit will now be colouring, a cooler and drier atmosphere, with increased ventilation as the fruit becomes ripe, will be necessary. Discontinue the use of liquid manures, but do not allow the Vines to suffer from want of water at the roots. Allow the laterals to develop a fuller extension of growth at this stage to supply the necessary shade. Home-grown canes raised for fruiting next season must be encouraged to grow freely and strongly by keeping the atmosphere of the house moderately moist, and by paying careful attention to the matters of ventilation, pinching the laterals, and watering.

Planting Vines.—If it is intended to plant in the borders young Vines raised from eyes rooted during February, which have been grown with a view to this planting, preparations for the work should be made as soon as the house can be cleared. In many cases a crop of fruit is taken from the old Vines before the new ones are planted, or the house may have been used for other purposes, but it must now be cleared and put in readiness for planting the Vines during next month. A border 3½ to 4 feet in width and 2½ feet in depth is sufficient for the first season after the Vines are planted, and much will depend on the natural drainage whether it is necessary to construct a concrete bottom. Good drainage of some kind must, however, be provided, at least a foot in depth. When preparing for drainage, commence by laying whole bricks or stones close together, cover these with broken bricks, and finish with a good layer of rough lime-rubble; over this latter place turves with their grass sides downwards. If good fibrous loam of a yellow colour and not too light in texture is used, very little artificial manure will be necessary. Apply a sprinkling of lime-rubble, wood-ashes, charcoal, and bone-meal on each layer, making each layer thoroughly firm as the work proceeds. The quantity of rubble, &c., that will be needed will depend on the nature of the loam. No green manure should be used with the exception of a few fresh horse-droppings, and a little Kirk's or Thomson's Vine Manure applied at the surface of the border. Plant the Vines as soon as the soil is warmed to the temperature of the house. The Vines when planted should be about 2½ feet high, and have sufficient roots to hold the ball of soil together. Plant them 4 feet apart in warm and finely-chopped soil, and afterwards water them, using the water at a temperature of 85°. Keep the atmosphere of the house rather close and moist for a time, and shade the Vines from the sun's rays in the middle of the day until fresh growth has started. Let the temperature at night be at about 65°, with a rise during the day of 10° or 15°, closing the houses early in the afternoon with plenty of sun-heat and moisture present. One-year-old Vines intended for planting should be watered previously, and at the time of planting should have their roots evenly arranged at different depths, varying from 2 to 4 inches. Disbud or cut back the Vines to suit the level of the front portion of the building, and to allow of their proper training.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Prancratium fragans.—Plants that are established well in 8-inch pots require very little attention beyond liberal applications of liquid-manure, obtained preferably from the soaking of sheep droppings in water. Under such treatment the plants will produce numerous spikes of fragant flowers suitable for cutting or otherwise, and well-matured healthy foliage. Unless it is desirable to increase the stock of plants by division of the bulbs they will not require potting for a long time, and an 8-inch pot is a useful size without being inconvenient to move. The plants require to be grown in a light position and a moist atmosphere, and under the following conditions we are able here to cut a quantity of well-developed flower-spikes in August. Through the winter months the plants are grown in a warm, moist atmosphere in a house facing to the north. They remain in this house until the latter end of April, and are then removed to a Fig-house facing to the west, and placed on the border underneath the trees, where they are allowed to remain until the Fig-trees begin to shed their leaves towards the latter part of September, when the Pancratiums are removed to the north house again. The present is a suitable time for dividing old plants. The potting soil should consist of good fibrous loam three parts, spent Mushroom-dung one part, and a little bone-meal, broken charcoal and silver-sand, all mixed well together.

Gloxinia plants that were potted in January are now developing their flowers, and should be afforded a teaspoonful each of Clay's Fertiliser once a week, besides frequent waterings of diluted liquid-manure obtained from sheep-droppings. Seedlings should be potted into thumb-pots without delay.

General Remarks.—After east winds followed by blight, an examination should be made of the plants both in frames and houses. Dipping or fumigating will be necessary in some cases and should be undertaken without delay. Forced shrubs that have passed out of flower should be gradually hardened with a view of planting them out in the pleasure grounds. Prick off seedling plants as they become ready for handling, and admit air sparingly to houses or pits containing plants of young and tender growth.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Phalænopsis.—Many of these plants will soon commence to make a new series of roots, and it is advisable ere these enter the old material that fresh sphagnum-moss or other suitable rooting medium be afforded. Plants grown in baskets should have the old moss removed, and as many of the old crocks as are detachable. When this has been done afford the plants fresh sphagnum-moss and clean drainage material. For several years past we have grown our plants in pans, in a mixture of equal parts of sphagnum-moss, peat and Oak leaves, with a sprinkling of sand and small nodules of charcoal to ensure effective drainage. The pans used should have perforations round the sides, and an inch or more of drainage material according to the size of the pot. When the compost has been worked-in amongst such living roots as are inside, place on the surface a layer 1 inch deep of chopped sphagnum-moss. The materials should be pressed moderately firmly, or in the middle of the season of growth, the leaves having decayed, the compost will be so loose that it will hold water like a distended sponge. When affording new receptacles to plants, separate the roots from the old ones by means of a thin-bladed knife, after soaking them for about an hour.

Cultivation.—If a few plants only are grown they should be allotted a well-shaded position in the East Indian-house, but they can be more easily managed when a separate compartment is provided for them. They may then be suspended from the roof, and the stages beneath may be occupied by many of the warm-growing Cypripediums. The house should be rather heavily shaded at all times when the sun shines upon it. The atmosphere should be carefully regulated in regard to heat and moisture, and at no season need there be an extravagant amount of heat employed. The temperature from the present time until the end of September should range between 65° in the morning to 75° during the day, increasing until with sunheat another 10° will prove beneficial if other conditions are favourable. Secure atmospheric moisture by damping the stages and floors early in the day, and as often afterwards as occasion requires, also by spraying overhead on bright mornings. After the plants have been top-dressed or transferred to new receptacles, they will only need sufficient direct waterings to keep the sphagnum-moss moist, but when rooting freely a fairly generous supply should be afforded. Plants growing in a mixture which

includes leaves must be given water less often than other plants, at first in the early stages by sprinkling the surface, and later on by an occasional dip, which should be done quickly to prevent the mass absorbing too much, always allowing them to become almost dry beforehand. Cleanliness is very essential to their health, therefore sponge the leaves several times during the year, and fumigate the plants each month. Fresh air is equally essential, but ventilation should be afforded in such a manner as will not cause draughts, or promote dryness in the atmosphere. Use the bottom ventilators at all times, and the top ones only on exceptionally hot, moist days. P. Schilleriana will stand most strong light, and green-leaved species the least. P. Luddemanniana P. speciosa, P. violacea, P. sumatrana, and others of this section are the most shade-loving. P. Esmeralda and P. Lowii are ofttimes deciduous, and need little water excepting when rooting freely. The stock of several species may be increased by allowing the old scapes to remain, on the chance of young plants developing from the upper nodes. P. Luddemanniana does this habitually, P. speciosa occasionally, P. amabilis and P. grandiflora rarely, and P. Stuartiana projects young plants from its roots occasionally. These may be taken off when they are making roots and be treated separately.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Raspberry-canes.—Let any suckers now appearing which will not be needed be cut off with the hoe, that the plants may concentrate their energies into the development of those required for fruiting next year.

Peaches and Nectarine-trees.—In many districts the trees will have advanced sufficiently for the shoots to be disbudded. The growths from these buds tend to stimulate root-action, therefore the operation of disbudding should be extended over a period of three weeks, and performed by removing occasionally the most advanced shoots, and in such a gradual way that little or no check may be felt by the roots. The work ought to be performed by an experienced man, because no shoot should be left on the tree that will not be required afterwards, nor in a position where it cannot develop perfectly without preventing other growths and fruit from maturing fully. The first operation will be to remove all shoots growing straight out from the branches and those growing towards the wall; a few of the intervening buds may be removed at the same time. After a few days the trees should again be examined, and all weak and badly-placed growths be removed. Then at the final thinning remove those of the remaining shoots which the operator has not selected for the extension and furnishing of the tree. One shoot should be left at the apex of each branch for extension, which if not required for that purpose may be pinched when the limits of space are reached; a second shoot should be left half-way down the branch, and a third at the base in a well-placed position for laying in. Where trees were pruned as advised previously, three growths will be sufficient to leave, but if last year's branches were laid-in full length it may be necessary to leave more. Try and secure young growths to furnish the base of the tree, which in old trees is liable to become bare by reason of the extension system of training. Maiden trees that were planted this season should have their buds reduced to three or five, and the growths that result from these will need to be trained-in at intervals afterwards. If one strong shoot is taking the lead, tie this down first, allowing the others free growth for a time before tying them down, which will help to restore a proportional flow of the sap. Trees which had five shoots trained-in last season may now be allowed thirteen shoots.

Stone Fruits of various kinds are now in flower or unfolding their petals; during the cold winds which are now prevailing means should be taken to protect them. Plums and Cherries may be successfully protected by double fish-netting, but Pears require a more efficient means, especially where the trees are in an exposed position.

Fig trees that were recently uncovered should be afforded temporary protection during such cold weather, increasing the protective material in thickness should there be signs of frost.

Pyramidal and Bush-trees may be protected by Spruce and Laurel boughs tied at intervals to the branches throughout the tree, or a few bushy Pea-sticks may be struck into the ground and covered with Spruce. We have nearly 2 acres of trees here protected by wire-netting. While protecting all individual trees as far as possible, mats are tied to the wire on the east side where the trees are exposed most, and these help to check wind.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Potatos.—Afford free ventilation to the latest Potato plants in warm pits, and should the quantity of soil about them be considered insufficient, that to be added should be placed in a cold frame for a few days previous to being used. Afford water to the Potatos when this is considered necessary, but let it be in moderate quantities and at a temperature not lower than that of the soil in which the plants are growing.

Runner Beans.—In order to secure crops of Runner Beans in the best possible condition, it is essential that the ground be well prepared before they are planted, as few vegetables respond more satisfactorily to liberal treatment than these. The general practice obtaining in these gardens is to prepare the ground as if for Celery, although if the ground be well trenched and heavily manured it will be sufficient for the purpose. It must be remembered that Runner Beans root deeply and are gross feeders, for which reason give liberal supplies of good half-decayed farm-yard manure, and incorporate this well with the soil. It is a good practice when preparing the trenches to do the staking at the same time. The stakes should not be less than 12 feet in length, of which 2 feet is inserted in the ground. If these are placed in single lines no difficulty is experienced in putting in the plants or in inserting the seeds, and it obviates all danger of injury to the roots that would be occasioned if performed later. The alleys between the rows should be about 10 feet in width. The sowing of seeds of Runner Beans out-of-doors for an early supply, and even for the general crop, is a much less satisfactory practice than that of sowing in pots or boxes and afterwards transplanting the seedlings. Plants raised from seeds sown 3 inches apart in boxes can be easily removed, and without injury. The transplanting should be done when the first growth appears beyond the seed-leaves. They must be raised in quite a cool place, and be given plenty of ventilation from the time the seeds are planted in order to secure strong plants. By doing this much anxiety will be saved should frost appear, and insects can be kept in check and the best results secured. The improved types of this vegetable, such as Neal's Ne Plus Ultra, are a great advance upon the old varieties generally grown. Last season the variety "Hackwood Success," raised by Mr. Bowerman, gave good results here. This season we are trying the merits of Carter's Mammoth, a variety raised by Mr. Lye. The first and second weeks of May will be sufficiently early to sow seeds of Runner-Beans.

French Beans.—A sowing of French Beans should now be made upon a narrow border facing to the south. For the first sowing out-of-doors we make the drills 4 inches in depth, and at 18 inches apart. If old potting soil is placed under and over the seeds it will considerably assist germination. In the event of late spring frosts, protection can be provided by placing light Yew branches or any similar material among the tender seedlings. Suitable varieties of French Beans are Favourite, Magnum Bonum, and Canadian Wonder.

Peas.—Pay close attention in the matter of earthing and staking the plants. Neglect in not providing early support to Peas will in a great measure often cripple the crop. Make further sowings as soon as the latest-sown batches are above-ground. Peas growing in pots, or those planted in pits, must be allowed an abundance of air, and a free supply of water at the roots with occasional applications of weak liquid-manure.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Annuals. — Prepare the ground for those annuals, seeds of which will be sown in the positions where the plants will flower. A sandy loam is the most suitable soil for annuals, and it should be deeply dug and a moderate application of manure be given. Make the surface of the ground fine, and sow the seeds in drills so that a dutch-hoe may be used between the rows when the seedlings appear. Small seeds only require to be barely covered, but an inch deep will suit most kinds.

Bamboos.—The present is a suitable time for planting Bamboos. Choose a sheltered position for them where the plants will have the advantage of a background of other trees or shrubs. They will grow in sunshine or partial shade of trees, and by the side of water. Afford them a rich compost, or a plentiful supply of potting bench refuse will suit them admirably. If the plants are in pots turn them out carefully, and do not attempt to disentangle the roots, for they are brittle. After the planting has been done, afford a liberal mulch of manure, and apply water when this becomes necessary. Bamboos can be successfully transplanted at this season. If the "ball" of a plant that is being moved is of large size, it may be easily got out of the hole by tilting it carefully on one side, then placing a stout board under, and on this a transplanting fork; then let the weight of the soil fall on to the fork. A push and pull will send the ball up the board to the surface, when it can be trailed to the new station, unless it is some distance away. Our fork has twenty prongs, and there is a good bend on them. If the plant has to be conveyed for a considerable distance, put it on the removing carriage. Some Bamboos may be divided now, but keep as much soil as possible to the clumps. Remove the winter coverings from established plants, and afford them a liberal top-dressing of cow-manure. The following Bamboos are hardy, and make good growth:—Arundinaria japonica, A. Simoni, Phyllostachys kumasasa, P. aurea, P. Henonis, P. nigra-Boryana, P. Quilioi var. Castillonis, and P. viridi-glaucescens.

Paths.—Now that most of the rough work has been done the paths will require attention. Edge the grass, and level the paths, then apply fresh gravel and roll it well. Take advantage of fine days to kill the weeds.

Fernery.—Ferns require good drainage and a considerable depth of soil, consisting of loam, peat, and crushed stones. They should be cultivated in a shady glen, sheltered from prevailing winds. In addition to the well-known kinds, Struthiopteris germanica and S. pennsylvanica are effective. The young foliage of the plant last mentioned is tender and needs protection.

A Branching Palm.—In the *Proceedings of the Agri-Horticultural Society of Madras* for September, 1904, is a figure of a Palmyra Palm (Borassus flabelliformis) with "twelve fully-developed heads and twenty-eight "blind" branches which are at first curved downwards but afterwards turn upwards." No reason for this appearance is suggested, though occasionally the injury caused by the grub of some beetle is responsible for the outgrowths.

"Farm and Home Year Book for 1905."—This is an "annual" intended expressly for the use of farmers. In addition to an Almanack it contains a variety of articles of special interest to agriculturists, and the dry details of business are enlivened by ten pages devoted to "humours" of the country. There are numerous illustrations, a table of contents, and a complete index. It is published at the office of *Farm and Home*, 17, Furnival Street, Holborn, E.C.

APPOINTMENTS FOR MAY.

MONDAY,	MAY 1	—Bank Holiday (Scotland).
THURSDAY,	MAY 4	—Linnean Society, meeting.
FRIDAY,	MAY 5	Royal Botanic Society, Lecture at 4 P.M.
SATURDAY,	MAY 6	Société Française d'Horticulture de Londres, meeting.
TUESDAY,	MAY 9	Royal Horticultural Society's Committees meet. National Rose Society's Committee meets.
THURSDAY,	MAY 11	Royal Gardeners' Orphan Fund, Annual Dinner at Hotel Cecil.
FRIDAY,	MAY 12	—Royal Botanic Society, Lecture.
WEDNESDAY,	MAY 17	Royal Botanic Society's Show at Regent's Park. Devon County Agricultural Society's Show at Exeter (3 days).
FRIDAY,	MAY 19	Royal Botanic Society, Lecture, 4 P.M.
SATURDAY,	MAY 20	Paris International Horticultural Exhibition (9 days).
TUESDAY,	MAY 23	Royal Horticultural Society's Committees Meet. and National Tulip Society's Show combined.
WEDNESDAY,	MAY 24	Linnean Society, Anniversary Meeting. Royal Caledonian Horticultural Society's Spring Flower Show at Edinburgh (2 days).
FRIDAY,	MAY 26	Royal Botanic Society, Lecture and Meeting of Fellows.
MONDAY,	MAY 27	Annual Dinner of the Members of the Kew Guild at Holborn Restaurant.
TUESDAY,	MAY 30	Royal Horticultural Society's Show in the Temple Gardens, Thames Embankment, London (3 days). Bath and Western and Southern Counties Society's Show at Nottingham (5 days).

SALES FOR THE WEEK.

TUESDAY and WEDNESDAY NEXT—
The "Bank House" Collection of Orchids. Important three days' sale of the entire collection of Cattleyas, also duplicate plants of Odontoglossums and Cypripediums, at Bank House, Accrington, near Manchester, by Protheroe & Morris, at 12.30 o'clock.

WEDNESDAY NEXT—
Palms, Plants, Hardy Border and Herbaceous Plants and Perennials, Carnations, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Palms, Azaleas, Gladioli, Lilies, &c., at Stevens's Rooms, King Street, Covent Garden, at 12.30.

FRIDAY NEXT—
Imported and Established Orchids in large variety, from various sources, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —51·5°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April* 26 (6 P.M.): Max. 58°; Min. 49°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, April* 27 (10 A.M.): Bar., 30·0; Temp., 55°. Weather dull and calm.
PROVINCES.—*Wednesday, April* 26 (6 P.M.): Max. 53°, Guildford; Min. 45°, E. coast of Scotland.

Deterioration of Asexual Varieties.

THE discussion at the Scientific Committee of the Royal Horticultural Society has elicited a great deal of interesting information, especially with regard to the Potato, but it can hardly be said to have led to any decisive result. Nor, indeed, was it expected to do so. As a means of obtaining the opinion of practical growers it has been of great value, and it has shown that no general rule can be laid down until the matter has been deliberately tested by comparative experiment extending over a series of years. This is another instance of the kind of work that might be done at Wisley. But already the proposals made as to what should be done at that establishment are such that a lifetime would not be too much to carry them out, nor would a brigade of observers and experimenters be too numerous to accomplish them!

We have already summarised the main points that were laid down for the discussion on the alleged deterioration of variations propagated asexually (see p. 200), and need only for the moment refer to two points on which some misapprehension may arise. (1) It has been affirmed that when the Potato is propagated by tubers or sets, the produce does not consist of new individuals, but only of sub-divisions of the old one—that all the plants of Eldorado or of any other variety, for instance, are mere offsets from the original tuber or tubers. If we suppose the variety to have been raised from one original tuber, naturally the amount of inherent variation would be less than if the variety had a multiple origin. No two tubers on the same haulm are alike, and thus we get from the beginning a source of variation. But if, for the sake of argument, we take it for granted that a Potato, or a plant of any kind, raised from a cutting *is* a mere repetition or extension of the original plant, we must also admit that there is still abundant scope for variation in this wise: A seed-tuber is planted, it grows not only in size, but it develops new shoots, new haulm, new foliage, perhaps new flowers, new fruits, and new seeds, not a trace of which was in the original tuber. When all this growth and development are completed at the end of the season, when the cycle of growth is terminated, and the conditions for further growth are no longer favourable, how much is there left of the old tuber? In fact, nothing is left but a new tuber or a new set of tubers, the result of the growth and development of an entirely new set of cells; and these new cells and the tubers formed from them, although the direct descendants from their predecessors, can hardly be considered, from this point of view, as portions of them; rather may it not be said that they have cast off their original dependence on their progenitor and assumed an independent existence? They may, it is true, carry with them some of the parental protoplasmic germs or attributes, but for all that they are independent organisms, with a life of their own, separate from that of the stock from which they proceeded.

The second point which has been raised is that of "old age." Individuals die of old age when the waste and the wear and tear of life are no longer compensated for by the processes of repair and rejuvenescence, and when in consequence the individual is no longer able to contend against opposing conditions; when it is, to use the expression of the day, no longer in harmony with the environment.

But is the variety or the species subject to the same law? That is the main point at issue. Inasmuch as species and varieties are mere aggregations of individuals, they must, it would seem, be subject to the same sequence of events—they must originate, develop, and ultimately decline. How long they may endure before their life cycle is complete must depend on circumstances, and over those circumstances the gardener has to a certain limited extent a control. His business is to find out for himself the amount of control he can exercise, and how he can best in the short time at his disposal utilise it for his own purposes. The letter which we publish from Mr. ARTHUR SUTTON in another column will be read with all the attention that is due to a thoughtful observer with such exceptional opportunities and experience (see p. 258).

Sir Hugh Low.

AGAIN we have the grave duty of recording the death of a gentleman well known in the horticultural world. Sir HUGH LOW, G.C.M.G., whose death took place at Alassio on the 18th inst., had more than forty years' experience of colonial administration in the East Indies. He was born in 1824, and on May 10 would have completed his eighty-first year. He was created a K.C.M.G. in 1883 and promoted to a G.C.M.G. in 1889. He was a Fellow of the Linnean Society, the Zoological Society and the Society of Antiquaries.

Some time about the year 1840 Mr. Low had obtained an appointment to the Hon. East Indian Company, but happening to go out on the same vessel with Mr., subsequently Sir JAMES BROOKE, who was then again on his way to Borneo, they became so attracted to each other that Mr. Low gave up his Indian appointment and joined the future Rajah as secretary and companion. Mr. LOW spent nearly three years in Borneo and the vicinity on his first visit, and on returning to England he published, in 1848, a very interesting illustrated volume of three hundred and fifteen pages, *Sarawak: Its Inhabitants and Productions*, one of the first and best accounts given of a residency in the island under the rule of Rajah BROOKE. In Sarawak he discovered such unique species of Orchids as Vanda Lowii, Cœlogyne pandurata, Cypripedium Lowii, and many other rare plants. To have discovered such a regal Orchid as Vanda (Arachnanthe) Lowii and the great mountain pitcher-plants of Borneo would alone suffice to give Sir HUGH LOW worldwide fame as a botanist.

When Mr. BROOKE was made Acting Governor of Labuan in 1848 Mr. Low accompanied him, and eventually became Colonial Treasurer of the island. He loved the Borneans and their beautiful country, in which he was destined to spend so many years of a useful life.

Mr. Low's love for natural history was a broad one. Not alone did he collect plants both living and dried, but also animals, birds, reptiles, fish, and insects, many of which were new and rare. Coming as he did from a fine old horticultural stock—the "Lows of Clapton"—it is not surprising that he possessed a keen eye and ardent desire for botanical things.

When Colonial Treasurer in the then new British colony on the island of Labuan, he made one or more trips to the Lawas and other rivers near the capital city of Brunei on the main island, where he found Dendrobium Lowii and Nepenthes of several kinds, including the remarkable N. bicalcarata. Mr. Low, in 1851, made the first attempt to ascend Mount Kina Balu, accompanied by natives only, and the results of the journey were very remarkable from a botanical point of view. On the rocky sides of this great mountain, at a height of from between 5,000 and 10,000 feet (the total altitude being 13,700 ft.), he found the great urned Nepenthes, never before seen or imagined in dreams. These included N. Rajah, N. Edwardsiana, N. villosa, and N. Lowii, figures and descriptions of which were published in *Linnean Society's Transactions*, vol. xxii., by Sir JOSEPH HOOKER.

In 1851 Mr. LOBB, a well-known Veitchian traveller and collector, had reached Kian, a

village at the foot of the great mountain, but was not allowed by the natives to ascend. Again, in 1858, Mr. Low, accompanied by Mr. (now Sir) Spencer St. John, again ascended Kina Balu, and a full account of this journey, with maps and coloured plates (after Hooker) of the great Nepenthes already named are given in St. John's *Life in the Forests of the Far East*, a work well known to Bornean travellers.

Apart from Nepenthes, however, other beautiful plants were discovered on Kina Balu, including rare Orchids, and some remarkable Rhododendrons—R. ericoides, with scarlet flowers on a scrambling Heath-like bush; R. stenophyllum, with larger waxy red bells in lax clusters on a plant singularly like the Sciadopitys, or Umbrella Pine of Japan; R Brookeanum, with enormous clusters of rich golden-orange flowers, on plants resembling the large-leaved Himalayan kinds; R. Lowianum, and several others, dried specimens of which exist at Kew. Even to this day Low's name is revered by the Europeans and natives alike who knew him in Labuan, Borneo, and in Perak, to which province he succeeded Mr. Birch, H.M. Resident, who was murdered there under very distressing circumstances about thirty years ago.

Sir Hugh Low's personality was a charming one, his knowledge of the Malay language, both written and spoken, was great, and, like every born traveller, explorer, or ruler, he had keen sympathy with the natives, their laws and their customs. When I was in Borneo in 1877—78, the mountain people at Kian were most enthusiastic when my guides told them I was a friend of "Tuan Il Low," the native name by which he was there so well known. *F. W. B.*

Magnolia Kobus (see Supplementary Illustration).—The Magnolias furnish us with some of our most beautiful spring-flowering shrubs. The one we now figure resembles M. stellata (illustrated in our issue for April 27, 1895, p. 521), but has fewer and broader petals, and the leaves are broadly obovate-oblong, acute, instead of being simply oblong. M. Kobus has been shown lately at various exhibitions by Messrs. R. Veitch & Son, of Exeter, to whom we are indebted for the specimen from which Mr. Worthington Smith's drawing was taken. Messrs. Robert Veitch tell us that it is a very fast-growing shrub, small plants introduced seven or eight years ago being now 12 to 14 feet high in spite of having been transplanted two or three times. All the Magnolias of this section have bloomed earlier than usual this season. The species is of Japanese origin, as is probably the specific name, the meaning of which we do not know. The following extract relating to this tree is taken from Sargent's *Forest Flora of Japan*:—

"In the forests of Hokkaido a second species, Magnolia Kobus,* occurs. This tree sometimes grows in the neighbourhood of Sapporo to the height of 70 or 80 feet, and develops a tall, straight trunk, nearly 2 feet in diameter, covered with rather dark, slightly furrowed bark. The branches are short and slender, and form a narrow pyramidal head, which only becomes round-topped when the tree has attained its full size. The branchlets are more slender than those of most species of Magnolia, and are covered with dark reddish-brown bark. The flowers appear near Sapporo in the middle of May, before the leaves, from acute buds an inch long, half an inch broad, and protected by long, thickly-matted, pale hairs. They are from 4 to 5 inches across when fully expanded, with small acute caducous sepals, and narrow, obovate, thin, creamy-white petals. The stamens, with short broad filaments, are much shorter than the narrow acute cone of pistils. The leaves are obovate, gradually narrowed below, and abruptly contracted at the apex into short broad points; they are pubescent on the lower surface at first, especially on the stout midribs and primary veins, but at maturity are glabrous or nearly so, and are bluish-green, and rather lighter coloured on the lower than on the upper surface; they are 6 or 7 inches long, 3 or 4 inches broad, rather conspicuously reticulate-veined, and are borne on stout petioles ½ to 1½ inch in length. The fruit is slender, 4 or 5 inches long, and is often contorted or curved from the abortion of some of the seeds; it is dark brown, the carpels being conspicuously marked with pale dots.

Magnolia Kobus is exceedingly common in the forests which clothe the hills in the neighbourhood of Sapporo, where it grows to a larger size than in any part of Japan which I visited: near the shores of Volcano Bay it occurs in low swampy ground and in the neighbourhood of streams, in situations very similar to those selected by Magnolia glauca in the United States. On the main island Magnolia Kobus is much less common than it is in Hakkaido, and I only met with it occasionally on the Hakone and Nikko Mountains at considerable elevations above the sea. This handsome tree was introduced into the United States by Mr. Thomas Hogg, and was distributed from the Parsons' Nurseries as Magnolia Thurberi, under the belief that it was an undescribed species. In cultivation it does not flower freely in the young state, although trees in Pennsylvania and in the Arnold Arboretum, where it was raised from seed sent from Sapporo fifteen years ago, have produced a few flowers. In New England, Magnolia Kobus is the hardiest, most vigorous, and most rapid-growing of all Magnolias."

* *Magnolia Kobus*, De Candolle, *Syst.* I, 456.—Miquel, *Prolus. Flor. Jap.* 146.—Maximowicz, *Melang. Biolog.* viii. 507.—Franchet & Savatier, *Enum. Pl. Jap.* i., 16.

Magnolia tomentosa, Thunberg, *Trans. Linn. Soc.* ii., 336 (in part).

The Vilmorin Memorial.—We have on more than one occasion alluded to the very numerous adhesions to the proposal to erect a monument to the late Henry de Vilmorin. At a recent meeting of the Committee in Paris, a model executed by M. Carlier was unanimously approved, and the sculptor requested to proceed with the work. The monument consists of a group symbolising Agriculture and Horticulture, and three children, one winnowing the Wheat, another uprooting a Beetroot, the third holding a garland of flowers. In this way the idea of the Committee in issuing its appeal for subscriptions is carried out. "Without the Vilmorins there would probably be less Wheat in our fields, certainly less sugar in our Beetroots, and surely fewer flowers in our gardens." On the pedestal supporting the group are four medallions representing four generations of the Vilmorin family.

Mushroom Disease.—We very frequently receive specimens of diseased Mushrooms with a request that some remedy may be suggested. The disease is caused by a parasitic mould, probably introduced with the manure. An illustrated article on the subject is given in the last number of the *Journal of the Board of Agriculture*. There seems to be no cure. The houses should be cleared out and thoroughly sprayed with a solution of copper sulphate, using 1 lb. of sulphate to 15 gallons of water. This should be done three times in ten days.

Cypripedium Fairieanum.—The missing Orchid has been re-discovered in the country where its re-discovery was expected. It is to be hoped that now that it has been re-introduced Orchid-growers will be more fortunate in its cultivation than formerly. It was at one time not uncommon, and was figured in the *Botanical Magazine*, t. 5024, and in the *Flore des Serres*, t. 1244. One small specimen remains in Sir Trevor Lawrence's collection, and there are a few similar ones in Paris, but with these exceptions the plant has been lost to cultivation, though it is represented by a numerous hybrid progeny. The reported rediscovery of Cypripedium Fairieanum in the Eastern Himalaya has, we learn, been placed beyond doubt by the arrival at Kew of two fine plants, one with twelve, the other with seven "leads," and in as perfect health as if they had been there for months. The exact locality of this most interesting find has not been divulged, but as the Eastern Himalaya includes Bhootan and Assam, we may conclude that the now famous sale at Stevens' Auction Rooms some fifty years ago of a "collection of East Indian Orchids sent from Assam" did actually include this Cypripedium, and indicated its habitat. Many attempts have since been made to find it, the country between the Brahmaputra and the Irrawady rivers having been systematically searched by Orchid collectors, such as Boxall, Fosterman, Gibson, Giesseliere, and Barton Groves; and by botanists, including Sir Joseph Hooker, Dr. Thomson, Mr. C. B. Clarke, Sir Henry Collett, Sir George Watt, and others, but none of them found C. Fairieanum. Van Houtte said he received it from Bhootan, and Captain Tronson's plant is labelled as from Assam. We shall be glad to learn from the successful collector whether the plant grows at a high elevation or, as we have hitherto believed, in the lowlands. The Kew examples might be taken for C. insigne did they not bear the unmistakable slender hairy scape, which by the way is a foot long, the ovate bract, and purple ovary of C. Fairieanum.

Mr. G. H. Weigt, of the Royal Gardens, Kew, has been appointed Curator of the Botanic Garden, Sao Paulo, and Superintendent of the Government trial stations at Estado Sao Paulo, Brazil. He will commence his duties in June.

Cucumber Spot.—Mr. A. D. Hall, writing in the *Journal of the Board of Agriculture*, reports unfavourably of the treatment recommended by Mr. Massee, which seems to be only partially successful. Mr. Hall suggests that experiments should be made with a view of raising a disease-proof variety. Those who may experiment with carbolic acid for the prevention or cure of this fungoid disease, may be reminded that extreme care should be exercised in its use. We have already heard from some readers whose plants have suffered a little injury to the foliage from this cause. Plants grown with little ventilation, and young plants are of course most easily injured.

Flowers in Season.—We have received a selection of Pansy and Viola flowers from Messrs. Dobbie & Co., Rothesay, N.B., of such varieties as were exhibited by them at the meeting of the Royal Horticultural Society on April 11. Many of our readers will remember the excellent forms of these old-fashioned flowers put up on that occasion by this firm, who evidently possess an excellent strain.

—— Mr. J. Crooke, Forde Abbey Gardens Chard, recently sent us a selection of umbellate Primroses remarkable for the size of the bloom, each measuring on the average 1¾ inch (35 mm.) in diameter, and specially for their rich and varied colouration. The strain is evidently one of great excellence.

Popular Daffodils.—At the exhibition of the Midland Daffodil Society, of which a report was published in our last issue, there was an interesting ballot for the purpose of finding out which were the most popular varieties with the general public. Fifty varieties of Daffodils under numbers instead of names were set up on a table in a prominent position. Visitors to the exhibition were asked to mark on a card the twelve varieties which in their opinion were the best. Subjoined are the names of the varieties staged, and the number of votes each variety received. Altogether there were 242 who voted:—

Madame de Graaff, 157; Gloria Mundi, 142; Crown Prince, 139; Emperor, 128; C. J. Backhouse, 122; Katherine Spurrell, 121; Barri conspicuus, 108; Glory of Leiden, 100; Ornatus, 100; Duchess of Westminster, 94; Flora Wilson, 89; Sensation, 80; Sir Watkin, 80; Madame Plemp, 79; Titan, 77; Mrs. Langtry, 72; Palmerston, 62; M. J. Berkeley, 55; Duchess of Westminster, 57; Falstaff, 52; Horsfieldi, 48; Golden Ball, 49; Lulworth, 47; Princess Mary, 41; Autocrat, 41; Beauty, 41; Campernelle Jonquils, 40; J. B. M. Camm, 38; Incomparabilis plenus, 38; Stella, 38; Orange Phœnix, 34; Whitwell (Seedling), 34; P. R. Barr, 34; Grand Duchess, 34; Maurice Vilmorin, 33; M. M. de Graaff, 29; Semi partitus, 29; Seedling (unknown),

23; W. Goldring, 22; Cynosure, 21; Nelsoni major, 21; Frank Miles, 19; Portia, 18; Princess Mary, 18; Orphee, 14; Princeps, 14; Mary, 13; Hogarth, 9; Baroness Heath, 9; Queen Bess, 6.

HODSOCK PRIORY GARDENS.—Through the kindness of Col. MELLISH the well-known gardens at Hodsock Priory were thrown open to the public on Easter Monday. A small charge was made for admission, and a sum of about £10 was thus raised for the benefit of the Gardeners' Royal Benevolent Institution. Mr. MALLENDER, the head gardener, is not only a consistent worker for the Institution, but a well-known grower and raiser of Daffodils. These and many other flowers were exceedingly attractive.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

DENDROBIUM WARDIANUM.—Mr. Higgie is quite right in his remarks on the treatment of Dendrobium Wardianum. It ought never to be placed in anything but a quite cool greenhouse, whether summer or winter. Its habit is peculiar, because the young shoots for next year begin to grow in the autumn almost before it loses its leaves. These continue to grow all through the winter in a cold-house which is only just kept above freezing-point. They are now from 6 to 10 inches high, perfectly healthy, the flowers with which the old pseudo-bulbs have been as crowded as possible for the last six weeks being now nearly over. It is quite wrong to grow this plant in a hot-house. It makes long, weakly shoots there, and ultimately dies. *C. W. Strickland, Hildenley, Malton.*

ROSA SOREIFLORA, FOCKE.—There appeared in the *Gardeners' Chronicle* in vol i., 1905, p. 227, a description by Dr. Focke of a Chinese Rose under the name of Rosa sorbiflora, an illustration of which was also given. The description was drawn up from specimens collected by Mr. E. H. Wilson (No. 828) in Central China. The specimens in the Kew herbarium under the same number, after careful examination, cannot be specifically distinguished from R. microcarpa, Lindley, a common Chinese Rose, and of which there is at Kew abundant material collected over a wide area. Judging from Dr. Focke's remarks on the limitations of the group Banksianæ, one would almost be inclined to supposed that he had inadvertently overlooked the existence of R. microcarpa as a member of that group. I may mention that Mr. Hemsley agrees with me in regarding R. sorbiflora and R. microcarpa as identical. *J. F. Duthie, Herbarium, Kew.*

DISCOVERY POTATO.—Stored under similar conditions for planting purposes, I have found this fine variety to be the most restful of all the twenty I have, although those include Eldorado, Northern Star, Up-to-date, Evergood, Duchess of Cornwall, Empress Queen, Lord Dundonald, and other fine varieties. That is a matter of considerable moment to those who wish to have really good edible tubers late into the spring. The winter, having been so mild and open, has been a rather trying one for Potatos, as they have felt its influence and pushed growth, though stored under the most favourable conditions. When at this late period of the spring (April 7) tubers of Discovery, although grown on warm Surrey sand at Englefield Green, are found not to have started growth at all, conclusive evidence is furnished that it is a first-rate keeper. When the recent cooking test of Potatos took place at Marks Tey it was found that Discovery from Essex soil obtained ten marks. That was very high praise indeed for a late Potato. *A. D.*

WEATHER IN WARWICKSHIRE. —Until to-day the weather during this month has been miserably cold. We have had no frosts to do harm, but there have been continuous north, north-east and east winds, with occasional showers of hail and sleet, but not very much rain. Plum blossom is strong and abundant, and if frosts will only keep away there is every promise of a heavy crop. Some varieties of Pears are in full and profuse flower, and also, in absence of frosts, there will be some Pears. Apple trees, which bore so liberally last year, show less bloom this year, but taking them altogether they are very promising. During many consecutive days of cold weather bees were unable to come out, we therefore, according to instructions from our local bee expert, gave them some food within their hives; but we have to-day a decided change for the better. The wind has veered round to the south-west, bringing with it much warmer weather; bees are about and birds are in joyful song, and all vegetation appears to have already assumed a more encouraging appearance. The season so far has been a splendid one for farmers and gardeners, enabling them to get well forward with their ploughings, digging, sowings, and plantings. *W. Miller, Berkswell, April* 24.

PHŒNIX ROBELINI.—In all our gardens in the South of France there is, so far as I know, but one specimen of this Phœnix. This is at Mentone, in the garden of the villa belonging to the late Mr. Kennedy. This Palm, which, according to a note in the *Revue Horticole*, 1891, p. 783, came originally from Siam, but has withstood 7° below zero (Centigrade), being only sheltered by the foliage of a very large Cocos botryophora. *B. Chabaud, 7, Place de la Liberté, Toulon.*

AURICULAS.—A show of Auriculas with other allied spring flowers may be considered in a sense to be unique, inasmuch as it can be produced but once in a year. For many years past the Royal Horticultural Society has fostered the little Society devoted to these plants by awarding grants of money and tickets, and also space in its Hall for its exhibitors, so that the growers of the beautiful and fascinating Auricula and kindred spring flowers have been enabled to give the public a yearly exhibit of the products of spring, which under ordinary conditions it would have been beyond the power of this struggling little Society to give. The Auricula Society ought to be more largely patronised and in a more flourishing position than it is, as its members work valiantly to display an annual show of unequalled excellence and beauty. All the offices in connection with the Society are honorary, and its income is practically absorbed by its numerous and deserving prize-winners. Last year terminated the periodical exhibition of the Auricula at the Drill Hall, Buckingham Gate, which was for some years the location of the Royal Horticultural Society. The space was not adequate to enable the members and public to have a fair view of the exhibits of the conjoined shows without inconvenience from overcrowding. But in the beautiful and commodious new hall recently erected and opened by the Royal Horticultural Society in Vincent Square, Westminster, there is sufficient space for exhibitors all round. A regrettable feature in relation to the Auricula is the small number of its growers as compared to their numbers in the years that are gone. Our ancestors discovered its value and possibilities, and therefore removed it from its natural habitat and put it under new conditions, and by cross-fertilization they and their successors have wonderfully enriched it. The endless variety of seedlings which are produced every year, with very rare exceptions, would not, from a technical point of view, be worth perpetuating, and therefore when any new seedlings worthy to attract the judges' eyes are exhibited they are welcomed with delight, and their careers afterwards in regard to development and increase are closely followed, as all advents of accepted varieties are urgently wanted to fill the vacancies which are caused by the withdrawal of plants which shall have played out their part on the floral stage. At last year's show it was gratifying to observe the special efforts made by some of our most successful growers, several of whom brought forward some very promising seedlings. Many growers are afraid of distressing their plants by allowing the offsets to remain long attached to their parent, but it should be noted that as offsets are typical of plants which cannot exist for ever, it is necessary that to obtain robust progeny they should not be excised until they are well rooted and of healthy form, so as to secure as long a life as possible to all the best types which are so rarely reproduced from seed—in some cases never. The Auricula has several malignant enemies, one of which is the pubescent aphis (Trama Auriculæ), a very diminutive insect of subterranean habit which lives entirely on the delicate root-fibres of every plant it attacks, and sucks therefrom, like a leech, every particle of the life-moisture provided by Nature for the sustenance of the plant, leaving it in a deplorably emaciated condition. Numerous suggestions and nostrums have been recommended for its destruction, but have ended in negative results. Its extirpation can only be accomplished by turning the plants visited by it out of their pots, and removing every portion of the soil affected. To amateurs of limited leisure who have but small and shaded gardens, the cultivation of the show and also the alpine Auricula should have a special attraction. *S. I. Culpeck, 63, Knighton Park Road, Sydenham.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

APRIL 25. Notwithstanding that the meeting on Tuesday last was held on a day which followed immediately upon a general holiday, the new Hall in Vincent Square, Westminster, was well filled with exhibits. The National Auricula Society's show was held in conjunction with this meeting, and the visitors to the Hall included a considerable number who are specially interested in the cultivation of that flower.

Orchids were shown in several good groups, and the ORCHID COMMITTEE recommended four First-class Certificates, one Award of Merit, and one Botanical Certificate to new varieties.

The FLORAL COMMITTEE'S chief award was that of a First-class Certificate to the new Meconopsis integrifolia from Western China and Thibet, which, upon flowering in this country, has proved to be fully as handsome as it was described to be in our issue for October 1 last year, when it formed the subject of a Supplementary Illustration. A Botanical Certificate was also awarded to this plant by the Scientific Committee. Awards of Merit were recommended to Cyrtanthus angustifolius grandiflorus and Tree-Carnation "Elizabeth." The same Committee recommended as many as nineteen Medals for groups of plants or flowers exhibited.

The FRUIT AND VEGETABLE COMMITTEE had but one item for consideration, and this consisted of tubers of "The Factor" Potato, which, having been awarded already an Award of Merit, was recommended a First-class Certificate.

The NARCISSUS COMMITTEE made six Awards to forms of Narcissus, and two to Tulips.

At the General Meeting held in the afternoon upwards of sixty new Fellows were elected, and a LECTURE by Mr. James Hudson on "The Japanese Garden at Gunnersbury House, Acton," was read by the Rev. W. Wilks, M.A. The lecture was illustrated with lantern views.

Floral Committee.

Present: W. Marshall, Esq., Chairman, and Messrs. C. T. Druery, C. E. Pearson, Geo. Nicholson, R. Wilson-Ker, R. C. Notcutt, C. J. Salter, W. Howe, Jno. Jennings, C. Dixon, Chas. Jeffries, W. Cuthbertson, W. P. Thomson, H. J. Cutbush, E. H. Jenkins, Geo. Paul and R. Hooper Pearson.

Messrs. FRANK CANT & CO., Braiswick Nurseries, Colchester, exhibited H.-T. Rose Gustave Grunerwald, of rich pink or rose colour, and also a very fine H.-T. Rose named Madame Paul Olivier, a very full flower, whitish with tints of orange-yellow and pink colours. The Committee expressed a desire to see the variety again as plants.

Lord ALDENHAM, Aldenham House, Elstree (gr., Mr. Beckett), displayed a comprehensive exhibit of cut sprays of flowering trees and shrubs. Most of the subjects were from the open, but there were Azalea mollis, Deutzia gracilis, Lilacs, &c. The exhibit was demonstrative of the numbers of hardy flowering trees and shrubs available for planting. Among others noticed were Phillyrea Vilmoriana, Daphne pontica, Pyrus salicifolia pendula, Berberis aquifolium, Ribes pumilum aureum, Myrica Gale, Ribes Gordonianum, Cercidiphyllum japonicum, Xanthorhiza apiifolia, and Veronica Hulkeana (Silver-gilt Banksian Medal).

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, staged a number of hardy flowering shrubs,

all of which had been growing in the open borders. Among these we noticed Magnolias, Spiræas, Erica mediterranea, Berberis Darwini, Pyrus Malus in several varieties, Cerasus sinensis, &c.

Flowers of Iris tingitana, a Tangerian species of rather shy-flowering habit, were shown from the Society's gardens at Wisley.

A basket containing Ranunculus asiaticus, grown from plants collected in the Holy Land between Jerusalem and Bethlehem, was displayed by Mr. Arthur W. Sutton, Reading.

A Pansy named Frank Mills, also shown by Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, having very large flowers of good form, and the ground-colour of rich brown edged with golden-yellow, would be very effective for bedding. The markings and "eye" are not quite in accordance with the florist's view of what an exhibition Pansy should be.

Messrs. Hugh Low & Co., Bush Hill Park, Enfield, showed well-flowered plants of Schizanthus wisetonensis, a batch of the dwarf-growing yellow Calla, pans containing a good blue-flowered Lobelia named Low's Triumph, choice Carnation flowers, and a splendid specimen of Amaryllis procera Impératrice de Brésil. This plant carried four flowers of a pale blue almost heliotrope colour, with petals nearly covered with tiny blue dots. A handsome and highly decorative plant (Bronze Flora Medal).

Messrs. Jas. Veitch & Sons, Ltd., King's Road, Chelsea, set up a semi-circular group of plants. There were the two new Chinese plants, Actinidia chinensis and the beautiful Meconopsis integrifolia, several species of Acer, A. japonicum laciniatum (in flower), A. palmatum dissectum, &c. An edging was furnished by plants of Rhododendron racemosum, and the pleasing dwarf Ghent Azalea, "Taylor's Red." Messrs. Veitch also displayed a number of flowering greenhouse plants, showing many interesting subjects. Medinilla magnifica grandiflora was shown in flower, the brilliant inflorescence contrasting well with the dark-green foliage. Rhododendron Williamsii has a pleasing head of pure white flowers that are lightly maculated with yellow on the posterior petal. A batch of Kalanchoe felthamensis was shown in good character.

Messrs. Richard Smith & Co., Worcester, showed a collection of greenhouse plants, prominent among which were a number of pot plants of Clematis. Such things as Maples, Boronias, Solanums, Hippeastrums (Amaryllis), Phyllocactus, Genista præcox and Deutzia gracilis carminea were interspersed in the group to the best advantage and enhanced the effect produced by the plants of Clematis. Of the latter there were such varieties as Nellie Moser (excellent), Miss Bateman, Edouard Desposse, The Queen, &c. (Silver Banksian Medal). The same firm also showed a large plant under the name Phlebodium Smithianum, and described as a supposed cross between P. aureum and P. sporodocarpum. The fronds were divided more narrowly than those of P. aureum.

Messrs. Gilbert & Son, Dyke, Bourne, Lincolnshire, showed Anemones even better than those of their previous displays this season, and certainly more extensively. The variety King of Scarlets well deserves its name, while those of the St. Brigid type embrace the most exquisite forms of the double A. coronaria. A. fulgens var. græca oculata has a refined scarlet flower, and was well shown in this collection; Queen of the Roses is a double flower (Bronze Flora Medal).

Messrs. John Laing & Sons, Forest Hill, London, showed a batch of Streptocarpus of an improved type, some of the plants having rich purple-coloured flowers.

Messrs. Watkins & Simpson, Tavistock Street, Covent Garden, showed many varieties and forms of the common Wallflower. Golden King is an excellent yellow form; Rupert has large dark crimson flowers; Vulcan is very similar to the last-named; Eastern Queen is a light-coloured form, while Ruby Gem approximates to the colour indicated by its name.

Messrs. H. Cannell & Sons, Swanley, Kent, again showed vases of brilliant bunches of zonal Pelargoniums in the best and choicest varieties (Silver Flora Medal).

Messrs. Dobbie & Co., Rothesay, N.B., staged a collection of Pansy and Viola flowers similar to that displayed by them at the last meeting. The Violas were especially showy, the colours being excellent. Pansies of large size and good shape were displayed on boards (Silver Banksian Medal).

Mr. C. Engelmann, Saffron Walden, Essex, contributed a number of vases containing Sweet Peas cut from plants growing in borders inside. They were shown in excellent condition, and embraced many of the choicest varieties of these highly-refined flowers. In addition to the display of lovely colours, the exquisite perfume was much appreciated. The varieties Hon. Mrs. Kenyon, Mars, and Dorothy Eckford were especially good (Bronze Flora Medal).

Messrs. J. Carter & Co., 237, 238, and 97, High Holborn, London, W.C., exhibited an extensive collection of pigmy Japanese trees in the native pots, which were in many cases as curious as the plants themselves (Silver Banksian Medal).

Messrs. B. R. Cant & Sons, The Old Rose Gardens, Colchester, brought a small exhibit of pot Roses, and cut flowers of the same. The new climbing Rose Blush Rambler was presented in good form, also that lovely single-flowered "Austrian Yellow," whose flowers are of the purest yellow colour (Silver Banksian Medal).

Messrs. Frank Cant & Co., Braiswick Rose Gardens, Colchester, showed some boxes of excellent cut Roses, also vases containing sprays of the variety "Fortune's Yellow." A box contained the variety Souvenir de Pierre Notting in first-class condition (Silver Flora Medal).

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, staged a group of pot Roses of the Rambler type, arranging the plants on the floor of the hall. Interspersed among the Roses were greenhouse plants, including Statice profusa, Astilbe (Spiræa) japonica, and a number of choice varieties of Ferns (Silver Flora Medal).

Mr. W. Taylor, Hampton, Middlesex, staged a small collection of Roses, which contained some exquisite examples. A vase of the variety Captain Haywood was almost perfection (Silver Banksian Medal).

Twelve vases of excellent flowers of Rose Fortune's Yellow were shown by Lady Wantage, Lockinge Hall, Wantage (gr., Mr. W. Fyfe).

J. A. Young, Esq., Stone House, Putney (gr., Mr. G. H. Street), put up a fine group of Cinerarias, chiefly of the stellata type. The plants were excellently flowered, and made a bright display (Silver Flora Medal).

Messrs. John Laing & Sons, Forest Hill, London, N., furnished one of the ends of the south annexe with a group of Cinerarias, arranging them so as to slope from a higher background toward the front. The plants were all of the lax growing stellata kind, and the inflorescences carried a profusion of flowers in many excellent shades of colour. A number of pot plants of Ferns and Palms were worked into the group with excellent effect (Silver Banksian Medal).

Mr. L. R. Russell, Richmond Nurseries, Richmond, Surrey, showed a group of flowering shrubs and other plants. Clematis, Azaleas, Gueldres Roses, Cytisus, Lilacs, &c (Silver Banksian Medal).

Messrs. Wm. Cutbush & Son, Highgate, London, N., showed a collection of Primulas. Over 200 species and varieties were included, the whole forming an exhibit of educational interest to lovers of hardy plants. A number of other plants, such as Liliums, Maples, Pæonies, Spiræas, &c., formed a background. Messrs. Cutbush also showed a new dwarf polyantha Rose named Mrs. William H. Cutbush, and a new Rambler Rose named Mr. F. W. Flight. The latter has pleasing semi-double flowers of a light rosy-pink colour.

Mr. A. R. Upton, The Guildford Hardy Plant Nursery, Guildford, showed a number of seedling Saxifrages. The one labelled S. Guildford Seedling is of a pleasing crimson colour.

Messrs. R. Wallace & Co., Kilnfield Gardens, Colchester, set up a group of hardy plants, arranging vases of Daffodils and Japanese Maples toward the background. Plants of Gentiana verna were well furnished with the exquisite blue flowers; Arnebia echioides was good; Anemone fulgens bicolor, novel. The flaming red Tulipa Greigi was well displayed. A collection of Fritillarias was included in the display (Silver Banksian Medal).

Messrs. John Peed & Son, West Norwood, London, displayed pans and boxes containing alpines. Saxifrages were largely represented. We noticed some good Polyanthus, also Auriculas. Messrs. Peed also exhibited flowers of their strain of Gloxinias.

Messrs. Geo. Jackman & Son, Woking Nursery, Surrey, set up a small rockwork on which were arranged many plants in flower. Ranunculus amplexicaulis was shown well; Meconopsis cambrica aurantiaca was noticed in flower, also Sarracenia purpurea. There were some good forms of Primula Sieboldi in the collection (Bronze Flora Medal).

Mr. G. Reuthe, Keston, Kent, showed some splendid forms of Primula Sieboldi, quite a collection of hardy Orchids, many good varieties of Daffodils, coloured Primroses, &c. (Bronze Flora Medal).

Mr. M. Prichard, Christchurch, Hants, showed Alyssum saxatile flore-pleno, a good yellow form. We noticed also a good pan of Uvularia grandiflora, well-flowered plants of Adonis vernalis, and many good species of Irises. Carex Frazeri is very curious, and has pure-white flowers (Silver Banksian Medal).

The Misses Hopkins, Mere, Knutsford, Cheshire, showed many useful border and rock-garden plants.

Awards.

Carnation, Elizabeth.—This is a seedling obtained from the variety America. The growths are somewhat slender and the leaves long and whitish in appearance. The flowers are of good form; the calyx is said to remain good invariably, and the colour of the petals is clear, bright cherry-red. Though the flowers are less full, perhaps, than those of some varieties, they will be likely to become exceedingly popular. Shown by Sydney Morris, Esq., Wretham Hall, Thetford (gr., Mr. G. Henley (Award of Merit).

Cyrtanthus angustifolius grandiflorus.—A description and illustration of this plant will be found on p. 261; we need only remark here that Miss Willmott, Great Warley, Essex, exhibited a plant in flower in a pot, the inflorescence bearing ten flowers (Award of Merit).

Meconopsis integrifolia.—This magnificent species from Western China and Tbibet was fully illustrated and described in our issue for October 1, 1904. Messrs. James Veitch & Sons on Tuesday last showed plants in flower, which had been lifted from the open ground. The plants were very strong, about 1½ foot high, and bore large, clear yellow flowers. The Committee unanimously awarded a First-class Certificate. The Scientific Committee with much more appropriateness awarded the plant a Botanical Certificate.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Secretary), De B. Crawshay, J. W. Odell, F. J. Thorne, R. G. Thwaites, A. A. McBean, W. H. White, G. F. Moore, H. Ballantine, H. T. Pitt, H. A. Tracy, W. Boxall, W. H. Young, F. W. Ashton, H. J. Chapman, H. Little, W. A. Bilney, and W. Thompson.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), was awarded a Silver-gilt Flora Medal for a very beautiful group, containing some of the highest examples of blotched Odontoglossum crispum, and all in a splendid state of cultivation. The most remarkable were the unique O. crispum Grairianum, which has developed into a wonderful variety, the greater part of its surface being of a glowing orange-tinted rose; O. c. Britannia, and O. c. Bryan, grand flowers heavily blotched with dark purple, and of the class of O. c. Cooksonæ; and O. c. Frederick, a large flower with white sepals and petals tinged with rose, and bearing effective dark purplish blotches, &c.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), was awarded a Silver-gilt Flora Medal for a fine group containing a varied selection of hybrids, species, and varieties. The Odontoglossums were the leading feature, O. crispum being well represented. The best of the blotched forms were O. c. Britain's Queen, which received an Award of Merit at the last meeting, and O. c. Britain's King, a still finer form, with some of the good qualities of O. c. Pittianum in its large, richly-coloured blotches. The lip is a very fine feature, being almost entirely of a bright claret colour with a narrow silvery-white margin and orange crest. Among other species, O. luteo-purpureum "Secundum Nulli" is one of the highest and most richly coloured forms of the species. In the group also were a bright batch of good Miltonia vexillaria, a number of M. Roezlii, some excellent forms of Cattleya Schroderæ, C. S. Pitt's variety, having a purplish-crimson labellum, much like C. Percivaliana; and C. S. Nellie had lavender-tinted sepals and petals and a purple blotch on the lip. Others noted were Epidendrum sceptrum, Trigonidium spatulatum, good specimens of Oncidium concolor and O. leucochilum, Gulcandra devoniana, Cypripedium Sanderianum, Sarchochilus Fitzgeraldi, Dendrobium revolutum, &c.

Messrs. Sander & Sons, St. Albans, received a Silver Flora Medal for a group containing several fine hybrid Odontoglossums, one form of O. × Wilckeanum having very large creamy-white flowers effectively blotched with chestnut-brown, and the varieties of O. × crispo-Harryanum were of fine quality. Two forms

of Miltonia × Bleuana and M × B. nobilior raised at Bruges had fine flowers delicately tinged with rose-colour, and were of a free-flowering type, one plant having four spikes. Others noted were an exquisitely-coloured form of Odontoglossum luteo purpureum with large white lip, bearing a brown blotch in front of the crest; Angræcum Sanderianum, Cattleya intermedia alba and nivea, Cypripedium glandulíferum, the new C. × Mastersocallosum, Lælio-Cattleya × Ruby Gem (C. Lawrenceana × L.-C. × Schilleriana), a bright rose-purple flower; good L.-C. × Dominiana, Masdevallia × Pourbaixii, and on one end a pretty set of "botanical" Orchids, comprising three species of Polystachya, Nephelaphyllum pulchrum, with handsome leaves, &c.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr., Mr. Duncan), secured a Silver Banksian Medal for a neat group, principally of good Odontoglossums, among which were O. × warnhamensis (Halli × Pescatorei), a pretty flower well intermediate between the parents; O. triumphans latisepalum Bird's variety, with broad, yellow sepals and petals heavily barred with brown; O. crispum Mabel, prettily spotted; a very fine O. polyxanthum, good O. Edwardi, and other Odontoglossums, &c.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), showed Cypripedium × Gowerianum giganteum, a very large and finely-coloured form; and Lælia × Mrs. Gratrix Westfield variety, of good size and shape, and of a bright, light orange colour.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr., Mr. Ballantine), sent Odontoglossum crispum "Queen's Birthday," a showy variety evenly spotted with dark claret colour.

W. THOMPSON, Esq., Walton Grange (gr., Mr. W. Stevens), showed the prettily-marked Odontoglossum crispum heliotropium, O. × Stella, and the remarkable new O. × Thompsonianum (see Awards).

J. BRADSHAW, Esq., Southgate (gr., Mr. Whitelegge), sent Cattleya × Empress Frederick var. xanthoglossa (with rich gold-veined lip), and Brasso-Cattleya × Digbyano Schröderæ var. Empress of India (a fine white flower with delicate blush tint on the sepals).

W. C. WALKER, Esq., Winchmore Hill (gr., Mr. E. Bunney), showed a compact plant of Odontoglossum coronarium with a fine spike of flowers.

DE BARRI CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), showed Odontoglossum Rossii immaculatum, with white flowers exhibiting none of the usual brown markings on the sepals and petals.

G. F. MOORE, Esq., Chardwar, Bourton-on-the-water (gr. Mr. Page), again showed his fine Lælio-Cattleya × Pallas magnifica.

Mrs. HAYWOOD, Woodhatch, Reigate (gr. Mr. C. J. Salter), showed Odontoglossum crispum "Woodhatch variety," having large white flowers with distinct brownish blotches.

G. W. NICOL, Esq., Banchory (gr. Mr. Andrew), sent a spike of a spotted form of Odontoglossum crispum.

Awards.

FIRST-CLASS CERTIFICATES.

Brasso-Cattleya × *niralis* (B. fragrans × C. intermedia), from Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White).—A very pretty and fragrant hybrid, with flowers of the size of those of Cattleya intermedia, but of the form of those of Brassia tuberculata (fragrans). Flowers white with primrose disc to the lip. The plant had two spikes of five and six flowers.

Cattleya Schröderæ alba var. Madame Louis de Hemptinne, from the Marquis de Wavrin, Chateau de Rousele, Somerghem, Belgium (gr., M. Gerard de Geest).—One of the finest white Cattleyas yet shown. Flower of perfect shape, and with beautifully crimped petals and lip. Pure white with yellow throat to the lip.

Cattleya Schrödera "*Robin*," from J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. Whitelegge).—A model flower, white tinted with lavender, and bearing a distinct violet-purple blotch in the centre of the lip.

Odontoglossum × *Thompsonianum* (Edwardi × crispum), from W. THOMPSON, Esq., Walton Grange, Stone (gr., Mr. W. Stevens).—A very remarkable hybrid, beautiful in itself, and likely to aid in the production of still more remarkable hybrids. The plant had the purple-tinted bulbs of O. Edwardi, and its tall branched inflorescence, only one flower on which had yet expanded. The flower was 2½ inches across, and shaped much like O. crispum, of a rich claret-purple, with rose tips and margin to the segments; crest of lip yellow.

AWARD OF MERIT.

Odontoglossum crispum Smeeanum, from NORMAN C. COOKSON, Esq. (gr., H. J. Chapman).—A very distinct variety with large rose-pink flowers, bearing on the inner parts of the segments uniform light-brown spots.

BOTANICAL CERTIFICATE.

Oncidium O'Brienianum, *Rchb. f.*, from Miss WILLMOTT, Great Warley, Essex (gr., Mr. Preece).—A curious species of the O. pubes section, with dense branched spikes of brown flowers with red-brown labellums.

Narcissus and Tulip Committee.

Present: H. B. May, Esq. (Chairman), and Messrs. A. R. Goodwin, Rev. S. Eugene Bourne, Jas. Walker, J. T. Bennett-Poe, W. Poupart, E. A. Bowles, R. W. Wallace, P. R. Barr, W. W. Fowler, Chas. T. Digby, J. R. D. Boscawen, W. M. Copeland, J. D. Pearson, Geo. Reuthe, John Pope, W. Goldring, W. T. Ware, Miss E. Willmott, Rev. G. H. Engleheart, and C. H. Curtis.

There were several important exhibits before this Committee, and not a few novelties were staged.

Messrs. BARR & SONS, King Street, Covent Garden, staged a representative gathering of choice kinds, in addition to many seedlings of merit, the more important of these latter being confined to white Ajax kinds. The following are some of the best varieties in this collection: Pharaoh (a fine bicolor), Primrose Phœnix, and Apricot Phœnix (in double kinds), Bobs (a whitish incomparabilis with paleish cup of orange colour), and Maggie May. Cassandra is a fine variety of the poeticus type. Probably the most distinct thing among novelties is Narcissus odorus rugulosus maximus, the flowers being of a very rich yellow colour and three times larger than the ordinary forms of this kind. Early Tulips were also largely shown by Messrs. BARR (Silver-gilt Banksian Medal).

Messrs. POPE & SON, King's Norton, Birmingham, again showed King's Norton (a giant yellow Ajax), and Progress (a flower of the same type, but possessing more colour in the trumpet). Cristata shows evidence of doubling. White Queen and Orangeman are also worth noting (Silver Banksian Medal).

Messrs. VEITCH & SONS, Ltd., Chelsea, contributed a collection of Tulips and of Narcissus in many good kinds. Among the latter were King Edward VII., a very fine poeticus and cristatus, the latter very handsome. Tulips King of Yellows and L'Unique were remarkable for their distinctive colour and good form.

The Gold Medal group from Miss WILLMOTT was replete with the choicest kinds, and contained not a few novelties. A noticeable feature was the great size of many of the plants, and the remarkable substance of stems, leaves, and flowers. We have space to name but few of the varieties, but we may mention Great Warley (approximating a giant bicolor Sir Watkin), Selson (a big bicolor Ajax), Francesca, White Ajax, Warley Scarlet, Incognita, White Queen, Seagull and Betty Berkeley (Gold Medal).

Messrs. R. H. BATH, Wisbech, contributed both Tulips and Narcissus, among the latter Albatross, Golden Rain, White Lady, a lovely lot of Gloria Mundi with richly-coloured crowns, Madame de Graaff in abundance, Snow Queen, White Ajax, &c. A brilliant lot of Tulips was included in this exhibit (Silver-Gilt Banksian Medal).

Messrs. J. R. PEARSON, Lowdham, Notts., also staged Daffodils of the choicest kinds, the freshness of the flowers being remarked—Maggie May, Minnie Hume, Gipsy Queen, Avalanche (a very handsome white Ajax), &c. (Silver-gilt Banksian Medal).

The Cup offered by Messrs. BARR & SONS was won by Mr. E. M. CROSFIELD, Little Acton, Wrexham, who had a choice and varied assortment.

Mr. A. S. LESLIE MELVILLE, Branston, Lincs., was the only other competitor for the Cup. He also staged a good collection, and was awarded a Silver Flora Medal.

Awards.

Narcissus Wm. Foster.—From Miss R. SPURRELL, Norwich (Award of Merit). We were unable to locate this variety.

N. Helen Countess of Rudnor.—A very handsome white flower of the Ajax type, showing a tendency to develop buff colour in the upper portion of the crown. From Miss WILLMOTT, V.M.H., Warley, Essex (Award of Merit).

N. Banzai.—This is virtually an enlarged Madame de Graaff, with longer perianth-segments leaning to the trumpet (Award of Merit).

N. Countess of Stamford.—Also a white Ajax, and certainly a meritorious variety (Award of Merit).

Both exhibited by Mr. E. M. CROSSFIELD, Wrexham.

N. Cornelia.—A self yellow of the Ajax type, with nearly cylindrical trumpet, rendering it a very distinct flower (Award of Merit).

N. Marie Hall.—This in effect is a bicolor "Queen of Spain," with a distinctly cylindrical crown. A very pleasing variety (Award of Merit).

These two were exhibited by Messrs. R. H. BATH & Co., Ltd., Wisbech.

Tulipa Fosteriana.—A very handsome species of a rich or intense glowing crimson colour, and a coloured base internally suggestive of a modified T. Greigii. From Miss WILLMOTT, Warley Place, Essex (Award of Merit).

Tulipa dasystemon.—A very profuse flowering species, bearing as many as six or eight flowers in succession on a single spike. The plant is dwarf, with furrowed glossy foliage, and white-and-yellow flowers, the segments of which are acutely pointed. From Messrs. CUTBUSH & SONS, Highgate (Botanical Certificate).

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., Chairman; and Messrs. Jos. Cheal, Ed. Beckett, A. Dean, W. Fyfe, H. Parr, W. Pope, Geo. Kelf, J. Willard, G. Reynolds, J. Jaques, Owen Thomas, T. Arnold, and S. Mortimer.

FIRST-CLASS CERTIFICATE.

Potato The Factor.—Tubers of this variety were shown by Messrs. DOBBIE & Co., Rothesay. The variety obtained an Award of Merit from the Committee on October 1, 1901, and since then it was found to be the best variety in the National Potato Society's trials, and in the Cambridge University trial; it was also awarded 1st prize at the Crystal Palace show in the class for cooked tubers. The general excellence of this Potato received further appreciation on Tuesday, for the Committee recommended it a First-class Certificate.

Lecture

ON THE CONSTRUCTION OF A JAPANESE GARDEN.

A paper on Japanese Gardening, written by Mr. Jas. Hudson, of Gunnersbury House Gardens, Acton, was read before the Fellows by the Secretary. Our readers will doubtless remember the descriptions of the Japanese gardens at Gunnersbury House which appeared in our issues for April 5, May 10, and July 12, 1902, when many scenes in the gardens were illustrated. We take this opportunity of presenting another view (see p. 269), which will further enable our readers to appreciate the beauty of this style of gardening. Mr. Hudson, in his paper, pointed out the best manner of adapting a garden for this style of planting, the necessity for a bountiful supply of water, and the need for a well-sheltered situation to enable many of the tender plants from the southern parts of Japan to withstand the influences of bitter north-west winds, such as we have experienced recently. A list of plants that are suitable for the Japanese garden was given, also of the best materials for constructing paths, bridges, fences, and the proper manner of making these. The provision of water-gardens and rock-pools is essential for producing the best effect, as may be seen on reference to our illustration on p. 269, fig. 111. It was unfortunate that Mr. Hudson was unable to be present, as no explanations were given of the lantern-slides, which were exhibited promiscuously, without direct reference to the paper read.

A paper by Monsieur Albert Maumené, of Paris, on "Japanese Dwarf Trees, and their Production and Treatment," was taken as read, and will, with that of Mr. Hudson, be published in the *Journal* of the Royal Horticultural Society. In this paper Monsieur Maumené describes the various forms of these trees in Japan, the different methods of raising and of training them, the varieties of plants most suitable for dwarfing, and their treatment in this country. The main points brought out were the unwearying patience and perseverance of the Japanese in producing these plants, and that the dwarfing is principally due to

limiting the space available for the roots, and also by reducing their number, and by providing a minimum supply of water and nourishment to maintain the life of the tree, while the twisting and curving also retarded the sap. The trees might be roughly classed as those which represent miniature reproductions of their natural appearances, and those which are twisted, curved, and shaped to a certain preconceived idea.

NATIONAL AURICULA & PRIMULA.

April 25.—This Society's exhibition, held in conjunction with the ordinary meeting of the Royal Horticultural Society in the Horticultural Hall, Vincent Square, Westminster, resulted in a very excellent all-round display of the Primula race. It was feared that the cold northerly winds which have prevailed for at least a week previous to the show would have affected the flowers, thereby producing a certain amount of roughness in the blooms, but this was not apparent, except in a few instances. On the whole the "show" varieties were exhibited in as good character as in years past, and seeing that six collections of twelve varieties were staged, and nine of six varieties, no one can venture to say with truth that the cult of the Auricula for exhibition is on the decline.

[From a photograph by J. Gregory.

Fig. 111.—view in the japanese garden at gunnersbury house.

(See Report of Lecture by Mr. Hudson on p. 268.)

The northern growers were represented by the Rev. F. D. Horner, and by one or two Birmingham growers, but the greater part of the displays were staged by the southern growers. Mr. J. Douglas, was, as he usually is, most successful.

Show Auriculas, "Edged" and "Self."—In the class for twelve show varieties, "edged" and "self," Mr. J. Douglas, Great Bookham, was 1st, having "Green edges": Mrs. Henwood (with seven very finely-developed pips), Abbé Liszt, and Abraham Barker, the latter with a somewhat narrow body colour. "Grey edges": Olympus (a good addition to the section) and Geo. Lightbody. "White edges": Magpie, Venus, and Acme. "Selfs": Ruby, Mrs. Barnett, Mrs. Phillips, and Favourite. The Rev. F. D. Horner, Burton-in-Lonsdale, was 2nd. He had of "Green edges": Dr. Horner (bright green with good pip), Henry Wilson (somewhat resembling Mrs. Henwood, but with a brighter edge), Redoubtable (having a bright green edge and a good colonred body), and Ben Simonite. "Grey edges": Coronation and Orpheus. "White edges": Frost, Melanie, and Quicksilver. "Selfs": Favourite (black), Little Nell, and Red Flag. Mr. J. H. Wilson, Handsworth, Sheffield, was 3rd. He had Gerald ("self") in good character.

There were, as stated, nine collections of six varieties. Mr. J. Douglas was again placed 1st, with the varieties Mrs. Henwood and Abbé Liszt, "Green edge"; Geo. Lightbody, "Grey edge"; Acme, "White edge"; Mrs. Barnett and Raven, "Selfs." The Rev. F. D. Horner was 2nd with Orion, Promethus, and Shirley Hibberd, "Green edges"; Orpheus, "Grey edge"; Red Light and Loveliness, "Selfs." 3rd, Mr. M. R. Smith, Hayes Common (gr., Mr. C. Blick), his three best plants were Mrs. Henwood and Shirley Hibberd, "Green edges"; and George Lightbody, "Grey edge."

There were six collections in the class for four varieties, Mr. W. H. Shipman, Altrincham, was placed 1st, he having Mrs. Henwood (very bright Edge) and Abraham Barker, "Green edge"; Geo. Rudd, "Grey edge"; and Ruby, "Self." 2nd, Mr. Purnell-Purnell, with Dr. Kidd, "Green edge"; Heather Bell and Acme, "White edge"; and Ruby, "Self."

The best pair of "show" varieties came from Mr. F. Wellesley, Westfield, Woking, who had Geo. Rudd, "Grey edge," and Mrs. Potts, "Self." Mr. A. S. Hampton, Reading, was placed 2nd with Vanity, a bright "Green edge," and Rachel, "White edge."

Single Specimens, Show varieties.—"Green edge": 1st, Mr. W. Smith, with Mrs. Henwood, whose plant had seven well-developed pips. 2nd, Mr. J. T. Bennett-Poë, also with the variety Mrs. Henwood. Mr. A. S. Hampton was 3rd. "Grey edge": 1st, Rev. F. D. Horner with Orpheus. Mr. J. Wilson was 2nd with Rachel; and Mr. F. A. Wellesley, 3rd with William Brockbank. "White edges": 1st, Mr. J. T. Bennett-Poë with Acme. 2nd and 3rd, Mr. Wellesley with the same.

Collections of Fifty Auriculas.—In this class, as usual, Mr. James Douglas was 1st with a varied collection of good quality. The leading "Green edges" were Rev. F. D. Horner, Abbé Liszt, Abraham Barker, and Gladiator. "Grey edges": Geo. Rudd, Beauty, Lancashire Hero, Olympus and Rachel. "White-edges": Venus, Heather Bell, Wild Swan, Amy Robsart and Miss Prim; "Selfs": Ruby, Mrs. Phillips and Buttercup. Several of the foregoing varieties were duplicated. This was also seen in a good collection staged by Mr. W. Smith, Bishops Stortford, who has made many excellent attempts to gain the premier prize in this class. 3rd, Mr. W. B. Cranfield.

The Premier Show Auricula was Mr. Jas. Douglas's fine plant of Mrs. Henwood in Class I.

Alpine Auriculas.—These were both numerously and well shown, their brilliancy of colour commanding general admiration. There were seven collections of twelve varieties, resulting in a close contest for the supremacy between Messrs. Phillips & Taylor, of Brackley, and Mr. J. Douglas, in favour of Messrs. Phillips & Taylor, who had a grand dozen, many of which were seedlings. The varieties were Richard Dean (a brilliant alpine), Duke of York, Cavalier, and unnamed seedlings. "White centres": Boadicea (edged with pale rosy-lilac), and seedlings. Mr. J. Douglas came 2nd with Duke of York, Rosy Morn, Ettrick (a flower of fine quality), Premier (with bright yellow centre, the colour mauve shading to rose); and of "White centres": Teviotdale, Hilda, Thetis, and Ganymede. 3rd, Mr. M. R. Smith.

There were six collections of six varieties, and Mr. J. Douglas was placed 1st with a fine even lot, having of "Gold centres": Duke of York, Firefly, and Rosy Morn. "White centres": Urania, Thetis, and Teviotdale. Messrs. Phillips & Taylor came 2nd with "Gold centres": Mrs. Martin Smith, Duke of York, and two seedlings. "White centres": Boadicea and seedlings.

In the class for four alpines, Mr. F. W. Price, Beckenham, was placed 1st, apparently the only competitor.

Single specimens.—"Gold centres": Mr. F. W. Price, Beckenham, was 1st with a highly-refined seedling; 2nd, Messrs. Phillips & Taylor, with Pluto and Calypso. "White centres": 1st, Mr. J. Douglas with Teviotdale, who was also 2nd with the same variety. This promises to be a valuable addition to those with violet-shaded white centres. Mr. E. Danks was 3rd with Thetis.

In the class for six Alpines shown by maiden growers, Mr. E. Danks was awarded 1st prize.

Alpine Seedlings, single specimens.—"Gold centres": Messrs. Phillips & Taylor came 1st with a fine seedling of promise; Mr. F.W. Price, 2nd. The best "white centre" was Rockdale, from Mr. J. Douglas.

Mr. A. Spurling took the 1st prize for six seedling alpines raised from seeds supplied by Mr. J. Douglas.

The Premier Alpine Auricula was Ettrick, shown by Mr. J. Douglas. The flower develops a bright yellow centre with groundwork maroon coloured shading to rose and margined salmon.

Fancy Auriculas.—As usual, Mr. J. Douglas was placed 1st. He had Rolts Green with its bright rosy-red body colour; Buttercup, and various eccentric, unnamed sorts, too good to be rejected, but to be classed only as fancies. Mr. W. B. Cranfield, Branley House, Enfield, was 2nd.

Species of Primulas.—The class for twelve specimens was not represented.

In the class for six specimens, Mr. J. Grandfield was 1st, and he had P. obconica, P. verticillata, and four well-flowered varieties of P. Sieboldi. Mr. Purnell-Purnell, Streatham Hill, was 2nd.

Primulas and Auriculas.—The class for a collection made a very attractive feature, Mr. J. Grandfield taking the 1st prize. Mr. Purnell-Purnell was placed 2nd.

Polyanthus, Fancy.—Three collections of twelve plants were staged. Mr. S. Mortimer, Rowledge, Farnham, took the 1st prize with a bold and striking collection. Mr. G. Baskett, Virginia Water, was 2nd.

Groups of Primrose and Polyanthus Plants.—Mr. S. Mortimer was placed 1st, with an excellent collection. Mr. Baskett was 2nd.

Seedlings.

Certificates of Merit were awarded to the following:

The Mikado.—A "self" having an excellent tube and paste, dark, with well-displayed body colour, the pip being smooth and stout; foliage green. A highly promising variety. From Mr. N. Smith, Bishop's Stortford.

Richard Dean.—An "alpine" with bright golden centre and dark ground shading to fiery salmon. A large, smooth, flat, well-proportioned flower.

William Smith.—Also an "alpine," having the pip smooth and highly refined; colour bright gold with a dark body shading to fiery rosy-crimson. Both from Messrs. Phillips & Taylor, Bracknell.

Mrs. H. O. Crowther.—The flower possesses a golden centre, dark body colour with bright ruby shading, somewhat paler on the margin of the pip; very smooth and of excellent quality.

Miss Winifred.—This also has a golden centre; the anthers are set somewhat shallow; body dark, shading to rose and paler salmon. From Mr. C. Blick, Hayes Common.

LINNEAN.

April 6.—A meeting was held on the above date, when Mr. A. C. Seward, F.R.S., Vice-President, presided.

Mr. W. Botting Hemsley, F.R.S., F.L.S., exhibited a number of specimens and drawings of pitchers of Nepenthes, supplemented by slides, prepared by Mr. L. Farmar, to illustrate the various types of pitchers and their marvellous glandular systems (see p. 241).

Prof. R. J. Harvey Gibson, M.A., F.L.S., gave the substance of his paper on "The Axillary Scales of Aquatic Monocotyledons." He compared the ligule of Selaginella with the scales in question, and suggested that the latter may be looked upon as evidence that the Monocotyledons may be regarded as modern representatives of primitive Angiosperms, and in turn may have been genetically related to some ancestral form allied to Isoetes. These scales had been examined in seventeen species of Zostera, Potamogeton, Ruppia, Aponogeton, Triglochin, Alisma, Sagittaria, Butomus, Limnocharis, Halophila, Stratiotes, Hydrocharis, and Vallisneria, belonging to six natural orders of Helobiæ. The author's remarks were illustrated by lantern-slides.

Mrs. L. J. Veley, F.L.S., presented a paper, "A Further Contribution to the Study of Pelomyxa palustris (Greeff)," illustrating her remarks with a series of lantern-slides.

Dr. D. Prain read a note on "Mansonieæ, a New Tribe of the Natural Order Sterculiaceæ," and exhibited specimens and diagrams of a species of the tribe, sent to the Calcutta Botanic Garden by Mr. F. B. Manson, of the Indian Forest Department. The species is the type of a new genus, Mansonia, J. R. Drumm. MSS. Its nearest ally is an African genus, Triplochiton. Definitions are given in the paper of the tribe Mansonieæ and of the genus Mansonia; a description is also given of the species, M. Gagei, J. R. Drumm. MSS.

ROYAL BOTANIC.

April 19.—The Society's show held on the above date was fairly representative, many exhibitors displaying groups, the principal of which were arranged in the conservatory. Several spaces were well filled with economic plants from the Society's greenhouses, while a bright display of flowering plants in the conservatory and in the gardens presented a pleasing appearance. The weather unfortunately prevented a large attendance of visitors.

Among the nurserymen's exhibits the most important was that displayed by Messrs. Cutbush & Sons, Highgate, who arranged a large rock-garden planted in a natural style, and having a backgrounnd composed of Bamboos and other subjects (Gold Medal).

Messrs. R. & G. Cuthbert, Southgate, put up a fine group of hardy deciduous flowering shrubs arranged with suitable foliage. The group contained some fine varieties of Azalea rustica flore-pleno, A. sinensis hybrids, and the finest mollis varieties (Large Silver-gilt Medal).

Messrs. Cannell & Sons, Swanley, presented a large collection of cut flowers of zonal Pelargoniums. The trusses and individual flowers were alike remarkable for their size and for their wide range of colour (Large Silver-gilt Medal).

Messrs. F. Cant & Co., Colchester, made a fine exhibit of cut Roses, including some new varieties (Large Silver-gilt Medal).

Mr. Geo. Mount, Canterbury, had an equally interesting exhibit of Roses. Most of the blooms were carried on long stems with remarkably fine foliage and strong growth (large Silver-gilt Medal).

Messrs. Barr & Sons, King Street, Covent Garden, had many choice sorts of Daffodils similar to those seen the previous week at the Royal Horticultural Society's meeting (large Silver-gilt Medal).

Messrs. Bath, Ltd., Wisbech, received the same award for an equally interesting exhibit, while Messrs. Hogg & Robertson brought a fine collection of these flowers from Ireland, in addition to St. Brigid Anemones, Tulips, &c. (Silver-gilt Medal).

Dr. Boxall, showed Begonia Lorenziana, a free-flowering variety of the President Carnot type, and to which a First-class Certificate was awarded.

H. L. Bischoffsheim (gr., Mr. C. G. Ellis), The Warren House, Stanmore, put up a fine group of plants, consisting chiefly of Anthuriums and Orchids. The Warren House variety of Odontoglossum Andersonianum was awarded a Certificate of Merit (Gold Medal).

Miss Anderson (gr., Mr. Kelf), Regent's Park, put up a large group of spring flowering plants and foliage (Gold Medal).

Mr. E. Wagg, The Islet, Maidenhead, showed well-grown plants of the best type of Cinerarias (Silver-gilt Medal).

Sir F. T. Barry, Bart., Windsor (gr., Mr. R. Brown), staged a collection of Camellias, cut from bushes in the open ground (Silver Medal).

A Cup, valued seven guineas, offered by Messrs. Barr & Sons for the best collection of Daffodils, was secured by H. R. Darlington, Esq., Potters Bar, who put up a very nice collection, which included many of the newer varieties.

Mr. Sage, Richmond, brought examples of the Bruce-flower displayers; while Mr. Williams, Ealing, showed flower stands adapted for light table arrangements.

CHESTER PAXTON.

April 11, 12.—This Society's fourth annual exhibition of spring flowers was held in the Town Hall, Chester, on the above dates. The opening ceremony was performed by Her Grace Katharine Duchess of Westminster. Large collections of cut Daffodils were staged, those displayed by Mr. Hugh Aldersey, of Aldersey Hall, and Messrs. Dicksons, Ltd., being particularly good. Both of these exhibits were awarded the Society's Medal. His Grace the Duke of Westminster (gr., Mr. N. F. Barnes) staged an attractive exhibit, which included about forty dishes of Apples and a collection of Souvenir de la Malmaison Carnations.

The President of the Society, Major MacGillycuddy, J.P. (gr., Mr. E. Stubbs), put up a most extensive collection of plants, including some remarkably fine Callas and Azaleas, and a collection of choice Daffodils. An interesting stand of Storrie's strain of ornamental Kale was also staged by Mr. Stubbs.

The exhibit sent by Dr. Mules, of Gresford, included choice and rare species of hardy Primulas, Narcissi, and other spring flowers.

Messrs. Sutton & Sons, Reading, put up an admirably-arranged stand of Cinerarias (Silver Medal).

Messrs. McHattie staged a choice lot of Hyacinths. Other exhibitors included Mr. T. Gibbons Frost, Mollington Banastre (gr., T. Gilbert); Mr. J. M. Frost, Upton Lawn (gr., W. Seddon); Mr. J. Garrett Frost, Boughton Hall (gr., J. Clack); Mr. Tyrer, Plas Newton (gr., A. Ellams); Mr. Townsend Currie, Christleton Hall (gr., J. Weaver); and Miss Humberston, Newton Hall (gr., R. Wakefield).

THE BRITISH GARDENERS' ASSOCIATION.

In addition to those previously reported meetings were held:—

At *Penrith*, on the 5th inst., at the Exchange Hotel, Mr. A. Statham, of Edenhall Gardens, presiding over a good attendance of local horticulturists. The objects of the Association having been explained by Mr. J. W. Mallinson, it was, after a good discussion, unanimously resolved "that a local branch of the British Gardeners' Association be formed." Mr. Mallinson, whose address, Edenhall, Langwathby, R.S.O., Cumberland, readers in the district are requested to note, was appointed local secretary.

A special general meeting of the *Tunbridge Wells* Gardeners' Association was held in the Friendly Societies' Hall on Tuesday, April 11, to hear an address by Mr. W. Watson, Secretary of the British Gardeners' Association. Mr. C. Taylor, of Messrs. Cripps & Son, occupied the chair, and about 160 members and others were present, including the principal gardeners and nurserymen of the district. Mr. Watson's address was on the same lines as that given at Birmingham, Kingston, &c. A resolution to form a branch of the British Gardeners' Association for Tunbridge Wells and district was adopted with only three dissentients, and a committee was at once elected, with Mr. Goacher as Secretary.

At *Sutton* on the 11th inst., a meeting convened by the local horticultural society was addressed by Mr. R. Hooper Pearson.

GARDENERS' DEBATING SOCIETIES.

BOURNEMOUTH AND DISTRICT GARDENERS'.—A meeting of the above Society was held on Tuesday, April 18, presided over by Mr. F. W. George, Thornleigh Gardens. Mr. A. King, of the Parkstone Nurseries, exhibited well-grown plants of Schizanthus wisetonensis, also pots of Mignonette and examples of the St. Brigid Anemones. Mr. King also delivered a lecture on the cultivation of these plants. A good discussion followed.

Obituary.

JOHN NEWBIGGING.—The death of Mr. John Newbigging, of the firm of Messrs. T. Kennedy & Co., seedsmen and nurserymen, Dumfries, took place on Tuesday of last week at Las Palmas, Grand Canary, whither he had gone for the benefit of his health. Deceased, who sailed for Las Palmas on the 22nd of last month, had been ailing for a considerable time, and had been disabled for business since Christmas. He was in his forty-fourth year, and he leaves a widow and two children to mourn his untimely death. He was a partner with his brother, Mr. T. K. Newbigging, in the well-known firm of Messrs. Kennedy & Co., whose extensive business, founded in the town by his great-grandfather, was successfully carried on by his grandfather, Provost of Dumfries, and by his father, a former Bailie of the town, since whose death it has continued in the hands of the deceased and his brother. The department of the business to which Mr. John Newbigging more particularly applied himself was that of the nurseries, and he developed these with marked success. He made a special study of arboriculture, and on behalf of his firm he carried through more than one Government order in connection with forest-planting operations in Ireland and elsewhere. In 1903, when the Highland and Agricultural Society held their show in Dumfries, he was appointed Secretary of the exhibition in connection with the Scottish Arboricultural Association. But besides being a first-rate business man, he possessed personal qualities that made him a great favourite with everyone with whom he was brought into contract, and in social as in business circles he will be much missed.

JULIEN VICTOR BURVENICH.—We regret to have to record the death, on the 21st inst., at Ghent, of this gentleman, who held the office of Curator of the University Botanic Garden. Mr. Burvenich was in his forty-eighth year.

JOHN HORNE.—The death is announced of Mr. John Horne, F.L.S., late Director of the Botanic Gardens, Mauritius, who latterly has lived at Sea Braes, St. Clement, Jersey. Deceased, who left the Royal Gardens, Kew, in 1860, was an occasional correspondent to these pages.

POTATOS.

Dunbars, 100*s.*; various, home-grown, 50*s.* to 80*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

Although there are indications of increased trade, there is little advance in prices. Zonal Pelargoniums in several varieties are of good quality; Ivy-leaved varieties are also good, but at present are not well furnished with flowers. The show or regal sorts are also plentiful. Good Indian Azaleas are still seen; "whites," which went up to 5*s.* each last Saturday, are again down to about 3*s.* Some good A. mollis are seen; these do not sell readily. Well-flowered plants of Rhododendrons are to be had, but there is little demand. Good Genista plants are still coming in, but some are very rough in quality. Spiræas are plentiful; these vary much in quality. Supplies of Cinerarias are now shorter; there are also very few good Cyclamen to be seen. Ericas continue plentiful, and now include E. ventricosa magnifica, E. hybrida, and E. mirabilis; the last named is an old variety now rarely grown. Verbena Miss Willmott is well grown and sells readily. Rhodanthe is arriving from several growers. Mignonette varies in quality; some very fine samples can be had. Plants of Hydrangeas are good; the variety Thos. Hogg sells readily, but H. Hortensia does not clear quite so well. Intermediate Stocks are now at their best; with milder weather they will be in demand. Plants of Marguerites are good, and sell fairly well. Supplies of Roses are now larger, including many H.P.'s; these vary much in quality. Madame Levavasseur is coming from several growers; some of the specimens are very good, but many are of indifferent quality. Crimson Rambler is obtainable in various sized plants. The cold weather quite stopped the demand for Heliotropes last week. There is little difference in the amount of supplies and in the prices of foliage plants. There is a better demand for Ferns and Palms; supplies of these are quite equal to all demands, in fact small Ferns are over abundant. The trade for bedding plants has not increased much. The cold weather has deteriorated much of the stock.

CUT FLOWERS.

Prices for Roses were high at the end of last week, but they are now down again, and the demand for special blooms does not equal the increased supplies. Medium-sized flowers sell rather more readily. Supplies of Lily of the Valley are scarce, and prices for these flowers have advanced considerably. Liliums are down again in price. Good Callas are not over-plentiful. Among Daffodils the bicolors and Barrii conspicuus

are the chief varieties seen. Spanish Irises are good and plentiful. Flowers of Gladiolus Colvillei (the pink variety) are good; there is little of the white variety in the market. Sweet Peas are now of good quality. The best market sorts are Dorothy Eckford, Miss Willmott, Princess May, King Edward VII., and Navy Blue. In Carnations the Malmaisons are now of good quality. American varieties are not quite so plentiful. Tulips of the English garden sorts are now of good qualities. The "Darwin" and "Parrot" varieties are seen in quantities. Mignonette is of very fine quality. Supplies of Orchid flowers are more than equal to all demands, especially Odontoglossums. Cattleyas maintain high prices. The trade in the French market is almost over for the season. Flowers of good double white Stocks are now scarce, and being so much used for wreath-work, sell well, and at advanced prices. *A. H., Covent Garden, April 26.*

ANSWERS TO CORRESPONDENTS.

ADDRESS: *A. B.* Mr. S. T. Wright, Royal Horticultural Society's Gardens, Wisley, near Weybridge.

ALGIERS, FLORA OF: *Traveller.* You will find the *Flore Analytique et Synoptique de l'Algérie et de la Tunisie*, published at Algiers by Giralt, of great service to you. It is written by MM. Battandier and Trabut. The *Flore de l'Algerie* is a larger and more expensive work in four or five volumes.

AMERICAN CORRESPONDENCE: We have intimation that certain letters and pamphlets were despatched to us from Chicago and from North Easton, Massachusetts, on or about March 15, but these have not reached us. Enquiries will be made with a view to ascertain the cause of the omission, which we mention because it is probable that other correspondents may have sent communications and received no reply.

ASH-ROOT: *J. M.* Destroy the root by blasting it with dynamite, unless the wall is so near that the blasting would affect it, when strong carbolic acid might be applied on the stump. This would soon eat into the wood, and you could afterwards break it up by means of a pickaxe.

CORRECTION. On p. 245 of the last issue, in column 1, for flowers of Saxifraga Burseriana 3 inches across, read three-eighths of an inch across.

CYCLAMEN-CORMS: *R. W. R.* After flowering, the corms may be kept in their pots until they show signs of making fresh growth, or they may be planted-out into frames. We do not advise you to retain corms that are more than two years old. Younger plants usually succeed much better. Seeds may be sown at any time from August to November, in pans of loamy soil made freely porous by the inclusion of leaf-soil and silver-sand. They will germinate readily in a temperature of about 55°, and the seedlings should be put separately into small pots in the following February or March.

FREESIA: *G. M.* The scrap you send appears to be a Montbretia, not a Freesia; but it was withered when it reached us.

GERMAN SOUTH-WEST AFRICA: *J. B.* Herr Dinter is expected to return to Europe very shortly. We gave his address in Saxony in our last number. Of course you are aware the country is at present in a very unsettled condition.

HELLEBORE TEA: *J. M.* This is made from Hellebore powder, which can be obtained from any of the garden sundriesmen. Remember it is very poisonous.

LATHYRUS MAGELLANICUS: *J. B. L.* You should be able to get seeds of Lord Anson's Pea from the seedsmen. They are not expensive, but somewhat rare, because few people cultivate the species.

LAVENDER AND WOODRUFF: *R. M.* Cut off the growths just before the flowers open, and spread them out thinly on shelves, or suspend them in small bunches in some sunny, well-ventilated glass-house.

LILIUM CANDICANS: *H. W.* The fungus on the leaves is one which is found on many plants of Liliaceæ, and to it have been applied at different times and on different plants no fewer than fourteen names, of which the one now usually adopted is Uromyces Erythronii. The only remedy is to cut off diseased leaves and burn them as soon as they appear, so as to prevent their attacking healthy plants. It is our opinion that the disease can never be eradicated from affected plants, therefore they are better destroyed, in order to prevent diffusion, and a little Bordeaux-Mixture distributed by spraying over other plants of Liliaceæ in the immediate vicinity would do no harm. *M. C. C.*

NAMES OF FRUITS: *Hautbois.* 1, Golden Nonpareil; 2, French Crab, generally known as Winter Greening.

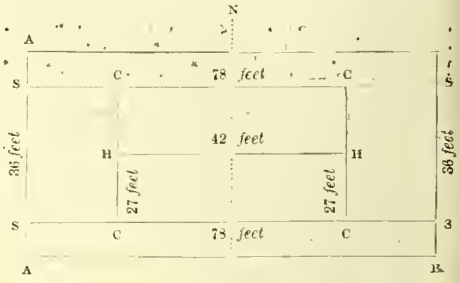
NAMES OF PLANTS: *J. M. R.* Tiarella cordifolia.—*A. G.* 1, Lycaste aromatica; 2, Milla biflora; 3, Polyanthus Jackanapes; 4, Kerria japonica flore-pleno; 5, Tulipa sylvestris. —*J. F. H.* The white-and-yellow Orchid is Cœlogyne ochracea; the other, Dendrobium crepidatum.—*Haslemere.* 1, Oncidium sphacelatum; 2, Bougainvillea spectabilis; 3, Dracæna hybrida; 4, Skimmia Fortunei.—*A. J. R.* Lissochilus purpuratus, Lindley.—*Felix.* 1, Oncidium phymatochilum; 2, O. cheirophorum; 3, Masdevallia striatella; 4, Bulbophyllum densiflorum; 5, Ada aurantiaca; *H. R., Norfolk.* Bifrenaria Harrisoniæ (often called Lycaste Harrisoniæ).—*H. C.* Billbergia nutans.—*J. W. A.* 1, Diacrium bilamellatum; 2, Epidendrum floribundum; 3, Adiantum decorum.—*Lea Ross.* Zephyranthes tubispatha. *A. J. S.* A form of Odontoglossum triumphans. —*A. F. P., Cornwall.* Dendrobium Pierardi.—*M. J. O., Wolverhampton.* Primula denticulata cashmeriana.—*Grateful, Salop.* 1, Anthurium crystallinum; 2, Dendrobium chrysotoxum; 3, D. Pierardi; 4, D. nobile. The Rose appears to be Rosa L'Idéal.—*E. Abbott.* Ornithogalum nutans.—*Constant Reader.* 1, King of Violets; 2, Admiral Avellan; 3, Princess of Wales (small flowers).—*A. C.* 1 and 2, Cupressus Lawsoniana; 3, C. nootkatensis; 4, Sequoia gigantea (Wellingtonia). —*R. N. H.* 1, 2 and 3, varieties of Odontoglossum Andersonianum; 3, a very pretty variety; 4, Odontoglossum Hunnewellianum.—*V. H.* 1, Polystachya luteola; 2, Megaclinium falcatum; 3, Maxillaria variabilis; 4, Stelis micrantha; 5, Masdevallia simula.—*A. G. F.* 1, probably Prunus Padus, send again when in flower; 2, Leucothoe floribunda; 3, Amelanchier canadensis; 4, Cydonia japonica; 5, Rivina humilis; 6, Hippeastrum reticulatum; 7, Rhœo (Tradescantia) discolor; 8, Spathiphyllum cannæfolium (syn. Anthurium Dechardi); 9, Fittonia argyroneura; 10, (broad-leaf) Chlorophytum elatum variegatum; 10, (narrow leaf) Liriope striata; 11, Mesembryanthemum species; 12, Staphylea colchica; 13, S. pinnata; 14, Saxifraga sarmentosa variegata. You have much exceeded our rules. A small contribution to the Gardeners' Orphan Fund would serve to absolve you. —*Japonica.* 1, Maranta Makoyana; 2, Phalænopsis amabilis, often called P. grandiflora; 3, Dendrobium parcum; 4, D. dixanthum. —*W. H.* Acer platanoides, Norway Maple.—*A. G. S.* Cydonia japonica, certainly, but we are not able to name the variety. Consult some nurseryman.—*H. N.* 1, Cupressus Lawsoniana; 2, the golden form of the Irish Yew; 3, Cupressus Lawsoniana aurea; 4, C. L. erecta viridis; 5, Cupressus Lawsoniana, silver variegated form; 6, Juniperus communis.—*J. S. U.* Amelanchier canadensis.—*D. R.* Narcissus Autocrat, of the Incomparabilis section.

PEACH HOUSE: *F. B. S.* On bright mornings at this season, eight o'clock or half-past eight will be sufficiently early. The house may be syringed and closed in the afternoon after three o'clock on any day, and generally it might be done earlier with safety. As the days increase in length, and the sun becomes more powerful a little air may be again admitted to the house one hour or so after the syringing has been done.

PELARGONIUMS: *D. A. T.* The leaves have been scorched by the sun when wet. Ventilate more freely.

RICHARDIA FLOWER: *T. P.* It is not at all uncommon for the plants to produce twin spathes. As your plant has behaved similarly for three years in succession you may still watch it with interest. Attempts have been made to "fix" the characteristic, but so far as we know without success.

TENNIS LAWN: *Constant Reader.* The following diagram (reproduced from *The Calendar of Garden Operations*, published at this Office, price 7½*d.* post free), will illustrate the amount of ground required for a double court, and the lines that are usually made and kept:—



The lines A B and B A, indicate a double court for three or four players, S S, S S, a single court for two players; A A and B B are the base lines; C C and C C, service lines; H H, half-court line; N N, net. A court for the single game is 27 feet wide and 78 feet long; and for the double game, 78 feet long and 36 feet wide. The posts for supporting the net should be placed 3 feet beyond the sides. The service lines run parallel to the net, and are 21 feet distant from the same. The net should be 3 feet high in the centre, and 3 feet 6 inches at the posts, which are put 2 or 3 feet outside the line, to allow of the net dropping. When the outside measurements have been taken, and a line drawn straightly and tightly, it may be marked with the machine made for the purpose, or by the use of a whitewash brush, and a solution of whiting, lime, and water. The machine is better, because by its use it is easier to obtain perfectly straight and thin lines. Both Messrs. Sutton, of Reading, and Messrs. Carters, 237, 238, High Holborn, publish small pamphlets on the management of lawns and bowling-greens. For names of Violets, see under "Names of Plants."

TOMATO LEAVES: *J. H. A.* The leaves were too much wilted and knocked about to make certain of anything in regard to them. There is no appearance of fungus upon them, but the foliage is not in a condition to give a decided opinion upon, as superficial mould may have been wiped away. Send fresh specimens.

TULIP BULB: *C. M. L.* Affected by a parasitic fungus, Sclerotinia parasitica. Burn all affected plants at once.

VINES: *W. H. S.* Your Vines are affected with "browning," a disease of mysterious nature and origin. Cut away and burn all affected shoots, and maintain as healthy a condition as regards ventilation and heat as you can.—*J. G.* We are sorry to say the cause of browning of Vines, a destructive malady, is still a matter of doubt. It was at one time considered to be due to a slime-fungus, but that view has, we believe, been disproved.—*A. S.* Your Grapes are affected with "spot" caused by a fungus. Burn the affected bunches, and spray the healthy ones with liver-of-sulphur, ½ oz. to 1 gallon of water.

WALLFLOWERS: *A. R.* The injury is due in the first place to a pith-boring maggot that lives in the stem during the seedling stage of the plant. The production of numerous crowded branches is a sign of this injury, and if the stem is split down the maggot may be seen. Such plants do not die at once, but during the second year few or no blooms are produced, and the plants gradually die and the dying portions are attacked by various fungi. It would be well to raise seedlings for some time to come in a totally different portion of the garden.

MAGNOLIA KOBUS, A DECIDUOUS SPECIES FROM JAPAN—FLOWERS WHITE; SLIGHTLY ENLARGED

Bradbury, Agnew & Co., Ld., Printers, London and Tonbridge

THE
Gardeners' Chronicle

No. 958.—SATURDAY, May 6, 1905.

CONTENTS.

ILLUSTRATIONS.

ROYAL ACADEMY.

THERE is a remarkable falling-off in the number of pictures of floral subjects at the Royal Academy this year; in some of the rooms there is none, in others only one, or at most two. There are a few paintings of flowers amongst minor works, and a few others, as usual, amongst the water-colours. There are practically no "impressionist" flowers this year, no shadows, no "symphonies" in anything. Pictures by ladies who only paint "what they can see" are absent. The floral world to them is very often a mix-up represented by atrocious drawing and foggy daubing. How easy it is to become a floral "impressionist," how difficult—so it would seem—to achieve draughtsmanship worthy of the name, and represent colour which is not a libel on Nature! The *Gardeners' Chronicle* here begs leave to thank the Hanging Committee for ousting the army of floral incapables.

Of garden scenes there are but few; of landscapes, views of woodland, pasture, hill, and stream there are many. Those by practised and well-known men at once arrest attention; the majority are middle-rate, indifferent—pictures to glance at and pass on without remark, pictures one has seen hundreds of times before, and hopes—perhaps in vain—never to look upon again.

It requires a very long day to walk through and note the chief pictures in the many galleries of the Royal Academy, and not a tenth part of the exhibits can even be mentioned by name in any journal. As space is valuable in this paper, all that can be done is to record a walk through the rooms, and mention a very limited number of pictures more or less relating to horticulture. Many works worthy of notice must through exigencies of space be omitted.

We start in GALLERY I., and taking the pictures in numerical order, the first we note is 36, *Chrysanthemums*, M. Cathelin Ludovici, an excellent picture of Chrysanthemums, with berried Holly and Ivy. 50, *The Farm Gate*, H. W. B. Davis, R.A., a fine spring-time landscape. 54, *A Morning in June*, George Clausen, A., an excellent piece of work, quite out of the ordinary run of landscapes, and powerfully new in treatment; one has not seen the like of it before: observe the perfection of the perspective in the clouds.

GALLERY II.—There are no flower subjects in this gallery. 79, *Sunshine and Shower on the South Coast*, B. W. Leader, R.A.; everyone knows Mr. Leader's extraordinary facility in landscape; this is a coast scene, with sea-holly in the foreground. 118, *Fruits of the Earth*, C. E. Perugini, a truly beautiful picture of a lovely girl carrying Peaches, Figs, and Grapes. 119, *Flowers of Alsace*, R. W. Macbeth, R.A., and the beautiful 121, *The Brimming River*, and *The Arun at Houghton*, R. Vicat Cole. 126, *The Happy Island of Salahat*—"*Sinbad*, (sic) *in his sixth voyage, relates his adventures to the Sultan*, Albert Goodwin. This is a fairy-like picture of Palm trees and Almond blossoms in Mr. Goodwin's well-known manner. There seems to be a lack of foreground to the picture. The name is painted correctly on the frame—"Sindbad," not "Sinbad," as in the catalogue. 172, *The Silvery Thames*, another of Leader's familiar works. 198, *The Black Mountains*, J. Aumonier. A good and faithful representation of these well-known hills, as often seen by the writer and other members of the Woolhope Club. 212, *The Finding of Moses*, Sir L. Alma-Tadema, R.A. This picture will be viewed with mixed feelings; it exhibits all the artist's unrivalled power of drawing and painting, his archæological knowledge, and his faithful attention to details; there is no daubing and smudging, and fudging over difficult parts, all is accomplished and perfect—gilt finger-nails, green line painted under the eyes, rings for finger and toe, musical instrument, Figs, Larkspurs, and last but not least, the very pronounced black-haired Hebrew child. This last is clearly a portrait; the original must have been sought and waited for. The cradle, supported on the left shoulder of one woman and the right of another, is curious. Could a cradle be so carried? The large collection of Larkspurs is remarkable; there is no rest for the tired eyes; artists belonging to other schools than that of Alma-Tadema will not altogether like the picture.

GALLERY IV.—250, *In a London Garden*, E. Margaret Woolhouse. A very good study of single Hollyhocks reduced in scale. 255, *The Tithe Barns*, David Murray, R.A. Elect. A very pretty rustic subject. *Swedes*, David Murray, R.A. Elect. A field of Swedes, undoubtedly a trying subject; amongst the Swedes are two kicking horses, a dog and apparently a dancing lunatic; a good picture, but peculiar. 258, *The Passage Perilous*, Sidney Paget. A knight on horseback with shadowy morris-dancers or something of that class. 334, *Early Morning in the Cotswolds*, Alfred East, A. A beautiful landscape, low in tone.

GALLERY VI.—366, *Bridesmaid Roses*, Florence W. Whitfield. This picture is a good one. It is both well drawn and coloured, and represents a group of Roses in a glass vase. 369, *An Unfinished Symphony*, Chas. M. Q. Orchardson. This represents a fiddler, fiddling before an unfinished portrait of a lady, with a child listening. The picture is well executed; but how it can be a "symphony" we do not know. There is usually a full band for a symphony, and sometimes the human voice is added. The fiddler may, indeed, be singing, but as his back is towards the observer it is difficult to say. We accept it as a "symphony" on a minor scale; certainly it is not an "impression."

Up to this point we were in despair as to floral pictures, but in GALLERY VII., under 421, the catalogue gives *Poppies*, Eisman Semenowski. The picture represents a reclining Turkish woman and a cockatoo! There is a mistake somewhere. The artist's name is peculiar; his handwriting may be the same, and the word he wrote may not really have been "Poppies." We turned away disappointed. Reclining on one of the luxurious seats, we directed our glasses to every recess of this gallery without discovering "Poppies." 458, *Flora's Bower*, Robert Christie. This can hardly be the Roman Flora. The picture represents a number of partially-clothed and plain-featured young women trespassing amongst growing Rhododendrons; Flora (really a twentieth-century young girl) is entirely nude—one does not usually see the Roman Flora so pourtrayed. A boy with blue wings is descending head-first from the sky to salute Flora. 459, *Trafalgar, 2.30 p.m., October 21, 1805*, W. L. Wyllie, A. This is one of Wyllie's large masterpieces, with representations of the old fighting ships of the past; every ship is named on the frame—a picture to be carefully examined and studied. 472, *Moorland, Dorsetshire*, Arthur Hopkins. A finely-executed piece of work, with Heather introduced with good effect. 473, *Lincoln Cathedral from the Castle Hill*, William Logsdail. A Canaletto-like picture, very photographic and correct. In the cathedral itself the pinnacles are not set correctly on to the turrets, as the writer well knows, as he was once commissioned to draw this front of this cathedral. We are delighted to see the turrets are in this picture as they in fact really are. The painting is, however, cold, unsympathetic, and without atmosphere.

GALLERY VIII.—485, *The Incoming Tide on the Cornish Coast*, B. W. Leader, R.A. An impressive picture of sea and rocks. 510, *An Ode of Pindar*, Isaac Snowman. A picture with an Alma-Tadema frame and a representation of an Alma-Tadema stone seat; the figures and faces are, however, not those of Alma-Tadema, and it is difficult to say in what manner the picture is Greek; there is, however, a Greek vase with red figures on a black ground. 527, *Theseus returning*

to *Ariadne*, W. E. Gladstone Solomon. Theseus, much flustered and evidently bent on mischief—a picture well worthy of study. It is a relief to turn to 532, *The Ploughman's Breakfast*, November, George Clausen, A. The picture represents the border of a field with a pasture in the distance; the light of early winter morning is given with marvellous effect; in the foreground are ploughmen sitting at breakfast, beside them are horses and a plough, speckled with the rays of the rising sun. 545, *The Bride*, Fortunée de Lisle. A bride in an Alma-Tadema frame carrying white flowers of an uncertain natural order.

Gallery IX.—This is a room of small pictures in which are a few floral subjects. 552, *The Flowers of Spring*, James V. Jelley. A long horizontal strip of Primrose blooms without leaves and with Blackthorn blossums behind well done. 572, *Westminster Abbey and School from Dean's Yard*, Alfred Fahey. Turn for a moment and compare this beautiful picture with its grace and atmospheric effects with 473, *Lincoln*, which has none of these qualities. 583, *A dry Pump*, Sydney Hayes, is really the head of a donkey, lovingly painted. 598, *Mushrooms*, Emily Stanton. The true pasture Mushroom, not the indigestible dung-heap form; very truly represented. 618, *Fleurs et Fruits*, Arthur Chaplin. Hops, Plumbago, Nuts, Campanula rotundifolia, Medlar, Zinnia, Grapes. Why should the name be in French, English is good enough for the assortment before us, which is very well executed. 638, *Roses*, Margaret Cornish, appears to be a good piece of work, but it is placed too high to be properly seen. 648, *The Nineteenth of April*, E. T. Sutcliffe. Another useful, long, horizontal strip of Primroses, this time with leaves. For some occult reason a reel of white cotton has been added to the picture. 651, *Building the "America" at Harland and Wolff's*. Robert P. Staples; 651 is really a picture of lambs, flowers, and a spirit-child; we cannot find this subject in the catalogue. 658, *A Labor of Love*, Henry E. Crocket, is a picture of a young lady engaged in the task of painting Chrysanthemums. 693, *Autumn Roses*, Catherine A. Lilley. Very well drawn and painted.

Gallery X.—753, *Irises*, Louisa G. Chapman, appears to be a well-executed picture of dark Irises on a dark background, but the work is placed too high to be properly seen.

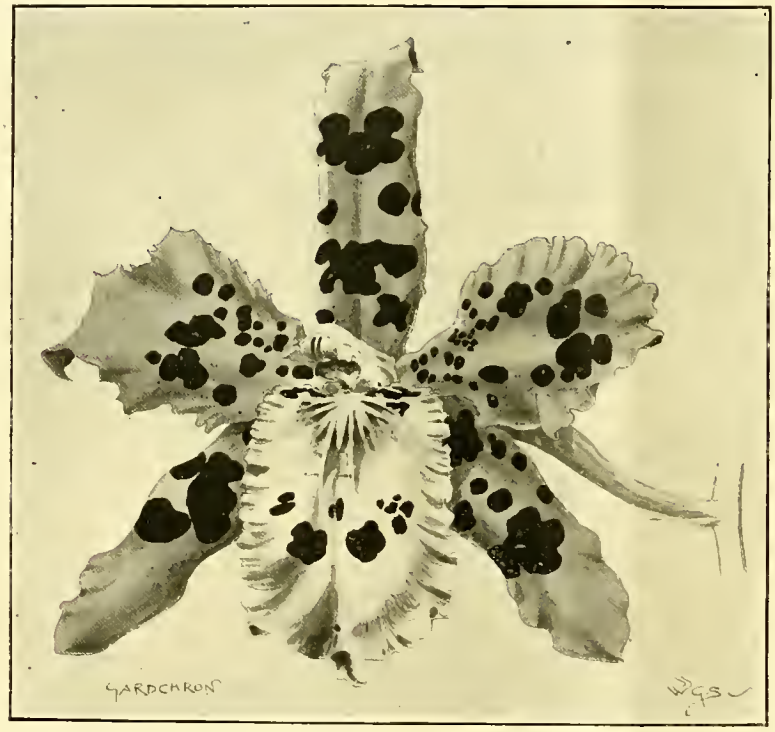

Fig. 112.—Odontoglossum wiganianum × : colour of flowers bright yellow with brown markings.

Awarded a First-Class Certificate at a Meeting of the Royal Horticultural Society when exhibited by Sir Frederick Wigan. (See Report on page 236 of our issue for April 15.)

831, *They'll Want us Again*, Alfred W. Strutt Four horses are supposed to be saying this; they are looking at and speaking about a damaged "road-hog," from which two real ladies and a gentleman have alighted. A large number of motors at lightning speed rush by our house night and day at Dunstable, close to Markyate; we have observed them for two or three years, and we have never seen ladies and gentlemen in them! 843, *Chrysanthemums*, R. Willes Maddox, a well-executed study of colour.

At last we arrive at the "Water Colour Room"—it is a "room" only, not apparently worthy of the name "gallery." Here one always finds flowers, sometimes very indifferently represented, but such is not the general quality this year; the Hanging Committee has severely winnowed out the chaff. 857, *Roses*, Clifford Toft, fairly good. 870, *Summer Jewels*, Jessie M. Silvester, a well-executed group of Sweet Peas. 893, *Christmas*, Woodhouse Stubbs, Hellebores, &c., well drawn and coloured. 903, *The Wealth of Summer*, same artist, Roses and Grapes. 920, *Water-Lilies and Poppies*, William J. Muckley. Everything this artist produces is of the first class. 942, *A Study in Silver and Gold*, Edith A. Tye, a very good study of Honesty and Helichrysum. 969, *Fleurs de Printemps*, Antoinette Chavagnat, Pæonies, too high to be properly seen. 996, *Spring*, Woodhouse Stubbs, Pansies, remarkably good both in drawing and colour. 1017, *Flowers of the Wood*, G. G. Simpson, Bluebells and pink Lychnis, but some parts so shadowy as to represent nothing. We now arrive at the end of our task with 1023, *Heralds of Spring*, J. Jessop Hardwick. Primroses, early Orchis, and the everlasting bird's-nest. Now this is too bad! For more than fifty years we have . . . . .

"I expect you are glad, sir, that your day's work is done," said one of the obliging attendants. "Yes, certainly I am," was the reply, "but—*which is the way out?*" *W. G. S.*

ORCHID NOTES AND GLEANINGS.

CŒLOGYNE NITIDA AND THE VARIETY ALBA.

Flowers of the typical form and of its rare albino are sent us by C. J. Lucas, Esq., Warnham Court, Horsham (gr., Mr. Duncan), who says that the plants were brought by a friend from Burma. The typical form has yellow and orange coloured markings on the lip, but in the other, which is entirely pure white, there is not a trace of colour. The late Professor Reichenbach once described an albino as Cœlogyne ocellata Boddaertiana, and which was probably similar to that now flowering with Mr. Lucas.

Cypripedium Fairieanum.

In view of the interest aroused by the re-discovery and re-introduction of this plant, it may be of interest to reproduce the original description by Dr. Lindley, which appeared in the *Gardeners' Chronicle* for October 31, 1857, p. 740. This was the first time the species was recorded.

"C. foliis loriformibus concoloribus apice obliquis apiculatis; scapo piloso; bracteâ brevi pallidâ apiculatâ; ovario glanduloso piloso; sepalis glanduloso-pilosis, dorsali erecto subrotundo apice recurvo, antico breviore concavo oblongo obtusissimo; petalis lanceolatis obtusis decurvis reflexis margine crispis et basi intus fimbriatis; labello sepalo antico duplo longiore glabro oblongo basi convoluto; stamine sterili lunato proboscideo piloso margine antico utrinque unidentato.

An exquisitely beautiful little species in the way of C. insigne, than which the flowers are much smaller. The leaves are narrow and whole coloured, the bract pale green, the ovary deep purple; the back sepal white, richly veined with green and crimson, the petal pale green with a rich purple crisp edge; the lip dull dirty green. It seems nearest to C. superbiens of Reichenbach, but is much smaller in every part, has no warts on the involute sides of the lip, is quite differently coloured, and has a long proboscis-like appendage arising from the middle of the concave side of the crescent-shaped sterile stamen.

It was shown at the late exhibition of the Horticultural Society in Willis's Rooms by Mr. Fairie, of Liverpool, an enthusiastic collector of Orchids, who we think may fairly claim the union of his name with that of the vegetable gem before us."

Living plants have now been received at Kew, where we lately had the privilege of seeing some of the leaves and a scape. The specimens of cultivated plants, dried at various times and preserved in the herbarium, are interesting as showing the gradual diminution in the size of the leaves, &c., as compared with that of the earlier specimens.

BULB GARDEN.

TULIPA SUAVEOLENS AND T. PRÆSTANS.

There is a growing tendency to consider Tulipa præstans, recently introduced from Bokhara, which received the Royal Horticultural Society's Award of Merit on April 7, 1903, as identical with the older T. suaveolens (Roth.), figured in the *Botanical Magazine*, t. 839. I have had an opportunity of closely comparing many individuals of each species, and I find differences that should do something to settle the question as to whether the two plants are distinct or not.

T. suaveolens has glaucous and hairy leaves, the largest ovate-acuminate, 6 inches wide, 12 inches long, the smallest lanceolate, 6 inches long, and they have a narrow but distinct brownish cartilaginous margin throughout. Flowers 2—3, borne on stems 12—18 inches high; segments ovate, crimson-scarlet, all equally about 4 inches long, the three outer flushed grey externally, leaving only a marginal crimson colouring, the three inner flushed grey at the bases only externally. Filaments ½ inch long, cylindrical, slightly compressed, coal-black. Anthers ashen-grey, ¾ inch long; capsules an inch long when the flower first opens.

T. præstans has glaucous, hairy, ovate-lanceolate leaves, generally longer and narrower than in T. suaveolens, and without the brown margins. Flowers 2 to 3, not flushed grey externally, save for a little at the extreme bases of the segments. Segments ovate, orange-scarlet, all equally 4 inches long. Filaments club-shaped, suddenly dilating at the junction with the anthers, vermilion coloured, one-third of an inch long; anthers one-quarter of an inch long, tinted bronze; capsule half an inch long in the perfect flower. The flowers are produced regularly ten to fourteen days before those of T. suaveolens.

The bulbs of the two plants present no difference. Just as the buds are piercing the soil T. præstans displays its orange-scarlet colouring as rich as in the perfect flower. T. suaveolens shows greenish-grey buds.

T. præstans I think the better plant of the two. Its self-colouring is more attractive than the greyish flushed flowers of suaveolens, and its vermilion filaments lend additional depth of colour to a glorious flower, whereas the black filaments of T. suaveolens seem to detract from the petals' colouring. I think there may be a doubt as to their being distinct specifically, but horticulturists will value T. præstans the more for its refined colouring, earliness, and greater brilliancy, and it should rank as a well-marked variety of T. suaveolens. *G. B. Mallett, Colchester.*

Watsonias.

These are lovely flowering bulbous plants having Gladiolus-like flowers, but quite regular. Among those in gardens are W. rosea, W. r. alba, W. Meriana, W. humilis, and the very pretty, white-flowered W. Ardernei, shown by Messrs. G. Jackman & Son, of Woking, at a recent meeting of the Royal Horticultural Society. The flower-scape is branched, and the inflorescence is in consequence less stiff than that of the Gladiolus. I do not know of any attempt having been made to cross the two genera (Watsonia and Gladiolus), choosing either species or hybrids for forming the crosses. Such a cross would seem to promise quite a new race. *F. M.*

"The Tropical Agriculturist."—The new series of this useful periodical, now edited by Dr. J. C. Willis, whilst losing none of its utilitarian character, is rendered more comprehensive by original notes on cultural matters and natural history. Naturally much space is occupied with rubber cultivation. It is still published by Messrs. A. M. & J. Ferguson.

MARKET-GARDENING IN THE MIDLANDS.

Very few districts in England are more fertile than the Valley of Evesham, beautifully watered by Shakespeare's Avon, and at this time of the year, when the hedges and trees are bursting into leaf and the fruit-trees are white with blossom, it is perhaps most beautiful. Acres and acres of garden-land are bright with Narcissus and Daffodil blooms. As the area of the cultivation of fruit is extending in the Vale the spectacle of the trees when in blossom each year becomes more beautiful. This spring it was seen at its best, and many people from the large towns took advantage of the excursions arranged to witness the sight. Now the leaves are developing and are not only toning down the snow-white effect, but also protecting the delicate fruit. The Plum blossom has been exceedingly good, and notwithstanding the fact that there was a heavy crop of fruit last year, present appearances indicate another abundant yield. Much anxiety has been caused the gardeners recently, when there was every appearance of a spell of severe weather, such as was experienced in the season of 1903, which proved so disastrous to the fruit-growers. On the morning of April 15 nearly 5° of frost were registered, and it was feared that the crop had been considerably thinned; on examination, however, it was found that little damage had been done to the blossom. It is too early to give an estimate of the probable yield, but from present appearances Pershore Plums seem to promise a fair crop; Damsons and Czars are scarce in places; Prolific, Early Orleans, and Victoria Plums are very promising. From some cause or other the blossoms fell off some of the trees almost as soon as they opened. Enquiries have elicited no satisfactory reason for this, but it is suggested that birds in quest of insects of some kind or other broke the blossoms off, and as this occurred in the stalk, it meant the loss of a Plum. The Prolific or Czar seems to be the chief sufferers in this respect.

A new Plum called The Heron is coming rapidly into favour with growers. This resembles the Victoria somewhat in shape, colour and size, but it is a better "carrier," and will keep much longer. To give an idea of the demand for this variety, it may be mentioned that fruit stocks have realised unusual prices, while single grafts have been making a penny each.

Apples promise but a partial crop, and this is not surprising, considering the extraordinary crop last year. Bush fruits promise well, especially Gooseberries, though some of these are being badly attacked by red-spider.

"Gilly" or Wallflowers are always grown extensively in the Evesham district, and one cannot describe the delicious scent experienced when passing a large plot of them, while their dark crimson blossoms are beautiful. It is the aim of the Evesham gardener to eliminate all the yellow blooms, and those of the darkest hue are cultivated exclusively. These flowers, which last year only met with a moderate sale, have this season realised good prices.

Vegetables.

Green Onions, the tying and washing of which employ many hundreds of women, have sold remarkably well. There has also been a good demand for "green stuff" of all kinds. Cabbages are being cut plentifully, but owing to the fact that the gardeners are anxious to be first on the market and get this vegetable out of the way before Asparagus appears, they are being cut too early, in fact, before the "hearts" have properly formed. This results in a poor price being offered, and even though the quality improves later, the price will not afterwards rise.

Fig. 113.—Fruit trees in blossom over Narcissus at Evesham.

Radishes are largely cultivated in the Vale, particularly by owners of land which belonged to the monastery in the time of Henry II. This land is wonderfully productive, being well watered, and sheltered from cold winds and frosts. The gardeners have a superstition that the bodies of the monks buried here fertilise the crops! Lovers of Asparagus will be glad to learn that a supply is already on the market, though in small quantities. The quality at present is only moderate, and prices have ranged from 2*s.* 9*d.* to 3*s.* 9*d.* per 100 "heads." It is expected that good prices will be obtained throughout the season, as the quality of the Asparagus grown in the Vale shows improvement every year. London buyers are beginning already to take up their residence in Evesham, where they remain until this vegetable is over, for the sole purpose of buying supplies for their own firms.

Lettuces are a thin crop in places, though they

are coming in well now, but only making from 1*s.* 6*d.* to 1*s.* 8*d.* per "pot." The gardens for growing this salad on the French system are hardly complete, still, one grower is making his glass pay admirably, and has now a supply of produce on hand to last till next February.

Owing to the dry season experienced last year, the land is now in better condition than it has been for some fifteen years past, and this argues well for the crops. All spring produce has done exceedingly well, and good prices have been maintained throughout. Evesham is not behindhand in anything connected with gardening, and when a contingent of gardeners visited Paris in February last they found that where they learnt one thing they might teach their foreign neighbours two! *Correspondent, April* 20.

FLORISTS' FLOWERS.

AURICULAS.

It is generally noticed that immediately following an exhibition of Auriculas some persons are led to attempt their culture, though their knowledge as to the management the plants require is often very limited. Such persons should make a commencement with low-priced, named varieties, of which there is a good selection, and then having succeeded with these they can gradually enrich their collections with more valuable and newer varieties. If certain conditions are observed, success may be reasonably anticipated. There should be a suitable frame or house in which to grow the Auriculas. A start should be made with healthy, vigorous young plants. The ground or stage upon which the plants are to stand, whether in the form of an ash-bed or of wood, should have provision for water freely passing away. The plants should be potted so that the lowermost leaves may rest upon the soil, as the plants will put forth roots from the axils of these leaves. The drainage at the bottom of the pots, of whatever material it may be formed, should occupy one-fourth of the inside depth of the pots. Over-potting should be guarded against—3-inch pots for small plants, 4-inch and 5-inch pots for larger ones, if well rooted. There should be free ventilation in fine weather, whether of house or frame. The plants should never be watered when the soil is moist about the roots; before water is applied the soil should be of such a porous character that water can quickly pass through it. Winter and summer alike the plants should be in soil sufficiently moist to maintain their vitality. A sodden soil is dangerous to the plant. Plants die from wet-rot and also from dry-rot. Obtain a proper compost in which to grow the plants, and afterwards afford them the constant attention they require, success in cultivation may then be confidently looked for. *R. D.*

FIG. 114.—ODONTOGLOSSUM × CRISPO-HARRYANUM "KING EDWARD": FLOWER CREAMY-WHITE, BLOTCHED WITH ROSY-PURPLE COLOUR.
Shown by Messrs. Sander & Sons at the Royal Horticultural Society's Meeting on April 11, 1905.
(See Report on page 236 of our issue for April 15.)

THE WISLEY GARDEN IN SPRING.

To those who feared that members of the Royal Horticultural Society would not travel to Wisley, it will be a surprise to learn that more members are attracted there than were induced to visit the old garden at Chiswick in recent years. The arrivals by motor-car and carriage are increasing rapidly, especially on Saturdays, and Weybridge and its neighbourhood are waking up to welcome this fresh centre of interest. Residences of a moderate size are being erected about half a mile from Weybridge, and land has been laid out for building along the main road, but not so near to the gardens as ever to threaten to interfere with their amenity.

I visited Wisley in typical Easter weather, but in spite of the bracing air the nightingales were audible in the bushes about the wild garden. They were heard on April 12, two days earlier than last year. The wood-wren and other warblers were noticed flitting about and singing as though spring had really come, and I have since wondered what can have become of the tender creatures during the recent fall in the temperature. The "wild garden" is however much sheltered, and birds and flowers have, I hope, escaped injury. The plenteous Oak-leaves are never gathered up, and as they decay excellent leaf-mould is formed, and during the process the crowns and bulbs of lowly flowers are sheltered from the frost and cutting winds. To those who love a wild garden, many useful hints can be obtained at Wisley. All that the late Mr. Geo. Wilson did there has been religiously respected, and the same objects and system are being intelligently carried out.

His bird-boxes were, I was glad to see, occupied by his "feathered friends," and one could not stand still a moment without hearing the rustle of some small creature hidden in the bushes Flowering trees and shrubs this year are more forward at Wisley than in the suburbs of London, and the ground was bright with a great variety of spring flowers. One meets with many surprises at Wisley. The double-flowered variety of Arabis albida "Snowdrift" fails totally in some localities where the single variety thrives, but at Wisley it greatly surpasses the single form in every respect. Narcissus maximus, which is doubtful in some places, here succeeds admirably, being very free and bright. The deep yellow colour is unsurpassed if equalled by any other Narcissus, and its form is superb.

Dog-tooth Violets growing in deep leaf-mould under an Oak, sheltered from north and east

but exposed to the south, were never seen in such perfection before. The flowers were large, unsoiled, and varied in colour, being white, rose, lilac, and yellow. Trillium grandiflorum growing near was equally at home. Also white Oxalis, Viola biflora (yellow), a very free-flowering Anemone apennina, Narcissus "Angel's Tears," and other beautiful Narcissi in groups and informal lines. At an unexpected turn a long bank of Daffodils reminded me of Wordsworth's exquisite lines. The flowers were tossing their golden heads in the sunlight and breeze just as he described. Probably the late Mr. Wilson had the lines in his mind when he formed the long bank and planted the Daffodils with lavish hand. I fancy that in his later days he could say—

> "For oft when on my couch I lie,
> In vacant or in pensive mood,
> They flash upon that inward eye
> Which is the bliss of solitude;
> And then my heart with pleasure fills,
> And dances with the Daffodils."

Lilium auratum, L. giganteum, and other species were growing vigorously, some in partial shade, which seems favourable to them. Colchicums were in vivid green, showing the seed-pods of their autumn flowers amidst their luxuriant foliage. Anemone nemorosa Robinsoniana and Iris tingitana were blooming in perfection. As I passed over a little rustic bridge the sweet-scented Cape aquatic Aponogeton made itself evident by its numerous blossoms and delicate perfume. Fine clumps of the great foliage plant, Gunnera manicata, were growing on the bank, giving promise of enormous leaves. Its neighbour the Bog Myrtle was covered with catkins that when bruised gave a pleasant odour. At every step some fresh source of interest was aroused, and it was surprising to find so many plants thriving within the limits of the wild garden, the soil of which consists of light sandy loam and abundance of leaf-mould. The loam gives evidence of the presence of iron, and to this I attribute the unusual intensity of colour in Prunus Pissardi, Berberis stenophylla, Pyrus floribunda, and other flowering trees and shrubs. The double-blossomed Cherries and Plums were very beautiful and in great variety. Those sent from Japan some years ago were very similar to Cerasus Watereri, but not quite so double; Veitchii was undoubtedly the best. Other plants that caught my eye were Gaultheria procumbens, very pretty in glossy dark green foliage and ruddy berries; Andromeda floribunda in beautiful masses, Spiræa arguta, Cupressus Lawsoniana lutea, a nice specimen; red and white Camellias in partial shade, and Ilex Tarri (?), a fine specimen with broad, dark green leaves and large red berries. The correct name of this is wanted. The Amelanchiers were in beautiful condition, and if anything surpassed, them it was the fine specimen Cerasus sinensis pendula, which is the queen of the garden.

The varieties of Azalea mollis were full of bud, and will be a brilliant sight in the beginning of May; while Erica Veitchii × from Exeter was in bloom, and looking very pretty, and also a fine growth of Erica mediterranea.

A beautiful collection of single Camellias from Portugal has arrived, but without any clue to the name of the generous donor. Flowering trees and shrubs, fruit-trees, &c., have been presented by many of the principal nursery firms.

W. Roupell, April 24, 1905.

CHINA ASTERS.

The illustration at fig. 115 has been reproduced from a photograph taken in the seed trial grounds of Messrs. Webb & Sons, at Kinver, Staffordshire. The bed in the foreground of the picture consists of varieties of the type known as Victoria, which has large, finely-formed flowers composed of imbricating segments. The type is obtainable in many shades and hues, or in distinct colours, and is among the most excellent Asters for use in flower-beds.

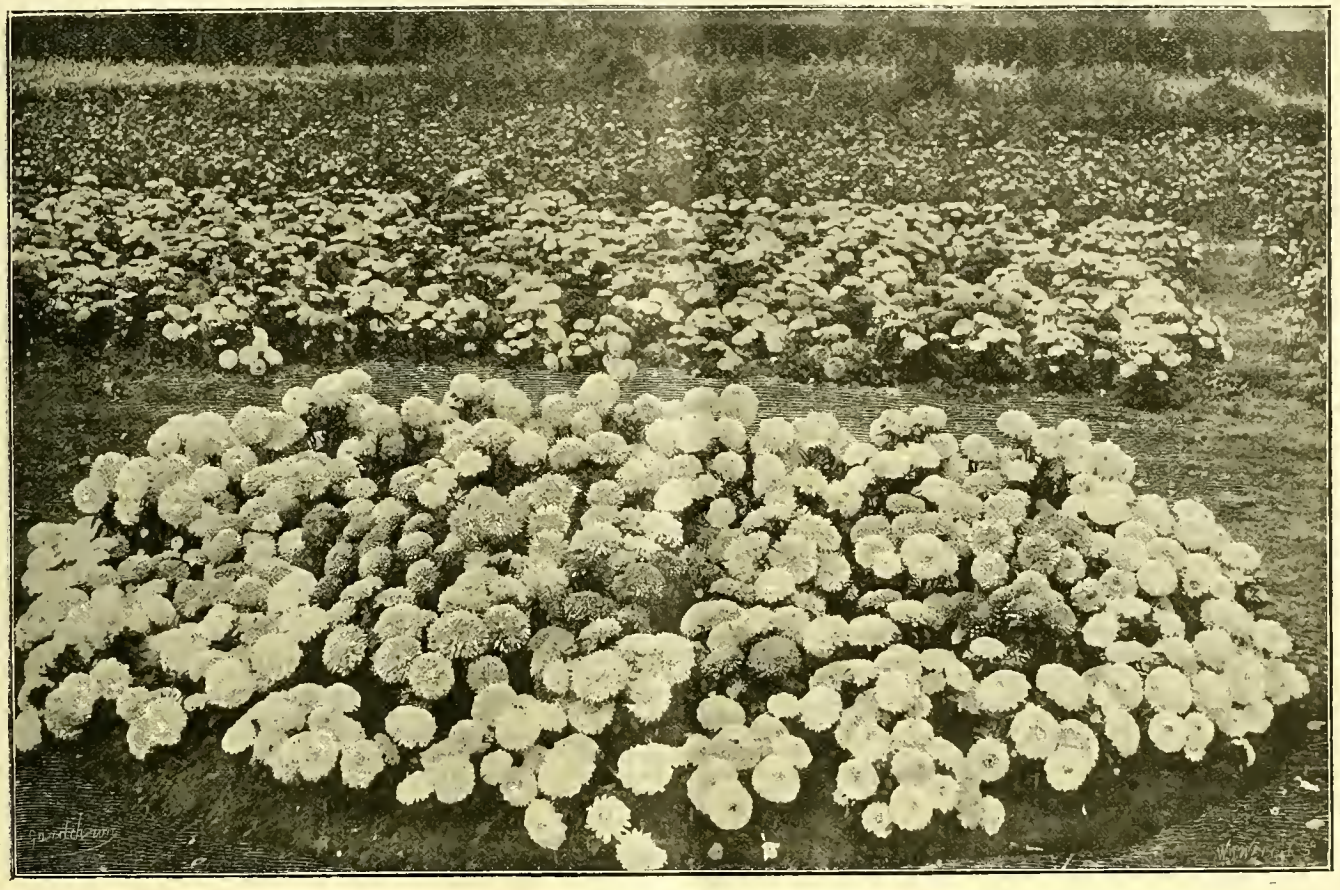

Fig. 115.—bed of "victoria" aster.

BOOK NOTICE.

Orchids and Their Cultivation in Apartments. With fifty Illustrations. Published by Trewitzsch & Son, Frankfort-on-the-Oder.*

In this work of 100 pages quarto we have the opinions and experiences of an enthusiastic cultivator of these rare, extraordinary, and precious plants, Orchids. He has found that most of them are just as capable of cultivation in apartments as unprotected plants as many other species, and even more so; and he regrets that the general public has hitherto felt disinclined to take up their cultivation, seeing how easy it is with proper care and a correct knowledge of their requirements when in active growth and during the rest period.

The author has with commendable brevity endeavoured to enlighten his readers in every essential point of cultivation, and to clear away the prejudices that still find a place in the minds of many German amateurs and professional gardeners against Orchids in general; and in this matter

* *Die Orchideen und ihrer Cultur im Zimmer, von A. Braecklein. Mit 50 Abbildungen.*

he refers to the absence in many large towns of nurseries cultivating Orchids for sale, and of any publications dealing with the cultivation of the plants in the dwelling. Such a venture, as he remarks, is still in the cradle.

After a few short chapters on the habitats of Orchids from Siberia to the tropics, on the forms and build of the plants, the magnificence, the colouring and the never-ending variety of form and size of the blossoms, he remarks on their resemblance to insects, such as bees, butterflies, moths, spiders, birds of paradise, &c., instancing the scarlet flower of Ornithidium miniatum (Bird'a-head Orchid) and Zygopetalum Mackayi, which has a close resemblance to the human countenance.

The freedom with which established Orchids flower every year once, and in some cases twice, as with Cypripedium Calypso, C. barbatum and some others, and the abundance of the blossoms produced are alluded to as good reasons for the cultivation of the plants in apartments, as well as their powers of resistance to untoward conditions in an equal degree with Dracænas, Palms, Bromeliads and Plectogynes, which belong to the hardiest classes of room plants. Orchids in such places suffer but little from plant pests, are never the prey of snails, earwigs or caterpillars, as in glasshouses is generally the case; moreover the plants take up but little space.

Among the first plants to be grown in rooms with success were Cypripedium insigne, Lycaste Skinneri, the valuable Cœlogyne cristata, and somewhat later Odontoglossum grande, and many others, the names of which were given in *Praktischen Ratgeber im Obst und Gartenbau*, 1901—1904.

The raising of new varieties is greatly recommended as adding to the interest and profit of the cultivator; and a chapter is given detailing the four most common objections to room culture, viz., the lack of beauty in the flowers according to some; the high prices asked by the dealers; the assertion that the plants cannot be grown in rooms by any possibility, and that they cannot be so grown without some form of glass protection. Each of these is set up only to be knocked down, and methods of cultivation are explained by which successful results may be obtained, such as the heating, ventilation, affording water at the root and to the pseudo-bulbs, leaves and incipient flower-buds. These are matters of great importance in Germany, where, from the greater degree of cold in winter, the air in the rooms is much dryer than in English houses, owing to the constant warmth emitted by the stoves. Great stress is laid on sufficient ventilation and light as a means of averting the decay of the leaves and the formation of fungus in the potting materials so common in Orchid-houses under ordinary conditions. This is the first essential of good cultivation.

For some species, such as Cœlogyne and Odontoglossum Rossi, shallow, unglazed saucers are recommended. These should not exceed 2½ inches in height and 8 inches in width, or the side of plant looking inwards will be too far from the light. Wooden baskets are advised for species of Stanhopea, and others like them, that push their flower-spikes through the bottom of the receptacle.

As potting materials, the author leans towards coarse leaf-mould and living sphagnum, intermingled with coarse quartz sand to assist the drainage of water away from the mass. He thinks that the use of charcoal will decline, because of the use of materials containing more nutriment than is found in sand, crocks, charcoal, and Polypodium roots. The coarser the mixture of sphagnum and leaf-mould the better, and the sand should be well washed of all earthy particles. The application of water receives the attention it demands, and much good advice, evidently the result of years of close observation, is given, which should be of the greatest value to young and old practitioners alike.

The rejuvenation of Orchids has a chapter to itself, and it is made clear by an illustration. Insects and other enemies infesting Orchids fittingly round up the cultural part of the book. To this follows a list of those species of Orchids, with hints on cultivation, which up to the present have been found thoroughly amenable to room culture, among which we note Ada aurantiaca, Bifrenaria Harrisoniæ, Cattleya labiata Mossiæ, C. l. autumnalis, C. Schröderæ, C. Dowiana aurea, Cœlogyne (several), Cymbidium Lowianum; Cypripediums, many, including several crosses with C. insigne; C. Boxalli, C. Charlesworthi, C. Curtisi, C. hirsutissimum, C. Sedeni, C. Leeanum, &c.; Dendrobium Jamesianum, D. nobile, D. Ainsworthi, D. thyrsiflorum, and D. Wardianum, Lælia anceps and L. purpurata, Odontoglossum crispum, O. grande, O. luteo-purpureum, O. Pescatorei, &c.; Oncidium crispum, O. Forbesi, O. leuchochilum, O. Marshallianum, Stanhopea insignis and S. tigrinum, and Zygopetalum Mackayi.

To those of our readers who have an acquaintance with the German language, especially amateurs not in possession of a special glasshouse for the cultivation of Orchids, we would say, "Obtain this book, if only for the suggestive nature of its contents and the clear enunciation of the principles underlying these." The "why" and the "how" are abundantly described, and we have but little of the rule-of-thumb in evidence. *F. M.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Cymbidiums.—Nearly all the valuable species of Cymbidium, whether old or new, may be grown in a cool-house under similar conditions of cultivation. Flowers of C. Lowianum, if permitted, would keep in good condition for months, but for the benefit of the plants the flower-spikes should be removed at the end of a month or five weeks, and the needs of the plant supplied after a further period of one week or so. When repotting plants of this species, also C. giganteum, C. grandiflorum, C. Tracyanum, C. Winnianum, C. eburneo-Lowianum, C. elegans, and the new C. Sanderi, they should be put into moderately large pots containing drainage material to more than half their depth. The rooting medium may consist of a mixture of one-half peat, and a fourth part each of fibrous loam and sphagnum-moss, with a good "dash" of sand and small crocks to secure porosity. The above species are all in a fit state for being repotted or surfaced at the present time, when new growths are coming away. Stage the plants in a house that has ample means of ventilation, where there will be a natural atmospheric temperature of about 60° to 70° during the daytime, remembering that fire-heat will only be needed to keep the temperature up to near 55°. For a considerable time after repotting, a very moderate supply of water should be afforded. Provide shade from bright sunshine, damp the surroundings and spray the plants overhead on bright mornings. Admit air first through the wall ventilators, and when the temperature approaches to 70° open the top ones a little. During the early summer months close the top ventilators early in the afternoon and syringe the plants overhead, but on the approach of autumn expose the plants to the cool dewy night air by leaving all ventilators open. Afford copious supplies of water when the plants are rooting freely, and to those that have not been repotted during the season a little weak liquid farmyard manure may be given.

Cymbidium eburneum, the gem of the genus, must be provided with more shade than is required for those species enumerated above, and may therefore be staged beneath some of the larger plants. So long as the drainage of these plants is in perfect order repotting is seldom necessary, as the old decayed materials may be picked out and be replaced with new. To the mixture recommended for the other species may be added some old lime mortar-rubble. Use smaller pots, in proportion to their size, but otherwise treat the plants similarly to other species. C. Mastersianum and the new C. Sanderæ require similar treatment; C. devonianum and C. tigrinum thrive in the Masdevallia-house, and unless the plants are of large size, they are best suspended. They may be planted in well-drained pans, in the compost recommended for C. Lowianum. It is only when growth is most vigorous that much water is needed, and even then the compost should be allowed to become almost dry before a fresh supply is given. Repot or re-surface the plants when new growths appear, which in their case will not be until the season is well advanced. Thrips being the only enemy of importance to Cymbidiums, these can be kept under with the usual vaporising compounds. The warm-growing species, such as C. aloifolium, C. Findlaysonianum, C. madidum, &c., need a very restricted supply of water, except when rooting freely and the weather is hot and dry. They are of little horticultural value.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Withes, Esq., Copped Hall, Epping, Essex.

Richardia (*Calla*) *Elliottiana.*—Plants that were started into growth early in February and have flowered, should be encouraged to make growth by allowing them to remain in a warm, moist atmosphere until they are fully matured, and in the meantime should receive copious supplies of diluted liquid manure, obtained from soaking sheep droppings, and an occasional sprinkling with Clay's Fertilizer. When the foliage shows signs of turning yellow gradually withhold water and harden the plants off, finally removing them to a cold frame where they will be fully exposed to the rays of the sun. Here they will ripen, and water must be entirely withheld.

Nerine Fothergillii.—Care must be taken not to ripen the bulbs off too quickly; a good season of growth and a long resting period are essential to get the plants to flower, and if the same treatment is afforded them as advised for Calla Elliottiana, no difficulty should be experienced. Unless it is desired to increase the stock, the bulbs should not be disturbed, an occasional application of artificial manure and liquid feeding being sufficient for their requirements for a long time.

Rhododendron (*Azalea*) *indicum.*—Remove the flower-stalks carefully from plants which have passed out of bloom, and examine the leaves for thrip. These insects should be removed by fumigating, or dipping the plants in "Quassia Extract" or a solution of "Gishurst Compound." Azaleas are most serviceable for furnishing a conservatory or corridor, and should be given the little attention they require. Encourage the plants to make satisfactory growths by placing them in a warm atmosphere for a time, and by shading them from the direct rays of the sun. Syringe them freely about, above, and beneath the foliage. If repotting is necessary the work may be done at once, but if the plants are required for "furnishing" purposes it is necessary to keep them in as small pots as possible, and in this case a top-dressing only should be given. Good fibrous loam, pulled to pieces by hand, with a little leaf-soil and silver sand added, will form a suitable compost. When growth is finished the plants may be gradually hardened and removed to a position out-of-doors, where they will have slight shade.

Boronias heterophylla, elatior, and megastigma, —The plants should be pruned somewhat severely, and treated in the first instance as advised for Azalea indica, but when they have completed their growth should thereafter be kept in a cool-house or frame.

Gardenias.— A batch of cuttings should be propagated each season, and the plants kept for two years only. Let cuttings be taken at the present time. Plants that are to be grown-on for another year should, after flowering, be cut back a little and top-dressed with fresh soil. A little bone-meal dusted round the roots before the new soil is added will benefit them. Shade the plants from the direct rays of the sun, and syringe them freely.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Disbudding.—The instructions on this subject given in last week's Calendar applied to Peach and Nectarine trees, but disbudding may be practised upon all kinds of fruit-trees, and if carried out skilfully the branches may be so arranged and controlled that the tree will be more fertile than if periodically pruned by means of a knife. The energies of the tree also will be directed to the formation of fruit buds. Examine horizontally-trained trees of Pears, Apples, and Plums, and in the first place give attention to those shoots which are to form the extension of the tree. Of the growths proceeding from the extremity of the leading branch, choose one on either side, to be tied or nailed-in horizontally as growth proceeds, and a leading shoot to be trained in an upright direction. Other growths proceeding from below the two shoots which are to be tied-in should be removed entirely or pinched so that the sap may be directed to the development of the others. If the trees are growing against walls young shoots growing towards the wall may be removed entirely, and a judicious thinning of the growths be made throughout the entire tree, so that each individual shoot may have free light and air circulating about it. If it is found that in some cases the terminal bud on growths required for extending the tree is a flower-bud, remove this, and select the next nearest growth to form the extension.

Fan-trained Trees.—Choose shoots in the best-placed positions throughout the tree for laying-in, and remove some entirely if they will not be required, the remainder should be subsequently pinched to about three leaves. Plum trees and dessert Cherries fruit very freely from spurs, therefore the formation of these should be encouraged. Old trees may have young shoots laid-in throughout the tree to fill the place of barren branches, which should be removed entirely in the autumn.

Strawberry Plants are now showing their flower-trusses, and the plantations should be afforded a mulching with some strawy litter to keep the fruits from coming into contact with the ground, or from being splashed with rain, which would make them gritty and unfit for use. If the litter be left in a somewhat uneven state and partially covering the plants, it will act as a protection to the blossom should frosts occur, for the Strawberry bloom is very tender, and the early flowers are often destroyed by 2° or 3° of frost.

The Loganberry, Blackberry, and Rubus of sorts are now throwing up suckers from their base; select only sufficient of the strongest for laying-in to fruit next season, and remove all others, continuing this operation from time to time during the season, as they make their appearance above ground.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Asparagus.—The cold winds and frosts (5°) experienced here recently have retarded vegetation, and few vegetables are more sensitive of change than is Asparagus. Examine the beds every morning, and make every effort to gather the shoots when they are 6 inches long, in order not to spoil the appearance of the "dish" by lack of uniformity. Asparagus plants are sometimes injured by being cut too severely. Where there is sufficient space there is something to be said for the practice of having a bed in reserve and cutting from the plants every other year only. In any case it is essential that a sufficient number of growths should be left to enable the plants to grow well and produce good "crowns" for the following season. Young plants should not be cut until the third year, and even then only a few of the strongest shoots should be cut from each stool. When gathering Asparagus we never use the knife here, but with a wooden peg in the shape of a label remove a little soil from around the shoot, gripping the shoot between finger and thumb, and then by a simple twist the work is done without the risk of causing damage. Asparagus should be eaten as soon after being cut as practicable, or the flavour will not be so good. Prevent weeds from growing by lightly disturbing the surface of the soil.

Brussels-Sprouts.—Plants that were pricked-off early we are now planting in the open ground in rows 3 feet apart, and allowing 2 feet between the plants in the rows. In order that the plants may become well studded with firm, compact sprouts they must have sufficient space to stand clear of each other when fully developed. The soil need not be very rich, but it should be made moderately firm. Sutton's Exhibition and Dwarf Gem are good varieties of this valuable vegetable.

Cabbage "Ellam's Early" and Cauliflower "Extra Early" sown at the same time are now being planted. The distance allowed between the lines is 18 inches, and the plants are put 12 inches apart from each other.

Broccoli.—The unbroken supply of this vegetable affords evidence of what the season has been like. Leamington having done good service, is followed by Model, the best of all late spring Broccolis.

Lettuce.—Tie up for blanching plants that were put out in the autumn. Bath or Brown Cos is the variety used here for planting at that season, and no Lettuce to my knowledge is more worthy of general cultivation, because of the agreeable nutty flavour it has. Fortnightly sowings will be necessary to maintain a supply, and if the seeds are sown thinly where they are to remain until matured they will not run to seed so soon. Superb White Cos and Perfect Gem are suitable varieties for sowing at this season.

Tomatos.—We are now putting into 6-inch pots plants that will be planted out in June. Tomatos will succeed in any ordinary soil, if a good sprinkling of wood-ashes be added and care be exercised in the matter of affording water to the plants. The single stem system of training is the best under glass or in the open. Keep the plants at present near to the glass, and afford ventilation freely.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Fruiting Pines.—The earliest Queens that were started at the beginning of January will now be swelling their fruits rapidly, and will require special care. Recent weather has included many sudden changes; the work of ventilating the structure has been one of much difficulty, it being essential to avoid having occasion to unduly heat the water-pipes. Close the house early, and allow the atmospheric temperature to rise to 95°, provided that there is plenty of atmospheric moisture. Spray the fruits and plants overhead lightly at closing time. Liquid manure and guano-water may be afforded the plants once or twice each week as required, and a handful of guano should be placed in the evaporating pans occasionally. Syringe the surface of the beds and the base of the plants with guano-water, and damp the paths with liquid manure. Afford slight shade to the plants during the very brightest part of the day, and let the amount of ventilation be determined by the power of the sun's rays at the time. Keep the atmosphere of the house slightly drier when the fruits change colour, and discontinue the root-waterings, or the plants may be removed to a vinery where the Grapes are colouring or other suitable place where the atmosphere is cooler and drier than that of the Pine-stove.

Plants in Flower.—Keep these in slightly drier conditions until the flowers are fertilised, and afterwards give them similar treatment to that advised for the earliest plants.

Successions.—Admit air freely on favourable occasions to the compartment containing plants that have become established, and maintain the bottom-heat steady. Take advantage of bright days to close the house early. Syringe the beds and all available spaces, and lightly spray the plants overhead at closing time. As the plants increase in growth give them occasional waterings with liquid-manure and soot-water, applying the liquid at the same temperature as that of the bed. Provide slight shade from bright sunshine. Pot-up fresh suckers according to the requirements of the establishment.

Strawberries.—Where sufficient plants are grown to provide a continuous supply of ripe fruits until Strawberries ripen out-of-doors, it is necessary to remember that the plants will now require more plentiful supplies of water, and they should be syringed freely to keep them in a clean and healthy condition. All plants should now be removed from vineries and Peach-houses, and be ripened in a cooler house or Peach-case, where the water from the syringe can be applied more effectively. Thoroughly wash and cleanse the shelves that have been used for Strawberry-plants, with some insecticide to clear them of red-spider. Later plants in cold pits or frames may be retarded by admitting abundance of air, or even by removing the lights on bright days. If it is necessary that they be pushed forward, syringe the plants lightly, and close the structure early in the afternoon.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Roses.—Tea Roses in pots and intended for planting-out may be planted during the present month, either for the furnishing of new beds or to fill up blanks in others. Free-growing varieties, such as Madame Lambard and Marie van Houtte, are most reliable. Look out for caterpillars, and crush them between the finger and thumb. Have some Compound Liquid Quassia Extract, or a preparation of nicotine and soft-soap, in readiness to use against greenfly. Sulphur specifics may be necessary to destroy mildew. Let the surface of the beds be hoed and raked on favourable occasions.

East Lothian Stocks.—Plants that have been raised from seeds sown in February will now be ready for planting into the beds or borders. Let the soil be well worked, and incorporate with it a plentiful supply of rich manure.

Antirrhinums are admirably adapted for cultivation in dry and sunny positions. Plants that were rooted last autumn may now be put out. Antirrhinums raised early this year may be planted out in the middle of the month.

Alpine Plants.—The present is a suitable time for planting these. Bear in mind that though the plants are of small size, they nevertheless require a depth of soil of at the least 18 inches. Be careful to plant firmly, and see that there are no unfilled spaces amongst the fissures. Morisia hypogæa (yellow) is almost a perpetual flowerer, and is of very easy culture. It lies close to the ground. Aubrietia "Craven Gem" is a superb purple-flowering variety, and A. "Dr. Mules" is of good merit. Saxifraga "Guildford Seedling" is rich and deep in colour.

Cannas.—Roots that have been stored all winter in a frost-proof shed should now be put into boxes in any light soil, and placed in moderate warmth, in order to induce them to start into growth. The plants require a warm and sheltered position, also a rich, deep soil. They are effective in beds, and are useful for filling up blanks in borders of mixed plants.

Early-flowering Chrysanthemums.—Suckers that were put into boxes last autumn, and that were wintered in a cool-house, are now hardened off. They are sturdy plants, and will soon be fit for planting into the borders. The various forms of C. maximum (Shasta Daisy) are invaluable. Use autumn-struck plants or divisions obtained from old plants.

Violets.—New plantations may now be made. Pull the old stools to pieces, and select the strongest offshoots. Plant them in a border that is very slightly shaded, and one on which a good dressing of well-rotted hotbed-manure has been incorporated.

"INSECT LIFE."—We have received a book entitled *Insect Life*, a short account of the classification and habits of insects, by FRED. V. THEOBALD. The volume is already in its second edition, and letterpress and illustrations alike seem to promise further success for it. We hope to refer to it at greater length as soon as space permits. The publishers are Messrs. METHUEN & Co., 36, Essex Street, W.C.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAY 9 { Royal Horticultural Society's Committees meet. National Rose Society's Committee meets.

THURSDAY, MAY 11 { Royal Gardeners' Orphan Fund. Annual Dinner at Hotel Cecil at 6 30 for 7 P.M.

FRIDAY, MAY 12—Royal Botanic Society's Lecture.

SALES FOR THE WEEK.

WEDNESDAY NEXT—
Palms, Plants, Liliums, Herbaceous and Border Plants, Ferns, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY NEXT—
Imported Orchids, by order of Messrs. Sander & Sons, Renanthera Imschootiana, Established Orchids, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —53·2°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May* 3 (6 P.M.): Max. 59°; Min. 35°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May* 4 (10 A.M.): Bar., 30·2; Temp., 55°. Weather dull with occasional sunshine.

Hereditary Transmission of Anomalies caused by Wounds.

A paper is published under the above heading by M. BLARINGHEM in the *Comptes Rendus* for February 6, in which the author says that trials commenced in 1902 and successfully carried on since appear to justify the following hypothesis:—When the aërial shoots of certain herbaceous plants are cut during a period of rapid development the development of numerous shoots is encouraged, and these for the most part present anomalies of the vegetative apparatus and of the inflorescence.

Cutting of the principal stems produced the following anomalies:—

1. Fasciation in the panicles of Maize, of the branches of Mercurialis, fusion of the branches of the panicle in Sorghum.

2. Torsion of the stems of Maize, Barley, Oats, and the branches of Mercurialis, displacement of the leaves of Maize which are grouped in whorls, alternate arrangement of the leaves of Mercurialis.

3. Metamorphosis of the male flowers or sterility in the female or the production of hermaphrodite flowers in Maize, Barley, Hemp, and Coix lacryma.

4. Increased number of stamens in the male flowers of Maize, the spikelets of Barley, of the spikelets on the lateral axis of Maize, on an ear of Barley, and of the panicle of the Oats In the same plant a a co-relation is shown between its several anomalies. Thus fasciation of the branches of the terminal inflorescence of Maize involves the metamorphosis of the male flowers into fertile female flowers. On many varieties of Maize the inverse anomaly was produced, the torsion of the ears during the progress of growth provoking a thinning of the axis and the metamorphosis of female into male flowers.

Actuated by these experimental results, M. BLARINGHEM sought and found, in artificial meadows that were cut several times before maturity, anomalies which he believes were due to a similar cause. At the beginning of September, 1904, and in the same locality, where the soil is very fertile, he found in the fields of Trifolium pratense sown that year a proportion of from five to eight per thousand plants bearing leaves with four or five segments, and in the fields where the same variety, sown the previous year, had been twice mown a proportion of from twelve to thirty-seven per hundred of abnormal plants. The anomalies in the latter instance were present in many cases on the same plants; the leaves had from four to eleven petioles, and showed pitcher-like growths. Further, the shoots of Onobrychis sativa (Sainfoin), after cutting, showed in the pinnate composite leaf, leaflets grouped in threes and fours. Lolium perenne under the same conditions had branched spikes or multiple spikelets given off from the same point. The most curious anomaly was furnished by Leucanthemum vulgare, which showed plain traces of the stems having been cut; in one case the ligulate flowerets of the ray were partly transformed into tubular florets; in another case the bracts of the flower-head bore in the axil supernumerary ligulate florets doubling, as it were, the crown formed by the strap-shaped florets of the normal flower-head. Some of these variations were particularly interesting, as they showed a hereditary transmission clearly traceable to an artificially induced anomaly.

The metamorphosis of male flowers of the terminal inflorescence of Maize into female flowers yields seeds that, in spite of the absence of self-fecundation, furnish a large proportion of distorted plants.

The degree of heredity attained by a plant mutilated in 1902, and seeds of which planted in 1903, was seventy-five per cent., and in 1904, in spite of the drought (which seems to be unfavourable to variation), about fifty per cent.

Further, for a variety of Vilmorin's Maize, which in consequence of cutting of the principal stem had put forth leaves and female ears in the twisted panicle, the torsion of the panicles was markedly inherited (sixty per cent.) in cultural experiments carried out in the Pas-de-Calais, as well as in the environs of Paris. This fact led the observer to seek a possible explanation of the cause of the hereditary variation of Dipsacus silvestris var. torsus, studied by DE VRIES. The learned Amsterdam professor announced that after having cut the principal stems of plants which had not inherited the anatomical peculiarity of the mother plants, he observed a very remarkable tendency to torsion in the shoots developed after the mutilation. He repeated the experiment for two successive years with the same result.

It would seem, then, that cutting the main stems of herbaceous plants in full growth induces exceedingly rapid development of adventitious buds, which receive perforce an excess of nutrition. In rich soil even the abnormal buds yield fertile seed, which reproduce the anomaly markedly. These injuries seem then as if they might be utilised in securing the appearance of characteristics latent in the plants that are in a state of "mutation," if they are not themselves one of the causes of these spontaneous and hereditary variations.

We may here add that we received from Professor DE VRIES, several years ago, seeds of the twisted Teazle which did not reproduce the twisted condition, nor have their descendants, which come up freely in the garden every year, shown any tendency to twist. Last year we endeavoured to induce torsion by pinching out the terminal bud and by other mutilations, but although adventitious buds are produced in abundance, the shoots preserve their normal appearance.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held at Vincent Square on Tuesday, May 9, when lectures will be given by Mr. N. HAYASHI on "Japanese Horticulture," and by Mr. R. E. FARRER on "Japanese Plants and Gardens," which he will illustrate by lantern-slides. It is hoped that on that occasion there will be a good exhibition of Japanese trees and plants.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the lecture hall on Monday, May 15, 1905, when a paper will be read by Mr. J. D. WALLIS (Fellow), entitled "The Licensing Act, 1904, with special reference to the question of Compensation and Monopoly Value." The chair will be taken at 8 P.M. The Council has accepted an invitation from the Devon and Cornwall Provincial Committee of the Institution to hold the next country meeting at Exeter, on May 25 and 26. Visits have been organised to the principal places of local interest in Exeter, and excursions, as follows: (1) To Torquay and Totnes, and by steamer down the river Dart to Dartmouth. (2) To Plymouth, and by steamer to the Devonport dockyard extension works, the Devonport and Keyham dockyards, and other places.

SALE OF ORCHIDS AT BANK HOUSE, ACCRINGTON.—The first day's sale of duplicates on Tuesday last in the collection of R. BRIGGS-BURY, Esq., successfully presided over by Mr. HAROLD MORRIS, of the firm of Messrs. PROTHEROE & MORRIS, 67 and 68, Cheapside, brought a total of just over £3,330. The three-hundred-and-fifty lots sold contained fair examples of many noted Orchids, but the highest prices were obtained for albino Cattleyas and Odontoglossums. Of white Cattleyas, C. Mendeli Quorn House variety realised 75 gs. and 90 gs. respectively; C. M. "The Queen," 26 gs.; C. M. Duchess of York, 24 and 23 gs.; C. Countess of Derby, a white Hardyana, 150 gs.; C. Schröderæ alba Bank House variety, 60 gs.; C. labiata alba Bank House variety, 75, 50, and 35 gs. each for the three plants sold. Many fine varieties of C. Mossiæ Reineckiana realised from 20 to 40 gs. each, and all fully sustained their values. Odontoglossum crispum Georgiana went for 40 gs.; O. crispum Petersii, 160 gs.; O. crispum Queen Victoria, 190 gs.; O. c. Mariæ, 85 gs.; O. c. Madame F. Peeters, 200 gs.; O. c. Queen Margherita, 120 gs.; and O. c. Mrs. F. Sander, 55 gs. Other good prices were obtained for Lælia tenebrosa Walton Grange variety, 70 gs.; Cypripedium × Mandiæ, 30 gs.; C. × Milo Westonbirt variety, 20 gs.; C. × aureum Surprise, 18 gs.; C. insigne aureum accringtonensis, 22 gs.; C. insigne Berryanum, 28 gs. C. insigne Harefield Hall variety and other rare Cypripediums sold well. The amount realised from the sale on the first day was £3,330, and on the second day £2,763, making together a total of £6,093. The interest in the sale continued to the last lot, and all the good things rather rose than declined in value. On the second day the best prices were Odontoglossum crispum Madame Valcke, 140 gs.; O. c. Duchess of Connaught, 150 gs.: O. c. Petersii, 150 gs.; O. c. Charlesworthii, 50 gs.; Cattleya labiata alba Bank House variety, 60 gs.; C. × Hardyana alba, 50 gs.; C. Countess of Derby, 140 gs.; C. labiata alba, 36 gs.; and others at equally good prices.

THE "ECKFORD" MEMORIAL.—The secretary, Mr. HORACE J. WRIGHT, reports that up to the present time 440 shillings have been contributed to this fund.

SEEDLESS APPLES.—As we have already intimated these are no novelties, nor are they of such quality as to render them desirable for commercial purposes at present, although as botanical curiosities they will always be interesting. Mr. W. T. MACOUN, the Government horticulturist at Ottawa, has an article in the *Canadian Horticulturist* for April, in which the conclusions we have above mentioned are elaborated in detail. A still more vigorous statement is made by Professor CRAIG, of Cornell University, in the same number. The whole story, says he, "of this wonderful creation savours of quackery, and I am inclined to lose patience with horticultural journals which offer their columns to the exploiting of an absolutely unknown plant-production in this generous, free, and decidedly unsophisticated manner. Can it be that horticultural journals are becoming inoculated with the germ which develops a craving for sensationalism? Are they imitating the yellow hue of some of their strictly news-dealing contemporaries?" We do not think the English horticultural Press in general can fairly be accused of proving false to their trust in this matter. It stands aside in wonderment at the random statements in the lay Press, but it does not endorse them, nor adopt the sensational methods which are creeping into journals even of the highest standing. The expression "absolutely unknown" above cited must be taken in a limited sense, as is obvious from the context.

—— The two specimens of this Apple which were purchased by Messrs. SHEARN & SONS, of Tottenham Court Road, some weeks ago, and about which so much has been written, were, as we are informed, cut open, in the presence of several representatives of the Press, on Tuesday the 2nd, when it was found that the Apples had well-matured seeds and quite a hard woody core. In cutting a Tasmanian Apple it was found to have much less core. The above result will not surprise those who understand the subject, but there are doubtless many who have believed in the phenomenon, and we know there have been a good many anxious to procure trees, therefore they should be undeceived.

THE INTERNATIONAL BUILDING TRADES' EXHIBITION, held during the past week at the Royal Agricultural Hall, Islington, London, N., was of interest to those concerned in the management of estates, and contained some exhibits more or less instructive to those having gardens under their charge. There were to be seen the latest devices for cheap and expeditious erection of buildings, outhouses, and the like; the best preservatives for coating perishable woodwork, &c.; the thousand-and-one uses to which iron, wood, and stone are applied; garden furniture and ornaments, rustic buildings, improved methods of heating greenhouses and other buildings, economical fuel-consuming boilers, improved methods of ventilation, glazing, paving, and preserving glass and other structures, &c. The EXPANDED METAL CO., Ltd., York Mansions, York Street, Westminster, had many useful things, such as tree-guards, fencing, gates, arches, tennis-guards, &c., all constructed from their speciality, which is stamped out of solid sheet-iron. Messrs. HARTLEY & SUGDEN, Halifax, displayed on their stand the latest designs among boilers, radiators, hot-water piping, valves, and other engineering appliances. Messrs. T. W. PALMER & Co., Westminster, showed examples of cheap fencing, also tree-guards, buildings, &c. Preservatives for wood and iron-work were largely shown. Messrs. WALTER CARSON & SONS, Lombard Road, Battersea, showed their non-corrosive paint on woodwork treated with the same; also examples coated with "Vitrolite," a paint specially manufactured for the protection of conservatories and other horticultural buildings. The sanitary washable distemper known as Hall's Sanitary Water Paint, made by Messrs. SISSONS BROS. & Co., Ltd., is another inexpensive paint, and is recommended for almost any kind of building. Quite the latest styles in garden-gates were to be seen on the stand of Messrs. G. F. BRAGGINS & Co., Oxford. Messrs. FELTON & Co., Tudor Street, E.C., exhibited portable greenhouse heating systems, radiators, boilers, &c.

FORESTRY.—The Forestry Exhibition at the Royal Agricultural Show at Park Royal last summer was so interesting that we are glad to see that it is proposed to renew it this season, from June 27 to June 30. Offers of exhibits should be addressed to the Secretary, Royal Agricultural Society, 13, Hanover Square, London, W.

HORTICULTURE AT LYONS.—A horticultural exhibition will be held at Lyons from June 8 to June 18 in connection with the National Agricultural competitions. The jury will be chosen among those who are not resident in the city or its environs. All branches of horticulture will be represented.

THE ABUSE OF FLOWERS.—A correspondent sends us the following extract from the *Morning Post* of April 29:—

"The Easter decorations of Brixham Parish Church consisted of 27,336 bunches of Primroses, each bunch containing two dozen flowers. All the Primroses were picked by Sunday-school children, to whom book prizes were offered. A girl who picked 4,000 bunches won the first prize, and a boy who picked 2,940 bunches the second prize."

Our correspondent justly remarks, "Do you not think it would be well if real flower-lovers protested against this barbarous slaughter of lovely spring flowers? These thousands of bunches were presumably strung up without any water, and could therefore only last for a few hours or a couple of days at the most. How about the despoiling of the copses and lanes where people walk to enjoy the sight of these flowers, which would have gone on blossoming for perhaps a fortnight, and then produced seed? If this is 'Sunday-school' education, we shall have a much spoiled England in the future, because this paragraph is, I suppose, *pour encourager les autres*, and other gatherers will compete for prizes. Most of my life I have been planting Primroses, Cowslips, Narcissus, Anemones, Squills, Ornithogalum, and plants too numerous to add here in wild places, but never contemplated their being ruthlessly gathered in this way, to fade almost before they are blown. I thought of their cheering the eyes of the wayfarer who has no garden of his own. Every year I am obliged either to strip the berries of many of my large Holly trees, or throw lime on them shortly before Christmas, or they might chance to be cut down for decoration (in places where they are specially needed as screen or shelter). It has so happened a few yards from my place. Why cannot the church decorators be content with moderation in their decorations? A clergyman's wife told me some years ago that there was such keen competition now between parishes as to the extent and intricacy of the ornamentation of their churches that it was getting to be an overpowering burden; and this lady was really fond of her decorations, and a good gardener, and did not grudge time and trouble. But the growing tendency to extravagant and absurd redundance is serious, and I cannot help hoping that some commonsense comments may be coming forth from the public." We are in entire sympathy with the views thus expressed. If such vast quantities of flowers are required for this and similar purposes, let them be obtained from commercial establishments, where they are cultivated expressly for distribution. It should be everybody's business to help to maintain our lanes and woodlands as attractive and interesting as possible.

THE NATIONAL FRUIT GROWERS' FEDERATION AND THE ROYAL HORTICULTURAL SOCIETY.—A Conference has been arranged under the united auspices of these two societies for October 10, 11, and 12 next, when it is understood the following will be amongst the subjects of discussion: "Foreign Competition and how to meet it; Grading and Packing; Land Tenure and and Rating Difficulties; Railway Grievances; Proposed Establishment of an Experimental Fruit Farm by the Board of Agriculture; and Insect Pests." The chairmen for the different discussions will probably be Sir TREVOR LAWRENCE, Bart, Mr. A. S. T. GRIFFITH BOSCAWEN, M.P., Sir ALBERT ROLLITT, M.P., Col. C. W. LONG, M.P., and Mr. F. S. W. CORNWALLIS. As the great Autumn Fruit Show of the Royal Horticulutral Society will be held in the new Hall, Vincent Square, at the same time as the Conference, the combined attractions should secure a large attendance and a very successful gathering. Arrangements for this event will form part of the business at the Council and Annual General Meeting of the National Fruit Growers' Federation on May 8.

THE ANNUAL FESTIVAL OF THE ROYAL GARDENERS' ORPHAN FUND.—In connection with this event, which will take place at the Hotel Cecil, Strand, on Thursday next, we have once again to remind our readers that a larger annual income is needed if the Fund is to be enabled to help all gardeners' orphans who are in necessitous circumstances. As was shown in the report published on February 18 last, the amount received from annual subscriptions falls very far short of the sum required, and were it not for the money raised each year by means of the Festival Dinner the committee would only be able to afford assistance in a few instances, leaving the greater number of candidates totally unprovided for. The objects of the Fund are so good that it should not be necessary for us to plead them, and the expenses of management are low, and moreover they are covered by the interest obtained from investments. At the forthcoming Festival the President will be the Earl of MANSFIELD, and it is hoped that he will be accorded a very large measure of support. The Secretary, Mr. BRIAN WYNNE, whose address is 30, Wellington Street, Strand, will be glad to hear from anyone who will afford help, or can be present at dinner. Donations may be forwarded to any of the following Stewards:—W. R. Alderson, Bell Farm, Hersham, Walton-on-Thames; John Assbee, Market Office, Covent Garden, W.C.; W. Y. Baker, Thames Bank Iron Co., Upper Ground Street, S.E.; George H. Barr, 11, 12, 13, King Street, London, W.C.; W. Bates, Cross Deep, Twickenham, S.W.; Wm. Bull, 536, King's Road, Chelsea, S.W.; G. Caselton, Garden Superintendent, Crystal Palace, S.E.; George Cuthbert, The Nurseries, Southgate, N.; Herbert J. Cuthush, The Nurseries, Highgate, N.; W. H. Cutbush, The Nurseries, Barnet, Herts; James Douglas, V.M.H., Edenside, Great Bookham, Surrey; W. Howe, Park Hill Gardens, Streatham Common, S.W.; David P. Laird, Pinkhill Nursery, Murrayfield, N.B.; J. Lyne, Foxbury Gardens, Chislehurst; J. F. McLeod, Dover House Gardens, Roehampton, S.W.; J. McKerchar, 35, Giesbach Road, Upper Holloway, N.; H. B. May, Dyson's Lane Nursery, Upper Edmenton; George Monro, V.M.H., Covent Garden Market, W.C.; J. W. Moorman, The Lodge, Victoria Park, E.; T. A. Morris, 67, 68, Cheapside, E.C.; Whitpaine Nutting, 106, Southwark Street, S.E.; R. Hooper Pearson, 40, Brocklebank Road, Wandsworth, S.W.; W. Poupart, Marsh Farm, Twickenham; G. Reynolds, Gunnersbury Park Gardens, Acton, W.; E. Rochford, Mill Lane Nurseries, Cheshunt; W. Roupell, Harvey Lodge, Roupell Park, S.W.; T. W. Sanders, 124, Embleton Road, Lewisham, S.E.; R. Saxby, Westbury Terrace, Westerham, Kent Edward Sherwood, 152, Houndsditch, E.;

William Sherwood, Dunedin, Streatham Hill, S.W.; P. Murray Thompson, S.S.C., Secretary, Royal Caledonian Horticultural Society, 5, York Place, Edinburgh; W. P. Thomson, 25, Bollo Lane, Chiswick, W.; H. J. Veitch, F.L.S., 34, Redcliffe Gardens, S.W.; and J. H. Witty, St. James' Villa, Swain's Lane, Highgate, N.

TRANSFORMATION OF PRINCE'S RESTAURANT.—Not only has the Salle de Restaurant itself been redecorated and refurnished, but, most important of all, a fine winter garden has been added on the site formerly occupied by the shops on the Piccadilly front. These important works have been entrusted to the Société d'Entreprise et de Fournitures, of Paris, and have been executed according to the plans and designs of their architect, our friend and colleague Monsieur MARTINET, the editor of *Le Jardin*. To give a detailed description of the task that has been so successfully accomplished by the architect would be wellnigh impossible at this stage. From the Piccadilly entrance we enter into a handsome vestibule, from which we pass direct into the winter garden. The Louis XVI. style has been adopted throughout, giving to the interior an impression of beauty and delicacy. The lines of the vaults of the ceiling supported by ten pilasters of rose-coloured marble, the jardinières of living flowers, the tropical plants, the furniture and upholstery, give to this apartment the appearance of an imposing "orangerie," the parallel of which could only be found in the historical Trianon. At the end of this abode of flowers a statue of Flora will, a little later, complete this production of an artist's genius. Flowers in fact supply the general idea of the whole, for from the garden it is carried with great skill and with most striking and pleasing effects into the *salle* of the restaurant itself. Here flowers climb along the pilasters to the vaults above, intermingle with the consoles, entwine the panels, gently encircle the ceiling, to descend in a most natural manner down the electroliers. The idea is quite modern in its conception and execution, and yet the Louis XVI. style is strictly maintained. Beautiful paintings embellish the various divisions of the ceiling, the central one being worthy of special notice. It represents Apollo staying his chariot to dwell yet longer amongst the flowers before the temple of the Sun. Lower down and towards the centre flowers are arranged in bouquets which seem as if they were showered on to the assembled guests by groups of Cupids. This masterpiece of the painter's art is signed by MAITRE LEQUÊSNE, one of the most prominent French painters of the day. Four beautiful statues, the work of the young but already renowned sculptor DUCUING, and a pupil of FALQUIÈRE, representing Spring, Summer Autumn, and Winter, complete the decorating of this apartment. Apart from the electroliers of unique design and works of art in themselves, a very clever effect has been obtained by hiding electric lamps inside the cornices framing the various paintings of the ceiling, so that they will appear as if bathed in perpetual daylight. The appearance of the room will be extremely light, for white is the predominant colour, tempered by imperceptible shades of rose and ivory. The carpets display branches laden with delicate flowers, and even the table-lamps represent graceful stems ending in soft blooms within which electrical lights will be hidden. We may add that the Galleries of the Institute of Painters in Water Colours have also been entirely re-arranged and decorated.

MONSTERA DELICIOSA.—I received several requests for plants of this species, but two or three of them have got misplaced or thrown away. Will those who wish for plants apply again for them, and they will get them in due time? At present the weather here is rather cold for moving them. The plant is a large one, and will make eight or ten large, well-rooted pieces. *C. W. Strickland, Hildenley, Malton.*

PROPOSED ROSE SHOW AT SOUTHAMPTON.—The Southampton Royal Horticultural Society is endeavouring to make its coming summer exhibition the principal Rose show for the Southern Counties. With that end in view the Council have instituted a special subscription list, the proceeds of which are to be devoted to improving the classes in the schedule that are exclusively for Roses. The Council of the Society have themselves voted £20 to this fund.

PRINCESS CHRISTIAN AT CARDIFF.—On the arrival of H.R.H. Princess CHRISTIAN at Cardiff, on April 28, the Mayoress presented a bouquet made by Mr. BAGGESEN, Florist, Albany Road, Cardiff, and composed of Orchids and other choice flowers. Her Royal Highness stayed at St. Fagan's Castle for several days, where Lord WINDSOR has a very interesting and well-maintained garden.

FLOWERS IN SEASON.—We have received a box containing a number of choice varieties of Daffodils from Messrs. DICKSONS, Chester. The varieties, although not all of them new, embraced some of the best kinds in the various types, and exemplified the great divergences of forms to be found among Narcissus. Thus the giant white trumpet of Madame de Graaff differs widely from the corona of Elaine, while the form of flower of Queen of Spain is quite unique in itself. Lulworth and Albatross both possess an orange-scarlet chalice, but are otherwise quite distinct. The modest manner in which the variety Mrs. Camm hangs its head has the effect of keeping its pollen dry.

—— Mr. G. REUTHE, Keston, Kent, sends us a few "heads" of species of Himalayan Rhododendrons, which he declares to be quite hardy at Keston, provided the flowers are protected during severe frosts, and that the plants are moved during spring only. The varieties and species included R. Maddeni (white), R. Aucklandi (white), and a gigantic pink form of the latter species, R. Thomsoni (a very fine species, having large crimson flowers of a campanulate form), and R. arboreum album.

THE HAMPTON COURT VINE.—The old Vine at Hampton Court can now be seen in full growth, and revelling in its old age in an entirely new habitation. Could the Vine speak, it would doubtless tell a thrilling story of its emotions when last autumn its giant branches were detached from their old positions, hard pruned, swathed in coverings to give the eyes protection, then secured to some improvised supports whilst the old vinery was removed and an entirely new light one, more lofty, of three-quarter span-roof, and fitted with all the best appliances, was erected in its place. Still further, all the old floor of stone slabs, the ancient brick flues, and much of the former soil and useless base were cleared out, the large floor practically converted into a modern Vine-border, on which is now laid some movable wood trellises as footpaths for the use of the veteran cultivator, Mr. JACKS, who still has charge of the old Vine under Mr. MACKELLAR, of Frogmore. The public no longer has admission into the vinery proper, as before. Then the passage of several thousands of persons on particular days through the house not only created an undesirable atmosphere, but raised clouds of dust, coating foliage and fruit very harmfully. By cutting out a side room from Mr. JACK'S residence a semicircular lobby has been formed, divided from the vinery by a large glass partition. This lobby has both entrance and exit, and visitors can see the old Vine admirably without doing it any harm. Many loads of good turfy loam have been utilised to form a new border, and literally floor the house, and also to form a moderately-wide border outside. A broad gravel-path that formerly ran along close in front of the vinery has been removed, and a footway on an iron grating has replaced it. Already many of the previous years' rods are throwing capital breaks, and there is generally an excellent show. In a few years the Vine will be, no doubt, wonderfully improved.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—By the kind permission of Earl BEAUCHAMP, K.C.M.G., President of the Worcester Auxiliary, the beautiful gardens at Madresfield Court were thrown open to the public on Easter Monday. A small charge was made, and upwards of 800 people paid for admission, the sum of £32 being taken at the gates. The event was advertised as a "quiet day for quiet people." Some 500 picture postcards (the Rocks, Madresfield Court) were sent out, also 1,000 small circulars and 500 large posters; in addition there were advertisements in the local Press. Tea and other refreshments were provided in a tent erected near to the maze. The modern system of grouping and massing naturalised hardy bulbs and other spring flowers in the grass was to be seen at its best, giving great pleasure to many, whilst others admired and took notes of the up-to date collection of hardy flowering shrubs; others, again, devoted considerable time to an examination of the kitchen gardens, hothouses, the home nursery, or the complete collection of hardy fruit trees, now wreathed in all their glory of blossom.

BLAIRGOWRIE HORTICULTURAL SOCIETY.—The Society has published in pamphlet form a summary of the horticultural lectures delivered before the Society in 1904. The subjects treated of were:—Roses, by Mr. J. SIMPSON; Tomato-growing, by Mr. G. B. BEALE; Fruit-culture, by Mr. STORRIE; and Vegetables, by Mr. JOHN LAING. The lectures were evidently of a thoroughly practical character, and as such likely to be appreciated by working gardeners. The annual exhibition will be held on August 25, 26, in the Public School, Blairgowrie; and the second Chrysanthemum show in the Public Hall at the same place on November 9.

A REPUTED MOSQUITO-PLANT.—We have received the Annual Report for 1903—4 on the Gardens of His Highness the MAHARANA FATEH SINGHJI, Bahadur, of Udaipur, Mewar, and note that the Superintendent, Mr. THOS. H. STOREY, has been making experiments with a view of abating the mosquito nuisance. He says that he received seeds of Ocymum viride, the so-called mosquito-plant, from Sierra Leone, and planted this and Ocymum sanctum, but without visible effect. "I took," he says, "much interest in the cultivation of the latter plant, which grew most vigorously tall, and not unlike our English Nettle. I may mention that I tried bundles of each variety in rooms at my house, and watched the result. I found numbers of mosquitos settled on the drying leaves, but, so far as my experience goes, I have no belief in either plant for exterminating mosquitos."

ASHTON AND THE "BLACK LAD."—The usual ceremony of riding the "Black Knight," or the "Blake Lad," took place at Ashton-under-Lyne on April 24. Early in the morning a Blake Lad was to be seen riding about the principal streets, followed by a large crowd of people. The custom is one peculiar to Ashton-under-Lyne. It arose in the 15th century, and was established by Sir JOHN DE ASHTON, Lord of the Manor of Ashton-under-Lyne, a branch of which family is still in existence at Downham Hall, Clitheroe. Owing to the lands being overrun with a

destructive weed he appointed his son, Sir Ralph Ashton, to ride round and see that the tenants used all possible means to extirpate the weed. Tenants who neglected to do so were punished. What the weed was we are not told.

Wild Flowers.—Mr. F. E. Hulme, F.L.S., F.S.A., has prepared forty new drawings in colours of wild flowers, which will appear in the new and enlarged edition of his well-known work, *Familiar Wild Flowers*, the first part of which was published by Messrs. Cassell & Co. on April 27. In the new edition of this work there will be 320 full-page coloured plates, and in the first part is given an index in which all the flowers will be arranged according to their colour.

Objectionable Leaflets.—One of our contemporaries complains, with ample reason, against the practice of some newsagent or agents who inserted in its copies leaflets of an insulting character to the members of a particular Church. In another case betting circulars were introduced. Of course, our contemporary is in no wise to blame for these horrible procedures, and knew nothing about them till attention was called to the matter by outraged correspondents. As it is possible that similar malpractices may have occurred in our own case without our knowledge, we join with our contemporary in its protest.

"The Culture of Sweet Peas."—Under this title the Agricultural and Horticultural Association, 92, Long Acre, W.C., has published a *brochure* by Mr. Richard Dean, which is to be the first of a series of "One-and-All Practical Handbooks." It is a useful paper, already in its third edition, and should be well received by those with small as by those with large gardens. The information given is up to date and quite trustworthy. Various illustrations are included. Mr. Richard Dean writes with authority as one of the founders of the National Sweet Pea Society.

The Garden City Association. — According to the April issue of *The Garden City*, this Association is making considerable progress. The above-mentioned periodical contains an article by Mr. Thomas Adams on "Garden City in the making," in which he mentions the building of cottages and factories connected with the scheme. There are also pages relating to Mr. Cadbury's village of Bournville, on allotments for Londoners, and on how to make a garden, by Mr. R. C. Notcutt. Notes and news connected with the Association are also included. We notice that Messrs. Bemrose & Sons, of Snow Hill, E.C., are publishing a book by Mr. A. R. Sennett, entitled *Garden Cities in Theory and Practice*.

Kew.—Go when one may, one is always sure to see something interesting in the National Garden. Just now, in the little morass in the rockery devoted to the species of Meconopsis, M. integrifolia, with its large globe-like flowers of softest primrose-yellow, is very attractive. This is decidedly one of the finest introductions among hardy plants that has ever been made. There is also a plant of Aubrietia "A 1" in the rock-garden which is almost startling in the size and brilliancy of its flowers. It was raised, we believe, by Mr. Prichard, of the Christchurch Nurseries, and deserves to be better known. In the tank in the Victoria-house the stately Lissochilus Mahoni rears its elegant spike. Apparently it is very like L. giganteus, figured in the *Gardeners' Chronicle*, May 19, 1888, p. 617, but in the absence of a ladder or a lift it is not possible to examine the flower (see also *Gard. Chron.*, April 22, p. 250). Among other Orchids in bloom are Chloræa virescens, a beautiful terrestrial species, with spikes of yellow flowers streaked with red, and with the lip studded with short, strap-shaped processes. Cymbidium rhodocheilum is remarkable for its green flower-segments spotted with red and the pale carmine-coloured lip. Streptocarpus Haygarthi forms a fine group at one end of the T-range, and in the same range is now in flower a small plant of the highly curious and by no means unattractive Euadenia eminens, of which an illustration was given in the *Botanical Magazine*, t. 6578.

Horticultural Club.—Mr. E. H. Wilson has promised to read a paper entitled "Journeyings through China" at the next meeting of the Club on May 9.

Publications Received.—*Chelsea Window Gardening, or some Notes on the Management of Pot Plants and Town Gardens*, by L. M. Forster. An inexpensive and useful little pamphlet, published by T. Fisher Unwin.—*Bulletin of Miscellaneous Information, Trinidad*, April. Contents: Phosphoric acid required by Cacao; Cacao Disease; Cuba's Agricultural Experiment Station; How a small Settler should Cure his Coffee, &c.—*Agricultural Bulletin of the Straits*, February. Contents: Facts about Gutta-Percha, A. M. Burn-Murdoch; Timber Trade in the Dindings, &c.

ORCHIDS AT KEW.

Epidendrum ciliare, *L.*—A grand specimen is now in flower. It forms a conical mass, composed of a large number of Cattleya-like growths, with pseudo-bulbs 6 inches in length, the leaves being from 6 to 8 inches long; the terminal racemes are four to eight-flowered, each flower having a diameter of 5 inches. The sepals and petals are rather narrow, and greenish-white in colour. The beautiful fringed lip is pure white, being the most prominent part of the flower. There are between seventy and eighty flowers open on this plant, making a very fine display.

Dendrobium undulatum, *R. Br.*

This species has very stout growths, 6 to 8 feet in height, with leathery leaves 3 to 4 inches long by 2 inches broad. The Kew specimen is now carrying six large racemes, the flowers of which are of brownish-yellow colour and about 2 inches in diameter, the sepals and petals being much undulated on the margins. The largest raceme on the plant is bearing forty flowers. The species is a native of N.E. Australia.

Dendrobium chrysotoxum, *Lindl.*

This well-known species is well represented by a finely flowered mass of growths, having a diameter of about 2 feet, and carrying eighteen spikes, each of which is composed of from twenty to twenty-five of its beautiful bright yellow flowers.

Other Orchids in Flower.

The following list is a selection from the large number of Orchids now in flower, and represents about half the total number:—Cyrtopodium punctatum, Cynorchis kewensis, Bulbophyllum falcatum, Megaclinium falcatum, Aërides Michotzii, Lissochilus Mahoni, Oncidium leucochilum, O. exasperatum, O. Marshallianum, O. superbiens, Chloræa virescens, Epidendrum elegantulum, E. elongatum, E. glumaceum, E. kewense, E. O'Brienianum (this last-named species is a large plant, with growths 6 feet in height, the dense heads of bright red flowers being very handsome), Lælia Latona, Lælia-Cattleya highburiensis, Cattleya intermedia, Broughtonia lilacina, Maxillaria Sanderiana, M. flava, Dendrobium albosanguineum, D. atroviolaceum, D. Bensonæ, D. Devonianum, D. pulchellum, D. Loddigesii, Masdevallia O'Brieniana, M. simula, M. tridactylites, M. Chestertoni, Plocoglottis Lowii, Leptotes bicolor, Diacrium bicornutum, Eulophia delicata (n. sp. Rolfe), E. Keithii, E. andamanica, Odontoglossum retusum, and many well-known species of this genus; Mormolyce lineolata, Epiphronitis Veitchii, Aspasia lunata, Physosiphon Moorei, Saccolabium gemmatum, Dendrobium Parishii, D. hercoglossum, and Maxillaria sanguinea. *W. H.*

KINGSWOOD, SYDENHAM HILL.

[See Supplementary Illustration.]

The Supplementary Illustration to this issue affords a view of one of those ornamental structures found in pleasure grounds and gardens, and which, when utilised with good taste and with due consideration of their surroundings, are very effective. Kingswood, wherein is contained the scene depicted in our illustration, is a truly suburban residence. It is situated on the confines of the metropolis, on the borders of Kent and Surrey, at Sydenham Hill, the heart of a large residential neighbourhood, near to the famous Crystal Palace and its beautiful grounds.

The estate at Kingswood occupies an area of over thirty-two acres, most of which consists of lawns and grasslands, and is thus a moderately large demesne for one situated so near to the City of London, Unfortunately, it is at present unoccupied, and the small garden staff retained cannot do more than maintain the grounds in a degree of order. Although the estate cannot lay claim to be regarded as a show place, it nevertheless contains many interesting and picturesque features. The ornamental water, which is spanned by the bridge shown in our picture, has been formed with exceptionally good taste by Messrs. Pulham, and is a pleasant feature immediately opposite the mansion—a handsome castellated building faced with Kentish rag. A view from the bridge enables one to enjoy a fine panorama of the surrounding district. To the right can be seen the immense structure of the Palace, its glass roof on the occasion of our visit scintillating in the bright sunlight; to the left is seen the palatial building of Dulwich College, while nestling in the vale below and crowning the heights around are many other stately edifices standing in their well-wooded grounds. The water below winds its course here and there, interrupted now by a miniature island, and again by an abutment of ornamental rock-work, one of which is fashioned to resemble a miniature Merlin's cave, and forms an excellent boat-house. The late owner, J. Lawson Johnson, Esq., greatly favoured the use of ornamental rock-buildings in the grounds. A dripping pool constitutes a pleasing feature by the side of a walk, while on the terrace adjacent to the house are two fairy caves, down whose sides trickle tiny streams of water, the interiors of the caves having splendid imitations of stalactites and stalagmites, which one could easily imagine were produced naturally by the dripping water. Lower down the grounds is a well-modelled imitation of a ruined castle that forms a charming retreat, and from whose tower can be enjoyed a delightful view. Fountains too are placed on the lawns and by the side of the drives, and when the whole of these fantastic embellishments are illuminated by hundreds of electric lights at night-time the scene must be one of grandeur.

The glass-houses and gardens proper are not extensive, indeed the former are showing need of a new owner who would restore them to their former worth. One structure, the Camellia-house, is executed on well-proportioned lines, and forms a worthy adjunct to the mansion, while a very handsome conservatory is attached to the residence. The inmates of the houses are such subjects as are useful for summer bedding purposes — Hydrangeas, Fuchsias, Ivy-leaved and zonal Pelargoniums, &c.—and plants of decorative value in the residence. The Camellias are now at their best, while a batch of Azaleas were looking first-class, and demonstrated the capabilities of Mr. A. Thorn, the gardener, even with a reduced staff and an empty stoke-hole. Mr. Thorn has been connected with Kingswood for over fourteen years, and we hope the time may hasten when he will be allowed to exercise that pride in restoring the grounds and gardens which would be his delight.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

WALLFLOWERS.—I am sending a few specimens of two varieties of Wallflowers, Canary Bird and Kinver Favourite, which are greatly admired here. They are of dwarf, bushy habit, and come remarkably true to colour. *W. H. Shaw, Horsley Hall Gardens, Gresford, April* 27. [The flowers of the varieties Canary Bird (colour golden-yellow) and Kinver Favourite (colour deep crimson) are exceedingly good. ED.]

TACSONIA MOLLISSIMA FRUITING IN THE OPEN.—When at Falmouth in the first week of April I noticed that a climber on a cottage about a mile from Helford River Passage was bearing a number of white, egg-shaped fruits. Entering the gateway and walking through the small garden to the house I found that the plant was Tacsonia mollissima. I was told by the occupier that it usually fruited, and was given two of the seed-pods. These were ivory-white in colour, and about 3½ inches in length, and were filled with ripe seeds. I have no doubt that this Tacsonia has fruited in other gardens as there are large plants at Trebah, close to the cottage referred to, and also in Mr. Howard Fox's garden at Rosehill, Falmouth; but I have never personally met with it fruiting in the open before. *S. W. Fitzherbert.* [Tacsonia mollissima has usually elongate fruit, tapering at both ends, and of a greenish-yellow colour. ED.]

BLACK CURRANT BUD-MITE.—I purchased some three years ago three varieties of Black Currant-bushes from a nursery which became badly infested with the mite. All the affected buds were picked off the first season, then the trees were cut to the ground in the winter. The following season each shoot which grew up from below was infested with mite. The trees I have dug up and burnt this spring. Two months ago I visited the nursery from which the purchase was made, and to my surprise I saw that the whole stock of Black Currant-trees in this nursery was infested with the mite. Now I am wondering how many gardeners and market-growers have purchased their stock from infested sources, and if there is any nursery in England where clean, healthy young Black Currant trees can be bought. What can be done to prevent nurserymen sending knowingly infested stock to different parts of this and other countries when executing orders? *Head Gardener.*

CUCUMBER SPOT.—Mr. Ward, in a letter in the issue for April 22, stated that I unwittingly misrepresented him by attributing to him the suggestion that among other causes likely to invite an attack of this disease was the heavy cropping of the plants in market gardens as compared with the lighter cropping practised in private gardens, where the disease is practically unknown. The following is what Mr. Ward said in the issue for February 18 in commenting on the freedom from the disease enjoyed in private gardens:—"Moreover the plants in private gardens are cropped lightly, the young fruits being thinned out, the object being to obtain a regular supply of a few dozen fruit a week from a given number of plants, say a period of five months, whereas the object of the grower for market is to take all the saleable Cucumbers that the plants under skilful and generous treatment are capable of yielding in as short a time as possible." On reading the above in a discussion on the probable cause of this disease of the Cucumber most people, I think, would take it to mean that Mr. Ward wished to infer that the over-cropping and over-forcing of the plant in market gardens, with the natural consequence of the more or less enfeeblement of the plants, might be taken as a contributing cause to its presence in market gardens, and its absence in private gardens. If this was not his intention, it is difficult to understand the reason why he wrote the paragraph in this connection. *O. Thomas, April* 29, 1905.

ANTI-DRIP APPLIANCES.—In reply to Messrs. Foster & Pearson's remarks on p. 234 in the issue for April 15, I may say that I can get the inch beading as illustrated on p. 86 in the issue for February 11 already bevelled for the cost mentioned, and where the rafter is in good condition why not save the extra expense? Gardeners should spend their employers' money as they would their own, then I think in many cases necessities would not be debarred them. The method I adopted at Brentwood answers well; the rafters are practically new, it being only the putty that was at fault. *F. G. Brewer, Bryntirion Gardens, Bontddu, Dolgelly.*

RAISING APPLE STOCKS.—I do not think the raising of stocks for grafting by cuttings will ever become popular. I have inserted many of various kinds, but with ill-success. If they make roots they fail to grow with sufficient vigour to have any value as stocks. Manx's Codlin I found succeeded best; but even that makes sorry progress as a tree. If amateurs are at all wishful to raise their own stocks for grafting choice or favoured varieties upon it would be far better for them to collect the seed or pips from ordinary Apples. Sow the seed early in spring in sandy soil in a box in a cold frame. The seedlings will soon push through the soil, and if planted out early in the autumn will quickly grow large enough to receive a graft. *E. M.*

POTATO PRICES.—Whatever may be the cause of the extraordinary low prices of seed Potatos just now, it is certain that they are not due to foreign competition. It is doubtful whether prices ever were lower; indeed, it seems incomprehensible when we remember the mad efforts made last year to obtain the highest prices ever heard of in connection with seed tubers, that now they should have fallen to the lowest on record. Even the famous Northern Star is quoted in all directions at but 5*s.* per 112 lb., and it would seem even at that very low figure it does not find purchasers. If there be not planted this year immense breadths of Potatos, seed tubers being so cheap, it will be because this very cheapness in the trade just now exists. But no one should be discouraged from planting for that reason; we may see a big demand for seed Potatos another year. The Potato trade is doubtless feeling that depression which has been felt by all trades. Still, all past experience shows that periods of depression are few and relatively brief. The wisest man now may be he who plants most largely. *N. P. S., April.*

APPLES FROM THE CAPE.—If we may judge these by the specimens shown at the recent Colonial Fruit Show of the Royal Horticultural Society, they are inferior to home-grown fruits in appearance, as they all lack colour; and I doubt if they are half so good in flavour as our own. Moreover, after such an abundant crop as we had last year, we might easily have plenty of our own; it is chiefly a matter of care in gathering and in providing suitable storage. I have still a good lot of fruits of Barnack Beauty left which will last for dessert a considerable time, and fruits of Blenheim Pippin, Cox's Orange Pippin, Ribston Pippin, Rosemary Russet, and Duke of Devonshire are as plump as when they were gathered, and of excellent flavour; those who enjoy a sharp Apple would add the Old Northern Greening to those enumerated above; it is one of the best keepers, and fit for dessert at this time of the year. Cooking varieties still fresh and good comprise Newton Wonder, Alfriston, New Northern Greening, Old Northern Greening, Bramley's Seedling, and Hormead's Pearmain. Too little attention is paid to the arrangement of the fruit store-room when the garden offices are built. One often sees it erected over other buildings, or arranged behind the forcing-houses, instead of being placed in the coolest position that can be found. *W. H. Divers, Belvoir Castle Gardens, Grantham, April* 20.

POTATO PLANTING AND POTATO SPROUTING.—The dibble was generally used amongst the crofters of Scotland twenty years ago, and suited admirably in light soils; but on heavy lands it made a hard, case-like enclosure for the seed-tuber. However, as Mr. Jefferies stated, the "thorough working of the soil" is the best means to obtain success. According to statistics given by the agricultural instructors of the Irish Department of Agriculture, both early and late varieties of Potatos yield larger crops of good Potatos when tubers have been sprouted before planting, the difference being sufficiently great to pay for the cost of trays, extra labour, &c., in the first year. The increase per acre is from 31 cwt. to 4 tons. These figures speak for themselves. Counties so far apart as Down and Wexford are satisfied as to the increase of a superior sample of Potatos resulting from the sprouting system. In the *Farmers' Gazette*, April 1, Dublin, a report by Mr. Megaw (Down) respecting the advantages of planting sprouted seed contained the following paragraphs:—"(1) It is the safest possible system of storing seed Potatos; under no other system will seed be kept so sound and free from rot. (2) The tubers which do not sprout properly are seen, and can be laid aside when planting is being done. (3) In a wet and backward spring planting could be deferred even until late in May, so as to have the ground in good order. When the seed is well sprouted the crop will be as far advanced in growth as it would be from seed planted in the ordinary way a month earlier, the farmer would therefore be less at the mercy of a backward spring. (4) Because of the rapid growth of the crop, weeds are more easily kept under. (5) The Potatos, owing to maturing early, will be of better table quality." It is all very simple and reasonable, and I am sure under the weight of evidence conservative ideas and prejudices must give way. Those of the Irish farmers who wish to be up to date have adopted the system, and mean to stick to it as long as it yields the best returns. *A. Pearson, Co. Cork.*

THE ALLEGED DETERIORATION OF VARIETIES.—The facts you record in paragraph 1, p. 264, are extremely important, and I do not know that they have been previously stated so definitely or so clearly in print. May I suggest one point where I think there is room for a little more information? In the first place every seedling Potato is, of course, the result of sowing one grain of seed; this grain of seed produces a plant, and under the plant are a certain number of tubers. You state that "no two tubers on the same haulm are [exactly] alike, and thus we get from the beginning a source of variation." Now it is quite true that there is always some variation in the shape or size of tubers attached to the haulm of any Potato plant, due probably to the period of the plant's growth at which the tubers began to be formed, but the difference is chiefly that of size, though there is always some slight variation in shape. Your words "no two tubers on the same haulm are [exactly] alike," may possibly lead to misunderstanding, because all seedling-Potato raisers know quite well that each of these tubers, notwithstanding any irregularity of shape, is essentially identical with the others, and if planted side by side will, in the following year, give plants which are [for practical purposes] absolutely identical in every characteristic. The consequence of this is that whether in the second year the raiser plants one of the original tubers or all the original tubers, the result will be the same, and without any opportunity for variation. I quite accept your statement that the Potato plants and tubers of one year's growth cannot correctly be termed "portions" of the plants of the previous year, but nevertheless there is much to be said for their "identity," for the seed-tuber or set does not disappear in the ground until it has given its own life to the new plant, and experience shows that this new plant never varies from the plant of the previous year, any more than a cutting of Pelargonium varies from the plant from which it is taken. It is also noteworthy that a Potato plant raised from a tuber in the ordinary way corresponds as identically with the plant of the previous year as does a Potato plant raised from a stem-cutting made in the same year. Another point to which I think you do not allude, but which is obvious, is that in any period of its growth it is as possible for a Potato plant to "sport," as to variation of colour, as for any other plant to do so; but so far as my experience goes there is no evidence of any "sports" having been observed, except as regards the colour of the tuber. *Arthur W. Sutton.*

CARNATION "ELIZABETH."

THE Tree Carnation illustrated at fig. 116 is a seedling obtained from the variety America. It possesses a well-balanced flower of a clear bright cherry-red colour, with a non-splitting calyx, and is very free-flowering in habit. Flowers were shown by Sydney Morris, Esq., Wretham Hall, Thetford, at the meeting of the Royal Horticultural Society on the 25th ult., when it was given an Award of Merit.

FIG. 116.—TREE CARNATION ELIZABETH: COLOUR OF FLOWER CHERRY-RED.

NURSERY NOTES.

MESSRS. TRESEDER & CO., TRURO.

WHILE on a visit to Falmouth for the purpose of attending the Cornwall Daffodil Society's show at Truro early in April, I took the opportunity of inspecting Messrs. Treseder & Co.'s nursery near that town, being anxious to see what tender plants suitable for open-air culture in the south-west were included in the collection. Messrs. Treseder make a speciality of tree Ferns, and in many gardens in South Devon and Cornwall, such as Bosahan, Trebah, Menabilly, Trewidden, Greenway, Elfordleigh, and others, numerous fine specimens supplied by the firm are to be seen luxuriating in the best of health.

A large structure, whose roof and walls are covered with laths that provided shade while admitting air, contained a number of tree Ferns and other tender subjects. Fourteen species of Eucalyptus are grown, and of these Mr. Treseder especially recommends E. "Beauchampiana" as one of the hardiest. Several Acacias are stocked amongst these being the new A. Baileyana; and amongst the Olearias I noted the Musk-leaved O. argophylla, formerly classed as Aster, which is fairly common in the south-west. The Callistemons, generally catalogued by nurserymen as Metrosideros, included C. lanceolatus, C. rigidus, and C. linearis, and the quaintly foliaged Australian Casuarina quadrivalvis was also present. Of this I know a fine specimen about 12 feet in height, which has been unprotected in a South Devon garden for many years.

Among the Pittosporums were included P. nigrescens, P. undulatum, P. eugenioides, and P. e. variegatum. Numbers of small plants of Benthamia fragifera, now called Cornus capitata, were in evidence, and the same may be said of the splendid Embothrium coccineum, the most brilliant of all flowering trees, Cornish examples, 20 feet and more in height, being in the month of May sheets of glowing scarlet. That fine foliaged New Zealand shrub, Brachyglottis repanda, formerly called Senecio Fosteri, was remarked. The flowers of this shrub have been said to be inconspicuous and unattractive, but a large panicle about a foot in diameter, exhibited in the 2nd prize stand of hard-wooded plants at the late Plymouth Daffodil show, was very delicate and distinct.

Of tender climbers the Hardenbergias drew attention Of these H. monophylla, with blue flowers, H. candidissima, with white blossoms, and H. nigricans, which appears identical with Kennedya nigricans, were noted. In one or two gardens these are grown in the open. Polygonum complexum, the climbing Maidenhair from New Zealand, was also present, as was the bright-flowered Berberidopsis corallina.

Among other noteworthy plants were Anigozanthus flavidus from New Holland, the graceful Grevillea pendula and Coronilla glauca pygmæa, while of better-known subjects the collection comprised Boronia megastigma, which in Cornwall attains to a height of over 4 feet in the open; Clianthus puniceus, Desfontainea spinosa, Fabiana imbricata, Calceolaria violacea, Ozothamnus rosmarinifolius, Cassia corymbosa and C. Decandolleana, the Australian Tristania conferta, Myoporum lætum, Melaleuca ericifolia, Smilax glycyphylla, and Edwardsias or Sophoras, none of which are hardy in the open except in the south-west. There was a good collection of Rhododendrons and herbaceous and rock plants; Roses, greenhouse plants, fruit-trees, coniferæ, aquatics and hardy shrubs and trees were also present in quantity. *S. W. Fitzherbert.*

ODONTOGLOSSUM × THOMPSONIANUM.

THIS remarkable hybrid was shown at the Royal Horticultural Society's meeting on April 25,

FIG. 117.—ODONTOGLOSSUM × THOMPSONIANUM.

by W. Thompson, Esq., Walton Grange, Stone (gr., Mr. W. Stevens), when it was recommended a First-class Certificate. The flower was of a rich claret-purple colour tipped with rose at the margins, and was 2½ inches in diameter. The inflorescence was tall and branched, while the pseudo-bulbs were tinted with purple, similar to those of O. Edwardii. The lip of the flower possesses a yellow crest.

THE APIARY.

Fitting-up Sections.—A little skill is required in fitting-up sections, as those who have tried to do the work know to their cost. Few joints will break however if the following method be adopted: Take say a hundred sections as received in the flat, and have some clean water boiling on an oil stove or gas ring; wet the joints of the sections well on both sides with a paint-brush, and place them, when wetted, in a pile. When the whole have been under this process, overturn the pile, and fit up with whole sheets of extra-thin foundation.

Fitting up the Section Rack.—In placing the sections in the rack put a metal divider between each line, and, when they are all in, wedge up as tightly as possible, because the bees will fill up all crevices between the sections with a sticky substance termed propolis. This will give the sections a dirty appearance in addition to providing a great deal of unnecessary labour.

Wrapping up the Rack when on the Hive.—It is seldom that beginners realise how necessary it is

that section racks should be packed tightly all-round, and have a good covering of quilts on the top. A very skilled bee-keeper that I know has advised me to try the effect of a sheet of brown paper between the quilts. He had tried it last year and the results were excellent.

How to get Bees into Sections. — Every one knows how difficult it is generally to get the bees to work up in sections. A few years ago a number of experienced bee-keepers were discussing the question, and one of them said he always placed shallow frames (with drawn-out comb) on first. The bees took readily to them, and when well started the section racks were substituted. I have tried the plan, and find that there is a distinct gain. *Chloris.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

April 25.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Dr. M. C. Cooke, Prof. J. Percival; Messrs. Saunders, Bowles, Güssow, Sutton, Holmes, Douglas, Massee, and Chittenden (Hon. Sec.)

Malformed Iris.—Dr. Masters showed a sketch of the stamens of the flowers of Iris tuberosa, brought to the last meeting by Mr. Worsley. The filament had branched so that each stamen bore two anthers.

Forms of Narcissus Bulbocodium.—Regarding these shown at the last meeting, Miss Willmott writes:—"I have some 200 geographical forms of N. Bulbocodium collected some fifty or sixty years ago by the late M. Alexis Jordan. They were cultivated by him at Lyons until his death, a few years since, then they passed into my hands. By his notes upon them, and my own observation during the years they have been in my possession, I find that the same amount of variation continues which M. Jordan observed fifty years ago. The time of flowering also varies by several weeks in some of the forms."

Injured Horse Chestnut Shoots.—Mr. Saunders reported upon these shown at the last meeting: "I cannot find any cause for the injury. I can only suggest that the shoots may have been injured by blows from other branches in a gale, or from some other cause. The injuries were received some months ago."

Diseased Arums.—Mr. Güssow reported: "I have kept the roots under observation since March 28, but could not discover any cause of the injury whatever. The bacteria present in the decayed portion at the base of the tuber were saprophytic. . . . The plant should be kept dry for a period, and then transplanted into fresh sandy soil containing some charcoal. After forming new rootlets they should be transplanted and cultivated in the ordinary way.

Striped Auricula.—Mr. Douglas showed a plant raised by Mr. Horner from seed from a dark-red flower. The seedling at first bore yellow flowers, but later the flowers produced were striped with dark red. Offsets from the plant had, with one exception, borne yellow flowers.

Primrose Malformed.—Mr. A. W. Sutton brought specimens which had been raised by division from the plant shown before the Committee two years ago, in which "the umbel was partly formed, but with multifold flowers of twelve parts, and with a partly petaloid calyx, &c." The original plant was found in a wood close to Bucklebury Place, Berks, and seventy or eighty plants have been raised from it by division. Four of the plants have reverted to the common Primrose, and show no variation whatever from the ordinary type. All the rest have partly formed umbels with multifold flowers, with the exception of three or four, which more or less closely resemble the form of the Polyanthus. The plants, after division, have been left to the care of themselves, planted under an east wall on poor soil.

Double Primrose.—Mr. Sutton also showed double flowers of Primrose gathered from a plant growing wild.

Ranunculus asiaticus var. sanguineus.—Mr. Sutton also submitted specimens of the single wild Ranunculus asiaticus, "which is, perhaps, the commonest wild flower of Palestine, where the plains are frequently carpeted with it. This is so much the case on the plain of Sharon that it has by many travellers been supposed to be the 'Rose of Sharon' of Scripture. Wherever this Ranunculus grows it is preceded in bloom by the single Anemone, which flowers some two or three weeks earlier. As the single form of the Ranunculus is seldom seen in England, travellers usually confuse the two plants, and speak of both as Anemones. The Anemones are generally of the same colour as the Ranunculus, but in certain localities produce flowers of the most lovely shades of mauve, purple, cerise and white." The Ranunculus shows little variation, but forms with orange or bronzy-yellow flowers are occasionally met with. Mr. Bowles said he had flowered the plant in his garden last year.

Spur of Dendrobium.—Dr. Masters showed drawings of a flower of Dendrobium chrysotoxum, received from Mr. Bowles, in which the spur had not developed fully. The structure seen in this flower clearly showed that the spur is not an outgrowth of the sepal, as is usually supposed, but is partially an axial structure.

Meconopsis integrifolia. — This newly-introduced plant, shown by Messrs. Veitch, was, on the motion of Dr. Masters, seconded by Professor Percival, awarded a Botanical Certificate.

Diseased Montbretia.—Mr. Bowles showed corms of Montbretia which were decaying at the base. Mr. Massee undertook to examine them.

Apple-buds Injured.—These sent by Mr. Dunlop, Armagh, appeared to be eaten away at the sides, and were taken by Mr. Saunders for examination.

Fruit tree Twigs Injured. — Shoots of Apple and Pear having poorly-developed and injured buds were taken by Mr. Saunders for examination.

Deterioration of Potatos.—In continuation of the discussion on this subject, Mr. A. W. Sutton said that the length of time any variety lasted without deterioration depended very largely upon its vigour at the time of its first production: be found that, as a rule, cross-bred plants were less likely to degenerate than those from seed produced from flowers fertilised by pollen of the same variety; he had never found that the selection of tubers from the stock of any one variety had ever resulted in the improvement of that variety, although, of course, the selection of plants which had been produced from seed was all-important. Professor Percival thought that there were well-authenticated cases of sports (or bud variations) having arisen which were perpetuated after selection.

Coloured Leaf of Richardia.—Mr. Charrington, of Bury's Court, Reigate, sent a specimen of Richardia Elliotiana having a large yellow blotch on the leaf which left the flower-stalk just below the spathe—a kind of second spathe. This specimen has shown the same peculiarity for the past three years.

CROYDON SPRING FLOWER SHOW.

April 19.—The Croydon and District Horticultural Mutual Improvement Society's Spring Exhibition was held on the above date at the Art Galleries, Park Lane, Croydon. The number of exhibits displayed was equal to that of former years, while the exhibition generally showed an advance in quality. The attendances, both in the afternoon and in the evening, were the largest the Society has ever had.

One of the prettiest displays was a collection of hardy flowering shrubs, Narcissus, Tulips, and Pansies set up by Mr. E. Mills, gr. to Frank Lloyd, Esq. Mr. Lloyd also showed a small collection of Alpines in pots.

Messrs. J. R. Box & Co., of West Croydon, showed a collection of Narcissi, mostly new varieties, among them being the variety Van Waveren's Giant.

Mr. J. Filce, of 27, Handcroft Road, showed Tulips, Forget-Me-Nots, and Auriculas.

A capital exhibit of Narcissi and Alpine plants came from Messrs. J. Cheal & Sons' nurseries, Crawley; whilst probably the most effective display in the building was that made by Mr. J. R. Box, of West Wickham, with alpine plants, comprising seventy or eighty varieties, all named, arranged on a rocky groundwork.

Mr. R. A. Laing, of Shirleyhurst, Radcliffe Road (gr., B. Acock), displayed a collection of Primula obconica and Clianthus Dampieri.

Miscellaneous groups of plants, tastefully arranged, were exhibited by F. R. Docking, Esq., of Grafton House (gr., Mr. D. J. Ricketts), and Geo. Curling, Esq., of Elgin House, Addiscombe (gr., Mr. W. Bentley), the last-named gentleman's display including specimens of the beautiful Crinum Moorei.

Messrs. John Peed & Son, of West Norwood, were represented by a collection of Alpine and other plants in pots. Mr. J. J. Macdonald, of Armadale, Howard Road, South Norwood, showed a charming basket of flowers; and Messrs. E. W. & S. Rogers, of Croydon, a collection of Hyacintha and Daffodils.

Amaryllis and Orchids were the principal feature of a group of plants shown by Mr. Wickham Noakes, of Selsdon Park (gr., Mr. Bye). A display of Orchids was also set up by Mr. F. W. A. Radford, of Southernhurst, Park Hill Road (gr., Mr. Padley).

A collection of Cinerarias was shown by J. Pascall, Esq., of Ambleside, Addiscombe (gr., Mr. A. Edwards); while Mr. T. Butcher, of Croydon and South Norwood, was represented by a group of plants, with a tasteful shower bouquet at one end of the group, and a basket of flowers at the other.

Mr. John Gregory displayed a decorative fireplace, which was quite one of the best artistic arrangements in the show.

GARDENERS' DEBATING SOCIETIES.

Shirley (Southampton) Gardeners'.—Nearly fifty members of the above Association were present at the monthly meeting on Monday, April 17. The evening was devoted to a debate on "Carpet Bedding." Mr. Risbridger, of The Gardens, Rowuhams Mount, opened the debate with a speech in favour of carpet bedding, and he was followed by Mr. Wilcox, of The Gardens, Aldermoor House, who was opposed to this form of gardening. A brisk discussion followed. There were several exhibits of Daffodils at the meeting, those shown by Mr. Wilcox and Mr. Cook being especially noteworthy.

Bath Gardeners'.—A meeting of the above Association was held on April 13, Mr. W. F. Cooling in the chair. Mr. F. W. E. Shrivell, F.L.S., delivered a paper on "Up-to-date Manuring." The lecturer pointed out the increasing difficulty of obtaining good organic manures owing to the lessening use of the horse through the growth of trams and motor-cars. His opinion was that chemicals could not entirely replace organic products, and condemned mixing soot with lime, for the ammonia was lost by so doing. Mr. Edwin Ponter was elected a Vice-President. Clevedon was suggested for the Society's summer outing, but a decision was deferred until the next meeting.

Bristol and District Gardeners'. — The seventh annual meeting of this Association was held on Thursday, April 27, Mr. P. Garnish presiding. Mr. W. Ellis Groves presented the report and balance-sheet, which showed that the Society was still maintaining its position as one of the foremost of gardeners' mutual improvement associations. Colonel Cary Batten was again unanimously elected President, while Mr. Lee was elected Chairman for the ensuing year, and Mr. Curtis, Vice-Chairman. Mr. W. Ellis Groves, on being re-elected Secretary, received a unanimous vote of thanks. Mr. H. Kitley was invited to again act as his assistant. The remaining officers and committees were also elected. The competition for three flowering plants brought a good number of entries, 1st prize being awarded to A. Shipley, Esq. (gr., Mr. Wakefield). *H. K.*

Worthing Horticultural.—At the April meeting of the above Society Mr. Evans, head gardener to the Borough Corporation, addressed the members on the value of the Coniferæ for town planting. Different varieties of Conifers were mentioned, but particular attention was directed to the advisability of planting Pinus species, mentioning that Bournemouth owed its reputation as a health resort to their presence. It was stated that in a report to the Council Dr. P. W. G. Nunn, the medical officer for the district, emphasised the necessity for replacing trees which have been cut down, and advised the appointment of a skilled arboriculturist.

Redhill, Reigate and District Gardeners'.—The last of this Society's meetings for the season was held on Tuesday, April 25, Mr. W. P. Bound in the chair. Mr. Horace Wright delivered a lecture on "Exhibiting." Mr. Wright advised all exhibitors to make themselves thoroughly acquainted with the rules laid down in the schedule, as many exhibitors find themselves disqualified owing to want of knowledge of the conditions contained therein. The lecturer also dealt at some length with the method of staging plants for exhibition. *F. C. L.*

REMARKS.—Trade in general is very quiet, consequent on the period following general holidays. Supplies of Strawberries are more numerous.

POTATOS.

Dunbars, 100*s.* to 110*s.*; various, home-grown, 55*s.* to 80*s.* per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

THE prospect of better trade has not been realised. Zonal Pelargoniums sold somewhat more readily this morning. Marguerites have also an increasing demand. Intermediate stocks are seen of good quality, but many plants were left unsold at closing time. Cinerarias also sell slowly. Spiræas are good in quality but lower in prices. Supplies of Azalea indica are almost finished for the season, while those of Cyclamen are practically over. Ericas are of good quality. E. ventricosa magnifica in beautifully flowered plants realise up to 4*s.* each; E. Spenceriana is very pretty; supplies of E. Cavendishii hold out well. Boronia elatior can now be had in excellently-grown plants. Some good plants of Metrosideros are now obtainable. Hydrangeas are good and plentiful. Show Pelargoniums, now that the zonals are so good and plentiful, do not sell as freely as formerly. Ivy-leaved varieties include Galilee, Mrs. Hawley, Madame Cronsse and Souvenir de Chas. Turner. Plants of the newer varieties Baden Powell and Leopold are seen, but for general work the older sorts still hold their own. Saxifraga pyramidalis and Verbena Miss Willmott are both good in quality. For extra fine specimens of Rose Crimson Rambler prices vary from 5*s.* to 10*s.* 6*d.* each. The H.-P.s are not so good, and many of the variety Madame Levavasseur are of poor quality. Heliotrope does not sell very readily; Rhodanthe clears out well. There is little variation in trade for Palms, Ferns, and other foliage plants. Ferns have a somewhat increased demand, but supplies are very large. Bedding plants are now plentifully arriving, the stalls under the new French Market being well filled.

CUT FLOWERS.

Never was trade more uncertain; there seemed a little revival at the end of last week, but this morning things were very quiet, and large quantities of splendid material were left over at closing-time. Supplies of Roses are considerably in excess of all demands, and splendid blooms remain unsold. Prices for Lilium longiflorum are down to the lowest ebb. Supplies of Daffodils are now getting short, but good "bicolors" are plentiful. Spanish Iris are over-plentiful; the best English-grown flowers make good prices, but Jersey supplies are overdone, and are offered at low prices. Stephanotis flowers are good; Gardenias are very plentiful and low in price. Gladiolus Colvillei "The Bride" and the pink variety are noticed on the stalls, also double and single scarlet Anemones. Lily of the Valley is again more plentiful, and consequently lower in price. Carnations are over-abundant. Sweet Peas are good, but supplies are large. *A. H., Covent Garden, May* 3, 1905.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending April 29, 1905.

1905. April 23 to April 29.	Temperature of the Air. At 9 A.M. Dry Bulb.	Wet Bulb.	Day. Highest.	Night. Lowest.	Lowest Temperature on Grass.	Temperature of the Soil at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	Rainfall.	Sunshine.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	50	46	55	42	37	47	47	47	Tot 0·11	4 20

THE WEATHER IN WEST HERTS.

Frequent Showers with High Winds.—The day temperatures have been about average and very equable—the highest readings varying only from 51° to 58°. The nights were all warm, and on none of them did the exposed thermometer fall lower than to within 4° of the freezing-point. The ground is rather warmer than it was a week ago, and is now at about a seasonable temperature at 2 feet deep, and about 1° colder than the average at 1 foot deep. Rain fell on five days to the total depth of three-quarters of an inch. The percolation through both gauges, which had almost ceased on April 25, recommenced on the following day, and small amounts have come through every day since then. The sun shone on an average for three hours a day, which is nearly two and a half hours a day short of a seasonable duration at this time of year. The winds have been high, and the direction mostly some point between south and west. On the 1st the mean velocity for the windiest hour amounted to 18 miles, direction south-west. The average amount of moisture in the air at 3 P.M. was as much as 8 per cent. in excess of the mean

APRIL.

Frequent Rains and Cloudy Sky.—The day temperatures were as a rule low. Indeed, there at no time occurred more than five warm days in succession, and even then the highest reading was only 61°. On the other hand the nights were mostly warm, and for the greatest cold, as shown by the exposed thermometer, was 9° of frost, which is a high extreme minimum for the month. Rain, hail, snow or sleet fell on as many as twenty days the average number for April being thirteen. The falls, although very frequent, were never very heavy, the measurement on the wettest day falling short of half an inch. The aggregate quantity for the month was just over 2 inches, which is slightly in excess of the April average. Of that amount about one-third, or three-quarters of an inch, came through both percolation gauges. This was a very gloomy April, the average daily record of clear sunshine being only 3¼ hours, which is 1½ hours a day below the mean for the month, and making it the most cloudy April since 1888, or for seventeen years. The winds were, as a rule, light, and in no hour did the mean velocity exceed 18 miles—direction W.N.W. For 174 hours, or seven days, the direction of the wind was some point between north and east. The atmosphere was unusually humid, the mean amount of moisture in the air at 3 o'clock in the afternoon being as much as 9 per cent. in excess of the average for April. *E. M., Berkhamsted, May* 2, 1905.

[*For actual temperature and condition of barometer at time of going to Press, see* p. 280.]

GARDENING APPOINTMENTS.

MR. C. MUNNINGS, for the past five years General Foreman in the Gardens, Blickling Hall, Lincoln, as Gardener to Sir G. WHICHCOTE, Bart., Aswarby Hall, Folkingham, Lincoln.

Mr. W. PARKER, formerly Gardener to LORD ST. LEVAN, St. Michael's Mount, Cornwall, as Gardener to F. HALL, Esq., Park Hall, Mansfield, Notts.

Mr. DAVID ROBERTSON, for nearly three years Foreman in The Gardens, Springkell, Dumfriesshire, as Gardener to the Hon. Mrs. DEAN MORGAN, Ardcandrisk, Wexford, Ireland.

Mr. F. G. BREWER, The Grange Gardens, Brentwood, and previously three years Gardener to R. E. JOHNSTON, Esq., Terling's Park, Harlow, Essex, as Gardener to C. G. BEALE, Esq., Bryntirion, Bontddu, Dolgelly, Merioneth.

Mr. F. TILBURY, for some time Foreman in Mr. JOHN PROCTOR'S Nursery, Portobello, and previously at Lynford Hall, Norfolk, as Gardener to JAMES PARKER, Esq., Clovelly, Kilmacolm, Renfrewshire.

Mr. P. J. LUCKING, previously with the late F. G. LLOYD, Esq., Langley House, Slough, as Gardener and Bailiff at Hopedene, Holmbury, St. Mary, near Dorking.

Mr. CHARLES COUSINS, for two years General Assistant to Mr. LOCKIE, Diddington Hall Gardens, Huntingdon, as Gardener to G. D. NEWTON, Esq., Croxton Park, St. Neots, Hunts.

Mr. H. MOSSOP as Gardener to R. R. LEMPRIERE, Esq., Rozel Manor, Jersey.

Mr. H. TREEN, for upwards of eight years Gardener to A. H. BENSON, Esq., as Gardener to S. M. ROOSEVELT, Esq., Roosevelt Hall, Lake Skaneateles, New York State, U.S.A. He will sail on May 10.

Mr. W. HOWE, Jun., for the past two and a half years Foreman in the Gardens at Park Hill, Streatham Common, as Gardener to Lord STANLEY, Coworth Park, Sunningdale, Berks.

Mr. JAMES WHITE, for some time Foreman in The Gardens, Thoims House, Wakefield, as Gardener to Colonel TORIN, Upper Berwick House, Shrewsbury.

Mr. WILLIAM MCNICOL, for the past three years Gardener to Colonel WILSON, Bannockburn House, as Gardener to Captain GRANT, Kilgraston, Perthshire.

CATALOGUES RECEIVED.

WM PAUL & SONS, Waltham Cross—New Roses, Cannas, Phloxes, &c.

AMOS PERRY, Hardy Plant Farms, Winchmore Hill, London, N.—Water Plants.

HARRY BARKER, Rosemount, Whittlesford, Cambs.—Hardy Plants.

ANSWERS TO CORRESPONDENTS.

Apple-shoots: *An Old Reader.* There is not sufficient evidence in the shoots themselves from which to determine whether the flowers have been eaten by birds or have fallen after injury from frost. We suspect the latter is the cause, but as you have the trees under your immediate observation, it should be an easy matter to form a correct opinion in such a case. The seeds received are under examination.

Auricula: *A. K.* The Auricula truss is one from an ordinary border variety. The farina in the centre of the flower shows it to be of the Primula Auricula parentage. It is doubtless adapted for border culture, but is of no value whatsoever as an exhibition variety.

Books: *Perplexed. Pictorial Practical Tree and Shrub Culture,* by W. Dallimore, is an excellent and inexpensive book on the subject, price 1s. 2d. post-free. *Beautiful Flowering Trees and Shrubs,* by John Weathers, price 5s. 4d. post-free; and *Trees and Shrubs for English Gardens,* by E. T. Cook, price 12s. 6d. post-free, are more elaborate works on the same subject. The above works can be obtained from our Publishing Department.

Bordeaux Mixture: *G. J. R.* We copy the following recipe from page 136 of the *Calendar of Garden Operations,* issued by our Publishing Department, price 7½d. post free. Dissolve in a large wooden or earthenware tub 2 lb. of sulphate of copper (blue vitriol) in two gallons of hot water. Then put 2 lb. of freshly-slaked lime into another tub with two gallons of water so that a creamy fluid is made. Then pour the lime solution into the copper solution and stir well. Add twenty gallons of water and continue to stir. The mixture (which should be of a blue colour) is applied with a syringe or a special form of spraying machine.

"Browning" in Vines: *W. H. S.* This disease is called by the French "Brunissure." We have not heard of its having any other name. The issue of the *Gardeners' Chronicle* for August 19, 1893, can probably be obtained on application to our Publishing Department.

Cabbage Plants: *H. & Son.* You should know better than we what is the matter. We do not see any fungus, but it is possible the slime-fungus is present.

Cucumber Leaves: *Reader.* There is no trace of disease. The leaves have been scorched, and the bleached edges strongly suggest the presence of deleterious fumes, or the use of an insecticide when the foliage is damp.

Foliage of Snowdrop and Daffodil: *J. K. L.* The spots are due in the first instance to insect punctures. Fungi of various kinds afterwards have settled on the wounds. The injury is not serious, and is not likely to appear another season unless the punctures are repeated.

Friar's Balsam: *E. C. C. D.* Populus balsamifera has nothing to do with benzoin. This is obtained from Styrax Benzoin, and possibly from other plants. We do not know that a commercial preparation of any kind is obtained from the Poplar, which, however, is very fragrant.

Gardeners' Notice: *A. E. W.* In the circumstances you describe you cannot be legally dismissed at the end of the first week. We cannot undertake to reply to questions through the post.

Lantern Slides: *Enquirer.* Apply to Mr. W. G. Smith, 121, High Street, South Dunstable, or to Mr. J. Gregory, 60, Canterbury Rd., Croydon.

Laurels: *J. H.* The yellow appearance will probably disappear as growth goes on. [illegible]

Leea amabilis: *J. B. W.* This handsome-leaved species requires to be cultivated in a stove temperature, and if planted out is capable of producing a good effect trained to the pillars of the house. The plant is very ornamental also when grown as dwarf specimens in small pots. You may propagate the species from cuttings inserted in a porous compost over bottom-heat.

Nectarine Leaves: *J. C.* Your leaves are affected with the Silver-leaf disease, supposed to be due to a fungus, Stereum. Cut the affected shoots away and burn them. Turn out as much of the soil as you can, and replace with fresh loam.

Names of Plants: *M. B. F.* Antirrhinum Asarina.—*C. W. P.* Sparmannia africana.—*A. B. H.* 1 and 2, both forms of Iris pumila; 3, Anemone nemorosa var. Robinsoniana; 4, apparently Arabis lucida, specimen small and inconclusive.—*H. R. W.* Gnaphalium lanatum.—*C. S.* 1, Miltonia flavescens; 2, Maxillaria porphyrostele. — *E. L.* Brassia verrucosa.—*C. L.* Cœlogyne nitida and variety alba.—*B. R. J.* Magnolia conspicua.—*F. W. C. S.* Saxifraga granulata.—*Landscape.* 1, Cryptomeria japonica; 2, Sequoia sempervirens; 3, Tsuga canadensis; 4, variety of Thuya orientalis; 5, Abies nobilis; 6, Libocedrus decurrens.—*J. S.* 1, Viburnum plicatum; 2, V. tomentosum; 3, Forsythia suspensa; 4, Prunus pseudo-Cerasus, semi-double variety; 5, next week; 6, Polygonum cuspidatum.—*Brook, L.* 1, Pyrus aria variety; 2, a Poplar, probably the Weeping Aspen, P. tremula.—*G. D.* Fritillaria obliqua, Thuya dolabrata, Eupatorium, perhaps Weinmannianum, Cytisus austriacus. The specimens were in such a miserable condition that we are unable to name them more fully.—*C. J. P.* Cytisus austriacus.

Peach-leaves: *L. F.* See answer given below to "Perplexed." Cut back the shoots to a point below the diseased leaves, and spray with potassium sulphide next spring.

Photograph: *J. C.* We believe the plant is Eucomis punctata. If so, it is not uncommon.

Plants for Vineries: *M. M. P.* In answer to your question respecting the best plants for furnishing a supply of cut flowers, and to be grown against the back wall of a vinery, we should advise Pelargoniums, both the Ivy-leaved and the zonal types. These would furnish a supply of flowers early in the season and before the Vines had completely shaded the interior of the house. The various species of Asparagus used for decorative effect would succeed in this position, but any plants that are grown under such conditions will become more or less weak in growth, as soon as the foliage of the Vines has excluded direct rays of light from reaching them. In any case, be careful that you do not select for planting in a vinery any species of plants that are known to be specially liable to attacks from mealy bug, thrip, or other insect pests. The introduction of flowering plants into a vinery is frequently productive of disappointment and loss rather than of pleasure and profit.

Plum-tree: *F. G.* The shoot is very badly infested with the "Silver-leaf" disease, common to stone fruits, and it would be advisable to burn the tree at once.

Raspberry Grub: *S. F. P.* The buds are attacked by the grub of the Raspberry-moth (Lampronia rubiella, fig. 118). The caterpillars pass the winter in the earth. The eggs are hatched in the flower, the caterpillars making their way out by a hole at the base. Cart-grease smeared round the base of the canes, or kerosene emulsion washed round the stems, might be tried. In any case all affected canes should be burnt. For a fuller account, see Westwood in *Gardeners' Chronicle* for 1853, p. 757.

Fig. 118.—Lampronia rubiella: raspberry moth.

Scum on Water: *F. W. F.* Your weed is one of the Confervoid Algæ. For means of eradicating it from your water, see answer to "M. M. P."

Tomatos: *E. J. W.* There is no disease present. The spotting is caused by a chill and will not affect future growth. Probably one part of the house is more exposed to draughts than the other.

Tulips: *J. S.* We do not see any fungus, and attribute the appearances to hail or violent rain-storms.—*D. R. M.* The plants are attacked by a fungus, Sclerotinia parasitica, and should be burned at once.

Untidiness and Disaster at the late Auricula Show: *J. C.* You should address your complaint to headquarters.

Vine and Peach Leaves: *Perplexed.* The blotches on the Vine-leaves have been caused by drip from the roof, and then sunlight acting on the wet surface of the leaf scalding has resulted. The Peach-leaves are attacked by a fungus causing "leaf-curl" (Exoasus deformans). The most certain cure is to cut back all affected shoots to just behind the diseased leaves. Spray the trees with potassium sulphide next spring just when the leaf-buds are beginning to expand.

Vine Buds: *W. J. Kendall.* Two species of mites were present in the Vine-buds: (1) an active species belonging to the family of cheese-mites (Tyroglyphidæ), but is probably predaceous and harmless to the Vines; (2) the Vine-bud mite, Eriophyes (Phytoptus) vitis; this is undoubtedly the species which is causing the injury to the Vines. It is a very destructive species on the continent of Europe, but is fortunately very rare in this country. It is closely related to the Currant-bud mite, and like the latter is very difficult to deal with when once established. You cannot do better than cut away all the infected buds and burn them; but even this method may not materially check the pest. Various washes have been recommended, both at home and abroad, as a remedy against the Currant-bud mite; but the careful experiments conducted at Woburn have abundantly proved that both dipping and spraying with various compounds have proved absolutely useless.

Vine Leaf: *J. S.* The small spots have been caused by minute drops of water falling on the leaf at a time when the temperature is falling. These spots becoming chilled the green colour of the leaf is destroyed and changed into a brown gummy substance. Effective ventilation, especially early in the morning, will check the disease.

Violets: *E. W. D.* Our rule as to varieties of florists' flowers applies to Violets, which we cannot undertake to name. Send them to some nurseryman who cultivates these plants in large numbers, and he will compare them with growing specimens.

Weeds on Ornamental Water: *M. M. P.* The method adopted with success by the Michigan Agricultural College in destroying noxious weeds in lakes and ponds was as follows:—By means of a spraying-machine, a mixture of copper sulphate 4 lb., unslaked lime 4 lb., water 60 gallons, was applied over the surface of the water. Although the entomologist at that college reported that no harm resulted to fishes and frogs by these sprayings, it would be advisable to keep stock and waterfowl for a reasonable period from water thus treated.

White Primrose: *Halstead.* This is not uncommon.

THE CHELSEA PHYSIC GARDEN.

THERE are some among us still who have an affection for the old Physic Garden at Chelsea, which is associated with so many personal reminiscences, and hallowed by so much that is of enduring botanical and historical interest. In the struggle for existence it seemed more than once as if the garden must succumb. Its natural protectors found its maintenance beyond their powers. The associations with Sloane, Philip Miller, Lindley, N. B. Ward, Fortune, Thomas Moore, and many others who laboured within its walls went for nothing. The Royal Society, which was asked to come to the rescue, politely declined to assist the Society of Apothecaries in carrying on the establishment. The College of Physicians was equally unsympathetic. The Society which had done so much for medical botany in the past ultimately applied for permission to relinquish their trust. The Treasury was applied to in order that the students of the Royal College of Science might obtain the privileges which had hitherto been enjoyed by the medical students of the London hospitals. Enquiry was made, and eventually a scheme was elaborated for providing an income for the garden and for re-establishing it as a botanic garden. By this scheme the Trustees of the London parochial charities were invested with the care of the garden and the management of its funds (less than £1,000 a year), of which the Government supplies the magnificent sum of £150! A Committee was appointed, consisting of seventeen persons, the Society of Apothecaries having, alternately with the College of Physicians, the right to nominate a member, so that the connection with the original holders is still in some slight measure preserved. The Committee seems an unwieldy one, comprising many members not generally known as in any way connected with botanical or horticultural science. Among them, however, are others, such as Sir Herbert Maxwell, Dr. Scott, Sir M. E. Grant Duff, and Professor Farmer, who can appreciate and direct the work of the garden. As scientific adviser the Committee is fortunate is possessing such a man as Professor Farmer.

The first Annual Report of the Committee of Management, dated January, 1905, is now before us, and from it we learn what has been done up to this time.

So far as the proper work of the garden is concerned, we have already had opportunities of commenting upon that. We now learn that on the new buildings which were necessitated a sum of £6,000 has been expended, of which £4,050 was advanced by the Trustees, to be repaid in thirty years out of the income of the garden, so that the financial prospects of the garden can hardly be said to be very brilliant. The laboratory and lecture-room have been found to be admirably suited to the purposes for which they were intended. These purposes, stated briefly, are (1) to render assistance in the teaching of botany; (2) to provide material and opportunity for botanical investigation.

Courses of lectures in advanced botany have been or will be given by Sir W. Thiselton-Dyer, Dr. Scott, Professor Reynolds Green, Professor Farmer, Professor Oliver, Dr. Rendle, Mr. A. D. Hall, Mr. V. H. Blackman, and Mr. A. G. Tansley. The average attendance on Professor Green's lectures on "Vegetable Physiology" was about seventy.

The laboratory is chiefly used by the students of the Royal College of Science and one of the smaller laboratories has been placed at the disposal of Mr. Francis Darwin for his experimental researches. Mr. Darwin has also removed the scientific library belonging to his father, the late Charles Darwin, to the lecture-room in the new building. This library is available for the use of students under proper regulations. The connection with the name and work of Darwin will add greatly to the prestige of the establishment. Sir William Ramsay is also mentioned in the Report as engaged in making certain experiments in connection with the nutritive value of certain classes of manures.

The garden is not intended as a recreation-ground, but for the use of students and their teachers, and for the supply of specimens to various educational bodies in London.

The old Lebanon Cedar, the last of the four which were the earliest planted in this country, had to be removed. It had been dead for some years, and though its removal was objected to on sentimental grounds, it was really a matter of necessity.

The Committee regret to report the resignation from various causes of several of the original members, including Lord Redesdale and Professor Vines. Professor Farmer's services are appropriately acknowledged, and the Report concludes with the following commendation of the work of the Curator:—

"The Committee desire to express their highest approbation of the work performed by the Curator, Mr. Hales. The wonderful improvement in the state of the garden . . . is patent to all who have known it in recent years. The Committee recognise that the time, attention and constant care bestowed on the garden by Mr. Hales have been a labour of love, and they are glad to have this opportunity of formally congratulating him on the success of his work."

This is high praise, but we know that it is well merited. Long may the old garden flourish!

EXPERIMENTAL CULTIVATION.

(*Concluded from p. 132.*)

POT-CULTURE EXPERIMENTS.—Criticism of pot-culture experiments as occasionally conducted on the Continent and elsewhere has at times been justifiable, chiefly from defects in the methods and from general conclusions being founded upon very limited evidence. Faulty work of this kind is of little consequence so long as it is simply indulged in as a form of amusement, but when it is claimed as scientific and the results are given to the world, the matter assumes a different aspect, and it is not surprising if such experiments are attacked by critics.

Well-organised systems of pot-culture, on the other hand, are capable of rendering substantial service in several directions. As an introduction to more extended work, as a means of reducing time, labour, and expense in preliminary investigations, also for dealing with bye-questions or problems arising out of larger experiments, pot-culture should constitute an important aid to the student.

The best example in this country of well-designed work in the direction indicated may be seen in the Pot-culture Station at the Royal Agricultural Society's Woburn Experimental Farm. It was founded under the Hill's Bequest to investigate the effects of certain soil substances which occur in very small quantities, but much other useful work is included in its scope. Dr. J. A. Voelcker is the Director, and under his experienced supervision it is developing into a most interesting department of the Society's work. Photographs are taken of the plants in all stages, analyses are also prepared of soils and crops, and much valuable information is accumulating, a portion of which has already been published as reports in the Society's *Journal*. The Director has the assistance of a fully qualified chemist of long practical experience in Mr. H. M. Freear, and the utmost care is bestowed upon the whole of the work. Any institution or private investigator desiring to commence such experiments would do well to take this establishment as a model. Permission to inspect it can be readily obtained on application to the Director.

Under the best of systems there is much that is unavoidably artificial in pot-culture, and results may be unduly influenced in several ways. Soil temperature, moisture, aeration, and root area are all difficult to assimilate to the conditions prevailing when plants are grown in the open soil. The kind of pot employed influences the first to a great extent, and many forms have been tried with varying results. Zinc pots have been most largely used, but are objectionable for several reasons, the chief being the effects produced by quick heating and cooling, which are difficult to guard against, even when a double-cased form is used. These are now being generally discarded in favour of glazed earthen-

ware pots, which are not subject to such sudden changes of temperature, but they are heavy, and require much care to avoid breakages.

The regulation of the soil moisture necessitates the same attention in each case, the amount of water supplied must be noted, and if the drainings have to be examined for the determination of their constituents, a tap is provided for the purpose at the base of the pot. In some cases where the experiment is of short duration, nothing is removed until the completion of the work, or at the end of each season; but this is open to serious objections if there is much accumulation of water beneath the roots.

Aëration is still more difficult to control in a manner approximate to natural conditions. It is usually attempted by means of a false bottom to the pot, to which air is admitted either by a pipe rising to the top and remaining constantly open, or by an aperture near the base covered with metallic or other netting to exclude insects, &c. Both systems are necessarily artificial, and if not controlled with great care they may result either in excessive or in insufficient aëration, which will affect the behaviour of the plants to some extent.

The root area affords another difficulty when dealing with many farm and garden plants, the roots of which extend far into the soil. A pot 18 inches deep and 14 or 15 inches in diameter is a large size, and filled with soil it becomes a heavy object to move about; yet this does not provide adequate space for the free rooting of most field crops. In the majority of cases, therefore, root restriction is induced, which again influences the behaviour of the plants.

In regard to all these defects it must be said that if kept uniform, all the plants being subjected to exactly the same conditions, and a sufficient number being employed, they will be all fairly comparable amongst themselves, though the actual growth may not correspond to that of plants under natural conditions. This will not prevent useful work being accomplished with due judgment; the danger is when total crops, &c., are calculated from the results by the acre, and compared with field crops. The differences between the various experiments may be shown in that way for the sake of illustration, but even that is open to objection, and perhaps the best form of displaying the results is as percentages of a normal crop experiment.

One difficulty in such experiments is to have in each pot as nearly as possible an equal amount of soil in an equal degree of consolidation. To aid in this the soil must be thoroughly mixed before it is used, and it should be in an even state as regards moisture; if wet it will settle into too hard a mass, and if dry it will not be easy to moisten it adequately afterwards. If the soil is weighed out in amounts of 50 or 60 lb., it will be found a difficult matter to fill that in to an equal level in a number of pots, and if several persons are entrusted with the work there will be a marked difference. A few pounds should be placed in at a time, and lightly "firmed" with a wooden rammer; but too much care cannot be exercised in this operation, and some experience is also needed to regulate the process of consolidation satisfactorily.

Records must be kept of the weight of pots, soil and plants. Measurements will also be advisable in some cases, and every detail in the growth of the plants should be noted. The weather conditions must be observed, and injurious or beneficial influences duly valued. The amount of foliage, development of individual leaves, the time of flowering, the maturation of seed, fruit, root, or the whole plants, are all points which demand attention and recording. In manurial experiments it may be essential to prepare a series of exact analyses, so that altogether a great amount of work is involved.

Protection of the plants from birds is necessary in many instances, and at Woburn this is accomplished by means of an arched iron structure covered with wire netting, but anything of this kind could be easily made without much expense.

FIG. 119.- LISSOCHILUS PURPURATUS.

For convenience also in moving the pots about these are in the institution named placed upon low wheeled trolleys running upon rails, so that the pots can be taken under the cover of a glass roof when requisite.

The pot-culture experiments specially referred to in these remarks are those devoted to field crops, garden vegetables, or fruit-trees, but it is obvious that many others can be undertaken on a smaller scale, for which an ordinary greenhouse would suffice. The general principles of management, recording, &c., are equally applicable, and can be modified to meet particular requirements. A complete record should be had at starting of plants and soil; everything supplied must be noted; and at the conclusion a full record must be taken of the results.

Much more could be written upon the important subject of experimental cultivation, for it is practically inexhaustible. For example, experiments in plant improvement, in the application of insecticides and fungicides, and in the best commercial sources of the essential elements, all come within its scope. Enough has, however, been said to show how much interest there is in work of this character, and to indicate to untrained beginners the methods upon which it should be founded. In the future horticulturists will probably be called upon to do much more in this direction than hitherto, and every gardener who desires to stand high in his calling should, if required, be at least prepared to carry out work of the kind upon a sound scientific basis. *R. Lewis Castle.*

ORCHID NOTES AND GLEANINGS.

LISSOCHILUS PURPURATUS, *Lindl.*

An inflorescence of this fine species is sent us by Mr. A. J. Reid from The Gardens, The Chase, Farnham Royal, Bucks, with the information that the tubers were received from Central Africa, and that the leaves are long and narrow. The inflorescence, over 3 feet in length, bore on the upper part a number of very attractive flowers. The sepals and broader petals are of pale rosy-lilac colour. The side lobes of the labellum are greenish with some indistinct purple markings, and the expanded front lobe, down which extends some irregular raised lines, bright rose-purple colour.

The Lissochilus and allied Eulophias of this class are widely distributed in Africa, and are among the showiest of terrestrial Orchids, but owing to the fact that their requirements are not yet understood in gardens, it is only occasionally that they are seen in flower. The probability is that they are grown in an atmosphere that is too close and moist, for a correspondent writing from the Transvaal recently, after remarking on the beauties of the yellow Lissochilus speciosus and some other white, rose-coloured, and purple species, stated:—"The conditions under which these beautiful and hardy Lissochili grow are as follows: In the open veldt among grass; soil a sandy loam, light or dark. They commence to grow about the end of July, and flower throughout September and October. There is no rain from end of April till August at the earliest. Thermometer in summer at a maximum

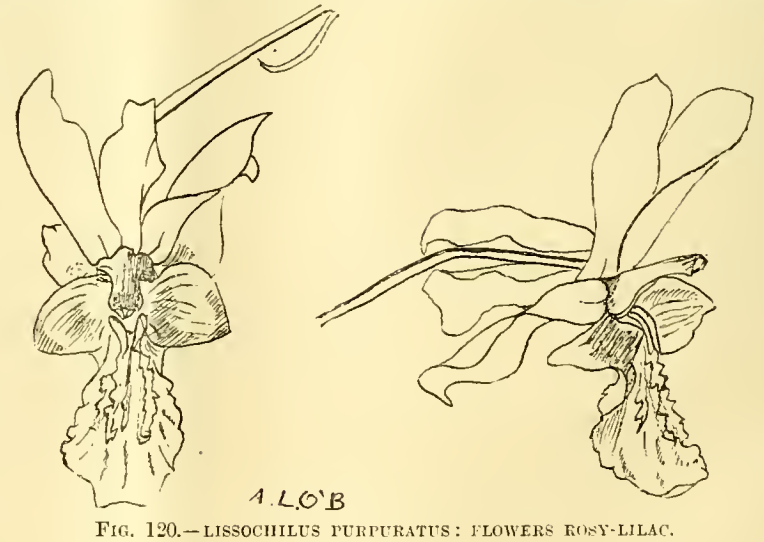

FIG. 120.—LISSOCHILUS PURPURATUS: FLOWERS ROSY-LILAC. (*Natural size.*)

of 90°; in winter, at the end of May and June, down to 16°. Altitude 5,000 to 6,000 feet. Their bulbs are only about 1 inch below the surface, and the ground is hard and dry during winter. There is no shelter of any kind for them." This applies to the Transvaal species, and it suggests that they would be nearly, if not quite, hardy in this country if they could be got to work into our seasons, which are the reverse of those in their native habitats. The treatment for Lissochilus purpuratus and others of the more tropical African species of the class which form chains of underground tubers might also be regulated in some degree in the light of the notes given.

MECONOPSIS INTEGRIFOLIA.

In the *Gardeners' Chronicle* for April 1 last, a paragraph appears in which a doubt is expressed as to whether the plant figured under the above name in the *Flora and Sylva*, Part 24 (March, 1905), from a plant flowered by Messrs. "Bee & Co.," of Neston, is of the same species as Messrs. Veitch's plant illustrated in the *Gardeners' Chronicle* for October 1, 1904.

In the figure of Messrs. Bee's plant cited above, the two immature capsules are drawn with styles respectively $\frac{3}{8}$ and $\frac{1}{2}$ inch long. Appended is Franchet's original description of Meconopsis integrifolia,* from which it will be seen that this plant has a very short thick style with broad, radiating stigmas. Indeed, so short is the style that the stigma may almost be described as sessile.

An inspection of some fifty-odd specimens from my herbarium, and of the plants exhibited by Messrs. Veitch at the Horticultural Hall on April 25 last, failed to reveal a single example showing any tendency towards the production of an elongated style.

In the description of Messrs. Bee's plant, which appeared in the *Gardeners' Chronicle* for September 17, 1904, the following statement was made:—"The flowers, each borne on a stout peduncle 12 to 14 inches in length, are of a delicate soft yellow colour, *and rise in succession from the thick tuft of leaves*, different from other Eastern members of the genus, so that it is expected to prove a perennial plant."

From the part of the above statement which is italicised, it is to be inferred that the writer means the plant is scapigerous. Franchet† describes Meconopsis integrifolia as caulescent. In the *Gardeners' Chronicle* for October 1, p. 241, the above important difference was noted, and the suggestion made that it was "probably because English-raised plants are weak." Neither in the Kew Herbarium nor amongst my specimens and the living plants raised from seed sent home by him is there a single example in which the flowers are other than cauline. Further, I never met with a scapigerous example of Meconopsis integrifolia in my travels.

In having a definite cymosely sub-umbellate inflorescence, Meconopsis integrifolia differs from all other species of the genus save M. grandis, Prain. In having a very short, thick style and broad, radiating, almost sessile stigmas, M. integrifolia differs from all others of the genus save the scapigerous M. punicea of Maximowicz.

With these facts before us, it is evident that, if the description and figure of Messrs. Bee's plant are correct — and there is no reason to doubt this—their plant varies from the typical M. integrifolia. Messrs. Veitch's plants are identical with the type specimen as described by Franchet, and figured by Maximowicz in his *Flora Tangutica*.

The statement that Meconopsis integrifolia will not seed in England is entirely premature.

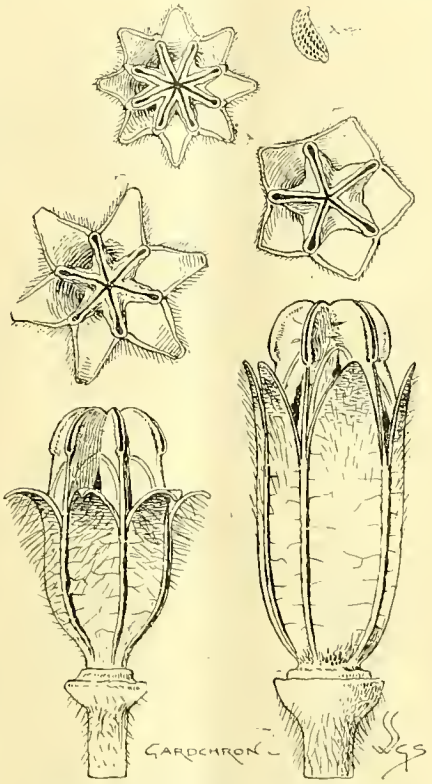

FIG. 121.—MECONOPSIS INTEGRIFOLIA, SHOWING VARIATION IN LENGTH OF CAPSULES, STIGMAS AS SEEN FROM ABOVE, AND SEED.

Many scores of strong plants are now blooming in Messrs. Veitch's Langley nursery, and are as vigorous as in their native home. The root system as observed at Langley is shallow and fibrous. Some of the dried specimens show indications of a tap-root, so that the form of the root is probably dependent on the nature of the soil.

Maximowicz founded the species on a plant collected in Kaneru (N.W. China) by Przewalski in 1873, but he considered it a Cathcartia. Subsequently Franchet secured ripe capsules, and found it to be a Meconopsis. In his *Flora Tangutica*, Maximowicz gives excellent figures under the name of Cathcartia integrifolia. His T. 9, fig. 7, shows the caulescent habit; his T. 23, figs. 22—25, shows the broad radiating nearly sessile stigmas. Franchet considers M. integrifolia near to M. simplicifolia, Hooker and Thomson, but it is certainly more closely allied to M. grandis, of Prain. This last is a Sikkim species, and differs in having smaller purple flowers, and slightly different style and stigma, and toothed leaves. *E. H. W.*

* *Meconopsis integrifolia*, Franchet, Bull. Soc. Bot. France, xxxiii. (1886), 389.—"Souche épaisse, couverte au collet des débris des anciennes feuilles; plante toute hérissée de longs poils roux, très abondants surtout sur les pédoncules; feuilles basilaires tripli-uervées étroitement lancéolées ou lancéolées-linéaires, longuement atténuées à la base en un pétiole ailé, souvent plus long que le limbe, brièvement atténuées, un peu aigües au sommet, très entières sur les bords; tiges de 2—4 décimètres, portant 3—5 feuilles semblables aux basilaires, les supérieures contigües aux fleurs; deux ou trois fleurs en grappe, ordinairement longuement pédonculées, très grandes (7—10 cent. diam.) d'un jaune soufre; pétales largement obovales, arrondis au sommet; filets staminaux glabres, peu dilatées vers le haut; anthères ovales; ovaire obloog, couvert des soies apprimées jaunâtres; style convexe-pyramidal très brièvement rétréci à la base, avec 5 stigmates radiés-décurrents; capsule obovate-oblongue, longue de 3 à 4 centimètres, s'ouvrant au sommet par 5 valves courtes."

"La plante ressemble singulièrement au M. simplicifolia, Hook. et Thoms.; mais les tiges sont constamment pluriflores, et la portion rétrécl constituant le style est très raccourcie."

BOOK NOTICE.

LEHRBUCH DES GARTENBAUES MIT BESONDERER BERUCKSTICHTIGUNG SCHWEIZERICHER VERHÄLTNISSE. Von Max Lobner. Mit 45, Abbildungen. Verlag von Cäsar Schmidt, Zurich.

This manual of Swiss horticulture has been written with the idea of affording the possessor of a garden employing a gardener an insight into garden matters so far as to enable him to form a just opinion of the labours and activities of the latter. In order to serve this purpose, the subject-matter is greatly condensed, and in order to obtain wide-spread acceptance of the book among amateurs and gardeners the price is very small. The æsthetic side of gardening receives pretty full attention, as in this matter the greatest mistakes are made by those who lay-out gardens.

The illustrations in this part of the book are well chosen and exceedingly pretty and interesting. The so-called "English style" of laying-out introduced from England by Sckell, an example by him, the *Englischer Garten* at Munich being cited as one of his successes; and another, the Park at Nymphenburg, laid out originally in the French, is now being altered to the English style. Prince Pückler-Muskau did much to further the adoption of the English style at Muskau, and his work, entitled *Änderungen ber Landschaftsgärtnerei*, no longer in print, but of which a cheap edition will shortly appear, helped to bring it into favour on the Continent, and more particularly in Germany and Central Europe. Since the middle of the last century a natural style, suited to the manners, customs, and views of the various nations, localities, and soil formations, has arisen, with the right to be entitled the German (Deutscher) style. Where formerly only princes and the upper ten thousand had the enjoyment of a park or garden, the people now have their house-gardens laid out according to true landscape rules.

For small gardens and parks, the author favours, and with right, the older, regular style, French by preference, rather than the more free, natural or English style. He treats of summer-houses, arbours, arcades, pergolas, garden seats, and other adjuncts to a garden, giving some capital illustrations; affords rules for the construction of roads, paths, and drains in a correct manner. The treatment of plantations, groups, and shrubberies comes next under consideration, the species of trees that succeed in Alpine woods, in the lower hills, and in the plains being named; and allusion made to the liability of the young shoots of the Silver Fir to be injured by late spring frosts, when planted in low grounds, thereby crippling and spoiling its beauty. The advice is given the planter to note carefully the indigenous timber trees of the district, and to plant chiefly those, so as to obtain in the artificial landscape the bold and majestic appearance of a natural wood, or, as Goethe wrote, "Im Grossen gros."

Thinly scattered among these, Tilia, Platanus, Acer, Salix, and Betula, should be planted, and in the larger plantations Fagus, Ulmus and Quercus arranged in small groups or singly, and in swampy ground Alnus in variety.

The bad practice of most villa gardeners in cutting up the lawn into small divisions by the formation of numerous flower-beds is justly condemned, and an illustration of such a spoiled lawn is given from a photograph.

The chapter on the treatment of shrubs from time of planting and subsequently, contains much useful information. In regard to evergreens the author states that it is not the cold which injures or kills, but the varying temperatures in the months of January and February, from warmth by day to great cold by night; and it is always advisable to plant in half shade, thus

Fig. 122.—Calodendron capense: flowers creamy-white sprinkled with purplish glands.

(See p. 293; also Supplementary Illustration.)

obviating the evaporation of moisture from the leaves, which cannot be replaced by the roots owing to the frozen condition of the soil.

We learn that Roses in dryish land must be protected in winter by burying them in the earth, and in wet land by a covering of tree-leaves laid on the bent-down plants, which are merely pegged down to the soil. In April the Roses are uncovered, but kept lightly bedecked with litter till all danger from frost is passed.

Lawns and rockeries come next in review, and special instructions are given concerning the proper treatment of Alpines, which, in regard to species from the glaciers and higher Alps, seem to be as difficult of management at low altitudes as in our own country. The flower garden, the water-garden and the vegetable garden are given brief notice; as also the fruit garden and orchard, with directions for pruning, manuring, the destruction of insects infesting fruit-trees, &c. We note an illustration of a Grape-vine, carrying numerous bunches of Grapes, accommodated in a rough kind of hotbed frame. *F. M.*

CALODENDRON CAPENSE.

[*See Fig. 122, and Supplementary Illustration.*]

Our Supplementary Illustration to this issue has been prepared from a photograph kindly sent us by Mr. Maiden, Director of the Botanic Gardens, Sydney. In an accompanying letter Mr. Maiden included the following remarks respecting the effect the tree has in the Sydney Gardens. It is quite possible that the tree may have been planted by our old correspondent, Mr. Charles Moore, whose recent death we regret to have to announce (see p. 298):—

"Every December the Cape Chestnut (Calodendron capense) is a beautiful picture, with its exuberance of brightly-coloured flowers. This summer, however, it has been especially gorgeous. You will observe what a large tree it is, but on no portion of its circumference could a man's hand be placed without covering some of the blossoms. They make a very pretty table decoration."

The species has been known for very many years in English greenhouses, but having been lost sight of for a time, was re-introduced by Mr. Bult in 1882. It is Rutaceous tree or shrub, and is a native of Natal and South-Eastern Africa. The leaves are studded with oil-cysts, which look like translucent spots when held up to the light. The species was described in the *Flora Capensis*, vol. i., p. 371. At fig. 122 the inflorescence is reproduced about natural size, and a good idea can be obtained therefrom of the individual flowers, which are of creamy-white colour with purple glands. In this country the species requires to be afforded the protection of a greenhouse.

HOW TO MAKE A GARDEN-SEAT IN BAMBOO.

The garden-seat in Bamboo illustrated at fig. 123 will be found worthy of the attention of those who are fond of making articles to help furnish the garden. The work is simple, few tools are required, and the material is inexpensive. It is, however, essential that good, sound joints be made. By carefully following the instructions given below the skill will be acquired with very little practice. Those who have not attemped Bamboo-work before are advised to practise first on a spare piece of Bamboo to properly acquire the art of jointing; it is more economical than starting directly on to a piece of furniture and running the chance of spoiling parts of it in gaining experience.

The design given in fig. 123,[1] is purposely plain, and of such stability as to stand rough usage. The tools required are chiefly a fine-toothed saw, a brace and two bits, a rasp, hammer, and a pocket-knife; a glue-pot and good glue, some odd pieces of hard wood for plugging the joints, as will be shown, and a few wire panel pins will also be required. The latter have butt-shaped heads, and can be purchased at any ironmongers. The only special tool needed is the rasp, which differs from the ordinary wood rasps, being deeper in segment, but in section it is practically half round. A 1-inch rasp will be found the most suitable size, and can be bought at any well known tool dealer's. The seat is made of 1½-inch Bamboo for the main part, and the upright bars of ¾-inch. The Bamboo is imported in lengths of 6 feet 6 inches, and is to be bought at any oil and colour stores. In selecting the canes always pick out those whose knots are closest together, as they are the stronger, being the root-end of the cane. It will be noticed in fig. 123,[1] that the back legs and arm rests are represented as having root-ends to form a finish. There is no difficulty in getting these, and the method of treating them will be explained below. The seat as drawn measures 4 feet 6 inches in length and 18 inches in depth; the other measurements are given subsequently; but first let it be shown how to make

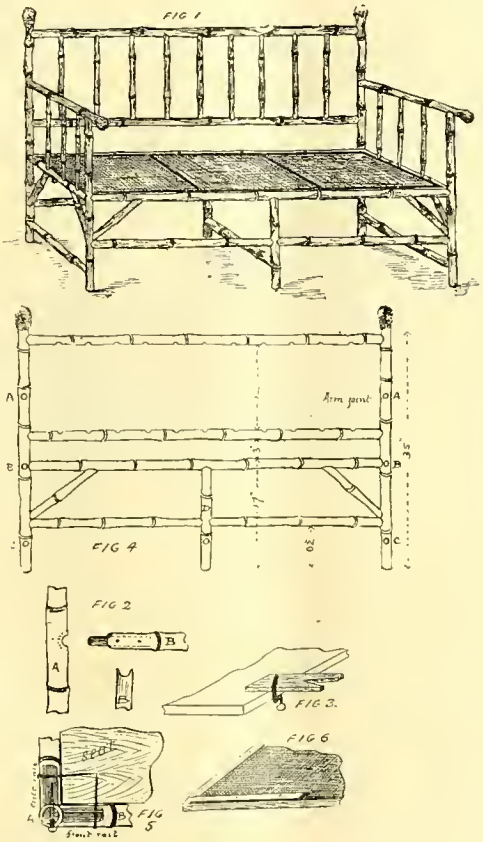

FIG. 123.—A BAMBOO GARDEN SEAT AND DETAILS SHOWING CONSTRUCTION OF SAME.

a good joint, one that is known as a "dowel joint," and illustrated in fig. 123,[2]. The piece marked A represents a leg, and B a horizontal rail which it is required to join to A. The end of the rail B is first rasped out to nearly a semi-circular shape to fit neatly against the leg A, and any pith found inside the Bamboo is to be scraped out with the knife. Now get a piece of wood (hard in preference) 6 inches long that will fit tightly in the Bamboo (B) without having to use force to get it in. Leave it in temporarily whilst cutting a hole in the upright A that will just take this wood plug. The hole is cut with a centrebit, working it to and fro to avoid any possibility of splitting the cane. Again scrape out the pith and roughen the immediate surface round the hole with the rasp, as represented by the dots. Now take the wooden pin and glue it into the hole as far as it will go; then apply plenty of glue to the remainder of the plug and to the inside of B and slip it on over the dowel, and in addition secure the plug with two 1½-inch wire panel pins, through the rail on each side and one on each side of the leg. Two chief points to remember are: first, to use plenty of good glue, and to see that it is hot. Any that oozes out easily chips off when dry, as it will not hold to the surface of the Bamboo unless the latter is roughed first; and, secondly, remember that all holes, even for thin wire pins, must be drilled with an ordinary awl. Never attempt to drive in a wire pin without first making a hole for it, or otherwise the Bamboo will split, as it has a long, straight grain. For indoor furniture, the addition of wire pins in a joint of this kind is not necessary; it is only done when the work is likely to be exposed to the weather, whilst the glue is protected by the varnish which the seat is finally coated with.

When rasping the end of a Bamboo, instead of holding it in a vice, the proper way is to provide a piece of hard wood, about 8 inches long, 5 inches wide, and ⅝ inch thick, and cut a V-shaped jaw in one end (see fig. 123,[3]). This is then clamped to the bench or table; the Bamboo can then be held with one hand in the jaw, whilst the other hand has the rasp.

Another joint necessary to understand is called "direct doweling," and this is used in fixing the thinner uprights into the main framework. In this instance these uprights are of ¾-inch Bamboo, and should be cut 1 inch longer than they appear when fixed, which allows ½ an inch at each end for letting into the 1½-inch canes. Select them as true to size as possible, then rasp the ends to a slight taper, so that they will fit into a ⅝-inch hole. Holes of this kind are cut in the horizontal canes with a centre-bit; tap the uprights in gently with a hammer, and then secure each end with a wire pin.

The third and last joint necessary to be familiar with is that one used in fixing the diagonal stay pieces shown under the seat to give it rigidity. The Bamboo being cut to the length required, the ends are rasped to fit neatly, then insert a plug at each end, fixing it with glue and pins, and rasping it to the shape already made in the Bamboo; roughen the surface against which the stays will fit, and then fix them with glue and using 2-inch wire pins. These few particulars being mastered, we can now proceed with the construction of the seat. All measurements given are "when fitted," so that allowance must be made for rasping the ends of the horizontals, say ½ inch for each end. First cut the legs, the front ones being 27 inches long, the back ones 35 inches to the top rail. Allowing for the root ends, the back legs are cut 38 inches over-all. Of course these root-ends are optional, but they make a very novel finish, besides which the root-end is the strongest part of the cane. When bought they are generally in their rough, natural state, and require burning by holding them in the flame of a spirit lamp or a Bunsen burner, the latter of course where gas is used, and when softened by the heat, trim them off with a rasp to a conical shape. The back legs are connected with four horizontal rails, two forming the back, then comes the seat rail, and below this, the fourth rail, to which the centre leg or support is connected. Fig. 123,[4] shows a plan of the back, and in it are given the various measurements for the positions of the rails. It will be seen that the bottom rail is in two lengths on account of the centre leg D, and the method of making the joint is similar to that shown in fig. 123,[2], except that the hole in the upright goes right through, and the dowel or plug must be proportionately longer, extending say three inches on either side, the two ends of the rail being fitted on to it. All the various joints must be made and temporarily fitted, for example the uprights between the two top rails must be fixed first before the rails are permanently fitted on to the legs.

The holes shown at A, B and C, fig. 125,[4], are for the arm-rests, side seat-rails and bottom side-rails respectively, and with regard to the side seat-rail B, as it comes on a level with and at right-angles to the front and back seat-rails, the dowel must be shorter, as it butts against the one already made, so that to give it the necessary strength it has the addition of a 3-inch round-headed screw as shown in section in fig. 123,[5]. The arm-rails come 9 inches above the seat-rails. The back section being completed, including the holes for the side joints, joint up permanently, clamping it together with stout cord, and put it on one side, taking care that all parts are squared and that there is no twist in the frame.

The next section to prepare is the front, consisting of the two front legs, centre leg, seat-rail and lower rail, the top of the outer legs being rasped to take the arm-rails. There is but little work in this section, and whilst it is setting prepare the side-pieces, the rails being 15 inches long when fitted, the depth of the seat being 18 inches outside to outside measurement. The bottom side-rails are 3 inches lower than the front and back ones, also the one connecting the centre legs; whilst the arms are about 20 inches long when fitted, including the root ends. The upright rails for the back are 4½ inches apart, whilst those on the sides are 3¾ inches from centre to centre.

Having connected the front and back sections, next fix on the diagonal stays, and the framework is completed. Be careful not to hurry the work; let the glue in the joints set thoroughly, and the result will be a perfectly rigid and substantial seat-frame.

With regard to the seat itself, get two boards of ¾-inch deal to make up the width of 15 inches, and fix them together with stout battens underneath. The seat must just fit neatly within the seat-rails, so that it will be necessary to rasp the knots on the Bamboo on the inside of the framework, flat, and fix the seat with stout wire pins through the frame, as shown in fig. 123,[5]. Before doing this, however, it is covered with yellow Japanese matting, which in a good quality costs 1s. a square yard. Lay the matting on the wood, allowing a little margin all round, and fix it with split cane on the top edge, and also at equal distances from back to front, as shown in fig. 123,[1]. The cane, known as beading-cane is ⅜ inch thick, and costs 2*d.* a length of about 8 feet. This is then split in halves lengthways with an ordinary knife, and fixed with ¾-inch wire beading-pins. When fixed, trim off the surplus matting, and then nail the seat into the frame. Fig. 123,[6] shows how the split beading-cane is fixed. All that remains to be done now is to clean off the joints by chipping away any superfluous glue, and finally to give the structure, including the matting-seat, two coats of good copal varnish, not spirit varnish, as this will not stand the weather. By carefully covering all parts with the varnish, the glue will not be affected by the weather. The whole seat should be revarnished at least once a year. *S. W. N.*

FOREIGN CORRESPONDENCE.

THE GRAPE-FRUIT.

IN regard to Mr. G. Marshall Woodrow's note on Grape-fruit, on p. 171 of the *Gardeners' Chronicle* for March 18, I beg to state that the words "Grape-fruit" and "Pomelo" are recognised as synonyms by good pomological authorities. Grape-fruit is also given in the *Century Dictionary* as a synonym, and not as a variety of Pomelo. It would be interesting to know what fruit Mr. Woodrow refers to as Grape-fruit, and why he refers to it under that name in contradistinction to the Pomelo. *H. C. Henricksen, United States Department of Agriculture Experiment Station, Mayaguez, Porto Rico.*

The Week's Work.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Leaf-Blister or Curl.—In consequence of the cold and changeable weather, trees in exposed positions and ineffectively protected are attacked by the leaf-blister fungus, Exoascus deformans. The first stage can be detected by a pale, powdery bloom on the underside of some of the leaves similar to an attack of mildew. If allowed to continue unabated the disease develops quickly, and soon the whole leaf is in a malformed and useless condition; the young shoots are likewise attacked, and the tender growths ultimately shrivel and die. Spray such trees twice each week with sulphide of potassium at the strength of half-an-ounce dissolved in 1 gallon of warm soft water. Continue the sprayings until healthy growth has recommenced,

FIG. 124.—PEACH LEAF AFFECTED WITH "BLISTER" (EXOASCUS DEFORMANS).

applying the solution if possible in the evening, when the sun's rays are not directly on the trees. All infested leaves and shoots should be cut down to a point where the growth is healthy, and the attacked portions burnt. Syringe the trees each afternoon sufficiently early for the foliage to become dry before nightfall.

"The Yellows."—Frequently Peach and Nectarine trees suffer from this disease, and in most cases it is the result of the roots and root-fibres having descended into an unsatisfactory rooting medium, or because the drainage is inefficient and stagnant, or there is a lack of mineral constituents in the soil. In cases where the drainage is known to be good, apply a dressing of superphosphate of lime and muriate of potash, mixed at the rate of two parts of the former to one of the latter. An application of 2 oz. to the square yard often serves to correct the evil.

Orchard Trees which were "headed" down and grafted last season will now require some support to the grafts, which otherwise would be liable to be blown off as growth proceeds. Strong sticks or canes, if made secure to the main branches, will be sufficient to hold the grafts by means of ties. All growths emanating from any part of the tree, excepting the grafts, should be removed at once. Such treatment should be applied to all trees that were grafted and budded last year.

Suckers.—Remove suckers from the base of all fruit-trees immediately they make an appearance. Persistent attention to this matter is necessary, especially in the case of Plums.

Gooseberry and Currant Plants which were planted out from the "cutting bed" this spring will now be making growth. If they are required to form bushes the shoots may be allowed to grow, excepting the lower ones, for at least 1 foot of clear stem is necessary. If standards are required, pinch all the shoots excepting the leading one. Should fan-trained or double or treble upright cordons be required, cut out entirely all the branches that will not be required for the proper formation of the trees.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Capped Hall, Epping, Essex.

Winter-flowering Begonias.—These plants having had a sufficient period of rest are now showing signs of growth, and should be transferred to conditions in which the growth will become healthy and strong. Of the many winter-flowering subjects none, to my mind, is brighter or more useful when grouped together than these Begonias, which were obtained from crosses between B. socotrana and various tuberous-rooted varieties. They are not difficult of culture, but they nevertheless require close attention from the time the cutting is inserted until the plant flowers. As the plants show signs of renewed activity they should be stood in a house where shade, heat, and moisture can be given them. Beyond an occasional syringing overhead, no water will be needed until a moderate amount of growth has been made. Cuttings may be taken as the growths become sufficiently advanced, but three of the strongest growths should be allowed to remain on each plant. When these three shoots are from 4 to 6 inches in length, the plants should be repotted after carefully removing the loose soil from about their roots. A suitable compost is one of fibrous loam two parts, leaf-soil one part, and a little broken dried sheep-manure and silver-sand added. Turn over and mix these together thoroughly before using the material. Be careful to avoid the use of pots of a larger size than is necessary. In the first instance the pot should be just sufficiently large to receive the bulb, and allow of a very little of the new compost being added around the "ball"; but the plants may be potted-on when the first pots have become moderately filled with roots. It is of vital importance that great care should be exercised during the whole season in the application of water to the roots. The plants should be immersed or syringed in a solution of Quassia Extract not less frequently than once a week. During this period of growth let the plants be kept in a "brisk" warmth and a moist atmosphere, shading them from the rays of the sun, and syringing them frequently overhead. Of several varieties, the most useful are in the following order: John Heal, Winter Cheer, and Ensign.

Coleus thyrsoideus.—This winter-flowering plant is very decorative, and may be raised easily from cuttings or from seeds. I prefer plants raised from cuttings, for I think they have a less tendency to make lanky growth. A few early cuttings may be inserted at the present time singly in small pots of soil composed mainly of peat and sand. Cuttings for raising the main batch of plants may be inserted at about the middle of June.

Thyrsacanthus rutilans.—A batch of cuttings should be inserted now in a propagating-frame, using old potting soil for the purpose. These will make useful plants in the first season.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Peaches and Nectarines.—Fruits in the earliest forced houses will now be ripe or approaching to that stage. Maintain a drier atmosphere and allow a free circulation of warm air from the time the fruits commence to colour. Discontinue syringing the fruits, but damp all available spaces in the house. When all the fruits are gathered the trees should be syringed with a suitable insecticide in order to remove red-spider and other insects; the trees should also be syringed twice daily with clear water to maintain the foliage healthy. Keep the laterals pinched, and remove all useless wood, also any that, having borne fruit, can be replaced by young shoots. Give the roots

of the trees a good watering, and to any that require it supply an occasional application of liquid-manure. Mulch the trees again if necessary; this will be a preventive against dryness at the roots. Ventilate the houses to their fullest extent.

Succession Houses.—Continue to tie the young growths as often as it becomes necessary, at the same time giving the fruits full exposure to the sunlight. A good plan is to place small strips of wood across the wires and beneath the Peaches, and thus to expose the fruits well above the foliage. Mulch the trees, if this has not already been done, with fresh horse-droppings, and give plenty of water to the roots, with frequent applications of liquid manure. If the trees appear to require it, they may be allowed at intervals a light dressing of some suitable artificial manure. There is very little danger of over-watering trees that are growing in well-drained inside borders. Admit air freely on all favourable occasions, being always careful to avoid cold draughts. Maintain a steady temperature at night of about 60°. Nothing is gained by trying to hurry the growth of the trees until the stoning period is passed.

Later Houses.—Trees in these houses will now be rapidly growing, and the work of disbudding the shoots and thinning the fruits will require constant care. Pay careful attention to the ventilation of the houses and to the proper waterings of the roots. Syringe the trees twice daily during bright weather. In unheated houses this syringing should be done sufficiently early to allow of the foliage becoming dry before night-time. Newly-planted trees should be mulched and have their shoots carefully disbudded. In some cases it will be found necessary to pinch-out the points of the strongest-growing shoots in order to encourage a more even flow of the sap. Green-fly and other insect pests can be kept down by occasionally syringing the trees with Quassia-extract.

Figs in Pots. — As soon as the first crop of these fruits is removed, cleanse the trees from red spider, and afterwards give the same atmospheric treatment as for trees swelling their fruits. Thin the second crop of fruits freely if the trees are intended to supply an early first crop of fruit in the following year. Discontinue the use of manure, and apply less syringing to trees that are maturing their fruit. Maintain a free circulation of warm air in the house. Give liberal treatment to trees that are swelling their fruits, and endeavour to keep the plants clean by vigorously syringing them with water on bright days.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Hardy Biennials.—Sow seeds of biennial plants in moderately-rich ground facing to the east. If the soil is of a heavy nature scatter some sifted leaf-mould over the surface, and if weather is dry thoroughly moisten the soil before sowing the seeds. The seeds may be sown broadcast or in drills. If they are sown broadcast mark off beds 4 feet wide, and sow thinly. Slightly covering the seeds with fine soil that has been passed through a half-inch sieve assists germination. If the weather is very dry, afford the beds a little shade by using mats or tree-boughs. These notes apply to Wallflowers, Canterbury Bells, Sweet Williams, Rockets, Œnotheras, &c. For planting in the wild-garden the following strong-growing hardy biennials are effective, and may be sown at the present time:—Cnicus eriophorus, Michauxias, Onopordons, Anchusa capensis, Reseda alba, Silybum, Verbascum Chaixii, V. olympicum, V. phlomoides, and V. libani.

Annuals.—Proceed with the sowing of annuals, bearing in mind that the Mignonette requires a considerable depth of rich soil, and that Shirley Poppies are brilliant in effect and of simple culture. Double Wallflowers, if desired, can be propagated now, by inserting cuttings in sandy soil under handlights in a shady place. Choose short growths that are moderately firm. Cheiranthus Allioni and C. alpinus can best be propagated just after the flowering season.

Miscellaneous Work.—Perennial Poppies that were sown in heat and subsequently pricked off are ready for being planted out. Papaver alpinum and P. nudicaule varieties are suitable plants for cultivation in rockeries and dry places. P. pilosum and P. orientale should be planted in borders. Plant out Gaillardias. Divide the clumps of Schizostylis coccinea, and replant them in a warm situation. Afford these plants plenty of water during dry weather.

The Wild Garden.—The following are blue-flowering plants that will bloom in August and onwards:—Delphiniums and Aconites, which are a little later and flower well in ordinary soil, even under the shade of trees. They have a good effect if associated with Phloxes, Solidagos, &c. The following are good varieties:—Aconitum autumnale, A. napellus Brauni, A. n. longi-bracteatum, and A. n. strictum, &c. Owing to the poisonous character of the plants, care must be exercised in planting them. Aster acris and Campanula pyramidalis succeed well in sunny positions. Salvia Horminum grandiflorum violaceum, if grown in rich soil and in an open aspect, makes a fine display in autumn. Salvia virgata, Symphytum caucasicum, Scabiosa succisa, Anchusa italica, Echium vulgare, and Cichorium Intybus are good; the last can be sown where intended to flower, also the annual Larkspur and Borage. Large clumps of Clematis Jackmanni and Sweet Pea Captain of the Blues are effective if properly supported with stakes. Amongst blue-flowering shrubs there are Caryopteris Mastocanthus and the Ceanothuses. Both species require sunshine and shelter from cold winds.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Leeks.—If seeds were sown early as advised, the plants will have filled the 5-inch pots with roots by this time and be sufficiently hardened to be transferred to the trenches prepared for them. The Leek being a very gross feeder requires a large quantity of stable manure. The trenches should be prepared as for Celery 2 feet deep and 18 inches wide for a single row, planting the Leeks at distances of 12 inches apart and sufficiently deep to cover the "ball" well. Immediately after planting place a brown-paper collar 6 inches deep round each plant by slipping it over the top. Then place a few inches deep of fine soil around it. When the heart of the plant appears above the top of the collar, the collar must be raised and more fine soil added, repeating the process until the stem is of the desired length, which may be 12 or 15 inches. Much watering and feeding will not be necessary until the plants have attained the desired length, and the ridge is well filled with roots.

Cardoons.—If well grown and properly blanched, the fleshy leaf-stalk or "ribs" of Cardoons make a "dish" at a season when there is not much variety in vegetables. For producing an early crop seeds should now be sown in small pots in a moderate degree of heat, but with free ventilation. When the plants have become large enough transplant them into trenches prepared as for Celery, putting the plants 2 feet apart. Afford water whenever this is necessary so that the plants may suffer no check. Seeds may also be sown in patches out of doors in fine soil. Sow a few seeds in each patch and thin them out to one plant only.

Celery.—Select a hard foundation in a suitable position and place about 3 inches deep of well-decayed manure over the space required, covering this with about 2 inches of fine soil. The Celery plants may be pricked out into this as soon as they are sufficiently large to handle, putting them 4 inches apart from each other. If treated in this way the plants will remove with compact "balls" of roots when they are required for planting into the trenches.

Potatos that were planted early on warm borders must be moulded up or given protection in some way as soon as the growth appears. On the morning of May 4 we had ice here of the thickness of a penny, and 5° of frost. We have only just completed planting such varieties as Up-to-Date and Northern Star, as the soil here is not favourable to early planting. Tubers that have sprouted in trays are superior to those planted a month earlier. The soil is in better condition than it was then, and we have the knowledge that every set put in is in perfect condition for making growth.

Box Edging.—If any of the Box-edgings need to be relaid, let the work be done now. If any blanks have to be filled up, let the plants be given the benefit of fresh soil. When spring frosts are past, Box plants stand clipping well, and cuttings about 6 inches in length inserted firmly in sandy soil will soon develop roots.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cultivation of Orchids in Summer.—The summer treatment of Orchids should now be practised whenever the weather is seasonable, with a view to secure atmospherical surroundings that will induce good sound growth in the plants. The warm or East Indian house should have during the daytime an atmospheric temperature ranging from 70° to 80°; the surface should be damped frequently enough to keep the atmosphere moist, and ventilation should be afforded gradually and efficiently through the lower openings. Shade from strong sunlight will be necessary. At about 3 o'clock in the afternoon close the ventilators and afford a final and thorough damping, and as the sun declines let the blinds be rolled up. Where the automatic sprayer is used, the necessary root waterings should be afforded before spraying overhead is done, or the surface of the compost may get damped, and give a wrong impression as to its condition beneath.

The Cattleya House should be treated similarly in the morning, but if the whole of the ventilators be closed in the afternoon, it is advisable to again open those on the leeward side an inch or two at night. If overhead spraying is done it should be performed in the morning, and expanded flowers should not be wetted.

The Mexican House may be treated in the same manner, excepting that shading should not be afforded until later, and it should be taken off earlier in the day. Top ventilation should also be admitted whenever the wind is not very cold or strong.

The Intermediate and Cool Houses should have free ventilation, but not severe draughts, and the atmosphere should be kept moist by frequent dampings. The plants in these houses require shading from all direct sunshine. The cool compartments should be kept cool, but not cold and clammy, and if fire-heat is not required to to raise the atmospheric temperature, it is advisable to have a little in the pipes to induce evaporation and promote the circulation of air at night. When the weather is dull or uncertain in character, the above cultural directions must be considerably modified, and overhead spraying must be confined to the warm houses, or it may not be necessary to practise it at all.

Dendrobium Phalænopsis and allied species, such as D. bigibbum, D. Statterianum, D. Gouldei, &c., after a long rest, are now pushing forth new growths. As soon as new roots are expected pick out the old material from plants that do not need to be repotted, and replace with new. In repotting the plants shake away the decayed material and cut off dead roots. Then fix the plants into pans by tying some of the pseudo-bulbs to the wires, half fill the pans with drainage material, and use equal parts of good fibrous peat and sphagnum-moss for placing about the roots. Suspend the plants in the most exposed and warmest part of the East Indian-house, or in an ordinary plant stove, as they need much heat and almost unobscured sunlight. For some considerable time after having been afforded fresh compost few direct waterings are needed, provided the surroundings be kept moist, but when rooting freely syringe the plants two or three times a day, and dip the pans in water when the material shows signs of drying. Other Dendrobiums that have arrived at the rooting stage may be treated liberally with water whenever the weather is favourable to evaporation. Do not permit the atmosphere to become close and stuffy, and on occasions when ventilation cannot be employed freely, restrict the use of water.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR**, **41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY,	MAY 17	Royal Botanic Society's Show in Regent's Park. Devon County Agricultural Society's Show at Exeter (3 days).
FRIDAY,	MAY 19	Royal Botanic Society, Lecture, 4 P.M.
SATURDAY,	MAY 20	Paris International Horticultural Exhibition (9 days).

SALES FOR THE WEEK.

MONDAY, MAY 9—
Palms, Lilies, &c., at Stevens's Rooms, at 12.30 P.M.
WEDNESDAY NEXT—
Palms, Liliums, Carnations, Ferns, Begonias, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.
FRIDAY NEXT—
Orchids in variety, by order of Messrs. Stanley & Co., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 30.

(For further particulars see our Advertisement columns)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —54·6°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May* 10 (6 P.M.): Max. 69°; Min. 43°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May* 11 (10 A.M.): Bar., 30·2; Temp., 61°. Weather fine with bright sunshine.
PROVINCES.—*Wednesday, May* 10 (6 P.M.): Max. 68°, E. coast of England; Min. 51°, N.W. coast of Scotland.

Rust Propagation through Seed.

THERE is a curious problem in connection with the parasitic rusts which infest cultivated plants which has never received a satisfactory solution. It is whether there is any ground for the belief in the propagation of rust through the medium of the germinating seed of the host plant. It may be well to collect all the facts available which can throw any light upon this subject, so that if proven, or even fairly suspected, cultivators may endeavour to guard against one source of infection.

Our valued correspondent, Dr. COOKE, favours us with the following note on this subject:—

"I have been led," he says, "to these reflections by a recent perusal of some remarks in one of the periodical pamphlets issued by the United States Department of Agriculture, which touches upon this important problem. In the spring of 1893, it observes, the writer's attention was called to a very young rusted seedling of Euphorbia dentata. In this instance, as is usually the case with young plants of this host, the pods were first badly affected by "æcidia." This fact, taken with the common observation that the seed-pods were usually affected by all stages of the rust, led at once to the thought that it was a case of rust propagation through the medium of the germinating seed of the host.

To test the theory of rust propagation in this manner experiments were instituted and carried out in that thorough manner which characterises the experiments of the United States Department. It is unnecessary to recapitulate the details of these experiments, which are set out in the Bulletin alluded to.* In 1895 rusted seeds of Euphorbia were planted at Washington. From these three plants grew, which were kept under a bell-jar. Soon one of the plants rusted badly, first with the "æcidium," then with a slight amount of "uredospores," and later with "the teleutospores."

In the following year a third series of experiments was conducted, with similar results. 'The proof that the rust actually penetrates the hulled seed is easily obtained, not only from microscopical demonstration, but also from the fact that the actual "peridia" may often be seen with the unaided eye in the seed. These experiments, however, further demonstrate the ability of the rust to propagate itself through the medium of the germinating seed of the host, and also point to the probability that this is even the common method of reproduction in Euphorbia dentata. To this record must be added the testimony of T. S. RALPH in the *Victorian Naturalist* (vol. vii., p. 18), of a rust attacking the seed of Senecio vulgaris, when it is stated that 'with the microscope we were able to trace the fine yellow sporular matter into the covering of the seed, and into the seed itself.'

I am reminded also of some experiments made by Dr. ERIKSSON with Puccinia glumarum on Wheat, which by themselves and whilst unsupported received but little credit. At the time when the Hollyhock disease was at its height in this country Mr. WORTHINGTON SMITH, in the pages of this Journal, adduced evidence of the presence of Puccinia malvacearum in the seeds of the Hollyhock (see July 15, 1882, p. 87).

Another instance came within my own experience in 1866 in connection with the common Celery-rust, Puccinia Apii, which suddenly made its appearance in a garden at Highgate. A friend sent me some specimens, requesting to be informed of the name, and at the same time remarked that he had two separate stocks of Celery plants growing side by side in the same garden, but that only one stock was attacked by the parasite. The seed which produced the infected plants had been given to him by a fellow-gardener, because he had not sufficient of his own, and this friend has since informed him that his own plants were similarly affected. The seed from which the healthy plants were raised was of his own saving, and not a pustule of the rust could be detected upon the leaves. The conclusion at which any one would arrive, in accordance with the evidence, was that the germs of the disease were present in some manner in the seed, or if not why did not all the celery plants from whatever source in the same garden and under the same conditions, suffer alike from the parasite? This is an important point to settle, because if the common rusts and similar diseases can be propagated through the medium of the germinating seed of the host plant, it is of little use to try the effect of fungicides, when the plant is permeated by the virus of the disease.

The examples which I have furnished may perhaps be added to from the experiences of other observers, but even as the matter now stands there is grave reason for the belief that rust propagation is possible through the medium of the germinating seed of the host plant." *M. C. Cooke.*

* *Investigations of Rusts*, by M. A. Carleton, in Bull. No. 63, July, 1904.

THE KEW GUILD DINNER.—We are requested to remind our readers who are "Old" Kewites that the annual dinner will take place at the Holborn Restaurant, on the 29th inst., at 7.30 P.M. The Secretary, Mr. WINN, Royal Gardens, Kew, would be glad to hear before the 22nd inst. from all who intend to be present.

RAILWAY RATES.—The President of the Board of Agriculture and Fisheries has appointed Mr. JOHN FRANCIS SYKES GOODAY to be a member of the Departmental Committee on Railway Rates for agricultural produce in place of Mr. ALFRED BALDWIN, M.P., resigned.

"BOTANICAL MAGAZINE."—The plants figured in the May number are:—

Prunus pseudo-Cerasus, Lindley, t. 8012.—To this lovely flowering tree the following synonyms are attached, which we cite as the tree is cultivated in our gardens under most of the names mentioned:—Prunus paniculata, *Botanical Register*, t. 800; Cerasus Sieboldi, *Revue Horticole* (1866), p. 371; C. Lannessiana, *Revue Horticole* (1872), 198, and (1873), 351c., t.; C. caproniana flore roseo-pleno, *Flore des Serres* (1875), t. 2238; C. serratifolia, Carrière, *Revue Horticole* (1877), 389; C. Watereri, *Hort. ex Lavallée Icon. Arbor. et Frut. Segrez*, p. 119.

Rhipsalis dissimilis var. setulosa, t. 8013.—A curious species, with slender, straggling stems, the branches of which are sometimes verticillate, and bear small yellow flowers.

Listrostachys bidens, Rolfe, t. 8014.—A curious West African Orchid, with sessile, ovate, lanceolate green leaves margined with yellow, and with pendulous racemes of small cream-coloured, fragrant flowers. Kew.

Colchicum libanoticum, Ehrenberg, t. 8015.—A charming species from the snowy parts of the Lebanon. The flowers are of medium size, white, flushed with pink or rose. In its native country it flowers in June, but in the alpine-house at Kew the blooms were produced in December and January.

Hippophae rhamnoides, Linn., t. 8016.—A well-known British shrub, the female plants of which produce a profusion of orange berries.

FRAUDULENT REPRESENTATIONS.—We had occasion to draw the attention of our readers, in the issue for April 8, to certain fraudulent representations that had been made by a person in the Liverpool district when calling upon gardeners and others. Information to hand shows that a man was recently convicted of such practices in the same district, and was sent to gaol for six months with hard labour.

ROYAL WARRANT FOR FLORISTS.—We are informed that Messrs. FELTON & SONS, 7, 8 and 9, Hanover Square, W., have recently had the honour of receiving a Royal Warrant of appointment as florists to His Majesty the KING.

GUNNERSBURY HOUSE.—At this seat of progressive horticulture, Mr. HUDSON is now engaged in constructing for Mr. LEOPOLD DE ROTHSCHILD an "annual" garden. A suitable site in a sheltered position has been selected, so that no doubt this will form an additional feature of interest in a garden already rich in variety and interest.

BOTANICAL LECTURES.—Dr. A. B. RENDLE, M.A., is delivering a course of six lectures, at the Chelsea Botanic Gardens, on the "Tubifloræ." The lectures take place on Fridays at 6 P.M., and the first was given on May 5.

THE HENRY ECKFORD TESTIMONIAL.—Mr. HORACE J. WRIGHT, 32, Dault Road, Wandsworth, announces that the sum received until May 8 was 643 shillings.

"AMATEUR GARDENING" comes of age on May 7, and is very naturally and justly jubilant over its successful adolescence. Now that it is entering upon the manhood stage we doubt not that it will be more useful than ever to the amateur. The vast diffusion of a taste for gardening on which our contemporary comments is illustrated by the increase in the number of gardening journals and by the increased circulation of the older ones. Whether there has been a proportionate increase among gardeners in the knowledge of plants and of their life-history is, we think, doubtful; yet it is to this increased knowledge we must look for progress.

"FLORA AND SYLVA."—The May number contains, among other articles, one on two rare Crocí, C. caspius and C. dalmaticus, by Mr. BOWLES; a useful article on Nerines, by Mr. O'BRIEN, with an excellent illustration of N. Bowdeni; a note on giant Reeds (Arundo Donax), which was a feature in our gardens long before Bamboos were thought of. The curious hybrid or alleged hybrid Medlars come in for notice. Too much cannot be said in praise of the Algerian Iris, I. stylosa, or of the Incarvilleas. Scented Pelargoniums find an exponent in Miss WHITE, whose article is accompanied by a good illustration of the variety known as "Lady Mary Fox." Gazanias (here called, we know not why, "Treasure Flowers") form the subject of a garden-monograph based on the researches of M. JULES RUDOLPH.

FLOWERS IN SEASON.—Messrs. R. D. WHITMORE & Co., The Rose Nurseries, Sutton-at-Hone, Kent, have sent us excellent flowers of the following varieties of Roses: Catherine Mermet, The Bride, Kaiserin Augusta Victoria, Bridesmaid, and Liberty. The very long stems attached show by the foliage that the plants are given unusually good cultivation.

NATIONAL CHRYSANTHEMUM SOCIETY.—It has been suggested that after such a serious and prolonged illness as our old esteemed friend and Secretary, Mr. R. DEAN, has passed through, and is still suffering from, it would be a fit and proper time for the above Society to initiate and organise a fitting testimonial, and invite the co-operation of all lovers of horticulture in showing their sympathy practically, as a recognition of long and indefatigable services rendered to the Society (ever since the lamented death of Mr. W. HOLMES, the first secretary to the Society) and to the horticultural world in general. It is thought the form which the testimonial shall take, as being most practicable and useful, should be a purse of money, without any part of it being spent on an illuminated address or anything of the kind, and it is hoped that all subscribers will send in their donations early, so that arrangements may be made to present the testimonial to Mr. DEAN at Carr's Restaurant, 264, Strand, on July 12 (the second day of the Royal Horticultural Show at Chelsea). *J. H. Witty, Hon. Secretary and Treasurer to the Testimonial Fund, St. James's Villa, Swains Lane, Highgate.*

THE LATE PROFESSOR EMILE LAURENT.—An imposing ceremony took place on Sunday, May 7, at Gembloux, Belgium, on the occasion of the unveiling of a *médaillon*, executed to commemorate the late Professor and African explorer, who died on his homeward journey from the Congo, where for the third time he had been to collect plants, especially such species as possess economic value. The numerous assembly comprised representatives of French and Belgian societies, many former and most of the present pupils of the Institute at Gembloux, the staff of professors, also ladies and intimate friends of the deceased. Having passed in review the services rendered to science in general and to the Agronomic Institute in particular by Professor LAURENT, who from the simple village school rose by his own merit and by hard work to the proud position which he so worthily occupied when he undertook his last voyage, the various speakers drew attention to his method of tuition, and concluded by saying that Professor LAURENT being a man of incontestable merit, he had in that way traced a line of conduct which should be followed with advantage by his successors. Professor LAURENT was an occasional visitor to English horticultural establishments and kindred institutions, in which he always took the greatest interest, and a portrait of him appeared in the *Gardeners' Chronicle* for March 12, 1904.

OVERSEA SUPPLIES: APRIL.—Compared with April of last year, the IMPORTS show a drop of £1,898,937—the totals being for last month £43,282,826, for April in last year £15,181,763. The respective class values in comparison are:

IMPORTS: DESCRIPTION OF PRODUCE.	1904.	1905.	Difference.
	£	£	£
Class I.—Cereals, and other field crops—Wheat, Barley, Oats, &c.	5,147,545	5,283,883	+136,338
Class II.—All other food cultures—Tea, Coffee, Fruit, &c.	4,328,340	3,736,420	−591,920
Class III.—Used in manufactures—clothing, household goods, &c....	6,324,202	6,139,569	−184,623
Class IV.—Miscellaneous—including seeds, flowers, &c.	1,585,411	1,664,484	+79,073
Values of Produce...	17,385,498	16,874,356	−511,142

Our fruit supplies were as follows:—

IMPORTS—APRIL.	1904.	1905.	Difference.
Fruits, raw—	£	£	£
Apples	171,403	139,631	−31,772
Apricots and Peaches	41	37	−4
Bananas	93,793	144,776	+50,983
Gooseberries	2	...	−2
Grapes	3,725	7,270	+3,545
Lemons...	25,649	34,868	+9,219
Nuts—Almonds ...	18,782	24,499	+5,737
Others used as fruit	40,276	39,990	−286
Oranges...	265 524	172 206	−93,318
Pears	1,945	4,684	+2,739
Plums	...	249	+249
Strawberries	12	2	−10
Unenumerated ...	12,828	13,549	+721
Vegetables, raw—			
Onions ... ...bush.	103,327	160,233	+56,906
Potatos ... ... cwt.	321,059	62,163	−258,896
Tomatos ... ,,	75,297	90,992	+15,695
Unenumerated ,,	75,566	54,492	−21,074
Totals ...	1,209,209	949,641	−259,568

We note that the supply of fresh flowers last month is valued at £32,146, as against £42,638 for the same month last year—a decline of £10,492. An effort is being made to supply the wants of Northern China in the shape of forest products from the woods of Japan, and this new development is to be entrusted only to representatives of native firms who can show a large yearly cash reserve-balance at bank in "yen," a provision which will regulate contracts. Our own supplies of wood and timber show an increase this month, a novelty of recent times; thus the values for last month were equal to £1,252,133, against £1,110,954 for the same period last year—difference + £141,179. To finish the tale for the month we should state that the EXPORTS are given at some £24,138,468, as against £23,484,834, a gain of £653,634—not much, but still a gain.

THE SMALL HOLDINGS ACT, 1892.—The President of the Board of Agriculture and Fisheries has appointed the Rt. Hon. the Earl of Onslow, G.C.M.G., the Rt. Hon. the Earl Carrington, G.C.M.G., the Rt. Hon. Jesse Collings, M.P., Sir Ralph Anstruther, Bart., Major Patrick George Craigie, C.B., Mr. Charles Bidwell, Mr. William Brown, Mr. Francis Allston Channing, M.P., Mr. James Long, Mr. John William Willis-Bund, and Mr. Robert Armstrong Yerburgh, M.P., to be a Committee to enquire into the administration and working of the Small Holdings Act, 1892; to examine the various arrangements made by landowners in recent years for the provision of smaller agricultural holdings; to report as to the conditions under which such holdings are most likely to be attended with success, and as to the measures which may most advantageously be taken, either by legislation, co-operative association, or otherwise, to secure the increase of their number. The Earl of ONSLOW will be Chairman of the Committee, and Mr. THOMAS HICKLING SUTTON, of the Board of Agriculture and Fisheries, will act as Secretary.

PAUL JONES.—A correspondent sends us a newspaper clipping which contains the following curious story of a "gardener." We cannot give the name of the paper from which we take the following extract, for the title had been removed. In the circumstances we hope we shall not be accused of piratical appropriation:—

"Americans are searching for the body of PAUL JONES, whose memory they desire to honour. In his native country it is doubtful whether, even in these days of memorials innumerable, anyone would desire to commemorate the exploits of the redoubtable pirate chief. But if such a proposal were ever made, his native shire of Kirkcudbright would have the first claim. Like his father, JOHN PAUL, to give him his real name, was a gardener, and worked not far away from St. Mary's Isle, formerly the seat of the Earls of SELKIRK. St. Mary's Isle has a curious association with the pirate.

The young gardener had run away to sea, and after committing his first murder changed his name to PAUL JONES. In 1778 he visited British waters, and conceived the bold plan of carrying off the Earl of SELKIRK and holding him to ransom. Fortunately for himself, the Earl was in England at the time; but PAUL, determined to make St. Mary's Isle remember the gardener, sent some of his crew ashore with orders to bring him the Countess's silver plate.

The feelings of the lady may be imagined when she saw these sea dogs at her door. She behaved apparently with courage and good sense, and at once complied with the demand by handing over various articles of silver plate, evidently enough to satisfy the privateersmen, for they departed without further ado; but PAUL JONES did not keep his booty long. The robbery was brought to the notice of BENJAMIN FRANKLIN, then representing the newly-fledged American Republic in Paris. The consequence was that when the commander of the *Ranger* (the privateer commanded by PAUL JONES) arrived at Brest he found a message waiting for him from the Ambassador, reprimanding him for his piratical act, and ordering him to send the stolen plate at once to Paris, so that it might be restored to its owner. This was in 1778, but in consequence of the war the Countess did not actually get back her property until seven years later."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

HOMERIA COLLINA.—This pretty Cape bulb is now in fine flower in the open garden, and presents a lovely picture, there being over a hundred flower-spikes on the clump (see *Gard. Chron.*, August 11, 1888, p. 163, fig 19). The flowers are charming in colour, of an apricot-pink tint flushed with orange and having a bright yellow eye surrounded with faint purple pencillings. They are 2½ inches in diameter, four or more being borne on an arching stem about 30 inches in length, and the leaves are 1 feet in length and rather over an ½ inch in breadth. The flowers close in the evening and remain shut during the night. In the same border the brilliant Sparaxis Fire King, S. grandiflora and Freesia refracta alba are still in bloom. It is curious that the Homeria should be so uncommon, as it appears hardier than the Sparaxis, and much more so than the Ixia, which

diea out in this garden. It increases very rapidly, the small clump given me three years ago yielding, when lifted last autumn, over 250 bulbs, 150 of which I gave away, only retaining the largest. The chief drawback in the cultivation of the Homeria arises from the fondness of snails for the succulent stems. The snails climb to a height of 18 inches or 2 feet, and then eat through. A nightly watch is necessary when the flower-stems are about a foot in height, in order to destroy these visitants. *S. W. Fitzherbert, South Devon.*

THE LATE GALE IN SOUTH DEVON.—Much damage was done on April 30 at the mouth of the Dart by the severe gale which caused so many disasters at sea. It commenced from the south-east, blowing into the harbour's mouth as through a funnel, with tearing hail squalls, and gradually veered to the south and south-west. The foliage of the Potatos is perfectly black and laid level with the ground; the expanded fruit-blossom and the young leaves of the trees are scared. Cytisus racemosus and Banksian Roses 20 feet high against a house are brown and shrivelled as if by fire. The foliage and flower-buds of hardy plants, such as Clematis montana and Lilacs, are ruined, and a fine tree of Acacia verticillata just coming into blossom has been blown down. Out of eight good plants of Ostrowskia magnifica all but three have been broken off at the ground level, and the rest have not a single perfect leaf remaining. Pages would be required to recount the mischief done in surrounding gardens. I have received a letter from a well-known amateur in the neighbourhood of Penzance, saying that more damage had been done by this gale in his garden, which contains a most valuable collection of Australian and New Zealand shrubs and plants, than by any he has experienced during twelve years at his present home, so that it appears the effects of this tempest have been felt over the whole of the south-west coast. *S. W. Fitzherbert, South Devon.*

BLACK CURRANT-BUD MITE.—May I remind readers of the *Gardeners' Chronicle* that the present is the proper time to attack this pest? During the months of May and June the insects change their quarters from the old buds which they have occupied last season into the young buds, and if the bushes are sprayed at intervals of ten days during the time named with a mixture of soft-soap and quassia—2 oz. of the former and 4 oz. of the latter to each gallon of soft water—the bushes will probably be found to be quite free of the pest at the end of the season. I say probably, because the result will depend somewhat upon the manner in which the mixture is applied and slightly upon the severity of the attack, but if one season's work will not effect a perfect cure two certainly will. After the leaves have fallen in the autumn examine the bushes, and if any "big buds" are to be seen pick them off and burn them; also give the bushes a dressing of manure to enable them to grow freely. The remedy is so simple and cheap that many people will not try it. Yet it can only do good, and no one who tries it will regret the experiment. If it cost many pounds per acre and needed the services of specialists to apply the remedy, it would no doubt have found more favour with the public. I say this because, although the remedy was described in the gardening papers a year ago, I have never heard of one single case of its having been tried. *A. H. Pearson, Lowdham.*

FUCHSIA SEEDLINGS.—It is very easy to raise seedling Fuchsias by sowing the seeds in the autumn, taking care to sow only those that are plump, firm, and of large size, and not the hollow and otherwise defective ones. As the seeds are very small they should be rubbed out of the ripe fruits on a clean fine cloth. When dry sow them at once in shallow pans filled with loam one-third and leaf-mould two-thirds, with a good proportion of silver-sand, and place the pans on a mild bottom-heat until germination has taken place, when the pans should be stood on a shelf in a warm pit, and the seedlings, when large enough, potted singly in thumb-pots. Mr. Burbidge, in his useful work *The Propagation and Improvement of Cultivated Plants*, asserts with truth that "there is yet plenty of new ground to be broken up in this genus. Many of the Chilian species have not been hybridised, and the newly-introduced F. procumbens, with its upright or erect flowers and slender drooping habit, fruits freely and will probably give a new race in the hands of the hybridiser. We have erect-flowered Gloxinias, and let us hope to see more erect-flowered varieties of Fuchsias with large blooms, since much of the beauty of the Fuchsia is lost at present unless its drooping flowers are seen from below." This fact is as true to day as in 1876 when it was written. An erect-flowered Fuchsia named erecta superba was mentioned in *Revue Horticole*, 1868, p. 407. The true species cross readily with the hybrids, and may be used to impart fresh life and vigour to the latter. Of the results of crossing modern varieties with F. fulgens, see *Gardeners' Chronicle*, 1875, p. 655. *F. M.*

THE ASSOCIATION OF ECONOMIC BIOLOGISTS.

APRIL 19, 20.—The first actual Congress was held in the University of Birmingham on the above dates. The President, Mr. FRED. V. THEOBALD presided. We are obliged to confine our report to those communications which are of horticultural importance.

Green-fly, &c.—The first paper read came from the President, and was entitled "A Plea for the Study of British Aphides in connection with Cultivated Plants." Mr. THEOBALD reminded his hearers that in 1904 plant lice, or aphides, were more in evidence than in any year during the last quarter of a century. Rare species were very plentiful, and common species swarmed. Many could not be identified at all, and disappeared from the trees and plants they infested as rapidly as they apparently made their appearance. Moreover, in 1904 he observed several aphides migrating in vast swarms, aphides that in previous years had been far from common in the locality. The enormous reproductive powers of these insects at certain times was well known, but we know nothing of the causes that regulated the reproductive phenomena—why an excessive reproduction took place now and again, accompanied by a vast active migration, or so-called "blight." One instance showing the unsatisfactory state of our knowledge in regard to plant-lice and cultivated plants might be taken in the case of the Apple aphides. The majority of writings by economic entomologists on Apple aphis were valueless, because they had treated two or three totally distinct species as one. In 1902 Saunderson worked at the Apple aphides in Delaware, and found that there were three common Apple aphides—viz., Aphis pomi, Aphis sorbi, and the commonest Aphis, a hitherto undescribed species, which Saunderson named Aphis Fitchii. With the object of seeing if this new species was our common spring and autumn aphis, he (Mr. Theobald) made collections in various parts of the country, and found Saunderson's species to be by far the commonest. This was very important, because the Aphis Fitchii was a well-known migrant. It fed on the Apple in spring and early summer, and was the cause of damaged buds, withered blossom, and deformed fruits, but only caused slight leaf curling. It left the Apples in early summer, and did not return until the autumn, when a sexual brood was produced. He was inclined to believe that the Aphis Fitchii migrated to corn and grasses. But Aphis pomi was permanent on the Apple, and was a great leaf curler, producing a terribly crumpled-looking leaf if allowed to work on unmolested. Aphis Fitchii hatched much earlier than Aphis pomi, and commenced to attack the Apples long before the blossom was open. Spraying was of use in spring for destroying this species; it is not useful, however, against Aphis pomi. It was therefore very important to know what Apple aphis they had to contend with. It was because they had not known what they had been giving advice upon that they got such varied results in spraying. Leaf-curling aphides were the most difficult to cope with, because the curl protected the plant-lice from any spray they chose to use. In fact, with such species as the Plum aphis and the Currant aphis it was only a waste of time and money to spray when the leaves were once deformed. A knowledge of the life-history of an animal pest was most important, for it would show us where one could attack it with some hope of success. A great deal was known about the vagaries of the Hop aphis that might be turned to advantage by the Hop grower. The Hop aphis came from certain Plums in spring, and many migrated back to them in autumn to deposit their ova on the Plums. Moreover, this ovation went on throughout the year on the Sloes and Damsons, so that there were successive winged generations flying to the Hops. Thus, to save the Hops, the farmer must wash his Damsons early in the year, and use drastic measures in destroying the hedgerows of Sloe. To prevent the rapid reproduction of the aphides, farmers should avoid using nitrogenous manures in large quantities, and should use a strong dressing for spraying the egg-laying generation before they had time to lay their eggs.

Dr. MACDOUGALL dealt with some Cecidomyid enemies of the genus Salix.

Mites.—Mr. WALTER E. COLLINGE (Birmingham University) submitted "A Note on some Species of Mites of the genus Eriophyes." He stated that he had found on Black Currant-buds mites that were larger than the Black Currant mite, and had reason to believe that they had migrated from the neighbouring Hazels. If this proved to be the case, hedgerows of Hazel would have to be cut down to prevent them from becoming a source of infection. He was now experimenting to see whether the Hazel-mite would migrate to the Black Currant and continue to live there.

Economic Botany in the Colonies formed the subject of a paper by Mr. W. G. FREEMAN (Superintendent of the Colonial Economic Collection at the Imperial Institute, London). The Royal Botanic Gardens at Kew, in co-operation with the Colonial Botanic departments, he said, distributed economic plants throughout the Empire, and important colonial industries were directly traceable to this work. The Imperial Institute maintained colonial economic collections illustrating the products and resources of the colonies, and carried on investigations—scientific, technical, and commercial—to further the economic utilisation of colonial products.

THURSDAY, APRIL 20.

The Porosity of Wood.—Mr. HERBERT STONE read a short paper on this subject. It had been taken too much for granted, he said, that the mature vessels of dicotyledonous wood were very limited in length, and that they remained interrupted by septa at frequent intervals, as at the time when they were newly formed from the cambium. If so, of course they could not be looked upon as ventilating media. But if, as he believed, they were continuous tubes running the whole length of each annual cone of wood, then it was clear that important movements of water, vapour and air might take place in them. If this assumption were granted, then every decrease in the pressure of the atmosphere would permit water to escape from the vessels, and with every increase of pressure air would enter them to become saturated and to pass out again when the mercury rose. The whole of the argument depended on whether the vessels were continuous or not. To this end he had made a number of experiments by which he had ascertained that air could be blown freely through the wood of some dicotyledonous trees in the direction of their vertical axis. He had employed Ash, Birch American Birch, and Oak. In applying the results of his experiments to practice he believed that high temperature was less adapted to the drying of wood than frequent alterations of atmospheric pressure. Heat, when it had penetrated into the wood, would cause expansion of the water vapour within, which would then pass outwards. But it must act on the outer layers first, and it was uneven and violent in its action, causing twisting and shakes. The employment of fans to keep the air moving was good, but they were local and superficial in action. Timber suffered from keen draughts as badly as from heat. If mechanical means were necessary the most rational were such as kept the timber cool and the air dry, and provided frequent fluctuations in the pressure of the air.

Springtails as Injurious Insects.—Professor CARPENTER read a paper on this subject. Every student of insects, he said, was more or less acquainted with the group known as springtails. They were small wingless insects, which he believed to be primitively wingless. They had hitherto attracted little attention from the economic biologist, because they had never been regarded as injurious to cultivated plants—at least not to any extent. During the last two or three years he had noticed several cases in which the springtail had been the primary cause of injury to cultivated plants. They occurred in large numbers in damp earth, and the plants which had come under his notice as having been injured were Beans and Bean seedlings, the roots of Cauliflower and Cabbage, various kinds of bulbs, and also fallen fruit. The insect was but a millimetre or a millimetre and a half in length, but when associated in large numbers they did a considerable amount of damage. As to the method of destroying them, Professor CARPENTER pointed out that they had no system of air tubes, but breathed through the whole surface of the skin. They were therefore very intolerant of dry conditions. An application of lime was usually recommended for getting rid of the creatures, and it succeeded as a rule. In the course of a short discussion the Chairman remarked that the springtail was found to be extremely injurious in glasshouses, and was especially damaging to young Orchids.

The next Conference will be held at Liverpool on December 28 and 29, 1905.

ENQUIRY.

ANTHURIUM PROSCHERSKYANUM!—Will some reader oblige by furnishing information as to the work in which the above-named plant is described? *Berlin.*

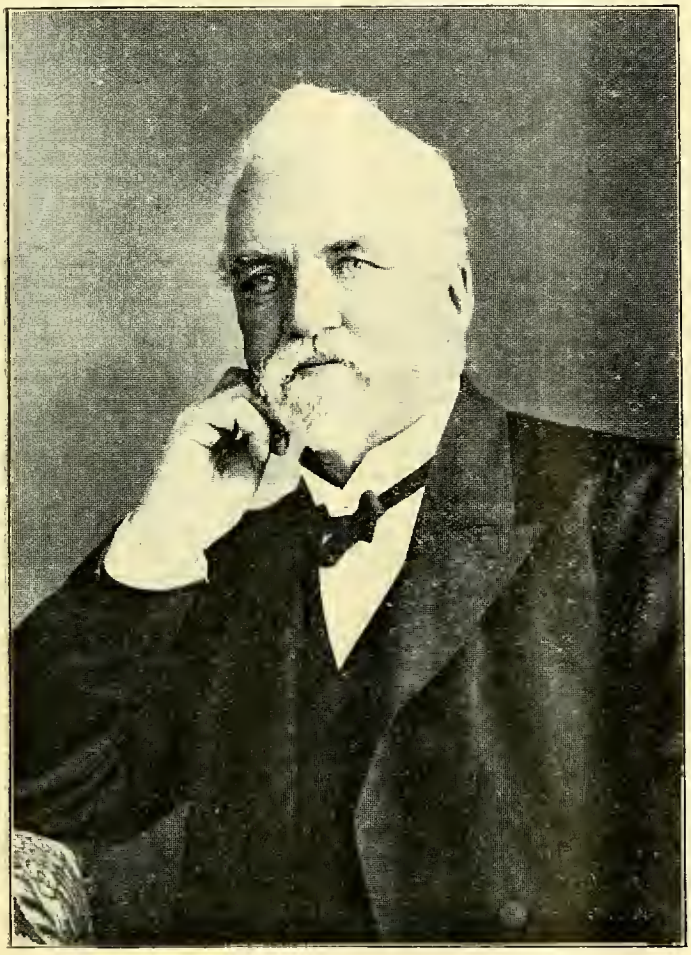
Obituary.

ROBERT FEATHERSTONES. — Full of years and honours, this gentleman passed away on the 5th inst., in his 74th year. He had been ailing some two or three years, suffering from heart affection, but only gave up work a few days before his death. He was a man of extraordinary industry, courage, and perseverance, and a man moreover fully determined in all he did to at least deserve success.

Starting as a private gardener in his native county, York, he found himself as a comparatively young man, some thirty years ago, thrown out of a situation, like many more, through no fault of his own. He decided that a fair prospect for success opened out to him at that time as a florist and floral decorator in the neighbourhood of Leeds. Securing a piece of land about 4 or 5 acres in extent, which at that time was of little value, on the Kirkstall road, about a mile and a half out of Leeds, he was not long in erecting a cottage and four glasshouses. I have often heard him say what a hard struggle he had to keep his head above water for the first few years. But courage, and well-sustained perseverance rarely fails in bringing success, and so with him. The whole of the land has been covered with glass for many years, and the business is now one of the most successful of the kind in the north Midlands.

Few men were better known or more respected in Leeds than the proprietor of St. Anne's Nursery, Kirkstall. His remains were laid to rest with every manifestation of regret and regard by the side of those of his wife in Kirkstall churchyard on the 8th inst. *Correspondent.*

CHARLES MOORE.—It is with great regret that we have to record the death recently of this veteran botanist, in the eighty-sixth year of his age. He was a brother of the late Dr. David Moore, of Glasnevin, and commenced his professional career in Dublin, under Dr. Townsend Mackay in the College Botanical Gardens, about the year 1832. Subsequently he joined his brother, who had been appointed botanist to the Irish Geological Survey Department. On a vacancy taking place in the Botanical Garden at Sydney he was examined by the late Dr Lindley, and, having passed with honours, was, on his recommendation, appointed Director of the Sydney Botanic Gardens, and later on of the Government Domain and Plantations. Moore was, we believe, the last of the civil servants of New South Wales appointed by the British Government, and he was one of the first officials to be retired under the new regulations as to age. Amongst other good work at Sydney, he laid out the beautiful Victoria Park. The Botanical Gardens at Sydney in Moore's hands soon became noted as being amongst the richest and most beautiful in the world. Moore was not only a strenuous worker of more than ordinary education and ability, but he travelled widely in Australia, and more especially amongst the adjacent islands, whereon he discovered and whence he introduced many new and rare plants, such as Palms, Cycads, and Ferns. He also wrote (date 1893) works on the flora of New South Wales; and more than this, the credit of having introduced the Kentia Palms, or Howeas, from Lord Howe's Island to British gardens, was due to Moore. There are four species growing on this island—viz., at the highest elevation, about 3,000 feet, in misty air and boggy soil, is Howea Moorei; at about 1,500 feet H. canterburyana is found; while the two most useful decorative kinds, H. Fosteriana and H. Belmoreana, grow mixed together near the sea-level. H. Fosteriana is locally known as the Thatch Palm, H. Belmoreana as the Curly Palm, and their seeds are very similar in appearance; but the first-named has four to eight branches to its inflorescence, while the latter has a much longer simple spadix. Other Palms of Australasia are the Areca sapida of New Zealand, A. Baueri of Norfolk Island, while in Australia itself are four distinct species: 1, Seaforthia elegans and its distinct form S. e. Cunninghami; 2, Corypha australis (Cabbage Palm); 3, Calamus australis; and 4, the Queen's Palm, Ptychosperma Alexandræ.



THE LATE CHARLES MOORE,
Formerly Director of the Botanic Gardens, Sydney.

Moore now and then paid visits to England and Ireland, and he accompanied Dr. David Moore to the Florence Exhibition of 1874, or about thirty years ago. His last visit was in 1896, when I met him in the College Gardens at Dublin, and had the above summary of the Palms of Australasia from his own lips, together with interesting reminiscences of British horticulture in the days of Sir Wm. Hooker, Lindley, Paxton, Sir Joseph Hooker, the Balfours, and McNabs of Edinburgh, and many others of that good old school.

Tall in stature, with a commanding but genial manner, Charles Moore was a man to admire and remember. In fact his conversation on matters botanical and horticultural was so full and interesting that one could not but regret that in the course of a long and active life he published comparatively little.

The following are a few only of the rare and beautiful plants with which his name is connected:—Todea Moorei, Fagus Moorei, Alsophila Moorei, Macrozamia Moorei, Kentia Moorei, Rubus Moorei, Villarezia Moorei, &c.

Loved and respected by all who knew him, his memory will long remain green to all who are interested in the botany of Australia. *F. W. B.*

THOMAS SMITH.—We learn with deep regret of the death, on Sunday evening last, at Sibsey, near Boston, of Mr. Thomas Smith, of the firm of Smith Brothers, nurserymen and seedsmen, of Uitenhage and Port Elizabeth, South Africa, in his forty-seventh year. In business circles great sympathy is felt for Mr. Smith's brothers and sisters in this country and in Cape Colony, as only so late as March 26 last another member of the firm, his brother Richard, died at Aliwal North, where he was staying for the benefit of the mineral baths. Both of the deceased brothers were natives of Skirbeck, in Lincolnshire, and went out in the early seventies to Port Elizabeth, where in Nelson Square they started a nursery business. This was attended with so much prosperity that they soon had to seek a wider sphere for their energies, which they found at Uitenhage, where they were joined by their youngest brother, Walter. British all through, kindly natured, energetic and enterprising, they created perhaps the largest business of its kind in South Africa, and gained a worldwide reputation as importers and exporters of British and Cape seeds, bulbs and plants.

PUBLICATIONS RECEIVED.—*Agricultural Gazette of New South Wales*, March. Contents: Barleys at Bathurst Experimental Farm; Bunt Preventives and their Effects upon the Germination of the Grain, R. Peacock; Notes on Forest Conservation; Weeds of New South Wales; Experiments with Potatos &c.—*L'Hybridation des Plantes*, par Raphäel de Noter.

SOCIETIES.

THE ROYAL HORTICULTURAL.

MAY 10.—The capacities of the new Hall in Vincent Square, Westminster, were tried to the uttermost on the occasion of the usual fortnightly meeting on Tuesday last. All the space available for exhibits was well filled, and the brightness so characteristic of spring-flowering plants was observable in every part of the building.

The ORCHID COMMITTEE recommended two Botanical Certificates, two First-class Certificates, and six Awards of Merit to novelties, and there were several unusually good groups of Orchids exhibited.

The FLORAL COMMITTEE recommended one First-class Certificate and nine Awards of Merit to novelties, among which several were new plants of much value introduced by Messrs. JAMES VEITCH & SONS from China. A large number of Medals was awarded in respect to groups.

The FRUIT AND VEGETABLE COMMITTEE recommended an Award of Merit for Rhubarb "Hobday's Giant," and there were several other exhibits of fruit and vegetables.

The NARCISSUS AND TULIP COMMITTEE was concerned chiefly with the consideration of varieties of Tulips, of which there were numerous exhibits.

In the afternoon a considerable number of new Fellows were elected, and papers on "Japanese Gardening" were read by Mr. N. Hayashi and Mr. R. J. Farrer.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. R. Dean, Jno. Green, Geo. Nicholson, J. W. Barr, Geo. Paul, W. J. James, E. H. Jenkins, W. P. Thomson, Chas. E. Shea, H. J. Cutbush, Chas. Dixon, Chas. Jefferies, W. Bain, H. J. Jones, C. R. Fielder, R. Hooper Pearson, J. F. McLeod, Geo. Gordon, Chas. T. Druery, W. Howe, and R. C. Notcutt.

On the motion of Mr. E. H. Jenkins, a vote of congratulation to Mr. R. Dean was passed on his attendance again after a long absence caused by illness.

Messrs. W. BULL & SONS, King's Road, Chelsea, exhibited a new Draæna with leaves about 1½ foot long and 6 inches wide, mottled with green and yellow. The plant is described as coming from Borneo, and will probably make a first-class foliage plant for cultivation in the stove. The Committee requested that the plant be exhibited again when it has made further growth. Messrs. WM. BULL & SONS also presented a number of ornamental foliage, stove and greenhouse plants, Caladiums, Codiæums (Crotons), Talisia princeps, Browneas, Cupania, &c. Blandfordia aurea and B. nobilis were shown in flower.

Messrs. R. VEITCH & SON, Exeter, among other interesting specimens, showed flowering sprays of Sophora tetraptera [see fig. in *Gardeners' Chronicle*, June 8, 1878, p. 729], and very large flowers of a brilliant crimson-coloured Poppy having no black markings, under the name of Papaver "Devonia"; also a plant of Campanula under the name of C. phyctidocalyx. The inflorescence was nearly 2 feet high, and the flowers of deep blue colour, resembling those of C. persicifolia, but the leaves were quite different, being only 1½ inch long.

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. Bain), exhibited a form of Rehmannia angulata with leaves slightly different from those of the type, and with larger, more maculated flowers. Also a small plant in pot of Philadelphus Lemoinei "Rosace," a variety in which the flower-buds before expanding have an appearance exactly similar to that of Rose buds. Deutzia myriantha Lemoinei was shown from the same garden.

Mr. CHAS. TURNER, Royal Nurseries, Slough, exhibited a collection of alpine Auriculas, also a fine group of varieties of Primula Sieboldi, the plants being arranged in about one dozen baskets (Bronze Flora Medal).

Messrs. FRANK CANT & CO., Braiswick Nurseries, Colchester, exhibited a collection of cut Roses, showing the variety Maréchal Niel very prominently, also Mrs. W. J. Grant, W. A. Richardson, Lady Roberts, and many other varieties.

Messrs. JAS. VEITCH & SONS, Ltd., King's Road, Chelsea, brought many new and interesting plants. Meconopsis integrifolia was again a source of much attraction. Near by was M. punicea, whose flower was not inaptly likened to that of a Sarracenia (see Awards). Both these have been recently figured in the *Gardeners' Chronicle*. Clematis montana var. rubens is another notable acquisition. This plant and two new Primulas, P. Veitchii and P. japonica var. pulverulenta, also received awards. Hydrangeas with blue flowers contrasted greatly with others of rose colour; the blue in some plants was very pronounced. Senecios, Cinerarias, and dwarf, well-flowered plants in pots of Cerasus pseudo-Cerasus "James H. Veitch" also found a place in this exhibit (Silver Flora Medal).

W. M. CASZALET, Esq. (gr., Mr. Cubberley), Fairlawn, Shipbourne, Tonbridge, set up a magnificent batch of Schizanthus Wisetonensis, the plants being covered with flowers, and with the addition of a number of Ferns, Palms, and similar plants constituted a group that was greatly admired (Silver-gilt Flora Medal).

Mr. W. A. WATTS, Bronwylfa, St. Asaph, brought a good strain of Polyanthus Primroses (Bronze Banksian Medal).

Messrs. DOBBIE & CO., Rothesay, again showed a collection of Pansies and Violas of similar varieties to those shown in their exhibits at the last two meetings of the Society (Silver Banksian Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, made a feature of Lobelia nicotianæfolia, but they had also sprays of flowering trees and shrubs, Pyrus Malus in several named kinds, a double form of the Bird Cherry, Syringa pubescens, and a new pink Rhododendron named H. M. Arderne.

Messrs. SUTTON & SONS, Reading, showed a group of Wallflowers. The colours ranged from almost white to dark blood-red. The varieties were arranged in semi-circular bands, giving the group a novel and good appearance. Some of the best varieties were Cloth of Gold (yellow), Blood Red, and a magenta form labelled Purple Queen (Silver Banksian Medal).

Messrs. GILBERT & SONS, Dyke, Bourne, Lincolnshire, presented a collection of Anemones, almost a replica of the group shown by them at the last meeting (Silver Banksian Medal).

A whole table was occupied by a display of Cinerarias set up by Messrs. CARTER & CO., High Holborn, London. The plants were nearly all of the ordinary florist's type, but a raised centre was composed of plants of the stellata kind. This extensive exhibit was much admired, and presented a wealth of colour, relieved at intervals with small Palms (Silver Flora Medal).

Messrs. J. LAING & SONS, Forest Hill, London, staged a group of Caladiums, interspersed by a number of Palms and Ferns.

Mr. H. B. MAY, Dysons Lane Nurseries, Upper Edmonton, had a collection of zonal Pelargoniums. The plants were flowering freely, and were shown with a groundwork of small Ferns interspersed with Palms. Lord Aberdeen (scarlet), Mme. Roseleur (rosy pink), and Gabriel Monod (magenta) are varieties worthy of mention.

Messrs. THOS. CRIPPS & SON, Tunbridge Wells Nurseries, Kent, showed a handsome group of Japanese Maples, also Hydrangea Hortensia, and smaller Maples in 48 pots. The foliage was well coloured, and the varieties included many of the best types of these handsome foliage plants.

Messrs. FELTON & SONS, florists, Hanover Square, showed a number of decorative plants, "Malmaison" Carnations, pot Roses, Spiræas (Astilbe), &c. A specimen of Metrosideros floribunda exhibited in flower was a good specimen of this interesting Australian plant.

Mr. A. F. DUTTON, Iver, Bucks, showed two vases of Carnations, one containing the variety Fair Maid, with flowers of a soft blush-pink; also a white variety named Lady Bountiful (see Awards).

Messrs. W. & J. BROWN, Stamford, showed plants and cut flowers of "Cactus-flowering" Pelargoniums, Dimorphotheca Eckloni, Verbena Miss Willmott, and pot plants of the climbing polyantha Rose "Miss Dorothy Perkins."

Mr. GEO. MOUNT, Canterbury, put up a splendid stand of Roses, having a background of dwarf plants of the variety Crimson Rambler that were literally crowded with flowers. The variety Liberty was superb, and we doubt if Mrs. John Laing and Caroline Testout could be produced in better condition than that in which they were exhibited. The exhibit was excellent (Silver Banksian Medal).

Messrs. BEN. CANT & SONS, Old Rose Gardens, Colchester, also showed some commendable cut Roses, backed by pots plants of Blush Rambler and similar varieties (Bronze Flora Medal).

Messrs. WM. PAUL & SON, Waltham Cross, showed Roses in pots. A very fine new hybrid rambling Rose named "Waltham Bride" has large white semi-double flowers, that are produced in lax clusters, and are admirably set off by their yellow centre of stamens. A magenta form of Crimson Rambler, and other good varieties were included.

Messrs. CANNELL & SONS, Swanley, Kent, brought half-a-dozen plants of Rose "Dorothy Perkins," that were perfect specimens, and almost hidden with their bunches of flowers. A row of Myosotis "Star of Love" was placed in front of the Roses. In addition Messrs. Cannell contributed an extensive collection of zonal and show Pelargoniums, such as they have displayed at the last few meetings of the Society, and which would be more pleasing if green foliage plants were more freely intermixed with the over-brilliant colours (Silver-gilt Banksian Medal).

Mr. E. POTTEN, Camden Nursery, Cranbrook, Kent, showed plants of Rose "Philadelphia Rambler," a variety with larger and deeper-coloured flowers than Crimson Rambler, although it does not appear to be quite so free flowering as the latter. Mr. Potten also showed a good form of Trollius europæus (Bronze Flora Medal).

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, had a number of interesting greenhouse plants. Chorizema ilicifolium was presented in good form; there were also a fine specimen of Clerodendron Balfouri, a batch of Schizanthus Wisetonensis, another of Dimorphotheca Eckloni, and pans of Lobelia "Low's Triumph." Vases of Carnations, &c., completed the display (Silver Banksian Medal).

Mr. GILL, Tremough Gardens, Penryn, Cornwall, brought from that favoured district some inflorescences of Rhododendrons from the open. There were excellent "heads" of R. Falconeri, R. campylocarpum—resembling the former, but having pale yellow flowers instead of buff-cream—R. glaucum, R. Aucklandi, &c. The same grower displayed a branch of the beautiful Embothrium coccineum, from a tree growing in the grounds at Tremough, and a spray of Clianthus puniceus.

A box of flowers of Rhododendron Falconeri from the open was also shown by E. HEATH, Esq., Kitlands, Holmwood, Surrey.

Messrs. JOHN WATERER & SONS, Ltd., Bagshot, Surrey, furnished a portion of the concert platform with a display of Rhododendrons, edged by a row of Ledum palustre, and intermixed with Japanese Maples. Pink Pearl was prominent in the centre of the group, having a batch of the variety Cynthia on either side. There were also William Austin (a fine dark crimson) and John Henry Agnew (a light-coloured variety with darker upper petal) (Silver Banksian Medal).

The remaining space on the platform was occupied by a group of dwarf Japanese trees in pots, staged by Messrs. BARR & SONS, King Street, Covent Garden.

Messrs. J. CHEAL & SONS, Crawley, showed a number of sprays of flowering trees and shrubs, relieved with branches of ornamental foliage. Magnolia Lennei was conspicuous, Exorchorda grandiflora was very showy, as were the flowering Cherries, Crabs, &c. Messrs. CHEAL also showed trays containing "alpines" and a basket of their new Pansy "Mark Mills" (Bronze Flora Medal).

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, put up a showy group of flowering plants—Clematis, Azaleas, Ixora superba, Olearia stellulata, Philadelphus, &c. The display presented a wealth of colour, and was nicely finished by an edging of the small variegated Funkia (Silver Banksian Medal).

Messrs. R. & G. CUTHBERT, Highgate, showed a large group of forced shrubs and other plants arranged in good style (Silver-gilt Banksian Medal).

Mr. JAS. DOUGLAS, Edenside, Great Bookham, contributed a number of Auriculas, two of which are mentioned under Awards (Silver Banksian Medal).

A collection of "Alpines" was shown by the GUILDFORD HARDY PLANT NURSERY CO., Millmead, Guildford. Androsace coronopifolia was shown well. We also noticed Daphne Fioniana and Haberlea rhodopensis. Saxifrages were a feature in this firm's exhibit (Silver Banksian Medal).

Mr. AMOS PERRY, Winchmore Hill, London, showed an extensive group of Alpine plants. A batch of Phlox canadensis Perry's variety was prominent; it is an advance on the type. Irises were shown well. We also noticed Euphorbia Wulfeni (see Awards), Convolvulus Cneorum, and a large tank of the fragrant Cape pond weed, Aponogeton distachyon (Silver Banksian Medal).

Messrs. WM. CUTBUSH & SON, Highgate, London, N., staged an extensive group of alpine plants, displayed,

as usual, to the best advantage. Prominent among the group were a number of hardy terrestrial Orchids, a batch of Cypripedium spectabile being a feature. We also noticed C. japonicum in flower. Other interesting plants were Eritrichium nanum, Daphne Gwenka, and Anemone magellanica. On another table Messrs. CUTBUSH displayed Ericas and a dwarf growing polyantha Rose named Mrs. W. Cutbush (Silver-gilt Banksian Medal).

Mr. M. PRICHARD, Christchurch, Hants, exhibited hardy plants—Phloxes, Irises, Aubrietias, Alyssums, Primulas, many forms of Scilla nutans, and S. campanulata. Interesting were Myosotidium nobile, that had the appearance of a huge Forget-me-Not, and our own beautiful bog-plant, Menyanthes trifoliata (Silver Flora Medal).

Mr. G. REUTHE, Keston, Kent, put up a collection of alpines and similar plants, among which were not a few novelties, especially of Irises; we noticed the new I. vaga and I. Hebe, a lot of I. Susiana, Tulips, a few Daffodils, hardy Orchids, Rhododendrons, Primulas, &c. (Bronze Flora Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, showed alpine and border plants. We have space only to mention Cypripedium pubescens, Ranunculus monspeliacus, Iris sofrana var. magnifica, and Edrianthus serpyllifolius. A large collection of Trollius was included in the group.

The Misses HOPKINS, Mere, Knutsford, showed a small collection of alpine plants.

Messrs. GEO. BUNYARD & Co., Maidstone, showed a collection of alpine hardy plants. There were good forms of Primula Sieboldi, Aubrietias, Saxifrages, Trollius napellifolius, Iris grandiflora, Tulips, &c. (Bronze Flora Medal).

Messrs. PULHAM & SON, 71, Newman Street, Oxford Street, London, set up a fine piece of rockwork, on which they arranged a number of well-flowered alpine plants, Ferns, &c. One portion of the structure representing a cave was well executed.

Messrs. T. S. WARE, Ltd., Ware's Nursery, Feltham, showed a number of their new "Tree" Carnation Leander, a variety having salmon-pink-coloured flowers, and from the number of buds present of very free-flowering habit. They also displayed a fine collection of alpine and hardy plants. Chamælirium Carolinianum was flowering in a pan, also Wulfenia carinthiaca, Aubrietias, Irises, Primula japonica in varieties, and Lobelia laxiflora were shown well. There were also flowers of tuberous Begonias in single and double varieties (Silver Flora Medal).

Messrs. JOHN PEED & SON, West Norwood, London, showed a nice display of Gloxinias. The specimens were well grown, the type of flower being commendable in size, colour, and form. Messrs. PEED also displayed a group of Japanese Maples and Clematis montana (Silver Banksian Medal).

Awards.

Auricula Vesta.—This is a very pretty white-edged variety, shown by Mr. JAS. DOUGLAS (Award of Merit).

Auricula Rifleman.—A green-edged variety of considerable refinement. From Mr. JAMES DOUGLAS (Award of Merit).

Carnation "Lady Bountiful."—A tree variety with pure white fragrant flowers of large size and possessing non-splitting calyces. Like most of the American varieties the flowers of this one have petals with marginal fimbriation. Shown by Mr. A. F. DUTTON (Award of Merit).

Clematis montana rubens.—A variety in which the flowers are pinkish or rose in colour. Shown by Messrs. JAS. VEITCH & SONS (Award of Merit).

Euphorbia Wulfeni.—A strong-growing plant, having linnear oblong leaves and very large inflorescences of greenish-yellow coloured bracts. A suitable plant for cultivation on a boldly-constructed rockery. Shown by Mr. A. PERRY (Award of Merit).

Meconopsis punicea.—This species, like M. integrifolia, which received a First-class Certificate at the previous meeting, is an excellent hardy-flowering plant recently introduced from China. We published a large illustration of the plant in our issue for Oct. 22, 1904, p. 289, when it was fully described. The plant as shown on Tuesday last had a flower-spike about 20 inches high, and its large, rich, red-coloured, drooping flowers, which are produced solitary, are certainly very handsome. From Messrs. JAS. VEITCH & SONS (First-class Certificate).

Primula japonica var. pulverulenta.—A variety of P. japonica with exceedingly rich purple-rose-coloured flowers, and having the inflorescence covered with a whitish powder. From Messrs. JAS. VEITCH & SONS (Award of Merit).

Primula tangutica.—A curious species with brightly coloured, blackish-purple flowers with very narrow petals, to which we shall refer again. Shown by Messrs. JAS. VEITCH & SONS (Botanical Certificate).

Primula Veitchii.—This is a new and hitherto unpublished species introduced from China. It has some resemblance to P. cortusoides, but is very distinct, and it will make a first-class garden plant. The flower-spike is about 14 inches high, and some of them bear as many as twenty flowers of rosy-purple or violet colour. The flowers themselves might be described as having an appearance similar to those of a very richly-coloured variety of P. obconica. We hope to publish a full description of the plant shortly. From Messrs. JAMES VEITCH & SONS (Award of Merit).

Pteris cretica generosa.—This is an elegant plant shown by Mr. H. B. MAY, Edmonton. It reminds one of the variety Summersii partly skeletonised, for instead of being unusually plumose, in the variety generosa the fronds have little beside the vascular tissue developed. To this characteristic its light appearance and elegance are due (Award of Merit).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Secretary), De B. Crawshay, W. A. Bilney, J. Douglas, J. Colman, F. Wellesley, W. H. White, H. T. Pitt, F. Sander, H. G. Morris, F. W. Ashton, H. A. Tracy, G. F. Moore, R. G. Thwaites, H. Ballantine, T. W. Bond, J. W. Potter, W. H. Young, W. Boxall, W. Bolton, W. Cobb, H. Little, and H. J. Veitch.

Among amateurs, F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr., Mr. Balmforth), secured the highest award, a Silver-gilt Medal, for a very beautiful and well-arranged group, in the centre of which was a cluster of plants of finely flowered Oncidium concolor. Arranged around and beside were many good forms of Odontoglossum crispum, O. × Adrianæ, and other Odontoglossums; and arching over from the back fine sprays of Cymbidium Lowianum and its variety concolor; C. × eburneo-Lowianum, Lælia cinnabarina with five spikes, Odontoglossum triumphans, &c. At the extreme end was a grand specimen of Cypripedium Rothschildianum, with fourteen flowers; Cattleya intermedia alba, with sixteen pure white blooms; a fine specimen of Cypripedium Lawrenceanum Hyeanum, three of C. callosum Sanderæ and C. × Maudiæ, a nice example of the pretty white purple-spotted C. × Mrs. Herbert Druce, good Lycaste Skinneri, Miltonia × Bleuana, a patch of scarlet Sophronitis, &c.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr., Mr. Ballantine), was awarded a Silver Flora Medal for a fine group containing several very handsome blotched forms of Odontoglossum crispum, the best being O. c. Rex (a very finely-coloured flower), O. c. Lindeni, and O. c. Princess Beatrice. These had already had awards, and so also has the handsome O. × Harryano-crispum Duchess of York. Specially fine were Cattleya Skinneri, with nine heads of bloom; Odontoglossum × Wattianum, O. Oerstedi, with twenty-three pretty white flowers; Brasso-Cattleya × Digbyano-Mossiæ, the original plant; Cypripedium Mastersianum, C. × Maudiæ, C. Lawrenceanum, with six flowers, and a strong plant of its variety Hyeanum; the singular Bulbophyllum barbigerum and B. Dearei; Masdevallia cucullata, Renanthera Imschootiana, and other rare kinds.

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. W. H. White), was awarded a Silver Flora Medal for an interesting group of fine Orchids, for several of which see Awards. One of the finest in the group was Cattleya Mossiæ Goossensiana, with pearly-white sepals and petals and very rich violet-purple lip. Others shown were the singular Epi-Lælia × radico-purpurata, Brasso-Cattleya × striata, Lælio-Cattleya × Fascinator splendens, quite a bush of the pretty orange-coloured Dendrobium Jerdonianum, and the slender white D. crumenatum, Masdevallia × Rushtoni, M. × Ferrieresensis, M. × Doris, and other hybrid Masdevallias, and the pretty Cattleya intermedia Aquini.

H. S. GOODSON, Esq., Fairlawn, Putney (gr., Mr. G. E. Day), received a Silver Flora Medal for an effective group in which were a good selection of forms of Odontoglossum crispum and other Odontoglossums; a fine example of Dendrobium Bensonæ, others of D. thyrsiflorum, and D. Devonianum; a fine specimen of Angræcum sesquipedale, good Cattleya Schröderæ, and C. Mendeli, C. intermedia alba, Dendrobium atroviolaceum, Cymbidium Lowianum, Phaius × Norman, the handsome Miltonia × Bleuana radiata, and other showy Orchids.

Messrs. J. CYPHER & SON, Exotic Nurseries, Cheltenham, secured a Silver-gilt Flora Medal for a fine and tastefully arranged group, the forms of Odontoglossum crispum being prominent. The finest was O. crispum giganteum, a noble white flower tinted on the sepals with rose colour. It is fine in shape and size, and very delicately tinted. Good forms of O. Pescatorei (a pretty white-ground), O. × loochristyense Empress Frederick, and some other hybrids were also included, and good examples of Phalænopsis Rimestadtiana, scarlet Masdevallias, Lælio-Cattleya × Hippolyta, L.-C. × highburyensis, Diacrium bicornutum (with two fine spikes), Oncidium cernigerum, Calanthe veratrifolia, Odontoglossum Uro-Skinneri, &c. The Cattleyas included good C. Mendeli (one with a very large delicately-veined rosy magenta labellum), and the white C. M. Duchess of York being specially remarkable; good C. Schröderæ, C. Skinneri, C. Aclandiæ, pretty tufts of Tetramicra bicolor, &c.

Messrs. CHARLESWORTH & Co, Heaton, Bradford, secured a Silver Flora Medal for an excellent group, in the centre of which was a selection of the reddish-orange-coloured Lælio-Cattleya × G. S. Ball, and beside them several L.-C. × Myra, L.-C. × Mercia, L.-C. × Hyeana, and other Lælio-Cattleyas. The Odontoglossums were represented by good forms of O. crispum, the spotted ones including O. c. Luna (clear white with brownish spots). Others noted were several pretty unnamed hybrids; a good form of O. × excellens (home-raised), O. × Brandtiæ, O. × loochrisytense (of fine form, yellow blotched with chocolate-brown), the orange-coloured Saccolabium curvifolium, Brasso-Cattleya × Digbyano-Mossiæ, and a strong specimen of Cypripedium × Edithæ (bellatulum × Chamberlainianum).

Messrs. HUGH LOW & Co., Enfield, staged a group, including Trichopilia suavis and its white variety, Saccolabium ampullaceum, a very fine Dendrobium clavatum, Cattleya Lawrenceana, C. intermedia, C. i. alba and cærulea, Pholidota ventricosa, Chysis bractescens, various Odontoglossums, &c. (Silver Banksian Medal).

C. J. LUCAS, Esq., Warnham Court (gr., Mr. Duncan), staged a group of Odontoglossums comprising two very fine forms of O. polyxanthum, O. × Andersonianum obstupefaciens, O. Hallii, O. × Adriana, O. triumphans, and with them a good plant of Cattleya × Apollo (Aclandiæ × Mossiæ) (Silver Banksian Medal).

M. CHAS. VUYLSTEKE, Loochristy, Ghent, showed the fine Odontoglossum × Rolfeæ "Palma," and several other hybrid Odontoglossums.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), again showed the handsome yellow, purple-spotted Cypripedium × Wellesleyanum, which had previously secured an Award, and also C. Lawrenceanum hackbridgense.

G. H. ROLLS, Esq., Arcadia, Bournemouth, showed a fine form of Cattleya Mossiæ.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), showed Odontoglossum crispum Bonnyanum Crawshayanum (!), a very fine flower and remarkable in that the splendid plant had been grown in a clear glass pot; also O. × Andersonianum "Raymond Crawshay," and O. Lindleyanum aureum, the last named, a clear yellow unblotched variety, securing a Botanical Certificate.

W. C. WALKER, Esq., Winchmore Hill (gr., Mr. Bunney), showed Odontoglossum × Adrianæ "Avice Walker."

Mr. H. WHATELEY, Kenilworth (gr., Mr. J. Howes), sent three good spotted Odontoglossums—viz., O. crispum "Hubert Whateley," O. c. "Eric Whateley," and O. × Andersonianum Whateley's variety.

FRAU IDA BRANDT, Riesbach, Zurich, sent a fine flower of the extraordinarily large Angræcum infundibulare, illustrated in the *Gardeners' Chronicle* [see Supplement, August 20, 1904], and for which Lord ROTHSCHILD had received a First-class Certificate at the first meeting in the new Hall (Vote of Thanks).

JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), showed a remarkable cross between Diacrium bicornutum and Epidendrum radicans, bearing a terminal head of reddish scarlet flowers. The habit is like that of a stout dwarf E. radicans.

Messrs. COWAN & Co., Gateacre, Liverpool, showed a fine specimen of Cypripedium aureum virginale with six flowers.

Awards.

FIRST-CLASS CERTIFICATES.

Odontoglossum crispum "*Louis L. Sander*," from J. LEEMANN, Esq., West Bank House, Heaton Mersey (gr., Mr. Edge).—One of the finest of the prized blotched forms of O. crispum, and although still only a small plant showing qualities of the highest order. The backs of the segments are of a rich rose-purple colour. Two-thirds of the surface are covered with fine purplish-crimson blotches, the main blotches following the outline of the flower up to the clear white margin. Lip white, with several reddish blotches. A remarkably beautiful variety.

Cymbidium rhodocheilum, from J. BRADSHAW, Esq., Southgate (gr., Mr. Whitelegge).—This is a fine Madagascan species now also flowering at Kew. The plant bore a strong inflorescence; sepals green; lip, magenta-rose with dark spots at the base.

AWARDS OF MERIT.

Brasso-Cattleya × *Mrs. J. Leemann* (B. Dighyana × C. Dowiana aurea) from Sir TREVOR LAWRENCE, Bart.—Flowers, yellow, slightly tinged with green and pale rose-colour; lip fringed.

Bulbophyllum Reinwardtii, from Sir TREVOR LAWRENCE, Bart.—Similar in habit to B. Ericsoni. Inflorescence bearing one large flower; sepals and petals green, striped and spotted dark-purple; lip hinged, crimson-purple on the upper surface.

Epi-Lælia × *Sylvia* (L. cinnabarina × E. Cooperiana), from Sir TREVOR LAWRENCE, Bart.—A graceful hybrid, with an arching inflorescence of a dozen pretty white flowers tinged with salmon-red.

Lælio-Cattleya × *G. S. Ball* "*magnifica*" (L. cinnabarina × C. Schröderæ), from Sir TREVOR LAWRENCE, Bart.—A very handsome variety, with uniformly-coloured bright orange flowers.

Odontoglossum crispum "*Titus*," from J. LEEMANN, Esq., Heaton Mersey.—Flowers white, effectively blotched with chocolate-purple colour.

Odontoglossum crispum aureum West Bank House variety, from J. LEEMANN, Esq.—Flowers clear canary-yellow colour.

BOTANICAL CERTIFICATE.

Dendrobium crumenatum, from Sir TREVOR LAWRENCE.—Pseudo-bulbs continued into slender stems bearing numerous white flowers with yellow disc to the lip.

Odontoglossum Lindleyanum aureum, from DE B. CRAWSHAY, Esq.—Flowers wholly yellow.

Narcissus and Tulip Committee.

Present: Mr. H. B. May (Chairman); J. R. De C. Boscawen, J. T. Bennett-Poe, W. Poupart, J. D. Pearson, Rev. G. H. Englehcart, E. H. Bowles, G. Reuthe, E. Willmott, Jas. Walker, R. Sydenham, S. Eugene Bourne, Walter T. Ware, R. W. Wallace, A. Kingsmill, and C. H. Curtis.

Messrs. WALLACE & Co., Colchester, in addition to many early kinds, exhibited a very remarkable collection of Darwin Tulips. We noted Inglescombe Pink, Flame, Mrs. Moon, Orange King, Jaune d'Œuf, Inglescombe Scarlet, Clara Butt, King Harold (the two last-named secured awards), Rose Queen, Margaret, Negro, &c. Many species were included in the exhibit (Silver-gilt Banksian Medal).

A very nice collection of Tulips was exhibited by Messrs. VEITCH & SON, Ltd., Chelsea, representative principally of the May-flowering, bedding, and Darwin kinds (Silver Flora Medal).

Messrs. BARR & SONS, King Street, Covent Garden, contributed some very imposing flowers, the Cottage Tulips and the Darwins being in a majority. We noted Empress of China (bronzy-yellow), Courante fulgens (a painted flower), the rich colour of Bouton d'Or, with Mrs. Moon (a yellow and painted Cottage kind). The Darwin section was well represented, and commanded attention. The curiously coloured T. viridiflora præcox was also interesting (Silver Flora Medal).

The exhibit from Messrs. WALTER WARE, Ltd., Bath, contained many fine varieties of Tulips, the fully-formed flowers being especially good. The variety Clara Butt (see Awards) was very imposing. Other good varieties were Gertrude (Cottage), White Queen, Inglescombe Pink and Painted Lady.

Messrs. HOGG & ROBERTSON, Dublin, contributed Narcissi as well as Tulips, and of the former we noted Maggie May (still very good), Glory (a fine poeticus), White Lady (Leedsii) and Mrs. Betteridge.

Messrs. DOBBIE & Co., Rothesay, brought a varied collection of cut Tulips, chiefly of the bedding sorts, and in which double and single varieties were almost equally balanced.

Messrs. R. H. BATH & Co., Wisbech, contributed a collection of Tulips, chiefly of the Darwin section, and including Madame Krelage, La Noire, Pride of Haarlem, Europe, Ant. Roozen, Maiden's Blush, and others (Silver Flora Medal).

Miss WILLMOTT, Warley Place, Essex, exhibited a group of her choicest novelties in Daffodils. None of the varieties was named on this occasion. The collection was not only representative, but the flowers were in excellent condition.

Awards.

Tulip Clara Butt (*Darwin*).—A variety of the highest refinement in beauty and colouring. The predominating colour is a mixture of rose-and-salmon, and may not easily be described. The flower attracts one's attention immediately it is seen. From Messrs. WALTER T. WARE, Ltd., Bath; and Messrs. R. W. WALLACE & Co., Colchester (First-class Certificate).

Tulip Ariadne (*Darwin*).—A very handsomely proportioned flower, crimson or ruby-crimson in colour. From Messrs. BARR & SONS, Covent Garden (Award of Merit).

Tulip Claude Guillot (*Darwin*).—A very shapely flower, and coloured crimson, with clearly coloured base having internally a well-defined white border (Award of Merit).

Tulip Orange Beauty (*Breeder*).—A fine and showy variety, orange or orange-scarlet in colour, painted with gold. A fine Tulip for massing in beds. The last two varieties were exhibited by Messrs. WALTER T. WARE, Ltd., Bath (Award of Merit).

Tulip King Harold (*Darwin*).—A massive, well-proportioned flower, supported on a tall stem, the colour being a glowing shade of ruby-red or crimson. The interior of the base is dark-coloured. A noble self-coloured Tulip of great merit. From Messrs. R. W. WALLACE & Co., Colchester (Award of Merit).

Fruit Committee.

Messrs. JAS. VEITCH & Co., Ltd., King's Road, Chelsea, staged a collection of Apples and Pears in forty-seven baskets. Taken collectively, the fruits were very meritorious, especially when the lateness of the season is considered. The finest examples were Smart's Prince Arthur, Winter Peach (an exceptionally handsome exhibit), Northern Greening, Barnack Beauty, Norfolk Beefing, Norfolk Bearer (a good-looking variety), and Duke of Beaufort. A few Pears were included in the display, Directeur Alphand being prominent (Silver Banksian Medal).

Mr. S. MORTIMER, Farnham, Surrey, showed six fruits of his new Cucumber, Aristocrat. They were dark in colour and about 14 inches in length. An Award of Merit had been previously granted.

Messrs. GEO. BUNYARD & Co., Maidstone, showed fourteen dishes of Apples of varieties now in season. Although the late period for English-grown Apples was apparent in the specimens shown, they were nevertheless instructive, and exemplified what kinds are available for use now. The best dishes were those of the varieties Calville Rouge, Winter Peach, Alfriston, Tibbett's Pearmain (good examples), Striped Beefing, and Annie Elizabeth.

Mr. T. GRANDFIELD, The Gardens, Hayes Place, Hayes, showed six good fruits of Hero of Lockinge Melons (Cultural Commendation).

Mr. T. Chamberlain, gr. to S. HEILBUT, Esq., Holyport, showed twelve heads of "Sutton's Golden Ball" Lettuce. They looked very appetising, and were worthy of the Cultural Commendation awarded them.

Messrs. CANNELL & SONS, Swanley, Kent, had a row of King Edward VII. Peas in what resembled a large window-box, and the growths were trained several feet high. The numerous pods were fully developed, although the seeds were sown as recently as March 4, 1905. Excellent Cabbages and Broccoli were also shown (Cultural Commendation).

Awards.

AWARD OF MERIT.

Rhubarb Hobday's Giant.—This variety is well named, the petiole being almost 4 feet in length. The exterior has a beautiful rose colour, but the leaves shown gave evidences of having been protected from the light, and were thus somewhat "drawn." One "stick" would be sufficient for an ordinary dish of pastry.

The Lectures.

At a meeting held in the afternoon, H. J. VEITCH, Esq., in the Chair, about seventy new Fellows were proposed and elected.

The lecture-room was crowded, the speakers were clear and interesting, and the lantern illustrations excellent. Two papers on "Japanese Horticulture" were read. The first of these, read by the Assistant Secretary, was from a Japanese point of view, and had been written by Mr. N. HAYASHI, and was illustrated by some fine photographs and pictures. The lecturer pointed out that although his nation was one of the oldest now in existence, 2566 years having passed since the first Emperor's ascent to the throne, the fact of her complete isolation from the Western World had prevented her people from profiting by the advance in Western civilisation, and thus they had been compelled to look to China as their teacher and to Chinese civilisation as their model, until the reformation and subsequent opening of the country to Western influences and civilisation some fifty years ago. Horticulture also had been developed on Chinese principles and was bound by Chinese conventional rules, but as horticultural progress depended largely on the tranquillity of the country it was not until Shogun Tokugawa, the great feudal ruler, had brought about peace by the formation of a powerful government in A.D. 1595, that the art made any marked development. For the next 200 years soldiers and commoners alike paid very great attention to horticulture, and even at the present time the Tokigawa dynasty is still regarded as the golden age of Japanese horticulture. Then, too, the revolution, or more strictly speaking, the reformation of forty years ago aimed at effecting a complete change in the things which had appeared to the leaders thereof to be impediments in securing the advantages of Western civilisation. Thus the beautiful gardens attached to the town houses of feudal lords in Yedo (now Tokyo), the then capital of the defeated Shogun, were remorselessly destroyed; trees and shrubs were cut down and converted into fuel for the popular furnace, and ornamental stones were dug up to pave the streets. Thus horticulture had for a while been entirely suppressed. Immediately after the civil war, which fortunately was soon over, Japan started a new life, and the whole nation devoted itself to making the country "the equal in civilisation and in powers of defence and offence of any European nation"; and education, law-making, and many other matters also occupied its attention. Consequently, though the cultivation of utilitarian fruits and vegetables has been more or less encouraged by the Government, the cultivation of garden plants and flowers had not occupied the people's attention so much of late years as formerly. "Moreover only a few years after the last Chino-Japanese war they had been again called upon to fight for their national existence, as well as for securing permanent peace in the Far East; but he (Mr. HAYASHI) sincerely hoped that the conclusion of this terrible war would bring the much-desired peace in the East, in which case horticulture would not be slow in reaping the fruits of such a millennium." He then described the work of the Japanese agricultural, horticultural, and special flower (such as the Chrysanthemum, Rose, and Primula) societies and of the Fruit, Dwarf Trees, and other societies. He gave a short account of the vegetables of Japan. The fruits of Japan were generally eaten raw, and never appeared on the table with meals. Few kinds were dried and crystallised for use, and jam-making was quite a recent thing learnt from abroad.

The cultivation of the Chrysanthemum was also described. This flower was first cultivated in Japan in about A.D. 300, and reached its zenith in the sixteenth century. The lecturer had himself investigated the origin of the Japanese Chrysanthemum, and had found that similar kinds to the present varieties of flower could be obtained by various processes of hybridisation, and he mentioned what he believed to be the parent varieties, and described the principal varieties now cultivated. The methods of both the Japanese amateur and professional Chrysanthemum cultivators were also described in the paper.

The second paper was by Mr. REGINALD FARRER, on "Japanese Horticulture," with special reference to Japanese soil and weather. He pointed out that all Japanese plants grew with more or less bottom-heat, an

that their soil is generally of rich, warm loam, mixed in different degrees with minute volcanic deposits. As to climate, they endured intense extremes of heat and cold at least in Hon do and Hohkaido), both accompanied by almost perpetual rain, October and December being the only two months in which any clear spell of fine weather could be confidently expected. In these circumstances it could not be wondered at that Japanese gardening should differ so much from English gardening. But in fact it was fair to say that the Japanese are not so much lovers of flower gardens as of garden architecture in stone and topiary work. As to wild flowers, Japan contained many species which might be well acclimatised in British gardens, and would he very valuable additions to our alpine and herbaceous gardens. Mr. Farrer then proceeded to give short descriptive notes of numerous Japanese plants, mostly well known in this country. His lecture concluded with an exhibition of coloured lantern-slides from photographs taken by himself in Japan.

HORTICULTURAL CLUB.

MAY 9.—On Tuesday last, on the occasion of the monthly dinner and meeting, there was an unusually large attendance of members and friends to hear Mr. E. H. Wilson read a paper on "Journeyings in China." Sir Jno. T. D. Llewellyn, Bart., presided, and the visitors included Dr. Henry, Mr. W. Watson (Kew), Mr. Gill, of the Botanical Station at Cawnpore, J. Weathers, W. Hales, and others. It is well known to readers of this journal that Mr. Wilson has been sent to China on two occasions by Messrs. Jas. Veitch & Sons to collect new and rare plants, and many of the herbaceous species he has introduced to this country have been already illustrated in our pages. In the issue for February 25 last may be found a summary of the work Mr. Wilson did during his five years' experience in China and Thibet, and of the 5,000 species of plants he collected, more than 2,000 of which we believe he has succeeded in introducing into this country by means of seeds or plants, some of what appear at present to be most noteworthy were there mentioned. Even in this present issue further evidence of the value of Mr. Wilson's work may be seen in the report of the Royal Horticultural Society's meeting, when several new plants from China received awards from the Floral Committee. Mr. Wilson's paper at the Club described some of his experiences during his travels in southern, western, and central China. He had much to say upon the richness of the Chinese flora, especially in the district around Hupeh and on the borders of Thibet. He also said that many plants bearing the specific name of japouica, as Anemone japouica, Kerria japonica, Senecio japonica, Spiræa japonica, &c., were really Chinese species, and though some of them were common to both countries, others were cultivated plants in Japan, and indigenous only to China. Mr. Wilson acknowledged the help afforded him by Dr. Henry upon his arrival in China, and went on to speak of the physical character of the country, and of the customs of the Chinese and Thibetans. The pressure upon our space this week, however, will not permit us to enter more fully into the subject, but Mr. Wilson will probably do so on a future occasion.

Dr. Henry, who is always interesting when speaking of China, having spent twenty years in that country, paid a high tribute to the courage, sagacity and energy which Mr. Wilson had displayed during his singularly successful career as a plant collector. Dr. Henry afforded his hearers much information upon the flora of China, and related some interesting details concerning a botanical tour made by Mr. Wilson and himself.

Mr. W. Watson spoke of the circumstances connected with Mr. Wilson's service in the Royal Gardens, Kew, and which led to his being selected to proceed to China. Owing to the kindness of Messrs. Jas. Veitch & Sons, a large number of mounted specimens from Mr. Wilson's herbarium were exhibited before those present, and in addition there were photographs taken in China during Mr. Wilson's travels. The meeting was a very enjoyable one, and Mr. Wilson was invited to give another paper on the subject to be illustrated with lantern-views.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MAY 8.—A Committee meeting was held on the above date at the Royal Horticultural Hall, Vincent Square, Westminster, Mr. C. H. Curtis presiding. Three new members were elected and one nominated. The death certificate of the late Mr. R. H. Robinson, of Heversham, was produced, and the amount standing to his credit in the Society's books was directed to be paid to his nominee. Fourteen members were reported on the Sick Fund; the amount paid out for sickness during the month being £11 8s.

REMARKS.—Strawberries are now arriving daily in great quantities, consequently prices for these fruits are very low. A few Cape Pears arrived during last week, and were sold at 5*s.* to 7*s* per case; others from Australia made from 4*s.* to 12*s.* per case. Quantities of Apples, shipped from Australia and Tasmania, are due to arrive this month, the bulk of which will be sold in London. A boat is expected to arrive on or about Saturday, May 13, with about 16,000 cases. The quantity estimated to arrive from now till the end of the present month is about 111,000 cases.

POTATOS.

Dunbars, 100*s.* to 110*s.*; various, home-grown, 55*s.* to 80*s.* per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

THE spring trade in plants has now commenced in earnest, and for the next few weeks trade should be busy. Prices do not rule high, and supplies of the usual plants for spring use appear to be plentiful. Scarlet and other zonal Pelargoniums sell in large quantities, but only realise moderate prices. Ivy-leaved varieties sell better; of these the varieties Galilee and Madame Crousse are most in demand. Show and decorative sorts do not sell at all briskly. Yellow Calceolarias and Lobelia Emperor William are now seen. The last-named plant is scarcely in full flower. Fuchsias sell better, and at advanced prices. Hydrangeas continue to sell well, dwarf plants being in demand for window-boxes. Ericas of good quality are still to be had. Most growers have now finished with Cinerarias, but there are still some to be had. Supplies of Mignonette are not quite so plentiful, that raised from spring-sown seed is not ready for the market, but may be available in the course of a few days. Intermediate Stocks are very good, but they do not sell at all readily. Rhodanthe is abundant. There are still some very good Indian Azaleas seen, but they will not be available for a much longer period. Begonia Gloire de Lorraine and the Turnford Hall variety are present, but the quality is less good.

FOLIAGE PLANTS.

Although many Fern growers now fill a portion of their stands with bedding plants, there is no scarcity of Ferns except for some kinds in large sized pots. Aspidistras are scarce; growers do not care to bring them into the market while they are developing their new leaves. Palms of various sizes sell better, but there is little variation in the demand or in the prices for any foliage plants.

BEDDING PLANTS.

These are now selling freely, and good plants in 3-inch pots are cleared out early. Zonal Pelargoniums (Geraniums) of scarlet and other colours

make from 1s. 9d. to 2s. 6d. per dozen, while "tricolors" command somewhat more. Petunias are well grown and sell freely at from 1s 9d. to 2s. per dozen. Allother varieties of bedding plants are procurable at ordinary prices. Pansies do not sell readily, and hardy flower roots are in less demand.

CUT FLOWERS.

Trade in cut flowers is a trifle better, but there appears to be little variation in prices. Some things are considerably in excess of all demands. Roses continue good, but large quantities are left over at closing time. Supplies of Carnations are over plentiful. Liliums are at their lowest prices. Callas are not so plentiful. Supplies of Daffodils are almost over, but the double white Narcissus and Poeticus still appear fresh and in good condition. Spanish Iris are plentiful. Gladiolus Colvillei, The Bride, and the pink variety, are more abundant than they were. Orchid bloom does not sell readily. Many hardy flowers are now arriving in the market. Double Trollius are very pretty. The trade in imported flowers is now nearly over for the season, but Gypsophila, Roses, Carnations, Marguerites, and Cornflowers still come from France, while there are also some Dutch-grown flowers. *A. H., Covent Garden, May* 10, 1905.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 159 feet. The following are the "mean" readings for the week ending May 6, 1905.

APRIL 30 TO MAY 6, 1905.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	Wet Bulb.	DAY. Highest.	NIGHT. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	49	45	58	41	35	50	50	48	Tot 0·47	8 18

THE WEATHER IN WEST HERTS.

Almost Continual Sunshine.—The days have been mostly warm, while the nights, on the other hand, were all more or less cold. Consequently the range in temperature has been on most days unusually great. For instance, on the 9th, the difference between the lowest and highest readings in the thermometer screen amounted to as much as 38°. On the two warmest days the temperature in the thermometer screen rose respectively to 69° and 67°, the highest readings as yet recorded this year. On the two coldest nights the exposed thermometer showed 5° of frost. The ground is at the present time slightly warmer than is seasonable both at 1 and 2 feet deep. No rain has fallen for a week, and for the last three days no measurable quantity of rainwater has come through either percolation gauge. There has been a splendid record of sunshine, the average daily duration amounting to nine and three-quarter hours, or nearly four hours a day longer than is usual at this season. Light airs and calms, as a rule, prevailed, and for eighty-two hours, or nearly half the week, the direction of the wind was from some point between north and east. The mean amount of moisture in the air at 3 P.M. was as much as 9 per cent. less than is seasonable. A Blenheim Pippin Apple tree growing in my garden came first into blossom on the 5th inst., which is one day earlier than its average date for the previous nineteen years, and eight days earlier than last year. *E. M., Berkhamsted, May* 10, 1905.

[For actual temperature and condition of barometer at time of going to Press, see p. 296.]

ANSWERS TO CORRESPONDENTS.

ANTHURIUM PROSCHERSKYANUM: *Berlin.* We have been unable to find any such name.

BERBERIS VULGARIS: *E. G. C.* It is not usual to find the fruits hanging for so long a period. The other plant is Rubus spectabilis, the Salmon Berry.

CATERPILLARS ON APPLE-TREE: *J. J.* The small caterpillars are those of the Winter Moth (Cheimatobia brumata). Syringe the trees now with a solution of Paris Green or of Quassia-extract, and in the late summer place grease-bands round the stems to prevent the wingless female moths from ascending to the branches. CAUTION.—Paris Green is an arsenical poison, and should be used with great care, and in the proportion of 1 lb. to 200 gallons of water, working in 2 lb. of lime to diminish the risk of injuring the foliage.

CODIÆUMS (CROTONS): *J. E. G.* The injury is caused by the accumulation of drops of water on the leaves; this afterwards becomes chilled and kills the tissue of the leaf. Moisture should not be allowed to condense on the surface of the leaf during the night.

FRUIT FARMING DISTRICT: *J. G.* Such a district as you describe will be found around Evesham in Worcestershire. Book to Evesham Railway Station.

GLOXINIAS: *Anxious.* The corms are alive with the bulb-mite. It is possible that the corms were wintered in unsuitable conditions, which induced decay, and that the mites have increased in numbers since then. In any case, the only thing to do now is to burn the plants and raise a fresh stock, there being no cure for such a severe attack.

GOOSEBERRIES: *F. W. T.* There is no evidence of attack by insects or fungus. We are disposed to think the injury has been caused by birds.

GOOSEBERRY LEAVES: *A. D.* The leaves are attacked by the Gooseberry fungus, Æcidium

FIG. 126.—GOOSEBERRY DISEASE: ÆCIDIUM GROSSULARIÆ.

grossulariæ, fig. 126. Spray the plants with Bordeaux-mixture (see p. 288 in our last issue), taking care to decrease the strength of the solution as the fruit approaches maturity and to cease spraying altogether before the fruit is fully ripe. Permanganate of potash solution is also a good preparation to use as a fungicide. Dissolve crystals of permanganate of potash in water until the solution is of a pale rose-colour. Apply this as a fine spray, especially on the undersurfaces of the leaves. One stage in the life-history of Æcidium grossulariæ occurs on plants belonging to the Sedge family. These weeds should as far as possible be eradicated. Currants are not immune from the attacks of this disease; it even attacks the flowering Currants of the shrubbery.

HONEYSUCKLE: *E. G. C.* Our opinion is similar to your own. The soil and roots smell strongly of paraffin-oil, and of course this liquid, if present in sufficient quantity, is quite capable of killing the plants.

NAMES OF PLANTS: *Subscriber, Milan.* Phlox subulata variety.—*F. K.* Pyrus prunifolia, the Siberian Crab.—*J. S.* 5, Asparagus sarmentosus. —*W. T., Gloucester.* Cypripedium ciliolare.— —*H. L.* Milla (Triteleia) uniflora.—*R. N. H.* Odontoglossum gloriosum. There being only a few flowers on the spike, they are slightly larger than when the normal quantity is borne. —*Japonica.* 1, a Dendrobium of the Aporum section, not to be determined without flowers. All the section bear small white flowers; 2, Dendrobium crepidatum; 3, D. thyrsiflorum; 4, Oncidium maculatum; 5, O. sarcodes, a very fine variety.—*W. C.* 1, Odontoglossum cordatum; 2, Masdevallia coriacea.—*G. R. D.* 1, Olearia stellulata; 2, Asperula odorata.— *A. W. G.* 1, Cratægus crus-galli; 2, Limnanthes Douglasii; 3, probably Salix capræa. Thank you for enclosure, 1s., for the Gardeners' Orphan Fund.

PALMS: *W. M.* Palms frequently outgrow the limits of the house in which they are grown, and unless they are growing in pots or in tubs and can be lowered by forming a trench in the house, there is no alternative but to shorten them at the top. The plants have to be thus treated occasionally in the Palm house at Kew.

PEACH-LEAVES: *T. M.* The leaves have been checked in their growth by cold draught or some other cause. They seem also to be attacked by fungus.—*S. D. O.* Some of the leaves look as if they were scorched, others have the Shot-hole fungus (Cercospora). Spray them with a solution of liver-of-sulphur: ½ oz. of sulphur to 1 gallon of water.

PIG'S EARS FUNGUS: *Lord Kesteven.* The fungus sent under this name is Peziza (Cochleata) reticulata (Greville), figured in Cooke's *Mycographia*, plate 58, fig. 227. It is found growing on the ground in spring, and is esculent. It is found not only in Britain, but in several other countries of Europe. The cups sometimes attain to a diameter of 5 inches. *M. C. C.*

SEEDS: *An Old Reader.* The seeds are of the Flamboyant, Gold Mohur, or Gulmohr tree (Poinciana regia), a handsome evergreen Leguminous tree, native of Madagascar, extensively planted throughout the warmer parts of India, and frequently in towns and villages on the eastern coast of Tropical Africa and in Angola. The tree grows very quickly, and is described as gorgeous when in flower, with its large corymbs of crimson and its bright green leaves.

SOIL ANALYSIS: *J. W.* We cannot undertake this laborious, costly and time-consuming task. See reply to "E. G."

TOMATO LEAVES: *J. H. A.* There is no fungus present. The brown enlarged veins are caused by too much acid in the soil. Water the soil with a solution of nitrate of potash, 1 oz. to a gallon of water, three times, at intervals of four days between each application.

VINE LEAVES: *M. P.* The small warts on the under surface of the vine leaves are due to the presence of excess of moisture in the house. Better ventilation, more especially early in the day, will set the matter right.—*E. G.* The warts on your leaves are the result of defective ventilation and excessive moisture. It is quite possible that there is also a mite concerned in the matter. If you wish the soil and water analysed, you should send samples to some competent analyst, or to the chemist of the Royal Horticultural Society, but you must be prepared to pay his fee.

VINES: *J. B.* The branches are quite free from any disease due to insects or fungi, and it is impossible for us to ascertain the cause of the injury.—*J. H. H.* We suspect that the dressing contained too much Fir-tree oil, or it was put too thickly upon the canes and smeared over the buds. A properly-mixed dressing, if applied with care and at the proper season, does no harm to the Vines.

ILLUSTRATIONS.

SOME ASPECTS OF GARDENING IN AUSTRIA AND GERMANY.

A TRAVELLER, seeing the gardens of these extensive countries, will remark the paucity of the rarer species of coniferous trees and evergreens generally. Those which he finds are in many instances indigenous and possessed of no great beauty, there being hardly any Japanese, Chinese, Chilian, New Zealand, or Californian species, which in our own country have largely added to the beauty of our gardens and pleasure-grounds during the last fifty years. One greatly misses the Cypresses, Cryptomerias, Retinosporas, Eucalyptus, Podocarpus, and Araucarias among arboreal forms; and the Veronicas, Olearias, Aucuba japonica, the female form of which last is one of the best berried plants; Azara, Carpenteria, Osmanthus, Pittosporum, and others among more lowly forms. The cause of the scarcity of evergreen shrubs from the countries named is in most parts due to the severity of the winters prevailing from the North Sea to Kärnten (Carinthia).

The Yew in its many varieties is largely employed as solitary examples and as material for hedges and wind-breaks, and sometimes as game coverts, although for these the common Spruce (Picea excelsa), maintained at a height of 4 to 5 feet by occasional cutting, is met with. Several Arbor-Vitæs (Thuya) as T. gigantea and its varieties, T. occidentalis, the American species; Thuiopsis nootkatensis, from British Columbia; Wellingtonia (Sequoia) succeed in sheltered gardens, as also Cedrus atlantica, but I have never observed the Lebanon or the beautiful Deodar Cedar in the open ground, these being considered to be safe only in the glasshouse or winter-garden during the winter season, placing them out-of-doors along with other partly hardy things from early May till October. The deciduous Cypress (Taxodium distichum) does well in some parts, as for example in the gardens of Graf Harrach at Bruck-on-the-Leitha.

The Pines furnish a more numerous contingent. P. Strobus (Weymouth Pine) grows to a large size, its horizontally-poised upper branches supporting the heavy falls of snow without injury. The Scots and Austrian Pines, the Pitch Pine, P. insignis, P. excelsa, a Himalayan species, and P. Pinaster, are garden and forest trees. The American and Siberian Larches are common, and the Maidenhair-tree (Ginkgo) is often met with of large size, and when raised from seed the tree has a handsome contour. Lawson's Cypress in its several varieties is quite hardy, and is one of those rarely browsed upon by roe and red-deer during hard weather.

The Red Cedar (Cupressus virginiana), the wood of which is almost exclusively used in the manufacture of lead-pencils, grows fast, and being well adapted to wet and swampy soils, is employed for forming groups, shelter-belts, and garden-hedges. Of the Hemlock Firs (Tsuga), T. Menziesii, the Columbian species, and T. canadensis (Pseudo-tsuga), T. Pattoni, and T. Hookeriana withstand the climate, and form fine ornamental trees. Of the Silver Firs that are hardy mention may be made of Abies grandis, A. lasiocarpa, A. nobilis, A. Nordmanniana, A. balsamea, and A. concolor. Picea excelsa in its many varieties is found in forests and gardens, and P. nigra, P. orientalis, and P. pungens are met with in gardens only.

Among deciduous species of trees, Acer campestre, also A. fraxinifolium in white-and-yellow variegated varieties, are common garden and park trees, as are also the Norway, the Scarlet, and Sugar Maples, Horse-Chestnuts in variety, also Æsculus flava and Æ. macrostachya, the latter forming a spreading flat-headed bush, very decorative when in flower. The Ailanthus glandulosa, which grows to large dimensions, is commonly employed as a street tree; and Mountain Ash (Pyrus Aucuparia) is quite hardy. It forms a beautiful avenue half-tree, which when loaded with ripe fruits is exceedingly effective. Hornbeam, American Walnuts, and Catalpa syringæfolia and C. speciosa are common in some parts, the latter growing to large dimensions if the soil be moist; likewise the Nettle-tree, which forms round-headed specimens, and is well adapted for planting on the margins of lakes and rivers, are commonly met with.

The Thorns (Crataegus) grow well and flower profusely, and Quinces (Cydonia) make the garden gay when in flower, as do Pyrus Malus (Crabs), P. prunifolia (the Siberian species), P. spectabilis, and others. The true Service tree (Pyrus Sorbus) and P. torminalis grow to a large size, and fruit abundantly. Most species of Oak attain to full size, especially beautiful in late autumn being the American Quercus rubra, Q. rubra aurea, Q. coccinea, Q. palustris, and Q. tinctoria. The common Beech in its many varieties finds a place in gardens; and of the Ash family Fraxinus Ornus is to be found in fine examples, its compound leaves sometimes reaching a length of 3 feet. In the more northerly parts of the country this tree needs protection against frost.

The Gleditchias are favourite trees, and in the south their fruits (pods) are produced in abundance. The Tulip tree (Liriodendron) reaches to a height of 60 feet, and blossoms well in the generality of years. A handsome picture-tree, not much planted in England, viz., Magnolia acuminata, is sometimes observed as a lawn tree. The flowers are greenish-yellow, and when the Cucumber-like seed-vessels burst the scarlet seeds within become visible.

Most of our commoner deciduous shrubs are largely planted, and when not treated in the pernicious manner common in some places, that is, by being clipped into shape in winter and late summer, they bloom profusely as a rule. This clipping is in a measure rendered necessary by the fashion of planting shrubberies close to the margins of the walks for the purpose of affording only small glimpses of the landscape at a time. These surprise views are all very well when indulged in in moderation, but in excess they are productive of monotony.

The traveller misses the Portugal and common Laurels, the glorious Rhododendrons, the pride of many English gardens; the Arbutus, Daphnes, Cistus, Japanese Euonymus, the Holly (which is disfigured or killed by exposure to ardent sunshine, but is otherwise hardy), the Laurustine, Bamboos and Yuccas. Perhaps it is for the best, as such plants would have but small decorative value for half the year, whilst snow and frost reign over all the country withering their leaves and giving them a distressing appearance. Better a garden free of evergreens possessing large leaves, and rely for winter shelter upon Conifers, such as Cypresses, Arbor-vitæ, Yews, and the like, which withstand the severe frosts and suffer scarcely at all in appearance.

Gardening in Germany, Austria, Hungary, Bohemia, Bavaria, and Central and Eastern Europe in general, has no existence for the many, excepting in the public parks and gardens. There are few horticultural societies, and these only to be found in the larger cities and towns, and but rarely in the villages.

The seats of the nobility and rich gentry are not scattered over the face of the country as in these islands, but, on the contrary, are nearly always found in close proximity to towns or villages, a condition of things that is due in great part to the interminable state of war that prevailed in past ages, which drove men to live in fortified places for mutual protection and safety. Plant nurseries are few and far between, and seeds of any kind can only be purchased in the large towns. The writer resided in a village fifty miles distant in any direction from a florist, nurseryman, or seedsman. In many parts the farmers possess no house garden, their few wants being furnished from patches in the open fields, with usually no other cultivation than that given the field crops. The staple crops consist of Potatos grown on an extensive scale in fields by themselves for house consumption, distillation, and

export. There are no Eldorados or Up-to-Dates among these, still, the raising of new varieties is not neglected. Gourds in plenty are grown, and in the countries warm enough in summer for the ripening of Maize under the shade of the latter, as are also Gherkins and short, thick Cucumbers, mostly for putting in salt-and-water pickle, and Cantaloup Melons. Onions are largely grown, and the indispensable Garlic; Haricot Beans, for winter consumption as well as eating in the unripe state; Cauliflowers, Cabbages, Cabbage-Lettuces, and long, white Radishes are in common use in most households; Broad Beans (Saubohnen), Broccoli, Celery for blanching, Rhubarb, Seakale, and Asparagus are but little grown, and usually can only be obtained at the shops of the foreign fruit and vegetable importers. Strawberries are much grown, and the old Carolina still remains a favourite variety. In some parts the alpines are much appreciated, and preferred generally to named varieties. It is seldom that bushes of small fruits find a place in gardens, excepting in those of the wealthy, although they are proof against such frosts as occur.

Cranberries and Plums take the place of the Red Currant in the making of sauce to be eaten with game. The first-named berries are gathered generally from wild plants. The Black Currant is not much grown. The Schwetche Plum—a small blue-black fruit, that bears abundantly and is good for culinary and dessert uses—is universally grown, and as far south as Bosnia and Servia.

The Peach and Apricot are usually raised from seed, excepting in the better class of gardens, the vine-farmers in Austria, Hungary, Croatia, and Kärnten planting the trees sparingly among the Vines, and seldom keeping them after their sixteenth year. When ennobled varieties are grown, the stock chosen on which to bud them is the Almond, this being the best for a hot summer climate, its roots going deeper into the soil in search of moisture than do those of the Plum. In northern Germany these fruits are usually afforded wall-protection, and fine, named varieties are planted.

As one travels south the Grape vine begins to find a place on sunny walls, the fruits of most varieties ripening perfectly in ordinary years; and in Lower Austria and in the countries bordering the Rhine below Cologne, vineyards become common, and many varieties of wine and dessert Grapes are grown on short stocks in them and in fruit gardens, the vine-stocks being cut down similarly to our basket Willows. A stock will carry from 10 to 15 lb. of Grapes.

The Fig requires protection everywhere north of the Danube in winter, and given this and full exposure to the sun from May till September, enormous crops of fine fruits reward the cultivator.

Apples, Pears, and Cherries find cultivators almost everywhere; by the sides of the highways and in orchards and gardens as standards, bushes, pyramids, and espaliers. Where proper attention is given to the requirements of the trees the produce is commendable, Pears and Cherries more especially. Apples, like those grown in the northern and eastern United States of America, are usually of high colour, but light of weight for their size. Root-pruning to produce fertility is not much understood. *F. M.*

PINUS NELSONI.

In Southern Nuevo Leon, a state of North-eastern Mexico, to the eastward of the town of Doctor Arroyo, and on the lower slopes of the Peña Nevada, a mountain with a conspicuous exposure of white chalk, Pinus Nelsoni grows in great abundance with P. cembroides, Zuccarini. It is a small tree, smaller than cembroides, rarely exceeding 20 or 25 feet in height. Its trunk, which may acquire a maximum diameter of 8 or 10 inches, is covered with a smooth grey bark, as smooth as that of the American Hornbeam, and of somewhat the same colour. Its long, tough, supple branches are very slender, the lowermost dying first, but persisting in conspicuous grey masses, so that the tree never loses the outline and appearance of a large bush. The foliage is grey-green and sparse, contrasting strongly with the closely-packed rich green leaves of cembroides. On all the trees the three leaves which form each fascicle are permanently adherent, and the

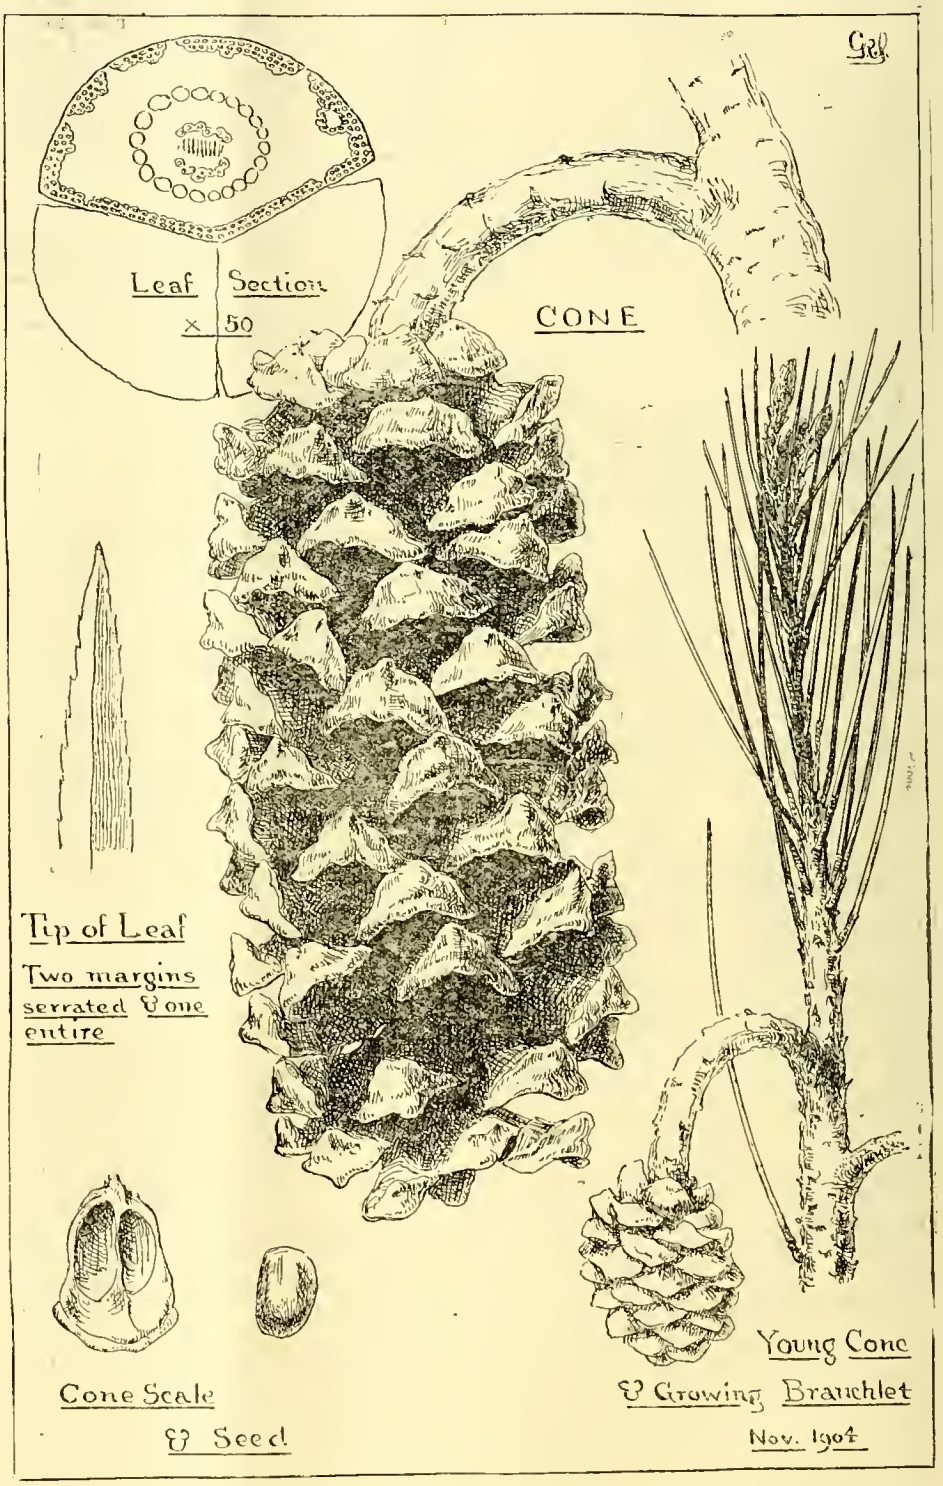

FIG. 127.—PINUS NELSONI.

basal sheath is persistent, characters which enable the specimens of this species to be easily identified.

The cones of Mr. Nelson's specimens, on which the species was founded (*Gardeners' Chronicle*, August 20, 1904), prove to be very immature. The mature cones vary in size, even on the same tree. The largest collected were 5 inches long, exclusive of the 2½-inch curved stalk. In colour the ripe cone is a deep red or orange-red, the colouring peculiar to the group of nut Pines, of which cembroides is the type. The projections of the scales, which on Mr. Nelson's specimens were mistaken for the umbos, prove to be outgrowths of the apophyses. The umbo is not defined, the result, probably, of the continuous growth of the cone, which, unlike the cone of cembroides and other known Pines, seems to have no resting season.

In November (1904) the young cone was comparatively large, green, and the scales tipped with a purple area of indefinite outline and varying size. At maturity the cones open (they do not remain closed as stated in the first description), and remain on the tree into the third season, when the basal scales become weakened from exposure, and the cone falls, leaving the persistent stalk, and often a few scales with it, on the tree. After falling the cone disintegrates rapidly. The seeds are large and wingless, and, according to the testimony of the natives, are eagerly eaten by the macaws (guacamayas). They were found exposed for sale in the market of Matehuala, the nearest railway-station.

An additional peculiarity of this remarkable Pine is the indefinite growth of the branchlets. Probably at the beginning of their growth the young cones were sub-terminal, but in November they had become lateral by reason of a continuous growth all over the trees. Beyond all the young cones were growing shoots with leaves of graduated lengths, and buds elongating for still further growth.

Specimens collected in this locality by Mr. Pringle (No. 10,016) have the young cones of the first year attached to them. It is essential to a proper understanding of these specimens that this fact be borne in mind. The size of the young cones and their apparent lateral position would naturally suggest a growth of the second season.

There is a specimen of this Pine in the Zuccarini Herbarium at Munich, collected by Karwinski "in imperio Mexicano," but with no other locality and with no date. As Karwinski's last voyage was in the early forties, the specimen must be over sixty years old. Its catalogue number is 519, and it is classified by Zuccarini with his species P. cembroides. *George Russell Shaw, Boston, U.S.*

THE FERNERY.

BLECHNUM SPICANT VARIEGATED.

THIS variety of British Fern has not been recorded in any of the Fern books as having been previously found by anyone except the writer, who discovered it on the Mourne range of mountains in Co. Down, first at Rostrevor in 1876, and again in 1885 and 1904 at Newcastle. It may therefore be considered as exceedingly rare.

The writer, accompanied by Mr. W. Porter, made an excursion to the Mourne Mountains on April 22, 1905, specially to hunt among Blechnum spicant which grows there in abundance. After a rapid railway journey to Newcastle, they walked to Bloody Bridge, and ascended the mountain at Glen Fofany about 300 feet, working along the slopes towards Newcastle, closely examining everything they saw. Several very good forms were observed, such as crispate, trinerved, pectinate and multifid. But the reward of their labour came later on, when on the way to the railway station, walking together, the keen eyes of Mr. Porter detected a fine plant of Blechnum spicant, beautifully variegated.

On examining it carefully, it became evident they had indeed been fortunate in finding a great prize. It was dug out tenderly, and after careful packing so as to avoid damage, the botanists proceeded on their homeward way rejoicing.

The fronds, about thirty in number, were of normal outline; length, 14 inches; breadth, 1¼ inch; the colour a dark green with diagonal yellow stripes running from the midrib of the pinnules to the margin, sharply defined. This plant was growing by itself in a large clump quite separate from the surrounding normal forms. *W. H. Phillips, President of the British Pteridological Society, and President Belfast Naturalists' Field Club.*

ANEMONE NEMOROSA.

WE all know and appreciate the exquisite Wood Anemone. It is one of those accommodating plants that does as well in many gardens as in woods and meadows. Rosarians will doubtless be horrified to learn that in a garden we know the Anemone found its way into a Rose-bed, and thrives so well while the Roses are asleep that we have never had the heart to dislodge it. There is a double form which is not uncommon, but though of great botanical interest, it will not, for all its larger flowers, compete with the single form.* Recently Mr. W. Marshall was good enough to send us flowers of a variety growing in his woods at Bexley which is a veritable little gem. It is a double flower, with the supernumerary petals so neatly disposed as to disarm all prejudice such as some people feel as to double flowers. The outer flower-segments were normal; within them, but almost quite concealed, were stamens, some perfect, some distorted. The centre of the flower was occupied by a rosette of "quill"-like white petals with slightly incurved edges, which represent the pistils. The whole formed such a charming little flower that we sent it off at once to Mr. Worthington Smith to draw for us (see fig. 128).

FIG. 128.—ANEMONE NEMOROSA VARIETY.

THE ECKFORD TESTIMONIAL.—The secretary announces the receipt up to May 13 of 704 shillings, and states that the *Florists' Exchange* has opened a subscription list in America on behalf of the Fund.

* See A. P. de Candolle, *Organog. Végétal.*, tom. ii., p. 277, t. 35 (1817); Penzig, *Plant. Teratol.*, vol. i. (1890), p. 176; *Garden*, xxxii., p. 618; Masters' *Pflanzen Teratologie*, ed. von Udo Dammer, p. 294, &c.

BOOK NOTICE.

MANUAL OF THE TREES OF NORTH AMERICA (exclusive of Mexico). By Charles Sprague Sargent. (Boston and New York: Houghton, Mifflin & Co.). 1905. 8¾ × 5¾. Pages 826, figures 642.

THOSE who know and have occasion to make use of the monumental *Silva of North America* will rejoice that its author has considered the necessities of the great body of tree-lovers, to whom the acquisition of the fourteen copiously-illustrated quarto volumes of the "Silva" is a matter for solicitude rather than for realisation.

The present volume contains in a compact form a digest of all that is generally known concerning the trees of the United States, from Canada to Florida, from the Atlantic to the Pacific. The arrangement followed is that of Engler and Prantl, which is most in accordance with what is now known as the genetic sequence of the various families of plants. The numerous gaps entailed by the omission of other families than those producing trees or shrubs, of course, interfere with the presumed line of pedigree; but in a book of this character, intended for practical use rather than for transcendental speculation, provided the requirements of the student are met, the arrangement of the material is of relatively little consequence.

What we have is, first of all, a very brief synopsis of the several families, sixty-one in number, beginning with the Conifers and ending with the Caprifoils. This is followed by an analytical key to the families based upon the leaf-characters. The value of this table can only be gauged by actual use. It has every appearance of being most carefully and accurately drawn up, but none know better than those who have had to construct similar tables how many pitfalls there are, and how the next batch of specimens may upset the careful elaboration based on the comparison of those previously examined. This is of course inevitable. No harm will arise if the student is made to realise the difficulty, and to use the table only as a suggestive guide, or, as we might term it, as an unrevised proof subject to revision as further knowledge becomes available. Who, for instance, could frame a table which should satisfactorily include all the leaf-variations of the Araliaceæ? This illustration, by the way, would not apply to the United States, whence but one species of this order is recorded, but nevertheless it will serve to exemplify our meaning.

After the analytical table to which we have referred, we come to the more detailed account of the several genera and species. Each species is described and figured. Allusion is made to its timber-producing properties, or to any other circumstance which may render its cultivation desirable. No synonyms and no bibliographical references are given. Reference to the "Silva" is even omitted, which is unfortunate, for that book supplies references which form a valuable feature, and are of great assistance to the student.

The geographical distribution of the several species is sketched with that masterly grasp and precision which is the despair of those not so familiar as is Professor Sargent with the details of the geographical botany of his native country. So many Pines, Oaks, Walnuts, Maples, and other trees, both from the North-eastern and from the North-western States of the Union, are now cultivated in this country, that this book will be particularly useful to those who are planting for effect or for practical utility. The extraordinary richness of the United States in trees of various kinds is illustrated by the fact that nearly fifty Oaks are described under the unfamiliar heading of "Fagaceæ." There are also enumerated thirteen kinds of Maples, sixteen Ashes, eighteen species of Prunus, and no fewer than 132 species of Crataegus.

The task of recognising and of differentiating the species of Crataegus might appal even

a student of Brambles or Hieracia. To assist him they are here classified under eighteen different sections, and illustrations by Mr. Faxon will materially lessen the difficulties of determination.

A glossary and a copious index complete a volume which will be absolutely indispensable to all those interested in any way in the trees of North America.

THE WARREN, HAYES, KENT.

When paying a visit to Mr. Blick at the well-known gardens of Martin Smith, Esq., recently, I was impressed by the smart appearance and methodical keeping observable in the various departments. When writing of The Warren I shall be expected to say something about Carnations, but there are other good things there also. A long border of herbaceous plants, in which were some scores of clumps of the double Arabis planted at intervals, was by far the finest exhibition of this plant I have seen. These clumps had each from 60 to 100 spikes of flowers. Between these clumps was a pretty dark-coloured Aubrietia in the way of A. deltoides, and the effect was gorgeous. There were also large clumps of Doronicum, Anemones, Pansies, Tulips, Polyanthus, &c. In the kitchen-garden, by the edge of the trimly-kept walks, was an abundance of flowers, notably a very fine border of Polyanthus, in which all the best varieties of Messrs. Douglas & Mortimer's celebrated strains were included. Other walks were bounded by double and single-flowered Wallflowers and Myosotis, all of which were extra good. The fruit-trees appeared in perfect condition. In the early vineries, which are lofty three-quarter-span-roofed structures, were good crops of Grapes, and a fine batch of pot Figs. The varieties Negro Largo and Brown Turkey are highly appreciated here. Bourjassotte Grise, Brown Ischia, Villette Sepia, and other varieties were also showing good crops in another house.

Muscat Grapes promise well. The back wall of the house containing these Vines is utilised for growing Asparagus plumosus. In the succeeding house, containing various late varieties of Grapes, some very large bunches were showing of such varieties as Black Alicante, Gros Colmar, Appley Towers, &c. On the back wall here were Roses—W. A. Richardson, Niphetos, &c.

In a greenhouse were some blue-flowered Hydrangeas, and other species of plants. The adjoining house contained a fine batch of Royal Sovereign Strawberries, and a good crop of Tomatos in pots. In another house were Melons on the one side and Cucumbers on the other, all in excellent condition. Melons are a very prominent feature, and are cultivated in several houses. Some of the earliest fruits will soon be ripe. Royal George is a fortnight earlier than any other variety; it is a fine-looking Melon, after the type of Earl's Favourite. Ringleader, Hero of Lockinge, Blenheim Orange, and a seedling were the other varieties. In each of these houses good batches of Strawberries were on the shelves over the centre path. Strawberries for succession filled two more houses, and I noticed the latest batch outside. In the frames were nearly a thousand Chrysanthemum plants, and in other pits and frames were zonal and fancy Pelargoniums, Potatos, Carrots, &c.

In an orchard-house there was a good set of Plums and Cherries in pots; also Apples, of which sorts I noticed Cox's Orange Pippin, Blenheim Pippin, Emperor Alexander. A fine batch of Carnations—Mrs. Martin Smith, Cecilia, Lady Hermione (which is a perfect flower, and one of the very best that has been raised here), Sarah Bernhardt, Baldwin, Horace Hutchinson, Lady Rose, and Nautilus—were also in bloom.

In another house Rivers' Early Nectarines in pots would be ripe after a few days. There were also more Carnations, of which Princess of Wales was flowering well.

In another large house there were 20,000 seedling Carnations; and raised high above these, on pedestals, were Cherry-trees ripening their fruits. Guigne d'Annonay, Early Rivers, Bigarreau de Schreken, B. Noir de Luben, Black Tartarian, Bigarreau Ludwigs, and Bedford Prolific were among the best.

There was a good crop of Apricots in another house, and these trees, I was informed, had not failed to give satisfactory crops for fourteen years. In this house were also large quantities of flowers set out on either side of the broad walk; these included excellent Schizanthus and Pæonies. The Pear-trees in pots had just been turned outside and given the protection of wire-netting and canvas.

A fine collection of Auriculas filled one house, and judging by the successful way these are being cultivated we shall hear more about them another season. The frames adjacent to the Carnation-houses were filled with thousands of strong plants. The lawns and shrubs and Roses appeared in the best possible condition. *W. A. Cook, Shirley House, Surrey.*

IRIS KÆMPFERI AND OTHER BOG PLANTS.

It is not generally known with what ease these beautiful plants can be grown. Anyone possessing a garden of the meanest order can grow them, provided the plants are supplied with abundance of water during their growing and flowering seasons. The dampest part of the garden should be selected for their culture, and they must be planted in rich, well-prepared ground.

At Aston Rowant we grow them in the water close to the lake's bank, where they are planted in triangular boxes formed of two pieces of stout thick Elm or Oak, protruding from the bank in the shape of a ∧ and fastened at the apex of the triangle by a stout square stake driven into the bottom of the lake, which at the edges is only about 2 feet deep. The bank itself forms the third side of the triangle. These boxes project about 6 inches above the water-line, and are from 18 inches to 2 feet in depth. To prevent the soil from being washed from under the Iris roots, the bottoms of the triangular boxes are covered with rough flints, on which is placed a layer of turves with the grass side downward, the remaining space being filled with a compost composed of three parts rotten manure and one part of loam.

When thus planted these Iris require but little attention—we merely keep the boxes free from weeds and make an application of a heavy dressing of rich cow-manure each autumn. Immediately in front of these Iris on the grass close to the water's edge are planted clumps of Narcissus and English Iris.

In the early months of the year clumps of Snowdrops embellish the spot with their delicate flowers, to be outvied later by the glorious whites and yellows of the nodding Narcissus, with a good companionship in our lovely native Primrose.

But the beauty of these heralds of spring passes away, the silvery-white Gardenia-flowered Narcissus being the last to follow. After these have all departed we wait and watch, and presently see the beautiful Iris Kæmpferi pushing up their flower-shafts or spears, making great haste to captivate in turn the admiration so recently bestowed on their predecessors. After furnishing the lake-side with beauty for a space of from six to eight weeks these, too, are over, and our thoughts revert to the beauty of the

[*Photograph by W. J. Vasey.*

Fig. 129.—A clump of Trillium grandiflorum: flowers pure white.

TRILLIUM GRANDIFLORUM.

This plant is a native of North America, where it abounds in the woods from Quebec to Florida. It is a singularly handsome plant, and one that is easily grown in the rock-garden or in the wild pleasure grounds, where it requires a moist sheltered position. If placed in too sunny or exposed position, the large soft green leaves will not develop properly. A deep, well-drained bed of peaty soil is the most suitable medium in which to grow the plants, which may be increased rather slowly by dividing the roots, or by seeds.

Trillium grandiflorum is the best species of the genus for garden purposes, and is worthy a place in any collection of hardy plants. The white flowers are produced solitary, and have sometimes a somewhat pendulous habit. The name Trillium alludes to the parts of the flowers and the leaves being in whorls of threes or multiples of that number. The species flowers during the present month, and is now in bloom in the rock-garden at Kew with the purple-petalled T. sessile and others.

Iris gardens in Japan, whence our stock of about 300 plants was imported direct, with the mystical names which are quite a conundrum to all excepting those versed in the language. It would be interesting to know what the words Koki-no-ero, Shigar-no-ura-nami, Tsurugi-no-mai, &c., as they are labelled, mean.

The flower-stalks are removed immediately after flowering, in order that the seed-vessels may not weaken the plants. The dark-green spear-shaped leaves remain and form an excellent boundary between the greensward of the lawn and what is a still further attraction—the beautiful Nymphæas planted one to two yards away; these flower abundantly in water scarcely knee-deep. N. Laydekeri lilacea, with its beautiful lilac and-carmine flowers, at once strikes the eye of the observer. Other varieties up and down the lake are all bursting forth in their glorious attire, including N. Laydekeri rosea, N. aurora, N. sulphurea, N. Richardsoni, and the enormous white N. Gladstoni. The sacred Lotus of Japan, Nelumbium speciosum, was given a favoured spot near, but after one feeble attempt to raise its head above water it sank into its aquatic surroundings. I fear the water was too cold for it. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

NARCISSI FROM CORK.

To Messrs. W. B. Hartland & Sons, of Cork, we are indebted for specimens of various Narcissi, among them two new varieties raised at Ard Cairn, of which we are able to give illustrations.

Pelops is one of the Burbidge section, with flowers 4 inches across the segments, spreading, somewhat revolute at the margins; pale lemon-yellow becoming white; cup ¾ inch deep, rich yellow broadly edged with orange.

Nectarine would be classed in the Leeds section. The flowers are 3½-inches across, ivory-white; the cup is ¾-inch in depth, and of the colour of a Tangierine Orange; the reddish colour is probably an endowment derived from a cross with N. poetarum. Mr. Hartland has been for some years endeavouring to secure this result, and his patience has been rewarded, for the flower is very beautiful.

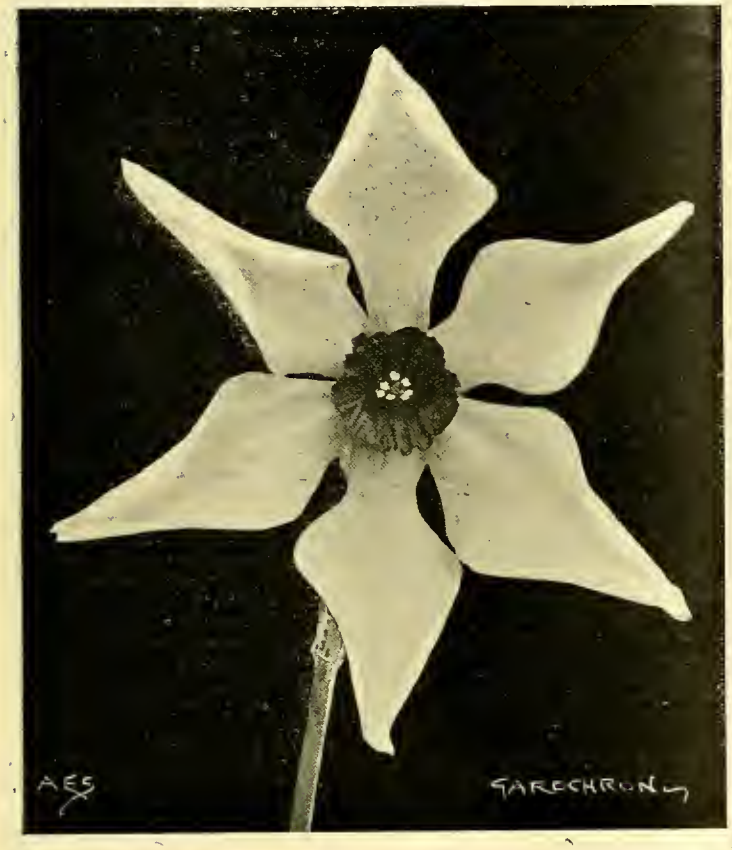

Fig. 130.—Narcissus "Pelops": flowers ivory-white; cup yellow with a darker edge.

Fig. 131.—Narcissus "Nectarine": flowers ivory-white; cup cylindric plicate, of deep orange colour.

FRUIT REGISTER.

PEAR PIUS X.

This is a new Pear raised by the Frères Alexiens, at Tirlemont, Belgium. The tree is said to be very prolific, the fruits are large, somewhat cylindric, greenish-olive, with a few brown spots; flesh creamy-white, perfumed. The Pear ripens in October and is said to be of first-rate quality. It is illustrated in the *Bulletins d'Arboriculture*, &c., for April.

ORCHID NOTES AND GLEANINGS.

MESSRS. CHARLESWORTH & CO.'S COLLECTION.

One of the consequences of phenomenal success in modern trade horticultural establishments is the necessity for providing accommodation for the ever-increasing number of plants cultivated, and the great Orchid establishment of Messrs. Charlesworth & Co. has had to follow the rule. The original space beside the reservoir at Heaton, Bradford, was soon covered with glass; another site acquired on higher ground shared the same fate; an establishment was started on the South Coast (Sussex), and still there is a desire for fresh territory to cover with glass structures to be filled with the popular Odontoglossums and the endless and already bewildering hybrid Orchids, the production of which Mr. J Charlesworth has made his chief study.

But although most of the houses are filled with well-grown hybrid Cattleyas, Lælio-Cattleyas, and Odontoglossums, interest in the species and in importing new and rare Orchids is still maintained. Considerable space is devoted to Cattleya Mendeli, C. Schröderæ, C. Trianæ, and other large-flowering Cattleyas and Lælias, of which there are great quantities of fine plants in sheath and bud; also to Oncidium macranthum (of which a quantity of vigorous plants have strong flower-spikes), O. varicosum, and the rest of the cool-house Oncidiums, and, generally speaking, to selections of all the best of the showy species. Some time ago a large Phalænopsis-house was started and filled chiefly with P. Schilleriana, which made a fine show when in flower, a photograph of the house being reproduced in the *Gardeners' Chronicle*, March 4, p. 131. These are still in fine condition, and giving promise of an even better show of flowers than previously. But the new Phalænopsis Rimestadtiana, the highest type of the amabilis section, commonly called P. grandiflora Rimestadtiana, having been found to be easier to cultivate, and to require a much cooler house than the other species, a large importation of this was made. The new arrivals consist of some ten thousand specimens of all sizes, and now occupy the tolerably cool house prepared for them. Mr. Rimestadt, the collector, urged from the first that his Phalænopsis should be cultivated in a cool house, and his notes on the subject, together with illustrations of the plants, were published in the *Gardeners' Chronicle* at the time of the advent of this variety. It is evidently a grand florist's flower, worthy of being grown in quantity. Other new importations, including Phalænopsis Aphrodite, and some unrecognised species, also Cœle-

gyne pandurata, arrived at the same time. But probably the finest of the importation is a new Dendrobium of the habit of D. Phalænopsis, of which the collector says, "I found it on a remote island in the Indian Archipelago; have seen it in bloom; the flowers are absolutely pure white, similar in size and shape to those of D. Phalænopsis, and borne in a similar manner. It is much more floriferous than thats pecies; the flowers last six weeks in perfection." The island was carefully searched, but only twenty plants were found.

In the many houses devoted to them there are thousands of vigorous examples of the best type of Odontoglossum crispum and the other showy Odontoglossums. Of the more recent importations the greater part are unflowered, and some are flowering for the first time, among them being a few promising spotted forms. Of the most interesting things in these long cool-houses noted were a fine lot of Odontoglossum × Adrianæ, several of which, having a white ground spotted with purple colour, approached very closely to O. crispum. There were good O. Hunnewellianum, and two rather singular hybrids of it which seemed distinct from O. × Adrianæ. Then followed a fine lot of O. Pescatorei, with several home-raised O. × excellens, with rich yellow ground colour handsomely marked with purple, and superior to most of the imported forms. Of O. cirrosum there were many plants in flower; O. × dicranophorum bore a spike of stellate yellow-and-brown flowers; O. × mirandum, O. Lindeni, good forms of O. × Rolfeæ, and O. × Harryano-crispum and its reverse cross were also in bloom. With regard to these crosses of O. Harryanum it is found that when that species is the seed-parent the plants are much freer-growing than when the seeds are borne on O. crispum, though those from the reverse cross have finer-coloured flowers if good parents are used. Others in bloom in this block were Odontoglossum × elegantius, a batch of Epidendrum Wallisii, and at the end of one of the houses a fine lot of the taller orange-and-scarlet coloured hybrid Epidendrums.

In the intermediate-range, filled principally with Cattleyas and Lælias in bloom, were a number of hybrid Brasso-Cattleyas, the handsome Brassia brachiata, a good show of Miltonia vexillaria and M. × Bleuana, together with several nice plants of the rare M. Schroderiana; a good lot of Cattleya Schröderiana, a batch of Lælio-Cattleya × Mercia and L.-C. × Andromeda varying much in colour; brightly-coloured L.-C. × Hyeana, and other Lælio-Cattleyas; Zygopetalum × Perrenoudii, and the dark-coloured Z. Protheroeanum of gardens; a healthy batch of crosses of Sophronitis grandiflora, some of which seem to be always in flower; and a large number of the best forms of Cypripedium insigne, many of them of the C. insigne Sanderæ class.

Another house had a general collection of intermediate house plants, a good batch of Odontoglossum Uro-Skinneri, and some others being in bloom. Suspended overhead was a collection of Pleurothallis and other Orchids of botanical interest.

In one house was a collection of Masdevallias—M. Pourbaixii and the handsome M. Schröderiana being in bloom; also good examples of the scarlet Cochlioda Noezliana, a fine lot of Trichopilia suavis, the batch of which now commencing to bloom is expected to continue to afford flowers until November. Oncidium cheirophorum, O. ornithorhynchum and its pure white variety O. hastilabium, some Maxillarias, &c., were also noted.

In the warm-houses, in addition to the fine lot of Phalænopsis previously alluded to, were noted a small importation of the large form of Pachystoma Thompsonianum, a number of pretty Cirropetalums and Bulbophyllums, some species of Angræcums, including strong-flowering specimens of A. sesquipedale and the trailing A. imbricatum, a very fragrant, white species. This plant was recently erroneously named Saccolabium Barbeyæ. There are also large specimens of Vanda Amesiana, V. Kimballiana, and small ones of the hybrid V. Moorei, and a small collection of Anæctochili.

Other houses are filled with a grand lot of hybrid Brasso-Cattleyas, Cattleyas, and Lælio-Cattleyas, batches of several of the showier kinds being in bloom. None but the best procurable species have been used as parents, and the field of primary crosses of showy species and albinos being nearly worked out at Messrs. Charlesworth's, the greater part of the energies of the firm are being directed to Odontoglossums, and to the intercrossing of fine varieties of hybrids already obtained. Some very richly marked and handsome Odontoglossums are already in bloom, and those in bud give great promise.

At the end of each of the long houses there was a number of Orchids in bloom, and one of the most interesting, though not the most showy, was a group of Epi-Cattleyas, Epi-Lælias and other singular crosses.

In the new department, at a short distance away, the raising and development of hybrid novelties and showy kinds is carried on in the most careful manner, and several houses are devoted to the plants from the earliest stage until they are large enough to take their place among the adult specimens.

In the houses containing mature plants was a good display of Lælio-Cattleyas and Odontoglossums, including a selection of fine forms of O. crispum named and unnamed. One spotted form flowering for the first time was of the O. c. Grace Ruby type, and another had very large white flowers with chrome-yellow disc to the lip and light-orange blotch. There is also a vigorous little batch of albino Cattleyas of the labiata section. Hybrid Trichopilias, Oncidiums, and other species are making good progress, and certainly the interest in the work will not cease for want of material.

Every operation in this model establishment is carried out methodically, and equipped to be as self-contained as possible, even the lath-roller blinds being made on the place by specially-constructed machinery. Respecting the lath blinds, it should be noted that formerly, when they used to be rolled up to the ridge by cords, the wear and tear and the cost of cords were found to be very great. Consequently the blinds are now made in short lengths, and rolled on and off in sections running lengthwise.

The Cypripedium-houses contain a fine collection of rare species, varieties, and hybrids, the large sections, such as C. insigne, being represented only by plants of that class. Among those noted were C. callosum Sanderæ, C. Lawrenceanum Hyeanum, C. × Maudiæ, quite equal in beauty to either of those of its class; C. Charlesworthii album, and a new species, C. Crawshayæ, collected in the same region, but which until lately did not make much progress. In the Cypripediums, as with other hybrids at Ilcaton, much attention is given to secondary crosses, and with good promise so far as the matter has been tested.

The Week's Work.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Hardy Vines. — On warm, sunny walls in southern districts the Vines will have commenced to grow, and disbudding should be performed as soon as it can be seen which shoots are carrying the best bunches, for these must be retained and the remainder rubbed off, unless the spurs are at considerable distances apart, when two shoots may be retained. These shoots should be stopped two leaves beyond the fruit, allowing one bunch of fruit on each. Keep the sublaterals closely stopped, and if the Vines are growing in a hot, dry situation, afford frequent applications of liquid manure.

Morello Cherries.—On a wall 100 yards in length planted with trees of the Morello Cherry, the wealth and size of bloom at the present time are equal to those of many of the ornamental varieties. The Morello has a habit of casting a certain number of its fruits, and this prevents the tree from becoming over-burdened. Examine the trees at the present time, and pinch back or, better still, remove all the shoots which will not be required for laying in. This will prevent any over-crowding of the branches when the fruit is ripening. The Morello Cherry requires similar treatment to that afforded Peach-trees, except that more shoots should be retained for laying in.

Plums, Dessert-Cherries, and Pears. — Many varieties of these are now making abundant growth. In some cases four to six shoots are growing from one spur, which is far too many. On Cherry-trees these growths may be pinched back to about four leaves, which will result in the formation of fruit-spurs. On Plum and Pear-trees a general thinning is necessary, leaving two or three growths in a position that will furnish fruit-bearing wood as near to the main branches as possible. Those shoots not required may be removed at this date by a slight twist with the finger and thumb.

Affording Water.—In consequence of the dry weather experienced during the past three weeks, wall-trees having passed their flowering stage may require water. Those growing on light, sandy soils may advantageously be given a good watering with liquid-manure, taking care that sufficient is afforded to soak down to the extremities of the roots.

Cleansing from Pests.—A diligent eye must be kept for the appearance of black and green fly. Commercial Quassia-extract is probably the best means to employ to eradicate these pests, but use it at a little under strength at this season, when strong insecticides would do harm to the tender foliage. If there are severe attacks it will be necessary to repeat the application several times.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Summer Bedding.—The planting of tender bedding plants may soon be commenced. Have all the beds made ready by thoroughly disintegrating the soil with fork and rake to get a friable surface, which, however, need not be reduced too finely, or after the first heavy shower a hard crust will be formed that would conduct heat and moisture out of the soil.

Spring Bedding Plants may soon be removed to a partly-shaded border. The plants can then be divided, and afterwards be planted in nursery lines, at sufficient distances apart to allow of the Dutch-hoe being worked between them. Daisy Alice, Auricula Alexandra, and Primrose G. F. Wilson are a worthy trio. Other useful plants are Ajuga reptans, Arabis fl.-pl., and Valeriana Phu aurea.

Watering. — Freshly-transplanted trees will require the first attention. Have "saucers" made in readiness by putting a ridge of adhesive soil at about 3 feet from the stem. A thorough drenching of the soil once a week is better than daily driblets. The application of a mulch of rotten manure will afford nourishment and prevent excessive evaporation. If the weather is dry flower-beds should be afforded a good soaking with water directly they have been planted. Loosen the surface soil with the dutch hoe on the next day after applying water, as a caked surface must not be permitted to remain.

Lobelia, Hollyhocks, and Sweet Peas.—Plants of scarlet Lobelia, treated as described in former Calendars, are now ready for planting. Plant the clumps closely together so as to form a compact mass of flower-spikes, and afford them very liberal treatment. Hollyhocks obtained from early sown seeds, and that are properly hardened-off can be planted soon in good loamy soil that has been heavily manured. If possible choose a moderately exposed position, for when planted at the back of borders, the plants are apt to get drawn and become more liable to an attack of the fungus Puccinia malvacearum. Sweet Peas raised from late sowings in pots must now be planted-out and afforded twiggy shoots to support the slender growths.

Affording Stakes. — This work will need the exercise of forethought, taste, and a knowledge of the habits of plants. Such subjects as Phloxes, that have numerous shoots, may have a string put round them to steady the growths until they are long enough for sticks. Thin out the weakly shoots. Do not have the clumps of too large a size, and be careful to use as many sticks as may be necessary. Never allow the plants to become bent and crooked, as

no subsequent treatment will make them as effective as they would otherwise have been. Avoid the bunching or besom-like method, and use stakes of such a length that when the plants are in flower the supports will be hidden, or at least inconspicuous. Green stakes are the best for general use, and spiral wires are admirable supports for Carnations.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Peas.—Prepare the ground for late crops of Peas as for Celery, and sow such varieties as Autocrat. Owing to the exceedingly robust and remarkable branching habit of this variety it is necessary to sow the seeds much more thinly than is generally done, or the consequence will be that the plants will choke each other. I have grown this variety yearly since its introduction, and it has never disappointed me, being the best late variety. Autocrat grows 4 feet in height, continues to bear well-filled dark-green pods for a long time, and is seldom if ever attacked by mildew. The Gladstone Pea is a fine and prolific late variety, bearing long, sickle-shaped pods. It is a first-class exhibition variety, height 3½ feet. Succession Peas that were raised in pots may now be removed from under glass. Plunge the pots in some light material in a sheltered warm corner, and give close attention to watering the plants with frequent applications of liquid-manure. Should it be desired to obtain large and handsome pods, pinch the tops off the plants and reduce the number of pods on each plant.

Endive.—Seeds may be sown at intervals of a month until the end of August. While the weather is hot and dry the earliest batches should be sown thinly in drills drawn 1 foot or 15 inches apart, allowing the plants to mature without transplanting them. This will help to prevent their running to seed. Thin the plants out to 1 foot or 15 inches apart. Broad-leaved Batavian and Green Curled are the varieties generally grown.

Onions.—Plants raised early and transplanted will now be growing freely. Slightly stir the surface soil with the Dutch-hoe. Afford the plants light and frequent waterings; and if only hard water is to be had, the addition of some washing soda will make it more suitable to the roots. If the revolving sprayer is used, as is the case here, grind the soda to a fine powder and sprinkle it over the ground previous to watering.

Broad Beans.—Sow seeds now and again after a month has elapsed for late crops. Broad Beans require deep cultivation, a liberal supply of manure, and a change of ground each season. Use the hoe freely between the rows of plants, and when the plants are 2 or 3 inches above the ground draw the earth up to them on each side. When the growths are from 2 to 3 feet in height, pinch out the tops with the finger and thumb to assist the early maturing of the pods. It is often the means of preventing the early development of black-fly, that common enemy of the Bean. Let the plants be afforded plenty of room to grow sturdily, and thus become self-supporting. Carter's Green Leviathan, Beck's Dwarf Green Gem, and Improved Green Windsor are excellent varieties of this vegetable.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Early Vines.—The Grapes in the earliest house will now be colouring, and in some instances ripe. Warm diluted liquid-manure may still be afforded to Vines that are cropping heavily, or if there is any doubt as to their finishing properly. Plenty of time must be allowed to obtain the much desired "bloom" on the berries. Maintain a constant circulation of warm air with less atmospheric moisture. The temperature at night may be reduced, allowing it to fall to 60° in the morning. Admit more air at night than formerly whenever the weather is favourable. In order to maintain ripe Grapes in a good condition, a cool and comparatively dry atmosphere will be necessary, but the roots must not be permitted to suffer for want of water. If an application of water becomes necessary owing to keeping the Grapes hanging for a long time on the Vines, let the work be carried out on a bright morning. Examine the foliage for red-spider, and endeavour to keep the pest in check by carefully sponging the leaves on its first appearance rather than by applying sulphur on the pipes, which is always dangerous unless extra care is afterwards given to the ventilation of the house early in the morning. When the Grapes have been cut, thoroughly syringe and cleanse the foliage of the Vines, and supply the border liberally with water, using liquid manure occasionally.

Succession Vines.—Pay attention to the tying of shoots and stopping of laterals as growth proceeds, and apply liberal supplies of liquid manure, also sprinklings of Kirk's or some other approved Vine-manure to Vines that are swelling their fruit. Close the houses early in the afternoon, with abundant moisture in them, allowing the temperature to increase afterwards to 85° or 90°. Admit a little air again for the night at about 8 P.M. Stir up the fires early in the afternoon to such a degree that the temperature in the houses will fall gradually until 10 P.M. Early in the morning it should be at about 65°. Tie up the bunches of fruit if necessary, and carefully remove any seedless berries which have been overlooked previously. Early plants of Muscats require similar treatment, excepting that the temperature should be 5° higher than is recommended for Black Hamburghs.

Later Vines.—Maintain a constant circulation of moderately dry air in houses in which the Vines are coming into flower, and the temperature may now be a little higher at night and by day. Remove all surplus bunches of fruit as soon as they have set, and thin all free-setting varieties, such as Black Alicante, as soon as is possible. Defer the thinning of Muscats until it can be seen which berries will swell best. Laterals should not be pinched during the time the vines are in flower, but they may be stopped directly afterwards and the shoots tied down as carefully and as evenly as possible to cover all parts of the trellis. Afford the border a light mulching as soon as the bunches have been thinned, and pay daily attention to damping and watering of the borders. Such varieties as Muscat of Alexandria and Lady Downes', or any Vines that are weak, should be provided with slight shade from the sun's rays. Lady Downes', being subject to scalding, should not be shut up very early in the afternoon, and a small amount of air should be always admitted to the house during the night.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Lycaste Skinneri.—When the new growths are about an inch long, the plants should either be re-surfaced or repotted. The latter operation should only be adopted when the pot is unsuitably large or too small, or when the drainage is in an imperfect condition. The pots should be half filled with drainage material, and a compost used of equal parts of good fibrous loam, peat, sphagnum-moss, with the addition of a "dash" of coarse silver sand. Stage the plants in a moderately light part of an intermediate-house, and afford them little water until the roots are growing freely. A good supply will be needed until the pseudo-bulbs have formed, but it should be gradually diminished afterwards.

Summer Quarters.—In a mixed collection of Orchids there are many plants which need a different position during the summer season to that which they occupy in the winter months, and they should be moved before the difference of the one season from the other becomes extreme. The plants of the "Chimæra" section of Masdevallia, which in the winter months are usually placed in more warmth than is afforded Masdevallias generally, may now be replaced. These plants are grown in baskets without drainage material, and should any plants need fresh surface materials these may now be afforded them. Afford shade from strong light, keep the materials well moistened, and have the leaves of the plants sponged frequently. Miltonia vexillaria varieties which develop their growths and floral spikes in a Cattleya-house may, now they are in bloom, be removed to a cool intermediate compartment where drier conditions should be maintained for the better preservation of the flowers and to check the development of new growth. The plants need a moderate supply of water until the flowers have passed, but afterwards they may be kept moderately dry; at the same time dampings between the pots and overhead sprayings will be necessary several times a day. The Pleiones—other than P. Wallichiana, which grows best in the Cattleya-house throughout the year—have to be kept rather cool and dry until the present month. They should now be placed in an intermediate-house where there are more light and heat. The plants will require larger quantities of water afforded more frequently. Platyclinis glumacea having completed its leaves and tiny bulbs should be placed in a light part of an intermediate-house, and the supply of water may be gradually diminished. There are numerous plants whose present requirements may be easily determined by the presence or absence of growth, and these should be treated either with a view of encouraging growth or of inducing rest.

Odontoglossum hastilabium.—This stately species is now in flower. Do not allow the spikes to remain on the plants for a long time, as this would cause expansion in the pseudo-bulbs, from which they take a long time to recover. The plants require an intermediate temperature, and succeed best when planted in a leaf-mixture, being kept under comparatively dry conditions at all times, except when rooting freely. O. Uro-Skinneri is another species whose progressive spikes continue in flower for a long time. This is a cool-growing species, needing similar treatment to O. crispum. The spikes are now visible in the developing growths, and as root-action is also vigorous, a good supply of water at the base is essential.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Wythes, Esq., Copped Hall, Epping, Essex.

Heat, Ventilation, and Shading.—At no period of the year are greater care and watchfulness required in the culture of plants under glass than at the present time. Warm sunny days followed by cold nights necessitate the use of considerable artificial heat, and it is therefore very important to take every precaution against attacks of thrips and red-spider. In structures containing plants that require very little ventilation, much moisture must be maintained in the atmosphere by the frequent damping of the stages, paths, &c. Shade from direct sunshine will also be necessary for most plants of this nature. Air should be admitted through the top ventilators only, and with great care, closing them again early in the afternoon before the sun has quite lost its power. Blinds made of tiffany are always preferable to the use of permanent shading.

Seedling Plants that require to be pricked-off or potted-on should be attended to, and afforded shade for several days afterwards. Examine them occasionally for traces of mite, using a small lens for the purpose. Very close inspection will be necessary to detect this pest before it has effected mischief. Employ frequent syringings with Quassia-extract, or where practicable immerse the plants in the liquid. A weekly fumigation with a nicotine compound is time and money well spent.

Cyclamens that were potted early last month have rooted freely into the new soil and will be transferred to cooler quarters. Shade them from the sun's rays, but do not employ material that is so dense that the plants under it would be likely to become drawn and weakly. A temporary frame under a north wall with a cool ash bottom is a perfect place for them during the hot summer months, and in such conditions no additional shade is needed. Seedlings will require no further potting, and much care must be exercised in affording them water.

Tuberous-rooted Begonias raised from seeds are ready to be shifted into 5-inch pots. Employ a rich compost consisting of loam and leaf-soil in equal parts, also one-third of silver-sand, and a little bone-meal. Pot the plants rather firmly, and after affording them a thorough watering, place them in a somewhat close atmosphere and shade them for several days. Air may be admitted freely again when the roots have entered the fresh compost.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAY 20 { International Horticultural Exhibition at Paris (9 days).

TUESDAY, MAY 23 { Royal Horticultural Society's Committees' Meeting, and National Tulip Society's Show at the Royal Horticultural Hall.

WEDNESDAY, MAY 24 { Linnean Society, Anniversary Meeting, 3 P.M. Royal Caledonian Horticultural Society's Spring Flower Show at Edinburgh (2 days).

FRIDAY, MAY 26 { Royal Botanic Society, Lecture and Meeting of Fellows.

SALES FOR THE WEEK.

WEDNESDAY NEXT—
Palms, Plants, Ferns, Liliums, Araucaria excelsa, Begonias, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY NEXT—
Imported Orchids, by order of Messrs. Sander & Sons, 300 Established Odontoglossum crispum, Established Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —53·4°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May* 17 (6 P.M.): Max. 71°; Min. 49°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May* 18 (9 A.M.): Bar., 30·2; Temp., 66°. Weather brilliantly fine.
PROVINCES.—*Wednesday, May* 17 (6 P.M.): Max. 65°, S.E. coast of England; Min. 51°, S.E. coast of Scotland.

Baron Schröder.

THE retirement from the Council of the Royal Horticultural Society of Baron Sir HENRY SCHRÖDER is an event which should not be allowed to be passed over in silence. Whilst we must regretfully acquiesce in the Baron's wishes, we must retain the warmest sense of gratitude for what he has done for the Society. To him more than to any other single individual we owe the fine Hall in which the fortnightly shows are now held; to him we are mostly indebted for the commodious meeting-rooms in which the work of the Society is carried on; to him, as the last act of generous sympathy, we owe the installation and fitting up of the Lindley Library, which at last has a home worthy of its importance. A brass tablet in the Library records, in terms of grateful appreciation, the work done by the Baron. The last meeting of the Orchid Committee afforded evidence that, although Sir HENRY feels himself debarred from taking the active part that he has hitherto done in the work of the Society, he will still continue to enrich the shows with exhibits from his particularly choice collections. Those who know the energy and zeal that the Baron has shown in the affairs of the Society, and the manner in which he has contributed to the success of its exhibitions, will heartily join with us in tendering to him thus publicly the warmest thanks of the horticultural community.

The Colours of Flowers.

WHATEVER may be thought about the disadvantages of special societies, it is a matter beyond dispute that in their own particular way they sometimes do work and accomplish results that, if left to societies dealing with horticulture in a general way, would never see the light of day. Men with special hobbies and with special abilities can only find congenial surroundings amidst like-minded *confrères*, and not in a miscellaneous crowd. The mere association with others who are like-minded draws out abilities and efforts that would otherwise lie dormant or else be crushed entirely.

The French National Chrysanthemum Society has been established ten years, and its aims and efforts certainly seem to be concentrated upon other and more important things than the mere holding of shows and the consequent disbursement of large sums of money among greedy exhibitors. In fact, its exhibitions are organised and the whole Society worked at an annual cost that would surprise some of the officials of English Chrysanthemum societies.

Not long ago this Society published a capital little treatise on the diseases and insect-pests that afflict the popular oriental flower, the author, Dr. J. CHIFFLOT, of Lyons, being a well-known authority on such matters. But this was not sufficient, for a very interesting coloured chart accompanied the volume, in which diagrams, true to nature, of the various diseases and insects were given, and the remedies set forth beneath each illustration. A chart of this kind should be hanging up in the greenhouse or potting-shed of every grower of the Chrysanthemum, for it is at once the easiest and simplest method to enable the inexperienced to identify any of the troubles likely to infest his plants.

The work now lying before us* is the outcome of a suggestion made at one of the Society's annual gatherings. Although primarily intended to lay down a standard of colour description for Chrysanthemums, it has been extended so as to serve for almost anything, and anybody that has to do with the defining of colours.

M. HENRI DAUTHENAY is practically the editor of the work, and has been assisted by five gentlemen of French, English, German, Italian, and Spanish nationality, viz., Messrs. MOUILLEFERT, HARMAN PAYNE, MAX LEICHTLIN, N. SEVERI and MIGUEL CORTES.

Two cases of coloured plates, each colour in four different shades, and all the plates detachable for facility of comparison with the object whose colour is to be determined, comprise the work. The explanatory text is contained in a volume of eighty-two pages, the contents of which, briefly stated, are the names of the authorities consulted and the origin of the repertory, CHEVREUL's method, the choice of names, classification of colours, instructions as to the use of the work, &c. Then follows a list of colours in numerical order, the whole work being divided into twelve series—viz., whites, yellows, orange shades, reds, pinks, purples, violets, blues, greens, browns and ochres, chestnuts, blacks, and greys. An alphabetical list of the names of colours, with the reference to the number of each plate, is given in French; another in German, a third in English, and two others in Spanish and Italian respectively, so that the repertory may be useful to a very much larger extent than if it were confined merely to French-speaking readers.

We know of nothing of the kind that has yet been published excepting a sheet of colours published by the *American Florist* ten years ago, but in that case only thirty-six colours were given, while in the French work there are three hundred and sixty-five colours named, mostly in four different shades, which must mean a gross total of something like fourteen hundred colour-variations. The classification is simple in the extreme, for, presuming we had before us a green leaf, the colour of which we wished to describe accurately, we should turn up the Section IX., "Greens," and there among the sixty-two different greens we should find one of the shades that would apply to the colour-name we required.

We take at hazard Plate 63, Abricot rougeâtre, to explain what appears on each plate. There are four oblongs, 1¼ inch by 1¾ inch, each coloured a shade darker than the other, and numbered 1, 2, 3, 4. The printed matter is as follows: Origin, one of the shades observed in the skin of the Apricot. French synonyms: Coppery-red, Capucine madder-lake. Foreign synonyms: German, Aprikosenrot; English, Reddish apricot; Spanish, Albaricoque rojizo; Italian, Albercocca rossastro. Remarks. Tone 1: Reflexion in the centre of Chrysanthemum Charles Davis. Tones 1 to 4: Different degrees of intensity in the centre of the Rose Ella May (when seen in diffused light). Tone 3: Lateral petals of an example of Lælio Cattleya Cappei. Note.—Tone 4 is identical with salmon in the chart of colours of the *American Florist*.

The work has involved an immense amount of labour, and the expense must have been considerable. It is issued by subscription at £1, and if once generally adopted by florists and others having to do with colours would obviate very much of that uncertainty that always exists when we read what are called catalogue descriptions. Our Chrysanthemum friends can still rejoice in their plum-coloured violets, lilac mauves, rosy magentas, salmon carmines, and bright fiery reds, but with this difference: that instead of each man having his own notion of what these names imply, he must by comparing his flower see that it is identical in tone with the plate bearing that name. And Dahlia-growers, Rose-growers and other admirers of popular flowers can have a standard of authority, if they choose to adopt it, which will justify in the minds of the uninitiated some of the apparent extravagance of colour description that has been the bewilderment of many of us in days gone by.

* *Répertoire de Couleurs pour aider à la détermination des couleurs des fleurs, des feuillages et des fruits*, published by the French National Chrysanthemum Society and René Oberthür. (Imprimerie Oberthür à Rennes and Librairie Horticole, 81 bis, Rue de Grenelle, Paris.)

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on the 23rd inst., when the National Tulip Society will also hold their annual show for the southern division. Mr. E. N. HOLMES, F.L.S., will deliver a lecture on "Medicinal Plants, Old and New," which will be illustrated by lantern-slides.

LINNEAN SOCIETY.—The next meeting of the Society will be the anniversary meeting on May 24, 1905, at 3 P.M.

Flowers in Season.—Messrs. E. Webb & Sons, Wordsley, have sent us flowers of a number of varieties of stellate-flowered Cinerarias, showing very pleasing shades in red and blue colours in addition to some flowers which are quite white.

"The Rational Almanac."—This is a book containing in small space the opinions of Mr. M. B. Cotsworth as to the present anomalous condition of the Almanac and of the usual methods of measuring time. The author traces the evolution of our present systems from the earliest times when records were made, and would have a more "rational" system introduced. The year, in his view should be divided into thirteen months of exactly four weeks each, and the calendar should henceforth be constructed on a fixed instead of a shifting basis. How many disciples Mr. Cotsworth will attract, whether some or any of his arrangements will be adopted, time only can show, but there is no doubt as to the interest of his book, and that among the mass of information therein contained every reader will find something attractive.

The Royal Society.—At the meeting for the election of Fellows held on the 11th inst., Professor F. W. Oliver, of University College, London, and Lieutenant-Colonel D. Prain, the Superintendent of the Botanic Garden, Calcutta, were elected. That two botanists out of a total of fifteen chosen from all branches of science should be selected in one year is noteworthy.

Southern California Acclimatising Association.—Dr. F. Franceschi has forwarded to us a list of the exotic plants grown by him and now ready for distribution from his garden at Montarioso, Santa Barbara. The catalogue is worth consideration, because many of the plants mentioned in it are uncommon, of great interest, and some are rare in cultivation. Correspondence respecting them should be addressed to P. O., Box 1500, Santa Barbara, Cal., U.S.A., with the name of Dr. F. Franceschi or of the Association added.

Coreless Apples.—It may be that the qualifications of this Apple might be appreciated more highly if those responsible for advertising it were a little more judicious in their methods of making it known. To call it a "Horticultural Wonder of the World" is at once to lower it to the level of a quack "cure-all." The owner claims that he has the "only commercial seedless Apple in existence that you can bud or graft from, and always, as a result, get trees that will produce seedless Apples. He also claims that he has the only seedless Apple of good commercial value in the world. In six months, as we learn from *American Fruits*, the United States will be covered with companies for the growth and sale of this Apple. A nursery of 60,000 trees is to be started this spring in Switzerland, "as well as a nursery of about the same number in Great Britain."

Mr. J. S. Gray, of York.—"Yorkshire Gardener" writes us as follows: "Amongst the numerous horticulturists occupying responsible positions north of the Trent, few are better known than the above-named gentleman. For fifty years he has been connected with the well-known firm of York nurserymen, Messrs. James Backhouse & Sons. Age and a desire for some release from active duty have compelled him to resign the position of general manager to this firm. As a small mark of their esteem for his long service and faithful discharge of his duties, the directors of the firm recently presented Mr. Gray with a handsome silver tea and coffee service and illuminated address, to the purchase of which the principal *employés* of the firm freely added their mites. During the time he has been connected with the firm, Mr. Gray has served three generations all named James Backhouse. To each of them he paid a well-deserved tribute of respect as just and honourable employers, when thanking the present head of the firm for the handsome present that had been given him. If it were possible for Mr. Gray to write a history of Northern horticulture during the last half-century, I feel sure the result would be an interesting book for all horticulturists. The writer has had business dealings with Mr. Gray for over thirty years, and has always found him to be a strictly upright conscientious man, with a marvellous amount of general horticultural insight and knowledge."

Do Varieties Propagated by Buds Degenerate?—We desire to call the attention of our readers to the summary of the discussion on this subject initiated by the Scientific Committee of the Royal Horticultural Society. The communications and reports have been published in full in former issues, but many will be glad to see the careful digest prepared by Mr. Chittenden, the Secretary, which is included in this number under the head of the proceedings of the Scientific Committee (see p. 318).

The Cultivation of the Morel.—Experiments on cultivating the Morel have been made by M. Molliard in the laboratory, and this month the results have been published in the *Comptes Rendus*. M. Molliard has succeeded in raising Morels from the spore to the perfect fungus on Apple pulp and on various nutritive matters of a similar composition to that of the Apple. He was led to make these trials by the fact that Morels frequently grow in Apple orchards and upon the refuse of the fruit. He ascertained that the mycelium (spawn) requires for its development nutriment that contains a large proportion of hydrocarbons, and that inulose, glucose, and starch are highly favourable to it. It is less exacting as regards mineral matters, but at the same time prefers phosphates, nitrates, and salts of lime or of magnesia in situations that are neutral or very slightly alkaline.

The British Gardeners' Association.—A public meeting of the British Gardeners' Association will be held in the Memorial Hall, Farringdon Street, E.C., on Thursday, June 1, at 8 p.m. Members of the Association are expected to be present in large numbers, and it is hoped that other gardeners interested will attend to hear the Report of the present Acting Committee, which will, we believe, be very encouraging to the movement. The voting papers for the election of the Executive Council have been distributed, and the result will be announced at the meeting.

Kew Guild Dinner.—Old Kewites are reminded that the annual dinner will take place this year, as usual, on the eve of the Temple Flower Show, May 29, at the Holborn Restaurant. The meeting is announced to commence at 7.30 p.m. The Secretary, Mr. Winn, Royal Gardens, Kew, will be pleased to hear before the 22nd inst. from those members intending to be present.

Gentiana acaulis alba.—We have received specimens of the albino form of Gentiana acaulis from Messrs. James Smith & Sons, Darley Dale Nurseries, near Matlock, who state that it was found in bloom, growing amongst a large quantity of the ordinary blue Gentianella (G. acaulis) raised from seed. It is a beautiful pure white variety, free blooming. The plants are now in full flower, and worth travelling many miles to see. The habit and growth is the same as the ordinary Gentianella.

Influence of Climate upon Vegetation.—In a paper contributed by M. Gaston Bonnier to a recent number of the *Comptes Rendus* (April 10), in which the author is writing of plants on the Nilgherri plain, he makes special mention of the garden at Ootacamund. This garden is situated at an elevation of some 7,475 feet, close to a meteorological observatory, so that the influence of the climatic conditions upon indigenous and cultivated plants can easily be noted. Observations of indigenous or naturalised plants, of plants acclimatised, and of cultivated plants not yet acclimatised in the Ootacamund Garden, led to the following conclusions:—The Nilgherri Plain (Southern India) is not of sufficient altitude to permit plants to develop all the characteristics of the vegetation of the alpine region, though they show certain of them. Further, the temperate climate of the Plain enables plants cultivated in our temperate countries to increase and to multiply themselves, modifying their form and structure so as to adapt themselves to the special meteorological conditions of the region. The plants at Ootacamund showed all stages of this progressive adaptation.

Raffia Tape.—This is the name given to a new material for tying up plants and parcels. The name explains it character, and it should be added that it is flat and corrugated, and therefore will not twist or slip. West's Raffia tape is too soft to injure delicate plants, and is of an unobjectionable green colour. It is sent out conveniently wound on reels with a holder and hook attached, and is obtainable from seedsmen and ironmongers. For using instead of raffia for plants and instead of twine for parcels it is well worth a trial, being efficient, handy, and inexpensive.

Wise and Unwise Planting.—In tree-planting, the suitability of the species to its surroundings is rarely considered with sufficient care. Mr. D. E. Hutchins, in the April number of the *Agricultural Journal of the Cape of Good Hope*, mentions this point in his paper on "Extra-Tropical Forestry." His opinion is to the following effect: "Before you begin tree-planting, make a careful study of your climate, and obtain the best advice on climatic forestry. Do not plant the Blue Gum, a native of a wet country, in a dry climate, where it will either grow badly or suck up the water from springs, watercourses, or your garden. Do not take Eucalypts from the eastern summer rainfall of Australia and plant them in the western winter rainfall of Cape Colony; nor, *vice versâ*, the western Jarrah and Kari in the eastern summer rainfall districts of Cape Colony. Do not plant near the coast mountain trees, such as the Deodar or Wellingtonia. Every tree has its own habitat, its own peculiar air and temperature, and it is of little use attempting to plant it out of its habitat. Many trees grow fairly well as specimens in a garden, but fail in the forest, while a number will succeed for five, ten, or twenty years, and then fail. Of such are the Grevillea and many of the eastern Eucalypts in the Cape Peninsula. Others will prosper till a bad season arrives, such as the dry summers of 1897 and 1902 after wet winters in the Cape Peninsula, which killed off a heavy percentage of Cupressus macrocarpa trees; or the drought of 1900 in the eastern districts, which had more disastrous effects."

Publications Received.—*Journal of the Scottish Meteorological Society.* With tables for the years 1902-3. Contents: Treatment of Climatological Observations, W. N. Shaw, Sc.D.; Rainfall of the Ben Nevis Observatories, Andrew Watt, &c. Regret is naturally expressed at the closing of the Ben Nevis Observatories owing to lack of funds. Not only regret but disgust may be felt at the abandonment of this mountain station.—*Department of Agriculture of Western Australia: Annual Report to June, 1904.* "The season was good for the country generally; the Wheat yield was good. Potato-growing is still going steadily ahead."—*Bulletin of the Department of Agriculture, Jamaica*, April. Contents: Roses, by W. Jekyll; notes on Fern Culture, Discovery of Manicoba Rubber Forests, &c.

PLANT PORTRAIT.

Lobelia tenuior.—*Revue Horticole*, April 16. See *Gardeners' Chronicle*, 1901, i., 37, fig. 20. M. Mottet considers that L. ramosa, L. heterophylla, and L. coronopifolia, hort., are synonymous with this.

WALMER PLACE, NEAR DEAL.

[See Supplementary Illustration.]

On the south-east coast of Kent and adjoining the historic castle at Walmer, of which an illustration was given in our issue for February 18, 1905, stands Walmer Place, the subject of our supplementary illustration. It forms the residence of A. L. Ocks, Esq., who has since purchasing the estate entirely remodelled the grounds and gardens, and has converted them into one of the finest gardens in this part of the country. The mansion has also been entirely remodelled, and is now an imposing and commodious building. For how long a period this site has formed a place of residence it would be difficult to determine, but there are evidences that, even as far removed as the Roman period, some noble family had its place of abode on some portion of the estate, for when constructing new terraces and walks extensive remains of these early settlers were discovered. These relics have been placed in a suitable show-case, and form an object of interest in the hall.

The contour of the ground is such that it slopes from the north towards the south-west, and advantage has been taken of the elevated northern portion to form the site for the residence. A considerable area has here been levelled and surrounded by a beautiful terrace constructed in the Italian style, and from which the grounds and gardens proper are reached by series of ornamental steps. The plateau thus enclosed is of considerable area, and has afforded scope round the houses for the inclusion of flower-beds and borders, which in summer-time are gay with flowers and decorative plants. The balustrading is surmounted at intervals with ornamental stone vases, that are also furnished in summer-time with flowering and trailing plants. The terrace affords an uninterrupted view of the grounds and, on the east side, of the sea, where can be seen the ships lying at anchor in the Downs, also in the distance the breakers on the Goodwin Sands, and, under certain conditions, the cliffs of France are distinctly visible. The house, together with the masonry of the terrace, furnishes a good "wind-break" to the gardens, a very necessary feature, owing to their being fully exposed to the cutting winds from the north and east, which in winter and early spring-time expend their full force upon this portion of the English coast. Were it not for this protection gardening would be impossible in such an exposed situation, for even the most hardy subjects would be injured by the cutting blast. A continuation from the terrace in the form of a terrace-walk runs for a considerable length towards the south, where it terminates in a summer-house built of masonry and furnished with a tower. From the top of this may be enjoyed an excellent view of the pleasure-grounds and one of the finest seascapes obtainable on the southern coast. The pillars and balustrading of this erection are furnished with a variety of climbing plants, including a collection of Ivies. The whole of the ornamental masonry, fountains, sundials, and similar objects have been constructed by Messrs. Pulham & Sons, while Messrs. Mawson Bros., of Windermere, were responsible for the remodelling of the grounds and gardens, which has been accomplished in the "formal" style. The grounds immediately below this elevated terrace-walk are laid out as a Dutch garden, the proportions of which have been designed in good taste, in a style that is both bold and effective. A central lawn has a series of beds at either end, in which are planted specimens of clipped Yew trees, Bay Laurels, and other suitable plants. The design is strictly symmetrical, the walks being formed with mathematical precision, and terminated in most cases with either an ornamental gateway, a sundial, a flight of stone steps, or some similar garden ornament. Proceeding across the Dutch garden one arrives at the central walk, seen in the bottom picture in the supplementary illustration. This walk intersects the grounds from north to south, and terminates on the north end in an old Roman column; on the south in an ornamental pond and water-garden. This walk is flanked on either side by well-formed borders of herbaceous plants of which our illustration affords an excellent view. It will also be noticed that in consequence of the "fall" of the ground stone steps have been introduced at intervals along this walk; although not shown, there are other steps as the walk proceeds southwards, and on the top of one flight is a beautiful Spanish gateway, surmounted by a curious old weathercock—a ship in full sail. The path to the left of the sundial shown in the foreground of the bottom picture leads to a bowling-green, which is included in our view at the top of the picture.

The bowling-green is surrounded by a thick hedge, and can be entered from the opposite side by a path that winds its way beneath tall Poplars and through shrubberies, on to a sunken garden which has recently been made. The borders of this path are bright with the greater Periwinkle (Vinca major). This plant grows luxuriantly along this shady walk, and at the time of our visit was covered with its beautiful blue flowers. The Periwinkle is one of the best subjects for planting in shaded situations, being a native of woods and undergrowths. Shrubs grow well at Walmer Place. We noticed Weigela rosea, Rhododendrons in variety, Berberis Darwinii, B. Mahonia, B. vulgaris, Spiræas, Lilacs, Choisya ternata, Roses, Honeysuckles, &c., flowering well. Cytisus præcox was a splendid sight, contrasting greatly with the golden-yellow of the double Gorse. Clematis montana was also seen in its full beauty. Another feature near the bowling green is a pergola of Roses and Honeysuckles; while an avenue of Prunus Pissardi leads one to a lawn, the centre of which is occupied by a round flower-bed, at present filled with Wallflowers.

Roses have been planted with a lavish hand at Walmer Place, for in addition to numbers round the house and on the walls and pillars of the terracee, a Rose-walk has been formed at the lower end of the grounds. This is shown above the round bowling-green and running past the model farm in the top picture. Roses in thousands occupy the borders on either side of this walk, while arches at frequent intervals accommodate such varieties as are of climbing habit. Near by this Rose-walk is the fruit and vegetable garden. This occupies a considerable area, and although but recently formed and planted, has the appearance of a sometime established garden. We were surprised at the general appearance of the occupants, remembering the exposed position; but the erection of substantial walls has done much to lessen the effects of the "north-easter."

Peaches and Nectarines looked promising for fruit, and we were informed that last season the crop of these fruits was bountiful. Given an opportunity of "setting," fruit succeeds well in these gardens, for when the cold winds of March and April are over the situation is a favoured one, and reliable weather may be counted on until the winter sets in again. The promise for Pears appears to be a good one; indeed the fruit crops generally in this part of Kent are looking well.

The breadths apportioned to vegetables were well filled, and showed evidences of careful and good gardening. Produce cannot be obtained early, owing to the exposed situation, but vegetables of excellent size and quality are grown. A model farm and the stables shelter these gardens somewhat from easterly winds. Beyond the kitchen-garden is an extensive paddock that has recently been enclosed by a border of trees and shrubs. These include many choice flowering kinds, and a pond gives opportunity for planting in its vicinity water-loving plants, such as Willows, Rhamnus, &c. The water-garden already alluded to is in keeping with the general design of the grounds, and is oblong in form, with sloping banks that are furnished with "pockets" planted with such species as Caltha palustris, Arundo donax, Irises, Butomus umbellatus, Osmunda regalis, and other water and bog plants. The pond itself is gay in summer-time with Nymphæas, of which a fine collection has been planted. The water-garden is, in our opinion, rather too formal in character, in fact, if any fault is to be found with the landscape gardening at Walmer Place generally, it is for the rather severe formal character that has been adopted. This feature is even apparent in the kitchen-garden, which above all other places should be one of utility and not of ornament. The kitchen-garden is supplemented by a smaller one at the north end of the estate, and here are also situated the glass structures, but these are not extensive. They comprise a vinery, plant-house, conservatory, and propagating pits. The plants are such as furnish flowers for cutting, or as are of decorative value in the residence. Everything is maintained in a high state of excellence at Walmer Lodge, the grounds and plants being in the best possible order. Mr. F. Sparks, the present gardener, has been charged with the care of this estate for many years past.

DENDROBIUM PARCUM.

This singular little Burmese species has slender pseudo-bulbs furnished with generally two-flowered inflorescences. The flowers when mature

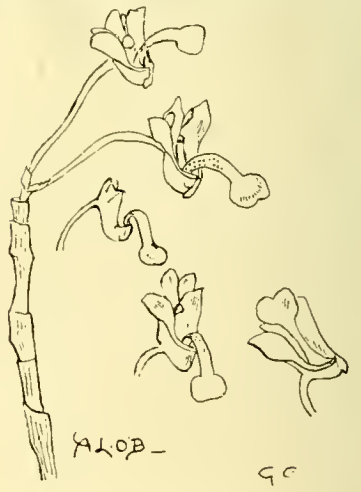

Fig. 132.—Flowers of Dendrobium parcum with movable spring-like labellum.

are rather over ½ an inch in length, and of very remarkable structure. The yellowish-green sepals and petals, the former of which are expanded below, fit closely together, and form a hood over the column, from the base of which, on the upper edge of the mentum, the labellum is delicately hinged and curved upward at the base, so that the singularly stalked labellum in the early stage of the flower juts out from the centre, as seen in the upper pair of flowers illustrated. The cuneate marginate front of the lip in this stage is nearly flat. When mature the labellum hangs point downward, the front being concave. If the flower is gradually turned so that the labellum is made to assume a more horizontal position it quickly moves over to the column as though attracted by a magnet. The action would carry the head of an insect moving on the blade and isthmus of the lip over to the polliniæ and

facilitate fertilisation, in the manner noted in some other Orchids. The lower figure on the left-hand side represents the mature flower with the labellum in the normal position. The right-hand flower shows the labellum in the position it suddenly assumes when the flower is placed at the angle represented in the drawing. The illustration in the centre represents a flower with the sepals and petals removed and the point and angle at which the labellum is attached shown. The flowers may readily be put through the movements described as often as desired, and it is very interesting to view, for the sudden attraction of the labellum takes place when the flower is at such an angle as to suggest that the laws of gravitation would be against the movement. Nor is explanation after cursory examination easy. The fact is that the axis on which the labellum hinges, owing to the curve in the lip, acts sooner than the observer expects. Then probably the elastic tissues, always strained to keep the lip in position, and which evidently keep strong hold during the early stage of the overbalancing, have a reflex action which brings about the sudden final movement. In any case it may be safely asserted that it is a wonderful piece of Nature's handiwork, and doubtless arranged to further the laws of reproduction. *J. O'B.*

[The diagram shows the way in which the horizontal lip is more or less at right angles to the erect column and then rises till it becomes parallel to it. Ed.]

THE PEAR MIDGE.

This insect pest has of late years increased to such an alarming extent that it has become imperative for growers to exert their utmost to

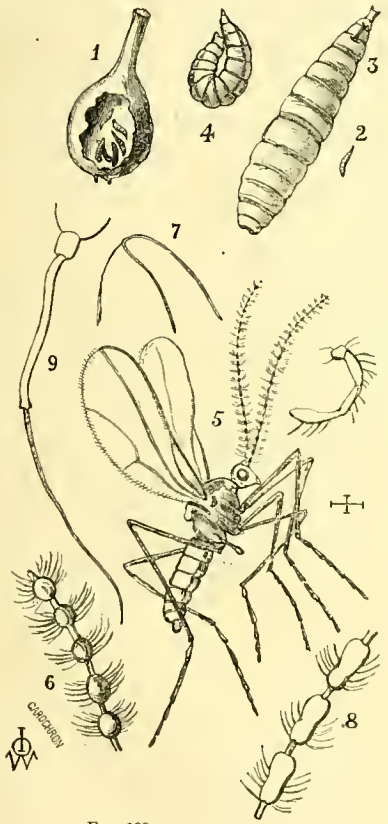

Fig. 133.—THE PEAR MIDGE.

prevent its spreading. Some districts are more affected than others, and unless timely means are taken for its destruction, the pest threatens to become as great a scourge as the Codlin-moth. Many growers fail to recognise in the small, deformed fruits the work of this pest, and attribute their diseased appearance to unfavourable weather or an unhealthy rooting medium.

The female insect may be seen depositing the eggs by means of her powerful ovipositor, with which she pierces the petals, sometimes operating from the top of the unexpanded flower, and at other times adhering to the side of the flower, and inserting the eggs through the calyx. I have watched this midge, which has long legs and a grey-coloured body, visit several flowers, and from close observation saw that the same operation was performed each time, which I concluded was the depositing of eggs. This was during the early days of April, and upon a subsequent examination of the marked blossoms some ten days later, I discovered the tiny grubs commencing to make an intrusion downwards into the centre or core of the fruit. The work of devouring the interior of the fruit will go on until only the outer skin of the Pear is left. The number of grubs present at this stage are about twelve to each fruit, but the fruit soon falls to the ground, when the insects quit their cradle of birth and bury themselves in the ground, at about an inch from the surface, where they remain and are metamorphosed into cocoons.

At this stage of their life-history they are easily destroyed by keeping the soil below the trees constantly stirred by hoeing or raking, and then allowing poultry a free access around the trees. Another remedy is to apply a dressing of kainit to the trees immediately the grubs have reached the ground, selecting a showery day for the purpose. This operation proves disastrous to the grubs or larvæ, and also benefits the trees by the addition of potash salts to the soil. All infested fruits should be immediately gathered and burnt. *W. H. Clarke, Aston Rowant, Oxon.*

[We reproduce our woodcut (fig. 133) which represents, 1, a young Pear cut open, showing the hollow made by the five enclosed larvæ; 2, the larva natural size; 3, the same magnified; 4, the same preparing to leap; 5, the male midge, the natural size being indicated by a small cross. The jointed process at the right side of the antennæ represents one of the palpi; 6, five of the terminal joints of the male antenna; 7, apex of the wing, showing the thickened margin continued into the extremity of the main vein of the wing; 8, three of the middle joints of the female antenna; 9, the elongated telescope-like ovipositor of the female. Ed.]

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

A GOOD AND EARLY MELON.—On April 23 last it was my good fortune to partake of a Melon which was remarkably handsome, of exquisite flavour and possessing an exceedingly thin skin, indeed, the latter was so thin that it was scarcely necessary to leave it upon the plate. The fruit was a new variety raised at Impney by Mr. Jordan, and he is very fortunate in having secured a Melon of such merit. The seed was sown about the middle of December, and the plants were grown in pots. The fruit was ripened perfectly on April 22, which, considering the sunless season, will be admitted to be early. Moreover, the flavour was so rich that it was superior to the majority of Melons produced in the hot weather of July and August, and very nearly equal to the best it has been my experience to eat or test at that period of the year. My notes of the fruit at the time are as follows:—"Fruit nearly spherical; short stalk; weight, 3½—4 lb.; very slightly corrugated; skin clear yellow and beautifully reticulated; flesh, white, 1½—2 inches in thickness and semi-transparent; skin, very thin, no thicker than a sixpenny piece; excellent flavour; a very beautiful Melon." It was the most handsome Melon I have seen during forty years; I completed my fortieth year of practical horticulture yesterday, May 6, and I have never been so reluctant to cut a Melon, though I am passionately fond of the fruit. *J. Udale.* [We have had an opportunity of tasting this Melon. It is a very handsome fruit in appearance, juicy, of good flavour, especially for the time of year, and, as described by Mr. Udale, the skin is unusually thin. Ed.]

ARE COMMERCIAL TRAVELLERS A NUISANCE?—One word will suffice to answer this question, and many readers I am sure will join me in saying that that word is "Yes." At certain times these are as great a nuisance to the head-gardener as book-canvassers are to the under men. Their coming is usually announced by a card bearing the name and the date of their proposed visit. Except in the case of a few who appear on the date fixed, the majority come when convenient to themselves, a week before, perhaps a month behind the appointed time, fully expecting the gardener in either case to be awaiting their arrival. The answer to their abrupt question, "Is the gardener about?" being in the negative, they turn to the foreman as a substitute, and ask him to escort them through the glass department, which is done more from courtesy than from pleasure. In the absence of the gardener I have shown men round, who have not had a single word to say in favour of anything, either inside or outside; yet the same person, when taken through a second time by the gardener himself, professed himself delighted with all he saw. I am of opinion that such men as these are more of a disadvantage than an advantage to the firm they represent, besides being a "pest to gardeners"; and may their answer be "No," although at that moment the gardener may be within easy distance. *A Foreman.*

PLANTS IN A GARDEN AT FALMOUTH.—In the *Gardeners' Chronicle* for May 6, Mr. Fitzherbert gives a list of thirty-two plants which he saw in a garden at Falmouth, and of which he says "none of these are hardy in the open except in the south-west." I should like to say something for Castlewellan, which is situated in the extreme north-east, about 20 miles from Belfast. If Mr. Fitzherbert will honour me with a visit, I shall be pleased to show him in this garden twenty-nine plants out of his list of thirty-two, all having grown in the open for many years, and some of them of a notable size—e.g., Desfontainea spinosa, 13 feet in height and nearly 60 feet in circumference; nineteen varieties of Pittosporums, several up to 20 feet in height and over 20 feet through. Edwardsia grandiflora is 12 feet high and the same in diameter; Embothrium coccineum against a wall 12 feet high; Benthamia fragifera is 15 feet high and 12 feet in diameter; Berberidopsis corallina against a wall is 14 feet high; Callistemon brachyandrus is 6 feet high. All these are in his list as not being hardy except in the south-west of England. We also find that the following plants are hardy here:—Lapageria alba and rosea, on a wall; Mitraria coccinea, 5 feet high and 6 feet through; Philesia buxifolia, 4 feet high; Plagianthus Lyalli, 12 feet high and 8 feet through; Puya chilensis, 8 feet high; Restio subverticillatus, Rhaphithamnus cyanocarpus, 8 feet high; Senecio rotundifolius, Disanthus cercidifolia, Carmichaelia australis, 7 feet high and 6 feet across; Cinnamomum sericeum, 5 feet high. If Mr. Fitzherbert will look at Earl Annesley's book on rare trees and shrubs published last year by Newnes & Co. (a book which no lover of choice trees and shrubs should be without), he will see that although Castlewellan is some 280 miles north of Cornwall, we have grown for many years quite as many tender and rare plants as are to be found in any garden in that county. *T. Ryan, The Gardens, Castlewellan.*

EFFECTIVE FLOWER-BEDS. — Oblong and circular flower-beds having a groundwork of the variegated-leaved light pink flowered Pelargonium Manglesi, or dark and light flowered Fuchsias, or Acacia lophantha with its beautiful Fern-like foliage, with Abutilons niveum, marmoratum and Thompsoni, with their elegantly marbled foliage and beautiful orange-yellow cup-shaped flowers, disposed somewhat thinly over the surface as "dot" plants, make very effective "mixed" beds either in the flower garden proper or on the lawns. Beds carpeted with blue Viola, edged with Pelargonium Mangles' var., variegated with "dot" plants of light-flowered Fuchsias, Acacia lophantha, Lilium candidum (the common

white garden Lily), and Celosia pyramidalis, coccinea and aurea, with their grand crimson and rich yellow blooms make a delightful combination of foliage and flowers. Similar-shaped beds planted with the yellow-flowered Viola Golden Queen, edged with a good broad band of blue Lobelia and "dot" plants of Heliotrope Madame Crousse, and Charles Turner Ivy-leaf Pelargoniums, tied up to stakes so as to form pyramids of their large trusses of satiny-pink and crimson flowers borne on long stems, show off to great advantage when contrasted with specimens of dark and white-flowered Fuchsias, and the beautiful blue-flowered Salvia patens. Again, beds edged with a good band of Pyrethrum aureum laciniatum, carpeted thinly with scarlet-flowered Pelargoniums, with "dot" plants of the richly-striped Japanese Maize, Dactylis elegantissima aurea (Ribbon-grass), Perilla nankinensis (dark foliage), Ageratum mexicanum (mauve-flowered), white-flowered Ivy-leaf Pelargoniums, and Plumbago capensis, and light-flowered Fuchsias, would produce a pleasing and quiet combination of colours. *H. W. Ward.*

THE CURRANT-BUD MITE.—It would be surprising if anyone had adopted Mr. Pearson's recommendation to spray with Quassia, &c., in order to destroy the Currant-bud mite. The mite is so well protected by the leaves of the bud that the only result would be to make the Currants uneatable without injuring the pest in the least. I find that the plague can be so far mitigated as to enable us to obtain a fair crop of fruit by picking off the infested buds in April, when they can be easily seen. In the spring of 1903 I found two of my bushes infested, and had them dug up at once and burnt. Notwithstanding this, in 1904 several bushes were infested. I had all the "big" buds picked off in April, and when they were very numerous on a branch, the branch cut off. This year the affected buds were apparently about the same as last, and we shall have a very fair crop of fruit. But whether it would pay a farmer to do this is another matter. *Alfred O. Walker, Ulcombe Place, Maidstone.*

BERMUDA ONIONS. — The Bermuda-grown Onions which the Dempster Steam Shipping Company has recently been distributing among the restaurant keepers of London, represent a small, serviceable, solid type of the brown Spanish Onion, which does not show the slightest tendency to start into growth. The firmness and solidity of the flesh is one of the principal features of the Onion, but in reference to its apparently good keeping qualities, it is requisite to know when and under what conditions the Onions were grown, and what steps were taken to preserve them. The object sought by the Company is to create a demand for the Onions, which, so far as it is understood, will be grown in Bermuda, but their distribution will be a monopoly of the Company. The Onion is said to cook well and be both succulent and tender to the palate. *R. D.*

VEGETABLE EXHIBITION POINTS.—It is very doubtful whether, since vegetable competitions have been established, a richer series of prizes for an open collection has ever been offered than is found associated with Class 174 in the schedule of the great international exhibition of the Royal Caledonian Society, to be held in Edinburgh next September. The number of dishes in this collection, which is open to all, is limited to twenty-four, and of these two varieties of any one kind may be included. There are four prizes of a total value of £51, the first prize being of the large sum of twenty guineas. But then it is hoped that such liberal sums may tempt first-class growers from a distance, and if such high-class exhibitors from England as Messrs. E. Beckett, J. Gibson, B. Ashton, and possibly one or two others, can be thereby induced to compete with other not less eminent Scottish growers, there should be a battle royal over vegetables which should prove to be one of the most exciting events of what will doubtless be a magnificent show. But as a special class for eighteen dishes follows, and is restricted to Scotland only, it is feared there may be for that reason some hesitancy on the part of northern men to enter the open competition. It is commonly assumed that the northern growers favour size in vegetable exhibits beyond what is ordinarily seen in England. That has to be fully proved. It may be that, should there be competitors from both countries, the one may present slightly larger exhibits than usual, and the other may be less large. It may afford some slight clue to the wishes of the framers of the open class when we read that whilst in all cases the maximum numbers to a dish are stated, it is significantly added the full number on a dish shall not outweigh by mere number quality on a smaller dish, the inference being that what is generally known as quality in the south is desired at Edinburgh. The schedule classes certain vegetables as numerical or point values. With these generally there is little room for objection, but in the south we put Carrots and Beets, the former especially, in the autumn as of the first class, whilst in Scotland they come into the third class. Broccoli, Leeks, Potatos, Onions, Mushrooms, Celery, Brussels-Sprout plants, Peas, and Tomatos, come into the first class with seven points maximum; Runner or Dwarf Kidney Beans the second class with six points; and Beets, Carrots, Parsnips, Turnips, with several others, coming into a third class with but five points maximum each. That Runner Beans, for instance, should as an autumn vegetable be placed in a lower category than Leeks or Mushrooms, and Carrots lower still, seems odd to southern growers, as here we regard both these as at once difficult to grow and of the highest importance. However, as the estimates put on these things by the Committee are the same for all exhibitors competition will be fair and square all round. *Reader.*

CUCUMBER SPOT.—I very much object to being misquoted by anyone in a discussion on any subject in a public journal or otherwise, and therefore, thinking that Mr. Thomas had done so unwittingly at p. 219, wherein he stated that "the most likely cause, in Mr. Ward's opinion, for the attack of the spot disease is to be found in the weak and worn-out condition of the plants after a period of continuous fruiting," I naturally enough wrote to the *Gardeners' Chronicle* for April 22 disclaiming having either entertained or expressed in writing any such opinion as Mr. Thomas has ascribed to me. And if readers interested in the subject of the spot disease in Cucumber leaves will be good enough to refer to my previous letters on the subject (see issues for February 18, March 25, and April 22), they will see how far Mr. Thomas is justified in the interpretation which he has placed on certain sentences of my letters in his article for April 8, and also in your issue for May 6. I think I was quite explicit in my statements and conclusions arrived at after careful observations and actual experience with the spot disease in its various stages of growth. Of course, I am not responsible for inferences drawn by your esteemed correspondent, Mr. Thomas, or any other writer on the subject. Mr. Thomas having quoted a passage from my article printed in your issue for February 18, without however giving the context, and placed his own interpretation thereon, asks: "If this was not his (Mr. Ward's) intention, it is difficult to understand the reason why he wrote the paragraph in this connection." The paragraph referred to by Mr. Thomas at p. 284 (without giving the context) was penned to show the entirely different conditions under which Cucumber plants are grown for market as compared with those practised in private gardens, and the consequent immunity of the latter class of plants from the spot disease. *H. W. Ward, Rayleigh.* [Enough has now been said on this subject. ED.]

RISKS OF ORCHID COLLECTORS.—As showing the difficulties that meet collectors of Orchids in their native haunts, I am forwarding some extracts from a letter my employer, Mrs. T. Fielden, has just received from a gentleman friend in South America, who recently sent us an importation of Cattleyas:—"I spoke to the collector 'K.' about Lælia Boothiana syn. Cattleya lobata, and he says it grows on naked rocks in the full glare of the sun, hence in cultivation it should have as much sunshine and dry heat as possible to ensure its flowering at all freely. He seems to have had a great difficulty in getting the plants. It appears they only grow on a mountain mass of rock at the northern entrance to the Bay of Rio de Janeiro. 'K.' was accompanied in his journey by a German friend and six workmen. After a tramp of some 12 miles they reached the mountain, which they ascended by a rough channel naturally cut out of its smooth surface, its height being about 300 feet. They then tied ropes to clumps of Cactus, and began to let themselves down the steep slope facing the sea. On getting about one-third of the way down they came to ledges of rock covered with small Cactus, rough grass, and clumps of Lælia Boothiana. One of the party being on the look-out for Lælia amanda, a natural hybrid, rushed to a large clump and began to pull the stems aside, when he saw a black roll—a poisonous snake, the kind called in the West Indies Fer D. Lance, I believe. They then got up a snake-hunt, and killed half-a-dozen in sizes from 2 to 7 feet in length. In order to get at the plants they had to walk about in prickly Cactus up to their knees, the spines of which pierced not only trousers but stout leathern shoes. Fortunately they did not get bitten by the poisonous snakes. They then found out it was too late to get back before dark, so made beds of rough grass on a rocky ledge and slept there. Next day they let themselves down to other ledges until they got to the perpendicular portion that reached direct to the sea. The heat was so overpowering that some of the party were almost overcome with faintness in pulling themselves up the last slope, which, fortunately, all reached in safety. After reaching the foot of the mountain by the same route they ascended, they began to count up their plants and found they had secured some 200 plants of Cattleya lobata, but a very much smaller number of Lælia amanda. One of the party set out to secure mules to carry the plants, and a hammock to carry one of the party who was overpowered with the heat. For some time the parts of the body exposed to the pricks of the Cactus and other scrub were sadly blistered." While the columns of the *Gardeners' Chronicle* have from time to time contained many graphic descriptions of the risks of Orchid collectors, perhaps these notes may be of interest, as they are from a gentleman engaged commercially in South America, and in no way interested in Orchid culture beyond admiring them as growing in their native habitats. *H. J. C., Grimston Gardens, Tadcaster.*

SEED-SOWING (see p. 212).—If the darkening of seeds when sown be productive of indifferent germination, how is it that the most successful growers of Mustard and Cress for market get such splendid germination in really huge quantities by closely covering up the seeds when sown with bass mats? The same results follow when similar seeds are sown in boxes in warm-houses, stood beneath stages and covered with paper. In each case warmth and moisture have far more to do with growth than light has. Admittedly the primary object in these cases is to obtain quick and tender growth, hence the exclusion of light until a few days after germination has begun. Then there is the common treatment of Radish seed as sown in great quantities by market growers. The soil of the beds is partially warmed by burying into it prepared manure, and when the seed is densely sown and covered with soil it is thickly covered further with straw-litter. Yet in such cases germination is always quick and complete. Are not all seeds sown in the open ground, if buried ½ an inch and deeper, practically in the dark? Do rays of light penetrate through 2 inches of soil—to Pea or Beans, for instance? That is not probable. The temperature of the soil and moisture are the primary factors in promoting germination, and that is just as good, and probably better, than is found in grass or Clover seed that is scarcely buried in the soil. No doubt where outdoor seeds are covered in addition to soil-covering, the primary objects sought are the exclusion of birds and drying sun-heat, as a sudden burst of such heat on germinating seed is often fatal to growth. Hence, when seeds are sown under glass some such protection is in spring and summer absolutely needful to secure germination, especially of very small seeds. Apart from protecting the soil in pots, pans, or boxes from sudden drying, the need for frequent waterings is also avoided, as

even with the greatest care small seeds may be washed out of the soil, as "Heather Bell" has said and many amateurs who seek to raise small tender seeds meet with failure in consequence. A piece of glass placed over a pan or box or pot containing seed, helps to preserve warmth and moisture, but would be dangerous, as concentrating too much heat, did the sun burst out suddenly and strongly. I have commonly in such cases, and to prevent such a misfortune, strewn a little sand thinly over the glass with excellent results. I have also covered the glass with paper in the daytime, removing it at night. The theory that light is indispensable to germination [this has not been claimed. Ed.] upsets the old belief that such germination is more rapid at night than it is in the daytime. *A. Dean.*

HERBACEOUS BORDER.

MECONOPSIS INTEGRIFOLIA.

This plant is now flowering here, planted in moist loamy soil, as a fringe to the Water-Lily pond. In our case the flowers, though retaining their cupped and poppy-like form, have opened more fully than any shown in the illustrations of the species that I have seen. The oviform seed vessels are divided into either five or six sections, showing at the apex a distinct five or six-pointed star, the number of elongated points on the star corresponding to the number of divisions in the seed vessel. This star peeping out from the large boss or pompon formed by the crowded yellow anthers, is very conspicuous in the early stages of the flower, as it is then almost black. Four is the greatest number of flowers borne by any plant here, but this number will undoubtedly be improved upon when the proper system of culture is attained. The leafage is rather sparse.

The plants were turned out of pots in November, which is, I think, rather too late, as little further growth was made by those which have since flowered, and the pushing up of the flower-stems without further growth of the plant seems to have been due to precocity induced through a check. The first flower opened on Easter Sunday, April 23, took five days to expand fully, and lasted in good condition for a fortaight, by which time those lower down the stem were expanding, so that one may reasonably expect from each plant a flowering season lasting a month, and as they do not all flower simultaneously, the season would be extended where the plants are largely grouped.

Before reading Messrs. Veitch's advertisement I had been hoping that the plant could be grown and treated like most other biennials, *i.e.*, raised during summer and planted out in October, after the summer bedding plants are cleared off, in which case it would make a grand addition to the spring flower-garden amongst bunch Primroses, Forget-me-nots, and the like; but if one has to wait an indefinite length of time, from three to fifteen months, for germination to take place, and to plant out in June to get the best results, it is obvious that too much dependence must not be placed on it for use in the formal flower-garden. Possibly, however, slow germination is due to long storage of the seeds, and when we are able to save our own seeds and sow them immediately they ripen, we may, as we already do with many hardy plants, obtain quick germination. I am looking forward to a trial on these lines, as the seed-vessels from the earlier flowers here are swelling up and look promising.

In any case, even if one cannot time the plants definitely, it will be largely grown in the mixed border, or grouped with charming effect in positions outside the formal garden. I may add that among the plants here are two that really seem to have got well hold of the soil, and are growing away without showing any signs of flower; the crowns of these have become sub-divided, consequently I am hoping for a still better, if later, display from these particular plants. *J. C. Tallack, Shipley Gardens, Derbyshire.*

[We have seen a number of plants growing and flowering very freely in the borders of herbaceous plants at Dover House Gardens, Roehampton, S.W. Ed.]

FORESTRY.

THE TIMBER VALUE OF EXOTIC TREES.

Both Sir Herbert Maxwell and Mr. Elwes appear to have interpreted my use of the word "exotic" on p. 177 rather too literally, as they both instance the European Larch as a valuable exotic tree, which was introduced to a certain extent by accident. I intended the word, however, to apply more particularly to non-European trees, and to those indigenous to countries with climates differing greatly from that of Great Britain, so far as summer temperature goes. My chief argument, however, has less to do with the nationality of an introduced tree than with its value for timber purposes when compared with those which have been grown in Britain for the best part of two centuries.

I take it that the value of any species for economic purposes depends mainly upon two factors—1st, the cost of producing it at a suitable timber size; 2nd, the value of the timber produced per acre. The expense of production depends principally upon the value or rent of the ground required, the cost of planting, and on the time required to bring the crop to the desired size. The value of the crop per acre depends partly upon its quantity and quality, and partly upon the demand that exists for it in the timber trade We know in a general way how most European trees stand when examined on the above points, and that Larch, for instance, is a more valuable tree, other things being equal, than Scotch Pine or Spruce. In the case of recent introductions, time has not yet elapsed fairly to judge many of them, although I contend that a period of fifty years should indicate their probable value, provided that they have been fairly extensively planted as specimen trees.

Taking the factors of value as given above, and applying them to recently-introduced coniferous species, I think it will be found that the value of most of them is greatly lessened, first, by their inability to grow at a fair rate on land of poor quality or at high elevations; and, secondly, by the relatively poor quality of the timber they produce. At the present time, of course, other serious drawbacks are the high cost of the plants and the low market value of the timber; but these might be removed by extensive cultivation, and can only be considered as temporary.

But judging them with respect to their ability to grow on poor soil at high elevations and the specific quality of their timber, and comparing them with the common trees of our plantations, Scotch Pine, Spruce, Silver Fir, and Larch, I think I am fairly entitled to ask how many can equal or surpass the latter as commercial timber crops. Taking the average soils and situations found at 500 to 1000 feet above sea-level, the only Pine I know at all superior to Scotch Pine is the Corsican, whether for hardiness, rate of growth or quality of timber. Sir Herbert Maxwell, on p. 202, mentions P. monticola, which certainly stands wind well; but is it as good as or better in this respect than Corsican Pine, and is it as free from disease? Dr. Somerville states that it has been attacked of late years by a fungus in many districts, which threatens to render its successful cultivation a difficult matter. Amongst Spruces, the only superior to Norway Spruce in this country is possibly Picea sitchensis, which grows more rapidly to begin with, but usually drops off after the fiftieth year or so. The most promising Silver Fir I should consider Abies grandis; but most of the genus Abies require fairly deep soil, and I doubt very much if the common Silver Fir is inferior to any of them after it once gets away from late frosts. Amongst other coniferous genera we have one non-European tree which stands well out from the rest—the Douglas Fir, but for its successful growth it requires conditions which are rarely found to prevail over a large area in the class of land we are considering. Mr. Elwes, p. 209, mentions Thuya gigantea, but my experience of this tree is that it requires both shelter and a fairly fresh soil to produce a good specimen, while, as I have already pointed out, it is difficult to find it as a well-shaped timber tree, or rather what looks like becoming one under proper conditions.

In sheltered spots, such as glens, ravines, or lowlying land generally, most species of trees grow well, but here introduced Conifers have to compete with hardwoods, and the only two I know able to do this successfully, considering them from a purely commercial point of view, are the Larch and Douglas Fir.

Mr. Elwes in the same article raises a question as to the value of the Locust-tree (Robinia) on certain soils in the south of England. I presume he means the sands and gravels on which this tree shows best to advantage, and so far as durability of timber goes, I am quite willing to admit that nothing can surpass it. As a matter of fact I called attention to the value of this tree in the *Gardeners' Chronicle* of April 11, 1896, pointing out the useful qualities of the wood for fencing purposes But it must be remembered that the Locust-tree never becomes big timber in the same way that the Oak does, while the districts in which it can be grown are usually well supplied with the tops and small thinnings of the latter tree, which serve the same purpose. As a timber crop I should say the Spanish Chestnut would be superior to it in many ways, although the wood itself may be less durable.

As to the value of introductions for ornamental purposes I am quite at one with Mr. Elwes, but this was a part of the question I was not dealing with. I have no doubt that their use in this connection will be extended, and their beauties appreciated by the economic forester as much as by anyone. The work upon which Mr. Elwes is engaged, by giving us trustworthy evidence as to what can be grown in this country, and the conditions under which existing specimens have been produced, should encourage their cultivation on correct lines more than anything which has yet been written about them. All I ask is that they should be regarded for the present by planters with profit in view as untried species, and that they may be left out of mixtures in which they can only fail to develop as timber-trees on the one hand or as ornamental specimens on the other. *A. C. Forbes, Armstrong College, Newcastle-on-Tyne.*

ENQUIRY.

A correspondent wishes to know from what Scottish poet the following lines are taken:—

"Give me the garden wild and wide
Where thorns and thistles side by side,
* * * * *
. . . Such place to me is Paradise," &c.

Manning's "Monographs."—These differ so much from the ordinary trade catalogues that we feel at liberty to make mention of them. The treatise on berry-bearing plants is really a valuable garden monograph from the number and variety of the subjects treated of, and specially from the way in which those subjects are handled. Many of the popular names are not familiar here, but this inconvenience is compensated for by the addition of the botanical names. Lovers of hardy shrubs will be astonished at the multitude of desirable plants that are mentioned. The "Monograph" may be had from J. Woodward Manning, Reading, Massachusetts.

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

May 9.—*Present:* Dr. M. T. Masters, F.R.S., in the chair; Professor Church, F.R.S., Dr. M. C. Cooke, Rev. W. Wilks, Messrs. Hooper, Saunders, Odell, Worsley, Bowles, Massee, Gussöw, Veitch, Gordon, Baker, Worsdell, Nicholson, Douglas, and Chittenden (hon. sec. Visitors: Dr. Johannsen of Copenhagen, Mons. Correvon of Geneva, and Mr. Roupell.

Welcome to the Visitors.—Dr. Masters introduced the visitors, and welcomed them in the name of the Committee.

Fruit-buds Injured.—Mr. Saunders reported on the specimens received at the last meeting from Mr. Robbins:—"I cannot find enough insects or fungi on them to account for their condition. There are a few specimens of the mussel-scale (Mytilaspis pomorum) and of the Apple-sucker (Psylla mali), both of which are decidedly injurious insects, but there were so few of them that they could not have done any appreciable harm; there were also a few mites belonging to the genus Trombidium, but they are quite harmless. There were a number of empty egg-shells on all the shoots, and a few unhatched eggs, which I will try to rear. The buds do not look as if they had been injured by insects, but as though the frost had killed them, or that much maligned combination of circumstance commonly known as the weather. I should certainly recommend the use of the caustic soda wash next winter." There was no sufficient evidence to show what had gnawed the Apple-buds received from Mr. Dunlop.

Montbretia Corms Failing.—Mr. Massee reported that these corms had for some reason or other failed to form new corms last season, and were therefore not growing this.

Deterioration of Potatos.—The Secretary read the following summary of the discussion on this subject, which he had drawn up at the request of the Committee:—

I. Do Potatos deteriorate? It is important to note that deterioration may take place from a commercial point of view, or from actual degeneration of the plant itself. (See II. below.)

1. In the broad sense they undoubtedly do deteriorate.
2. But deterioration, *per se*, also seems to occur. E.g., "Buffs" and "Dons," previously good, succumbed to disease in 1845. "Victoria" degenerated in time both as a cropper and in disease-resisting power. "Dunbar Regent," with its acknowledged excellent qualities, can have disappeared for no other reason than because it had deteriorated. Varieties degenerate sooner or later both in productiveness and resistance to disease, sometimes in as short a period as six years from the raising of the variety.

II. What are the evidences of deterioration?

1. As shown by the plant itself. (*a*) The leaves grow curly and stunted. (*b*) The plant does not develop properly, or (*c*) even fails to appear above ground at all. (*d*) The plant offers less resistance to disease (in eight years a reputed disease-proof variety became much diseased).
2. From the growers' point of view. (*a*) The produce is much lessened (in one case cited by 50 per cent. after two years) when grown on the same soil. (*b*) The size of the tuber is reduced ("in fifteen years the Potatos were no larger than marbles").

III. Why does deterioration occur?

1. It may be brought about by local conditions.

a. Treatment. (1) Wintering tubers under conditions causing premature sprouting. (2) Growing continuously on the same soil. (3) Unsuitable manuring. (4) Possibly by selection of small tubers (but this is by some regarded as unlikely).

b. Economic reasons. (1) Supplanting by varieties of greater productiveness or other desirable quality. (2) Ease with which new varieties are raised. (3) Novelty of later-raised varieties.

2. But it is also due to inherent causes. (*a*) Old age or disturbance in the balance between waste and repair. (*b*) Possibly the tendency to form seed, but there is a marked exception in the Ashleaf. (*c*) The Potato is an exotic, and is, therefore, never grown under absolutely natural conditions. It may be that even after 300 years' cultivation it has not become completely adapted to or in harmony with its environment.

IV. How is the fact that certain varieties (e.g., Ashleaf, Early Rose, Magnum Bonum, Maincrop) do not appear to have degenerated after long cultivation to be explained in view of the foregoing facts? It is probable that newly-raised varieties vary in vigour as well as in other characters, some having sufficient vigour to carry them through only six years, others through very many. Cross-fertilisation, as a rule, results in the production of longer-lived varieties than does self-fertilisation.

V. Points of practical importance. How may the life of a variety be prolonged?

1. Greater care should be exercised by raisers in introducing new varieties. Only those with plenty of initial vigour should be offered to the public.
2. Well-matured tubers should be chosen for "seed." Size of seed is not so important, but uncut tubers of medium size give, in the long run, the best results.
3. Selection of tubers in other directions can be expected to give little result, but "sports" do occasionally occur, but are usually of no practical value.
4. Sets should be stored so that they do not exhaust themselves by premature sprouting.
5. The seed should be frequently changed; the best seems to come from Scotland, but even there change of soil seems necessary. The second year's crop is usually the best.
6. Probably excessive manuring with nitrogenous manures may lead to more rapid degeneration.

VI. The main objections to the idea of degeneration naturally occurring in asexually-produced varieties were (1) the fact that some varieties persist apparently unchanged for long periods—this point is dealt with in paragraph IV.; and (2) the idea that plants produced asexually are entirely new individuals, and not merely parts of one individual; this question cannot be regarded as definitely settled.

VII. Other points. The discussion also brought out a considerable body of facts regarding other plants of great use and interest, and provided suggestions for a very large amount of experimental research.

Etherisation of Plants.—Professor Johannsen, of Copenhagen, the inventor of the process, gave a short account of the method of etherising plants in order to shorten their period of rest and induce them to flower more speedily (see *Journal of the Royal Horticultural Society*, xxviii., 1903, 45), explaining his conception of the action of ether, &c., upon the plants.

Shoots of Yew Injured.—Mr. Saunders, F.L.S., showed some shoots of Yew, the leaves of which appeared to be covered with a pale yellow alga. Mr. Massee undertook to examine these.

Hybrids.—Mr. Worsley showed flowers of a hybrid between Tropæolum peregrinum and T. Lobbianum, and between a Phyllocactus hybrid and a white night-flowering species of Cereus. The flower was intermediate between the parents in all characters except that the stigma was white, while in the female parent it was purple, and in the male yellow. The flowers of the hybrid opened in the evening, and were at first scented.

Seedling Scillas.—Mr. Worsley also showed seedlings of Scilla campanulata bearing pink flowers. The seed had been saved from plants with blue flowers, the only others near being white, no pink-flowered plants being in the garden.

Effect of Manures on Rye.—Mr. Baker showed specimens of Rye grown under different manurial conditions. What was apparently the best part of the field was untreated and bore very poorly, the other parts, on a poor, chalky soil, received dung or ashes from a destructor. The former gave a very lush growth, which was, however, weak and somewhat crippled at the nodes, while the crop on the portion manured with destructor ashes, which contained no nitrogenous matter and much potash and phosphoric acid, was strong and healthy-looking.

Shoots of Rose Injured by Weevils.—Mr. Saunders reported on some shoots of Rose, sent by Mr. Yarde, of Northampton, that had the young plants eaten, and rings gnawed round the stronger shoots, as follows: "The injury was caused by the 'clay coloured weevil' (Otiorhynchus picipes), which feeds only at night, when they may be shaken off the bushes into an open umbrella, or on to boards, or sheets of metal freshly tarred, or on to white cloths laid under the bushes. They will lie as if dead and remain still with their limbs close to their bodies for a minute or two, so that there is plenty of time to collect them. The insects hide very carefully during the day, and small bundles of dry moss or hay tied to the stems of the Roses would provide them with suitable shelter. These should be examined every morning to see if any weevils are present. The weevils often prove troublesome in greenhouses, and their grubs feed on the roots of Ferns, Cyclamen, Primulas, and other plants.

Pagoscope.—Dr. Masters showed a "pagoscope"—an instrument invented in France recently—by which it is possible to ascertain, with approximate accuracy, the previous night, the (1) probability of a frost before morning, (2) the possibility of a frost, or (3) the certainty of freedom from frost. He had tested the instrument, which was illustrated in our columns at page 133 of the present volume, for some time, and had found it to be satisfactory.

THE LIÈGE HORTICULTURAL EXHIBITION.

May 8, 9, 10.—Although somewhat incomplete the horticultural section of the exhibition was nevertheless interesting, and will certainly be more so as the season advances, and when in the autumn the exhibition of the fruits for which the country is justly well known takes place. For the present the interest centres round the plants under glass, which are exhibited in a well lighted temporary building, beds being disposed so that the plants may show themselves to the best advantage, while stages are arranged around the sides for the reception of plants of smaller dimensions. The exhibitors, native and foreign, did their utmost to make this great effort a success. Large groups of well-grown Palms were to be found occupying the corners of the horticultural hall, forming a fitting background for flowering and foliage plants of smaller dimensions. These were principally supplied by Messrs. Jacob Makoy, of Liège, and comprised plants of great interest, not only Kentias, Latanias, Phœnix, as usual, but also fine specimens of Ceroxylon andicola, Kentia Lindeni, &c.; and by Messrs. Duriez Frères, of Wondelghem, who in their group included a grand specimen of Cibotium Schiedei and a pair of tub-grown Pteris Ouvrardi, and Microlepia hirta cristata such as are seldom seen. Mr. Draps Dom, from Laeken, contributed besides a grand specimen of Cocoloba pubescens and a splendid plant of Croton "Lord Rendell," a group of deserving Dracænas, such as "Père Charon," "Madame Draps," and a number of unnamed seedlings. Mr. Arthur De Smet had a grand lot of forms of Anthurium Scherzerianum, including one with flowers of large dimensions, red and green.

Among the Orchids exhibited on this occasion Mr. Peeters, of Brussels, no doubt showed the most interesting group, consisting principally of hybrids between Odontoglossum Rolfeæ and O. crispum, and various other forms all beautiful; and also very pretty hybrid forms obtained by the crossing of O. Adrianæ and O. crispum "Queen Victoria," besides grand spikes of the much-admired O. crispum St. Gilles, Stanley, and ucclense.

Mons. C. Maron, of Brunoy, exhibited an interesting group of his own hybrids, the most remarkable being Lælio-Cattleya Madame Maron and Impératrice de Russie.

Mr. F. Lambeau, of Schaerbeeck, showed a very fine form of L.-C. Dominyana H. Greenwood, Merciana a curious and very pretty hybrid between C. amethystoglossa and flava; a good specimen of Cypripedium Helvetia superba, and numerous others.

A splendid bank of numerous forms of Odontoglossum crispum was staged by Mr. Arthur Salle, of Fleurus; while Messrs. Pourbaix, Frères, of Mons, among an interesting very varied group, showed Masdevallia Pourbaixi, a free-flowering plant, remarkable for the coppery colour of its medium-sized flowers.

Among new plants we noted Cymbidium insigne (Rolfe) exhibited by Messrs. Camille Frères; Dracæna Leopoldi, by Messrs. Jacob Makoy. The same firm also showed a collection of Bromelias, a very interesting collection of Maiantas, comprising M. Mazeli, M. insignis, M. Sallieri, M. illustris, &c.

"La Roseraie Belge," of Brussels, exhibited a fine lot of Chrysanthemums, with flowers as large and of as good substance and form as those usually seen in November. These were plants from 15 to 24 inches high and grown in 48's, bearing one flower each—white, yellow, bronze, purple, and pink.

Possibly the most striking lot was a collection of fine specimens of New Holland plants—various Acacias, Brachysema, Eriostemon, Polygala, Kennedya, Correa. These were shown in excellent condition by Madame Leonie Oesterrieth, of Antwerp, who sent also a magnificent Rhododendron Gibsoni, a beautiful pink Metrosideros semperflorens, several hybrids of Azalea amœna, with a well-flowered specimen of Adenandra fragrans, all of which attracted considerable attention.

LINNEAN.

MAY 4.—Professor W. A. Herdman, F.R.S., President, in the Chair.

The first paper was read by Mr. R. N. Rudmore-Brown, B.Sc., on "The Botany of Gough Island, Part I., Phanerogams and Ferns," and communicated by Mr. W. B. Hemsley, F.R.S., F.L.S.

Gough Island, or Diego Alvarez, lies in the mid South Atlantic, lat. 40° 20′ S., long. 9° 56′ 30″ W., and may be regarded as the most outlying member of the Tristan da Cunha group, a small island between 7 and 8 miles long and half as wide, rising to a height of 4,000 feet. It has been occasionally visited, but never permanently inhabited. The chief features of the vegetation are the tree Phylica nitida and the Tree-Fern Lomaria Boryana. Four of the seventeen species of phanerogams are almost certainly introduced, while two, a species of Cotula and an Asplenium, are new to science. The Scottish Antarctic Expedition lay off the island for three days in April, 1904, but, owing to high seas, landing was only practicable on one day, when the materials for the present paper were collected.

The second paper was by Professor A. G. Tansley, F.L.S., entitled "The Study of Vegetation: its present condition and probable development." The word "Œcology," introduced by Professor Häckel, means the study of the vital relations of organisms to their environment, and by Professor E. Ray Lankester has been termed "Bionomics." Restricting his remarks to a special branch of the subject, the author proceeded to consider the plant-association as the unit, the great fact being the association of plants under definite conditions of environment. Instances were given of sets of plants found in meadows, woods, cultivated fields, moors, and dunes. The actual subject is not new, but the publication of Professor Warming's *Plantesamfund* in 1895, translated into German the following year as *Lehrbuch der Ökologischen Pflanzengeographie*, made it for the first time possible to estimate what has been done, and how much remained to be done. It was in this volume that the importance of the plant-association as the unit, was first brought clearly into view. A "plant-association" may be defined as the smallest aggregation of individuals belonging to one or more species living under definite conditions. A "plant-formation" is an aggregate of a higher order, usually including many associations and determined by more general conditions. These may be studied in many ways. Thus the detailed study of the unit; the species forming it and the causes enabling them to maintain their position; its phylogeny. Then the same methods with regard to the plant-formations, classed into groups and still larger aggregates. For these, help must be drawn from various quarters, anatomical and physiological research, the physical conditions, the meteorology and geology of the localities studied, and the experience of foresters and cultivators must all be utilised. These may be plotted on maps of appropriate size, in colours or symbols, thus constituting Phytotopography.

Considerable progress has been made with a "primary analysis" of the plant-formations of Great Britain by these surveys. The initiation of this work was due to the late Robert Smith, of St. Andrews, and since his death it has been carried on by his brother, Dr. William Smith.

Cultivation has naturally interfered with the wild plants, but man's power is limited, and the plants he cultivates must also be taken into account. Thus in the northern districts the upper limit of Wheat cultivation is an important piece of information; but where Wheat is stopped Oats may still succeed. When conditions have been altered by drainage, grazing, or the like, these, however complicated, must be investigated. The study is still in its infancy, but the author believes that it will occupy the attention of the coming generation probably during the next half-century.

Dr. G. Herbert Fowler communicated a paper by Messrs. E. W. L. Holt and W. M. Tattersall, on the Schizopoda captured in the Bay of Biscay during a cruise of H.M.S. *Research*, to which he has added an appendix dealing with the distribution statistically.

ROYAL GARDENERS' ORPHAN FUND.

MAY 11.—On the foregoing date the seventeenth Annual Festival Dinner of the Royal Gardeners' Orphan Fund took place at the Hotel Cecil, when the Earl of Mansfield presided. In compliment to his Lordship, he and the guests were led into the Banqueting Chamber by a number of Scotch pipers. Earl Mansfield was supported on his right hand by Herbert Hicks, Esq., and on his left by Dr. Maxwell T. Masters, F.R.S., also by Messrs. H. J. Veitch, Edward Sherwood, W. A. Bilney, Leonard Sutton, George Munro, and a large company.

Upon entering the room the scene was an unusually bright one, for the tables were profusely yet tastefully decorated with an extensive variety of plants and flowers now in season. When the Royal toasts had been enthusiastically celebrated, Lord Mansfield proposed the toast of the evening, "The Royal Gardeners' Orphan Fund," and in a very clear and businesslike speech stated the objects of the Fund and the work that is at present being accomplished. There are 105 orphans receiving full benefits, and 24 candidates for election, of whom 20 are already enjoying a considerable amount of relief. Of the 105 orphans on the funds, his Lordship found that thirteen came from north of the Tweed, but he reminded his hearers that these by no means represented the number of those on the funds whose parents or forbears were of Scottish nationality. Proceeding to speak of the claims there might arise for help from this Fund, his lordship said that gardening was a very wide profession; there were large gardeners, small gardeners, and stupid gardeners. Appealing for continued and increased support for the Institution, Lord Mansfield said that there was nothing like helping oneself in order to get others to help you. It is the duty of every gardener to contribute to this Fund, and also a matter of common foresight and providence. In conclusion, and speaking in reference to the scene at the dinner, his lordship said, "It is the most marvellous galaxy of beauty, I think, that I have ever beheld in my life."

Mr. Leonard Sutton, trustee, and a liberal supporter of this charity, responded in a suitable speech.

The next toast was that of "Gardeners and Gardening," proposed by Herbert Hicks, Esq., and responded to by W. A. Bilney, Esq. Mr. Bilney incidentally mentioned that it is new no uncommon thing for 100 visitors to see the Royal Horticultural Society's gardens at Wisley in a single day. Mr. Bilney had found that gardeners generally were honest, sober, and industrious men; but a gardener was "like a wife, you can only get one good one in a lifetime."

The toast of "The Visitors" was proposed by Edward Sherwood, Esq., and responded to by the Rev. J. C. Eyre Kidson.

Mr. David Laird proposed "The Press," and said that the company had a good, respectable, and premier laird of Scotland in the chair, and he as a wee "laird" had pleasure in proposing this toast and coupling with it the name of Dr. M. T. Masters, F.R.S., whom, said Mr. Laird, they in Scotland regarded with great respect as one of the leading figures in contemporary horticulture.

Dr. Masters, in response, said that the Press arranged, decorated, and set out to the best advantage the fruits and flowers of literature supplied by its contributors, and hence in replying to this toast they were in a measure blowing their own trumpets. Occasionally the Press tried to caution its readers from being over-confident in the matter of over-boomed Potatos, coreless Apples and other such things, but he assured those present that no part of the work the Press had to discharge was more agreeable to its representatives than that of advocating the claims of such institutions as the Royal Gardeners' Orphan Fund.

The Secretary, Mr. B. Wynne, stated that the Chairman's list, including the stewards' lists of donations, amounted to £825. This included a donation of £50 from Lord Mansfield, £100 from Mr. Sherwood, £50 from Mr. Leonard Sutton and numerous smaller sums from various contributors. Friends in Covent Garden Market supplied £136 8s. 6d. The total is £10 more than last year, and the sum last year was the largest that had been obtained on a similar occasion since 1896.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 11.—The annual general meeting of the above Society was held at the Coal Exchange, Manchester, on the above date. S. Gratrix, Esq., occupied the chair, and about forty members were present.

The Hon. Secretary (Mr. P. Weathers) read the report for the past year, which was adopted. The Society's financial position is in a satisfactory condition, and the work of the Society had been up to the average.

A. Warburton, Esq., of Haslingden, was elected chairman for the session 1905—1906: and E. Ashworth, Esq., of Wilmslow, vice chairman.

There was a capital display of plants at this meeting, good groups were shown by A. Warburton, Esq., consisting of some fine Odontoglossums, viz., a beautiful variety of O. × ardentissimum (Silver Medal).

Messrs. Cypher & Sons also received a Silver Medal for a good, showy collection of plants.

Bronze Medals were awarded to T. M. Crook, Esq., Morecambe; W. Thompson, Esq., Stone; and Ch. Vuylsteke.

Votes of Thanks were passed to Messrs. Laverton, Holmes, and Schofield.

S. Gratrix, Esq., Whalley Range, received an Award of Merit for Odontoglossum crispum var. Northern Star.

P. Smith, Esq., Sale, received an Award of Merit for a fine plant of Eriopsis rutidobulbon.

R. Le Doux, Esq. (gr., Mr. Davenport), received a Cultural Certificate for a fine plant of Odontoglossum vexillarium in a 6-inch pot, carrying twelve spikes.

The next meeting will be held at the Botanical Gardens, Old Trafford, on May 25. *P. W.*

THE BRITISH GARDENERS' ASSOCIATION.

A meeting organised by the North Ferriby and District Gardeners' Society was held on the 6th inst. It was attended and addressed by Messrs. Donoghue and Carter as Delegates from the Yorkshire branch of the British Gardeners' Association. Nearly all those present promised their support to the Association, which it was agreed would do much to raise the standard of the profession.

EALING HORTICULTURAL.

MAY 15.—This Society, which has been established forty-one years, held its first annual dinner on the above date, the Mayor of Ealing occupying the chair. The object sought by the dinner was to rally to the support of the Society many of the residents in the borough who have charming gardens, but who appear to be unaware that such a Society exists among them. The attendance was not large, but it is hoped that the publicity given to the proceedings will have the effect of bringing in a body of new subscribers. The annual exhibition, which is held early in July, has during past years suffered by comparison with those of fifteen years ago, and there is great need on the part of the gardeners who grow subjects for exhibition to raise their ideals to a higher level. The meetings of the Royal Horticultural Society have no doubt been the means of drawing off from the locality an amount of practical support formerly given to the local Society.

ROYAL BOTANIC.

MAY 17.—The usual show held by the Society on this date was a great success, the conservatory and corridor being bright with a display of flowers and plants, in addition to the usual occupants of the plant-houses. The show was well attended, Tulips were a feature; there were also exhibits of Rhododendrons, Gloxinias, Roses, Herbaceous and alpine flowers, Orchids, foliage plants, bright masses of zonal and show Pelargoniums, &c.

Mr. George Hobday, Market Place, Romford, brought his new Rhubarb Hobday's Giant, to which was awarded a First-class Certificate.

Messrs. Barr & Son, Covent Garden, London, had a most extensive exhibit of Tulips. They had the new variety Clara Butt in excellent condition, its soft rose-pink flowers are very handsome; Europe is of a splendid scarlet colour, Mrs. Moon quite one of the best "yellows," Viridiflora was noticed, also Zephyr, and Dainty Maid. Messrs. Barr also displayed a large collection of pigmy trees (Gold Medal).

Messrs. Hogg & Robertson, Dublin, staged a large group of Tulips, having representatives of most of the types, the May-flowering kinds predominating. We noticed Cleopatra, a handsome dark scarlet variety with a good interior base. There were a few Anemone flowers included in the display (Large Silver-gilt Medal).

Messrs. R. H. Bath, Ltd., Wisbech, had a grand display of Tulips in vases, the flowers, although not large in size, were in the best possible condition, and made an imposing exhibit. Mrs. Moon (yellow) was noticed, also many good forms of T. Gesneriana. Cordelia (rosy-mauve colour), Gala, Beauty, and John Ruskin are also worthy of mention (Large Silver-gilt Medal).

H. T. Pitt, Esq. (gr., Mr. T. W. Thurgood), Rosslyn, 57, Stamford Hill, London, N., showed a commendable collection of Orchids, having representatives of many genera, and not a few novelties. Odontoglossums were a feature, several receiving awards. A plant of Odontoglossum Wilckianum Pittiæ carried a spike with eighteen well-developed flowers; it was given a First-class Certificate. O. crispum Fairy Footprints is another good thing (Gold Medal).

Messrs. John Peed & Son, West Norwood, exhibited a big display of Gloxinias, having pot plants and cut flowers in boxes, relieved with sprays of Asparagus plumosus, small Palms, Ferns, &c., and finished with an edging of the golden Sibthorpia europæa. The same firm also displayed a group of Japanese Maples, in which were introduced flowering plants such as Clematis, Callas, Ceanothus, &c. (Gold Medal).

Messrs. Cannell & Sons, Swanley, Kent, also displayed Gloxinias, having some excellent forms of this showy flower. The plants were in 32-pots, and were well grown. The same firm staged vases of show

and zonal Pelargoniums. Phyllocactus C. E. Wilkins was shown in flower (Gold Medal).

Messrs. WM. PAUL & SON, Waltham Cross, showed a group of pot Roses, and boxes of cut flowers. Prominent were a number of trained plants of the new climbing variety Waltham Bride. It received a First-class Certificate from the Society. The variety Mrs. Edward Mawley was well shown, also a basket of cut flowers of Maréchal Niel (Large Silver-gilt Medal).

Messrs. T. S. WARE, Ltd., Feltham, Middlesex, brought an excellent display. They had Carnations in vases and in fancy stands, cut Roses, and an extensive exhibit of alpine and hardy plants. Among the Carnations was the new white variety, Lady Bountiful. A grand spike of Eremurus Elwesianus was shown (Silver-gilt Medal).

Messrs. JOHN WATERER & SON, Ltd, exhibited several pot-plants of Rhododendrons in flower. The variety George Hardy has large, lax inflorescences of pale rose flowers. A number of Japanese Maples were worked into the group (Large Silver Medal).

Mr. AMOS PERRY, Winchmore Hill, London, N., brought many good things, including Tulips, herbaceous plants, alpines, &c. Among the Tulips we noticed excellent flowers of Sultana, an almost black variety; Phlox canadensis Perry's variety is an improvement on the type. It was given a Certificate of Merit by the Committee (Large Silver-gilt Medal).

Mr. G. REUTHE, Keston, Kent, staged, in addition to a large collection of alpine and hardy flowers, a group of Tulips that contained many good things, among which was a handsome scarlet variety named Whistler that received the Society's Certificate of Merit. Among the hardy plants was a collection of hardy Orchids. Iris Susiana was shown well (Large Silver Medal).

Mrs. SMYTHE, Tobarcooran, Carmoney, Belfast, showed vases containing varieties of St. Brigid Anemones.

Messrs. W. & J. BROWN, Peterborough, displayed a number of greenhouse plants, Pelargoniums, Verbena Miss Willmott, Carnations, Roses, &c. (Silver Medal).

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed a new Cucumber named Delicacy. It was raised from Matchless × Aristocrat. The fruits are of very dark colour and about 14 inches in length. It received a Certificate of Merit.

For "Gardeners' Debating Societies" and "Schedules Received," see p. x.

Answers to Correspondents.

*** EDITOR AND PUBLISHER. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

AMARYLLIS BELLADONNA: *C. C.* Your plants need to be taken out of the soil and replanted. This work may be done directly after they have flowered, or in July, when growth having been completed for some time, the bulbs will soon commence to make fresh roots. Before replanting take away the old soil and replace it with a compost of turfy leaf-soil and sand in about equal parts. Plant the bulbs quite 6 inches deep, surrounding each bulb with a little sand. The best position for the Belladonna Lily is one on a border facing to the south, and if the border is close to a hot-house wall, so much the better. When the bulbs have been planted as advised they will not need to be moved again for some years, but after becoming established they should flower better each season.

BERBERIS DARWINII: *R. B., Bucks.* Sow the seeds out-of-doors early in autumn as soon as they ripen, and they will germinate in the following spring.

BOOKS: *W. B. S.* Not specially for market growers, but you will find *The Book of the Carnation*, by R. P. Brotherston, very useful and reliable. It is obtainable from our Publishing Department, price 2s. 9d. post free.

CARBOLIC ACID: *R. L. P.* We have previously recommended that extreme care be exercised in the use of this acid for the prevention of the Cucumber disease. If your house contains a mixed collection of stove plants, it would be safer to remove them before employing the acid.

CATTLEYA: *T. W.* The malformation is not uncommon. The flowers are regular without a lip and the segments are in pairs. It is not uncommon, and has been frequently illustrated in the *Gardeners' Chronicle*.

CRICKETS, COCKROACHES, &c.: *W. W. and C. R., Leyton.* These can be destroyed by phosphoric poisoning. Smear some phosphorus paste on to pieces of bread, and place these on the stages and round about the plants. Another good plan for trapping these and similar pests is to roll garden mats and place these on the hot-water pipes under the staging. Allow the mats to remain during the night, and in the morning examine them, when numbers of insects will be found hidden in the folds of the mats.

CROQUET LAWN: *G. H. B.* The present season is too far advanced for an application of basic slag to be effective, and especially as the lawn is required for play in July. We would, therefore, recommend that a manurial mixture be made of three parts of bone-meal and one part of soot, and that 8 oz. of this mixture be applied per square yard on a damp day, or just before rain, that it may be soon washed in. A little sand may be mixed with the manure. We would not advise soil, as this will adhere to the shoes. Next autumn, immediately after the playing season is over, give a dressing of 1 lb. of basic slag to each square yard of lawn, to which finely-sifted soil may be added. A small quantity of basic slag is of no use to begin with, as it is a slowly-acting manure. The second year an application of ½ lb. of basic slag per square yard will be sufficient, and the third year 4 oz. per square yard will be enough. In early spring give an application of soot during damp weather, so as not to burn the grass, or 4 oz. of sulphate of ammonia mixed with sand per square yard will be beneficial.

DOUBLE-FLOWERED GORSE: *J. G.* The common Gorse always suffers more or less after transplantation. It is a good practice therefore to increase the double-flowered form by inserting cuttings in pots in a cold frame, keeping the plants in pots until they are required for planting into permanent positions.

ECONOMIC PLANTS: *A. W. St. Leger, Transvaal.* You had better subscribe to the *Tropical Agriculturist*, published by Messrs. Ferguson, Colombo, Ceylon.

FRUIT DISTRICT: *J. G.* In Cheshire and the neighbouring county of Shropshire a very large quantity of Damsons is grown, and this is probably the nearest district to Liverpool.

HOLLY BERRIES: *R. W. P.* It is unusual for the berries to hang so long. The birds no doubt have found other food plentiful in the neighbourhood.

HUMEA DISEASE: *W. E. P.* The plants are affected with a fungus for which up to the present time no cure has been forthcoming. The moment they are observed to droop at their inflorescences they should be removed, and the plant and soil burned to prevent the disease from spreading.

LEAVES: *G. K. C.* The leaves appear to have been eaten by mites. Dip the plants in tobacco-water, and syringe them with clear water after a short period.

LILY DISEASE: *W. H. G., Churchill.* Too common. Dig up the bulbs and sift flowers-of-sulphur all over them, getting as much of the sulphur between the scales as possible.

NAMES OF PLANTS: *J. K. B.* 7 and 8, both forms of Aubrietia deltoidea; 9, Olearia stellulata; 10, Saxifraga moschata rhei; 11, Pulmonaria officinalis; 12, Doronicum caucasicum.—*J. M.* The Norway Maple, Acer platanoides; Dendrobium nobile.—*A. Y. L.* 1, Nepenthes Mastersiana; 2, N. Wrigleyana; 3, Dendrobium Pierardi.—*J. W.* 1, Kerria japonica, fl.-pl.; 2, Spiræa hypericifolia.—*E. W. K.* Prunus Padus, the Bird Cherry.—*J. H. H.* Kerria japonica, double-flowered var.—*F. B., Balham.* Ornithogalum arabicum. — *Onager.* Woodfordia floribunda.—*H. R.* Odontoglossum × Adrianæ. Some check at the roots has caused the Camellia buds to drop.—*J. K., Brandon.* 1, Nephrodium molle; 2, Pteris serrulata cristata; 3, Asplenium bulbiferum; 4, Lastræa filix-mas; 5, Cephalotaxus pedunculata; 6, Thuya orientalis var.—*J. M., Notts.* 1, Dendrobium nobile; 2, Spiræa ariæfolia; 3, Berberis Darwinii; 4, Pyrus Malus floribunda; 5, Eranthemum leuconeurum; 6, Oxalis Bowiei.—*Japonica.* Jasminum pubescens and common Dodder (Cuscuta). — *D. C. W.* Mesembryanthemum acinaciforme.

NARCISSUS, ABNORMAL: *J. C.* Not an uncommon occurrence. It is due to fasciation.

NEWLY-PLANTED VINES: *W. H.* We assume that the Vines were planted not later than October last in a inside border. They will have been cut down in winter to 3 or 4 feet in length, more or less, according to the construction of the front of the house. They should not be allowed to carry more than one or two small bunches of fruit each. Disbudding should be done, leaving only the strongest shoots at distances of about 18 inches apart on each side of the canes. Stop the leading shoot when it has made three or four buds beyond the required length, but otherwise the laterals should be allowed to grow as freely as space will allow to encourage the plants to make an abundance of roots, and thus provide themselves with a good foundation.

PEACH MILDEW: *A. P.* The fruits are attacked by a fungus. Collect and burn all such fruits, and spray the trees and remaining fruits with potassium sulphide in the proportion of half an ounce to a gallon of water.

SEED-POD: *G. W. W. & Co.* Probably the capsule of an Iris, perhaps I. pseudo-acorus.

SYRINGING VINES: *R. P. E.* The general practice is to discontinue the syringing of Vines when they commence to open their flowers. In exceptional circumstances and in certain districts good may possibly result from syringing them again after the berries have set and until they are about to develop colour, but if there is much lime in the water that would be so used, the injury caused by deposit would more than counterbalance the gain. Frequent damping of the surfaces in the house are however essential.

TULIPS DISEASED: *J. P. L.* The plants are affected with the Tulip fungus, Botrytis parasitica. Burn all diseased bulbs, and take away the surface-soil, replacing it with fresh soil mixed with lime.

VARIEGATED HOP: *I. B.* If you have plants already of this variety, you can easily increase the stock by division in the spring.

VINE LEAVES: *V., Glasgow.* There is no disease present due to a fungus. The spots are the result of some cultural defect. Good ventilation early in the day will have a markedly beneficial effect.

VINES: *Director.* From the circumstances described in your letter it would appear that the medium in which the roots are growing is unsuitable. The soil may be too heavy, and therefore retentive of water, or it may be that no proper system of drainage has been carried out. Nothing short of an examination made on the spot can settle these points.

WISTARIA: *W. R. W.* We can only suggest cold nights and drought at the roots.

THE MUTATION THEORY.

THE first edition of Darwin's *Variation of Animals and Plants under Domestication*, which appeared in 1868, came in the light of a revelation to gardeners and plant-lovers. Up to that time—we are, of course, speaking in general terms—scattered observations on variations in plants and animals had been recorded in the various journals connected with natural history and gardening; but few had attempted to co-relate them, to compare them one with another, and to deduce from them any general conclusions. Darwin did this, and in consequence the "fanciers," "the florists," the discoverers and recorders of "freaks," found themselves suddenly promoted in their degree to the ranks of scientific observers. Their observations, made, it may be, from little other motive than curiosity or ignorant wonder, were suddenly found to be of value as affording facts in support of the great theory of evolution. Moreover, the heretofore disconnected phenomena were found, when duly co-ordinated, to be not only of theoretical value, but of practical importance also. People even now are to be found who sneer at what they call theory and disparage it in comparison with facts. Such people do not realise that a theory, to justify its name, must be based entirely on facts. By its aid the significance and value of observations are brought to light and their importance gauged. If the facts are imperfectly or incorrectly observed and badly co-ordinated, there can be no true theory till these defects are remedied. Darwin's book, to which we have made allusion, was issued in response to the demand for evidence. His *Origin of Species* had been published some years previously. It roused a storm of antagonism, and even those most disposed to agree with his views, saw the necessity for the publication of the evidence on which the great naturalist had framed his version of the doctrine of evolution.

That evidence was forthcoming, and gradually the conviction was forced on naturalists that the theory of evolution afforded the best explanation of the facts and phenomena of the material world that had heretofore been propounded. Without going into details unnecessary for our present purpose, it will be remembered that what, for convenience sake, we call "species" were shown to have originated from pre-existing species, just as succeeding individuals are derived from their predecessors. The development of new species was shown to be a very slow and gradual process. Variations in abundance are produced, but only those favourable to the individual or to the species in the circumstances in which they are placed at the time, are capable of surviving, the rest succumb and are obliterated. Hence the expression "survival of the fittest"—an expression that does not connote the preservation of what is absolutely the best but of that which is the best adapted under the conditions of time and place to hold its own among its rivals and competitors, or to come to the front in the battle of life. All this is well understood nowadays, and we allude to it merely to emphasise the exceeding slowness with which, according to this view, changes occur, and, as a consequence, the long period of time which is required for the formation of a new species.

Be this as it may, no one knows from experience better than the gardener that these changes are not all so slow in their progression. He is familiar with sudden variations among seedling plants, and especially in buds or shoots, to which variations he applies the word "sports." The explanation of bud-variations, when the conditions have apparently not changed, is not easy. Sometimes they may be looked on as due to reversion, or "harking back" to an ancestral condition which has become "recessive" or latent till some circumstance, we know not what, renders them again "dominant."

At other times, as we have often shown in these columns, the "sporting" is due to the loosing or separation of characteristics previously blended by cross-breeding, or, as would now be said, by the sudden dominance of what had previously been recessive.

The notion that such "sports" are or may be the beginnings of new species, was, till lately, not generally entertained. Of late years, however, Professor Hugo de Vries, who honoured us by his presence at the first Hybridisation Conference held at Chiswick in 1899, has brought forward evidence in support of his theory of "mutation," in which he assumes that new species and varieties are produced from existing forms by sudden leaps. Like Darwin, De Vries has produced his evidences, and they are before us in the shape of a book, to which we desire to call the attention of our readers.*

Professor de Vries had previously published his theory in a book written in German, and entitled *Die Mutations Theorie* (1901—1903). American and British readers will be pleased to have the Dutch Professor's views put before them in their own tongue. The book just published contains the substance of certain lectures delivered before the University of California. The purpose of these lectures was "to point out the means and methods by which the origin of species and varieties may become an object for experimental enquiry in the interest of agricultural and horticultural practice, as well as in that of general biologic science."

Starting from the same class of facts as Darwin did, De Vries endeavoured to gain demonstrative proof of the correctness of his views by methods of practical cultivation and careful record in the form of pedigrees. His attention was first aroused to the subject by the sudden "mutations" he observed in the Evening Primrose (Enothera Lamarckiana. According to the Professor, at a certain stage of its existence this plant (as well of course as others) throws off new varieties which under cultivation are found to behave as species.

These "new species" are not produced once or in single individuals, but yearly and in large numbers. Further, they are, he says, produced only at one period within the lifetime of the species, and probably it is only in a small part of it. This may account for the fact that this wholesale mutation had not hitherto been observed. The plant in question grows here in neglected gardens and waste places almost as a wild plant, and we have seen a large area covered with it under these circumstances without perceiving that amount of variation which would justify the belief that a new species was in process of sudden evolution. But of course negative statements are of no value and we allude to them here only to emphasise what Professor De Vries says as to the periodicity of the change. His own experiments and those of Dr. Macdougal in the New York Botanic Garden and of others leave no doubt as to the existence of the changes. Comparative observation is less important from this point of view than direct experimental evidence, but for all that it would be well to submit the specimens of the supposed new species to botanists in various countries for their opinion.

In olden times it was the genus that was looked on as the unit, then came the species, now it is the turn of the variety. It looks as if the analysts (irreverently termed "splitters") were to hold the fort, whilst those given to synthesis (the "lumpers") were to be deposed.

It is needful, however, to state that De Vries recognises two sorts of species—the "systematic species," which are the practical units dealt with by systematic botanists, the limitations of which are more or less arbitrary, and what he calls "elementary" species, the nature of which is not very clearly defined, which, indeed, may not be recognisable either in the field or in the herbarium, but which may be detected by "pedigree cultivation." Any form, says the

* *Species and Varieties, their Origin by Mutation.* Lectures delivered at the University of California by Hugo de Vries, Professor of Botany in the University of Amsterdam. Edited by D. T. MacDougal. (London: Kegan, Paul, Trench, Trübner & Co., 1905.)

author, which remains constant and distinct from its allies in the garden is to be considered an elementary species. This raises a difficulty at once. The species may be constant enough in one garden, it may be very variable in another under different conditions.

In the interests of science whatever supplies the nearest approximation to the truth must survive the longest, and in the process of enquiry the pendulum may swing now to one extreme and then to the opposite, according to new discoveries and the more complete explanations of known phenomena. These forms must be named, and herein lies one prodigious inconvenience to the practical cultivator in the constant "mutation" of names, or the equally frequent formation of new ones.

It would seem as if gardeners in practice must, to avoid this inconvenience, adhere to the established nomenclature so far as such a thing exists, and leave scientists to alter their nomenclature as new light dawns upon them or as it suits their purpose. The objection to this procedure is that by so doing we deliberately obstruct or ignore the progress towards the truth, and that involves a responsibility which no conscientious man cares deliberately to face. It is true that "species," as we now think of them, often embrace a whole series of minor forms, which are either deemed to be varieties or are ignored. These may be species in the making. Professor De Vries goes a step further, and declares them to be made. That is a matter of individual judgment. The facts are notorious, their interpretation varies with the experience and the prepossessions of the observer. When, as in Professor De Vries's case, experimental proof is obtained, opinions and prepossessions are put out of court. It therefore behoves those interested to study with all care the merits of Professor De Vries' statements, and to repeat wherever possible his experimental work under as many different conditions as possible. The twenty-eight lectures reported in this volume are obviously too numerous and too diversified as to their contents to allow us to enter into detail concerning them. They comprise the general historical introduction to the subject, the question of "elementary species," of retrograde varieties, of stability, and atavism, cross breeding, roguing (elimination), latency, the discussion of Mendel's law, sports and malformations, adaptations, mutations, fluctuations, experimental pedigree-cultures, artificial and natural selection. The special value of Dr. De Vries' labour resides in the experimental proofs he has demonstrated by systematic and long-continued cultivation.

There are no illustrations. These are not always needed by the botanist who is more or less familiar with the examples mentioned, but to novices, good comparative illustrations would be of great assistance. Bibliographical references again are not supplied as freely as might be desired. Lastly there is what is of course indispensable in such a book—a copious index.

Since the appearance of Darwin's work, covering somewhat similar ground, there has been no book of such interest to those interested in the biological side of horticulture as this, nor one so full of promise in all matters relating to the maintenance of the purity of old breeds or the production of new strains.

ODONTOGLOSSUM CRISPUM "SOLUM" (SYN. CALLISTOGLOSSUM, CRAWSHAY).

THIS remarkable form, the property of W. Thompson, Esq., of Walton Grange, Stone, Staffs, was originally named "solum" by him, and under that name was noted in your issue of March 25, 1905, on p. 181 by Mr. O'Brien. Though the word "solum" would mark the variety as unique, it occurred to me that "callistoglossum" would better describe it, and when at Stone on April 11 last Mr. Thompson acceded to my request to be allowed to rename it, which I now do. The extraordinarily deep, solidly coloured lip of intense claret-purple-brown, and

FIG. 134.—ODONTOGLOSSUM CRISPUM "SOLUM" (SYN. CALLISTOGLOSSUM, *Crawshay*).

the column, the whole of which, down to the very base, are the distinguishing features of this remarkable form. There is one more similar coloured spot in a sepal of the second bloom (or left side), otherwise it is unspotted. Mr. W. Stevens's photograph reproduces it perfectly. *De B. Crawshay.*

[The plant having been exhibited and recorded under one name, that name must be retained; but if individuals elect to employ another name, it must be as a synonym only, which others are not bound to accept. If the abbreviation "var." is used, the termination must be feminine—"a"; if the abbreviation is not used, the neuter "um" is more appropriate. This seems pedantic, but it is well to have rules and to stick to them. Ed.]

ABELIA UNIFLORA.

The genus Abelia consists of half-a-dozen species, natives of the Western Himalayas, China, Japan, and Mexico. They are all showy, decorative, free-growing shrubs, but are rather too tender for general cultivation in the open garden except in the milder parts of the country. In such mild localities few plants are more easily grown, and they make excellent subjects for the shrubbery border or as single specimens on the lawn. In many parts where they fail to thrive in the open they will do so against a wall, such species as A. floribunda and A. chinensis flowering profusely when treated in this way. In all cases it is essential to have the border in which they are grown well drained, as they require abundance of moisture at the roots at all times, but especially during the summer, when growth is taking place. They do well in almost any class of soil, provided it is of a porous nature.

By well thinning-out the old growths after the flowering period is over, the plants should be encouraged to make strong shoots from the base each season. Apply weak liquid or chemical manure to the roots of the plants until growth has finished; the plants will then furnish a profusion of flowers during the following summer. Propagation is easily effected by cuttings made from half-ripened growths, and inserted any time during the end of summer or autumn.

The illustration at fig. 135 of A. uniflora was prepared from a plant in the garden of F. D Godman, Esq., of Horsham, Surrey, where, at the time of my visit in May of last year, a large specimen plant was in full flower. It was growing in partial shade amongst Rhododendrons and other shrubs on the bank of a small brook, and formed a spreading bush some 7 or 8 feet in diameter, and about 6 feet high, the long arching growths being loaded with flowers. Although its flowers cannot compare individually with those of A. floribunda, either in size or in colouring, yet they are produced so abundantly that the whole plant becomes a sheet of white, many of the branches arching over to the ground with the weight of flowers. The habit of the plant is to send up strong growths each season from the base, the upper portions of which give off numerous short axillary branches from which the flowers are produced during the following season. The flowers are shortly pedicellate, and are borne in pairs on the ends of the short branchlets. They are pure white in colour, with the three lower lobes and the throat of the corolla prettily net-veined with yellow. They are three-quarters of an inch in diameter and one inch in length. A. uniflora is a native of Japan, also of the Chinese provinces of Fokien, Hupeh, Szechuen, and Chungking. It is figured in the *Botanical Magazine*, t. 4694; *Botanical Resister*, 1846, sub.-tab. 8; also under the name of A. serrata in Siebold and Zuccarini's *Flora of Japan*, vol. i., p. 76, t. 34. In the 1900 *Supplement to the Dictionary of Gardening*, A. serrata is erroneously referred to as A. chinensis. *C. P. Raffill.*

Fig. 135.—Abelia uniflora: flowers white, tube with yellow veins.

KEW NOTES.

Lissochilus ugandæ, *Rolfe.* — A new and exceedingly pretty species from Uganda is now flowering in the warm Orchid-house. The tubers were collected by Mr. J. Mahon, late Curator of the Botanical Gardens, Entebbe, Uganda; they were sent to Kew at the same time as L. Mahoni (see *Gardeners' Chronicle*, p. 250) namely, at the latter end of 1902. L. ugandæ is a much smaller-growing species than the one named in honour of the collector. It has erect linear, acuminate leaves, which are from 1½ to 3 feet in length, from ½ to 1 inch in width, and somewhat coriaceous in texture. The flower-scape is 3½ feet in height, and about as thick as an ordinary lead-pencil. The flowers are rather closely arranged at the apex of the scape, the total number on the specimen now in bloom being twenty-one, all of which are fully expanded, those which were first open some weeks ago being still quite fresh. The sepals are spatulate in form, the two lateral ones being twisted in such a manner as to arrange them in an upright position beside the dorsal sepal; they are 1 inch in length, light yellow in colour, and tipped with red-brown. The petals are oblong, rather less than an inch in length, curved closely downward over the labellum, and of a bright yellow colour. The lip is also yellow, prominently crested, and prettily marked with bright green veins, reminding one of the markings in the flower of Chloræa virescens.

Medinilla magnifica, *Lindl.*

Several handsome specimens of this lovely Melastemaceous stove plant are now making a fine display in the Palm-house, one large bushy specimen measuring 6 feet in height and about the same measurement in diameter. It has upwards of sixty of its large pendulous rose-coloured inflorescences.

Medinilla magnifica var. superba.

This variety is also flowering in the Palm-house. It differs from the type in having larger leaves, and also a larger inflorescence. The plant now in bloom has a measurement of about 4 feet each way, and is carrying twelve large racemes, the flowers of which are of the same colour as those of the species. Some of the racemes are 16 inches in length, and the stalk by which they are suspended 8 inches in length, giving a total of 2 feet for the complete inflorescence, which in general outline resembles a bunch of Grapes. The leaves of this variety are sometimes as much as 15 inches long by 9 inches in breadth. To illustrate the rapid growth of this fine plant, it may be mentioned that this particular specimen two years ago was a small plant with just two leaves, and contained in a 3½-inch pot. *W. H.*

BOOK NOTICE.

L'Hybridation des Plantes. Par Raphael de Noter. (Charles Amat, 11, Rue Cassette, Paris.)

The author of this little paper-covered volume of about 180 pages is a writer who has already contributed quite a series of books on gardening and allied subjects. The one now under notice is perhaps a little more pretentious in style than some of the others, which are but pamphlets. *L'Hybridation des Plantes* is a compact little manual that will no doubt be useful to gardener and amateur alike. Its aim is to point out clearly all the operations connected with the cross-fertilisation of flowers so as to produce novelties of improved and varied forms. There are in the opening chapters various instructions concerning the structure of flowers in general, the best subjects to deal with, and details as to the pollen, its application and action.

Then follow thirty-four chapters, in which plants are classed according to their families; and here of course the subject-matter deals particularly with the flowers included in each heading. Growers of some of the popular subjects who understand French may find such a work interesting and instructive, inasmuch as it is intended for those plants that will grow in the north of Europe. At a glance we notice that such things as Asters, Dahlias, Chrysanthemums, Pelargoniums, Tulips, Lilies, Cyclamens, Violas, &c., are all the subject of instructions; while there are many other plants in the various families mentioned about the cross-fertilisation of which less is generally known by the amateur, but which it will be very acceptable to have in so compact a form as this little 12mo volume supplies. The author has not been sparing of illustrations explanatory of the text, and the book, which is neatly printed, costs but a couple of shillings.

TRELISSICK LILY-POND.

OUR illustration (fig. 136) gives an excellent view of a pond in Trelissick Gardens, the banks around which are crowded with plants of the common white Arum (Richardia). Mr. Sanguin, who sends us the photograph, says: "Several views of this pond have already been published, but I think the accompanying photograph gives a better idea of the luxuriant and extensive growth of the Arums than either that has previously appeared. The unbroken border of Arums covers considerably over 300 yards, and when at their best from 7,000 to 10,000 flowers may be seen open at one time. The deep water-side is margined with hybrid Nymphæas, and the land side is backed by immense masses of Gunnera manicata, Pampas Grasses, Golden Willows, Bamboos, Japanese Irises, and many other water-loving plants, amongst them being great numbers of a very fine strain of Primula japonica of all colours. The Arums extend and propagate themselves; large pieces often break away from the sides and are blown across the deep water into the shallow mud at the upper end of the pond, where they anchor themselves, and grow well without further care or trouble." *W. Sanguin, Trelissick, Truro.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

MANURE-WATER AND PEACH-TREES.—Mr. Moore is of opinion "that if well-made borders consisting of loamy, naturally fertile soils, even when the staple is light, sandy, and shallow, are dressed annually with light, well-rotted stable-manure, but little more is required beyond affording plain water several times during periods of drought in the months of July, August, and September," adding, "that in wet summers even these applications are better withheld." Mr. Moore says, "he has in his mind only trees grown in the open-air," adding, "that the conditions are very different under glass, and that heavy applications of water more frequently afforded may be called for to assist the growth of shoots and give greater size to the fruit if the crop be an abundant one." I hope Mr. Moore will pardon my saying that it is owing to the fact of such views as he has advocated regarding the cultural requirements of Peach and Nectarine trees growing in the open-air—i.e., against walls having south and west aspects—having been carried out in many parts of the country by free-and-easy-going people (I will not say fruit-growers), that the bare, stunted, short-lived, unproductive specimens of the Peach that are frequently met with are to be attributed. This condition of the trees is put down to every cause but the right one. Of the correctness of this assertion I am thoroughly convinced, as the result of long and extensive experience in, among other branches of gardening, Peach-culture in the open. I had in my charge about 250 yards of walls from 9 to 12 feet high, and having south, south-west, west, and even east aspects, furnished with healthy, fruitful trees from base to summit. As soon as the pruning and training of the trees were completed, the surface of the soil was pricked over with a digging-fork to the extent of about 3½ feet or so from the stems of the individual trees on either side and out from the wall, and then mulched with well-rotted stable-manure and afforded a good watering of clear water, applied with the hose from a streamlet close by. This was done some time in February, the operation being repeated at frequent intervals up to within a week or two of the ripening of the fruits. Doses of liquid-manure took the place of plain water after the fruit had stoned, and in some cases before. The results in the way of vigorous, free-growing trees bearing heavy crops of extra large, well-ripened, luscious fruit amply repaid the care and labour bestowed upon the trees in the matter of watering, disbudding the young growths in due time, and keeping the foliage free from the attacks of aphis and red-spider. I know as a fact that the borders in which Peach trees are growing in front of walls facing south or south-west are as a rule "dust-dry," a foot or 15 inches below the surface, 4 or 5 feet away from the wall. In the process of excavating soil for footings for a Peach case 5 feet wide from the wall, I found this to be the case in the autumn following what might very well have been called a wet summer. This discovery led to my giving additional consideration to the natural condition of the soil, say a foot below the surface of the borders in front of south and even west walls, and afterwards induced me to make frequent applications of water to the roots of the trees growing therein. It is unreasonable to expect the soil of such borders as I have mentioned to benefit to any material extent from rain, say to a width of 5 feet from the wall. As the surface is hard and sloping southward, the rain falling thereon runs off into the looser soil farther out from the wall, even when the rain comes from the south. When it comes from any other point it has very little effect beyond wetting the surface of the soil. Moreover, consider the great power of absorption possessed by bricks and mortar, and the additional drainage thereby afforded! In short, it is almost impossible to keep the soil about Peach trees planted in well-drained borders or holes in front of the walls indicated above, too wet at the roots. The cause of most, if not all the draw-backs complained of from time to time in connection with unsuccessful Peach culture out-of-doors may truthfully be put down to the opposite extreme, the soil being kept too dry. Mr. Moore, as quoted above, says that under glass culture the conditions are very different from those in the open-air, and that therefore more free applications of water at the roots are necessary to assist the growth of shoots and swell up the fruits. True, the conditions are different in so far that the trees are growing under glass, and that a more uniform atmospheric temperature can be afforded them than it would be possible to give them in the open; but the cultural requirements as regards moisture at the roots, the application of manure-water at short intervals to assist the growth of shoots, and to give greater size to the fruit if the crop be—as should always be the case under good management and generous treatment—an abundant one, are the same as in the case of trees grown in the open-air. It is quite wrong to infer that the flavour of extra fine specimens of the Peach suffers in consequence of the fine size of fruit and the great depth of flesh. Can any practical reason be adduced to show why the flavour of well-grown fruits of, say, Hale's Early or Royal George Peach, turning the scale at from 12 to 16 oz., should be inferior in quality to that of fruits of the same varieties weighing respectively 10 and 12 oz.? Your correspondent objects to affording liquid-manure to the roots of lightly cropped Peach-trees upon imaginary grounds—namely, the supposed production of "strong willowy shoots that never ripen." No practical fruit-grower would allow such shoots to form part of his tree; he would cut them clean out. In the last paragraph of your correspondent's letter, gardeners are recommended, instead of following the advice given by Mr. Muir and myself in the *Gardeners' Chronicle* for April 1, to empty the contents of their overflowing manure-water-tanks on to such gross-feeding vegetables as Celery, Asparagus, Cabbages, Cauliflowers, and the like, and to aged Pear and Apple-trees. Surely this advice will not find many followers. To water Celery, Cabbages, &c., with the contents of manure-water-tanks in the autumn, winter, or spring—what for? *H. W. Ward, Rayleigh.*

FIG. 136.—RICHARDIAS GROWING IN THE OPEN AT TRELISSICK, CORNWALL.

GARDEN PATHS (see p. 226).—I must take exception to the advice given to make garden paths and roads of asphalt, and to the unnecessary expense involved in the method of making the roads recommended by Miss Turnor. At one time asphalt was popular, especially for use upon small paths, but it has fallen into disrepute owing to the objectionable smell it has during summer, and in the case of roads to the slippery nature of the surface during frosty weather. No material can equal gravel when properly laid, except it be pulhamite, and in some cases this is objected to on account of its hard surface and the cost of laying. There are few gardens now into which gravel cannot be brought by road or rail. That gravel paths are not always satisfactory is often because they are laid badly or laid at the wrong season of the year. In regard to the cost of making roads, Miss Turnor says excavate the road 2 to 4 feet deep, and fill in with stones, &c., one-third; this, taking the maximum depth, means 1 yard [1⅓ feet, ED.] deep of stones, and a third of smaller material such as broken granite. In this neighbourhood I cubic yard of granite costs 13s. Who would think of putting finer material to the depth of 1 foot on the top of a yard [1⅓ ft.] of coarse stones! If the base of the road when made is formed in the same manner or shape as the finished surface, and a drain laid on each side of

a wide road where necessary, a depth of 18 inches at the most is ample for drainage, placing of course the rougher material at the bottom, and even breaking the surface stones as they lie is sufficient. Before putting on the surface layer of gravel roll the stones thoroughly with a heavy roller to get the necessary shape and to fill in the interstices somewhat, so that less gravel will be swallowed up in them than would be the case where the gravel is laid on the loose surface. This is a much more economical method of road making than that advocated by Miss Turnor, and is similar to that which was carried out here twenty-five years ago. The roads have since borne all kinds of heavy traffic, such as traction-engines with 12-ton laden trucks, and have never required more than a surfacing of gravel very occasionally. Much depends upon how the base-water is taken away, as well as how that from the surface is treated. In the case of wide roads it is best to have a drain on each side, but in roads of not greater width than 10 feet, especially in ordinary garden-paths, one drain is sufficient, and this should be made in the centre. The catch-pits at the side should be properly made, and served with smaller outlet-pipes to the main drain. This system is a saving of one large drain, as well as labour. Socket or flanged pipes should always be used and put together with cement for the main drains. For the connecting drains ordinary land pipes may be employed close to the catch pits, for main drains where there are roots near the ordinary land drain-pipes with no socket quickly become choked with roots. It is surprising how quickly these will penetrate the small space between two pipes. On carriage-drives with a steep gradient, where the sides are sure to be washed with heavy rains, a channel should be formed on each side with cement and rough clean washed gravel to imitate the colour of the road as nearly as possible. These channels should be made 10 inches wide and about 3 inches deep in the centre. Such channels answer capitally if catch pits are arranged in them at convenient distances to carry off accumulated water. *E. Molyneux.*

MECONOPSIS INTEGRIFOLIA.—Judging from what "E. H. W." says in his article in the *Gardeners' Chronicle* for May 13, and taking into consideration our own observations on the subject, there seems no room for doubt that the plants grown under the above name by Messrs. Veitch and by the Co-operative Bees (late Messrs. A. Bee & Co.) respectively are dissimilar in some more or less marked details. The most notable difference is the varying length of the style. In the case of the plants which flowered at Ness last year, the style was in no instance less than five-sixteenths of an inch in length, while the longest noted was quite three-quarters of an inch from the base of the stigma to the apex of the capsule. These measurements, however, must be taken only as approximate, since the line of demarcation between style and capsule was never sufficiently well marked to enable one to determine *exactly* where the one finished and the other began. A second slight difference is visible in the stigma—that of our plant is more conical in shape than flat; while a third distinction is noticeable in the capsule, which in the illustration on p. 291 is decidedly angular, and only sparsely hairy, differing in these particulars from our plants, which have more rounded seed-vessels densely clothed with stiff long hairs. There is surely nothing in the description quoted from the *Gardeners' Chronicle* for September 17, 1904, to warrant the application of the term "scapigerous" in describing the inflorescence of our plant. Certainly the portion italicised might be applied in a description of the "Iceland Poppy," but no one would venture to say that the inflorescence of Papaver nudicaule was "scapigerous." Surely the inference is mistaken. We have nowhere made the statement that "Meconopsis integrifolia will not seed in England." In the article accompanying the excellent coloured illustration of our plant in *Flora and Sylva*, part 24, Mr. Bulley says: "My plants, even with artificial pollination, have *so far failed* to produce good seed; and from Messrs. Veitch's recent advertisements of "seeds collected in China," it seems possible that they have had no better luck in their drier and more southern position." Should Messrs. Veitch be successful in collecting seed from home-grown plants this year we shall be more than glad, since it would foster the hopes we entertain of saving seed from our "variety," as well as from M. grandis, which, though so far a good perennial with us, has not developed any seeds. There are other apparent differences between our M. "integrifolia" and that imported by Messrs. Veitch, which are only noticeable when the plants are seen growing side by side as we have them here. The chief of these are, first, the more numerous and narrower leaves produced by our plant; secondly, the colour of the hairs on the leaves. While the Chinese plants of Messrs. Veitch are clothed with brownish hairs, the hirsute covering on the leaves of our plants from Central Asia, especially when the latter are about to flower, presents a charming silvery, silky appearance. Referring to the note on the root-system of the plants at Langley and of the dried specimens, it may be interesting to know that our plants produce a decided "tap-root." In the case of our strongest plant, which succumbed after flowering, the "tap" was some 3 or 4 inches in length and rather over 1 inch in diameter in the thickest part, which was just below the tuft of leaves. A continuation of the "tap-root" formed the short stock from which were produced the long, narrow lanceolate leaves and solitary-flowered peduncles. The characteristics given by "E. H. W." as belonging to M. grandis do not apply to the plant grown here under that name from seeds supplied by Dr. Prain. The flowers are of the loveliest shades of blue imaginable; upon a ground colour of pale pure sky-blue are markings and veinings of a lovelier deeper shade. The leaves are not toothed, but have quite entire margins, while the capsule and stigma closely resemble those of the plants raised from seeds collected by the Koslov expedition in Central Asia, and sent to Mr. Bulley under the name of Meconopsis integrifolia. Trustworthy illustrations of Messrs. Veitch's M. integrifolia may not be available [!] but such reproductions as we have seen of sketches taken from the plants exhibited at the Horticultural Hall on April 25 last, show Tulip-shaped flowers with somewhat short segments, while the illustration of our plant in *Flora and Sylva* excellently portrays the magnificent open blooms, which varied from 5 to 7 or 8 inches in diameter. At the base of the petals in the flowers of our plant is a dark ring hidden by the mass of orange-coloured stamens. It would be interesting to know if this feature is present in the flowers of Messrs. Veitch's plant. Lovers of this genus will be glad to know that the seemingly impossible has been achieved, and the reputedly loveliest species of this beautiful genus, Meconopsis bella, is at present known to be past the seedling stage in one or two places, and is actually coming into bloom in the garden of one notable hardy plantsman. *The Co-operative Bees, Ltd., Ness, Neston, Cheshire.*

—— We have a plant of Meconopsis integrifolia in flower in these gardens which enables us to lay claim to be one of the first to have it in bloom in a private garden. An interesting point about the plant here is that although I tried to be generous to it by putting it into a compost of equal parts of loam and leaf-mould, with a sprinkling of sharp sand, it never moved, so I removed it from the above compost and put it in a really stiff clay soil. No sooner was it planted in this latter than it started into growth. I should like to hear other growers' experience with it. *J. C. Smith, The Gardens, House on the Creek, Maidenhead.*

TRILLIUM GRANDIFLORUM.—The note on this plant on p. 308 induces me to ask why it is not more often seen naturalised in Great Britain. Beautiful as it is in the garden border, it is far more so when allowed to spread through natural woodland. No exotic takes more kindly to our climate and soil. Planted out in a thick wood of deciduous trees, where the soil is either peaty or composed largely of decayed leaves, it thrives like a weed, spreading freely both from the root and by seed. It enjoys exactly the same conditions as the Lily of the Valley, but is not so thoroughly immune as is that plant from attack by rabbits. They nibble it occasionally, but do not persevere if other food is abundant. *Herbert Maxwell.*

ARE COMMERCIAL TRAVELLERS A NUISANCE?—I think competition is too keen among horticultural travellers for many of them to indulge in such erratic behaviour as "A Foreman" describes, p. 315. I do not think such unpunctuality would bring them many orders. Their expression of opinion on the condition of things as they go through the garden, if adverse, shows an absence of tact on their part, and doubtless when "A Foreman" becomes "head" he will be able to estimate such observations at their proper worth. *T. H. Slade.*

SEED-SOWING.—In reply to Mr. A. Dean's note on p. 316, although I did not state that darkness was productive of indifferent germination, I do maintain that seeds raised in semi-darkness are much more liable to die after germination has commenced. I go further, and maintain that light is absolutely necessary for perfect germination. Mr. Dean gives two examples to support his contentions, but the subjects he mentions will develop to a certain stage under any conditions, provided the seeds are kept moist. I have not grown Mustard-and-Cress for market purposes, but for many years past I have raised some each spring for home use. I simply sow the seed thickly on the surface, thoroughly soak the soil and the seeds, and after standing them in the path or under the stage for a day, I place the boxes on a shelf fully exposed to the light, where the seeds start away evenly and develop no sign of the slimy damping-off which I have seen in those grown under shaded conditions. We have only to look at natural conditions to prove the advantage of light. A year or two ago I was through a wood where the undergrowth was very thick and the ground quite bare of vegetation beneath the heavy shading. The wood was cut down shortly after my first visit, and on going over the same ground a few days ago I found innumerable seedling plants. Why did older raisers of Ferns so often fail? Simply because they covered their seed-pots too densely. I have sown some thousands of pots of Fern-spores, and only when the spores themselves were faulty have I had failures. On one occasion I placed some pots containing spores in such a position that the light fell on about half the surface of the pot only, and they happened to remain for a longer period than usual before being examined. When I did give them attention I found the spores had germinated evenly on the part exposed to the light, while there was no sign of germination of those on the spot where the light was excluded, although after being fully exposed to the light these spores also germinated. The first time I sowed seeds of Centaurea candidissima, I was instructed to put them in a frame and cover the frame with mats. I did so; the result was failure! Later on I sowed again, and this time placed the seed boxes on a shelf, where I should think every seed germinated, and what is more important lived after they had started. I know there is a medium in all things, and I should not expect to succeed with tender seeds in the full glare of the sun at mid-summer, or even before it was quite so powerful. Mr. Dean asks if light can penetrate to Peas or Beans when placed 2 or 3 inches below the surface. I answer No. The nourishment provided in the cotyledons is sufficient to bring them through to the surface. I remember once being told by a gardener that some seeds he had sown failed to germinate, but after being emptied out on a heap the seedlings came up. This was an instance of failure through burying seeds too deeply. Many more might be given. *A. Hemsley.*

A NEW (?) VEGETABLE.—Paragraphs are in circulation as to the Kwantung or Chinese Cabbage. There is nothing very new about it. It crops up now and again, but as it does not seem to be adopted in this country, we take it it has been found wanting. At the same time the apathy and disinclination on the part of cultivators to try anything out of the common routine are really astonishing. (See *Gardeners' Chronicle*, May 19, 1888, p. 619.)

TREES AND SHRUBS.

CORNUS FLORIDA RUBRA.

Of the many handsome Dogwoods which have been introduced, this variety is quite distinct from any which I have as yet seen in flower, and for its colour alone it should find a place where flowering shrubs are grown. Although named rubra, it would, I think, be best described as pink, as it shows more of that colour than rose. The four-petalled flowers are veined throughout a beautiful pink, the other portion of the flower being of a lighter shade. It is quite a distinct object just now among flowering shrubs by reason of its colour, the flowers attracting attention at once as they appear among the unfolding leaves. This handsome Cornel growing over a groundwork of the white Polemonium gives a charming effect, and it would be equally effective if grouped sufficiently far apart, with a groundwork of some other dwarf-growing herbaceous plant of a suitable colour. *T. H. Slade, Poltimore.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossum grande.—This large showy Odontoglossum, after a long rest, is now recommencing to grow. It will, however, be some time before root-action occurs, but that the roots may have fresh, sweet material to enter as soon as they emerge, pick away the old peat and sphagnum-moss, and replace with fresh materials. The plants thrive in well-drained pots or pans, and a couple of inches deep of turfy peat and sphagnum-moss. Place them in a moist shady part of an intermediate-house, and afford only a little water until the floral spikes appear in the new growths, when liberal supplies will be needed. When the flowers have passed and the pseudo-bulbs are made up, the commencement of a long dry rest should be instituted. Large plants having many old leafless pseudo-bulbs may be broken up, only retaining two or three bulbs to each progressive portion. Old pseudo-bulbs are of no value to any Orchid, the idea of their acting as a storehouse of food for the younger portions having long ago been exploded. Their retention merely pauperises the younger generations. O. Insleayi and O. Schlieperianum need similar treatment to O. grande, the former species, however, requires somewhat drier conditions during the growing season.

Phaius tuberculosus.—The species formerly so-called has been found to be P. simulans. The new growths are now emitting roots, hence fresh material should be given into which they may ramify. Owing to the spreading habit of the plant, it is difficult to confine it to the limits of a pot or a pan, but it may be kept in suitable bounds by training the growths upright to a few thin pieces of teak fixed in the pot or pan. The receptacle should be three-parts filled with drainage, the remainder being occupied with a mixture of equal parts peat and moss, a sprinkling of semi-decayed Oak-leaves, and some small crocks, surfacing the whole with a layer of chopped moss an inch in depth. When repotted place the plants in a well-shaded position in a warm intermediate-house, and keep them well supplied with water, both at the root and overhead during the growing season, but after growth has finished limit the moisture to sufficient to keep the moss alive. A too close atmosphere will cause the young growths to damp off, and if thrips are permitted to gain a presence they will also ruin the plants.

Phaius grandifolius, P. Wallichii, and other closely related species will need attention now that their new growths are developing. A renewal of the surface materials only will suffice where the drainage is in good order. Should repotting be decided upon, carefully remove the old materials from the brittle roots, replacing the latter in the new pots, and insert crocks amongst them to half the depth of the receptacle, then finish by filling to near the rim with a mixture of two parts lumpy peat, one of fibrous loam and moss, and sufficient sand with small crocks to keep the whole porous. These plants should not be stood on an open-work staging, but preferably on one that is covered with some moisture-holding material. Newly-potted plants must be very carefully watered until they are quite re-established, and others not repotted must not be given over-liberal supplies until they are rooting freely. Hybrids of the above species, also those of which P. Humbletii is one of the parents, may be grown with the above in a warm intermediate temperature. It is essential that sufficient ventilation be provided, as a stagnant atmosphere causes spotting in the leaves and sickly growth. They all need moderate heat, sweet pure air, ample but not dense shade, and a fairly moist atmosphere. The Phaio-Calanthes, of which there are several distinct and useful forms, may be grown in a somewhat warmer house than the Phaius parents, but otherwise they should be afforded similar treatment. They also appreciate a small portion of decaying leaves in the rooting medium.

Exhibiting Orchids.—Most owners and growers of Orchids generously support the many horticultural shows held during the year, and a word of advice may be given to those with less experience. Plants intended for exhibition should be allowed to become moderately dry before leaving their home quarters, and again, on their return, no water should be given for a day or two. If practicable, place the plants for a few days before the show in a compartment where drier and cooler conditions prevail. It is a curious fact that Orchids of the Cattleya tribe suffer the most readily from exposure at an exhibition, though the injury may not be apparent for weeks afterwards. Care in thrusting stakes into the pots should be observed, and never insert a pot in a larger one and then pack round with wet moss; dry wood-wool is far preferable. Whenever possible tie the spikes in their natural position, for often when a drooping spike has been tied upright the blooms, when released, fail to fall back into their former position.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Tree Carnations.—These should be ready for placing out-of-doors where they may enjoy the full benefit of sun and air, but require protection from rain. Sufficient garden lights for covering them should therefore be kept handy. If any of the plants have not yet been potted, let this work be done without delay. Such plants will require to be kept in a close frame for a week before being removed out-of-doors.

"Malmaison" Carnations.—Our stock of two-year-old plants are now furnishing us with a quantity of well-developed flowers. It is upon these same plants that we depend for our stock of layers for the season, and as soon as the different varieties pass out of flower steps are taken to proceed with the layering. To prevent a check in any form, the plants must receive a liberal supply of water at the roots, with frequent damping of the stages between the pots. They should also be shaded from the direct rays of the sun and allowed a free circulation of air between them. If these conditions are not strictly complied with red-spider soon becomes prevalent, and once this pest obtains a firm hold it is difficult to eradicate without spoiling the appearance of the foliage. Plants that were layered last year will require some support to prevent the foliage becoming broken, but the staking of the shoots singly should be deferred until the plants are repotted after flowering. The process of layering is an important matter, on which depends to a great extent successful cultivation in the future. My practice is to select a brick pit containing good soil in which the plants to be layered are planted, allowing sufficient room between the different varieties to avoid confusion of names. A quantity of old potting soil is passed through a ½-inch mesh sieve and placed round the plants, allowing sufficient soil for drawing over each growth when layered. The pit is kept close and shaded until signs of rooting in the layers is apparent, when as soon as they have made sufficient roots to support themselves they are separated from the plants and allowed a week before being lifted and potted.

Begonia Gloire de Lorraine.—Early-propagated cuttings intended for specimen plants should not be allowed to receive a check by becoming pot-bound, but should be well rooted before being shifted into larger pots. They should be shaded from the sun, syringed frequently, and grown in an intermediate temperatnre. These plants should not be pinched at any time, the stake will be sufficient, to which the growths should be "slung" rather than tied in tightly. The latest batch of cuttings should be inserted now. B. Agatha compacta makes a small and compact plant, and is valuable for furnishing or edging purposes. Grown in 60-size pots it is useful for decorating the dinner-table, &c.

Callicarpa purpurea.—Plants may be propagated from cuttings inserted now, or from seed gathered from the ripe berries and sown in the autumn. This plant when grown under warm and moist conditions retains the freshness of its foliage, while its purple berries are very effective and pleasing.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Cauliflowers.—Smaller-growing varieties such as Extra Early and First Crop, grown in 8-inch pots, will now be supplying compact "heads" of good quality. These when about the size of a teacup are in their best condition, and eminently suitable for table purposes. We are now making another sowing of these vegetables, while seeds will again be sown at about the end of June in order to maintain a succession, as every endeavour is made to continue the supply of these and other varieties, such as Early London, Walcheren, Autumn Giant and Self-protecting Broccoli, throughout the season. As a succession to Autumn Giant sown in April, another sowing of this variety has just been made.

Seakale.—In order to secure good crowns from root-cuttings in one season for forcing, all but the strongest growth should be removed. Plants in permanent beds that have not been required for forcing, and that have been allowed to develop their flowering stems, should be cut hard back in order to secure suitable crowns for forcing purposes. Use the hoe freely in such plantations.

Tomatos intended for planting in outside borders early in June should now be freely exposed on some warm sheltered position facing south, but not in too close contact with trees and shrubs. Remove all side shoots or laterals as they appear. This work must be done frequently during the growing season, in order that the energies of the plant may be directed toward the production of flower trusses, and not to excess of growth. The practice of removing the leaves has nothing to recommend it, as it deprives the plant of its organs of food-elaboration, and retards early maturation of the fruit.

Cucumbers.—Frames from which crops of early Potatos have been cleared may with advantage be planted with Cucumbers. Young, vigorous plants will soon become established in these structures, and the same soil in which the Potatos have been forced, with the addition of a quantity of partly-decayed stable-droppings, will suit the Cucumber admirably. When first planted they should be kept fairly close for a few days, and during bright sunshine shaded lightly with thin canvas. Cucumbers require plenty of light and moisture; the atmosphere in which they are grown should also contain abundant moisture. Guard against injury by cold winds and draughts. At Lockinge our practice is to plant Cucumbers in a ridge of soil formed at the head of the frame; this considerably lessens the difficulty experienced when watering compared with that of forming a mound in the centre of the frame.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Calceolarias.—Plants that were transplanted into cold frames or placed in improvised shelters a few weeks ago, and have been exposed on all favourable occasions, may safely be planted by the end of the present month. They require a deep, rich loamy soil, and should be allowed a distance of about 12 inches apart. C. amplexicaulis is well adapted for planting in large beds and for forming the back rows of borders, &c.; it also makes a good groundwork for tall Ricinus. A mulching of manure from an old Mushroom-bed will help to conserve moisture in the soil and encourage root-action.

Garden Vases, &c.—Plants such as Agapanthus umbellatus, Yucca recurva, Phormium tenax, and others of a hardy nature, may now be planted; but defer placing more tender subjects, such as Agaves, large Sempervivums, Aloes, &c., till later. The most suitable edging-plants for these garden ornaments are those of a drooping character, such as Lysimachia nummularia, Ivy-leaved Pelargoniums, Fuchsias, Convolvulus mauritanicus, Lobelia, Glechoma hederacea var., &c. Tall-growing Pelargoniums such as the Ivy-leaved Mme. Crousse are suitable for pillars, &c. Encourage the development of strong growth, and tie the shoots frequently as they are liable to broken easily. Towards the end of month place these plants against a wall or under a tree in order to harden them off, but see that they are suitably protected against cutting winds.

Work in the Garden.—Ply the Dutch-hoe on all favourable occasions. It will not only prevent weeds from growing, but when properly used will form a layer of fine, loose soil on the surface of the ground that retards the evaporation of moisture from the soil. Now that the period of danger from frost has nearly passed, box-edgings may be trimmed. Golden Willows may also be cut back. Remove old shoots of Rubus biflorus, and manure the plants to encourage strong growths. Clematis require tying often to prevent tangled growths.

Eryngiums, Verbascums, &c., raised on hotbeds can now be planted in nursery beds to grow on for next year. Prick off Astilbe Davidi, Campanulas, &c., when large enough to handle.

Wild Garden.—Remove the coverings from Gunneras, and afford the plants a good dressing of rich manure.

Shrubs.—The following are some of the best shrubs that are in flower at the present time:—Amelanchier canadensis, Amygdalus communis amara, A. persica, fl. pl., Cytisus scoparius præcox, Cerasus pseudo-Cerasus and C. J. H. Veitch, Pyrus baccata floribunda, P. prunifolia, P. spectabilis, and Rubus deliciosus. Standards of the above show to great advantage. The following dwarf shrubs and herbaceous plants are useful for covering steep and dry places:—Artemisia Stelleriana, Anthemis tinctoria, Evening Primrose, Pyrethrum Tchitchatchewi and Veronica Traversii.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Cucumbers.—During the next month these fruits will be more easily produced in frames. The plants have not made good progress recently, mainly owing to the prevalence of cold nights and little sun-heat during the day, but with the present favourable change in the weather the plants may be expected to improve rapidly. Early-grown plants that have been overcropped are liable to be attacked by red-spider. If it is necessary to retain the early-grown plants, thin the old growths out freely, and crop lightly for a period, and at the same time encourage them to make free growth by frequent applications of a light top-dressing of a sweet but not too rich compost composed of good fibrous loam, leaf-mould, and a few horse-droppings. Give occasional applications of clear liquid-manure and soot-water, and light sprinklings of Thompson's manure. If the foliage flags shade the plants from bright sunshine. Ventilate the house freely during the early part of the day, closing the structure early in the afternoon, securing plenty of atmospheric moisture.

Cucumbers in Frames.—If plenty of stable-manure and good pits or frames are available, a plentiful supply of Cucumbers can easily be obtained. Frames in which early crops of Potatos and other vegetables have been grown should be cleaned and planted as required. Pay careful attention to the watering of the plants, guarding against excessive moisture. Admit air freely, and at closing time on bright afternoons thoroughly syringe the plants with clear water. Thin the growths freely to avoid overcrowding, and pinch out the points of the fruiting shoots at the first joint beyond the fruit. Cover up the pits at night time, and see that the manure forms a proper lining to the frame. Cucumbers for exhibition purposes are best produced from young plants, which grow much faster and develop the more handsome fruits than older ones. Shade the plants lightly during the middle of the day, and encourage the fruits to grow straight by placing them in glasses, that can be obtained for the purpose.

Young Vines.—Home-grown pot Vines intended for fruiting next year will now be growing fast, and should be given applications of weak liquid-manure and sprinklings of a suitable Vine-manure. Keep the laterals closely pinched, and stop the canes at about three buds beyond the required length of the rods. Pay careful attention to ventilation, also to damping and syringing the Vines. Gradually withdraw the fermenting material from around the pots or the roots will grow through the drainage holes, allowing the plants to continue actively growing when they should be showing signs of ripening. Recently-planted Vines should be mulched, well syringed and watered when necessary. Stop the leading shoot when it is about 6 feet in length, or at a few buds beyond which it is intended to prune next winter. All other laterals should be allowed to grow as freely as space will permit in order to encourage as much root action as possible.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Fruit Trees.—Plum and Pear trees should be examined with a view of stopping the young shoots. The top portion of the trees should be operated on first, as this will afford time for the generally weaker lower branches to increase in strength. Suppressing excessive growth by pinching at this season is a great aid to fruit-production. After selecting the number of growths required for furnishing the wall or for the extension of the tree, and when eight or more perfect leaves have been formed, all growths should be pinched back with the finger and thumb to five leaves, except in the case of very strong and vigorous shoots, which may be left somewhat longer. If very strong growths are pinched too closely the oldest buds on the shoot will start into growth again, forming a lot of thin, useless shoots. In cases where a strong-growing shoot is proceeding from a part of the tree where an older shoot is barren, the former should be encouraged to grow to take the place of the latter. In this way the tree may be rejuvenated.

Thinning the Fruit.—Before performing this operation due consideration should be given to the amount of fruit the tree is capable of carrying. Some consideration must also be given to the variety, those whose individual fruits are of large size cannot be expected to develop as numerous a crop as a tree whose individual fruits are smaller. Small and imperfect fruits should be removed first, finally going over the trees and leaving as many fruits as the tree can suitably develop in a state of perfection. Heavy cropping means unfruitfulness to follow, whereas light and moderate crops enable the tree to maintain itself in a fruit-bearing condition.

Caterpillars are still continuing their ravages on trees that have not been sprayed as previously advised. Directly the trees pass out of the flowering stage they should be sprayed with a solution of Paris-green (POISON). I find Paris-green paste, used in the proportion of 2 ounces to 40 gallons of water, a perfectly safe insecticide for all trees growing in the open-air; but wall trees whose leaf-tissues are somewhat more delicate require an additional 10 gallons of water. I recommend Paris-green paste as it readily mixes with water and is not held in suspension, as the powder is, even when lime or flour has been added.

THE APIARY.

By CHLORIS.

Queen Raising.—Those who have purchased queens know how expensive this method of re-queening is. Further, it is a practice which often brings keen disappointment to the purchaser. Many an excellent queen, after a journey through the post, has died a few days after taking up her abode in her new home. This being the case, it will be well for the bee-keeper to breed them himself. Sometimes when a colony swarms late in the season, the bees in their haste choose larvæ instead of eggs to raise the future "mother bees," and these never mature as they ought to do. It is found that the best queens are produced during the early swarming season, or when the queen has become old or almost useless, and the bees have decided to cast her aside.

How to Proceed.—To perform the task successfully two stocks are needed. It ought not to be necessary to add that those stocks that are selected for this purpose should be the best in the apiary. But what are the best stocks? The queens in both cases should be two summers old, because such queens will then be in their prime, and the workers from such queens ought to be noted for their energy and hardihood. Having decided on the stocks to be utilised, feed them generously with syrup, and strong colonies will result, approximating swarming condition, which I have said tend to produce the most perfect queens. In one hive place foundation with worker-cell base in the centre of the brood-chamber. The workers will soon draw this out, and the queen will deposit eggs in the cells. As soon as there is a large number of eggs laid, remove the queen, and cut off the comb to the cells containing eggs, and enlarge these cells with a piece of conical wood. These the bees will generally convert into queen cells. Our next care is the other colony. Take out the centre combs and replace with foundation of drone base, and feed as plentifully as possible, which will induce the workers to build drone comb, and the queen to lay drone eggs. By utilising two hives in-and-in breeding is in a large measure prevented. In this manner a dozen or more queen-cells will be started, and in about eight to ten days the next operation will be necessary.

Nuclei.—A nucleus is really a colony on a small scale. Take two combs of honey and pollen and the adhering bees, and one comb of brood, placing the combs with honey on each side of that containing the brood, and take care that no queen is added. In the centre of the comb containing brood, cut a hole about 2 inches in diameter, and in it secure a queen cell taken from the hive which has been set aside to produce queens. It will be well to add a few more bees by brushing some from other combs. Proceed in this manner with each nucleus; remember to leave one queen cell for the stock which has produced them. In performing this work great care must be taken, first in handling the cells, for the least shake or squeeze will cause permanent injury to its inmate and render the queen useless, and secondly, by securely fastening in the queen cells by the aid of pins when grafting them on the new combs. All that remains to be done is to make the nuclei warm, keep them well apart, never nearer than 6 feet, make the entrances small to prevent robbing, turn them in different directions to enable the queens easily to find them when they return from their wedding trip, and finally to replace frames containing full sheets of foundation in the hives from which we took combs. In four or five days the queens will hatch, and in five or six days more will be fertilised by the drones from the selected hives. Before concluding, one word of warning is very necessary. Should the nuclei have no young brood when the queens leave to meet the drones, the workers will desert the hives with her, so take great care to insert a comb of brood a day or two after the queens have hatched.

APPOINTMENTS.

MONDAY, MAY 29—Annual Dinner of Kew Guild, at Holborn Restaurant, at 7.30 P.M.

TUESDAY, MAY 30—Royal Horticultural Society's Show in the Temple Gardens, Thames Embankment, London (3 days). Bath and Western and Southern Counties Society's Show at Nottingham (5 days).

THURSDAY, JUNE 1—British Gardeners' Association, Meeting in Memorial Hall, Farringdon Street, E.C., at 8 P.M. Linnean Society, meet.

FRIDAY, JUNE 2—Royal Botanic Society, Lecture.

SATURDAY, JUNE 3—Société Française d'Horticulture de Londres, meet.

WEDNESDAY, JUNE 7—Royal Botanic Society's Grand Horticultural Exhibition, Regent's Park (3 days). Royal Cornwall Show at Newquay (2 days).

FRIDAY, JUNE 9—Royal Botanic Society, Lecture, 4 P.M.

MONDAY, JUNE 12—Bank Holiday.

THURSDAY, JUNE 15—Linnean Society Meet.

FRIDAY, JUNE 16—Royal Botanic Society, Lecture. Gardeners' Royal Benevolent Institution, Annual Festival Dinner at Hôtel Metropole.

TUESDAY, JUNE 20—Royal Horticultural Society's Committees meet. National Rose Society's Committee meet.

WEDNESDAY, JUNE 21—Yorkshire Gala, York (3 days).

FRIDAY, JUNE 23—Royal Botanic Society, Lecture, and Meeting at 4 P.M.

MONDAY, JUNE 26—Isle of Wight Rose Society's Exhibition at Ventnor.

WEDNESDAY, JUNE 28—Richmond Flower Show. Southampton Flower Show (2 days).

THURSDAY, JUNE 29—Colchester Rose Show.

FRIDAY, JUNE 30—Royal Botanic Society. Lecture.

SALES FOR THE WEEK.

MONDAY NEXT—
Special Sale of rare Orchids in flower at 12.30.

TUESDAY NEXT—
Great Unreserved Sale of 100 magnificent Orchids, by order of Messrs. Sander & Sons, at 3.

WEDNESDAY NEXT—
Palms, Plants, Lilies, Begonias, Ferns, &c., at 12.

THURSDAY NEXT—
Special Sale of rare Established Orchids at 3 o'clock. Also Orchids in variety at 12.30.
At 67 and 68, Cheapside, E.C., by Protheroe & Morris.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —58·3.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May* 24 (6 P.M.): Max. 64°; Min. 43°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May* 25 (10 A.M.): Bar., 30; Temp., 62°. *Weather*—Bright sunshine with occasional clouds.
PROVINCES.—*Wednesday, May* 24 (6 P.M.): Max. 59°; Min. 42°.

The Paris Show.

FRENCH horticulture has been worthily represented during the present week in the Cours-la-Reine, Paris, in the form of an International Exhibition held by the Société Nationale d'Horticulture de France. The event aroused considerable interest on this side of the Channel, for although few English exhibits were forthcoming, the show was attended by a large number of English visitors; and the Royal Horticultural Society was represented by a specially-appointed deputation, consisting of Sir ALBERT ROLLITT, M.P., Captain G. L. HOLFORD, Messrs. J. GURNEY FOWLER, HARRY J. VEITCH, and Rev. W. WILKS. Sir TREVOR LAWRENCE and Lord ILCHESTER had also intended going, but were unable to do so.

How excellent the exhibition was from the English point of view is shown by the large number of medals awarded by the deputation; and we feel sure that the appreciation thus indicated was shared fully by every visitor from this country. Many of us could not help contrasting the delightful scenic effects, the perfect blendings of colours, the numerous and spacious promenades for the convenience of visitors, and the evidence throughout of artistic skill, with the opposite conditions that generally obtain in our own exhibitions.

After passing under an entrance portico of the Louis XVI. style and through the outside grounds planted with selected specimens of trees and shrubs, it was seen that the Orchids were arranged on stages in a perfectly circular apartment, and as the path led through the centre of this the Orchids described two half-circular groups with beds of choice Caladiums on the floor in front of them, the walls behind the Orchids being prettily draped in a neutral tint to give effect.

Emerging from this into a much larger building a perfect floral picture came into view, in which the plants were arranged on slopes, mounds, and undulations of various degrees, rather than on dead levels or monotonous stages. Every group of plants, whether in flower or not, was disposed in a position where it could be seen to the best advantage; thus most of them were below the eye-level, many being on the surface of the ground as a flower-bed. Moreover, the pots, though so necessary in the cultivation of plants, are not of value in an exhibition, they were therefore hidden from view wherever possible, not by the crowding of plants together for the purpose, but by the plunging of the pots in the soil.

It would appear that the committee charged with the arrangement of such a show must possess a complete knowledge of what will be forthcoming some considerable time beforehand, in order that every plant, *petite et grande*, can be provided with the position that is necessary to make it appear as a portion of a deliberately designed scheme.

In positions where the view could be improved by something for the eye to rest upon, immense specimens of Rhododendrons in flower were elevated in tubs many feet in height; and this provision suggested to our mind once again the necessity there exists for a circular stage or something of the kind in the centre of the new Hall in Vincent Square, which could be decorated with large Palms or other ornamental foliage plants, and occasionally with flowering plants.

Passing towards the other end of the Exhibition, the visitor found that the comprehensive exhibits of Rhododendrons were also grouped as in a garden, insomuch that he could have imagined himself to be in the Rhododendron Dell at Kew. Messrs. VILMORIN'S annuals were arranged in an equally effective manner. Another compartment was planted as a Rose-garden, having dwarf plants in the centre beds and standards around the sides, which were prettily draped with cream-coloured tissue. If we compare the Exhibition with our Temple Shows, it must be said that it greatly lacked the splendid collections of Orchids that we have; also that the Begonias, Cannas, Caladiums, Gloxinias, Roses, &c., were not superior, but in some instances were inferior to our own. Annuals were shown better than they have ever been seen in England, and zonal Pelargoniums were unsurpassable. Such a collection of Vegetables as was staged by Messrs. VILMORIN ANDRIEUX ET CIE. has never been seen here in the month of May. We may add that there was a very interesting exhibition of paintings of fruits and flowers, also a few exhibits of scientific interest.

The three special prizes offered by the PRESIDENT of the Republic were awarded to M. MOSER, Versailles, MM. VILMORIN, ANDRIEUX ET CIE, and MM. CROUX ET FILS.

The PRESIDENT of the Republic was received at the entrance to the Exhibition at 10.30 A.M., May 20, by M. VIGER, the Society's President, the premier Vice-President, M. ALBERT TRUFFAUT, the Secretary, M. CHATENAY, and others. In opening the Exhibition President LOUBET paid a high tribute to the organisers of the show, particularly to M. VACHEROT.

Among those who received honours from President LOUBET, in addition to M. VACHEROT and M. CHATENAY, we were glad to see the name of our esteemed correspondent, M. GEORGES TRUFFAUT, who is doing so much good work for scientific horticulture in France. At midday the members of the jury and of the deputation, with others, were entertained at luncheon, and speeches were made by M. VIGER, President of the Society and a former Minister of Agriculture, by M. RUAN, the present Minister of Agriculture; and M. DUJARDIN-BEAUMETZ, Assistant-Secretary for the Fine Arts. On Sunday there was a banquet at the Society's headquarters in the Rue de Grenelle, at which function Sir ALBERT ROLLITT was spokesman for the English deputation.

In addition to other social gatherings and receptions on subsequent days, a Congress was arranged at which M. LEON DUVAL was to read a paper on Orchids and Hot-House Plants; M. PHILIPPE DE VILMORIN, a paper on Hardy Flowering Plants, and M. TILLIER a paper on Ornamental Trees and Shrubs.

*** We have the satisfaction to announce that the Jury of the Paris Exhibition awarded a large Gold Medal to the *Gardeners' Chronicle* for its illustrations, of which a selection was shown. Other exhibits of a like character were made, to which awards of less value were given.

The Awards at the Royal Horticultural Society.

THE practice which is sometimes followed of giving an award to an old and well-tried variety, hitherto, by some accident, overlooked by the Society, has given rise to adverse criticism and occasionally provokes a sense of the ludicrous. It is absurd, say some, to make an award, we will say by way of illustration, to Cox's Orange Pippin, to Black Hamburgh Grape, or to any other variety whose merits are now generally recognised, although it may not have been stamped with the hall-mark of the Society. Perhaps it is. But would it not be equally absurd that such varieties should never receive recognition from the Society, and never be included in its honour-lists? Quite lately, two excellent Potatos, which have long been in commerce, were awarded First-class Certificates. Both had previously, when grown at Chiswick, received Awards of Merit, and having now, after several years' experience, proved to be first-class standard varieties, the Award of Merit has been found to be inadequate, but in these cases fittingly the stepping-stone to a higher award. But to many persons

wedded to traditional methods, and who think awards of the nature referred to should be made to new things only, the granting of First-class Certificates to comparatively old forms is a stumbling-block. In their estimation it is better to grant awards whilst the subjects of them are new and scarce, even if a great mistake eventually results, than it is to wait patiently for a few years until experience has shown whether the subject be worthy of an award or not.

The whole matter hinges on the purpose for which subjects are placed before the Fruit or any other Committee. If staged in the hope of getting a certificate that shall enhance the trade value of the subject, it is evident that a belated award, after several years' experience of its cultural value, can be of no service in that respect. If the sole object in staging new or assumed new things or varieties be to give the subject publicity, and to secure an award on the merits of the exhibit, without reference to any financial result, then nothing but good can follow if the granting of an award be deferred until time has shown whether it is merited or not.

Exhibits that come before the Fruit Committee often come into a different category from those presented to the Floral Committee. Such a remarkable plant as Meconopsis integrifolia tells its own story at once. Its claims to immediate and first-class honours were incontestable. With fruits and vegetables the case is different. What may be described as remarkable products never crop up with them. They come in the form of improved varieties, or what are assumed to be so, but beyond the sender no one has any proof that they are such. It is not possible for the Committee to determine whether they are so or not until time and experience have determined the question. When it is remembered how numerous are the varieties of fruit, for instance, that are put into commerce with Royal Horticultural Society awards, but which fail to secure any permanent position in gardens, is it not certain that the practice of granting certificates on the first appearance of a subject is a mistake.

A simple way of getting over the difficulty would, if it were only practicable, be to make Awards of Merit to all subjects provisionally, these awards being granted and regarded solely as evidences of *primâ facie* or apparent value or special usefulness, but subject to advancement to a First class Certificate if, as happily sometimes happens, the subject proves to be distinctly meritorious. So far as the Fruit and Vegetable Committee is concerned it is now happily possible to test so many things under favourable conditions in one or several years at Wisley, that the proposals now made would create no hardship, and would prevent mistakes generally.

A study of the honours bestowed during the past thirty years is rather unsatisfactory, because the lists contain so many records of awards which time has shown to have been given without due warrant.

It is, to our thinking, most desirable that Awards of Merit of any kind or degree should continue to be made by the Royal Horticultural Society and its Committees on other than commercial considerations, though we are afraid that in the case of individuals these influences must continue to exert their power till the Millennium comes. Of course we by no means wish to convey the notion that financial considerations should not have their due weight with exhibitors. What we desire to see is that neither the Committees nor the Council should be unduly influenced by them. What they have to do is to examine what is brought before them, and to record their impressions as to their abstract merits irrespectively of their possible value as commercial products. If a Welwitschia or a Rafflesia were brought before the Committee neither would have any financial importance, but the interest attaching to them from the point of view of the Society would be a thousandfold greater than that of a "new" Apple or of an Odontoglossum with four spots instead of three.

Take the case of the Meconopsis before alluded to. It received a First-class Certificate, but that, in our opinion, was decidedly inappropriate, and offered an unintentional insult to the plant by lowering it to the category of the commonplace. Fortunately it also received the far more appropriate award of a Botanical Certificate. But some will say that money value must be the ultimate test. Very well; let it be so. Let us have in that case a commercial committee to deal exclusively with that aspect of the case. This may sound Quixotic, but the higher the ideal the Society strives after the more will it gain in the respect of the public, the better it will be for the traders in the long run, and the greater good will it do to horticulture pure and simple.

We are told that some propositions are under the consideration of the Fruit Committee dealing with the matter of awards. Till they have been thoroughly considered and adopted by the Committee it would be premature to make further comments on them. It is nevertheless a good sign to see the Committees taking steps to remove existing improprieties and anomalies, and, as we hope, to reduce the extravagant and premature award of Certificates.

The very extraordinary Primula shown at the last meeting was, it is true, not in condition as an exhibition plant, and will doubtless receive a certificate when more fully developed. In the meantime, the Scientific Committee has saved the credit of the Society by awarding it a Botanical Certificate, otherwise the most remarkable plant shown on that occasion would have been entirely passed over.

ANGIOPTERIS EVECTA, HOFFMAN, VAR. TEYSMANNIANA, DE VRIESE (see Supplementary Illustration).—According to British scientists, Angiopteris evecta is the only well-characterised species of the genus. It is a gigantic Fern, and requires to be grown in a temperate-house. The other so-called species, generally considered on the Continent as distinct, are only varieties of the species. Professor DE VRIESE, the eminent Dutch botanist, in his *Monograph of Marattiaceæ*, published at Leyden in 1853, described sixty species, all native to Polynesia and Continental Asia so far as the Himalayas and Madagascar. Leaving on one side the various opinions of different authors, and taking into consideration the great similitude between A. evecta and A. Teysmanniana, it seems preferable to accept the opinions of British authors as admitted in the Kew *Hand-List of Ferns and Fern Allies*. This Angiopteris is there treated as the variety, Teysmanniana, De Vriese, of Angiopteris evecta, Hoffmann. This variety is a native of Java. It is characterised by the base of the rachis of the leaf, which is provided with coloured hairs. The inferior pinnules are nearly as long as the median ones, but the upper lobes are much smaller. There exists in Madagascar a very closely allied form, which might be considered as a transition between the varietal form A. Teysmanniana and the typical A. evecta. Our illustration shows a magnificent, indeed probably the finest specimen known of Angiopteris evecta var. Teysmanniana. This plant has been cultivated for over twenty-five years in the winter-garden or fernery of the State Botanic Garden at Brussels. It is planted in a square tub of 1 m. 25 cm. (about 49 inches) in diameter. There are eighteen leaves, some of them nearly 4 m. (6 to 7 feet) long. The whole plant is 7 m. (8 to 9 yards) in diameter. There is no appearance of true stem, but the base of the stock is 78 cm. (30 to 31 inches) thick. During the summer the tub is filled two or three times with cow-manure, the Angiopteris being an extraordinarily voracious plant. *Louis Gentil, Brussels.* [The photograph was taken by M. F. LAMBERT, and forms one of a series devoted to the rarities of the Brussels Botanic Garden, for which we are indebted to M. MASSART. In the recently published *Index Filicum* of CARL CHRISTENSEN, DE VRIESE's species are considered as certainly not distinct, though they are all enumerated. ED.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—In connection with the sixty-sixth anniversary festival dinner in aid of the funds of this Institution, which will take place on June 16 at the Whitehall Rooms, Hôtel Métropole, the Duke of WESTMINSTER, who will preside on the occasion, has issued an appeal for support, in which it is stated that in order to meet the liabilities incurred annually there is an assured income of £900 only, leaving nearly £4,000 to be raised each year to carry on the work. There are also at the present time thirty-two applicants on the list awaiting election, several of whom are afflicted with blindness. Further help is therefore much needed. Contributions will be gratefully acknowledged if sent to the Duke of WESTMINSTER, care of the Secretary, 175, Victoria Street, S.W.

SURVEYORS' INSTITUTION. — The annual general meeting to receive the report of the Council and the announcement of the result of the election of officers for the ensuing year, will be held in the Lecture Hall on Monday next, May 29, at 3 o'clock. The prizes awarded to successful candidates in connection with the recent preliminary and professional examinations will be presented by the President at the annual general meeting. The Council have accepted an invitation from the Devon and Cornwall provincial committee of the institution to hold the next country meeting at Exeter on May 25 and 26.

WOMEN'S AGRICULTURAL AND HORTICULTURAL INTERNATIONAL UNION. — The annual meeting of the above Society will be held, by kind invitation of Mrs. BRYANT SOWERBY, at the Museum, Royal Botanic Gardens, Regent's Park, London, N.W., at 11.30 A.M., on Wednesday, May 31, 1905. Mrs. WILTON ALLHUSEN in the chair.

PRESENTATION TO MR. C. SIMPSON.—The gardeners and friends residing in Ripon and district met on the 19th inst. to present to Mr. C. SIMPSON a testimonial on the occasion of his leaving Newby Hall Gardens. It took the form of a gold watch, also a gold brooch for Mrs. SIMPSON. Mr. SIMPSON takes with him from Newby the best wishes of a large number of friends, by whom he is held in very high esteem.

DR. AUGUSTINE HENRY will preside at the annual dinner of the Kew Guild, to be held at the Holborn Restaurant on Monday evening next. During the twenty years that Dr. HENRY was in China he rendered many valuable services to Kew, for which Kew men will ever be very grateful.

THE WEATHER has been extremely cold in England during the past week, and visitors to the Paris show experienced eqnally bitter winds on the other side of the Channel. Mr. W. H. DIVERS writes from Belvoir Gardens, Grantham, as follows:—

"We had a severe frost here on Monday night, May 22. The thermometer on the grass went down to 19° Fahr., and another fully exposed outside the Stevenson screen—4 feet above the surface of ground—it went down to 25°. Many of the Apple-trees were in full blossom, and have suffered considerably. Some of the earliest to flower were set and are safe. Pears also have set well; these and the bush fruits were well protected by their foliage. Strawberries have suffered very much, but have more flowers to expand yet. The Japanese Wineberry (Rubus phœnicolasius) is very much cut, but Raspberries and Loganberries by its side are scarcely touched. Even the flower-stems of the British weed, Plantago lanceolata, showed signs of severe injury."

Mr. F. C. CLARK, Wiston Hall Gardens, Leicester, writes:—

"We have experienced terrible weather in this district during May. Bitter cold winds have prevailed, and on the morning of the 23rd we registered 12° of frost, and 8° on the 22nd. Great damage has been done to growing vegetable crops, bedding plants, and Chrysanthemums, as well as to Strawberries, Apples, &c."

Mr. W. MILLER, Berkswell, Coventry, writing on May 22, states:—

"We have ice upon our waters this morning, and frost sufficient to blacken both Potatos and Kidney Beans. Plums and Pears have suffered by the continuous dry, cold, north-easterly winds. Whole clusters of Pear-blossom will fall off by the merest touch of the hand. This is the case all over the tree, and also of many trees. Very few fruits seem to be set. Plums are perhaps not so bad, but they too have had a terrible thinning. All this seems a pity after such a healthy and liberal show of flowers of these two fruits. Apples being later may perhaps fare better, but of them it is yet too soon to form an opinion. All crops on farms and in gardens want rain and warmer weather very badly. BURNS must have been inspired by better weather than we are having just now when he wrote those happy lines—

'Again rejoicing nature sees
Her robe assume its vernal hues,
Her leafy locks wave in the breeze,
All freshly steeped in morning dews.'"

An even worse state of things is described by Mr. W. H. CLARKE, Aston Rowant House Gardens, Oxfordshire:—

"Following a cold icy north-east wind which blew all day on the 21st and 22nd, a sharp frost, registering 8° and 10° respectively in the open, did considerable damage to fruit-trees during these nights. Late in the evening there seemed every appearance of the rain, so much needed by the agriculturists on the higher parts of these Chiltern Hills. During the late hours of the night or early morning the weather changed, and everything was covered by hoar frost at 6 A.M. Over-anxious amateurs have their early Potatos and Beans blackened. Early Strawberry-flowers are blackened, and Pears of the size of horse beans on pyramid trees are frozen black. Plums and Cherries are past flowering, but I am afraid the crop has not escaped injury; even the young fruits of the Damson appear to be in a very precarious state; wall trees, I am pleased to say, have escaped injury. In the pleasure grounds the young growths of Paulownia imperialis are quite blackened; so also are the large leaves of Magnolia Watsoni and M. acuminata, while the flowers and foliage of M. Soulangeana nigra escaped unhurt. Robinia hispida and Dimorphanthus mandschuricus suffered somewhat, but the sun's rays not falling directly on the foliage, allowed them to thaw gradually, consequently they will not suffer much. Buddleia globosa and Pavia macrostachya, although frozen, thawed gradually, and are unhurt. The frost on the night of the 22nd was still more disastrous, and those crops which had escaped the previous night were destroyed, even where some protection had been given. Trees which escaped the first night, such as the young leaves of Quercus coccinea, Ginkgo biloba, Tilia mississippiensis, Sophora pendula, Wistaria sinensis and W. multijuga are all cut and in some cases the leaves blackened. Many herbaceous plants and Ferns growing in a sheltered hardy fernery are likewise severely damaged.

LINNEAN SOCIETY.—The anniversary meeting of this Society, held on Wednesday under the presidency of Professor HERDMAN, was remarkable on more than one account. It was the first anniversary meeting at which lady Fellows were present as of right, and several availed themselves of their privileges. Next, to the great regret of the Fellows, Mr. CRISP laid down the office of Treasurer, which he has held with so much benefit to the Society for about a quarter of a century. Mr. CRISP leaves the finances of the Society in a very satisfactory condition, and the Fellows will remember with gratitude not only his skilful performance of his duties, his geniality and tact, but also his repeated acts of liberality. The expenses connected with the obtention of the new charter, by which it became possible to admit ladies as Fellows, were borne by him, and it was mentioned that he has commissioned a commemorative picture to be painted in honour of the event. The President's address dealt, among other things, with LINNÆUS's experiments on the production of pearls by artificial methods, and of Professor HERDMAN's own researches in this direction. In the course of the proceedings the Linnean Medal was delivered to Sir DIETRICH BRANDIS, to be by him transmitted to his fellow-townsman, Professor STRASSBURGER. It is difficult to conceive a more fitting recipient of this honour than the celebrated Professor of Bonn.

BRITISH GARDENERS' ASSOCIATION. — The meeting organised by this Association for Tuesday, June 1, in the Memorial Hall, Farringdon Street, E.C, will be open to the general public, and will thus afford an opportunity to gardeners present in town for the Temple Show of attending and learning something of the progress and aims of the Society.

MESSRS. BACKHOUSE'S NURSERY, YORK.—The *Yorkshire Herald* has an appreciative article upon this well-known establishment, the history and development of which are traced. There are two rather singular omissions—there is, so far as we see, no reference to the journeyings in Australia, actuated by philanthropic motives, of one of the firm. In the course of his wanderings Mr. Backhouse made extensive collections of plants, some of which, if we mistake not, were introduced into cultivation by him. The other omission consists in the fact that no mention is made of the collection of Orchids for which the firm has an enviable reputation.

"INDEX FILICUM."—A list of Ferns, completed to the present time, is a great desideratum. MOORE's *Index Filicum* was never completed, and is, of course, out of date. We have before us the first part of an enumeration of all the genera and species of Ferns published between 1753 and 1905, with the principal synonyms, indications of geographical distribution, &c. Under the heading "Angiopteris of Hoffmann" we find sixty or seventy species enumerated, mostly by DE VRIESE. The author of the present *Index* considers them as "certainly not distinct," but, in the absence of a recent monograph, he adopts DE VRIESE's names, adding that BAKER considers all these to be referable to one species, A. evecta. The author hopes that his book will do for Ferns what the *Index Kewensis* has done for flowering plants. He also proposes to include the names of garden Ferns which have appeared during the last thirty years. Dr. CHRIST, of Bâle, has lent his valuable co-operation. The systematic part of the volume will be based on ENGLER & PRANTL's *Die Natürlichen Familien*, on HOOKER & BAKER's *Synopsis Filicum*, and on Dr. CHRIST's *Die Farnkraute der Erde*. Great attention has been paid to the most detailed and exact citation of the literature and dates of publication. The book may be procured through WILLIAMS & NORGATE, or any foreign bookseller, or direct from H. HAGERUPS, Boghandel, Copenhagen. It will be completed in eleven or twelve parts at the subscription price of 3s. 6d. per part.

SUMMER BEDDING.

BY this term is not meant the geometrical carpet bedding of thirty or forty years since, but the planting-out of tender and half-hardy plants which can only stand our climate out-of-doors in the summer. The arrangement of colour and form, however, is as important as in former days, if not more so, consequently a few general hints may be useful. The arrangement most in vogue is to fill the beds with one or two species of plants, contrasting or harmonising as may be desired, and to cover the ground below with a carpet of some dwarf plant or a trailing variety pegged down. Now, almost any two colours can be combined provided the shade of each colour is the same, or at least harmonises, or one colour may be used in two or three shades, but contrasting colours in different shades always have a hard if not unpleasant effect.

For instance, a bright yellow Calceolaria looks well with a dark heliotrope, such as "Lord Roberts," while the soft yellow one is much better when combined with the almost French grey lavender of "Miss Nightingale." In the same way "Lord Roberts" combines well with any dark crimson or scarlet Pelargonium, while "Miss Nightingale" harmonizes with the pink Ivy-Pelargonium.

These are merely examples of harmonious shading. The general rule is to harmonize the shades of contrasting colours, and to avoid too violent contrasts between the dot plants and the carpet. A rich dark carpet well and evenly planted throws up the dot plants as a rule better than one of a lighter shade, but a light blue, pink, or even white carpet may be effectively employed when a "cool" effect is required, and in this case the dot plants should also be of a light tint.

In small beds it is generally better to employ only one species of plants for the "dots," but where there is enough space the effect is enhanced by mixing foliage plants with the flowering ones, the result being both richer and softer. Dark-leaved Cannas, Ailanthus, Ricinus, Eucalyptus, hardy Palms, striped Maize, Perilla, and Cineraria maritima are all useful for this purpose, and can be combined or contrasted with their companions as desired. Endeavour to avoid using too many varieties of plants, which leads to patchiness, and aim at a brilliant, bold effect. If there are a series of beds it is generally better to arrange a scheme of colour for the whole rather than for each individual bed. For instance, a scheme in crimson and pink, or in scarlet and orange, or orange and yellow, shading in each case from the darkest in the centre of the scheme to the lightest at the outside, will look far better than if one bed is scarlet, another yellow, and a third pink or blue. One word of warning. Only employ plants whose shades you know; do not trust to florists' descriptions. If you are not certain two plants will harmonise, replace one with a foliage plant. The effect may be tamer than the proposed combination, but it will not be an eyesore. *J. S. Turnor.*

VEGETABLES.

CABBAGE SUTTON'S "APRIL."

FOR many years I had pinned my faith on Ellam's Early as being the best Cabbage for early cutting, but I must now change that opinion in favour of Sutton's April. I saw an especially fine breadth of the latter recently. Sown on Angnst 20, and put out on firm, well-enriched, stiff soil, the plants took to their new quarters quickly, and turned in ready for cutting quite in the first days of April. The heads are not large, but compact and of good colour, and are most tender and succulent, and, what is important, there was not a "rogue" to be found in the batch. I look upon this Cabbage as a distinct advance upon all others for an early crop. *E. Molyneux.*

NEW OR NOTEWORTHY PLANTS.

PRIMULA COCKBURNIANA.*

Under this name Messrs. Veitch showed on Tuesday last a Chinese Primula new to gardens, which was properly awarded a Botanical Certificate. So far as the colour of the flowers is concerned, it differs from any other species of the genus known to us. From a tuft of obovate oblong, irregularly toothed, leaves, narrowed at the base and slightly farinose, rises a scape 3 to 4 inches high, but which is said to attain to as much as a foot in height in the wild state. At the top of this scape are borne two to three whorls of flowers as in P. japonica, each whorl composed of three to six blossoms. Mr. Worthington Smith's drawing, taken from the living specimen as exhibited on Tuesday last, will serve to give a general idea of the habit of the plant; but no doubt as the plants become stronger they will increase in stature. The colour of the flowers is a rich orange-scarlet! This colouration is in itself remarkable, and its potentialities in the hands of the hybridiser excite the keenest anticipations. In all the brilliant show of Tulips and other flowers, this little Primrose undoubtedly took rank as the most interesting if not the most conspicuous plant in the whole exhibition. The Meconopsis integrifolia attracted, as well it might, the admiration of all beholders, yet it must be remembered that this delightfully-coloured Poppy made its *début* some time ago, and was illustrated in our columns in 1904, p. 240, whilst the humbler Primrose made its first appearance only on Tuesday last.

FIG. 137.—PRIMULA COCKBURNIANA, A NEW SPECIES COLLECTED IN CHINA BY MR. E. H. WILSON: FLOWERS OF ORANGE-SCARLET COLOUR.

* *Primula Cockburniana*, Hemsley, in *Journ. Linn. Soc.*, xxix., 313 (1892).—P. Poissoni similis sed foliis tenuioribus fere obsolete denticulatis; scapo graciliore; floribus minoribus; calycis farinosi dentibus deltoideis; corollæ lobis retusis; bracteis minutis. Herba perennis, glabrescens, scapo gracili 4—12 poll. alto: floribus in verticillios 2—3 superpositos dispositis; verticillis 3—6 floris. Folia tenuia, obovato oblonga, decursum angustata sed non vere petiolata, apice rotundata, 2—4 poll. longa, primum plus minusve pulverulenta cito glabrescentia, obscure lobulata simul minute denticulata, venis primariis conspicuis. *Flores* circiter 6 lineas longa et 9 lineas lata, pedicellis gracilibus demum fere pellicaribus; calyx anguste campanulatus, circiter 2 lineas longus, dentibus erectis acutis; corollæ glabri tubus cylindratus, lobis obcordatis patentibus venosis. *Capsula* deest. Easily recognised by its slender habit among the species having superposed whorls of flowers. *W. B. H.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

May 23.—The display in the Hall of the Royal Horticultural Society on Tuesday last scarcely equalled that of the previous meeting, but a very fine exhibition was nevertheless got together. Tulips were especially prominent, for in addition to the entries in the National Tulip Society's classes, most of the firms who make the culture of these bulbous flowers a speciality staged extensive groups of these showy plants. There were also commendable exhibits of Orchids, extensive collections of herbaceous and alpine flowers, a meritorious display of Gloxinias, brilliant masses of florist's flowers—Pelargoniums, Calceolarias, Roses, Carnations, Clematis, and a host of other things. A beautiful exhibit of forced fruit came from the noted Gunnersbury House gardens, including Nectarines and Plums in pots. Many novelties were presented, comprising several new species of Primulas from China, and varieties of the beautiful Onco-Regelia type of Iris from Holland.

The Fruit and Vegetable Committee awarded a Certificate of Merit to a new Cucumber.

The Floral Committee recommended one First-class Certificate and three Awards of Merit; while the Orchid Committee gave two First-class Certificates and three Awards of Merit.

The building was well filled with visitors during the afternoon, in fact access to the various exhibits was at times difficult.

A Lecture was given at 3 P.M. by E. M. Holmes, Esq., on "Medicinal Plants, Old and New."

A very large number of new Fellows were elected.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. Jas. Hudson, John Green, Geo. Nicholson, J. F. McLeod, R. C. Notcutt, C. Blick, J. Jennings, Wm. Howe, Chas. Dixon, Chas. Jeffries, H. J. Jones, Herbert Cutbush, Chas. E. Shea, Wm. Cuthbertson, E. H. Jenkins, Wm. J. James, Chas. T. Druery.

One of the showiest exhibits in the Hall was a batch of Gloxinias, set up by Messrs. John Peed & Son, West Norwood, London. Both growing plants and cut flowers were included, the former excellently grown and flowering freely. We have only space to name a few, and of these King Edward VII. is of an intense scarlet colour, Countess of Warwick delicate rose-coloured, with a lighter throat, and very free flowering; Countess of Ilchester resembles the last-named, but has a deeper shade of colour. C. Young is a meritorious scarlet variety; Empress of India was one of the largest flowers shown, it is of good purple colour. Messrs. Peed also exhibited a number of alpine plants (Silver-gilt Banksian Medal).

A display of Roses set up by Mr. Geo. Mount, Rose Nurseries, Canterbury, was magnificent. Such lovely varieties as Mrs. Edward Mawley, Ulrich Brunner, Capt. Hayward, White Maman Cochet, Frau Karl Druschki, and Mr. John Laing were presented in large numbers in the best possible condition. The collection well merited the Silver-gilt Flora Medal awarded.

Some good Roses were shown by Mr. Kirkwood, gr. to E. Wormald, Esq., 15, Berkeley Square, W. The varieties were Maman Cochet and white Maman Cochet. Fancy glass vases were requisitioned for their display. Mr. Kirkwood is evidently a successful cultivator, being able to stage so extensive a group and in such good quality (Silver Banksian Medal).

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, brought a large collection of Gymnogrammas, with small specimens of other Ferns and Selaginellas interspersed among them for relief. Many of the best species and forms of this handsome genus of Ferns were included some of the most notable being G. pulchella var. Wettenhalliana, G. ochracea, G. gracilis (an appropriate name), G. Alstoniæ, whose pinnæ, intensely covered with golden farina on their under surfaces, have their tips reflexed; G. dobroydense, G. Cordreyi, &c. (Silver Flora Medal).

A batch of Onco-Regelia Iris sent from Holland by Mon. C. G. Van Tubergen, junr., of Zwanenburg Nurseries, Haarlem, excited great admiration. These are hybrid Irises between the regelia and Oncocyclus types. The flowers are delicately veined on groundworks of various shades, such as brown, lilac, violet, &c. To one variety the Floral Committee granted an Award of Merit (see Awards) (Bronze Flora Medal).

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, again staged a number of novelties. No fewer than four new Primulas were presented, to one of which was granted an Award of Merit (see Awards). Primula nivalis farinosa has heliotrope-coloured flowers that are dotted with tiny white spots. The under surfaces of the leaves have a white farina, from which the species evidently derives its name. The inflorescence is from 6 to 8 inches in height. Another species, P. Cockburniana, has scarlet-orange-coloured flowers, and is illustrated on p. 331. Primula deflexa develops a tall inflorescence, the specimen shown being about 18 inches in height. It carries a dozen or more pale blue flowers of a pendulous habit. P. vittata is described under Awards. A batch of Clematis montana var. rubens formed a striking feature (see Awards). We also noticed well-grown plants of Echium Wildpreti, Lobelia tenuior var. rosea (see Awards), blue-coloured Hydrangeas, Boronia polygalifolia (a good greenhouse subject), Schizanthus wisetoniensis, Cinerarias, &c. (Silver Banksian Medal).

Messrs. CANNELL & SONS, Swanley, Kent, exhibited a large number of herbaceous Calceolarias in pots, and a bright display of show Pelargoniums in vases. The Calceolarias represented a first-class strain, size, colour, and form being all alike good (Silver-gilt Flora Medal).

Messrs. SUTTON & SONS, Reading, exhibited a number of forms of Primula japonica. The colours of the flowers were of many hues, ranging from almost white to dark crimson. The strain is evidently a desirable one. An edging of small Ferns and Isolepis gracilis gave a pleasing finish.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, Middlesex, staged a number of greenhouse plants. Their display of Carnations was excellent. The variety Enchantress was prominent on a fancy stand. There were also earthenware baskets containing Schizanthus wisetoniensis, Saxifraga pyramidalis (grown well), Auricula Queen Alexandra (a useful bedding variety of sulphur-yellow colour), Aphelexis humilis, Clerodendron Balfouri. The same firm displayed large specimen plants of Bougainvillea glabra Sanderiana and B. g. Cypheri, improved forms of the type, the latter having much larger bracts (Silver Banksian Medal).

Messrs. THOS. CRIPPS & SON, Tunbridge Wells Nurseries, Kent, staged a group of Japanese Maples, similar to that displayed by them at the last meeting (Bronze Flora Medal).

Mr. L. R. RUSSELL, Richmond, furnished a long table with pot plants of Clematis. The variety Ville de Lyon has claret-coloured flowers. Edouard Desfosse is another good form with large mauve-coloured flowers (Silver Banksian Medal).

Messrs. T. S. WARE, Ltd., Feltham, Middlesex, set up an excellent exhibit of flowering subjects, having in addition to a grand display of alpine and hardy flowers, some good Roses and Carnations; hardy Orchids were included. We also noticed Polygonatum stellatum, Thermopsis montana (a Leguminous plant with spikes of pleasing yellow flowers), some well-grown examples of Ostrowskia magnifica, and Anemone palmata alba. The Oriental Poppy "Duke of Teck" is an excellent scarlet variety (Silver Banksian Medal).

Messrs. CUTBUSH & SON, Highgate, London, N., showed flowering shrubs and alpine plants. The alpines were arranged toward the front, the background being composed of Roses, Lilacs, Laburnums, Azaleas, Liliums, Pæonies, &c. Sarracenia flava was shown in flower. We also noticed a white form of Bletia hyacinthina. A batch of Lilium testaceum was prominent (Silver Banksian Medal).

Mr. G. REUTHE, Keston, Kent, in addition to a fine display of Tulips, showed some good things among hardy plants. We noticed a pan of Orchis fusca, and another containing Cypripedium pubescens. Fritillaria recurva has a lovely flower. Gentiana verna was shown well in this collection.

Mr. AMOS PERRY, Winchmore Hill, London, N., staged a batch of Phlox canadensis Perry's variety, a much improved form of the type.

Mr. PRICHARD, Christchurch, Hants, had a magnificent display of hardy plants, staged to advantage on the concert platform. The back row was furnished with tall spikes of Eremurus Elwesianus, while Irises, Oriental Poppies, Lupins, and a host of other herbaceous members were included. Papaver orientale Parkmanni is of the richest scarlet colour (Silver Flora Medal).

Messrs. PAUL & SONS, The Old Nurseries, Cheshunt, showed a number of alpine and hardy plants, sprays of ornamental foliage, a collection of Lilacs, and a variety of flowering shrubs, interspersed with single Roses. Prominent among the latter was R. altaica, whose charming white flowers were developed in large numbers. Fagus tricolor and F. "Paul's Yellow-margined" are two showy Beeches (Bronze Flora Medal).

The Misses HOPKINS, Mere, Knutsford, Cheshire, showed a small collection of border-plants and a number of hardy Ferns.

Mr. E. POTTEN, Camden Nursery, Cranbrook, Kent, showed a collection of named varieties of Lilacs. The same exhibitor also brought an improved form of Trollius europæus that attracted attention; Roses, Aquilegias, Spiræas, and other flowers completed the group.

Messrs. J. CHEAL & SON, Lowfield Nurseries, Crawley, exhibited flowering sprays of trees and shrubs, named varieties of Lilacs, Azaleas, Cytisus purpureus, Cercis siliquastrum, a double form of Prunus sinensis, &c.

Mr. CHAS. TURNER, Royal Nurseries, Slough, exhibited a collection of Lilacs (Bronze Flora Medal).

Miss WILSHERE, The Frythe, Welwyn, Herts (gr. Mr. J. Fitt), showed several interesting plants, including Hæmanthus insignis in flower, sprays of Mackaya bella, forms of Lily of the Valley, including one with golden-striped foliage, &c.

T. MARTIN, Esq., Treverby, South Devon, showed a hybrid Rhododendron, named sanguineum, which has heads of rich scarlet-coloured flowers.

Messrs. BELL & SHELDON, Castle Nursery, Guernsey, exhibited a new Carnation named Mrs. Bertie Bell. The form is irregular, but the dark-crimson flower is very fragrant.

Another new Carnation was presented by Mr. Phillips, gardener to J. H. BEESTON, Esq., Hunsdonbury, Ware, Herts. The colour is very similar to that of Mrs. Bertie Bell, but the flower is pompon-shaped, while the foliage is exceptionally strong in growth.

Mr. RICHARD ANKER, Addison Nursery, Kensington, staged Myrtles, Drosera rotundiflora, small pots containing Ericas, &c.

Miss J. EASTERBROOK, Fawkham, Kent, displayed a basket decorated with Sweet Peas, on a groundwork of Maidenhair Fern and Woodruff.

Mr. R. RASMUSSEN, Eastville Nurseries, Waltham Cross, showed a batch of Petunias grown in small pots. They represented a good type of these plants.

Awards.

FIRST-CLASS CERTIFICATE.

Clematis montana rubens.—A coloured form of the well-known Clematis montana. The petals are suffused with pale-rose colour. The specimens exhibited were in small pots, and were crowded with their star-shaped flowers, thus proving the variety to be as floriferous as the older form.

AWARDS OF MERIT.

Primula vittata.—A new Chinese species of strong-growing habit, developing a flowering-spike 18 or more inches in height. The flowers are disposed verticillately and in more than one tier. The individual flowers are drooping, campanulate, about ¾ inch across the mouth, and of a magenta-purple colour. The calyx tube is streaked with a white farina, that is also developed on the peduncle. The foliage is erect-growing, comparatively narrow, and markedly serrate.

Lobelia tenuior var. rosea.—As the name indicates, a rose-coloured form of L. tenuior, figured in the *Gardeners' Chronicle*, January 12, 1901, p. 46. The flowers are if anything larger than the blue form, and the colour resembles nothing so much as the bracts of Bougainvillea glabra. All the above came from Messrs. JAS. VEITCH & SONS, Chelsea.

Iris Persephone.—A beautiful hybrid Iris, of the type that created such an impression when first shown by Messrs. Tubergen, on May 17, 1904. It is of large substance, and has beautiful black markings on a groundwork of purple colour. The standards are erect and arching. Presented by C. G. VAN TUBERGEN, Jun., Haarlem, Holland.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. secretary), De B. Crawshay, F. Wellesley, R. G. Thwaites, H. T. Pitt, J. Charlesworth, W. Cobb, G. F. Moore, J. W. Potter, A. A. McBean, H. G. Morris, W. Boxall, W. H. Young, W. H. White, H. J. Chapman, H. A. Tracy, H. Little, J. Colman, J. Douglas, H. Ballantine, and W. A. Bilney.

There was a very good show of Orchids, including some remarkably fine Odontoglossums.

Baron Sir H. SCHRÖDER, The Dell, Egham, was awarded a Silver-gilt Flora Medal for an extensive group, in which were two fine examples of Odontoglossum × excellens, with enormous bulbs and fine spikes of flowers. The original was exhibited at the Orchid Conference, May, 1885; also the finely-blotched O. crispum Luciani, and other spotted forms; O. × Adrianæ varieties, O. cordatum, and other Odontoglossums; Cattleya Skinneri and its white variety C. Mendeli; two strong plants of Cypripedium callosum Sanderæ, each with three flowers; C. Lawrenceanum Hyeanum, large plants of C. × Euryale, C. × grande, C. × superciliare, and other hybrids; a fine example of Cymbidium Devonianum, Masdevallia tridactylites, M. Wageneriana, M. bella, and other Masdevallias; Trichopilia crispa marginata, Nanodes Medusæ, Dendrobium × illustre, Cochlioda Noezliana, and some Lælias and Lælio-Cattleyas.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), was awarded a Silver-gilt Flora Medal for a fine group rich in Odontoglossums, the stateliest among which was a noble plant of Odontoglossum × Wilckeanum Pittiæ, with a fine spike of very large yellow and red-brown flowers, and which had previously been awarded a First-class Certificate. On the present occasion a Silver-gilt Flora Medal was voted to Mr. Thurgood, the grower, for continued excellence of culture. Other remarkably good Odontoglossums were O. crispum Princess Victoria, O. c. guttatum, O. c. Maud Rochford, O. c. "Fairy Footprints," and O. c. Rosslyn variety, all finely spotted; O. Pescatorei Pitt's variety, one of the best purple blotched varieties; O. × mulus, O. luteo-purpureum Vuylstekeanum, O. × loochristyense harvengtense, and other hybrid Odontoglossums; Cattleya × Rochrsiana, and the new and fine C. × Pittiæ (see Awards); Dendrobium Victoria Regina, with fine blue-tipped flowers; Lycaste × Balliæ superba, Maxillaria Sanderiana, three good Angulon Clowesii, Cattleya intermedia Parthenia, alba and Lowryana; Brassia maculata, Cypripedium callosum Sanderæ, and other Cypripediums; Lælia purpurata varieties, including the light-coloured Littleana and Russelliana; various hybrid Cattleyas, Lælio-Cattleyas, and the singular green-flowered Epidendrum latilabre, an ally of E. umbellatum.

H. S. GOODSON, Esq., Fairlawn, Putney (gr., Mr. G. E. Day), secured a Silver Flora Medal for a pretty and varied group, comprising good Odontoglossum crispum, O. × Adrianæ, O. Hunnewellianum, and other Odontoglossums; Miltonia vexillaria Goodsoniæ, a very handsome bright purplish-rose flower (the specimen bore four spikes); Lælio-Cattleya × Goodsoni (L.-C. × Phœbe × C. Mendeli), with bright orange-coloured flowers and violet-purple front to the lip; some very good Cattleya Mendeli, and a finely-coloured C. Schröderæ of the C. S. Pittiana class; C. Lawrenceana, Lælio-Cattleya × Ascania, a remarkable form of Oncidium crispum, Cœlogyne speciosa, and many Cypripediums.

The Right Hon. Lord ROTHSCHILD, Tring Park (gr., Mr. Arthur Dye), sent a fine specimen of Lælia purpurata Tring Park variety, a dark-coloured form of the L. p. Brysiana class.

The Right Hon. Lord AUCKLAND (gr., Mr. Matthews), sent fine cut spikes of Lissochilus Krebsii, Oncidium sphacelatum, and Broughtonia sanguinea.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Lælia purpurata "Mrs. R. A. H. Mitchell," a pretty white form with violet-purple-coloured disc to the lip; Cattleya Skinneri "Minnie," silver-white with a purple base to the lip; Cypripedium Lawrenceanum "Majestas," with a very fine dorsal sepal; and Lælio-Cattleya × Lucia Westfield variety.

Messrs. JOHN COWAN & Co., Gateacre, Liverpool, showed a lavender-tinted Cattleya Mossiæ, and Odontoglossum crispum "Edith Bolton," a very singular form with the thick texture and broad petals of the O. c. "Marjorie" class, flowers white, the broad petals having a few reddish spots inside the margin, which is flecked with cinnamon-brown colour.

C. J. LUCAS, Esq., Warnham Court (gr. Mr. Duncan), showed Brassia Gireoudiana.

JOHN S. MOSS, Esq., Wintershill House, Bishop's Waltham, sent an inflorescence of a fine purple-blotched Odontoglossum crispum.

Messrs. HUGH LOW & Co., Enfield, staged a group in which were the handsomely spotted Odontoglossum crispum "Jeanette," and O. × Andersonianum Low's variety, Cattleya intermedia alba, varieties of C. Mossiæ, and good Dendrobium Bensonæ.

Awards.

FIRST-CLASS CERTIFICATES.

Cypripedium × *Dom Carlos* "*Rex*" (Godefroyæ leucochilum × Lawrenceanum), from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman).—A fine improvement on the original variety for which Mr. COOKSON previously had a Certificate. Flower large and round in all its parts; upper sepal white with purple dotted lines; the broad petals white, evenly spotted with purple. Lip cream-white with purple spotting at the opening of the pouch.

Cattleya × *Pittiæ* (Harrisoniana × Schilleriana).—A charming variety with several flowers on each spike, the individual flowers approaching those of C. Schilleriana in form, but of an uniform warm purplish-rose colour, with a few crimson spots on the sepals. Front lobe of the lip blush-white with close striation of dark rose colour.

AWARD OF MERIT.

Dendrobium × *Venus Cookson's variety* (Falconeri × nobile).—A very fine flower partaking more of D. Falconeri than the other fine Oakwood hybrid, D. × Venus grandiflorum, a large and heavily-flowered specimen of which was shown for comparison. Flowers white with rich rose-crimson outer halves to the segments. Disc of lip of maroon and orange colours.

Odontoglossum × *Lucasianum heutonense* (Hallii × cristatellum), from Baron SCHRÖDER (gr. Mr. Ballantyne).—Sepals and petals purplish-chocolate, except the pale-yellow tips and margin. Lip cream-white spotted with brown around the crest.

Zygopetalum × *Crawshayanum* (xanthinum × stapelioides), from De B. CRAWSHAY, Esq. (gr. Mr. Stables).—The largest and handsomest of the Promenæa section of Zygopetalum. The pretty dwarf plant bore two flowers, each 2½ inches across; golden-yellow with a greenish tint showing through from the back. Sepals bearing a few, and the petals and lip numerous effectively-arranged purplish-red markings. The record says, "Cross made July 20, 1901; [resultant seeds] sown February 9, 1902; [plant] bloomed May 15, 1905.

BOTANICAL CERTIFICATE.

Polystachya Haroldiana, from NORMAN C. COOKSON, Esq., whose son HAROLD sent the plant from the region of Lake Tanganyika.—A pretty tufted plant with short compressed pseudo-bulbs and bright-green leaves. The short inflorescences bore five flowers, each nearly 1 inch across, and white with a greenish tint on the sepals.

CULTURAL COMMENDATION.

To Mr. May, gr. to J. B. JOEL, Esq., Northaw House, Potters Bar, for an enormous plant of *Cypripedium Rothschildianum* in fine health, and bearing three tall spikes, each with five flowers open and one bud. A noble specimen.

Narcissus and Tulip Committee.

Present: H. B. May (Chairman); and Messrs. Robert Sydenham, John R. de C. Boscawen, R. W. Wallace, J. T. Bennett-Poë, James Walker, W. Poupart, E. A. Bowles, G. Reuthe, Walter T. Ware, J. D. Pearson, and Chas. H. Curtis, Secretary.

Messrs. WALLACE & CO., Colchester, had a fine collection, among them highly-developed blooms of Margaret, Gala Beauty, Gesneriana rosea, G. lutea, Madame Krelage, Clara Butt, Mrs. Farncombe Saunders, and several of the May-flowering species and varieties (Silver-gilt Flora Medal).

Messrs. BARR & SON, King Street, Covent Garden, staged a large and varied collection, which included Clara Butt, The Moor, Snowdon (white tinted pink), Baron de la Tonnag, Yellow Goblet (deep yellow), Early Dawn, Caledonia, Emanuel Sweet, &c.; also quite a collection of rectified English Tulips and others (Silver Flora Medal).

Messrs. A. DICKSON & SONS, Belfast and Dublin, staged a fine and striking collection, among them Yellow Queen, Duchesse de Modena, Nauticus, Royal Blue (of a novel colour), Gesneriana lutea, Jaune d'Œuf, The Dove, Suzon, La Tulipe Noire (very dark), Grand Master, Bronze King, Mrs. Moon, The Fawn, &c. (Silver-gilt Flora Medal).

Messrs. R. H. BATH, Ltd., Wisbech, staged a representative collection; some of the best were Cordelia (purple-rose), Edmee, Landella, Margaret, Isabella, Mrs. F. Saunders, Bouton d'Or (very fine flower), The Sultan, &c. (Silver-gilt Banksian Medal)

Messrs. HOGG & ROBERTSON, Mary Street, Dublin, staged a fine collection of superbly-developed flowers, which included Vitellina, Bouton d'Or, Millet (rich dark crimson), Theodore Jorisen, Ges. lutea, The Fawn, Yellow Perfection, Mrs. F. Saunders, Macrospila, Glow, Faeric Queen, Mrs. Moon, Sultan, Exquisite, Louis Memmerel (a fine rose self), Bride of Haarlem, Margaret, Madame Krelage, Firefly, &c. (Silver-gilt Banksian Medal).

Mr. G. REUTHE, New Plant Nursery, Keston, had some finely-developed flowers, such as Isabella Whistler, Buffon, Emilee, Harry Veitch, Rose Queen, &c. (Silver Banksian Medal).

Mr. A. WILSON, Spilsby, also had a collection of the leading Darwin and May-flowered varieties in well-developed blooms (Silver Banksian Medal).

Messrs. VEITCH & SON, Chelsea, had Margaret (very fine), Mrs. Krelage, Salmon King, Caledonia, Claude Gillot, Early Bird, Anna Paulowna, with "Parrot" and other varieties.

Messrs. W. BULL & SONS, King's Road, Chelsea, had a small collection, the blooms being rather undersized on the whole, but containing some good varieties.

AWARDS OF MERIT.

The following new varieties received Awards:—

Whistler, *Darwin.*—Bronzy-crimson-flamed and feathered with scarlet; dark base. A fine bold flower. From Mr. G. REUTHE.

Innocence.—A May-flowering variety, with long, pointed petals; white with yellow base. A fine addition.

Quaintness, having a rosy-lilac flame on each petal, with broad golden margin and golden base. A very fine late-flowering variety of good form.

The two foregoing varieties were from Mr. W. T. WARE, Inglescombe Nurseries, Bath.

Fruit and Vegetable Committee.

Present: Mr. A. H. Pearson (Chairman); and Messrs. H. Somers Rivers, O. Thomas, C. Foster, J. Jaques, G. Reynolds, F. Lane, Geo. Kelf, J. Lyne, H. Parr, John Basham, Horace J. Wright, Edwin Beckett, A. Dean, S. Mortimer, Geo. Woodward.

The principal exhibit brought before this Committee was a splendid collection of early-forced fruit, shown by Mr. Jas. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton. Three trees of "Cardinal" Nectarines and one of Early Rivers' Plum, all well furnished with fruits, were staged as the background, and in front were arranged boxes and baskets of Cherries, Peaches, Plums, and Strawberries. Cherries were more numerous, and included the varieties Belle de St. Tronc, Bigarreau de Schreken, Governor Wood, May Duke, Early Rivers (a box of perfect fruits), Empress Eugénie, Frogmore Early Bigarreau, Guigue d'Annonay, and Elton Cherry. A box of Royal Sovereign Strawberries looked tempting (Silver Knightian Medal).

A dozen punnet baskets of Royal Sovereign Strawberries were shown by Mr. C. Page, gr. to J. B. FORTESCUE, Esq., Dropmore, Bucks. The fruits were splendidly finished, and received a Cultural Commendation.

A box of Strawberries was also staged by the Earl of PORTSMOUTH, Whitchurch, Hants (gr., Mr. R. Percy).

Mr. JAS. FITT, the Fythe Gardens, Welwyn, Hants, showed a dish of Vilmorin's Early Dwarf French Butter Bean. The pods are butter-yellow in colour.

Award.

AWARD OF MERIT.

Cucumber Delicacy.—The fruits are very dark in colour, about 14 inches in length, with a good base, and one that is not greatly attenuated, thus rendering almost the whole of the berry edible. It was raised from Matchless × Aristocrat. Shown by Mr. S. MORTIMER, Rowledge, Farnham, Surrey.

NATIONAL TULIP.

MAY 23.—The Committee of the above Society are to be congratulated on the extent of their twelfth annual Southern Exhibition on above date, and, considering the retarding character of the season, on the general good quality of the exhibits. Miss WILLMOTT was successful in several classes, the warm southern position of her garden being in her favour; her stand of six dissimilar breeders was really superb. Lancashire sent its usual contingent of exhibitors, also Cambridge. There was excellent competition in all the leading classes, and visitors appeared to be greatly interested in the brilliant markings of the rectified flowers, and the richness of many of the self breeders. Manchester representatives pronounced it the very best Tulip Exhibition which had been held during the last fifteen years, and the Southern Show has now leaped into the first position. It was interesting to note that several counties sent competitors; flowers came from Wales, Cheshire, Cambridgeshire, Essex, and elsewhere, which goes to show that there has been a great growth of interest in the old-fashioned florists' Tulip.

Rectified Tulips.—In the competitive classes there were some stubborn fights for 1st positions. With twelve dissimilar, two flamed and two feathered in each class, Mr. J. W. BENTLEY, Stakehill, Manchester, was placed 1st, having good, even, bright, well-marked blooms of flamed Lord Stanley and Samuel Barlow, and feathered Garibaldi and Masterpiece, flamed byblœmens Talisman and Chancellor, feathered byblœmens Hannah and Elizabeth Pegg, flamed roses Annie McGregor and Lady C. Gordon, feathered roses Sarah Headley and Modesty. Mr. C. W. NEEDHAM, Kelmscott, Hale, Cheshire, came 2nd with flamed bizarres Samuel Barlow and Sir J. Paxton, feathered bizarres Masterpiece and W. Wilson, flamed byblœmens Geo. Ed. Schofield and Adonis, feathered byblœmens Bertha and Trip to Stockport, flamed roses Mabel and Annie McGregor, feathered roses Modesty and Mrs. Lea. Miss WILLMOTT, Great Warley, was 3rd with some well-marked flowers. Other prizes were awarded.

In the class for six blooms, one feathered and one flamed in each class, Mr. A. D. HALL, Harpenden, Herts, was 1st among six competitors, having flamed bizarre Samuel Barlow, feathered bizarre Everard, flamed byblœmen Geo. Edward, and feathered Elizabeth Pegg, flamed rose Annie McGregor, feathered rose Mabel. 2nd, Mr. J. W. BENTLEY, with bizarre flamed Lord Stanley, feathered bizarre Sulphur, flamed byblœmen Talisman, feathered byblœmen Duchess of Sutherland, rose flamed Mabel, and feathered rose Modesty. 3rd, Miss WILLMOTT.

With three feathered Tulips Miss WILLMOTT was placed 1st, having bizarre Lord Lilford, byblœmen Bessie, and rose Modesty. Mr. J. W. BENTLEY was 2nd with bizarre William Annabel, byblœmen Queen of May, and rose Modesty. There were seven entries in this class and seven in that for three flamed, the awards going as follows: 1st, Mr. W. PETERS, Hartington Grove, Cambridge, who had bizarre S. Barlow, rose Mabel, byblœmen Duchess of Sutherland. Mr. J. W. BENTLEY came 2nd with bizarre Samuel Barlow, rose Mabel, and byblœmen May Queen. Miss WILLMOTT was placed 3rd.

Breeder Tulips.—Some highly-finished blooms were shown in these classes, and Miss WILLMOTT proved very successful in several classes. There were eight stands of six dissimilar blooms, Miss WILLMOTT taking the 1st prize with bizarres Goldfinder and Hepworth's 180, roses Anne McGregor and Industry, byblœmens Janette and Martin's 117—a meritorious half-dozen flowers. Mr. A. D. HALL was 2nd, also with some very good blooms of bizarres Alfred Lloyd and Sir J. Paxton, roses Loveliness and Rose Hill, byblœmens Ashmorle's 112 and Adonis. 3rd, Mr. C. W. NEEDHAM. With three dissimilar breeders, one of each class, Miss WILLMOTT was also 1st with bizarre Hepworth's 15/64, rose Mrs. Barlow, and byblœmen Bridesmaid. 2nd, Mr. A. CHATER, Cambridge, with bizarres Sir J. Paxton, Mrs. Barlow, and Bridesmaid.

Single Blooms of Rectified Flowers.—Flamed bizarre Samuel Barlow was placed 1st and 2nd, both from Mr. BENTLEY; Sir J. PAXTON was 3rd. Feathered bizarre: Miss WILLMOTT was 1st with Lord Stanley; the 2nd and 3rd flowers were not named. Feathered rose: Miss WILLMOTT was 1st with Modesty, and 3rd with Miss Nightingale; Mr. BENTLEY taking 2nd with Sarah Headley. Flamed rose: Miss WILLMOTT was 1st and 2nd with Annie McGregor; and Mr. BENTLEY 3rd with Aglaia. The best feathered byblœmen was Elizabeth Pegg, but the name of the exhibitor was not apparent; Miss WILLMOTT came 2nd with Mrs. Jackson, and 3rd with Guido. The best flamed byblœmens were Talisman from Mr. BENTLEY, and he was 3rd with Chancellor; Mr. HALL was 2nd with George Edward.

Breeder Tulips.—Bizarres: 1st, Alfred Lloyd, shown by Miss WILLMOTT; the variety Wm. Lea was 2nd, but the exhibitor's name was not found; Mr. CHATER was 3rd with James Smith. Byblœmens: Talismar, from Miss WILLMOTT, who was also 2nd with Leach's No. 1, and 3rd with Jeannette. Roses: 1st, Mr. A. CHATER with Mrs. Barlow; 2nd, Miss WILLMOTT with Annie McGregor, and 3rd with Lady Grosvenor.

The Samuel Barlow Memorial Prizes.—These commemorate the services rendered to the advancement of

the Tulip by the late Mr. Samuel Barlow, and five prizes are offered in a special class for two rectified Tulips, one feathered and one flamed, of any class. Mr. J. F. KEW, Southend, was placed 1st.

The following classes were open to growers of limited collections of English Tulips:—Six dissimilar rectified blooms, Mr. J. F. KEW was 1st with bizarres Sir J. Paston and Sulphur; byblœmens King of the Universe and Adonis; rose Mabel and one unnamed; 2nd, Mr. R. W. HALL, Cambridge. With three feathered blooms Mr. HALL was 1st with bizarre Sir J. Paxton, byblœmen King of the Universe and rose Lloyds 200; Mr. J. F. Kew came 2nd with bizarre Richard Headley, byblœmen Elizabeth Pegg, and rose Modesty. With three flamed, Mr. J. F. KEW came 1st with Sir J. Paxton, Chancellor and Mabel; Mr. HALL being 2nd with Samuel Barlow, Elizabeth Pegg and Heroine. In the class for three dissimilar breeders Mr. KEW was the only exhibitor, having John Wills, Elizabeth Pegg, and Kate Connor.

Premier Blooms.—The premier feathered flower was bizarre William Annabel, a finely-marked flower, exhibited by Miss WILLMOTT. The premier flamed bloom was bizarre Samuel Barlow, from Mr. J. W. BENTLEY. The premier breeder was byblœmen Bridesmaid, from Mr. A. CHATER.

The Lecture.

A lecture was delivered by Mr. E. MORELL HOLMES on Medicinal Plants Old and New. The Lecturer pointed out that although horticulture must have begun at a very early period of civilisation, the plants required for medicinal use were chiefly collected from the fields and woods and were not specially cultivated. Even in the time of the Greeks and Romans, although horticulture had made great strides and pipless Apples and Grapes were known, Violets and Roses were found in winter, yet there is no record of distinct physic gardens. It was only in the records of monasteries, abbeys, and nunneries in the Middle Ages that we found any mention of a physic garden or portion set apart for the cultivation of medicinal herbs, usually near the surgeon's residence, and distinct from another portion of the garden retained for culinary herbs. One of the first lists of plants cultivated in these physic gardens was given in the *Capitulary of Charlemagne*. Subsequently wealthy citizens had physic gardens, and during the reigns of the Tudors there were physic gardens under the charge of the apothecary who attended Royalty. Private physic gardens were followed by municipal physic gardens, and these developed into the modern botanical gardens to which modern horticulture owes so much. Descriptive catalogues of the plants grown in these gardens, and containing an account of their medicinal properties were published by their owners and formed the "herbals" on which domestic medical treatment was based until the early part of the last century, when a large number of medical plants described in them were omitted from the pharmacopœias, and the herbals were succeeded by more advanced works on the medicinal plants official and the pharmacopœias. During the later half of the eighteenth century, the growth of the population led to an increased demand for medicinal plants and their preparations, and the cultivation of these was carried on on an agricultural rather than on a horticultural scale. The increasing use of quinine led to cultivation of Cinchona bark on a large scale in India and Ceylon, followed by that of Coca in various colonies. The Lecturer also alluded to the cultivation of Indian Hemp for medicinal purposes, and to the ancient and more extensive cultivation of the opium Poppy in various countries. The lecture was illustrated by numerous photographs, showing ancient gardens, also the cultivation of medicinal plants in farms in this country, and of Cinchona and Opium in India.

PUBLICATIONS RECEIVED. — *Southern Rhodesia*: Information for Settlers. Southern Rhodesia is here said to offer prospects for successful farming operations, and to be specially favourable for raising Maize, Wheat, Root crops, Tobacco and Cotton. This publication is attractively illustrated, and contains maps and illustrations useful to intending settlers.—*Transactions of the Royal Scottish Arboricultural Society*: Vol. xviii., Jubilee Volume. Among the contents are the President's Address, Forestry in Britain the Last Fifty Years, Reports on Excursions, Planting Waste Land for Profit, G. U. MacDonald; Colorado Variety of the Douglas Fir, the Douglas Fir Plantation at Taymount, &c.

INTERNATIONAL HORTICULTURAL EXHIBITION AT PARIS.

MAY 20 TO 26.—An International Horticultural Exhibition was opened by President Loubet, who was accompanied by Madame Loubet, on May 20, in the building known as Cours-la-Reine, Paris. Two separate buildings, erected in 1900, were utilised for this purpose, and a temporary structure of large size was erected between them to connect the two. The buildings thus joined covered an immense area, and at the same time their appearance was perfectly harmonious.

The deputation from the Royal Horticultural Society, mentioned on p. 328, awarded a large number of medals for exceptional exhibits, and these included two Gold Medals to the well-known firm of Messrs. Vilmorin, Andrieux et Cie. Messrs. W. Cutbush & Sons were the only English nurserymen represented by an exhibit, but visitors from England were numerous, and it has to be remembered that the near approach of the Temple Show may have deterred some of them from making exhibits. The show was remarkable for the displays of Rhododendrons, Pelargoniums, Annuals in flower, and flowering plants generally; also for devices of florists' flowers and collections of vegetables.

The disposition of the exhibits and the constituents in every exhibit were beyond praise, and the display afforded effects much superior to those of any exhibition we have attended in Britain. In connection with the event, which lasted over nine days, there were several social gatherings and receptions, in addition to a congress for the discussion of matters relating to the cultivation of plants, &c. Some details of the show are given below.

NEW OR RARE PLANTS.

Herr W. PFITZER, Stuttgart, Germany, exhibited a plant of a species of Ficus, brought from the "Côte d'Ivoric," having lanceolate, acuminate leaves 1 foot in length, and 1 inch across in widest part; also a new Aloe from Madagascar. Verbena hybrida "Etoile de Stuttgart" had white flowers with a vivid red stripe on each petal, and making a coloured star upon each flower, being very effective.

A plant of Davidia involucrata, about 4 feet high, was shown by M. G. BOUCHER, nurseryman, Avenue d'Italie, Paris.

A magnificent plant of the new Anthurium "Illustrée," a variety exhibited first at Ghent seven years ago, was included in a group of Codiæums, Marantas, Nepenthes, and other choice foliage plants shown by Messrs. CHANTRIER FRÈRES, Mortefontaine, Oise, who had an excellent collection of Sonerillas and Bertolonias. Other new plants shown by Messrs. Chantrier were as follows:—Codiæum "Duchesse de Gramont" (Silver-gilt Medal), a variety with broad leaves, the older ones being coloured green, yellow, and red, and about twelve of the younger ones wholly of a light red colour. This was a well-grown plant of a very beautiful variety. Kæmpferia Roscoeana (Silver-gilt Medal) was a plant with broad, ovate leaves, with recurved margins, coloured with shades of green and brown. A species of Maranta from Brazil (Silver-gilt Medal), having perfectly green leaves about 1½ foot long and nearly as wide; also Musa sapientum rubra, which has been already illustrated in these columns.

ORCHIDS.

The most important class for Orchids was one for 100 specimens in pots. The coveted Prix d'Honneur was awarded to M. A. MARCOZ, nurseryman, Villeneuve St. Georges (S.-et O.), and the same exhibit was awarded a Silver-gilt Flora Medal by the deputation from the Royal Horticultural Society (England). Among the most beautiful plants in the exhibit were excellent specimens of Odontoglossum crispum in very choice varieties, Phalænopsis grandiflora, P. Rimestadtiana, Lælia purpurata, L. tenebrosa, Cypripedium Rothschildianum, many Cattleyas, Oncidiums, Miltonias, &c. An Oncidium shown as O. species had magnificent flowers of great substance and rich brown-and-yellow colours. It is of the type of O. crispum, but of higher merit. 2nd, M. G. LESUEUR, 65 bis, Quai Président Carnot, Saint Cloud, Seine-et-Oise.

The best collection of Lælias, Cattleyas, and Lælio-Cattleyas came from M. CHAS. MARON, nurseryman, Brunoy, whose largest plant was a well-flowered specimen of L.-C. Mozart (Cattleya lobata × C. Lawrenceana). There were sixteen open flowers, and all of them were richly coloured, the colour in the lip being especially good. The curious Cirrhopetalum Mastersianum was shown in beautiful condition, with eight of its remarkable brownish, old-gold coloured flowers arranged in a semicircle at the end of the peduncle. Lælia-Cattleya × Hyeana and L.-C. callistoglossa were very good.

A class for Vandas, Phalænopsis, and Aërides was won by M. ALEXANDRE RÉGNIER, nurseryman, 44, Avenue Marigny, Fontenoy-sous-Bois (Seine). The Phalænopsis were best represented in this group, and were of one species only, P. amabilis. A plant of P. a. Dayana var. Regnieri having twenty-six extremely fine flowers on one spike was given a special award of a Silver-gilt Medal. Vanda cœrulescens and several species of Aërides were also shown. A specimen of A. Sanderiana superba, almost like a bush, with growths nearly 4 feet high, bearing profuse and vigorous-looking foliage, was given the special award of a Silver-gilt Medal, although not in flower. There are few such specimens in which the leaves have been retained to the base as they have been in this instance. A hybrid Cattleya obtained from a cross between Lælia purpurata and Cattleya Mendeli, and bearing the name of C. Regnieri, was also awarded a Silver-gilt Medal, as shown by M. REGNIER. It is specially remarkable for its extremely large, broad-spreading, richly-marked labellum.

In a class for a collection of twenty-five Orchids in flower, M. MAGNE, 15, Boulevard de Boulogne, Boulogne-sur-Seine, was awarded a Gold Medal for an excellent exhibit.

M. DUGOURD had an interesting exhibit of Orchids indigenous to the Forest of Fontainebleau and its surroundings; species of Listera, Ophrys, and Orchis were represented (Silver Medal).

M. ROBERT LEBAUDY, amateur, 24, Rue de Mesmes, Bougival, Seine-et-Oise, included some very pretty specimens in a collection of fifty Orchid plants, for which he obtained the 1st prize, Miltonia vexillaria and Lælio-Cattleya × cinnaharina being noteworthy. Messrs. DUVAL ET FILS, Versailles, who were placed 2nd, had a very pretty specimen of Cattleya Skinneri, &c.

STOVE FOLIAGE PLANTS.

Messrs. DUVAL ET FILS, 8, Rue de l'Ermitage, Versailles, were awarded a Gold Medal for an excellent collection of twenty distinct varieties of Anthurium Scherzerianum. We noticed Etandard (deep red), General Marcitte (mottled), and La Belle France (mottled), as being among the best. Messrs. DUVAL had other exhibits of Anthurium, and groups of well-grown Caladiums, for which Gold Medals were awarded them.

A very fine collection of stove and greenhouse plants, including a few Orchids, such as Vanda teres, Miltonia spectabilis, &c., was shown from the Luxembourg gardens.

A magnificent specimen of Phœnix canariensis, from M. J. VILLERENOIT, La Victorine Nursery, Nice, was awarded a Gold Medal.

Some seedling varieties of Anthurium in flower came from the authorities of the Royal School of Horticulture of Florence (Italy). Some of the spathes were of the Andreanum type, but others were of very much larger size, and almost green in colour. A variety named Madame Valassi, with a broad, pure white spathe, was remarkable, and several others of deep red colour possessed considerable horticultural value. The exhibit was awarded a large Gold Medal, and by the Royal Horticultural Society (England) a Silver Flora Medal.

Anthurium Scherzerianum variety, shown by Messrs. DE BOSSCHÈRE & CO., Eecheren, Antwerp (Belgium), was a magnificent specimen in a tub, which bore a very large number of good spathes, resembling those of the variety "Wardii" (large Silver-gilt Medal). The same exhibitors had a collection of Anthuriums for which a large Silver-gilt Medal was awarded.

Stove and greenhouse plants from Messrs. L. V. CHARON FILS, nurserymen, Paris, were capital, and included Palms of sizes and appearance such as we never see at exhibitions except when visiting Ghent or other places on the Continent. Anthuriums from the same amateur were excellent, and a variety of the A. Andreanum type named Robert Lebaudy, was as good as can often be seen (Gold Medal). Each of the fourteen plants of Begonia Gloire de Lorraine were 3½ feet across, and in as perfect condition and flower as we are accustomed to see this popular plant in December. It would appear that the Parisians flower the variety during the greater part of the year.

The best Caladiums were shown by M. ROBERT LEBAUDY, amateur, Bougival (S.-et-O.) (gr., M. J. Page). The specimens in this exhibit were in large-sized pots, and being well-developed, highly-coloured, choice plants, were more nearly equal to the quality of the best plants exhibited at our own shows. The Prix d'Honneur was awarded them. The same amateur was awarded the Prix d'Honneur for Codiæums (Crotons), which, though good, would not surprise Englishmen.

Messrs. RIVOIRE, PÈRE ET FILS, nurserymen, Lyons, exhibited a considerable number of Caladiums as small plants, but representative of the choicest varieties (Silver-gilt Medal).

Messrs. ANATOLE CORDONNIER ET FILS, Baillent, obtained a Gold Medal for Codiæums (Crotons), the spe-

cimens being from 3 to 4 feet high, and of good culture and development.

The Syndicat Horticole de la Région Parisienne made a display with Palms, Viburnums, Lilacs, Hydrangeas, Pelargoniums, Bougainvilleas, Roses, &c. (Gold Medal and Royal Horticultural Society's Silver Flora Medal).

GREENHOUSE FLOWERING PLANTS.

The zonal Pelargoniums from M. E. Poirier, nurseryman, Versailles, in which the colours were bedded out in triangles and panels of different shapes, formed one of the brightest features of the show. The plants were grouped in beds which surrounded three sides of a little grass lawn, and the Pelargoniums represented an arch lying on the ground. The varieties were of the very best and represented the brightest colours, whilst the cultivation and arrangement of the plants could hardly have been better carried out. The exhibit was awarded a Prix d'Honneur, and from the Royal Horticultural Society (England) a Silver-gilt Flora Medal.

M. Ch. Molin, Lyons, had a group of decorative Pelargoniums in pots, and F. Foucard Fils, Orleans, another group of similar plants (a Gold Medal and Silver-gilt Medal respectively).

Messrs. Piennes et Larigaldie, Successeurs Marchands Grainiers, 14, Quai de la Mégisserie, Paris, were awarded a Gold Medal for an extensive group of Cannas flowering in pots. Most of the varieties were similar to those shown so well in England by Messrs. H. Cannell & Co., but Curé (yellow), Inédit (rich apricot colour), and Comte de Bouchard (rose-colour), were of fine merit and less familiar (Large Gold Medal).

Messrs. Billiard et Barrie, Fontenoy, also obtained a Gold Medal for Cannas.

Metrosideros floribunda was grown grandly by M. Derudder, Nurseryman, Versailles, as standard plants 4 feet high, and covered freely with flowers. There were some two dozen plants, and the brilliant red colour was very effective, the plants being equal to any we have seen at Ghent or other continental shows (Gold Medal and Royal Horticultural Society's Silver-gilt Medal).

M. Aug. Nonin, Nurseryman, 20, Avenue de Paris, Chatillon-sous-Bagneux, exhibited Marguerite "Coronation," a very large-flowered Fuchsia named Robert Blatry, also Begonia giganteа, Impatiens Holste, with exceedingly bright orange-red coloured flowers (very noteworthy), Carnations, Pelargoniums, &c., and was awarded several honours.

The only important exhibit of Cactaceous plants was shown by M. Charles Simon, St. Ouen (Seine), but this was of very large extent, the group of Phyllocactus alone including several hundreds of plants in infinite variety, as well as of Mamillarias, Echinopsis, Cereus, Aloe, Agaves, Echinecactus, Opuntias, Euphorbias, &c. There were numerous well-cultivated specimens. The group was awarded a Prix d'Honneur, and a Royal Horticultural Society's Silver Medal.

Gloxinias, representing the best French strains of spotted varieties as well as a few plants that were more of the type of English florists, were shown grandly by Messrs. G. Fargeton Fils, 38, Rue Saumuroise, Angers. Two varieties were especially interesting, one of which had flaccid foliage that could be bent quite easily without breaking, an advantage when moving the plants or when arranging them near to other plants, and the other possessing rich cherry-red-coloured flowers with three paler stripes on each segment. The first-mentioned variety was called Madame Renée Fargeton, and the other Madame Louis Fargeton (Gold Medal and Silver Flora Medal from Royal Horticultural Society, England).

Messrs. Vallerand Frères, of Asnières and Taverney, also showed Gloxinias of very commendable merit, and they had a group of tuberous-rooted Begonias that would compare favourably with exhibits we may expect next week at the "Temple." The variety Phénomène or Monstruosa, a yellow flower, was one of the most curious developments we have yet observed in what is known as the "crested" section. "Rouge très foncé" was a single flower of extraordinary deep crimson colour. Caladiums from the same firm, and the exceedingly brightly-flowered Scutellaria Mociniana from the same firm were also worthy of remark (Gold Medal).

Messrs. Billiard Barrie, Fontenay, also showed Gloxinias (Gold Medal).

M. Arthur Billard, Succr., nurseryman, Avenue des Pages, Le Vesinet, was awarded a Gold Medal for a group of Tuberous-rooted Begonias, in which the types known in England were represented in good condition by plants of moderate size.

M. Aug. Chantin, Rue de l'Anaril Monchez, Paris, was also awarded a Gold Medal for Roses.

The exhibits of Carnations included a good one from M. Joachim Idot, gr. to Madame Ernest Dormeuil, 3, Rue de Saint Germain, Croissy. These plants were in pots, and the varieties of the Souvenir de la Malmaison type and of the "Tree" section were good, but not better than we are accustomed to see in England.

A collection of exotic species of economic plants was shown by M. Godefroy-Lebeuf, 4, Impasse Girardon, Paris, Montmartre; and another by the Minister for the Colonies, Jardin Colonial, Paris.

HARDY PLANTS.

Messrs. Cayeux et Le Clerc, 8, Quai de la Mégisserie, Paris, showed varieties of Tropæolum, said to have been obtained from crosses between T. Lobbi and T. peregrinum (canariense). They were of slender growth, very floriferous, and had laciniated petals. A pretty Calceolaria named "Phare" was also shown by this firm, and beds of annuals, Cinerarias, &c., for which a Gold Medal, &c., was awarded.

Messrs. Paillet Fils, Vallée de Chatenay, near Paris, exhibited a grand lot of Tree-Pæonies, which are worthy of appreciation. The flowers were numerous, of large size and of beautiful colour. A Gold Medal was awarded, and the Royal Horticultural Society's deputation awarded the group a Silver Flora Medal. The same firm had an exhibit of Clematis in pots that would hardly compare with similar ones to be seen at our own "Temple" shows.

Messrs. Honoré Defresne, Fils, Vitry, near Paris, also exhibited an excellent group of Tree Pæonies to name in an unusual number of varieties, the popular one known as Elizabeth being among the most effective (Gold Medal and from Royal Horticultural Society, England, a Silver Flora Medal).

Varieties of a curious type of Ageratum were shown by E. Dorsneau, Nurseryman, Rambouillet, in which the cellular parts of the leaves were puffed up above the ribs, the crinkled appearance thus caused being exceptional so far as our experience goes, but the altered effect would have little or no value in the garden.

E. Thiebaut, Sr., Place de la Madeleine, Paris, was awarded a Gold Medal for Tulips, the cut flowers being very fine. Another collection was shown by C. Angel et Fils, 10, Quai de la Mégisserie, Paris (Silver-gilt Medal).

A very large oblong bed was planted with varieties of Iris Kæmpferi by M. Tabar, Nurserymae, Montmorency, Seine-et-Oise. The plants were in pots, and the pots plunged. Most of the flowers were from 2½ to 3 feet high and of large size, the shades of colour being most charming. In effect this exhibit was one of the most gratifying features of the show. We have never seen this Iris exhibited in as good condition or with the colouring so tastefully disposed. A Gold Medal was awarded, and in addition the Royal Horticultural Society awarded a Silver-gilt Banksian Medal.

Messrs. Lemoine et Fils, Nancy, exhibited plants of their very fine hybrid Deutzias in flower; also large flower-sprays of varieties of Lilacs raised at Nancy. A plant in flower of the new yellow-coloured Pæonia lutea superba (illustrated in these pages after the last Ghent show), having two flowers, was an object of much beauty, and the best of the species we have yet seen (Gold Medal).

M. Grainier, Nurserymen, Avenue Victoria, Paris, and M. A. Séraud, Rue de Chatillon, Vauves (Seine), exhibited a group of hardy flowering plants in very good condition. Both were awarded Silver-gilt Medals, the latter firm the premier.

An exhibit in which plants of Azalea (Rhododendron) Anthony Koster were interspersed with R. Robert Croux (deep crimson) had a most agreeable effect, the colours being especially suited for mixing with each other. The exhibit was one from Messrs. Croux et Fils, Chatenay (Seine), who were awarded a Gold Medal. This firm and that of M. Moser et Fils, Versailles, showed very large bushes of numerous varieties of Rhododendrons and Azaleas, all of which were exceptionally good, being quite equal to anything of the kind we have seen at Ghent or other exhibitions. Many of the varieties, as Kate Waterer, have originated in our own country, and it was gratifying to see them as successfully cultivated as is possible even by our own firms of Waterer and others. Bed after bed was filled with plants from the firms mentioned above, and had time and space permitted it would have been possible to have made excellent selections of varieties in each section from the plants exhibited by these celebrated cultivators. Highest awards were made for these collections.

Messrs. Moser et Fils, Versailles, were also awarded a large Silver-gilt Medal for an exceedingly large Rhododendron bush of the variety Princesse Hortense, a variety with pink flowers marked with yellow spots. It was mounted very high.

Azaleas (Rhododendron indica) were not shown extensively owing to the season being advanced, but an exhibit of moderate-sized plants from Messrs. Royer Fils, Versailles, was of superior quality and obtained a Gold Medal.

ROSES.

One-half of a special Rose garden under cover was planted with dwarf plants and standards by Messrs. Levêque et Fils, 69, Rue du Liegat, Ivry-sur-Seine. These pot-plants, though not better than are shown in England, were nevertheless of excellent merit, and they were awarded the premier "Prix d'Honneur." Some of the flowers on the standard plants were of exhibition value, but we did not notice any new varieties especially noteworthy.

The other half of the same garden was planted similarly by Ad. Rothberg, Rue St. Denis, Gennevilliers, Seine, and was awarded a Prix d'Honneur.

Messrs. Levêque et Fils, Rue du Liegat, Ivry-sur-Seine, Paris, had in another situation a fine lot of standard Roses plunged in a bed and edged with the delightful variety Madame Lavavasseur. These were considered so good that a Premier Prix d'Honneur was awarded them, and the Royal Horticultural Society (England) awarded a Silver Flora Medal. The varieties Soleil d'Or lutea remontant and Persian Yellow were shown finely by the same exhibitors.

A bed of Roses of the Polyantha variety Madame Norbet Levavasseur, shown by M. Boucher, Avenue d'Italie, Paris, was very fine. The plants were from 1 to 2 feet high, and were covered with their bright rose-coloured flowers. A group of hybrid Clematises of the C. lanuginosa type, from the same exhibitor, was noteworthy (Gold Medal). Standard Roses and dwarf plants of numerous varieties of several sections were exhibited from the same nursery. All were good in quality, and several gold medals were awarded.

M. Léon Jupeau, 135, Route de Fontainebleau, Kremlin-Bicêtre (Seine), showed a very large number of small Rose plants in pots, sufficient to indicate the speciality of the nursery, but not advanced enough to brighten the show (Large Silver Medal).

Standard Roses were also exhibited numerously by M. Th. Niklans, nurseryman, 23, Avenue Rouget-de-l'Isle, Vitry-sur-Seine. The plants were standards, with heads of somewhat small size, but very well flowered (Gold Medal).

FLORISTS' DEVICES.

Some German florists sent from Germany a collective exhibit of arranged flowers, which included devices of a more or less novel nature. Some wreaths, composed exclusively of such materials as Pinus sprays, Fern fronds, Echeveria plants with inflorescences, Sedums, &c., were sombre in the extreme. Among French florists M. J. Maïssa, Boulevard Haussmann, Cannes, and Monte Carlo, was awarded a Prix d'Honneur for a table of Cattleyas and Oncidiums, and a large bouquet in vase composed of red Anthuriums, yellow Richardias, and Oncidiums, which was admirable.

M. Lachaume, 10, Rue Royale, Paris, whose exhibits were much admired at the last Ghent show, displayed a table decoration in which a mirror extended almost the full length of the table, and upon which were large Bamboo stands, bent into designs, and lavishly decorated with Orchids. Bouquets of Roses and Cattleyas were arranged along either side of the mirror, and together afforded an effect of lavish flower and colour blended with such taste as to be agreeable and exceedingly rich to the eye.

Among other skilful florists who exhibited in this section were MM. A. Lorin, 53, Avenue Kleber, Paris; A. Girard, 71, Avenue Marceau, Paris; M. Ponceblane, 12, Avenue de l'Alma, Paris; M. Lebosse, 3, Rue Mignard, Paris; R. Langlois, 11 bis, Avenue Victor Hugo, Paris; Ed. Debrie, 12, Rue des Capucins; and A. Lorin, Avenue Kleber.

ANNUAL FLOWERING PLANTS.

Several firms exhibited groups of annuals in flower arranged in beds, and of these the firm of Messrs. Vilmorin, Andrieux et Cie., 4, Quai de Mégisserie, Paris, was the best. It would be impossible to overstate the excellence of this exhibit, whether judged from the point of view of cultivation, excellence, or tasteful grouping. The major part of the plants were grouped in beds which had been built up in a sloping manner over portions of a very wide stone staircase on a side of a building having a much lower level than that of the centre of the hall, and with the waters of the Seine in view. All sorts of annuals, whether used for bedding out-of-doors or for cultivation in pots, appeared to be included in the different beds, and the quiet shades of colour possessed by the Nemesias, and the gaudy scarlet of the Poppies, were so arranged with every other shade of colour of the different varieties of plants, that each bed was a picture in itself; whilst the entire exhibit was a representation of almost every annual-flowering plant available for gardens. Messrs. Vilmorin were awarded a Gold Medal by the Royal Horticultural Society (England), and Gold Medals by the French Society. Other exhibits of Annuals were made by M. L. Férard, Rue d'Arcade, Paris, and several firms.

FRUITS AND VEGETABLES.

There were not many exhibits of fruits, but those that were displayed contained some excellent specimens.

Messrs. Anatole Cordonnier et Fils, Grapperies du Nord, Bailleul, showed Peaches, Grapes, Plums, Strawberries, &c., and were awarded a Prix d'Honneur, three Gold Medals, and in addition a Silver-gilt Knightian Medal by the Royal Horticultural Society England.

M. L. Parent, Rueil, exhibited pot fruit-trees which were carrying ripe fruits, such as Red Currants, Figs, Cherries, Plums, &c. These were exhibited in a glass cabinet, and reminded us of similar trees exhibited at Temple Shows by Leopold de Rothschild, Esq. Gold Medals were also awarded this exhibitor.

Messrs. Vilmorin, Andrieux et Cie. showed one of the most complete collections of vegetables and salads in season we have ever seen. The exhibit was several yards wide, and about 120 yards

long. We were informed that nearly 800 varieties were included, and it may be therefore easily understood why detailed reference to it cannot be made. It must suffice to say that everything was shown in excellent condition, and that certain salads and vegetables not in common use in England might be observed there. Such were Portulaca oleracea, Claytonia perfoliata, "Valerianella" or "Mache Dorée," &c. (Royal Horticultural Society's [England] Gold Medal, and highest prizes from the Exhibition authorities). Several other collections were exhibited.

EXHIBITS OUT-OF-DOORS.

In addition to the space within the large buildings, all the surrounding ground was pressed into the service to accommodate exhibits of one kind or another. Trees and shrubs were bedded out by various firms, and they furnished a very agreeable effect. The display of garden implements and sundries was varied and extensive. Rustic summer-houses in great variety were shown by many continental firms.

M. Felix Mansion, Paris, staged wooden tubs for shrubs and trees; as also did MM. Bl. Loyre, Passy, Paris; Lelarge, Paris; and Paul Figures, Fils, Paris.

Plant-frames, greenhouses, &c., mostly constructed of iron with iron stagings, were shown by A. Michaux, Asnières; H. Rondier and A. Crouzet et Cie, Paris; Perrier, Fils, Paris; J. Girardot, Paris; Auguste Danrée, Alfortville, Seine, and many others.

M. J. C. Tissot, 31, Rue des Bourdonnais, Paris, staged mowers, mats, sphagnum moss, peat, syringes, and a general collection of horticultural sundries, including an ingenious machine for cutting sphagnum-moss ready for potting.

M. Thureau, Paris, also staged a good assortment of sundries, including the Pagoscope, recently described on p. 133.

Garden statuary in many beautiful designs was exhibited by M. Val d'Osre, Paris.

Several types of spraying machines were on the stand of M. F. Besnard, Paris, and samples of a metal unkinkable garden hose were noticed at the stall of MM. Allouard et Cie, 72, Rue du Chemin Vert, Paris.

Fruit-storing trays and racks were well shown by M. E. Jollinet, St. Prix, Seine-et-Oise.

Boilers occupied a large area and were shown by many Paris firms, including Durand Vaillant, Paul Lebeuf, L. Blanquier, Maitre et Fils, Perrier et Fils, Dedieu, and Hallay.

The Strebel Counterblast Boiler was exhibited by the Paris branch of the house of R. O. Meyer, Ltd., Norfolk Street, Strand, London.

ENGLISH EXHIBITS.

There were only two exhibits from England, though visitors from this country were numerous. Messrs. W. Cutbush & Sons, Highgate, London, made one of their characteristic displays of Carnations, in which the best varieties of the Souvenir de la Malmaison type and of the "Tree" section were included (Gold Medal).

The other exhibit from England was one of framed illustrations that have appeared at various times in the *Gardeners' Chronicle*. This was shown among other similar productions from France and other countries, and was awarded a Large Gold Medal.

Obituary.

Alfred Mason.—We greatly regret to have to record the death of Mr. Alfred Mason, senior partner of the firm of Dobie & Mason, Manchester, which took place on Friday, May 12, 1905, on his sixty-eighth birthday. The business will continue to be carried on by his two sons, the remaining partners.

J. Hollingworth.—We regret to announce the death of Mr. J. Hollingworth, head gardener and agent to J. F. Campbell, Esq., of Woodseat, Staffs. Mr. Hollingworth, who had been in failing health for some time since, died on May 12, of heart-failure, at the comparatively early age of sixty years. Over twenty-five years ago Mr. Hollingworth took charge of the gardens at Woodseat, and, encouraged by an enthusiastic employer in the person of the late Colin Minton Campbell, Esq., won for himself a reputation as a Grape-grower, winning honours at the fruit shows in London, Birmingham, Manchester, Liverpool, and other places, while he excelled in all other branches of gardening. After a lengthy period of service Mr. Hollingworth left Woodseat to take charge of Lord Tredegar's gardens at Tredegar Park, Monmouth, and from there he moved to Margam Park, Glamorgan. A few years later he returned to Woodseat to take entire management of the estate and gardens, and continued there until his death.

Rev. Theodore Henry Marsh.—We regret to announce the death of this gentleman, which took place on May 14, 1905, in his eighty-first year. He associated himself closely with horticulture, and took up the mantle of Nelson of Aldborough, that other good and genial parson who did so much for local floriculture, and in fact succeeded to his collection of bulbs; and for the last half-century or so the garden at Cawston was the local Mecca of Norfolk gardeners. His "Daffodil Teas," when until very recently he showed once a year collections of rarities to flower-lovers, became one of the most looked-for and most enjoyable local functions.

ANSWERS TO CORRESPONDENTS.

Asparagus Cultivation in Germany: *English Grower*. Various methods are followed, including the French one of planting rather deeply in 5-feet-wide trenches with wide alleys between, and uncovering the plants at the commencement of winter, the removed soil being piled up in the alleys, and the crowns afforded a dressing of decayed manure. The plant is very hardy, and under this amount of protection and the snow, which scarcely ever melts before the month of March, it is quite safe. When growth begins in April the removed soil is sifted gradually over the crowns to the depth it is desired the edible portion should attain; and in cutting the produce the soil, which, owing to the action of the frost is friable, is scraped away by the hand or with a small wooden paddle, and the shoot broken or cut off close to the crown, no injury being done to the neighbouring shoots, and the soil is returned over the crowns. When the cutting season has come to an end, the removed soil is wholly returned to the beds, and the surface is made level. By this method growth is made in darkness, and necessarily the shoots are white almost to the tip. The same result is obtained by planting at a lesser depth, throwing or raking the upper crust of soil of the beds into the alleys for the winter, dressing with manure and returning the soil to the beds in early spring, the growing shoots being covered with pots having lids to exclude the light or with flower-pots which have the apertures stopped with a plug of clay. The English method of planting is followed, i.e., on flat beds without alleys, the rows standing at 2½ to 3 feet apart, or in beds raised above the surrounding area by taking the soil out of the alleys which run between the beds, and adding it to that of the beds. This last is the best in heavy and very moist soils, for although the plant requires much root moisture when in growth, the water must not be stagnant or sluggish in the soil. In short, the drainage should be efficient in any case or the roots will decay and the produce be of poor quantity and quality. The firm of L. Späth, Baumschulenweg, bei Berlin, publish a little book of instructions on Asparagus-culture.

Books: *M. S. S. Handbook of Hardy Trees, Shrubs, and Herbaceous Plants*, by Decaisne and Naudin, translated from the French by W. B. Hemsley. It can be obtained from our Publishing Department.

Bulbs: *J. C. H.* We do not recommend particular firms. Scan our advertising columns.

Caterpillars: *S. G.* The caterpillars are those of the Vapourer-Moth (Orgyia antiqua). The creature is not at all particular what it eats. We fear we can suggest nothing but hand-picking.

Cupressus Lawsoniana: *Gilmurie*. We find neither insect nor fungus, and suppose therefore that the trouble is at the root. Perhaps the drainage is bad, or the roots have got down into soil that is not suited to their requirements.

Grapes: *Anxious*. The berries are spotted with a fungus (Gloeosporium). It is too late to do anything but burn the affected berries. Next year try spraying with Bordeaux-mixture.

Hippeastrum Plant: *A. T.* We ourselves should certainly not accept an article that did not agree with the one ordered. We think your offer suggesting an exchange a very liberal and fair one.

Hollyhock Disease: *Salop*. The following preparation is recommended by Messrs. Webb & Brand, who make a speciality of these plants: To 1 lb. of Tobacco-powder add ¼ ounce of finely-powdered sulphate of copper, and well mix. Dust the under surfaces of the leaves with the powder every two or three weeks during the growing season, choosing dull, still days for the operations.

Japanese Pine: *M. G. B.* Probably it is Pinus parviflora. The fall of the leaf is a natural process, but you may have accelerated it by keeping the plant too dry. Keep the plants in an even temperature free from draughts. Apply water with discretion, but avoid the use of manure.

Names of Plants: *Paddy*. Sophora tetraptera microphylla.—*A. R.* Daphne collina var. Neapolitana.—*Herb*. Anchusa officinalis.—*Cecil*. 1, Prunus Padus (Bird Cherry); 2, Berberis vulgaris; 3, Cupressus nootkatensis, the Thuiopsis borealis of gardens; 4, Cupressus (Retinospora) pisifera; 5, Thuya occidentalis; 6, Thuya plicata (true), the T. gigantea of gardens.—*J. Y.* 1, Epidendrum vitellinum; 2, Dendrobium clavatum; 3, Maxillaria tenuifolia; 4, Pilea serpyllifolia.—*T. B. B.* Epidendrum selligerum.—*A. B*, 1, Odontoglossum Lindleyanum; 2, Odontoglossum Hunnewellianum; 3, Oncidium barbatum.—*W. D. M.* 1, Trillium grandiflorum (see last week's *Gardeners' Chronicle*, p. 308); 2, Cypripedium siamense; 3, Orobus vernus.—*E. L.* Prunus Padus, the Bird Cherry.—*C. B., Braintree*. Odontoglossum Hallii xanthoglossum.—*F. M., Epping*. Gongora bufonia.—*C. W. P.* Cupressus sempervirens.—*S. T.* 1, Thuya nootkatensis; 2, Pseudotsuga Douglasi; 3, Cupressus Lawsoniana; 4, Abies nobilis; 5, Sequoia gigantea; 6, Cryptomeria japonica.—*J. B. S. P.* 1, Prunus Padus (Bird Cherry); 2, Trollius europæus; 3, Veronica gentianoides, variegated form; 4, Helianthemum roseum.—*Salop*. 1, Pulmonaria officinalis; 2, Veronica gentianoides, a variegated form.—*Weed Killer*. 1, Cardamine pratense; Epilobium hirsutum. Yes, many. Epilobium angustifolium is a common garden plant. The common name is the Willow Herb.

Narcissus malformed: *A. L.* Fasciation of the stem, a not uncommon occurrence.

Onions: *A. L. J.* The Onion-smut, Urocystis cepulæ. You can do nothing now but burn the affected plants, and grow the Onions in another place.

Peach: *F. F.* The variety is Condor.

Peach Trees: *T. M.* The injury is caused by Cercospora circumscissa, the Shot-hole fungus. Spray now with rose-coloured Condy's Fluid every fourth day. During next winter, when the plant is resting and before the buds begin to swell, thoroughly drench every part of the house and trees with a solution consisting of 1 lb. of sulphate of iron in 3 gallons of water.

Solanum Commersoni: *H. R., Port Elizabeth*. The following extract from a paper of Mr. J. G. Baker, reported in the *Gardeners' Chronicle*, December 11, 1886, p. 746, will perhaps afford you the information you require: "S. Commersoni is a native of Uruguay, Buenos Ayres, and the Argentine territory, in rocky, arid situations at a low level. It is a dwarfer plant than tuberosum, with small, oblong, obtuse, subequal leaflets and larger flowers, with a corolla always pale lilac and deeply cleft. It has been successfully cultivated in France, but is probably too subtropical in its climatic needs to be adapted for our own country."

Tomato: *D. Y.* You might apply to Mr. J. J. Willis, Hecla Villas, Harpenden.

LEAVES FROM MY CHINESE NOTE-BOOK.

[*We are privileged to be able to state that Mr. E. H. Wilson will contribute to these columns an account of his wanderings in China—a fitting sequel to the similar articles supplied in former years to this Journal by Robert Fortune, John Gould Veitch, Charles Maries, Augustine Henry, James H. Veitch, and others. Original descriptions and illustrations of several of Mr. Wilson's plants introduced to the nurseries of Messrs. James Veitch & Sons will be given, in addition to those that have already been published.*]

I.—ICHANG.

THIS is a large and important town situated on the Yangtze river, about a thousand miles from its mouth, and near where the mighty river rushes out of the last of the stupendous gorges which have confined it for the last hundred miles. It is therefore right in the very heart of Central China, and practically on the edge of the great plain.

Ichang was opened to foreign trade in 1877. A British and German Consul and a large staff of the Imperial Maritime Customs reside there. Apart from the above, the foreign population consists of missionaries, Protestant and Roman Catholic.

The population is roughly some thirty thousand people. There is little local trade, but being the head of steam navigation it is a most important transhipping port. The six steamers and thousands of native craft attest to its importance as an entry port of trade.

The climate of Ichang is dry, and probably the healthiest on the river. The autumn, winter, and early spring are delightful seasons. The summer is hot, the thermometer often reaching 109° F. in the shade. An up-river breeze during the greater part of the day at all seasons of the year is the salvation of the place. Snow falls occasionally during winter, but seldom lays on the ground for more than two days together. The average rainfall is about 30 inches.

The country immediately around Ichang is broken up into low hills more or less pyramidal in shape. To the east these hills gradually merge into the great plain To the north, south, and west they are mere foothills, up to ranges 5,000 to 10,000 feet in height, these ranges themselves being spurs from the mighty Tibetan and Indian Alps. The rocks around Ichang are principally hard limestone, conglomerate, and a little sandstone. The soil of the fields is a warm, red, adhesive, loamy clay.

Facing the town, on the right bank of the river, is a large pyramidal hill singularly like the Great Pyramid of Egypt, and for this reason it is called the "Pyramid" by foreigners. This hill exerts a baneful influence over the town, and is, or rather was, held responsible for its poverty in local literati. Not until a temple was built on an eminence behind the town sufficiently high to enable it to overlook the Pyramid, was this evil influence counteracted, and the Goddess of Good-luck induced to smile on the town. The very year the temple was completed a student passed the Provincial Examination with high honours. Was not this proof in itself? The temple is richly endowed, and forms a very conspicuous object from all points of approach. I may also mention that a fine pagoda three miles below the town wards off all evil influences from the east.

FIG. 138.—CARGO-BOATS AT ICHANG UPWARD-BOUND—THE START.

PLANT-COLLECTORS.

The first person to collect plants at Ichang was Mr. Thomas Watters, who was appointed Acting Consul in April, 1878. This gentleman was the first to discover wild specimens of Primula sinensis. He also first discovered P. obconica, Rehmannia angulata, and Lysimachia crispidens, to mention well-known plants. Watters used to forward his plants to Dr. Hance, who described them in the *Journal of Botany* and elsewhere.

In the spring of 1879 Ichang was visited by the late lamented Charles Maries, who was then collecting for Messrs. Veitch, of Chelsea. This energetic and very successful collector discovered several new plants, including a new genus belonging to Rutaceæ —Psilopeganum sinense. He also introduced from here the now well-known Primula obconica.

To botanists in all parts of the world, and to not a few readers of this journal, Ichang is best known as the first field in which the indefatigable Dr. Augustine Henry laboured. How and why this gentleman prosecuted botanical study and collecting has been told by himself elsewhere. Suffice to note here that he was appointed Medical Officer and Assistant in the Customs Service at Ichang in 1882, and stayed till April, 1889. He began to collect plants in 1885, and despatched his first collection to the Kew authorities in the spring of 1886. This collection proved so interesting and rich in novelties that the authorities wrote to Henry urging him to continue. This he did with the energy and assiduity characteristic of the man. By the time he left he had collected no fewer than 7,948 numbered specimens, representing roughly 2,500 species. According to Mr. Hemsley's estimate (October, 1896), Henry's Ichang plants contain about 500 new species and 25 new genera. These figures speak for themselves. Dr. Henry in his letters frequently urged the desirability of sending out a collector to these parts. In time it chanced that the attention of Messrs. Veitch, of Chelsea, became drawn to the mass of material Henry had collected. The result of this was that they applied to the Director of Kew to nominate a likely collector. I was the fortunate individual selected.

I arrived at Ichang in February, 1900, and made it my base until January, 1902, when

I left for home. From early in May till the middle of September in 1900 things were very unsettled. War, rumours of war, threats, and attempts at local riots gave us an anxious time. All the Protestant missionaries left their posts, and I was only allowed to remain at my own risk. Fortunately no serious outbreak occurred, and eventually things assumed a normal state.

THE FLORA OF ICHANG.

It is my intention here to give a brief sketch of the flora immediately around Ichang, never ascending above 2,000 feet Other notes will deal with the flora of the mountains above this altitude.

The flora of Ichang and the neighbourhood as included in this article is essentially of a warm temperate character, and includes not a few sub-tropical forms. Nevertheless, we find also a number of cool temperate plants, so that what really obtains is a fusion of these three floras, with the warm temperate element in the ascendency. The following dozen characteristic plants will serve to illustrate the point: Aleurites cordata, Liquidambar formosana, Ligustrum lucidum, Cæsalpinia sepiaria, Toddalia aculeata, Wistaria sinensis, Azalea indica, Cratægus Pyracantha, Primula sinensis, Anemone japonica, Aspidistra punctata, Linum trigynum, and Woodwardia radicans. The low hills around Ichang are very barren-looking, being mostly clad with "spear grass" (Heteropogon hirtus), with a few shrubs and herbs here and there, and relieved by small woods of Pinus Massoniana and Cupressus funebris, with occasional groves of the common Bamboo, Phyllostachys mitis.

The "spear grass" is the abomination of the foreign sportsman. One end of the grain is capped with a tuft of barbed hairs arranged spirally, the opposite end terminating in a long flexible awn. The penetrating power of these barbed ends is truly marvellous. I have seen them drill their way through the tongue of a new shooting boot! However, it is not to these low hills that we look for the floral wealth of Ichang, but to the limestone cliffs of the glens and gorges. Here the variety is astonishing, a striking feature being the quantity of well-known flowering shrubs.

The two first shrubs to flower in the early spring are Daphne genkwa and Coriaria nepalensis. It is a thousand pities we cannot succeed with the Daphne in England, since it is such a lovely plant—by far the finest species of the genus. Here, at Ichang, it grows everywhere, on the bare exposed hills, amongst conglomerate rock and lime, stone boulders, on graves, and amongst the stones which are piled around the tiny cultivated plots in the gorge, sometimes in partial shade, but more usually fully exposed to the scorching sun. The plants are, on the average, about 2 feet in height, and are but seldom branched. Imagine the annual suckers from a Plum-tree, and you have the appearance of these Daphne plants. For two-thirds of their height they are so densely clad with flowers that they look like one large thyrse. The colour is lilac, often very dark; but a white form is not uncommon. Its outward resemblance to Lilac leads to its being so called by the foreign residents at Ichang. *E. H. Wilson.*

(To be continued.)

INTUMESCENCE OF TOMATO LEAVES.

SOME little time since some Tomato leaves were sent to me which were more or less curled up, but otherwise appeared healthy and of a dark green colour as of plants in luxuriant growth. On examination, the upper side of the leaves were found to be on the whole normal, whilst the ribs of the under side of the leaves showed on parts a whitish mat, and on other parts a light, rusty-brown, powder-like covering, which easily came off when handled. On the under side of the

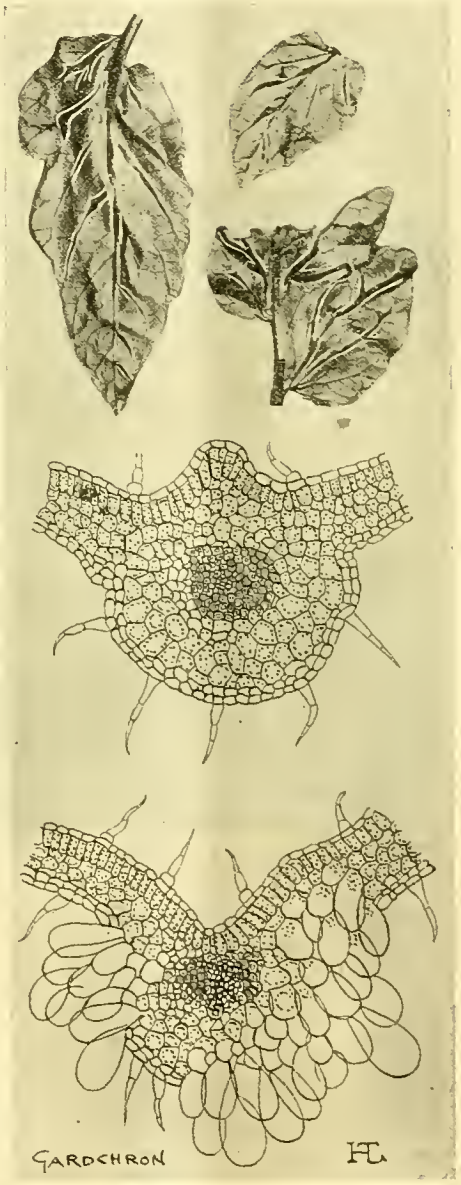

FIG. 139.—INTUMESCENCE OF TOMATO LEAVES.

leaves corresponding to these patches the upper epidermis showed slight "sunken-in" tissues, in no case very pronounced.

The accompanying illustration at the top of fig. 139 shows in between the white lines, though not so plainly as in the actual specimens, the seat of the obscure covering. Several microscopical sections were made through the affected parts, but no local irritant, bacteria, or fungus was detected.

In the illustration at the bottom of the figure a section of the affected part is reproduced, and one can, in comparison with the illustration in the centre of the figure (a cut through a normal central rib), easily observe the changes which have taken place in the tissues of the affected leaves. Such changes do not necessarily cause injury to the plant or endanger the crop, provided that no infection by any of the well-known Tomato-leaf fungi takes place. It is a case of swelling of the ribs of the leaves. The mesophyll or central cells of the leaf are much enlarged, and have forced their way through the skin or epidermal cells, as may be seen in the illustration at the bottom of the figure. In some small parts the epidermal cells were still present and uninjured. In those places where the cells had pushed aside the epidermis a whitish covering of the ribs could be observed by the naked eye. In examining the rust-coloured tissues it was found that they consisted of the old broken mesophyll cells, which had burst and dried up. Among other changes in the affected portions one was most pronounced. The chlorophyll grains, or green colouring matter, which in normal cases are distributed uniformly in the cells, had disappeared from the very-much-enlarged cells, whilst in those just enlarging they were found in small groups at the base of the cell. The absence of the chlorophyll accounts for the whitish appearance of the cells. The abnormal character of the leaves showed no very serious injury; on the contrary, the leaves were quite vigorous and full of sap. I believe that the plants so affected will outgrow their injury, and that it need give no rise to anxiety to growers. The leaves should, however, be watched as scores of fungus spores would find in the openings in the leaf suitable places for development, and serious diseases might thus ensue.

In considering the probable causes of such prolific growth of cells the appearance of the leaf on the whole must be taken into account. Though the leaf was curled it showed no signs of limpness, discolouration, or spots. This appearance cannot be regarded as a disease, and the cause must be looked for in another direction. Dr. Masters, in his *Vegetable Teratology*, deals in Book 10, p. 413, with "Deviations from Ordinary Size and Consistence of Organs." And the above abnormal growth may come under the general heading of hypertrophy. Of "hypertrophy" Dr. Masters says, "whatever form it may assume it may be so slight as not perceptibly to interfere with the functions of the part affected, or it may exist to such an extent as to impair the due exercise of its office." Prof. Sorauer, in his work, *Pflanzenkrankheiter*, vol. i., under the heading, "Excess of Water and Nutritive Matter," deals with the development of abnormal cell growth, causing on leaves of various plants grey, corky tissues—true cork-cells, as, for instance, on leaves of Ribes grossularia. In the Tomato, however, the outgrowth of cells does not assume a corky character, but remains soft and delicate. This careful investigator separates from the development of cork-cells what he terms "intumescentia," and from his description of such cases I feel justified in speaking of "intumescence" of Tomato leaves. Professor Sorauer refers to the frequency of such "intumescences" on Cassia tomentosa. The young leaves did not straighten themselves as in normal conditions, and distinct swellings of the central leaf-rib could be detected. On microscopic examination he found abnormal elongations of the cells beneath the epidermis, which in portions had burst through it. At the same time he observed the position of the chlorophyll in such cells, and states that most of the chlorophyll bodies are found at the base of the cells still *in situ*, slightly yellowish, and somewhat eaten away. The same appearance is found not at all infrequently on the leaves of Vines in houses. Excess of moisture and heat have been found to favour and produce the development of warts on Vines, and no doubt the same conditions are responsible for the occurrence in the Tomato-leaves. Over-

Fig. 140.—Iris tingitana, a somewhat shy-blooming Tangerian species: colour of flowers lilac-purple. From a Drawing made from specimens which flowered in April in the Royal Horticultural Society's Gardens at Wisley.

manured Potatos often show similarly curled leaves, and no local irritant has been detected, though in many cases the affected portions were afterwards inhabited by parasitic and other fungi. From this explanation it will be seen how difficult it is to determine the causes of the swelling of the Tomato-leaves, whether from excess of heat, water, or nutritious matter, as I was unable to ascertain the conditions under which the plants had been grown. *Hans Güssow.*

NOTICES OF BOOKS.

POISONOUS PLANTS.

UNDER this title Mr. A. Bernard Smith has compiled, and Messrs. J. Wright & Co., of Bristol, have published a small treatise dealing with the poisonous plants of all countries. They are arranged according as they act on the brain, spinal cord, heart, liver, and intestinal canal, or as simple irritants. The book conveys the impression that it is the work of one who is personally familiar with only certain portions of his subject. Whilst the symptoms of poisoning and the medical details are satisfactory, the botanical information is by no means complete; for instance, we find this entry:—

"Solanum tuberosum (cultivated in Britain), common Potato. Solanaceæ. A tuber; stem herbaceous; leaflets, ovate; flowers, in racemes, 1 f. ann., June to August, bright purple; stamens yellow, fruit green."

This is misleading, as the tubers are not, under ordinary conditions, poisonous, and it is inaccurate and incomplete, as any Potato-grower or botanist will see.

The misprints also reveal a want of care in proof-reading; for instance, we have "Scopala atrapoides, Umbellijeræ, Delphinium consolidata, Cystisus Laburnum, Saphora tomentosa, Gosophila struthiam," and others that we need not mention. A number of popular names are added which are mostly obsolete and not in general use. No indications are given as to what parts of the several plants are poisonous. Why "Narcissus Johnstoni," or Clematis Jackmanni, should be picked out as poisonous out of the hundreds of varieties, probably equally poisonous, but happily not used as poisons, is not obvious. It is new to us that "oil of hay" is contained in Asarum europæum. It may be so, but we should have been glad of a reference to the source whence this information is derived.

Erysimum is not usually included among Fumariaceæ, and the characters of that order would have to be considerably modified to permit of its inclusion. If another edition be called for it is to be hoped the author will call to his aid some friendly botanist. The strictly medical details show, as we have already mentioned, that the writer is more fully conversant with the practice of medicine than he is with botanical details.

THE COUNTRY GENTLEMEN'S ESTATE BOOK. 1905. Edited and compiled by William Broomhall.

THIS may be looked as the year-book of the Country Gentlemen's Association, an organisation which has its object the reciprocal benefit of all its members by means of co-operation.

The work comprises a series of articles on estate management, work, farming, forestry, gardening, fruit-growing, sports and pastimes, and various other subjects. The volume opens with a portrait of the Duke of Westminster, who, it will be remembered, is to preside at the forthcoming dinner of the Gardeners' Royal Benevolent Institution.

The book is full of information of value to country gentlemen and their agents, and may be had from the Country Gentlemen's Association, 2, Waterloo Place, Pall Mall, London.

BULB GARDEN.

LATE-FLOWERING TULIPS.

I WAS recently invited to see Messrs. Pearson & Son's collection of Tulips in full flower at Lowdham, Notts, and although Mr. Duncan Pearson's success in growing Narcissi is well known, I was not prepared to find such a fine display of late-flowering Tulips, covering as they did acres of ground. Many of the older varieties, such as Golden Crown, Picotee, and Gesneriana, were represented by thousands of plants, and the effect produced by their masses of colour can be better imagined than described. These plants are excellent subjects for producing a pleasing effect in the pleasure-grounds and shrubberies during May, if planted in large breadths among the shrubs and grass.

A few of the best and most distinct varieties noticed were: Loveliness, a fine rosy-pink flower; Inglescombe Scarlet—a large stock of this new kind was noted; it has a paler shade of colour outside, and is not tall in growth. La Panachée has variegated foliage, and the flowers are dark-red with white stripes, a nice thing for planting on a groundwork of Forget-me-Not or blue Aubrietia; Buonoventura has scarlet flowers with gold markings. It has a larger flower and is of dwarfer habit than Gala Beauty, which has similar colours, and is also a handsome variety; La Merveille has a fine large flower that is not stiff, the colour is salmon suffused with a purple tint. Others were Purple King, of a distinct purple colour; Glow, very bright red, one of the best; Donders, a fine large dark vermillion flower; Phyllis having white petals shaded with heliotrope, a very delicate colour; Margaret, a large flower, of blush colour, is very pleasing; Parisian Yellow and Mrs. Moon are two good pale yellow varieties, with long pointed petals; Striped Beauty has a large, well-shaped flower, the colour being pink with a darker-coloured stripe; Clara Butt is a magnificent Tulip, in colour clear pink—one of the very best varieties; Van Poortvliet, in colour dark rose; Pride of Haarlem, a fine large flower, also dark-rose-coloured; Mr. Farncombe Saunders, a vivid red, and one of the best Tulips of this colour; Sir Thos. Lipton, a very large dark-scarlet flower; and Vitellina, lemon coloured, quite a distinct shade, and a large flower. The large crimson variety of Gesneriana was represented by a very extensive collection. Picotee—when first open, the flowers possess a greenish-white tint, which changes to white delicately edged with rose; Fairy Queen is dark heliotrope with a pale greenish-yellow edge; Golden Crown is a yellow flower edged with red.

Many kinds of Narcissi were growing near, some in large breadths containing many thousands of plants. A number of the newer kinds were represented in considerable quantities, also many promising seedlings, among which Florence Pearson (which received a Royal Horticultural Society's award some two or three years since) was specially strong and vigorous; one could only regret that the flowering season was almost over. Time did not allow me to inspect the Roses and fruit trees on this occasion, but pot Vines and Fig trees in pots, under glass, were looking well. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

PRIMULA DEORUM (see illustration on p. 98).—This is one of the rarest, most distinct, and beautiful of alpine species, and has been said to be quite new to cultivation, it having flowered for the first time in this country this spring. This, however, is hardly a correct statement. The plant was collected and described in the *Bulgarian Flora* (as was stated on p. 98) by Professor Velonovsky, of Prague, in 1890. In 1891 Herr Max Kolh, of the Royal Botanic Gardens of Munich (Bavaria), sent Herr Kellerer, a young botanist, to find P. Deorum, Lilium Jankæ, and other plants, and he subsequently collected a number of P. Deorum, some of which came into my possession. I flowered several plants, and some of these were shown in flower at the Royal Botanic and Royal Horticultural Society's shows, and were sold and offered by Mr. T. S. Ware, Tottenham, with whose firm I was then connected. The plants were however quickly sold, and I have been able to trace some of them which are alive, thus the plant has not been quite out of cultivation, when all the hardy plant nurseries in this county obtained a plentiful supply this year, although these plants were nothing like the fine specimens of the 1891 supply. *G. Reuthe, Keston, Kent.*

HOLLY-BERRIES.—In "Answers to Correspondents," p. 320, there is a notice of Holly-berries hanging so long upon the trees. I have a similar experience on a tree in my grounds here, but the portion of the tree on which those berries now hang is unhealthy. The other portion of the tree which is healthy, bore berries plentifully, but they were all eaten by birds long ago. A tree on the opposite side of the road, but on other property, is also crowded with berries which birds have not touched. On close examination of this tree, I find it is also in an unhealthy condition, the berries, presumably, not being sufficiently luscious to tempt the birds to eat them. A few years ago I was living close to a couple of large White Beam-trees (Pyrus Aria), which bore every year, as far as I can remember, a crop of their large, red berries. During autumn, when these berries became ripe, one of those trees would be visited by a flock of birds, consisting of thrushes, blackbirds, jays, and even rooks. These would continue their visits daily until the tree was completely stripped of its fruit; whilst the other tree, which was only a few yards away, had no visitor whatever of any kind; its berries, so far as birds were concerned, remaining untouched. After a few years of this sort of thing the tree died. The tree having been evidently for some time in declining health, the berries would be without juice, and this the birds, being good judges, found in the berries of the healthy tree. *W. Miller, Berkswell.*

IBERIS CORIFOLIA.—It is difficult to beat this perennial Candytuft as a white-flowering plant in the border in May. Compact in growth and very free of bloom, the well-formed flowers admirably displayed on bold trusses, hardy and easily grown, it has all the good qualities of a first-class hardy plant. *R. D.*

SCOTCH "NEEPS."—When visiting Messrs. Sutton & Sons' seed farm at Reading recently, I was taken to inspect a batch of Swede Turnips in flower. Very unexpectedly, these plants furnished further illustration of the remarkable superiority in respect of robustness and productiveness of Scotch-grown roots over English-grown ones. We have become quite familiar with this fact in relation to Potatos, a matter that so far has not yet had a satisfactory elucidation. We know it is so, and that is all. Now there are planted on the Reading seed farm a large number of Scotch-grown roots of the Swede Sutton's Magnum Bonum, and these have sent up strong growths fully 7 feet in height and now a mass of bloom. Close beside are two rows of the same variety, the roots of which were obtained from Oxfordshire, yet were apparently in all respects equal to those procured from Scotland. They were all planted at the same time, and on soil equally treated. Yet the

growth on the Oxford roots is far less robust, ranging from 4 to 5 feet in height only, and certainly the seed produce per root will not be one-half that furnished by the Scotch roots. Here is presented, as with the Potatos, an interesting problem for the Scientific Committee of the Royal Horticultural Society to enquire into, and possibly solve. It need hardly be said that henceforth for the securing of a primary seed stock, as is done every year, the firm will henceforth secure roots of Scotch growth only. The ultimate seed-producers are seedling plants raised from the primary root-seed stock planted out in the spring. *Alex. Dean.*

ARE COMMERCIAL TRAVELLERS A NUISANCE?—As one of these, I should like to say a word or two. If gardeners only knew how they delay the poor, abused traveller by either letting him wait hours before they will see him, or listening to their conversation whilst they discourse about their products for as long as one likes to stand, they might get a glimpse of how impossible it is for them to keep the appointments per their advice cards. As to being "shown round," for one commercial traveller who wishes to be there are ninety-and-nine who, if their expenses would allow it, would willingly give each gardener five shillings for himself not to do so. As an example, I was at a large garden one night making the last of my calls in that district. I had an hour to spare with the gardener and then had to catch a local train which would bring me home by 8.30, not allowing time for tea (dinner at 12 noon). He was an affable man, and as I thought from his conversation there might be a chance of an order, I humoured him a bit and allowed him to "show me round." This, as he had had his tea, took two hours and a half, and in the end I was plainly told he could have no chance of doing business with me. He hastily bid me good-night, and left me with eight miles to tramp without food to the nearest city where I could just catch the last mail to my destination. This, I feel sure, must in a greater or less degree be the experience of horticultural travellers who have to humour gardeners with absolutely no business ideas at all. Speaking for myself, I can no more undertake a journey with a chance of being punctual in my appointments than I can change the tides, all through the mistaken idea of courtesy (save the mark!) of "like to have a look round." Is the traveller who wasted his time by allowing the foreman, from whom he could not get any orders, to "show him round" still at large, and where? *"Our Mr. (the Traveller.)"*

—— I fail to see that these gentlemen are a nuisance, even should they be a day behind their appointed time in calling, and unless "A Foreman" was instructed from the head gardener to show them round if he were absent when they came, I consider he was exceeding his duty and wasting valuable time, as my experience is that not one in a dozen travellers care to spare the time, and I am within the mark in saying that during the fourteen years I have been here I have only shown two through the gardens. *J. Mayne, Bicton, Devonshire.*

MECONOPSIS INTEGRIFOLIA.—Since writing my note on Meconopsis integrifolia, wherein it was stated that M. grandis had failed to produce seeds with us, I have ascertained that a batch of young seedlings now making nice growth are from home-saved seeds, and not from imported seed, as I had thought. *E. H. (The Co-operative Bees, Ltd.).*

—— This plant is now in bloom in the rock garden here. It is very distinct in character, bearing numerous large sulphur-coloured, Papaver-like flowers, that are very pleasing and attractive. Individual plants are very conspicuous, and the effect produced by a mass of it must, I feel certain, be very charming. *T. Challis, Wilton House, May 25.*

SCHIZANTHUS AS POT PLANTS.—More striking evidence of the great amount of bloom and beauty that can be obtained from pot plants raised in a few months from seed could hardly have been found anywhere than I had the pleasure of seeing in the conservatory at Sherfield Manor, near Basingstoke, the residence of J. B. Taylor, Esq., a few days since. The plants were in 6-inch pots, and from the Reading strains of Schizanthus pinnatus and S. retusus, were in height varying from 20 to 30 inches, charmingly varied in colour, and making undoubtedly a most beautiful display. To have well-grown specimen plants singly, it is well to sow three or four seeds in each of numerous small pots early in September, thinning the seedlings down to one later, then as growth ensues shifting into 6-inch pots, using good loam, and potting firmly. If the plants draw a little, as is inevitable, they are more decorative than are those of too compact a habit. Many very costly plants would fail to produce the charming display these annuals did. *A. D.*

LINES FROM SCOTTISH POETS.—A correspondent at p. 317 wishes to know from what Scottish poet the following lines are taken:—

> "Give me the garden wild and wide
> Where thorns and thistles side by side," &c.

From no Scottish or any other poet were these lines taken. They exist only in the correspondent's imagination. Allan Ramsay, a Scottish poet, who wrote perhaps the finest pastoral drama that ever was written, "The Gentle Shepherd," wrote some lines on a garden from which the above stupid couplet may have been evolved. They show Ramsay's contempt for the stated rules of such garden art as existed at the time. Allan was born in 1686, and must have known of the formal gardening introduced by the Prince of Orange into England, as he corresponded with Gay and Somerville. The following picturesque sketch reminds one of the late Mr. George F. Wilson's ever-to-be-remembered garden at Wisley:—

> "I love the garden wild and wide
> Where Oaks have Plum-trees side by side;
> Where Woodbines and the twisting Vine
> Clip round the Pear-tree and the Pine;
> Where mixed Jonquils and Gowans grow,
> And Roses 'mid rank Clover blow
> Upon a bank of a clear strand,
> In wimplings led by Nature's hand,
> Though Docks and Brambles here and there
> May sometimes cheat the gardener's care.
> Yet this to me's a Paradise
> Compared with prim cut plots and nice,
> Where Nature has to art resigned,
> Till all looks mean, stiff, and confined."

Your correspondent is evidently trying his hand at a poor joke at the expense of Scotsmen, although only a donkey would appreciate his couplet. *J. Douglas.*

FROST AND THE CROPS.—Growers in the Vale of Evesham have incurred heavy losses by the frosts of last week, and it is seldom that such general injury to fruits and vegetables has been experienced. Some damage was done on the morning of May 22, but it was on May 23 that the worst results followed a temperature which fell from 6° to 9° below the freezing-point. The crops in the lower parts of the slopes and banks of the river Avon have suffered the most severely, and it is only upon the higher land, such as Greenhill, that there has been any general escape from injury. Amongst fruits, the worst effects have been felt by Plums, Pears, Cherries, Black Currants, and Strawberries, which in some cases have lost all their flowers or fruits, and in all have been heavily damaged. A few Pershore Plums have been left on the high lands, and Czar seems to have escaped to some extent in similar situations, but Victorias and Rivers' Early Prolific have suffered terribly. Amongst vegetables, early Potatos, Runner Beans, and Peas have been generally injured, though Asparagus has escaped in most places with little damage. Tomato-plants that were put out early have been killed in thousands, and Vegetable Marrows insufficiently protected have also been caught by the frost. With a few exceptions, Red Currants, Raspberries, and Gooseberries have escaped fairly well. The long period of keen easterly winds and the extraordinary drought (up to May 28, no fewer than twenty-five consecutive days without rain) have combined to increase the growers' difficulties enormously, and the numerous industrious and usually successful small holders in this beautiful district will need all their energy this season. *R. Lewis Castle, Evesham, May 28, 1905.*

EFFECTS OF THE NORTH-EAST WINDS ON GOOSEBERRIES.—I notice that on the side of the trees exposed to the action of these cold winds, the sides of the fruit exposed to the north is of quite a ruddy colour, as if prematurely ripening. This remark applies to trees on my Primrose nursery at Hounslow, but I am informed that it is general in the district in the cases of trees exposed to the winds. The fruits look as if they were half paralysed. I am afraid there is much room for concern as to the promise of the fruit generally, owing to the persistence of the drought and the dry, cold atmosphere. Apples appear to be affected by blight, the young leaves curling at the points, as if injured by the cold. *R. D.*

TENDER PLANTS IN THE SOUTH-WEST.—When I wrote, in my note on Messrs. Treseder's nursery at Truro, p. 285, of certain plants being only hardy in the open in the south-west, I should, as pointed out by Mr. T. Ryan, p. 315, have made an exception in the case of Ireland. At the time of writing, however, I had only England in my mind. I know that in Ireland, especially in gardens I have visited in the south, tender shrubs grow as freely in the open as they do in Cornwall and South Devon; and a perusal of Lord Annesley's finely-illustrated book on the collection of choice trees and shrubs at Castlewellan, to which Mr. Ryan alludes, convinced me two years ago that in those far more northerly gardens subtropical subjects found a congenial home. I trust that some day I may be able to avail myself of Mr. Ryan's kind offer to show me the rare plants under his charge. *S. W. Fitzherbert.*

THE BLACK CURRANT BUD-MITE. — Your correspondent Mr. A. O. Walker, p. 316, evidently attaches more importance to a crop of fruit than to ridding his trees from the mite—a view which would not commend itself to everyone; but even so I fail to see how spraying the trees during the months of May and June, with a mixture such as recommended, would in any way injure the crop of fruit. As a matter of fact the trees we experimented upon in 1903 and 1904 bore splendid crops of fine fruit which were in no way affected by the spraying. Since writing to you last year I have received a copy of an interesting report upon this mite by Mr. Walter E. Collinge, M.Sc., Lecturer in Zoology, &c., in the University of Birmingham, from which I copy the following extract: "In 1901 some small bushes which were very badly infested were treated with the following spray-fluid twice a week during the migration season: Sulphur, 2 lb.; soft-soap, 25 lb.; water, 50 gallons, made as follows; Mix the sulphur to a gruel with water; the soft-soap should be mixed with 5 gallons of boiling water; then add the two mixtures together and mix well, after which add slowly sufficient water to make 50 gallons. The results obtained from the use of this spray-fluid are very encouraging. The new buds which came out in 1901 were very carefully examined until nearly the end of the year, and on only one bush were mites found, and only very few, the actual numbers in the different buds examined in August, 1901, were: 12, 3, 7, 5, 3, 3, 12, 3, 7, 7, 6, 5, 3, 12. In 1902 these same bushes were under constant observation, but no mites were seen or any indications of them. As these bushes were growing not far from some infested bushes, they were sprayed during the migration season as in the previous year. In 1903 they still remained free from mites, and an examination of almost every bud on one particular tree at the beginning of 1904 failed to discover either mites or eggs, and all the trees were free of abnormal buds. *Natural Enemies.*—In addition to those already mentioned, reference must be made to the larva of the lady-bird beetle (Coccinella septempunctata, *L*). During 1902 and 1903 I had a series of badly infested cuttings under observation, and these were practically all cured by keeping them artificially supplied with this beetle. The 1902 cuttings exhibited very few, and only slightly abnormal buds in the autumn, while in 1903 they seemed entirely free. Unfortunately this species of ladybird does not seem particularly fond of the Black Currant, but, in my own mind, I have little doubt but that a species could be found which, if bred in sufficient number, would materially lessen and keep in check this disease.

and possibly might exterminate it." It will be seen that the quantity of soft-soap recommended by Mr. Collinge is four times that mentioned in my previous letter, and he does not say that the foliage was injured, although I should have expected it to be so with this heavy application of soap. I must apologise for troubling you at such length, but I attach more importance to this question than to the loss of a year's crop of fruit, indeed I think the gravity of this matter can scarcely be over-estimated. *A. H. Pearson, Lowdham.*

THINNING PEACH CROPS.—The vigour and size of each tree must be considered in determining the number of fruits which it shall carry as a crop without in any way impairing its permanent welfare. The thinning out of the fruit is generally done at the same time as the last stage of disbudding is being completed, and, like that operation, it is advisable to extend the process of thinning the crop over a week, finally thinning out the fruit to a distance of from 9 to 12 inches apart every way on the trellis, wall, or fence, retaining, as a matter of course, the most even-sized and best-placed fruits on the face of trees growing against walls and on the upper surface (glass side) of trees growing under glass to form the crop. Many growers defer the final thinning of the fruits until they have completed the process of stoning, being afraid to do so before, in case some of the fruit left to constitute the crop should fall off in the progress of stoning. As a matter of fact, this cautious method of procedure is well calculated to bring about the very thing (dropping of the fruit) it is meant to prevent, seeing that the energies of the trees are needlessly and severely taxed in the stoning of a crop of fruit 50 if not 100 per cent. of which the cultivator intends picking off the trees when the process of stoning is completed, unmindful of the fact that his misapplied caution in this direction tends directly to the wasting of the tree's forces instead of directing them into the proper channels for securing the swelling of the crop and the due development of the tree, wood and foliage. In short, there is no fear of strong, free-growing, healthy Peach trees casting their fruit in the process of stoning when cropped as recommended above, and when the cultural details are properly attended to in the way of keeping the soil about the roots uniformly moist and the foliage clean. In the case of trees there is all the more necessity for reducing the number of fruit to 12 to 15 inches from fruit to fruit every way before the stoning stage is reached. Avoid over-cropping the trees as the greatest evil in fruit-culture. Always bear in mind that a dozen well-grown Peaches or Nectarines are preferable in every respect to three times that number of fruits of a like weight in the aggregate. Weakly-growing trees should be cropped very lightly, and the fruit, as in the case of robust-growing trees, should be thinned out to the distances recommended above before the stoning stage is reached, so as to enable them to swell decent-sized fruits, and at the same time make stronger wood for yielding fruit the following year. In thinning the Nectarine crops it must be borne in mind that the individual fruits of the Nectarines do not attain to such large dimensions as the Peaches do under the same conditions of treatment. The fruits should therefore be left closer together on the trees—say at from 6 to 9 inches apart every way—although where extra-fine fruit is desired, 12 inches from fruit to fruit will be none too much space to afford such varieties as Early Rivers, Dryden, Spenser, Newton, Milton, Pine-Apple and Humboldt. With good cultivation and generous treatment at the roots these varieties will yield fruit of grand size and appearance and fine in flavour. The foregoing remarks may be as useful to young fruit-growers and amateurs as they are opportune in the case of Peaches growing out-of-doors, which now require attention in the direction indicated above. *H. W. Ward, Rayleigh, May* 13.

GARDEN-PATHS.—My attention has just been called to Mr. Molyneux's letter on my article on "Garden-paths" in your issue of April 15. I do not think he has read it very carefully. I certainly never advocated asphalt for carriage roads, but only for paths in the kitchen-garden and back premises, where I prefer it to gravel, owing to its being easier to keep clean and tidy. Gravel requires constant raking and rolling; asphalt merely a brush over with a broom. Further, if prepared with cold tar, as I suggest, the paths do not smell in hot weather. I am particular, too, to state that in these paths there is no need to excavate so deeply for cart-tracks; 2 feet is generally ample; 18 inches the usual depth. Even for a cart-road it is only in very bad soil that 4 feet is often required, and if Mr. Molyneux will refer to my article he will see I specify stones, rubble, or clinkers for a foundation, and granite, flint, or slag as a surface, and I supposed people would choose which was cheapest. In Scotland I could get any amount of unbroken granite on the spot, and the men broke it during the winter, when they could do nothing else; or I could get it from the estate stone-mill broken to pass through a 2-inch sieve at 1*s.* 6*d.* per ton. In Lincolnshire broken Belgian stone costs 6*s.* 6*d.* per ton; iron slag, also broken, 2*s.* 6*d.*, and flints picked from the land, 2*s.* 6*d.*, and an extra 1*s.* 6*d.* to break. Certainly I never advocated filling a 4-feet cut with granite at 13*s.* per ton! *J. S. Turnor, May* 27.

FASCIATION IN AGARICUS.

IN April I found growing at Studley, on a bed of leaf-mould, a large number of Agaricus (Tricholoma) personatus, which were gathered and eaten.

The interesting point about these specimens is that they exhibit in a striking way an appearance similar to what is called fasciation in phanerogams. Many of them showed it some degree, but the most conspicuous was the one of which a sketch is appended. Fig. 141 (A) is a broadside view, and fig. 141 (B) a section at right angles to A through the dotted line.

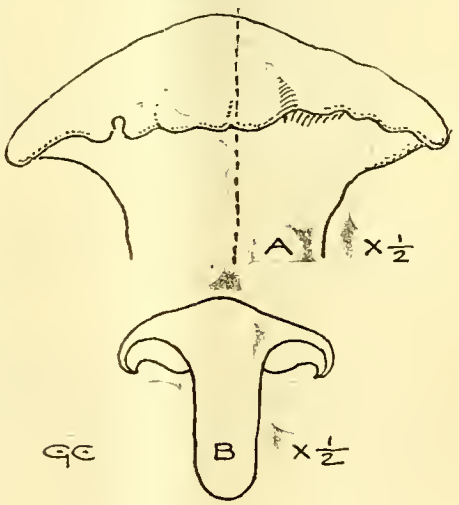

FIG. 141.—FASCIATED SPECIMEN OF AGARICUS PERSONATUS.

The stipes measured nearly 6 inches across where it joined the gills, by ¾ of an inch at its greatest thickness, the fungus being about 3 inches high. There was nothing in the substratum on which it was growing to account for this flattening. It was not caused like the flattening which is sometimes seen in Agarics growing between the joints of bricks, nor like the compressed stems seen in Agaricus confluens. The leaf-mould was loose and friable, and the fungi grew two or at most three together, and were not at all crowded. I have occasionally noticed the same thing in other Agaricini, such as Russula, but never in so marked a degree. *W. B. Grove, Birmingham.*

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to DR. CORBET, Impney Hall Gardens, Droitwich.

The Orchard-house.—The latest varieties of Peach and Nectarine-trees in pots will now be swelling their fruits, therefore afford them liberal supplies of water. If the pots are plunged, they should be placed on bricks in order that the water may pass away more quickly. Top-dress the roots as previously recommended, and apply other stimulants to those trees that require them until the fruits show signs of ripening, when such feeding should be discontinued, and clear water applied exclusively. Thoroughly syringe the trees every morning and afternoon in bright weather, and ventilate the house freely, always admitting a little air at night. Respecting early varieties, the fruits of which are ripe, let the borders be damped well under the trees, and the atmosphere kept cool by liberal ventilation. Any trees from which the fruit has been gathered, and which have been for a period in a cool-house, may be removed out-of-doors during this month, plunging the pots in an exposed position, and putting a few rough ashes under each pot to facilitate drainage. Syringe the trees daily, and give them liberal supplies of water at the root, and supply liquid-manure to trees that require it.

Pears and Apples.—These trees should be examined at least twice daily for water, for it is important that they should not become dry at the roots. Trees which are carrying heavy crops of fruit may be top-dressed with rough pieces of loam, horse-droppings, and bone-meal. Clear soot-water and diluted liquid-manure may be applied as may seem desirable. Thin out the fruits where they are too numerous, and pinch the shoots. Admit fresh air by day and night, and keep the trees clean from red-spider by syringing them and damping the surfaces in the houses. Any varieties that are not required to ripen inside may be removed out-of-doors, and the pots plunged in the earth.

Plums.—Continue to pinch the shoots as this operation becomes necessary, and apply nourishment freely, as no kind of fruit-tree repays better for liberal treatment or is capable of maturing heavier crops of fruits. Syringe the trees until the fruits are ripe, and when they have been gathered plunge the trees out-of-doors and treat them as previously advised for Peach trees.

Cherries.—In order to keep these fruits in good condition for as long a period as possible, protection from birds will be necessary, and shade from bright sunshine should be provided, unless the foliage is abundant. Such shading should be removed when there is no direct sunshine upon the glass. Do not allow the trees to suffer from want of water at the roots. Ventilate the house freely and damp all available spaces twice daily to keep the fruits fresh in appearance. Later kinds will now be making rapid progress, and an endeavour should be made to keep the foliage clean previous to the fruits changing colour, but be careful not to employ too much moisture or the fruits will split, especially those of Bigarreau.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Ixoras.—Considerable heat and moisture are very essential for these plants, and very little air should be admitted to the structure containing them at any season of the year. During the summer months moderately-heavy shading should be employed. A suitable compost for the rooting medium is one containing peat and loam in equal proportions, with silver-sand and charcoal liberally added, and the whole well mixed together. If the plants are kept free of mealy-bug little trouble need be experienced in growing them perfectly under the conditions described above. If cuttings are inserted at the present time in thumb-pots they will make roots easily, if the pots containing them are plunged in Cocoanut-fibre in a frame where considerable bottom-heat can be employed. From such cuttings nice plants can be raised before the dull days set in. The four following varieties

in the order given I find to be most useful:—I. Duffi, I. Williamsi, I. Westi, I. Fraseri. I. Duffi is inclined to a straggling habit, but the gorgeous trusses of flower this variety produces renders this habit a characteristic feature.

Tabernæmontana coronaria fl.-pl.—This is a useful and effective plant, requiring the same treatment as for Ixoras. By pinching out the side-shoots from a leading growth nice standards may be obtained.

Posoqueria longiflora and *P. multiflora* are, apart from their delightful fragrance when in flower, suitable for growing-on as specimens; and where room can be afforded for growing them in this manner every encouragement should be given them. Heat and moisture during their period of growth are very necessary, after which they should be rested in a slightly lower temperature. Cuttings may be inserted simply in pots and placed in the propagating frame or preferably under a bell-glass to make roots. They are very liable to damp off before rooting unless the lights are allowed to remain open each morning for an hour in order that excessive moisture may escape.

Gardenias.—As these plants pass out of flower let them be thoroughly cleansed, then cut them back moderately hard if they are intended for growing on, re-potting or top-dressing them according to requirements. If merely a top-dressing is employed apply a dressing of bone-meal before adding the fresh soil.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cattleya Aclandiæ. — An importation of this dwarf-growing species has recently been distributed. For a week or more after receipt protect the plants from strong light by covering them with a sheet of paper or other suitable material, and do not wet them in any way. New roots will soon appear, and before these attain much length the plants should be set in order for their growing season. Their habit generally precludes ordinary pot-culture, but many of the smaller pieces may be fixed in shallow pans that have been almost filled with drainage material, and a very shallow surfacing provided consisting of peat and sphagnum-moss in equal parts. In order to make the plants secure and firm, tie them down with fine copper-wire or tarred twine, and in a similar manner pieces that cannot be placed in pans may be secured to teak-wood rafts, with a small quantity of rooting material intervening. The pans and rafts should then be suspended near to the roof-glass in the warmest part of a Cattleya-house. On bright days they should be taken down and be sprayed around, but partial dryness of the materials should be permitted until growth and root-action is free. When the plants have become established and are growing well they may be dipped frequently, but after growth has again ceased atmospheric moisture will almost suffice to keep them in proper condition without root waterings. It is most essential never to have sour or stale materials about the roots of these plants. A characteristic of this species is that growths which have extended over the sides of the pans flower most satisfactorily.

Cattleya Schilleriana is by many regarded as a natural hybrid between the above-mentioned species and C. guttata. It requires the same treatment so far as position, the giving of water, and other particulars are concerned. It should be grown on rafts or in shallow pans. The plants having flowered, or arrived at the stage when they should have done so, they will soon produce a new series of roots from the bases of the new growths. It will be then advisable to pick out as much of the old material as possible, and replace it with new, afterwards keeping the material moist until root action has ceased. Subsequently throughout the resting period comparatively dry conditions should be the rule.

Cattleya superba, although distributed over a large area in equatorial South America, is always found growing on trees near to rivers, where the plants are well exposed to the light and deluged daily for six months of the year. In cultivation the plants succeed for a few seasons fixed in well-drained pans with a small quantity of material about the roots, and suspended in the highest and warmest part of the East Indian-house. When they are growing, but are not making roots, they need very little water, but as soon as root-action occurs afford them liberal and frequent supplies. During the long resting period waterings should be very infrequent. Afford new material just prior to new roots appearing. Thrips and scale would trouble these plants if the pest were not destroyed by the usual methods.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Celery.—We have made our first plantation of Celery from sturdy, well-hardened plants raised from seeds sown during the second week in March. Having prepared the trenches, give them a thorough watering the day before the seedlings are planted. In transplanting these slender, fibrous-rooted plants the greatest care must be exercised in order to avoid giving them a check. Plant moderately firmly, and apply water to ensure a quick and free growth. During the season give frequent applications of soot, and until growth is completed plenty of water. Damp the plants overhead at least once a day during dry weather. Make preparation for successional breadths.

Vegetable Marrows.—These plants should now be sufficiently hardened for planting in their permanent quarters. Being trailing plants, they are usually grown upon manure or rubbish-heaps, but a well-regulated bed in a good position may with advantage be given them. It will still be necessary to place either light frames or hand-lights over the plants at night-time. On the 22nd ult. we registered 7° of frost, and on the 23rd 9° on one glass and 11° on another, with 17° on the grass. Apples, Pears, Plums, Gooseberries, Strawberries, &c., all suffered severely from this cold snap.

Thinning Seedlings. — The thinning of such crops as Parsnips, Carrots, Onions, Lettuce, Beet, Parsley, &c., should now be proceeded with. It is advisable that the work of thinning should be done at intervals, and while the plants are in different stages, thus securing the best plants without allowing the seedlings to become drawn by overcrowding. Parsnips should be allowed a distance of 12 inches apart; Carrots, 6; Beet-root, 15 to 18; Lettuce, 12; and Parsley, 9 inches. Keep the surface of the soil light and loose by a frequent use of the hoe.

Early Potatos.—In order to secure tubers in the least possible time we seldom "earth-up" the plants; but during this season immediately the tops are through the soil, and in some cases even before, earthing-up has been carried out as a necessary means of affording protection from frost. Main and late crops of Potatos should be "earthed" as soon as the tops have grown sufficiently high that the work can be done conveniently.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Zonal Pelargoniums.—In order that the plants may make a moderately strong growth and produce a profusion of flowers, these Pelargoniums require light soil moderately supplied with decayed manure from a hot-bed. Variegated varieties require richer soil. Pelargoniums may now be planted, and if the weather is dry let the beds be given a watering previous to planting, and the roots of the plants be made moist also before they are turned out of the pots. If all available strength be brought to bear in the carrying out of a well-arranged plan, the work of planting will be done speedily.

Plants requiring Rich Soil.—Begonias require rich loamy soil, because such liberal treatment induces the plants to flower more continuously. Verbenas, Ageratum, Iresines, Heliotropes also require rich soils and plenty of moisture.

Carnations.—Seedling plants will soon require to be planted into their permanent quarters. Choose a border containing as much fresh virgin soil as possible, and in proportion to its degree of heaviness add other constituents to make it more porous, such as old mortar rubbish, sea-sand, &c. Autumn and spring-planted Carnations will be benefitted if given a mulching of short manure and abundant waterings in dry weather. Apply a dusting of tobacco powder or a syringing with Quassia-water on the first appearance of Greenfly and Thrips. Remove "Cuckoo spit" by means of the finger and thumb. Afford supports to the plants as soon as they become necessary, and in making the ties leave sufficient space for the flower-spikes to have perfect freedom, because the stems would soon snap if there was any tightness.

Roses.—Keep a constant look-out for caterpillers and other pests. Remove suckers as they appear. Stir the surface of the soil with a hoe soon after applying water or after rain. Liquid manure may be applied to Roses showing flower. Tie the shoots of climbing Roses at short intervals, and if mildew is apparent give a thorough wetting with Bentley's Specific, or apply sulphur.

Sweet Peas.—Stake the plants in good time, and spread the growths evenly amongst the twigs if they have become entangled together owing to wind.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Tying and Nailing.—If Peach and Nectarine trees have been properly attended to, all surplus growths will have been removed, and those which remain now will require their first tie or nail, as the case may be. They may first of all be tied in to the shoot from which they are growing, as this will best give the young growth a straight start; the continuation of the shoots may be secured to light pieces of Hazel or Privet. Any shoots that are unnecessarily taking the lead may be stopped. The fruits will have arrived at a safe size to be partially thinned. Remove first those which would get damaged by pressure against the wall or shoots, selecting those in the most prominent position for furnishing the crop. Do not thin them out severely at present, nor until the stoning period is past. The shoots at the top part of the tree being most vigorous the fruits may be left rather closer upon them than on the lower branches. Unusually vigorous shoots may be cropped heavily.

Trees of the Plum and Apricot will need similar treatment to Peach trees in securing the leading branches to the trellis or wall. A final thinning of the Apricot fruits may now be given, and in thinning them it should be borne in mind that those intended for dessert purposes should be given more room than is required for fruits which will be used for preserving. Keep a sharp look-out for green-fly and maggots, and do not let either pest injure the foliage. On hot, sunny days the trees would be much benefited by occasional syringings from the garden-engine.

Mulching.—The dry weather, together with cold winds from the north-east, have made the surface soil very dry, and there are signs of cracking. Where wall-tree borders have received a watering as previously advised and the surface has since become caked, let it be lightly forked over previous to applying a mulch. For trees carrying heavy crops the mulch should consist of decayed or partially decayed manure. Should any of the trees be making very vigorous growth omit the mulch, and hoe over the surface soil occasionally.

Strawberry Plantations.—Where the strawy litter was placed around the plants roughly it will have acted as a protection, and saved some of the flowers from frost. The litter may now be arranged more flatly, putting it under the flower-trusses, it being very unlikely that more frosts will occur.

General Remarks.—All portable copings should be removed forthwith, together with any other protective material. Let fish-netting be dried, and held in readiness for covering Strawberry-plantations. Late-planted trees should be afforded water at the roots, in order to keep the soil in a moist condition. Renew the mulch, if that placed round the trees earlier in the season is not sufficient for present purposes.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JUNE 7 { Royal Botanic Society's Horticultural Exhibition, Regent's Park (3 days). Royal Cornwall Show at Newquay (2 days).

FRIDAY, JUNE 9 { Royal Botanic Society, Lecture, 4 P.M.

SALES FOR THE WEEK.

TUESDAY NEXT—
Seventh Annual Sale of Bedding and Greenhouse Plants, at Mile Ash Nurseries, Duffield Road, Derby, by order of Mr. F. Lewis, by Protheroe & Morris, at 11.20 o'clock.

TUESDAY AND WEDNESDAY—
The Stand Hall Collection of Orchids, at Stand Hall, Whitefield, near Manchester, by Protheroe & Morris, at 12.30.

WEDNESDAY NEXT—
Palms, Plants, Liliums, Ferns, Bulbs, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY NEXT—
Imported Orchids in great variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —59·7°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, May* 31 (6 P.M.): Max. 68°; Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June* 1 (10 A.M.): Bar., 30·1; Temp., 62°. *Weather* —Bright sunshine with occasional clouds.

PROVINCES.—*Wednesday, May* 31 (6 P.M.): Max. 65°, Guildford; Min. 53°, N.W. of Ireland.

The Temple Show.

Of all the shows, now numerous, that have been held in the famous Temple Gardens, not one, we venture to say, has been more interesting and varied than that which is closing as these lines are passing through the press. A bold attempt had been made to break up the more or less inevitable monotony of these exhibitions. At the same time a more rigid selection seemed to have been exercised, and there was in consequence less of the commonplace and more that was interesting. The space applied for was nearly double what could be afforded. The outdoor groups were specially good on this occasion; the very first entry in our notebook was one of admiration at the fine group of hardy ornamental trees and shrubs made by Messrs. CRIPPS, of Tunbridge Wells, and we are interested to hear that the special jurors told off to award the Veitchian Cup to the best exhibit in the show awarded this, the highest distinction, to this collection.

Similar groups from Messrs. FISHER, SON & SIBRAY; CHEAL, CUTBUSH, RUSSELL, and others were amply worth notice; whilst Messrs. JAMES VEITCH & SONS showed several of their noble Meconopsis integrifolia, Incarvillea Delavayi, Rehmannia angulata, and a selection of new species of Primula from China, of some of which we give figures in our present number; whilst the very remarkable P. Cockburniana was illustrated in our last number. As exhibited on a grass-lawn these most interesting novelties did not show to advantage.

In the tents the groups were more attractively displayed than usual. The Roses of Messrs. PAUL & SON, TURNER, the two firms of CANT, WILLIAM PAUL & SON and others were specially fine, whilst Mr. MOUNT'S cut Roses were beyond praise. Messrs. SUTTON & SONS occupied the end of the tent usually filled with TURNER'S Roses, but on this occasion it was massed with glowing mounds of Calceolarias, Schizanthus, and other showy plants. The groups at the sides and end of the tent, furnished by Messrs. CUTBUSH, VEITCH, and CYPHER, were extraordinarily fine and varied, the plants interesting in themselves, excellently arranged, and superb examples of cultivation. Of the Orchids we give a special note, so that we need only here say that they were quite up to the average, both in quantity and in quality. One Orchid in particular, a variety of Cattleya Schröderæ called "The Baron," unique in its colouration, exhibited by Messrs. SANDER & SON, was acknowledged by the experts to be the most remarkable of all the Orchids shown, although, as it was "not entered" for a certificate, it received no award. We are happy in being able to give a representation of this very extraordinary Cattleya (fig. 142), a description of which is also printed in another column.

Mr. GEORGE ARENS, of Ronsdorff, Germany, showed a remarkably fine group of Primroses—hybrids between P. obconica and P. megaseæfolia. In this group the abundance of blossom and the wide range of colour were remarkable.

Gerberas were staged by several exhibitors, and gave abundant indication of the brilliant future in store for them. Ostrowskya magnifica was shown by Messrs. WARE in finer condition than we ever remember to have seen it, and Mr. REUTHE had flowering branches of various Sikkim Rhododendrons, the showy Crinodendron Hookeri, and Embothrium coccineum. Rhododendron aureum from Messrs. CUTBUSH was very noticeable. Messrs. BRUCE'S Sarracenias were also worth special attention, whilst the new or comparatively new plants exhibited by Messrs. VEITCH, SANDER, WALLACE and others confirm our statement that this was a show, not only of unusual beauty so far as grouping is concerned, but of quite special interest for the number of novelties it comprised and the comparative absence of the commonplace.

We can now only further comment on a remarkable bigeneric hybrid exhibited by A. WORSLEY, Esq., between Elisena longipetala and Ismene calathina. The flowers were snow-white, with narrow segments and a deep fringed cup. For full details of the Exhibition we must refer to another column. Unfortunately, the comfort of the visitors was seriously interfered with by a thunderstorm on the afternoon of the first day, though the number of visitors was as great as ever.

PRIMULA VEITCHII, DUTHIE* (see Supplementary Illustration).—This very handsome new Chinese Primula was discovered by Mr. E. H. WILSON on the mountains of West Szechuan, growing on cliffs and exposed spots at elevations between 8,000 and 10,000 feet. It was shown at the Temple Show of the Royal Horticultural Society on the 30th ult., together with some other novelties from that country. I have much pleasure in dedicating it to Messrs. J. VEITCH & SONS, to whom botanists as well as horticulturists are so much indebted for the knowledge afforded, by the discoveries of their excellent collector, Mr. E. H. WILSON, of so many interesting and beautiful Chinese novelties. Its nearest ally is P. cortusoides, L., but it is a much more robust plant; the leaves are relatively broader in proportion to their length, and their under-surfaces are clothed with white floccose pubescence; the flowers are larger and of a deeper rose colour; the pedicels are stouter, and the calyx is longer and not so deeply lobed.

* Rootstock slender, creeping. Leaves all radical; blade 3—3½ in. long and about as broad, rugose or subbullate when young; lobes imbricate, 3—7 lin. long, by about 6 lin. broad, coarsely 3—5 toothed; upper surface dark green, sparingly pubescent; lower surface densely clothed with white floccose tomentum; midrib and nerves impressed above, very prominent beneath; petiole about as long as the limb, cylindric below, channelled on upper surface towards the blade, thinly tomentose. Scape stout, up to 14 in. high, densely puberulous. Flowers 10—20, umbelled or in verticils. Bracts many, shorter than the pedicels, unequal, subulate, sparingly pubescent on both surfaces, margins ciliate. Pedicels ¾—1 in. long, puberulous. Calyx ⅓-in. long, brownish-green, pubescent outside, sparingly so within; tube ovate; lobes narrowly lanceolate, very acute, often unequal, the longer ones equalling the corolla-tube in the long-styled form; margins ciliate. Corolla rose-purple or violet, salver-shaped, about 1 in. in diameter, with a narrow, orange-coloured ring surrounding the yellow mouth of the tube; tube equalling or longer than the calyx, pubescent outside, often tinged with crimson; lobes 5 lin. long and 4 lin. broad at the deeply-bifid apex, sparingly pubescent outside. Capsule (when ripe) twice the length of the calyx. *J. F. Duthie, Kew.*

MESSRS. SANDER'S ORCHID SALE.—The sale of one hundred special Orchids from Messrs. SANDER & SONS, St. Albans, at Messrs. PROTHEROE & MORRIS'S Rooms, Cheapside, on Tuesday last, brought together a fine company, and consequent keen competition, especially for the best Odontoglossums. O. crispum "Roger Sander" secured the highest price ever brought by a single plant at an auction—viz., 875 guineas. O. c. Mundyanum realised 230 gs, O. c. Princess Helena 190 gs., O. c. Franz Masereel 200 gs., O. c. Queen Victoria 100 gs., O. c. President Loubet 70 gs., O. c. Imperatrix Regina 130 gs., and others went at equally satisfactory prices, the total amounting to over £3,500. Mr. E. Rogerson, Mr. J. Leemann, Mr. N. C. Cookson, Mr. Briggs-Bury, Mr. W. Thompson and Mr. H. T. Pitt were among the principal buyers.

THE PARIS SHOW.—In addition to the Orchids mentioned in our report last week, M. CH. BERANEK, 36, Rue de Babylone, Paris, informs us that he obtained a Prix d'Honneur and a Large Gold Medal from the Royal Agricultural and Botanical Society of Ghent for a collection of fifty Orchids. Among these were Cypripedium callosum Sanderæ, Cattleya Skinneri alba, C. intermedia alba, &c.

THE ROYAL BOTANIC SOCIETY'S Great Horticultural Exhibition will be held on Thursday and Friday, June 8 and 9, at Regent's Park. On Wednesday, June 7, a private view will be afforded the members of the Society and the Press.

THE KEW GUILD.—The sixth annual dinner of the members of the Kew Guild took place at the Holborn Restaurant on Monday evening last. Dr. AUGUSTINE HENRY, M.A., F.L.S., presided over a company of one hundred and forty-one, of which number four were ladies. As members of the Kew Guild are now engaged in work in almost every country, as well as in our own Colonies, these annual gatherings are usually attended by some who have travelled a considerable distance to be present, or are "at home" for a holiday. On this occasion there were Messrs. HART, of Trinidad; WILKE, Rotterdam; SILLITOE, Khartoum; DON, West Coast of Africa; GILL, Cawnpore; GENTIL, Brussels, and others. Some who had intended to be present were prevented, and (amongst others) a letter of regret was received from Mr. F. W. BURBIDGE, M.A., Dublin. In proposing the toast of the evening Dr. HENRY referred to the present distribution of past Kewites, and to the multifarious duties they have to undertake. Kew men, so said Dr. HENRY, were not merely imperial, they were cosmopolitan. He gave the young men some advice in regard to the carrying out of the work that is necessary to obtain practical experience and theoretical knowledge. His explanation of "don't work too much" was rather that they should not work too long and aimlessly. He recommended concentration and intensity of application whilst at work, and then a gardener who had worked conscientiously during the day would find that two hours' study at night was sufficient. Dr. HENRY referred to Mr. WILSON'S work in China as being of very great credit to the Guild. Mr.

W. WATSON, who responded, said that it was time that the Guild considered whether it could not do more than publish a journal, and dine together once a year. He suggested that the members should consider if the energies and influence of the Guild might not be advantageously exerted on behalf of the less fortunate of professional gardeners, and in such a manner that their legitimate grievances might be remedied and the status of gardening raised. Other speakers included Dr. SCOTT, Mr. HART, and Mr. J. WEATHERS. The tables were prettily decorated with Palms and flowers supplied by Mr. DROST, Richmond, a member of the Guild. Songs were contributed by Messrs. T. W. BRISCOE, J. M. HILLIER, &c.; and a pianoforte solo by Mr. W. J. NEAVE. Previous to the commencement of the dinner, the annual general meeting was held, at which all the retiring officers were re-elected. The report stated that the Committee had granted a sum of £10 to the widow of a Kew man who was killed some months ago in a bicycle accident. We are very pleased to find that the Guild has thus widened its sphere of work by the exercise of such appropriate benevolence.

AWARDS AT THE ROYAL HORTICULTURAL SOCIETY.—The discussion on the proposals for a modification of the awards originated at a meeting of the Fruit Committee has been postponed till July 18. This will allow of time for the whole question, as affecting all the Committees, to be considered.

ASPARAGUS AT EVESHAM.—An important portion of the market garden cultivation around Evesham is devoted to Asparagus, and considerable acreage is thus profitably occupied, even at high rents. For a long period an annual show has been held, at which prizes are offered for the best examples of the local growers' skill, and it is always an event of much interest in the district. At the exhibition held in the Town Hall on Monday last (May 29), the display was a good one for such a dry and difficult season, about fifty bundles of 100 heads each were shown, and the average weight per bundle was stated to be 15 lb. The prize-winning bundles ranged from 17 to 20½ lb. each, and the length was from 12 to 16 inches, with a diameter at the base of the individual stems of 1 inch or more. In some cases they were green and tender for more than half their length, in others the blanched portion preponderated, and these seemed to be generally most esteemed, though their edible value was questionable. The whole of the exhibits was sold by auction at the close of the show, and the highest prices realised per bundle of 100 were 16*s.* and 17*s.* 3*d.* In former years higher prices have been realised and more sensational weights have been obtained, but the long dry period has militated seriously against this popular vegetable in this country. *R. Lewis Castle.*

HORTICULTURAL COLLEGE, SWANLEY.—By permission of Lady FALMOUTH, a drawing-room meeting was held recently at 2, St. James's Square, in support of the appeal now being made for £2,000 which is required before the end of July to put the finances of the Horticultural College, Swanley, on a sound basis. Lady FALMOUTH explained that the meeting had been called to arouse sympathy with the College and its aims. Originally a "mixed" institution, it was converted in 1904 into a college for women only. There was, however, a considerable debt which it was now desired to clear off. If the money could not be obtained the College would have to close its doors. The training provided at the institution gave power and independence to women, and fitted them for work in the Colonies, and yet the College was hampered for want of financial support. The Hon. Secretary read a report dealing with the work carried on. She stated that in 1904 the total number of students was eighty-nine. Eight of them were awarded the College Diploma, and twelve the College Certificate. In the examinations of the Board of Education last year six students gained First-class Certificates for Elementary and nine for Advanced Botany, while nineteen took a First-class in Agricultural Science and Rural Economy, and King's prizes were won in both these subjects. Mrs. JOHN HOPKINSON read a paper on the work and aims of the Colonial branch. She stated that the Committee could now point to a number of students settled in South Africa and Canada, who were prepared for independent, salaried, or co-operative work and for the private management of colonial households. Three sisters, after training in poultry and dairy-work, had joined their brothers in a ranch in the North-west Territories and were doing well. Five students prepared for married life in South Africa, Canada, and New Zealand, and two were doing admirably on gardens in Natal, and were greatly appreciated. On the motion of Principal HOPKINSON a resolution was passed pledging the meeting to use every endeavour to raise the sum required.

NEW OR NOTEWORTHY PLANTS.

PRIMULA COCKBURNIANA, HEMSL.

THIS species, figured in our last issue, was first discovered by the naturalist Pratt in the neighbourhood of Talien-lu, on the Tibetan border. In 1890 he brought home dried specimens to the Kew Herbarium, and Mr. Hemsley described it in the *Jour. Linn. Soc.*, xxix. (1892). It was introduced into the Veitchian nurseries by their collector, Wilson, and was exhibited by this firm before the Royal Horticultural Society on May 23 last, and again at the Temple. In describing this species Mr. Wilson says:—"It is common in wet alpine meadows, between 10,000 and 11,500 feet, in the vicinity of Talien-lu. The scapes vary in height from 8 inches to 1½ foot, and have from three to six whorls. From its extraordinary colour it is one of the most striking of all the many species of Primula which occur in these wilds."

SOCIETIES.

THE TEMPLE SHOW.

(See also Supplement.)

GROUPS OF PLANTS, &c. *(continued).*

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, staged an admirable group of foliage plants, relieved with showy flowering subjects. Great taste was displayed in the method of staging, and a number of stands were requisitioned on which were placed choice forms of Nepenthes—N. Tiveyi, N. Curtisii superba, N. mixta, &c. Caladiums were a feature in the group, the foliage being not only of large size, but admirably coloured; a plant of C. Rose Laing in the centre of the group was superb. Other good varieties were Clio, Madame John Box, Marquis of Camden (rose ground with green margin), Madame E. Pynaert (red self), Oriflamme, Raymond Lemoinier, H. Hoffmann (new), Baron A. R. de Rothschild, Miss Elsie Hoffmann (new), Admiral Togo (green border, blotched rose with crimson veins). Marantas, Anthuriums, Heliconias, Codiæums, and Dracænas were shown in numbers and in excellent condition. Tillandsia zebrina and T. Zahnii were shown in flower. We also noticed a flowering plant of Medinilla magnifica, the curious Ochna multiflora with its showy coloured fruits, brilliant spathes of Anthurium Scherzerianum, A. Andreanum, &c. Some choice Cannas were utilised as corner subjects, while a batch of Hæmanthus Kalbreyeri, backed with plants of Rhododendron, Javanico-jasminiflorum hybrids brightened the centre with their pleasing flowers. The background was furnished with Cocos flexuosus and tall plants of Lilium Brownii and L. Henryi. Standard trained plants of Codiæum cordatum tortile, C. Massangeanum, and C. Laingii, were shown in first-rate condition.

Gloxinias.—Messrs. CARTER & CO., who had a varied collection of subjects staged, among them a small quantity of Gloxinias of good quality.

Messrs. CANNELL & SONS, Swanley, staged a collection characterised by high quality; among the most striking of the named varieties were Mrs. Avory, Cannell's Scarlet, Kaiser Wilhelm, Model, Petunia, Her Majesty (white), Empress Frederick (of which there was quite a panel staged), Dainty, &c.

Messrs. PEED & SONS, West Norwood, also set up a bank, and among the named varieties were Earl Bathurst, E. L. Peed, Brilliant, Countess of Ilchester, Duchess of York, Rudyard Kipling, &c.

Messrs. SUTTON & SONS, Reading, filled one of their fine-raised bays with Gloxinias of the first quality.

Cannas.—Messrs. CANNELL & SONS put up a superb group of some seventy or eighty varieties, the heads of bloom were very fine indeed, and they represented the very cream of the collection grown at Swanley. They were one of the features of the large tent. The plants averaged about 3 feet in height.

Cinerarias. — These were sparingly represented. Messrs. SUTTON & SONS had groups of the stellate type as wings to their large display.

Messrs. CARTER & CO. included among their miscellaneous plants panels of the same type.

Messrs. J. VEITCH & SONS staged a collection of dwarf-growing plants of a variety named Antique Rose, the flowers of a pinkish-rose tint.

Pelargoniums.—Mr. H. J. JONES, Lewisham, had a collection of cut decorative varieties in bold bunches. Some of the principal sorts were Viola, Conora, Kingston Beauty, Her Majesty, May Marks, Little Richard, &c.

Mr. H. B. MAY, Dyson's Lane Nursery, Upper Edmonton, staged a collection of single and double zonal Pelargoniums, the latter preponderating. Good varieties were seen in Duke of Bedford, Countess of Hopetoun, Hall Caine, The Sirdar, Tangare, Mme. Lauder, Golden Gate, Lady Ilchester, Blanche, Lady Dorington.

FERNS.

Fine groups of stove and greenhouse varieties were staged, but very few hardy Ferns were seen, and no new varieties were submitted to the Committee.

Mr. H. B. MAY, Upper Edmonton, put up a very fine group, which gained a "Silver Cup." Of Nephrolepis the American varieties Piersoni and Fosteri were very fine; N. Mayi, an erect-growing congested form, was quite distinct—this is prettiest in a small state; N. crispato-congesta is a curious miniature form, somewhat resembling a congested form of Scolopendrium. In Adiantums, Clæsianum, with a silver band down the pinnæ, is a distinct Fern. A. Farleyense was well shown; A. versaillense, a pretty dwarf-crested variety; A. curvatum, A. peruvianum, and others were good; Platycerium grande, P. æthiopicum, and P. Willincki were effective. Several pretty crested Pteris were seen; P. cretica generosa, which recently received an Award of Merit, is a distinct and pretty Fern, the pinnæ being cut down into narrow segments; P. Summersi and P. Childsi are beautiful plumose varieties. Gymnogrammas were good. Several Davallias on tall stems made a good effect. Acrostichum aureum, a large plant of which stood up in the centre of the group, was effective.

Messrs. J. HILL & SON, Lower Edmonton, staged a very fine group, which was made up of choice species and varieties displayed in the best possible manner. This group also secured a Silver Cup. In the centre was a good plant of Dicksonia Scheidei, Platycerium angulosa, with large broad fronds, was imposing; P. Hilli, P. Willincki and P. alcicorne were also good. Davallia fijiensis elegans, D. Veitchii and several other good species were seen. Gymnogramme grandiceps superba, G. Peruviana argyrophylla and others. Among Adiantums reniforme is always an attraction; A. macrophyllum striatum is a very pretty variegated variety. Polypodiums Schneideri and Mayi were good; the dwarf sorts, such as piloselloides, vaccinifolium on moss-covered stems were pretty. Asplenium formosum and A. cicutarium are choice species now rarely seen. Of Gymnogrammas, the best silver and gold-fronded sorts were well shown. Gleichenias speluncæ, flabellata, and others were good; Lomaria attenuata, with soft, rosy-tinted fronds, and Lomaria L'Herminieri, a choice gem with bright red fronds; Asplenium nidus, Polypodium iridioides in large specimens, were very effective.

Ed. ASCHERSON, Esq., Pett Place, Charing, Kent, exhibited some fine specimen Ferns, which included Adiantum trapeziforme, A. concinnum latum, A. Farleyense, Gymnogramma chrysophylla, G. peruviana argyrophylla, with smaller plants arranged among (Silver Flora Medal).

There were very few choice Ferns in the miscellaneous

groups. Messrs. VEITCH & SONS, Chelsea, had good specimens of Davallia Veitchianum.

Messrs. SANDER & Co., St. Albans, put up fine specimens of Polypodium Knightii and Nephrolepis Scotti, an American variety which closely resembles our N. exaltata, but is more compact in habit.

Messrs. H. LOW & Co., Enfield, exhibited Pteris Wimsetti compacta, a neat-growing crested variety, which should be useful for market.

Messrs. J. BACKHOUSE & SON, York, in their rock-garden, had some fine plants of the hardy North American Adiantum pedatum, and also Polystichum proliferum diversilobum.

CARNATIONS.

The greater portion of these flowers shown were of the so-called Tree and Souvenir de la Malmaison sections, the latter being readily distinguishable from Tree and border Carnations by their more vigorous fleshy "grass," compact habit, and larger and less regularly formed flowers.

The finest exhibit of these plants came from W. JAMES, Esq., West Dean Park, Chichester (gr., Mr. W. H. Smith), and this was placed at the eastern entrance of a tent running parallel with the Embankment road. The exhibit consisted of a number of plants with very large "Malmaison" flowers of the flesh-coloured type beautifully bloomed. A number of plants of a remarkably tall yellow-flowered variety—not "Malmaisons"—formed a dividing line from the contiguous exhibits, and some plants of a very choice, fragrant, dark crimson-coloured variety, resembling that of H. J. Jones, were arranged in the foreground.

R. WAGG, Esq., "The Islet," Maidenhead (gr., Mr. Phillips), had varieties of "Malmaison" in yellow, cerise, pale pink, white, scarlet, and light and deep crimson colours, the flowers large and of good development generally. All were growing in small pots.

Messrs. CUTBUSH & SONS, of the Nurseries, Highgate and Upper Barnet, had quantities of finely-grown "Malmaison" varieties dispersed among their admirable group of Roses, in a corner of the large marquee. A variety of a yellowish-pink colour was noted in Rittmeister.

An exhibit of twenty vases filled with fringed and smooth-petalled varieties was contributed by the Carnation specialist, Mr. A. F. DUTTON, of Iver, Bucks, among which the following were notable—viz., Fair Maid, tender flesh in colour; the now well-known Enchantress, of a rather lighter tint; Mrs. Thos. W. Lawson, cherry-red, showy, and of large size; Harlowarden, of the same size and colour as the Old Clove; Governor Roosevelt, almost identical in colour and size as is Harry Fenn; and lastly G. H. Crane, a pleasing flower of rosy-crimson colour.

Mr. MAURICE PRICHARD, nurseryman, Christchurch, Hants, exhibited many admirable "tree" varieties in great diversity, and particularly nice were the dark crimson-coloured H. J. Jones, and Mrs. Lawson.

Messrs. HUGH LOW & Co., Royal Nurseries, Bush Hill Park, Enfield, exhibited extensively "Malmaison" varieties, among which we indicate Albion (a dwarf plant having flowers of a deep salmon tint), Calypso (a large flower of a tender flesh tint, the central petals salmon coloured, with pink splashes on the petals), the crimson-coloured Churchwarden, Horace Hutchinson (a brilliant scarlet bloom), and Princess of Wales (a fine variety of a pink tint). Among Tree Carnations the new variety Liberty is worthy of notice, and others mentioned as being present in other collections were found on Messrs. LOW's exhibit.

Messrs. G. BOYES, Carnation-growers, of the Aylestone Park Nurseries, Leicester, exhibited a small but choice collection, in which we noticed the new Shakespear, Robert Burns, and Queen Alexandra; the first named a fine coral-pink, the second an equally fine rosy-pink, and the third a delicate shade of the same colour. We were informed these will be ready for distribution next year. Another fine Carnation was Dr. W. G. Grace, a bright scarlet variety sent out in 1903.

CLEMATIS.

A fine collection of these plants excellently bloomed was shown by Messrs. RICHARD SMITH & Co., Worcester, the plants numbering about thirty, and trained mostly on globular trellises. Of double and semi-double-flowered varieties, mention should be made of Lucy Lemoine, Countess of Lovelace, Venus Victrix, which have been many years in cultivation. Of single-flowered varieties there were Fairy Queen, purpurea elegans (a grand purple flower), Mrs. G. Jackman, Marie Lefebvre, Anderson Henry, Lord Neville, and the new lilac-coloured King Edward VII. The rosy-crimson Ville de Lyon and Wilsoni, a flower of pale lilac, were much admired by the visitors.

CALCEOLARIAS.

Of these showy plants a new, shrubby strain, mentioned in the *Gardeners' Chronicle*, June 4, 1904, p. 361, having an average height of 5 feet, and very floriferous, was shown in several examples by Mr. J. JEFFRIES, of Oxford. It is apparently perennial, and partakes of the characteristics of C. Burbidgei. As the crosses between different species of Calceolarias are more fertile than those from the original species from which they have originated, some good decorative hybrids may result from crossing the variety shown with the ordinary herbaceous Calceolarias. The floral colours resembled those of the latter, although in size they were much smaller, and the corymbs more lax.

An excellent exhibit of Calceolarias came from Messrs. SUTTON & SONS, Seed Merchants, Reading, and these were well shown in a flattish pyramidal manner along with other exhibits by the firm at the northern end of the largest marquee. The assortment was judiciously made as regarded the colours, the blooms were of enormous size, and generally finely inflated, and the habit of the plants stocky.

R. J. DURHAM, Esq., "Overton," Ealing, W. (gr., Mr. J. Cook), showed a small collection of dwarf, fairly well-grown plants.

T. H. LOWINSKY, Esq., Tittenhurst, Sunninghill (gr. Mr. Thomson), exhibited about fifty plants of a capital strain, having fine large blooms of beautifully varied colouring, and the height of the plants about 18 inches.

Messrs. J. CARTER & Co., Seedsmen, of High Holborn, London, staged a small group of medium-sized plants; and Messrs. W. CLIBRAN & SON, Nurserymen, Altrincham, showed about forty plants having flowers of medium size, foliage robust and clean and the colours of the flowers well selected.

RHODODENDRONS AND AZALEAS.

Messrs. JOHN WATERER & SONS, Ltd., Bagshot, Surrey, staged a lovely array of Rhododendrons, having the plants in the best possible flowering condition. Pink Pearl was prominent and eclipsed its neighbours in size of flower and truss, while the shade of colour is of the palest shade of rose-pink; Lady Howe, Charlie Waterer, and Marquis of Waterford are darker-coloured forms; Joseph Whitworth is almost a magenta colour; Gomez Waterer is of beautiful form, pale blush colour with yellow marking on the upper petal; B. W. Currie, Francis Hayes, and Strategist are other notable varieties.

Messrs. SANDER & SONS, St. Albans, staged a collection of Azaleas. They were sent from Messrs. SANDER'S nursery direct to the Show, being landed, as we were informed, on the Embankment pier. Next to the excellence of the plants themselves, the condition in which they arrived was the most astonishing feature. One could not detect an injured bloom, and the whole group presented the appearance of a wealth of flower. They were all selections from A. indica, and the great range of colours in the varieties was remarkable. We have space to name only a few, and of these we include Memoria Lowi, Phœbus, Theodor Keimers, Osiris, Madeleine, and Miss E. Jarret.

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, staged a large bank of hardy Azaleas that presented a wealth of flowers of brilliant colours, with suitable greenery furnished by such plants as Maples, Ferns, Asparagus plumosus, and backed by tall Cocos Palms. The arrangement was bold, the centre being raised, and flanked on either side by prominent corner plants. The charming yellow variety Anthony Koster formed the central bank, and here and there were introduced standard-trained plants breaking the continuity and adding to the effect. Among the more notable varieties we may mention J. C. Van Tol (excellently shown), Fanny (with rosy-pink flowers lightly tinted with yellow), Hugo Koster, Unique (an orange-scarlet variety), Raphael de Smet, Aida, Alphonse Lavelée (a handsome salmon-pink variety), Velasquez, &c.

Messrs. WM. PAUL & SON, Waltham Cross, exhibited a number of baskets containing sprays of Rhododendron flowers. Pink Pearl was prominent. Another good variety noticed was atro-rubrum purpureum.

BEGONIAS.

The collections of these plants scarcely equalled those of last year in extent, but the individual plants were quite up to the best standard of quality.

Messrs. JOHN LAING & SONS, Forest Hill, London, staged a grand lot of these flowers. They had some of their premier varieties in batches, such as Lord Kitchener, a "Camellia"-shaped flower of the richest scarlet colour; Mrs. T. V. McConnell, shaded a rich salmon-pink; Mrs. John R. Box, one of the best double "whites"; Lady Grenfell, also white; Lady Kerry, a variety with rose-coloured margin. We also noticed Duke of Fife, a large crenated flower of salmon-pink colour; Sir Howard Vincent, rich scarlet colour; James Buchanan, a "rosette," also rich scarlet colour; Lady Charles Beresford, a tall-growing variety, with primrose-yellow flowers. In addition to the foregoing, single varieties were freely represented; of these the variety Lord Kerry has a large flower of deep scarlet; Lord Howe is also a good single variety, the colour being rich scarlet.

Messrs. BLACKMORE & LANGDON, Twerton Hill Nurseries, Bath, exhibited an excellent strain of these handsome flowers, and presented their plants in the best possible condition. The varieties were all of the double type. A new frilled "Camellia"-shaped variety named Mrs. C. Russell is exceedingly handsome, being of a soft blush-pink colour and of excellent shape. The new variety Amy is a good wavy-petalled "Rose," with exquisite rose-pink colour and having a lighter centre. Snowflake is a new frilled "white." Countess of Warwick (apricot-orange with lighter centre), Frilled Beauty, Mrs. S. Pope, Percy Foster (rich scarlet), Sir T. Lipton, and Mrs. G. M. Soames (new) are notable varieties.

Messrs. T. S. WARE, Ltd., Ware's Nurseries, Feltham, Middlesex, showed a group of tuberous-rooting Begonias, nearly all of which were double varieties. Some of the flowers were showing evidences of the hot weather, the petals in some cases being injured. Miss Rhoda Pope is a "Camellia"-shaped flower with blush-pink margins merging to a lighter centre. Mrs. W. L. Ainslie is a new "yellow"; King Edward VII. has rich scarlet-crimson flowers; Mrs. Arthur Paget, Mary Pope, Lady Suffield, and Mrs. Bean are varieties all worthy of mention.

Mr. A. LL. GWILLIM, Cambria Nursery, New Eltham, Kent, staged a collection of tuberous-rooting Begonias, having single and double varieties in about equal quantities. Mr. J. Portbury is a good "scarlet"; the flower is "Camellia"-shaped, and of the best form. Eltham Glory (picotee-edged), Mars, Golden Crown (yellow), &c.

Messrs. CARTER, 237, 238, High Holborn, staged a batch of tuberous-rooting Begonias, none of the varieties being named.

Mr. H. J. JONES, Ryecroft Nurseries, showed a small collection of bedding varieties of tuberous-rooting Begonias.

FRANK LLOYD, Esq., Coombe House, Croydon, exhibited a batch of hybrid Begonias of the Worthiana type, having many forms and colours of this free-flowering species.

ROSES.

Messrs. WM. PAUL & SON, Waltham Cross, Herts, staged one of the finest exhibit of Roses. The group occupied the same position as last year and presented a galaxy of lovely flowers. The whole of the collection was comprised of pot plants, the members being excellently grown, well furnished with flowers, and of the choicest varieties. The beautiful Lady Gay (Wichuraiana) was represented by five finely trained plants (see Awards); Farquhar is somewhat similar, but not so bright or large. The whole of the background was staged with Roses of the Rambler type, and among the group were standards and bush-trained plants. Among the best examples seen we may mention Pharisaer (a large flower, soft blush colour), White Maman Cochet, Ulrich Brunner, Mrs. John Laing, Hélène Guillot (new), H.T. Mme. Hector Leuilliot (climbing Tea), Prince de Bulgarie, Crimson Queen, Mme. Abel Chatenay. A number of plants of the variety Débutante (see fig. 146, p. 347) (Wichuraiana), were prominent in the centre of the display. The group was set up with great taste and was much admired.

Adjoining Messrs. WM. PAUL'S exhibit was a display of Roses exhibited by Mr. CHAS. TURNER, The Royal Nurseries, Slough. The arrangement of this group was bold—tall standard and climbing varieties being liberally utilised to furnish relief to the general collection that formed the groundwork. This latter was composed of well-grown specimens of such types as Mrs. R. G. Sharman Crawford, Frau Karl Druschki, Souvenir de Pierre Notting, La France, Juno, and other equally beautiful varieties. Foliage plants, Ferns, Palms, Dracænas, &c., were utilised to enhance the effect.

FIG. 146.—TWO OF MESSRS. W. PAUL AND SON'S NEW (WICHURAIANA) ROSES: WALTHAM PRIDE, PURE WHITE; AND DÉBUTANTE, PINK.
Drawn by Mr. Worthington G. Smith.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, N., furnished one corner of the large tent with a magnificent group of Roses. Standard and other trained plants were freely utilised in the group, the back portion of which was wholly occupied by trained plants of Polyantha varieties, such as Crimson Rambler, W. K. Harris (Wichuraiana), Hélène, Blush Rambler, &c. Dwarf plants in pots freely flowering and all showing excellent culture, formed a groundwork, and the flowers were of the best possible quality, indeed the quality was quite equal to any in the show. Frau Karl Druschki was exhibited in all the magnificence characteristic of the variety, also Mildred Grant, Souvenir de Président Carnot (excellent), Rev. Alan Cheales, Glory of Cheshunt, Lady Roberts, David Harum (a new Tea, full flower, of rose-pink-colour; see Awards). We have no space to name a tithe of the other beautiful things in this excellent exhibit.

Mr. GEO. MOUNT, Canterbury, Kent, staged a collection of Roses. The position occupied by the flowers did not permit of their being displayed to the best advantage, but opportunity was taken of the sloping canvas roof of the tent to form a bower with such subjects as Dorothy Perkins. The Roses were displayed in batches of one variety and in boxes, the latter containing exquisite examples of many choice kinds, such as Liberty, Madame Gabrielle Luizet, Bessie Brown, &c. In the vases were arranged such beautiful varieties as Ulrich Brunner, Mrs. John Laing, Frau Karl Druschki, Mrs. R. G. Sharman Crawford, Madame Gabrielle Luizet, and Liberty, all in excellent condition—in fact, the flowers were some of the best in the show.

Messrs. BEN CANT & SONS, Colchester, set up a collection of Roses, among which the climbing varieties were a feature, Blush Rambler being especially fine. Hélène is a commendable variety; it produces large trusses of its pleasing flowers in profusion. Dorothy Perkins was shown well. We were pleased with the H.T. Gruss an Teplitz, a semi-double flower of a handsome rosy-pink shade. Leuchtstern, Ulrich Brunner, Frau Karl Druschki, and many other well-known varieties were included in the group. A tray contained flowers of the variety Maréchal Niel of the richest shade of yellow, the flowers in addition being large and of good shape.

HOBBIES, Ltd., Dereham Nurseries, Norfolk, put up a group of flowering subjects in which Roses were the principal feature. Varieties of the climbing and Polyantha type were made a special feature, and excellent indeed were the examples displayed. A new variety named Philadelphia Rambler was given an Award (which see). The standard plants of Dorothy Perkins, Alberic Barbier, Blush Rambler, and Waltham Rambler were covered with their trusses of bloom. The variety Noella Nabonnand is pleasingly scented, and the bright scarlet flowers are handsome; Madame de Watteville was shown well. Messrs. HOBBIES also staged a collection of Sweet Peas, utilising these brilliant subjects for an edging. Carnations, Clematis, and other greenhouse subjects completed the group.

Messrs. FRANK CANT & CO., Braiswick Rose Gardens, Colchester, showed an extensive exhibit of Roses. Many of the flowers showed signs of the hot weather, and were, if anything, past their best condition. The rich flowers of Liberty were displayed to advantage in this collection; also the Austrian Copper Briar. Mrs. W. J. Grant was noticed, also a large number of flowers of Souvenir de Pierre Notting. Such varieties as Blush Rambler, Waltham Rambler, Hélène, and the new variety Philadelphia Rambler, were trained at the background, or hung gracefully down over the plants and flowers on the staging beneath.

Messrs. T. S. WARE, Ltd., staged a miscellaneous collection of flowering subjects, including a good display of Roses. William Allan Richardson was noticed in bud and fully opened; the dwarf-growing Madame N. Levavasseur was shown to advantage and in good form. Another dwarf free-flowering variety is Gloire de Polyantha; this is a pink variety of very free-flowering habit. Aschenbrödel is a good dwarf "China." Comtesse de Cayla, also a China, has an unique colour, which may be likened to copper-orange. Boxes contained excellent examples of such varieties as Frau Karl Druschki, Zéphyrine Drouhin, Mrs. Ed. Mawley, &c.

ALPINE AND HERBACEOUS PLANTS.

If it is not possible to increase the area devoted to hardy plant exhibits at the Temple Show from year to year, it is obvious that improvements in the way of selecting and arranging them receive a greater share

of attention than formerly. The rockery exhibits increase in size and number, and the huge masses of cut flowers banked high and thick in a more or less meaningless fashion are fewer. For the rest we can only say that the hardy plants were good and numerous, and we noted many choice specimens that space will not permit us to mention even by name.

In the opening of the long tent on the Embankment side we came first into contact with a small rockery exhibit from Messrs. CARTER & Co., High Holborn, in which choice Saxifragas, Edelweiss, Hutchinsia alpina, Silenes, the brilliant Ourisia coccinea, Fair Maids of France, and tall spikes of Saxifraga pyramidalis were seen.

Near to this exhibit the Misses HOPKINS, Mere, Cheshire, had a very neatly arranged rockery group, in which the double Cambrian Poppy, Armeria Laucheana (rosy-pink, 3 inches high), Delphinium nudicaule, with Phloxes, Erinus, and many Aubrietias were seen to advantage. Many choice hardy Ferns were in this group, Athyrium glomeratum being noticeable by its density and dwarfness. It is a rare kind, and the name is not familiar.

Mr. H. C. PULHAM, Elsenham, Essex, staged many plants in a rockery exhibit, particularly the hardy Cypripediums, Saxifraga longifolia, Phlox divaricata alba, many Alpine Phloxes, Gentiana verna, the white-and-rose-coloured forms of Aster alpinus, the white trailing Saponaria ocymoides alba, and others.

From Mr. R. FARRER, the Craven Nurseries, Clapham, Yorks, came some of the choicest things seen at this exhibition; the lovely Eritrichium nanum for example, Myosotis rupicola, Haberlea rhodopensis, Ramondias, &c. A fine lot of the hardy Lady's Slippers, in which Cypripedium macranthum ventricosum was a finely-coloured example, was shown. Dianthus alpinus albus, Primula farinosa, a perfect gem, and the very rare white form in much less quantity. Meconopsis integrifolia was here too; and perhaps the best of the group was Edraianthus serpyllifolius, of which a large colony was adorned with the rich purple bells on trailing stems. Here and there amidst these flowers Saxifraga cæsia, a white-flowered crustaceous kind, appeared—a pretty picture indeed.

THE GUILDFORD HARDY PLANT NURSERY (Mr. A. R. UPTON) contributed, as is its wont, a neat and interesting array of choice alpine plants, with rock shrubs, &c.—Primula sikkimensis, P. japonica in colours, the Edelweiss, Globularia cordifolia, Veronica Hulkeana, Erinus in variety, the vernal Gentian (very rich blue), towering spikes of Eremurus, Ledum palustre, the Snowdrop Anemone, &c.

Messrs. J. CHEAL & SONS, Crawley, also had a rockwork exhibit planted and arranged with good species. Here we noted Achillea rupestris, Dodecatheons, Edraianthus serpyllifolius, Lotus siliquosus (a pale-yellow flower with trifoliate leaves), Aquilegia alpina, Linaria hepaticæfolia alba, and a large example of Lupinus polyphyllus roseus, which a year ago obtained the Award of Merit.

Mr. B. LADHAMS, Shirley, Southampton, contributed perennials, chiefly in the cut state Gaillardias, Pinks, Columbines, Heucheras and a large-flowered Armeria of the plantaginea type named A. gigantea. It is a good and showy plant.

Most interesting was the well-arranged rockery from Messrs. BACKHOUSE & SON, York. Here with a sandstone or millstone grit rock were associated many of the most delightful of plants that the alpine lover could desire. Slightly boggy depressions were covered with the vernal Gentian, Adiantum pedatum, Sarracenia purpurea, and such things, while near by fine masses of Cypripedium spectabile, C. acaule and others met the eye at once. Gynerium Westerlingi, the variegated Pampas, was here, and not far away such rare things as Gentiana pyrenaica in a fine tuft full of flower-buds, Dianthus Freynei, D. F. alba (very rare), Primula farinosa alba, also a gem, and others. We cannot pass this exhibit without expressing our appreciation of the excellence of the arrangement, and the remarkable proportion between the rock and the alpines employed. The weathered stone, too, was surely no accident, as it here appeared. The very essence of natural grouping was observable throughout.

Messrs. RICHARD SMITH & Co., Worcester, had a showy group in which Tree Pæonies were seen in good condition. We noted the varieties fragrantissima (extra fine white), Olivia (white), Perfection (rose), &c. Pyrethrums, Columbines, Aster alpinus (very fine), Irises, and Poppies were also in considerable array.

Mr. R. C. NOTCUTT, Woodbridge, also staged showy perennials, as Lupins, Pyrethrums in variety, of which Arminta is a fine single pink-flowered form. Irises were freely shown, also early Gladioli, Geum miniatum, &c. A very showy Poppy is Lady Roscoe, of rich salmon-orange tone, each petal having a dark blotch.

The Eastern Poppies from Mr. W. J. GODFREY, Exmouth, were a showy lot, the huge richly-coloured blossoms being of great size, and in some instances remarkable in colour. Exmouth Rival (rich claret), Loveliness (pink and salmon), were among those we noted at a glance.

Messrs. C. & A. CLARK, Ltd., Dover, contributed a nice lot of things, in which were some good single-flowered Pyrethrums, and such subjects as Papaver Mrs. Marsh, Achillea argentea, Lupinus Snow Queen, Heucheras, and the like.

Messrs. REAMSBOTTOM & Co., from Geashill, King's Co., Ireland, brought St. Brigid Anemones and others in capital form. King of Salmons is a distinct and novel colour in this lot.

Messrs. GEO. JACKMAN & SON, Woking, had an excellent group, showing a few good things in large numbers rather than an endless array; hence the effect was good. Trilliums, early Gladioli, Ramondias, double Cambrian Poppy, Gerberas, Eremurus, Eastern Poppies, hardy Cypripediums, &c.

Mr. G. REUTHE, Keston, Kent, had a very interesting exhibit, in which such semi-hardy plants as Embothrium coccineum, Crinodendron Hookeri, and various Rhododendrons mingled with the more hardy alpines and the like. Of the latter class Anemone narcissiflora with white flowers, Sarracenia purpurea, Pinguicula grandiflora, Eremurus Elwesii albus (see Awards), Incarvillea grandiflora, Gentiana verna and others were seen.

Messrs. BARR & SONS, Covent Garden, staged in their usual place a large array of Eastern Poppies, Shirley Poppies, Irises, Pyrethrums, Ixias, Pæonies, Lupins, and such things. Androsace villosa, Iris cristata, Anemone alpina, white Eremurus, with double Poet's Narcissus were also of note.

Messrs. PAUL & SON, Old Nurseries, Cheshunt, in a small group had Aster alpinus roseus, and A. a. albus (very good), also Iris Susiana, Heuchera hybrids, Poppy Mrs. Marsh, Anemone sulphurea, &c.

Messrs. B. S. WILLIAMS & SON, Holloway, had globe flowers, Anemones, Poppies, perennial Cornflowers, early Gladioli, and similar things in the cut state.

Messrs. BAKERS, Codsall and Wolverhampton, we believe exhibited hardy plants for the first time at a "Temple" show, and in a most creditable manner, everything being fresh and good. Long-spurred Columbines, Scillas, Poppies, Pyrethrums, Edelweiss, many Aubrietias, Dianthuses, Incarvilleas, alpine Phloxes, and other things in considerable numbers.

Mr. MAURICE PRICHARD, Christchurch, Hants, also had a good and highly attractive exhibit, in which Iris filiformis, a large kind midway between I. tingitana (see fig. 140, p. 339) and I. xiphion, was noticeable. Eremurus, single and double Pyrethrums in fine array and excellent condition, formed a big attraction; Irises, Lilies, and Pæonies were well shown.

Mr. AMOS PERRY, Winchmore Hill, had a showy group, in which the blue Phlox canadensis Perry's variety (see Awards) was a central figure. Other things noted included Hyacinthus amethystinus albus, many spikes of Eremurus, Primula sikkimensis, Irises of the Korolkowii set and the Cushion group, the showy Geum Heldreichi, Lilium colchicum, Ostrowskia magnifica, Incarvilleas, Papaver Mrs. Marsh, and many other good and showy plants and flowers.

The group from Messrs. WALLACE & Co., Colchester, was of more than ordinary merit, and of considerable extent. Lightness and elegance with excellent taste in arrangement were all here associated, and in part accounted for by the free use of plants in pots, as opposed to an exhibit entirely of cut flowers. The growing plant offers instruction of the best type, and cannot be overestimated. We would like to see more of this kind of thing at this great show. The plants too were as meritorious as was the arrangement. Here were a dozen or so Heuchera hybrids, all free flowering and elegant; here, too, a rich display of hardy Cypripediums in company with Primula sikkimensis, Viola pedata, Trilliums, Adiantum pedatum, &c.; and there, in drier quarters, the quaint early Calochortus or Cyclobothras. Lilies too were plentiful and good, and here again came the groups, such as Hansoni (orange), Martagon alba excelsa, Colchicum longiflorum superbum, with venustum elegans in variety, &c. Ixias, Ornithogalum arabicum, and quite a distinct form of Meconopsis integrifolia was noted here. A new unnamed Poppy with pyramidal habit had a small orange-coloured flower not unlike P. rupifragum, though deeper in colour and of distinct growth.

Messrs. BUNYARD & Co., Maidstone, had a capital lot of hardy things, in which Irises, Geum Heldreichi, Eremurus, Day Lilies, single and double Pyrethrums, Ranunculus, Thalictrum aquilegifolium, and others were seen.

Messrs. JAMES KELWAY & SON, Langport, had a showy lot of Tree Pæonies in pots, and in another place a rich and varied assortment of single and double-flowered Pyrethrums.

Messrs. JAMES VEITCH & SON, Limited, Chelsea, on the lawn arranged Columbines, Primula japonica pulverulenta, with other choice new species of Primula, and quite a host of Eremurus in cut spikes. Some highly-coloured Heucheras also came from this firm, and two species of Corydalis—C. thalictrifolia and C. tomentosa.

SOME CUT FLOWERS.

Pansies and Violas.—Messrs. DOBBIE & Co., Florists, Rothesay, had a brilliant collection of Fancy Pansies of large size and rich colours that attracted great attention. Among the leading flowers were Miss F. Warren, Mrs. Campbell, Archie Milloy, W. McKenzie, Miss A. B. Douglas, Victoria, David Wilson, Mrs. Sherwood, Miss Yorke, John Pickens, Mrs. W. Sinclair, and David Airdrie. Some of these blooms were 3 inches and more in diameter and correspondingly stout in texture. This collection was backed by sprays of Violas and flanked by some very fine blooms of African Marigolds and some finely marked French Marigolds. Mr. WILLIAM SYDENHAM, Tamworth, had a very fine and varied collection of Fancy Pansies, which seem to colour well in the Midlands. Chief among them were Alvaston Yellow, Asthore, Cavalier, Col. M. R. G. Buchanan, Device, Floria, Ida, Joe Nadin, Lord Roberts, Marmion, Mary Sydenham, Miss Neal, Mrs. S. Craig, Petunia, Robert G. Allan, Tamworth Herald, and Tamworth Yellow. The leading Violas, which were arranged in neat sprays, were John Quarton, Endymion, Commander, Peace, Beauty, Planet, Sunbeam, Bland Sinclair, Grey Friar, &c.

Mr. HOWARD CRANE, Woodview Terrace, Highgate, staged in the open some round baskets neatly arranged with Violas of such effective sorts as Imperial, Mary Hope, Marbled Rose, Dolly, Rosandra, Bridal Morn, Bessie, Devonshire Cream, Duchess of Fife, Ethereal, Marian Waters, Mrs. E. A. Cade, Seagull, White Empress, &c. Messrs. STARK & SON, Great Ryburgh, had a few Violas in the open, chief among them Royal Sovereign, deep yellow.

Tulips. — The late-flowering Tulips were not nearly so numerously represented as is usual at the the Temple Show, the heat of the previous few days had told upon the flowers, and those which were fairly fresh when staged soon expanded under the close atmosphere of the tents. A very good collection under the circumstances was staged by Messrs. ALEX. DICKSON & SONS, Nurserymen, Belfast and Dublin, who had such fine Darwin varieties as Clara Butt, Europe, La Tulipe Noire (very dark), Margaret (a delicate and beautiful variety), Ministre Roell (rich poppy-red), Norma, Pride of Haarlem, Prof. M. Foster, The Rev. H. D'Ombrain, Bronze King, Leghorn Bonnet, Prima Donna, Rev. Harpur Crewe, White Queen, Glow, &c. The flowers generally were characterised by great substance, and they appeared to stand the heat better than other collections. Mr. R. H. BATH, Ltd., Wisbech, had a limited collection of late varieties, chief among them Flambeau, Faerie Queen, Anthony Roozen, Mrs. F. Sanders, Margaret, White Queen, Glow, &c. Messrs. BARR & SONS, King Street, Covent Garden, had a collection which comprised Goldfinder, Bronze Queen, Edmée, Yellow Queen. Calliope, Louis XIV., Phyllis, Purple Perfection, Bouton d'Or, Jaune d'Œuf, and Negro, with examples of the English florists' and Parrot varieties. The Hon. H. A. E. DE MONTMORENCY, Carricksmines, Dublin, had a stand of twenty-four very fine blooms of rectified and breeder English florists' Tulips, which by their fine development recalled the palmy days of Tulip cultivation forty years and more ago.

Sweet Peas.—Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, staged a collection characterised by fine quality, the bunches set up in a very tasteful manner. Some of the finest varieties were Gladys Unwin, Celestial, Gorgeous, Janet Scott, Orange Countess, Lord Rosebery, Prima Donna, Duke of York, Scarlet Gem, Miss Willmott, Lady Grisel Hamilton, Black Knight, Triumph, King Edward VII., Florie Norton (deep lavender, a variety which keeps its colour well), and Rose Sydenham. Mr. H. J. JONES, Ryecroft

Nursery, Lewisham, had in fine character King Edward VII., Bolton's Pink, Mrs. W. Wright, Dorothy Eckford, Miss Willmott, Gladys Unwin, Gracie Greenwood, &c. Messrs. JONES & SONS, nurserymen, Shrewsbury, had a representative collection, including most of the varieties before mentioned (they were nicely set up) Spanish Iris, &c. Mr. C. W. BEARDMORE, High Street, Winchester, had a small but very choice collection of leading varieties. Messrs. DOBBIE & Co., seedsmen, Rothesay, also had a similar collection.

Rose Philadelphia Rambler.—A climbing variety, resembling Crimson Rambler, save that the flower is of a much richer type, the colour being dark scarlet. The flower is also of somewhat more substance than the older variety. Shown by HOBBIES, Ltd., Dereham.

Begonia Madame Adeline Patti.—A double-flowered variety of large size and good form; colour salmon-red approaching to orange-red. Shown by Messrs. BLACKMORE & LANGDON.

FIG. 147.—RAMBLER ROSE "LADY GAY": COLOUR OF FLOWERS CHERRY-ROSE. Given an Award of Merit at the Temple Show.

Awards.

AWARDS OF MERIT.

Rose Lady Gay.—This is a Wichuraian Rose, of American origin. It is quite one of the best things among climbing Roses, and should prove a valuable addition to the Rose garden. The trusses of flowers hang in the form of sprays on long growths, and are produced in clusters of a score or more flowers. The colour of the flowers is deep rose, and the individual blooms may be not inaptly likened to a small pink Carnation (see fig. 147). Exhibited by Messrs. WM. PAUL & SON, Waltham.

Rose David Harum.—A hybrid Tea, with flower of large substance and of a pleasing rosy-pink colour. The shape is good, and the petals when reflexed give deeper shadings of rose. The variety should prove valuable for planting in beds and borders. Shown by Messrs. PAUL & SONS, Cheshunt.

Begonia Madame Granby.—A large double flower of lemon-yellow colour. Shown by Messrs. WARE, Ltd.

Edraianthus pumila.—This is perhaps the most diminutive member of this genus, the pale blue erect bells freely produced on a very close, dense, and dwarf cushion-like growth. The plant figures among the most rare and choice of dwarf alpines. Exhibited by Messrs. WM. CUTBUSH & SON, Highgate.

Eremurus Elwesii albus.—A fine white-flowered form of Elwes's variety of E. robustus. The plant possesses the same style of growth and the identical character of flowering seen in the type. From Mr. G. REUTHE, Keston, Kent.

Ivy-leaved Pelargonium Hon. Mrs. Boyle.—A compact yet free grower of shrubby-like habit, the large double flowers of a pleasing rosy-pink tint freely produced in large trusses. From Mr. C. TURNER, Royal Nursery, Slough.

Ivy-leaved Pelargonium Mons. Rosoleur.—A variety with deep carmine-rose-coloured flowers, and of vigorous habit. Shown by Mr. W. J. Godfrey, Exmouth.

Phlox canadensis Perry's variety.—This is a good and improved variety of a well-known plant, and it is obviously a good border subject. Mr. Perry has frequently exhibited the plant, but never before in such perfection of colour and strength as upon this occasion. Exhibited by Mr. AMOS PERRY, Winchmore Hill.

Primula × Arendi.—This Primula was shown by Herr GEO. ARENDS, Ronsdorf, Germany, who described it as a hybrid between P. obconica and P. megaseæfolia. In general appearance the plant is similar to a glorified P. obconica. The flowers were individually nearly inches across, of rich lilac-pink colour, and are produced in many-flowered umbels. The leaves more nearly resemble those of P. megaseæfolia, and the petioles are exceedingly hairy. We think the hybrid will make a very fine garden plant for the cool greenhouse (Award of Merit). The same exhibitor showed plants of P. obconica which represented much variation of colour in the flowers, and one named P. obconica oculata had a ring of exceedingly deep and rich colour around the eye, having an effect almost similar to that seen in Messrs. Suttons' "Duchess" strain of the Primula sinensis.

Rhododendron Smithi aureum.—This is a hardy Rhododendron with creamy-yellow-coloured flowers. Shown by Messrs. W. CUTBUSH & SONS. It is very distinct.

Rhododendron (Azalea) Julius Koehrs.—This plant is a very handsome form of A. indica. The flowers are of immense proportions, but they are in addition of a most pleasing shade of colour, being scarlet-maroon. Some of the flowers were 5 inches in diameter, and they all show a tendency towards doubling. The habit is sufficiently lax to enable the greenery of the foliage to be seen. Shown by Messrs. SANDER & SON, St. Albans.

Sarracenia flava gigantea.—A very large-growing variety, in which the cylindrical growths come almost 3 feet high, green, except the "lid," which is marked with dull red veins. Shown by Mr. A. J. BRUCE.

Verbena hybrida The King.—This is a variety of Verbena similar in habit to that of Miss Willmott, but the flowers are of richer rose colour. Shown by Messrs. W. CUTBUSH & SONS.

EXHIBITS MADE IN THE OPEN-AIR.

The exhibits out-of-doors of trees, shrubs, alpines, and new plants from China were extensive and most interesting to the visitors.

Messrs. J. VEITCH & SONS, The Royal Exotic Nursery, Chelsea, exhibited a large number of herbaceous Pæonies grown in pots in variety, in colours ranging from white through various shades to deepest crimson. This method indicated the uses to which these plants can be put on terraces and paved spaces, where it is impossible to plant them out. There were plants of Primula japonica growing in shallow tubs, the flowers crimson and disposed on stalks of from 2 feet in height; of Incarvillea Delavayi, furnished with beautiful blooms of rosy-crimson; various species of Meconopsis, including integrifolia and punicea; Primula tangutica and P. Cockburniana, the latter possessing small red flowers. A large number of Eremurus robustus with immense flower-spikes were themselves a very remarkable exhibit, as was Acer palmatum corallinum with very distinct rosy-coloure foliage.

Messrs. FROMOW & SONS, Chiswick, exhibited a large collection of Acer japonica in variety, and as standards and bushes.

Mr. L. R. RUSSELL, Nurseryman, Richmond, Surrey, showed a miscellaneous assortment of "picture" trees, green and variegated Ivies, Rambler Roses, Ceanothus dentata (having bright blue flowers), the floriferous white-flowered Polygonium Baldschuanicum, Aralia Maximoviczii (with deeply-lobed palmate leaves which have dark-brown stalks), and many others.

Mr. DAVID RUSSELL, Essex Nurseries, Brentwood, staged a picturesquely arranged group of hardy trees and shrubs, similar as regards its constituent materials to the foregoing, but including Rambler Roses, Ghent and rustica Azaleas, Weigela, and Clematis as foils to the foliage plants.

Messrs. CUTBUSH & SON, Highgate and Barnet, had, at the cost of much labour constructed an irregular bank of tufa and earth, and planted it with suitable Alpine and rock plants with very good effect. In one part were massed large numbers of Eremurus robustus,

in others Gentianas and Azalea mollis. Near the base of the mound there were planted Osmunda regalis and other moisture-loving Ferns, Cypripedium Calceolus, Sarracenias, Gunnera scabra, &c. There were some inappropriate plants, but as a whole it was a bit of work done in a short space of time the firm had the right to be proud of, and it seemed to have a special attraction for the visitors whose note-books were constantly in evidence. Hardy Orchises, hardy Cypripediums galore, Bletias, Anacamptis pyramidalis were associated with Darlingtonias and Sarracenias, Trilliums, and Ourisias, and so forth. Myosotidium nobile was in good flower. Liliums were plentiful on the higher slopes; Water-Lilies in tubs were at one's feet; choice alpines had nooks all to themselves; and Funkias, Gunneras, Bamboos, and Phormiums each spoke of the study the arrangement involved. A touch of colour came from Azalea mollis, and these excepted, everything savoured of a well-equipped rock-garden of some standing. This firm was also the exhibitor of a great number of topiary objects in Box and Yew.

Messrs. T. CRIPPS & SON, Nurserymen, Tunbridge Wells, had arranged a large group of trees and shrubs that was rich in variegated forms of Acer, many of their own raising from seed—Quercus, Cornus, Cedrus, Retinospora, Dimorphanthus mandschuricus, with a white margin to the leaf; the yellow variety of Catalpa syringæfolia, Fremontia californica, Vitis, various species; Styrax japonica, a hardy shrub from Central Japan, carrying numerous white flowers during the summer months. The group was closely packed with choice things too numerous to be named in detail here. Everything shown was vigorous and in good condition, Conifers being especially good specimens of their respective kinds. The group was awarded the Veitchian Cup, as being the most generally meritorious exhibit in the show.

Messrs. FISHER, SON & SIBRAY, Ltd., Royal Nurseries, Handsworth, Sheffield, were the exhibitors of a large group or border of trees and shrubs with green or variegated foliage and in great variety. The more telling were Acer japonicum aureum, and other Japanese forms of Acer palmatum; large spreading forms of Dimorphanthus mandschuricus and Quercus Concordia.

The group set up by Messrs. CHEAL & SON, Crawley, Sussex, was very ornamental, as many flowering shrubs were included in the contents. There were Cytisus purpureus albus, C. Andreanus, Lilacs in variety, Wistaria sinensis and W. multijuga alba, numerous Azaleas; Viburnum plicatum, with its snowy balls of white flowers, relieved by masses of golden Elms, Thuyas, Sambucus, Quercus, and other variegated trees and shrubs.

Miniature trees from China and Japan were on show from Messrs. BARR & SONS, King Street, Covent Garden; and Messrs. CARTER & CO., seedsmen, High Holborn.

Messrs. R. SMITH & CO., Worcester, were exhibitors of Japanese Acers and Conifers.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed Rhododendrons.

Messrs. KELWAY & SONS, Langport, exhibited hardy Tree Pæonies in flower.

Messrs. PULHAM & SON, 71, Newman Street, Oxford Street, W., arranged a rockery exhibit in the open, planting it with alpines and shrubs. Not a few of the plants, however, were misplaced—Trilliums in the higher and drier positions, for example, could only fail miserably, and other plants would certainly not be found on a rockery under ordinary circumstances.

MISCELLANEOUS.

Mr. R. IRWIN LYNCH, Curator of the Cambridge Botanic Gardens, exhibited, as last year, a group of hybrid Gerberas in flower, hybrids that he has raised himself at Cambridge, and which are greatly admired wherever they are exhibited. Some of the varieties shown on this occasion were Montrose, a semi-double flower of carmine-pink colour; Jeanie Deans, pale-primrose colour; Amy Robsart, of slightly deeper tint; Lady of the Lake, white; and Guy Mannering, orange-crimson colour, with large stellate flowers in which the strap-like florets are twisted.

Mr. R. ANKER, Addison Nursery, Napier Road, Kensington, showed Bougainvillea glabra Sanderiana in flower in 5-inch pots, also plants of Erica persoluta alba, and other Ericas in bloom in "thumb" pots.

Messrs. GT. VAN WAVEREN & KRULIFF, Sassenheim, Haarlem, who showed the extraordinary Astilbes at the Holland Park Show last year, exhibited a group of hybrid varieties, most of which had white flowers, but one named Peach Blossom was pink.

Bomarea edulis variety Elwesii, of which flowers were shown by H. J. ELWES, Esq., had pink-coloured outer segments, with inner segments having green and cream-coloured ground, prettily pencilled with red.

Messrs. CARTER & CO., High Holborn, London, in addition to what has been already mentioned, exhibited plants of Verbena Miss Willmott and other varieties, the fine double white Stock Avalanche, also well-flowered Schizanthus, and finely-grown Mignonette, &c.

Messrs. HUGH LOW & CO. exhibited a few plants of Metrosideros in flower, also Nicotiana Sanderæ (the deeply coloured variety), Kalanchoe floribunda, Gerbera Jamesoni, Ericas, Pimelea Hendersoni, &c.

Messrs. H. CANNELL & SONS, Swanley, exhibited some Phyllocactus in flower, and a few other Cactaceous plants.

Messrs. WATKINS & SIMPSON, Covent Garden, made a very bright exhibit of annual flowering plants, amongst which Clarksias, Nemesias, Collinsia bicolor and the variety alba, French. Dwarf and other Marigolds, Mignonette "Macbet," Erysimums, &c., were finely shown.

Mr. T. JANNOCH, Dersingham, near Sandringham, furnished the end portion of the central staging in the big tent with a group of Lilacs. They were dwarf plants in small pots, but were profusely furnished with trusses of bloom. The variety Charles Joly is a fine double form of dark colour. Mr. JANNOCH also showed a good strain of Lily of the Valley.

FRUIT-TREES IN POTS.

As is customary at this show, Messrs. RIVERS & SON, Sawbridgeworth, staged in the large tent a fine collection of fruit trees in pots, having over forty examples. Prominent in the centre was a fine tree some 30 years old of Guigne d'Annonay Cherry heavily fruited, an excellent example showing the age at which pot-trees can be made still productive. All the trees were in rude health, the bulk comprising the new Peregrine and Duke of York Peaches, with two unnamed seedlings and Nectarines Cardinal, Early Rivers, and an early seedling. Other Cherries were May Duke and Early Rivers. Baskets of gathered fruit of Cardinal and Early Rivers Nectarines fronted the group. Staged in a tent and surrounded by groups of rich-flowering plants, a collection of this nature suffered by contrast. That was particularly the case with another group placed at the end of the Orchid groups, which came from H. HEILBERT, Esq., Holyport, Maidenhead. The trees in this case were mostly unnamed, and included Peaches, Nectarines, Cherries, and Figs; and there were also well-fruited Vines, Black Hamburgh and Foster's Seedling, three fruiting Pines, one ripe; Melons Pride of Stourbridge and Triumph, and Strawberry Royal Sovereign.

COLLECTIONS OF FRUIT.

The best in this section was a remarkably fine and handsomely-arranged exhibit in one of the long tents, staged by Mr. W. L. Bastin, the able gardener to Sir ALEXANDER HENDERSON, M.P., Buscot Park, Berks. On elevated stands at the back of the exhibit were fixed Black Hamburgh and Foster's Seedling Grapes, five bunches on each stand, the white one in the centre. On raised dishes were superb fruits of Melons Best-of-All, Hero of Lockinge, British Queen, and Buscot Park Hero. Also Hale's Early and Early Grosse Mignonne Peaches; Elruge, Lord Napier, and Early Rivers Nectarines; Brown Turkey Figs; Governor Wood, Mammoth, and Guigne d'Annonay Cherries; Royal Sovereign Strawberries, and small Wellington Apples.

Messrs. G. BUNYARD & CO., Maidstone, set up a remarkable collection in baskets and dishes of not fewer than eighty-two varieties of wonderfully-preserved Apples, and dishes of fine Catillac and Uvedale's St. Germain stewing Pears. The collection was backed by some young trees in pots, well fruited, of Guigne d'Annonay Cherry. Amongst the Apples were Hanwell Souring, Striped Beefing, Smart's Prince Arthur (very conical shaped), Wagener, Murfitt's Seedling, Betty Geeson, Alfriston, Belle Pontoise, Bramley's Seedling, Tower of Glamis, Lane's Prince Albert, Annie Elizabeth, Barnack Beauty, Calville Rouge, Melon Apple, Baxter's Pearmain, Calville Malingre and others.

A collection of three dozen plants in pots of their new Strawberry Bedford Champion came from Messrs. LAXTON BROS., of Bedford. The plants were carrying very fine, richly-coloured fruits. The variety has for parentage on the one hand Scarlet Queen × John Ruskin, and on the other Noble × Sir J. Paxton, the immediate parents being seedlings from these crosses. The fruits have both Noble form and some of Cockscomb shape. Baskets of the variety and of Laxton's Reward were also shown.

VEGETABLES.

Cucumbers and Tomatos.—Mr C. DICKINGS, of Guernsey, sent fourteen dishes of nice Tomatos, the varieties including Challenger, Winter Beauty, Hanwell Gem, Stirling Castle, Hopper No. 1, and Kneller's Prize.

Mr. S. MORTIMER, Swiss Nursery, Farnham, set up a high-class collection, having at the back two flat-trained plants in pots of a new Cucumber "Delicacy," heavily fruited, and also a great quantity of very handsome fruits of the variety lying on the table; also other very fine fruits of Peerless, Lord Roberts, Telegraph, and others, some eighty in all. There were in pots finely-fruited Tomatos Winter Beauty, Peach Bloom, Best of All, Princess of Wales, Golden Perfection, and Golden Nugget, and twenty-four dishes inclusive of the varieties named and others.

Collections of Vegetables.—Messrs. SUTTON & SONS, Reading, had a singularly pretty, clean, bright collection of thirty-eight dishes of Potatos, including Ninetyfold, Supreme, International, Snowdrop, Satisfaction, Superlative (new), May Queen, Ideal, Up-to-Date, Abundance, Duke of York, Puritan, and several coloured varieties. These tubers were from a planting in frames made on March 1, and the samples were relatively quite large and handsome.

Sir ALEXANDER HENDERSON, M.P., was also an exhibitor of vegetables, Mr. Bastin having arranged his collection effectively. At the back were a doze heavily-fruited plants 6 feet in height of the Red Currant variety of Tomato, the racemes of fruit hanging most gracefully down. Facing these were clusters of Sutton's Purity, Magnum Bonum, and First-crop Cauliflowers Tomatos Winter Beauty, Princess of Wales, and Sunbeam; Cucumbers AI, Satisfaction, and Peerless; fine Mushrooms; Tender-and-True and Canadian Wonder Kidney Beans, Snowhall and Yellow Perfection Turnips, Early Giant Peas, baskets of Mustard-and-Cress, various Carrots, Radishes, Marrows, and Rhubarb. The joint collection of fruit and vegetables made a fine feature.

The finest collection without doubt was that from the UNIVERSITY COLLEGE, READING, of which Mr. Charles Foster is the garden superintendent. Backed by numerous well-fruited Tomato plants in pots, with which were interspersed plants of climbing and dwarf Kidney Beans, were some fifty baskets and dishes, including Improved William I., Ideal, Early Giant, May Queen, and Duke of Albany; Peas Telegraph, Every Day; Rochford's Peerless, and Sensation Cucumbers; Centenary, Superlative, Sharpe's Victor, Windsor Castle, Harbinger, and other Potatos. Crimson Cluster, Winter Beauty, and Up-to-Date Tomatos; Earliest and Flower of Spring Cabbages; Early Forcing, Champion, and Early Gem Carrots; First Early Cauliflowers, Long White and Perfection Marrows, numerous Radishes, and other things, all of fine form and great excellence.

Messrs. H. CANNELL & SONS, Swanley, had their capital collection backed with Peas Duke of York and English Wonder, flat-trained and heavily podded, in long boxes, fronting them being numerous fine heads of Defiance Cabbage and Model Broccoli. Potatos were very plentiful, including Lord Tennyson, Pink Perfection, The Factor, Eightyfold, Waverley, The Sirdar, King Edward VII., and Fylde Wonder; Cucumbers Favourite and Lockie's Perfection; Long Pod, Exhibition, and Dwarf Little Gem Beans; also diverse Carrots, Kidney Beans, Tomatos, Radishes, and other kinds all effectively arranged.

Messrs. JAS. CARTER & CO., High Holborn, had a small collection of excellent vegetables in eighteen dishes, unnamed, including Cucumbers, Cauliflowers, Cabbages, Carrots, Marrows, Kidney Beans, and Radishes.

From the LADY WARWICK COLLEGE, Studley Castle, Redditch, Head of Garden Department, Miss Crooke, came a rather too crowded but very good collection of some forty dishes, including Cabbages, Cauliflowers; Early Giant and Duke of York Peas, Kidney Beans Golden Ball, Early Nantes and Improved Horn Carrots, AI and Matchless Cucumbers, Supreme Tomatos, Asparagus, Radishes, Lettuces, Potatos, and Spinach.

Mr. A. H. T. DE MONTMORENCY, of Dublin, had four dishes of Potatos, very good samples of Sir J. Llewelyn, Royal Kidney, The Scout, and Snowdrop.

In striking contrast were bundles of Asparagus, home and French-grown. The former, stems stout and half-greened, over 12 inches high, came from Mr. R. STEPHENSON, Buswell, Cambridge; whilst from M. A. BETIN, Argenteuil, France, were staged equally long but really huge stems blanched throughout.

Awards.

FIRST-CLASS CERTIFICATES.

Peach "Peregrine."—Very handsome, rich-coloured, early, and of fine flavour, raised from Spencer Nectarine. From Messrs. T. RIVERS & SONS.

Cucumber "Delicacy."—Fruits long, smooth, short in the heel, very dark green, and very prolific; raised from Matchless × Aristocrat. Shown by Mr. S. MORTIMER, Farnham, Surrey.

AWARDS MADE BY THE COUNCIL.

GOLD MEDALS.

Sir F. Wigan, Bart., for Orchids; Sir A. Henderson, Bart., M.P., for Fruits and Vegetables; Jas. Veitch & Sons for Stove, Hardy and New Plants; F. Sander & Sons for Orchids and Nicotiana; W. Cutbush & Sons for Carnations and Alpines; Paul and Son, Cheshunt, for Roses; Charlesworth & Co. for Orchids; Cripps & Son for Shrubs; Sutton & Sons for Greenhouse Plants; Wallace & Co. for Alpines and Lilies.

SILVER CUPS.

Frank Lloyd, Esq., for Begonias; S. Heilburt, Esq., for Fruit; J. Coleman, Esq., for Orchids; W. James, Esq., for Carnations; J. Cypher & Sons for Orchids; Rd. Smith & Co. for Clematis; H. Canuell & Sons for Cannas and Vegetables; Barr & Sons for Alpines; G. Bunyard & Co. for Fruit and Hardy Plants; J. Peed & Sons for Caladiums; R. & G. Cuthbert for Hardy Azaleas; J. Cheal & Sons for Alpines; Wm. Paul & Sons, Waltham Cross, for Roses; Rivers & Son for Fruits; Hill & Sons for Ferns; H. B. May for Ferns and Flowers; Ware, Ltd., for Herbaceous Plants and Begonias; Reading College for Vegetables; Chas. Turner for Roses; A. J. Bruce for Sarracenias; J. Backhouse & Son for Alpines; M. Prichard for Alpines; F. Cant & Co. for Roses; G. Mount for Roses.

SILVER-GILT FLORA MEDALS.

J. Carter & Co. for Flowers and Vegetables; L. R. Russell for Shrubs, &c.; J. Laing & Sons for Gloxinias and Begonias; Dobbie & Co. for Hardy Plants; Hugh Low and Co. for Carnations, &c.; Fisher, Son, & Sibray for Shrubs; B. Cant & Sons for Roses; J. Waterer & Sons for Rhododendrons; Jackman & Sons for Hardy Plants; R. Sydenham for Sweet Peas; W. Bull & Sons for Orchids; Blackmore & Langdon for Begonias; R. C. Notcutt for Hardy Plants; Amos Perry for Hardy Plants; D. Russell for Trees and Shrubs; Hobbies, Ltd., for Roses, &c.; R. Irwin Lynch, Esq., for Gerberas.

SILVER-GILT KNIGHTIAN MEDALS.

S. Mortimer for Cucumbers and Tomatos; Laxton Bros. for Strawberries.

SILVER-GILT BANKSIAN MEDALS.

W. J. Godfrey for Hardy Flowers; H. J. Jones for Hardy Flowers; Hogg & Robertson for Tulips; Alex. Dickson & Sons for Tulips; "Bakers." Wolverhampton, for Hardy Plants; Geo. Reuthe for Hardy Plants; W. Iceton for Lily of the Valley.

VEITCHIAN GOLD CUP, Value £52 10s.

Messrs. T. Cripps & Son for Shrubs and Trees.

SILVER FLORA MEDALS.

E. Ascherson, Esq., for Ferns; John Rutherford, Esq., M.P., for Orchids; E. Wagg, Esq., for Carnations; Lord Aldenham for Flowering Trees and Shrubs; Jones & Son for Sweet Peas, &c.; Watkins & Simpson for Annuals; John Robson for Orchids; A. F. Dutton for Carnations; Kelway & Son for Hardy Herbaceous Plants; S. F. Stanley & Co. for Orchids.

SILVER KNIGHTIAN MEDALS.

A. J. Harwood for Asparagus; Lady Warwick's College for Vegetables; Hon. A. H. T. de Montmorency for Tulips; Charles Ritchings for Tomatos.

SILVER BANKSIAN MEDALS.

T. H. Lowinsky, Esq., for Calceolarias; A. Belin for Asparagus; Wm. Sydenham for Violas; B. S. Williams & Son for Hardy Cut Flowers; C. W. Breadmore for Sweet Peas, &c.; H. C. Pulham for Alpines; R. Farrer for Alpines; Guildford Hardy Plant Co. for Alpines; R. H. Bath for Carnations, &c.; T. Jannoch for Lilies of the Valley; W. Fromow & Sons for Maples; A. Ll. Gwillim for Begonias.

BRONZE KNIGHTIAN MEDAL.

R. Stephenson for Asparagus.

ROYAL CALEDONIAN HORTICULTURAL.

EDINBURGH, MAY 24 AND 25.—The show as a whole was somewhat thin. The date, though perhaps satisfactory from a financial point of view, being unsuitable for a variety of garden produce, and gardeners as a rule do not seem to have taken to it. During the afternoon of the first day the attendance was eminently satisfactory, the Lord High Commissioner to the Assembly of the Church of Scotland, Lady Leven and Melville, Lord Balfour of Burleigh, the Countess of Eglintoun, Lord and Lady Binning, and others of the Scottish nobility and gentry visiting the show, while the general public also attended in considerable numbers.

The great feature of the show was undoubtedly the fine bank of Orchids staged in competition for Mr. Brooman White's prize, which was worthily won by Mr. Sharp, gr. to C. L. WOOD, Esq., Frcelands, Fergandenny. Odontoglossums were conspicuous, both with regard to the varieties staged and the culture displayed. Stove and Greenhouse plants were moderately well shown, but among them were none of outstanding merit. Among other plants were good displays of Calceolaria, Lily of the Valley, Hoteias, Cinerarias, Alpine plants and Ferns, the groups being largely brought from gardens in the vicinity of Edinburgh. Of fruit there were dishes of good Strawberries and a collection of Australian Apples. Cut flowers were by no means numerous, the finest of these being the Roses, Mr. PARLANE as usual being prominent with lovely blooms of Ulrich Brunner, Charles Lefebvre, Margaret Dickson, Mrs. S. Crawford, Lawreuce Messimy and others.

Mr. CUMMING, Grandtully, showed some specially fine early Tulips in the classes for these flowers; while for stove and greenhouse flowers, Mr. MCINTYRE, The Glen, Innerleithen, was the chief prize-winner.

A bride's and an ordinary bouquet from Mr. PERKINS, Leamington, were easily 1st in the classes for these subjects. The same exhibitor also secured several minor prizes.

VEGETABLES as usual formed an interesting feature, Mr. Kidd, gr. to Lord ELPHINSTONE, Carbery Towers, securing 1st for a collection. Mr. MACKINLEY, Wrest Park, Beds., was 2nd.

TRADE EXHIBITS.

These, as is usual at Edinburgh, formed a notable feature of the show, but were perhaps less in extent than at last year's show. Both Messrs. R. B. LAIRD & SON, Pinkhill, and Messrs. DICKSONS & Co., Craigmillar, arranged particularly handsome groups, the former having as a *motif* a Japanese cottage with flowering and foliage plants trained over it, and extending around it. The latter firm restricted their grouping to the usual order of handsome flowering and foliage plants, Blush Rambler, Dorothy Perkins, Crimson Rambler, and many other Roses contributing greatly to the good effect. Wonderfully fine too was the extensive exhibition of Tulips from Messrs. HOGG & ROBERTSON, Dublin, even surpassing the display made by the same firm last year. Scotch-grown Tulips appear mere pigmies to these Irish-grown flowers.

Attractive rockeries were arranged by a North of England firm, in which Euphorbia pilosa major was well shown; and by Messrs. CUNNINGHAME, FRASER & Co., Comely Bank, Edinburgh, whose display contained a large number of first-rate alpines, Mr. Lindsay's seedling Saxifraga "Dr. Ramsay," to which a First-class Certificate was awarded, being a conspicuous object. Mr. YOUNG, Elgin, also showed alpines, among which Primula scotica was presented in great beauty.

Mr. RUSSELL, Richmond, delighted Scottish gardeners with a group of Clematises in small pots; and among other contributions those of Mr. JOHN FORBES, Hawick, and Messrs. DOBBIE & Co., Rothesay, contained a variety of florists' flowers not usually seen at this time of year. A Cultural Certificate was awarded to Mr. CAIRNS, gr., Balruddery, Dundee, for seedling Amaryllis.

Obituary.

JOHN HUNGERFORD ARKWRIGHT. — The death of this well-known amateur horticulturist is reported, in his seventy-second year. Mr. Arkwright lived at Hampton Court, Herefordshire, and the fine variety of Primrose named "Evelyn Arkwright," which was illustrated in these columns, on May 7, 1898, [p. 276], was, we believe, first exhibited by him. He was an occasional contributor to this Journal.

ROBERT MENZIES DEWAR. — Many of our readers will learn with regret of the death, on May 16, of this promising young gardener at the early age of thirty-one. A native of Perthshire, he served his apprenticeship in that county, and then went to Castle Craig, Peebleshire, and from thence to Yorkshire and Derbyshire. He became head gardener to the Hon. T. Dundas, of Ainderby Hall, Yorks, in 1898, and remained there till 1903. He showed excellent Chrysanthemum blooms at the York and Darlington shows of 1900, 1901, and 1902, where he gained several prizes, also the Gold Medal for the best bloom at Darlington. Deceased left Ainderby Hall in April, 1903, with the intention of obtaining a larger charge, much to the regret of his master. He went to Messrs. Backhouse's Nursery at York, and it was there that he was seized with what proved to be a fatal illness. He leaves a widow and one little daughter to mourn his loss.

REMARKS.—A consignment of Mangos arrived this week, and were sold at an average price of from 6s. to 12s. per dozen; also a novelty from the West Indies called Mammee Fruit. Strawberries have become a glut on the market on account of the hot weather, consequently prices are very low. The fruits are of medium quality. Bananas of an inferior kind are plentiful, but good fruit is very scarce indeed. Owing to the sudden spell of hot weather Bananas ripened very quickly on the journey, and arrived in an overripe condition. Pines are a little cheaper, but there are very few of these fruits arriving. Supplies of South Australian Apples are now nearly finished, but supplies are still arriving from Tasmania.

POTATOS.

Dunbars, 60s. to 90s.; various, home-grown, 60s. to 70s. per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

POT PLANTS.

THE market commands a brisk trade for all pot plants, but prices do not rise owing to increased supplies; in fact, the time has quite passed when high or fancy prices are made. Ivy-leaved Pelargoniums are much in demand. In addition to well-known varieties there are seen Baden-Powell, Leopard, and the distinct pink "Achievement." Ryecroft Surprise, which a few years ago was a favourite, seems to have quite gone out of fashion. Zonal Pelargoniums in various colours are in demand for decorative purposes. Yellow Calceolarias are of good quality, as are also the herbaceous varieties. Stocks are still procurable. The demand for Lobelia Emperor William does not seem equal to that of previous years. Good plants of Digitalis (Foxglove) in the best spotted varieties are seen. Hydrangea paniculata grandiflora is now arriving. Some plants are of good quality, while others are thin in substance and "leggy." Fuchsias are over plentiful and low in prices. Good Spiræas can be had, also Lilium Harrisi. The yellow Chrysanthemum segetum (or coronarium variety) in both single and double forms are good. I find growers now propagate these plants from cuttings instead of growing them from seeds, the result being the production of dwarfer plants that flower earlier.

CUT FLOWERS.

Hardy flowers are now marketed in large quantities, such things as Pæonies and Pyrethrums are sent in large waggonloads. The trade in Pæonies is very great. The best flowers of pink and other good shades sell well, but others are sold at very low prices. Lilium longiflorum is seen in large quantities in the street, an indication of the cheapness of these flowers. Iceland Poppies are now plentiful, Oriental and Shirley Poppies are also seen. Sweet Peas are abundant, but many have too short stems to be useful for decorative purposes. Long stems are of greater importance in flowers than ever. Roses on long stems continue plentiful; some good blooms of Mrs. W. J. Grant are seen; also Karl Druschki; but I doubt if the latter will prove a profitable Rose to grow in large quantities. There has been a much better demand for Roses and Carnations. On Monday morning there were very few really good Carnations left for sale at 7 o'clock. Spanish Iris, Gladioli The Bride, Blushing Bride, and some brenchleyensis are obtainable in quantity. Gardenias are over plentiful, and sell badly, as do Stephanotis. Double White Narcissus will be over in a few days. *A. H., Covent Garden, May* 31.

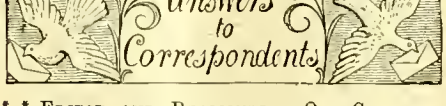
SCHEDULES RECEIVED.

READING AND DISTRICT ROSE SOCIETY.—The Annual Exhibition of Roses by the above Society will be held in the Forbury Gardens, Reading, on June 29.

READING HORTICULTURAL SOCIETY.—The date of the Summer Show is fixed for August 30, and it will be held as usual in the Forbury Gardens. The Secretary *pro. tem.* on both occasions is Mr. William Smith, London Street, Reading.

BOSTON HORTICULTURAL SOCIETY.—This Exhibition will be held on July 19. The secretaries are Messrs J. G. Killiogworth & Son, Market Place, Boston.

STOCKPORT AND DISTRICT CHRYSANTHEMUM, Flower and Fruit Show, to be held in the Volunteer Armoury, Stockport, on Friday and Saturday, November 10, 11, 1905.



*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

CROSSING CARNATIONS: *Carnation.* In many species of plants, and particularly in hybrids, it is not uncommon for the flower to develop the ovary, and apparently perfect this organ, and yet produce no fertile seeds. That the ovary swelled in the manner you have described may be due to pollen you applied, or to the slight irritation you occasioned, but as there were no seeds developed, this is sufficient proof that no actual fertilisation took place. Try again, and again if needs be, and you will doubtless succeed, taking care to apply the pollen when "ripe," and when the stigmatic surface is in a proper condition for receiving the pollen.

FUNGUS: *J. D. C.* The specimen was putrid on arrival.

FUNGUS TAKEN FROM TOMATO SAUCE: *H. Slade.* The substance is the mycelium or spawn of the common blue-mould, Penicillium glaucum; the spores of this fungus are present everywhere in the atmosphere, and some had fallen on the sauce after boiling and before sealing up.

GRAPES DISEASED: *P, J. S.* The berries are affected with the "spot" disease, Gloeosporium ampelophagum. Remove and burn all diseased Grapes, and spray the remainder with liver-of-sulphur in the proportion of ½ oz. to a gallon of water.

HOLLYHOCK AND PEACH DISEASES: *Derwydd.* The Hollyhocks are affected with a fungus disease—Puccinia malvacearum. For treatment, see answer to *Salop* in our last issue. The Peach leaves are also attacked by a fungus—Exoascus deformans or Peach Blister. You will find particulars, with illustration, on p. 294 of our issue for May 13, 1905.

NAMES OF PLANTS: *A. T.* 1, Doronicum austriacum; 2, Pteris tremula; 3, Salvia sp. (send when in flower); 4, Chlorophytum elatum variegatum; 5, Pteris serrulata cristata; 6, P. umbrosa.—*J.P.S.* Prunus Padus.—*G. Geddes.* Scilla hispanica.—*Max Leichtlin.* probably Crambe Kotschyana.—*A. H. Gibbins, Johannesburg.* Probably Gnidia sp. or some other Thymelaceous plant, so far as can be determined in the absence of flowers.—*F. E. S.* 1, Phacelia tanacetifolia; 2, Veronica gentianoides; 3, Pyrus intermedia.—*H. C.* We do not recognise the variety. Send to a grower of these plants.—*W. W. N. B.* Varieties of Gloriosa grandiflora (syn. Methonica grandiflora) and G. Leopoldi. The specimens are interesting as showing a transition between G. superba and G. virescens. We cannot name the Ipomœa.—*F. W. S.* 1, Pyrus Aria var.; 2, Cedrus Deodara.—*A. B. R.* 1, 2, 3, 4, 5, 6, not found; 7, Lithospermum prostratum; 8, Cerastium vulgatum; 9, Androsace lanuginosa; 10, Acer polymorphum variety; 11, Silene inflata; 12, Onosma echioides.—*G. C.* Prunus Padus.—*W. G. S.* Ribes speciosum.—*W. E. T.* Cercis siliquastrum; look again and see how widely it differs from a Pyrus flower.—*A. Y. L.* Lælia purpurata.—*A. L. P.* 1, Dendrobium aggregatum; 2, spotted Trichopilia tortilis; 3, Cupressus sempervirens.—*D. S. T. & Sons.* Aralia dactylifera.

ORANGE RUST ON ROSES: *C. A. Whitehouse.* The appearance is due to a troublesome pest called Phragmidium subcorticatum. The appearance of the disease in spring depends on the presence of resting spores from the previous autumn. Spraying with diluted Bordeaux-mixture or ammoniated carbonate of copper at intervals during the summer will check the disease. The fungus also grows on wild Roses, and these may become a source of infection unless precautions are taken.

PALM: *L. W. F.* There is no fungus disease present. The appearance suggests injury from an insecticide applied too strongly.

TOMATO DISEASED: *E. R.* and *W. B.* Your plants are attacked with Phytopthora, the same fungus that causes the Potato disease. Burn the diseased plants, and syringe the healthy plants once in three days with weak Bordeaux-mixture, ceasing to do so as the fruit ripens.

VINES: *A. R. S.* There is no disease present in the leaves you send. They are suffering from the effects of a check. We suspect the trouble is to be found in the borders, which have probably been kept either too dry or too wet. Cold draughts would also be sufficient to cause the appearance.

WATER SUPPLY: *J. C., Perplexed.* The analysis you give of No. 2 (from the service mains) appears to be more suitable for your plants than No. 1. We suspect the reason the Cucumbers curl when in a young state is that they receive a check, and we suggest that the water is too cold from the service mains. Can you not run the service water into a tank in the house, so that it may be warmed before it is applied to the plants?

ROYAL HORTICULTURAL SOCIETY.

THE TEMPLE SHOW.

MAY 30, 31, & JUNE 1.

(*See also pp.* 344 *and* 345).

THE Show which closed yesterday in the gardens of the Inner Temple, Thames Embankment, London, was the eighteenth of the series, and, as we have said elsewhere, it was one of the very best. The weather on the opening day (Tuesday) was indifferent, the dull skies of the morning were followed in the afternoon by a thunderstorm, accompanied by a heavy downpour of rain, which caused the visitors much discomfort. Nevertheless, the receipts at the gates on that day were up to the average. In order to obtain greater convenience in passing through the long, narrow tent which ran parallel with the Embankment, the side stages were made a little less wide than heretofore; but in spite of this the congestion was very great, and the atmosphere towards the centre of the tent most depressing. Such a show as this annual display occasions an enormous amount of extra work on the part of the Society's officials, and we join in the gratitude of our readers for the trouble taken by the Secretaries, also by Mr. S. T. WRIGHT and Mr. FRANK READER, to ensure that the arrangements should be as convenient as it is possible to have them. How difficult their task has been may be inferred from the fact that whilst 21,000 feet of space were applied for, only 12,000 could be allotted.

ORCHIDS.

The members of the Committee were in full force, though the number of novelties submitted were only about thirty. The quality of the large display of Orchids from the various exhibitors was at least equal to that of any former show, even the plants used to fill in the groups being well worthy of the show stand; and the arrangement, especially in the four leading groups—viz., those from Sir FREDERICK WIGAN, Bart., JEREMIAH COLMAN, Esq., Messrs. SANDER & SONS, and Messrs. CHARLESWORTH & Co.—were excellent. These four large groups formed the bulk of the exhibits in the large Orchid-tent.

First came that of Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), who staged a magnificent group, the fine varieties of Lælia purpurata, Cattleya Mossiæ and other showy favourites being also well represented. From the back there appeared graceful sprays of various Oncidiums and Odontoglossums, the large flowers of the purple Sobralia macrantha and its variety alba, one specimen of which had sixteen flowers and buds; Sobralia × Wiganæ, one of the handsomest, and other varieties. Along the group at intervals were effective arrangements of Miltonia vexillaria, each batch being composed of distinct types. The dominating specimen in one set was a fine specimen of M. vexillaria "Empress Victoria Augusta" with four spikes; and of another the purple-centred M. v. "Memoria G. D. Owen." The Odontoglossums had for their best O. crispum "Albion," O. c. guttatum variety, O. nebulosum pardinum splendens (very fine), O. × ardentissimum, O. × leochristyense, O. × elegantius, O. × concinnum, O. × amabile, and O. × Harryanotriumphans. Of Lælias and allied plants, were noted Lælia Boothiana (with three spikes), L. purpurata "The Pearl," Backhousiana and Russelliana, L. × cinnabarosa, Lælio-Cattleya × Hebe, Fascinator and its fine variety dulcis, L.-C. × Myra magnifica, L.-C × G. S. Ball, L.-C. × J. F. Birckbeck, L.-C. × Digbyano-Mossiæ, and other hybrids. Cattleya Mossiæ "Lady Wigan," a charming variety, bore ten fine flowers; C. M. Wagneri, five flowers, and others were equally good. The Cypripediums were represented by good C. bellatulum, and its white variety; C. Godefreyæ leucocheilum, C. Stonei candidum, the distinct C. × W. H. Young, a handsome form of C. Mastersianum and others. Brilliant Masdevallias brightened the group, and of things not frequently seen were noted Aerides Fieldingii, Brassia brachiata, Cymbidium Devonianum, C. tigrinum, Cœlogyne pandurata, the singular little Eria extinctoria, Tetramicra bicolor, various Phalænopsis, &c. There were eighteen genera, thirty-nine species, nine varieties and eighteen hybrids, represented by the best types of each.

Mr. JEREMIAH COLEMAN, Esq., Gatton Park (gr. Mr. W. P. Bound), had a very fine group effectively set up with Palms, &c. At each end at the back were clumps of the rich orange-scarlet Epidendrum × Boundii, and between them Cymbidium Lowianum and its variety concolor. Throughout the culture of the plants was excellent, and especially in the case of the Odontoglossums, one huge specimen of O. crispum

[*Photograph by J. Gregory.*

FIG. 142.—CATTLEYA SCHRÖDERÆ "THE BARON": THE ACKNOWLEDGED GEM OF THE TEMPLE SHOW, EXHIBITED BY MESSRS. SANDER AND SONS. (SEE P. ii.)

with four spikes, grown from a single bulb in two years, securing for Mr. Bound a Cultural Commendation. Of fine varieties, O. crispum Rosy Queen had blush-white flowers; O. c. Mrs. J. Colman was finely blotched; O. c. Margery Tyrrel Giles, blush-white with small spotting of purple, and others, were of a good type. Lælia purpurata Gatton Park variety had a fine veining of rose-purple; L. majalis bore two fine flowers; Vanda Denisoniana had a fine spike of white flowers; Cattleya Mossiæ varieties, including forms of C. M. Reineckiana, and other whites were good; C. Skinneri and its variety alba were well shown, and the group was brightened by scarlet Masdevallias, Cochlioda Noezliana, Spathoglottis aurea Gatton Park variety (the best bright yellow), and other showy kinds. Noteworthy also were Cattleya intermedia cœrnlea Gatton Park variety, Cattleya Mossiæ Dormaniana, Cymbidium × Lowio-eburneum giganteum, and Odontoglossum × Andersonianum Colmani.

J. RUTHERFORD, Esq., Blackburn (gr., Mr. Lupton), staged a small group of Odontoglossums, varieties of Cattleya Mossiæ, including the nearly white variety "Sir Alfred Milner," C. M. Rappartiana, and two varieties of C. M. Reineckiana; also Miltonia vexillaria and its variety Luptoni.

ED. ROBERTS, Esq., Eltham, showed a good selection of Cypripedium hellatulum, C. Godefroyæ lencocheilum, C. glaucophyllum, and a fine Cattleya Mendeli.

J. FORSTER ALCOCK, Esq., Northchurch, showed a small lot of Odontoglossums, including some spotted varieties flowering for the first time.

NURSERYMEN.

Messrs. SANDER & SONS, St. Albans and Bruges, staged a magnificent group occupying 200 square feet, splendidly arranged, and made up of nothing but plants of the highest order in each section. Their central plant, Cattleya Schröderæ "The Baron," named in honour of the respected orchidist Baron Schröder, was generally pronounced to be *the* plant of the show (see fig. 142). It was a model in form, with white sepals and petals, the large disc of the lip being of a glowing rosy-orange tint, shading off to violet towards the broad, white, crimped margin. C. Schröderæ "Princess Ena" was also fine, it being blush-white, with a blnish-purple blotch on the lip. In the centre was a selection of grand forms of Odontoglosnm × ardentissimum, some much like good blotched O. crispum, while others had most of the segments occupied by the rich purple blotching. Some of the best were O. × ardentissimum punctatissimum, O. × a. splendens, and O. × a. Her Majesty. The O. crispnm were uniformly good, the best noted being O. crispum Semontianum, O. c. leopardinum, O. c. punctatissimum, and some new unnamed spotted varieties, one very singularly marked form being near to O. c. Kinlesideanum. Hybrid Odontoglossums were well represented, one clump having a fine set of O. × Wilckeanum, the best being the variety imperialis, and other sections were of the O. × Rolfeæ and O. × crispo-Harryanum class raised at Bruges, together with other hybrids. The selections of Cattleyas were rich in white forms of C. Mossiæ, including Reineckiana and Wageneri, of which latter C. W. xanthina had a rich orange lip. C. Mossiæ Cooksoniæ was a grand white flower; C. M. Fascinator, a pretty flower of the Arnoldiana class; and C. M. Fairy Queen, the whitest of all, there being little of the yellow colour usnally seen in the lip. C. M. Empress of India was a fine, highly-coloured form, and the white C. × Mrs. Myra Peeters and other good Cattleyas and Lælias were plentiful. At one end was a fine batch of the large Java form of Phalænopsis grandiflora; at the other a specimen of Dendrobium thyrsiflorum with twenty-five spikes. Others noted were Lælio-Cattleya × Canhamiana "Rex," and a very fine selection of L.-C. × callistoglossa, L.-C. × Vulcan albo-marginata, and other hybrid Cattleyas and Lælio-Cattleyss; a fine selection of Cattleya Mendeli, that named "Gustaf Adolf" being a very large and fine flower; C. Skinneri atro-violacea and alba; Phaius × oakwoodiensis, Renanthera Imschootiana were also included.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a superb group occupying 200 square feet, and effectively arranged, the depth being increased by the taller plants being carried well up at the back, the more slender sprays of Oncidium macranthum and other graceful species arching forward. There was a very fine display of Odontoglossums, some of them being home-raised hybrids. The forms of Odontoglossnm had for the largest and best spotted form O. × oakwoodense; and other good forms were O. crispum Escamillo. O. c. Ruby Queen. O. c. Queen Empress, O. c. Victoria Regina, O. c. Grace Darling, O. c. Clarissa, O. c. Solario, and O. c. xanthotes, all with distinctive features, and some very fine. The hybrids were forms of O. × excellens, O. × Wiganianum, the pretty O. × Phœbe (cirrosum × crispnm), an elegantly-shaped white flower spotted with purple; O. × Othello and variety "Sultana," and a fine set of varieties of O. × Wilckeanum. Among Lælio-Cattleyas, the finest feature was made by a very beautiful set of varieties of L.-C. × Fascinator (C. Schröderæ cœrulescens × L. purpurata), of which all are beautiful, and the variation from light to dark rose tints remarkable; three of the best were named Admiral Togo, Ayesha, and Princess Ena; L.-C. × lumiuosa "His Majesty" had clear chrome-yellow sepals and petals tinted with red, and a fine purple lip; L.-C. × callistoglossa Princess was a grand flower; L.-C. Dighyano-Mossiæ, of a bright rose tint, and the selections of L.-C. × Phœbe and L.-C. × G. S. Ball were very effective, their orange and purple tints being admirable as a contrast with other colours. Other attractive

Mr. JOHN ROBSON, Altrincham, arranged a good group, the centre of which was of good forms of Cattleya Mendeli and C. Mossiæ, and the sides principally of Odontoglossnm crispum, among which were several good spotted forms. Also good O. × Adrianæ, two fine Cypripedium Rothschildianum, C. callosum Sanderæ, the very large C. × gigas Corndean variety, brightly-coloured Masdevallias, Cattleya Skinneri, &c.

Messrs. WM. BULL & SONS, Chelsea, had a very fine group, in which the forms of Cattleya Mossiæ, C. Mendeli, and Lælia purpurata were good. L. purpurata Schröderiana delicatissima was a charming white form, with pale rose marking on the lip; and L. p. Edward VII., an intensely dark variety; Odontoglossnm crispum The Pearl was clear white; O. c. Lady Clarice, and O. c. Mikado, spotted forms. O. × ardentissimnm, a very fine form of O. trinmphans, Cattleya Mossiæ Princess of Wales, and other showy varieties were also noted.

M. CHAS. VUYLSTEKE, Loochristy, Ghent, staged a small lot of hybrid Odontoglossums, for the two best of which see Awards.

[*From a sketch by Mr. Worthington G. Smith.*

FIG. 143.—ODONTOGLOSSUM × AMABILE VAR. IXION: FROM M. VUYLSTEKE. Awarded a First-Class Certificate at the Temple Show.

things noted were a selection of the large white Phalænopsis Rimestadtiana, and a plant of P. violacea superba, Scuticaria Steelii, Zygopetalum Protheroeanum, Aoguloa Clowesii, a fine specimen of the fragrant Maxillaria luteo-alba, and some specially fine Cattleya Mossiæ, including the very beautiful and large C. M. gargantua, C. M. bellissima, C. M. Wageneri, and varieties of C. M. Reineckiana.

Messrs. HUGH LOW & Co. staged an effective group, the central plant in which was Cattleya Mossiæ Ajax, with thirty six fine flowers. With it were C. M. Valhalla (very large, and with a finely-coloured lip), and other fine forms. C. Mendeli also were good, the variety Cicero a superb flower, good at all points. In the group also were some good Phalænopsis, the fine Cattleya × Parthenia "Prince of Wales," good Lælia purpurata, one bearing fifteen flowers, and the variety "Daintiness," a clear white with a dark purple blotch on each side of the lip. Cattleya intermedia alba and the Rosslyn variety, good Odontoglossum crispnm, Vanda teres and V. t. Little's variety, Dendrobium Bensonæ xanthinum, Epidendrum alatum, Miltonia Warscewiczii, and other pretty things were also shown.

Messrs. STANLEY & Co., Southgate, staged a group in which their fine type of Cattleya Mossiæ was displayed effectively. Also good C. Mendeli, varieties of Odontoglossnm crispum. Masdevallias, Cypripediums, Oncidium crispum grandiflorum, &c.

Of smaller exhibits F. MITCHELL, Esq., Blackburn, showed the pretty Cattleya Mendeli Maheliana.

FRANCIS WELLESLY, Esq., Westfield, Woking (gr., Mr. Hopkins), sent Lælio-Cattleya × zephyra alba, which had previonsly secured an Award of Merit.

Messrs. JOHN CYPHER & SONS, Cheltenham, had one of the finest exhibits in which Orchids were used so far as beauty and clever arrangement were concerned. The showy Orchids were arranged in a natural-looking group among Ferns, Palms, and other foliage plants, the principal kinds used being good Cattleyas, Lælias, and Odontoglossums. At the back were graceful Oncidiums, with a base of fine specimens of Cattleya Skinneri, one having twenty-four spikes. The middle area was filled in with fine forms of Cattleya Mossiæ and Miltonia vexillaria. In front were three raised designs, capped by light foliaged Palms and made up of Odontoglossum crispum, hybrid Lælio-Cattleyas, Cypripediums, &c.; the central design being principally of white Phalænopsis. All the plants in the group were good, and notably the Vanda teres gigantea, Cypripedium niveum, and other Cypripediums.

Awards.

FIRST-CLASS CERTIFICATES.

Cattleya citrina maxima, from the Marquis DE WAVRIN, Somergem, Belgium (gr., Mr. Gerard de

Geest).—A gigantic rich yellow form. The largest and best of this fine fragrant Orchid yet shown.

Zygopetalum × *Baltii* (natural hybrid of Z. rostratum), from Elijah Ashworth, Esq., Harefield Hall.—Sepals and petals white with rich purple markings up the middles. Lip white with purple blotches at the base. Previously given an Award of Merit. An ally of Z. Roeblingianum.

Odontoglossum × *amabile var.* "*Ixion*" (Harryanocrispum × crispum), from M. Chas. Vuylsteke.—A

with purplish-brown. Lip white with purple markings.

Odontoglossum × *loochristyense* "Arddaroch variety," from R. Brooman-White, Esq., Arddarroch, Garelochead.—A noble flower, well intermediate between a good O. triumphans and O. crispum, the bases of the segments being white, the outer portions yellow; blotching chestnut-brown.

Cattleya Mendeli "*Cicero*," from Messrs. Hugh Low & Co., Enfield.—A very large flower of fine substance,

GROUPS OF PLANTS, &c.

Mr. L. R. Russell, Richmond Nurseries, Surrey exhibited a group of choice foliage plants, in which some of the best specimens were of Anthurium crystallinum, Ananassa sativa variegata, Alocasia Thibautiana, Maranta Veitchii, varieties of Caladium, Codiæum (Croton), Cordyline (Dracæna), &c.

Nicotiana hybrids of the type of N. Sanderæ, crossed also, it is said, with other species, were shown by Messrs. Sander & Sons, St. Albans, and it is note-

[*Photograph by J. Gregory.*

Fig. 144.—Begonia "Ne plus ultra": exhibited at the temple show by messrs. sander and sons.

most beautiful hybrid with very large, broad-petalled flowers of a delicate blush-white tint. Sepals bearing a fine marking of reddish-rose, and the middle of the of the petals occupied by clusters of blotches of the same colour, a band of irregular markings encircling those in the centre. A very pretty combination. Lip white with reddish markings around the crest (see fig. 143).

Awards of Merit.

Odontoglossum × *Lawrenceanum* "Adonis" (triumphans × Rolfeæ), from M. Chas. Vuylsteke.—A very large, finely-formed yellow flower heavily marked

blush-white with magenta-crimson front to the lip, which is delicately veined.

Cattleya Schilleriana "*Westfield variety*," from Francis Wellesley, Esq., Westfield, Woking (gr., Mr Hopkins).—A splendid flower with olive-tinted sepals, and petals spotted with dark-purple, and magenta-crimson-veined lip, finely displayed.

Botanical Certificate.

Bletia hyacinthina alba, from Messrs. W. Cutbush & Sons, Highgate.—A clear white form of that known as B. Gebina. A fine pot of many spikes was shown.

worthy that succeeding exhibits of this plant continue to display greater variety of colour than ever. Some of the shades between pure white and crimson, and between pure white and purple, are indescribably pretty. Messrs. Sander also showed first-class foliage plants, in which magnificent specimens of Dracæna Victoria superba were conspicuous, also foliage Begonias, as Our Queen and His Majesty varieties (that were figured in these pages, Nov. 28, 1903, pp 368, 369), Mrs. H. G. Moon, Fearnley Sander, and Ne Plus Ultra. This last-mentioned variety is illustrated at fig. 144, being the identical plants exhibited at the show, and grouped together in a pan. The leaves are of deep maroon brown colour,

marked and spotted near to the margins with silvery-grey sheen. Cycas Micholitzii, Phœnix Sanderiana, Pandanus Sanderi (a splendid plant of this handsome variegated Pandanus, illustrated in a Supplement to the *Gardeners' Chronicle* April 23, 1898), Ficus pandurata, Alpinia Sanderæ, Nephrolepis Scotti, Furcræa Watsoniana (figured in these pages April 23, 1898, p. 243), were included, and the new Clerodendron myrmecophilum, figured in the *Gardeners' Chronicle*, May 9, 1903, p. 291, was represented by a plant in flower in a 6-inch pot.

One of the most distinct exhibits at succeeding Temple Shows is the collection of Sarracenias and allied plants exhibited by Mr. A. J. BRUCE, Chorlton-cum-Hardy. On this occasion the collection of these plants was even more noteworthy than usual, the selection of plants and varieties being of the very finest. Not only are the diverse forms of the "Pitcher," so well represented, but each plant is also an instance of superb cultivation; Sarracenia purpurea, S. Flambeau, S. Chelsoni, S. flava (and varieties of this, one of which received an Award of Merit), S. Atkinsoni, S. Williamsoni, also a plant of Darlingtonia californica in flower, Drosera capensis, D. binata, Dionæa muscipula, and others, were among the plants included.

Messrs. FISHER, SON & SIBRAY Handsworth Nurseries, near Sheffield, had a group in which were three good plants of Musa purpurea with leaves of purple-red colour, and a group of plants of Codiæum Duke of Portland, being a cross from the varieties Thompsoni and Hawkeri, and having rich green leaves with golden-yellow colour in the centre.

Mr. WILLIAM ICETON, Putney Park Lane, Putney, S.W., exhibited a group of Lilies of the Valley, Boronia elatior, Caladiums, and other ornamental foliage plants, with tall Palms, &c., at the back.

Messrs. JAS. VEITCH & SONS, Ltd., Exotic Nurseries, Chelsea, exhibited on a stage in one of the narrower tents, small groups of Lobelia tenuior, Rehmannia angulata, Kalanchoe flammea, K. × kewensis, and K. felthamensis; Senecio auriculatissimus, hybrid Gerberas in pots, their stellate flowers varying from pure white to deepest orange-red colour; Schizanthus wisetonensis, hybrid Phyllocactus, Primula obconica alba, Corydalis thalictrifolia, C. tomentosa, and Streptocarpus. Of Streptocarpus there were flowers from pure white to deep-lilac, with some charming shades of rose and pink.

Messrs. W. & J. BROWN, Stamford, presented batches of Verbenas Scarlet King, Miss Willmott, &c., also the star-like Dimorphotheca Ecklonis, &c.

Messrs. SUTTON & SONS, Reading, in addition to the Calceolarias and Gloxinias noticed elsewhere, had a group of finely-grown Schizanthus, in which pure white flowers and shades of pink and rose colours predominated.

Caladiums.—Messrs. JOHN PEED & SON West Norwood, London, staged an extensive group of Caladiums. The colour of the various varieties was well developed, and the plants were well grown. They were arranged from a higher background sloping towards the front, that was furnished with a pleasing edging of C. argyrites and small Maidenhair Ferns, the same subjects being also used for relief among the group. A specimen of C. Golden King was prominent in the centre. We also noticed Oriflamme, Ville de Hambourg, with a pleasing groundwork of red with white maculations and greenish margins; Duchess of Teck, a light-coloured variety tinted with the palest green colour. Triomphe de Comte has large leaves that are red merging to a green margin; Roncador possesses prominent green-coloured venation; Mikado, Raoul Pugno, rose centre with vivid green margin; Comtesse de Brosse, Lady Dorrington. The foliage of this variety is not large, but the rosy groundwork is splashed with deeper red, and terminates in a margin of a pale shade of green.

Messrs. WM. BULL & SONS, King's Road, Chelsea, staged an attractive group of foliage plants. The group, although arranged somewhat formally, was nevertheless pleasing, the colours of the various subjects being well developed. Two large plants of Dracæna Victoria were used as corner subjects for the group, the foreground being composed of small plants of Caladiums, Codiæums (Crotons), Ficus repens variegata, &c. Alocasias were prominent, including A. mortefontainensis, and the lighter-coloured variety A. argyreia. A plant of Cyathea dealbata at the back spread its fronds over neighbouring plants. Ferns, small Palms, and brilliantly coloured Crotons were worked into the group with good effect. Messrs. BULL & SONS also showed Hydrangea nivalis with green leaves, having a broad band of white in the centre, and the fine white double-flowering Stock Excelsior.

TULIPS.

A VISIT TO ARDCAIRN, CORK.

ONE goes to Holland to see Hyacinths and early Tulips, but there is always a sameness about the view; but here were glorious flowers that under a clear blue sky had withstood all the storm, hail and rain, followed by hot sunshine of three weeks since (May 10 as I pen these notes). To describe all the sorts minutely would take up too much space, so that I will make a start with yellow forms, and must first of all give prominence to Mrs. Moon. Amid such a quantity this is the finest of all yellow Tulips, the blooms sweet-scented, and the stems like walking-sticks. Another fine yellow variety is Gesneriana lutea, of the same tone but of the shape of a sugar-loaf and highly perfumed. Then there are in great quantity Ixioides (with its rich dark velvety base), "Cloth of Gold," "Sunset" and "Sunray" (all quite distinct), Grenadier, Bandmaster, Golden Spire, Illuminator, Leghorn Bonnet, &c. The two last are very pretty. Some Tulip judges say that Cloth of Gold and Sunset are the same, and that Silver Queen, York and Lancaster, and Shandon Bells, may all have come out of the one basket. As well may they get Northern Star, Myatt's Ashleaf, and Redskin Flourball Potatos out of the same pit mixed, and be pleased afterwards. To see the May-flowering Tulips in a mass for effect is the way to judge distinctions. The Fawn and its sport, La Perle, are here in great abundance and are very beautiful, but Mr. Hartland tells me the Pearl is not constant, that it reverts to the Fawn colour.

Among scarlet varieties Mars is the brightest of any; Koh-i-Noor is a lovely bloom, which when seen side-by-side with Scarlet Emperor, Coronation Scarlet, Inglescombe Scarlet, Mauriana, &c., looks extremely fine; Golconda and Koh-i-Noor are to my mind the finest, Golconda from its lovely sheen of crimson and great substance. The Moor, too, is a most useful bloom to gather late; so is Emerald Gem.

In rich crimson and deep claret colour, Glare of the Garden and its counterpart, Pompadour, are in shape alike, but distinguishable by colour; Crimson Globe is also most lasting and effective; Orange Globe should be grown by the thousand to contrast with the tall spatulata of Dutch gardens.

Then in the Fairie Queen class we have John Ruskin, Royal Visit, and most beautiful Kaleidoscope, a very appropriate title; then the dark shining, cup-shaped Othello should be noted to put in contrast with Bouton d'Or; Nutmeg also and the latter make a fine contrast. The lovely varieties from Savoy were, too, very noticeable, viz., aximensis, Marjoletta, and, as already mentioned, Mauriana; so are La Merveille, Columbus, and Orange Globe, which form fine contrasts. In white Tulips for cutting, no late-flowering variety that passes off without a speck equals Didieri alba, it is here in thousands, and Mr. Hartland tells me how scarce it was fifteen years ago, when he paid sixpence a bulb for it, got it recognised at Kew by Mr. Baker, to whom for classification he is much indebted, and forgives him freely for his Latin nomenclature, which puzzles the Tulip Committee nowadays. When cut in the bud-state, and put up with a bit of Fern, it would pass for a Rose.

To write more on the merits of this collection of Cottage Tulips is needless; they should be seen at noon for their centres, and at evening, when they go to sleep, for their shapes, and this in quantity. It is a great pity the south of Ireland is so far from Vincent Square, for here a whole breadth of one variety might be examined by the Floral Committee and seen to advantage, instead of a few famished blooms several hundreds of miles away from their native soil.

Mr. Hartland deserves great credit for his enthusiasm over the Daffodil and Tulip. Twenty years ago it was the yellow fever with him; now it is the scarlatina he has caught over the vermilion of his Tulip Mars, or the Tangierine Orange cup of his Leedsii Narcissus "Nectarine," or the same seen on the beautiful hybrid which he so justly calls Paint-brush. *Visitor.*

A COLLECTION AT COLCHESTER.

To the ordinary visitor, and to those generally interested in hardy flowers, the experience of a visit to Messrs. Wallace & Co.'s nursery at Colchester affords an object-lesson of considerable value. Quite recently there could be seen breadths of Tulips growing in a degree of perfection in a soil that is not far removed from brick-earth. During a recent visit there I was shown two or three acres of Darwin Tulips of the greatest perfection, and remarked the exceptional growth and great vigour of the plants. These handsome Tulips are evidently more at home and grow with an infinitely greater vigour in this heavy Colchester loam than is usually seen when they are cultivated in light sandy or shallow soils, and where organic manures have to be employed more liberally and with greater frequency.

In the case of some of the quarters of the nursery, Mr. Wallace informed me that the soil had been trenched 3 feet deep before planting the Tulips, and had been previously heavily manured for a former crop. The finest development was seen in those bulbs that were planted early, and not later than November; those planted after the sales were over were somewhat inferior, thus emphasising the need of planting at a seasonable time. Another point I noticed in these Tulip grounds was that the popular May-flowering type is grown and flowered entirely without protection, hence it would appear that in a soil of great depth the plant is rendered more vigorous and enduring.

A large collection of Tulips has been planted in a field apart from the general collection, and here I noted many of the best sorts. Taking the Darwin kinds first, I was impressed with the great beauty of Clara Butt, a gem among the salmon-coloured kinds, a flower of great beauty and refinement. Quite recently this handsome form received a First-class Certificate of the Royal Horticultural Society. It has been for some years in general cultivation.

Those who indulge in progressive gardening should become acquainted with the varieties Glow, Hecla, and King Harold, as these form stepping-stones to each other, not merely in height, but in degrees of colour, the last-named being a glowing ruby-crimson, probably the most stately "Darwin" extant. The first-named of these three is a most brilliantly coloured variety. Another large and gorgeous Tulip is Mrs. Farncombe Sandars. A shapely Tulip, very fiery in colour and of beautiful form, is Europe, which has, like the last-named, a whitish base internally. Rose Queen, Pride of Haarlem, Margaret, and Madame Krelage represent the varying shades of rose, rose-pink, and blush-pink, the last-named being of a deeper tone save for the margin of the petal, which shades to a more delicate hue. Zephyr and Phyllis possess beautiful and distinct shades of rosy-lilac, the handsome flowers of the former lasting for a long time in perfection. Negro and the Sultan are of the very darkest colours, the latter is of a blackish-maroon shade, and is probably the darkest Tulip known.

In the May-flowering and Cottage kinds the display was a most extensive one. More varied, probably more showy if less stately than the Darwins, these May-flowering sorts, with long, tapering buds, are well suited for effective bedding arrangements. Some varieties, like Leghorn Bonnet, possess a singularly beautiful colour, the term "soft-yellow" but very feebly describes its beauty, and gives no idea of its real merit. Mrs. Moon (syn. fulgens lutea), maxima, Gesneriana lutea pallida are other choice and showy kinds with yellow-coloured flowers. Maid of Honour is a beautiful flower painted scarlet-and-white. The flower of Kathleen is very large in the bud stage and of cream or very soft-yellow colour. Orange King is a mingling of orange and scarlet colours; its boldness displays its lustrous flowers to considerable advantage. Very conspicuous, too, was Inglescombe Pink, which with Inglescombe Scarlet, Scarlet Emperor, Innovation and others contributed not merely to a brilliant display, but to a feast of this popular flower as rich and varied as it was remarkable. *E. J.*

RHODODENDRONS.

AT a time when Rhododendrons are furnishing their usual abundant and brilliant contribution to the floral effects in our gardens, the photographs reproduced (figs. 148 and 149) may be of interest. Fig. 148 illustrates a fine plant of Messrs. Jno. Waterer & Sons' new variety, Pink Pearl, in flower in Major Joicey's garden at Sunningdale Park, Berks (gr., Mr. Thorne). As this variety has been distributed only a very few years, the plant illustrated would appear to be almost as large as the earliest ones, and it will be noticed that there is an excellent truss of the very large, delicately-coloured flowers on almost every shoot. Two larger plants of the same variety have been recently in flower in Baron Sir Henry Schröder's garden at the Dell, Egham, and during the present week we have seen it in bloom at Dover House Gardens, Roehampton (gr., Mr. J. F. McLeod), where there is a bed containing upwards of a dozen plants of Pink Pearl. A spray of flowers from Sir Trevor Lawrence's garden was illustrated in the *Gardeners' Chronicle*, July 28, 1900, p. 63.

The view reproduced at fig. 149 represents one of the principal roads through the nurseries of Mr. Anthony Waterer, Knap Hill, near Woking, a nursery which is famed for the cultivation of Rhododendrons and for trees and shrubs in general. The figures shown in the illustration are those of Mr. Anthony Waterer and Mr. Geo. Paul, the latter gentleman leaning on his umbrella.

FIG. 148.—A FINE PLANT OF THE PEERLESS RHODODENDRON PINK PEARL IN FLOWER IN SUNNINGDALE PARK, BERKS.

VEGETABLES.

BOLTING CABBAGES.

WHY there should be in some directions great complaints as to autumn-planted Cabbages bolting off prematurely to flower, literally reverting to their natural or primitive habit of annual form, and yet from others not a word of complaint comes, seems explicable only on the supposition that varieties planted are diverse, and that in the one case those which are best fitted for spring sowing are sown in the autumn, whilst those varieties which never depart from their biennial nature are grown in the spring. When recently visiting Hackwood Park, Basingstoke, I saw two large breadths, some 7,000 plants in all, from two diverse sowings and three diverse plantings, all hearting-in finely, and yet from the entire batch not a dozen had bolted, I failed to find cause for any complaint. Now the varieties there grown, and which by long experience Mr. Bowerman is assured will come true to character, are Sutton's April, Favourite, and Flower of Spring, Mein's No. II., and Veitch's Lord Beaconsfield. The two last are later than the others.

By far the greater bulk are Flower of Spring, evidently one of the safest Cabbages to grow that is in commerce. Soon after seeing this batch I visited Messrs. Sutton & Sons' Reading seed farm, where they have some 20,000 Cabbage plants put out, of many varieties, for ordinary seedmen's trials, and where also very interesting information could be found as to the habits of varieties in the spring. Now several years' practical experience with many varieties of Cabbages planted in the autumn have satisfied the firm that the bolting trouble arises solely from the planting at that season of unfit varieties. Still further, that if varieties that have had high reputations for biennial consistency and excellent hearting in the spring be seeded near other varieties of diverse characters, then the good stock will soon deteriorate, or lose its hitherto consistent nature.

Such varieties as Early York, Nonpareil, Sugarloaf, Winningstadt, Enfield Market, and others sown in the spring heart-in capitally in summer and autumn, but, sown in the autumn, many plants of each will either bolt freely or become coarse and quite out of character. Those features were to be seen on

these and similar varieties at Reading the other day, and where none had bolted the plants were still quite unrecognisable. Probably there is no section of the Brassica genus that is more difficult to keep absolutely true than are Cabbages. They need the most constant care in their selection for the production of seed stocks, and then of entire isolation of each variety when in bloom. Even with the greatest care a few "rogues" will show in the best of stocks, and it not infrequently happens that these, being most probably reversions, give the chief bolters. The Coleworts give literally all bolters from autumn sowings; St. John's Day, one-half; from Christmas Drumhead four-fifths, and others ranging down from one-fourth to one-sixth. Red Cabbages are far less true to character. By way of contrast, Sutton's April, the very earliest of upwards of 1,000 plants in trial rows of stocks and for seed selection, had not a single bolter. Of over 2,000 Flower of Spring, only one had bolted, and of 1,400 Sutton's Favourite again, only one had run to flower. Certainly facts such as these speak for themselves. All plants were put out at the same time, on the same exposed plot, and close beside were the seed beds or rows, in every case showing exactly the same characters as were found in the planted-out quarters. It would be very unfair did anyone assume that a trial of this nature is biassed or unreliable. No firm in the kingdom has greater interest in testing stocks from all sources annually than have the Messrs. Sutton; and if the trial be demurred to as a trade one, the 7,000 plants at Hackwood Park is absolutely an impartial one. But whilst the subject of Cabbage bolting creates so much interest, would it not be well, now there is ample room, for a trial of autumn-planted Cabbages to take place at Wisley, which would be void of suspicion? *A. D.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT BANK HOUSE, ACCRINGTON.

The collection of R. Briggs-Bury, Esq. (gr., Mr. Wilkinson), has recently undergone several changes. The rare Cattleyas, including one of the most varied collections of albinos, which were favourites of the late Mrs. R. Briggs-Bury, and the Lælias having been dispersed to allow of the extension of Odontoglossum culture. The cool-house Orchids will in future form the chief feature. A new range of houses is about to be provided, and alterations are to be made in the existing Odontoglossum houses. Recently there was a very good show of Odontoglossums, including several fine blotched forms of O. crispum, the best of which were O. crispum Empress of India, of the form of O. c. Luciani, and with flowers 4 inches across, white, handsomely blotched with purple; O. crispum "Stormberg," not so broad in the petal, but showily blotched; O. crispum Mrs. F. Sander, a good white flower with the bright-purple marking seen in forms of O. × ardentissimum. Of others noted were good forms of Odontoglossum × loochristyense, including the large and finely-marked variety figured as O. harvengtense, some specially-fine O. × Wilckeanum, one form with a white ground being very near to O. crispum. Also a number of large white O. crispum, good O. triumphans, including the broad-petalled variety latisepalum, and a number of other pretty cool-house Orchids.

In the warm-house range was a good selection of Cypripediums, two large plants of C. Lawrenceanum Hyeanum Bank House variety, bearing out the character of that variety for beauty and free growth; also strong plants of C. callosum Sanderæ and C. × Maudiæ, together with good examples of many other rare kinds.

In the central division was a display of Dendrobiums in bloom, including some of the best varieties of D. nobile, the finest-coloured form being D. n. nobilius. Others in bloom were D. nobile virginale, D. × Rolfeæ roseum, several forms of D. × Ainsworthii and D. × splendidissimum, and a specimen of the pretty yellow D. Harveyanum, whose petals as well as the labellum are deeply fringed. These were arranged with Cymbidium Lowianum and foliage plants.

Dendrobium Seidelianum.

A plant of this pretty rose-coloured species, with an orange disc to the lip, has been in flower in the gardens of Mrs. Brightwen, The Grove, Stanmore (gr., Mr. J. W. Odell), for a considerable time; and the plant has an interesting history, as it was sent originally from Shanghai folded in a newspaper. It forms a pretty close-growing plant, and is a profuse bloomer. It is commonly known as D. pulchellum in gardens, and was illustrated under that name in Loddiges' *Bot. Cab.*, t. 1935. In July, 1887, I sent specimens to the late Professor Reichenbach, who replied that the name D. pulchellum was not admissible, as it differed from Roxburgh's species of that name, and that he had decided to call it D. Seidelianum. About the same time the matter had been gone into at Kew, and the plant renamed D. Loddigesii by Mr. Rolfe, whose interesting note on the subject was published in the *Gardeners' Chronicle*, August 6, 1887, the same date as the note giving Reichenbach's reference was published in the *Gardening World*. *J. O'B.*

Odontoglossum crispum G. W. Law-Schofield.

A flower of this fine blotched Odontoglossum crispum, sent by G. W. Law-Schofield, Esq., New Hall, Hey, Rawtenstall, near Manchester (gr.,

Fig. 149.—View in the Rhododendron Nursery of Mr. Anthony Waterer, near Woking. (see p. 354.)

Mr. Shill), shows it to be a very handsome variety of the O. c. Lindeni class. The flower is 3½ inches across, the sepals 1 inch, and the petals 1¼ inch wide. The reverse of the flower has a purple band up each segment, and the rich spotting of the surface shows through to the back. The petals have one large irregular purple blotch ½ an inch across, and clusters of confluent purple spots nearer the silver-white base. The sepals have three to four large purple blotches, and the margins of all the segments are white, the petals being fringed. Lip fringed, white, with one large red-brown blotch in front of the yellow crest, and several smaller ones on each side.

ODONTOGLOSSUM THOMPSONIANUM.

I would like to supplement your favourable remarks on this plant in the issue for May 6 by stating that the plants were raised by Mr. Rappart, of Liscard, Cheshire. They were obtained by us when he parted with his collection in 1902, the plants being very small at that time. To him, therefore, is due the credit of raising this remarkable hybrid. *W. Stevens, Walton Grange Gardens, Stone.*

LEAVES FROM MY CHINESE NOTE-BOOK.—I. ICHANG.

(*Continued from p.* 338.)

THE Coriaria is not so well known to your readers, perhaps, and is not nearly so attractive. Its flowers are polygamous, and the plant when in fruit is rather showy. The Chinese consider its foliage and stem poisonous to cattle.

Wistaria sinensis is abundant, often scaling high trees, but the semi-bush form is the more common. Its flowers are borne in great abundance, and vary much in shade of colour, the white form being, however, rather rare.

Loropetalum chinense is another well-known shrub which abounds here. On the tops of the cliffs, amongst loose conglomerate and limestone boulders, it forms a well-nigh impenetrable scrub. The plants are seldom more than 3 feet in height, very much branched, and when in full flower look like patches of snow at a distance. Messrs. Veitch show the plant very well, but there is an enormous gulf between the best grown pot plants and the plants in a state of nature. In Devon and Cornwall, if planted in a rockery, it ought to thrive.

Rose-bushes abound everywhere, and in April perhaps afford the greatest show of any one kind of flower. Rosa lævigata and R. microcarpa are more common in fully exposed places. Rosa multiflora, R. moschata, and R. Banksiæ are particularly abundant on the cliffs and crags of the glens and gorges, though by no means confined thereto. The Musk and Banksian Roses often scale high trees, and a tree thus festooned with their branches laden with flowers is a sight to be remembered. To walk through a glen in the early morning or after a slight shower, when the air is laden with the soft delicious perfume from myriads of Rose-flowers, is truly a walk through an earthly paradise.

Sophora viciifolia is very fine in the glens and gorge. In March and April it is covered with masses of bluish-white flowers. This ought to make a very acceptable plant in gardens where it proves hardy. This plant has a very wide distribution. It is common in Yunnan, and in the warm valleys of rivers bordering Tibet. The Ichang plant is much less spiny than that of Yunnan and West Szechuan. Possibly the latter is really the Indian S. Moorcroftianum.

Two very common plants on the cliffs in the glen are Eriobotrya japonica (Loquat) and Chimonanthus fragrans. Both flower about Christmas. These are two out of many plants which were erroneously supposed to be natives of Japan.

Caryopteris Mastacanthus is common amongst conglomerate boulders, but is not nearly so fine as it is further west.

Cratægus Pyracantha and Vitex Negundo are exceedingly common, and so also is Cæsalpinia sepiaria. This thorny shrub is semi-scandent in habit, and very like the better-known C. japonica. Its handsome foliage and erect-thyrsoid racemes

FIG. 150.—GLOXINIA KAISER WILHELM: COLOUR OF FLOWERS PLUM-PURPLE AND WHITE. Shown at the Temple by Messrs. Cannell & Sons.

FIG. 151.—CANNA PAPA CROZY: FLOWERS OF RICH ORANGE-RED COLOUR. Shown at the Temple by Messrs. H. Cannell & Sons.

of bright yellow flowers make it a very conspicuous object.

Symplocos cratægoides, with its pretty white flowers and bright blue fruits, is abundant. This useful and charming shrub deserves to be better known. Deutzia scabra, Lagerstrœmia indica, Azalea indica, Jasminum floridum, Nandina domestica, Ilex cornuta, Viburnum utile, and Buddleia variabilis are all extremely common shrubs. Of other well or lesser known shrubs which are common, I may mention:—

Abelia chinensis, A parvifolia, Rhus Cotinus, Buddleia officinalis, B. asiatica, Ilex pedunculata, I. Oldhami, Deutzia discolor, Desmodium floribundum. Eleagnus pungens, E. umbra, Spiræa dasyantha, Eurya japonica, Hypericum sinense, Hydrangea aspera, Berchemia lineata, Euonymus alatus, Polygala Mariesii, Viburnum brachybotryum, V. propinquum, Camellia Grijsii, Rubus parvifolius, and many other species. Cydonia sinensis with red, and C. cathayensis with white or blush-white flowers, are commonly cultivated. Lengthy as is list, I am not justified in omitting Itea ilicifolia. This Holly-like shrub, with long, pendent racemes of pure white flowers, is one of the handsomest of all the Ichang shrubs. Of fluviatile shrubs, the commonest are Distylium chinense, Salix variegata, Ficus adpressa, Rhamnus davuricus, Adina globiflora, Myricaria germanica, and a curious form of Buxus sempervirens. Climbers are very much in evidence, and include such beautiful plants as Lonicera japonica, Trachelospermum jasminoides, Pueraria Thunbergiana, Clematis Henryi, C. Meyeniana, C. Benthamiana, C. Armandi, C. leiocarpa, Vitis flexuosa, V. Labrusca, V. Henryana, V. Thomsoni, and Mucuna sempervirens.

This last is a rather remarkable plant. Two miles above Ichang, on the right bank, is an enormous specimen, called by foreigners the "Big Creeper." It covers several hundred square feet of ground, climbing over several Pine-trees and many Bamboos. The base of the main trunk is almost as thick as a man's body; the flowers are dark chocolate coloured, and are borne in racemes on the old wood; the legumes are 2 to 2½ feet in length, and contain many large black Bean-like seeds. It flowers in May.

Ichang does not possess a great number of trees, but the variety is really astonishing. Paulownia imperialis and Melia Azedarach, with their enormous panicles of flowers, are very striking in the spring. In the autumn, Sapium sebiferum, with its wonderful autumnal tints, stands alone. In winter the evergreen Ligustrum lucidum, and Xylosma racemosum are very conspicuous. The latter nearly always shelters some wayside shrine. Perhaps the commonest trees are:—

Gleditschia sinensis, Rhus semialata, Platycarya strobilacea, Quercus aliena, Cedrela sinensis, and Pterocarya stenoptera. The Misleto occurs on the last-named tree. Other less common trees are Sterculia platanifolia, Populus tremula var. villosa, Cratægus pinnatifida, Celtis sinensis, Dalbergia hupehana, Acer oblongum, Cunninghamia sinensis, Ailanthus glandulosa, Broussonetia papyrifera, Ulmus parvifolia, Hovenia dulcis, Sapindus Mukorossi, Salix babylonica, Sophora Kronei, and S. japonica. Of this latter a curious variety occurs in which the leaves and young shoots are clothed with a dense white velvety indumentum.

As with flowering shrubs, so with herbs, though in a less degree. Ichang is the home of many favourite garden plants. One of the commonest and best-known is Primula obconica. This charming herb abounds everywhere, but more especially in moist, grassy places on the banks of the Yangtze and in the glens. Occasionally, under very favourable conditions, in height, size of flower, and luxuriance of foliage, it approaches the cultivated form, but more usually it is a dwarf and almost insignificant weed.

Again, Ichang is the home of the Chinese Primrose and the type of the cultivated Chrysanthemum. Other favourites which are common are:—

Corydalis thalictrifolia, Anemone japonica, Sedum sarmentosum, Saxifraga sarmentosa, Iris japonica, Linum trigynum, Lycoris aurea, L. radiata, Rehmannia angulata, Hemerocallis fulva and H. minor. Other characteristic herbs are:—Adenophora polymorpha, Bletia hyacinthina, Asarum maximum, Ophiorrhiza cantonensis, Viola Patrinii, Delphinium chinense, Lysimachia Henryi, L. clethroides, Potentilla chinensis, P. discolor, Fragaria indica, Thalictrum minus, Mazus pulchella, Verbena officinalis, Platycodon grandiflorum, and many Compositæ, Leguminosæ, and Umbelliferæ.

Perhaps Ichang is best known to horticulturalists generally as the home of the lovely Lilium Henryi. This acknowledged favourite occurs on the limestone and conglomerate rocks, but is now by no means common. Lilium Brownii and its variety chloraster are fairly common; L. concolor and L. leucanthum also occur, but are rare.

Ferns are not rich in species, but Woodwardia radicans, Osmunda regalis, Pteris longifolia, P. serrulata, Nephrodium molle, Cheilanthes patula, and Gleichenia dichotoma are very abundant. A variety of Adiantum Capillus-Veneris is very

common on stalagmitic limestone in the glen. Pieces of these rocks covered with Ferns are detached and find their way all over China, being popularly known as "Ichang Fern-stones."

A hasty reference to the common floating plants of the ponds and ditches around Ichang must bring this note to a close. Euryale ferox, with its handsome foliage, is very common; Nelumbium speciosum is, of course, cultivated. Other common aquatics are Limnanthemum nymphæoides, Jussiæa repens, Salvinia natans, Trapa natans, Azolla filiculoides, Marsilea quadrifolia, Monochoria vaginalis, Eriocaulon Buergerianum, and several species of Potamogeton and Utricularia. In late autumn, when the Azolla changes to a rich crimson tint, the ponds look very fine. In some Rice-fields near Ichang Dr. Henry found a very anomalous plant. It was made the type of a new genus—Trapella sinensis, and doubtfully referred to the natural order Pedalineæ. All my efforts to re-discover this interesting plant have met with disappointment.

(To be continued.)

A CHEAP GARDEN TENT, AND HOW TO MAKE IT.

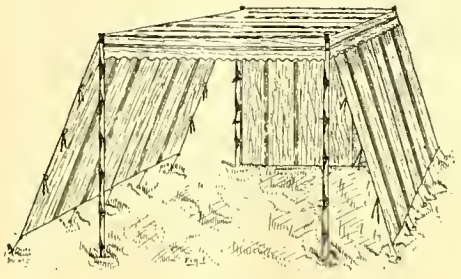
A DISADVANTAGE in many tents is that they are so hot and stuffy, whereas one only requires such a structure as a protection from the sun and from an occasional shower. It is also of much importance that a tent should be fairly commodious, and one that will meet the requirements mentioned above is illustrated in fig. 152 [1]. It is only reasonable to expect that a light tent is not intended to be out in all weathers. Rain, wind, and sun soon damage it, so that it is equally necessary that a light tent should be one that is easy to erect and equally easy to take down, and this can be claimed for the one here illustrated, which further has this advantage, that there is no occasion to always erect it in the same spot. This, in view of preserving the grass, is an important feature.

The framework is constructed with Bamboo, which renders it very light and yet strong, and when not in use the poles and canvas can be rolled up together in quite a small space.

The making of such a tent calls for no particular skill; the iron fittings to connect the various parts of the frame can readily be made by the local blacksmith, whilst the cover will possibly require the aid of one of the fair sex to stitch it together as described below; but in the meantime let me explain the framework.

The tent measures roughly 6 feet square, and is 6 feet 6 inches high, the latter measurement being that of the Bamboo as imported, which can be obtained in natural yellow, brown, or the more useful tortoise-shell pattern, which, as most people know, is an artificial decoration of the yellow Bamboo.

The poles should be 1½ inch thick, and selected as much alike as possible, eight being required, viz., four for the uprights and four for the top. The poles should first be ferruled at both ends, using either iron or brass ferrules, about 1¼ to 1½ inch deep. These should fit on tightly; and it may be necessary to rasp or shave the Bamboo a little in order that they should do so, and then to plug each end with a hard-wood plug about 4 inches long. Plugs can be driven in tight, as the ferrules will prevent the Bamboo from splitting. The plugs are then further secured with two or three wire panel-pins through the Bamboo; this prevents them drawing out should they shrink in dry weather. The bottom end of the upright poles are next fitted with iron pins (fig. 152 [2]), extending about 3 inches. These can be made by using 6-inch wire nails, letting them into the hole half their length and then cutting off the heads, or else the blacksmith will make four 6-inch pins of five-sixteenth or three-eighth inch round iron, with one end pointed to fix into the poles. The top ends of the uprights have a similar fitting extending 2 inches, which has a screw thread cut on it and fitted with a winged or fly nut (fig. 152 [3]). The horizontal poles which form the top of the tent are fitted with an eye at each end, see fig. 152 [4]. These eyes measure 4½ in. long over all, and are forged out of flat wrought iron, the eye part should be not less than 1½ inch over with a hole ¾ inch full. The tapered end should be jagged as shown in fig. 152 [4] to prevent any possibility of drawing out, and when fixed the eyes



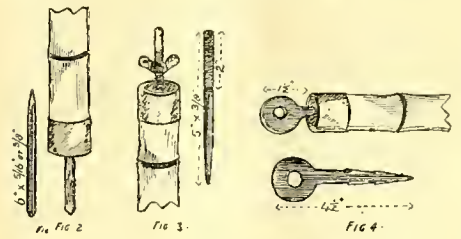


Fig 2 Fig 3 Fig 4

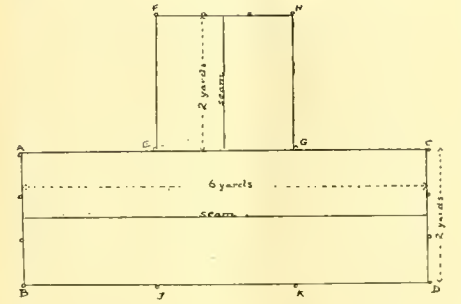

Fig 5.

Fig 6.

FIG. 152.—A CHEAP GARDEN TENT AND HOW TO MAKE IT.

1—The tent complete and fixed.
2—Bottom end of upright pole.
3—Top end of upright pole.
4—End of horizontal pole.
5—Plan of cover.
6—Iron peg.

should extend 1½ inch beyond the end of the pole. Eight of these are required, and will cost but a few pence from the local smith. In cutting the poles for the top these eyes must be allowed for in the length, so that for a 6-foot tent the poles will be 5 feet 10 inches long. It will be clearly seen that one end of two poles fit on to the screwed pin of each upright, and these are secured by means of the fly nut, although the latter is not screwed on until the covering is in position.

The covering is the most expensive part of the tent, but by following the lines laid down it is quite possible to economise in this respect unless it is absolutely necessary to have a water-proof canvas. For a cheap tent one can get a good striped canvas or ticking 36 inches wide, which is shower-proof and most suitable for the tent in question, at from 8*d.* to 9*d.* a yard. For the covering one needs 16 yards of this material for a plain tent, or if a vallance is preferred with scolloped edges, as shown in fig. 152 [1], another 2 yards are required. Fig. 152 [5] gives a plan of the covering, showing how to make it up. The part enclosed by A, B, C, D, represents the two sides and the top, made up of two widths of the canvas 6 yards long sewn together. The back is the part enclosed by E, F, G, H, which is two pieces 2 yards long sewn together and then attached to the centre of the long piece. At E, G, J, K, should be sewn a tinned iron ring ½ inch inside to attach the covering to the poles, the rings slipping over the screwed pins.

On the edges of the tent, sides and back are sewn strings of strong braid to attach them to the poles if required, whilst at the bottom are fixed similar tinned rings for holding the sides or back outwards at any convenient angle as illustrated; ¾-inch red braid is most suitable, and can be bought at any first-class general draper's with the covering material. All parts where rings or braid are attached must be strengthened on the inside with some strong material to prevent the force of the wind tearing the fixings away from the covering. This will no doubt be readily understood. The sides and back when extended require hooks or stakes, and short cords attached to the rings. In order not to disfigure the grass it is better to have hooks made out of ⅜-inch round iron, 9 inches long, as shown in fig. 152 [6], which, when fixed at an angle of say 45°, have a good holding strain, yet can be put in or withdrawn without injury to the lawn. Four are required for each side. Use solid blind-cord for the ropes. When the cover is fixed each pole should have a stay consisting of thin galvanised wire, one end having a loop to fit over the screwed pins, the other being attached to one of the hooks mentioned.

Referring again to the cover, if a vallance is required cut a 2-yard length of the 36-inch-wide canvas into three strips lengthways, form a scollop on one edge of each strip, and bind it with some of the ¾-inch braid, then attach these strips to the cover between the points E J, J K, and K G. A tent of this description can be erected in a few minutes, and given fair wear and tear will last for several seasons.

It is a very simple method to place a canopy on this tent if preferred. All that is required is to add an additional piece similar to the back piece upon the front side of the covering, edging it with the vallance. There are two additional poles required, and two horizontal poles to take the sides of the canopy, and two extra stays for the front of the canopy. They add but little to the original cost, and are a great addition to the tent. The writer can confidently recommend this tent to the consideration of amateurs, having had a similar one in use for several seasons. *S. W. N.*

ORIENTAL & AMERICAN LILIES.

NOTWITHSTANDING the scorching character of the present season, Lilies have grown with almost abnormal rapidity. The month of May, usually a growing period, was characterised by strong and long-continued sunlight, without a single shower of generous rain, which if it came providentially now, would be like Mercy as depicted by Shakespeare in its influence upon "the place beneath"; but doubtless the heavy showers of March and early April gave our Lilies a start in life, just when they were beginning to grow; and in my own garden that precious introduction called "gravitation water" has saved them ever since. I have seldom seen certain species, such as Lilium giganteum, Lilium

auratum, and Lilium monadelphum, so far advanced in their development at this season of the year.

The great Lily first mentioned—a native of India—demands much patience on the part of its cultivator. I have sometimes had immense bulbs that declined to send up a flowering stem, after growing steadfastly for a least four years! This no doubt may have been owing to my practice of withholding from Lilies of every description, strong manurial stimulants, for the late Dr. Wallace, of Colchester, used to assert, as the result of long experience, that Lilium giganteum was a great exception to the ordinary rule. Nevertheless, I am strongly disposed to think that in the direction of flowering it is not what my friend Mr. Matthew Arnold would have term "inevitable."

There are several other Lilies of considerably smaller dimensions, of which quite as much might truthfully be said. Lilium Browni, for example, is not very enduring, and where it does succeed for any length of time it seldom produces more than one solitary flower. It is a beautiful and effective Lily, but exceedingly transitory. Lilium Krameri, a plant of great beauty, and Lilium rubellum bloom in my garden for one short season and then wholly disappear. Of these the latter is if anything the less reliable. The bulbs are microscopic in size, and by reason of some secret and serious limitation, are subject to premature decay. Of all the many beautiful natives of the East and the West that adorn our gardens, the most entirely reliable, in my estimation, are Lilium auratum, monadelphum, tigrinum, davuricum (of which the finest form is incomparabile), pardalinum (the richly-spotted Lily of California), and the lovely Lilium Washingtonianum, which some cultivators have, however, discovered to be capricious. Here it has flowered in the same congenial situation for the last ten years. Lilium longiflorum is not of lasting character, and speedily degenerates by attempting too much in the direction of perpetuation; the fragrant Lilium candidum is only too frequently the victim of disease, but Lilium speciosum is entirely free from all such limitations, and grandly flowers, and nobly endures. *David R. Williamson, Wigtownshire, May 27.*

FOREIGN CORRESPONDENCE.

THE SPECIES OF EREMURUS.

I would like to say a few words about two species of Eremurus, called by Mr. G. B. Mallett, in his interesting notes (*Gardeners' Chronicle*, 1905, p. 148), "curious species of botanical interest." The true E. Kaufmanni, Regel, and the true E. turkestanicus, Regel, were discovered by my late husband, Alexis Fedtschenke, and myself in 1870, during our first travels in Turkestan (1868-1871).

E. Kaufmanni is the finest of all the species of Eremurus. It is small, but has large snow-white flowers, with a yellow spot in the middle, very thin and delicate, forming a dense spike. The leaves are densely covered with hairs turned backwards. It resembles small specimens of E. himalaicus, but is much finer. The coloured plate in A. P. Fedtschenko's *Travels in Turkestan*, fasc. 12, tab. 3 (= E. Regel, Liliaceæ, in the *Transactions* of the Imperial Society of Friends of Natural History, Anthropology and Ethnography), 1876, gives a good idea of the plant. E. Kaufmanni, Regel, is not yet known to cultivators. After having for years attempted in vain to get it alive, it is only during the summer of 1904 that I received some bulbs from Turkestan, which I am now trying to cultivate in my garden. They were collected by my son, Boris Fedtschenko, Chief Botanist of the Imperial Botanic Garden of St. Petersburg. The geographical area of this species is limited to a few localities in Turkestan.

The plant which Mr. G. B. Mallet describes as E. Kaufmanni is only a variety of E. spectabilis, M.B.

E. turkestanicus, E. Regel, was described in *Gartenflora*, 1873; in *Acta H. Petrop.*, 1873; and in the above-mentioned A. P. Fedtschenko's *Travels in Turkestan*, fasc. 12, 1876, cum. tab. ii. E. Regel's description is very good, but the figure does not represent well the colour and character of the living plant as I saw in it 1870 and 1897 in Turkestan, and as I see it in my garden (in Olgino, Moscow Government, Moshaisk District), where I cultivate many species of Eremurus, and where E. turkestanicus flowers every year. It is not handsome; it has a loose spike with white flowers (greenish on the outside), short purple-black filaments, long red anthers; the pedicels are erect and very stout at the top; the capsule is glabrous, pyriform; the seeds grey, and larger than the brown seeds of E. altaicus.

The same name, E. turkestanicus, was given by E. Regel, in *Gartenflora*, 1880, to another plant, figured on plate 997. This fault, after 1880, continues to be repeated by many authors, and by Mottet in his monograph of the genus Eremurus. The beautiful plate 997 represents, however, also only a variety of E. spectabilis, M.B., which I gathered in Turkestan in 1869 and 1897, and have cultivated in my garden since 1897. It is very hardy, flowers every year in early spring, but the seeds do not always ripen. I call this plant, in a large work I am preparing for the press, E. spectabilis, M. B., var. marginata O. Fedtschenko. It is no doubt this plant that Mr. Mallet calls E. turkestanicus, but, according to the laws of priority, this name appertains to the other plant, the one described in 1873. *Olga Fedtschenko, Imperial Botanic Garden, St. Petersburg.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Cypripedium bellatulum.—The repotting of this distinct "slipper" Orchid should be done, if necessary, soon after the plants have flowered, but as long as the drainage material is in good order renovation of the surface materials will suffice. Freshly imported plants should be fixed in ordinary Orchid-pans, with some old lime-mortar-rubble or fresh limestone worked in amongst the roots for drainage to a depth of a couple of inches. Over this work in a layer of good fibrous loam, peat, a little sphagnum-moss and semi-decayed Oak-leaves, well mixed together, and surface the whole with a thin layer of fine loam or chepped sphagnum-moss, the former by preference. Suspend the plants in a light part of an intermediate compartment, and for a long time apply only sufficient water to keep the surface materials moist, taking care never to wet the leaves. When the plants are growing freely, the pans may be dipped occasionally to the rim, so as to wet the whole mass; but this should be done only when the materials are approaching to dryness. The cool end of a Cattleya-house will suit the plants best during the winter season, when very infrequent waterings will be sufficient, so long as the thick, fleshy leaves retain their plumpness. If the conditions of the atmosphere in the house in which they are grown are suitable, the character of the rooting medium is of secondary importance, for plants are thriving here in coal-refuse and leaves, and others grow them well in small pieces of limestone alone, syringing them overhead almost daily during the summer season. Yet many fail when every conceivable detail is carried out with the utmost care.

Cypripedium concolor, C. niveum, C. Godefreyæ, and the variety "leucocheilum" may be treated as the above, the only practical difference being that more heat is needed. They may be suspended or stood on a shelf in an East Indian house in a position free from the influence of the sprayer and syringe. It is a difficult matter to re-establish plants whose roots have gone, a detail in the attempt being to tie a small lump of peat to the base of each piece to hold it firm in the new material. Use great care and discretion in the application of water, and when dipping is resorted to carefully refrain from immersing the receptacle beyond the rim.

Hybrids of this section are amongst the elect of the genus, and being somewhat difficult to rear are generally of considerable value. Those hybrids having C. bellatulum for one of their parents may usually be potted as other Cypripediums, using some limestone or old mortar rubble for drainage purposes. If combined with a warmth-loving species adopt similar treatment, but where a cool-growing species is concerned grow the hybrid with C. bellatulum. In the case of hybrids obtained from other members of the section warm treatment is always to be recommended. It is not always advisable to suspend plants of any of the above hybrids, though where a few only are grown and the stage is a considerable distance from the roof it is preferable. Keep them free from thrips by fumigating the house regularly. Never allow the rooting medium to become sour. A considerable degree of dryness may be beneficially permitted during the winter season. Beware of drip.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Wythes, Esq., Copped Hall, Epping, Essex.

Medinilla magnifica.—This is worthy of a place in a collection of stove-flowering plants, and very handsome specimens may in a few years be obtained from cuttings. As a specimen only should this species be grown. When the plants have ceased to flower and they are making fresh growth, potting on will be necessary, using for this purpose a compost consisting of two parts of rich fibrous loam, one part of turfy peat, and one part of broken charcoal, adding sufficient silver-sand to keep the whole porous. Make the soil very firm around the roots, and when the soil has become nicely filled with roots, afford the roots diluted manure-water obtained from soaking sheep-manure. These applications may be continued until the time for flowering arrives. During the period of growth considerable heat and moisture, shade, and overhead syringings with clear water are necessary. For providing cuttings select growths of the current year just as they begin to get hard, and detach them with a heel from the old wood. Insert each cutting singly in thumb-pots of sandy soil, and place them in the propagating-frame.

Hymenocallis macrostephana, when once established in 9-inch pots, needs very much feeding until it is again repotted. Make frequent applications of liquid obtained from sheep-manure, together with a teaspoonful of Clay's Fertiliser once a week. The same treatment as for Medinilla should be employed during their growing period, and if repotting is necessary the same compost may be employed. When the plants pass out of flower remove them to a slightly cooler atmosphere, and afford the roots clear water only.

Gesnera exoniensis.—The plants are now showing signs of activity, and should be potted in fresh soil after carefully removing the old soil from the corms. If the stock is sufficient for the requirements, the strongest corms only need be used, but if it is desirable to increase the stock this can be done later from cuttings. Care should be taken not to break the corms when removing the old soil. Let the fresh compost consist of loam and peat in equal parts, and add silver-sand in the proportion of a third part of the whole. For 48-size (5 inch) pots three corms should be used. Fill the pots to within 2 inches of the rim with the compost, on this place a layer of silver-sand and then the corms; fill up the pot with soil and gently press it with the fingers to make it firm. One application of water may be given to settle the soil, and frequent light syringings should then be sufficient until growth appears. Place the pots on a shelf near to the light in a warm house, but shade them from the direct rays of the sun.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Strawberries.—British Queen and other late-ripening varieties will continue to supply fruits until the earliest of those outside are ready. Apply diluted liquid-manure to the roots once or twice daily until the fruits change colour, and vigorously syringe the plants each day after the houses have been closed, in order to prevent red-spider. As soon as runners are available, layering must be carried out to raise plants for forcing next season. A great deal depends on an early start being made, and upon getting the plants into 5 or 6-inch pots early in the season. Various methods of layering are practised, and that of layering direct into 5-inch pots has much to recommend it for plants to be forced very early. If several thousands of plants are forced, a sufficient number for the earliest forcing purpose may be put into such pots. For raising the main batch of plants I much prefer putting the layers into 3-inch pots, owing to experience gained during a very wet season. Fill the pots with good loam, containing a little manure from an old Mushroom bed, and make it moderately firm. Obtain the layers from young plants set out last August if possible, as these supply the earliest and strongest runners. Secure the layers with a peg or stone, and pinch out the point of the runners beyond the layer, supplying the plants with water when necessary.

Melons.—It becomes more easy to keep up a constant supply of fruits after May is out. Young plants should be always kept in readiness to fill up vacancies as they occur. Plants bearing fruits which are now ripening should be afforded plenty of ventilation and a moderate supply of clear water. It is a great mistake to keep the atmosphere very close when the fruits are of full size and ripening. Heavily-cropped plants which are swelling their fruits and have only a limited root run, should be top-dressed, and diluted liquid manure may be applied to the roots two or three times weekly. Let the house be well charged with moisture at closing time in the afternoon.

Melons in Frames. — Keep the bottom-heat steady by re-lining the frames with manure when necessary. Top-dress the plants when the fruits have set, using a rather less rich compost than that employed for Melons in houses, as strong growths cannot be easily checked, but liberal feeding can be done later if it is considered necessary. Continue to cover the frames at night. Pay strict attention to stopping of the Melon shoots, and to the necessary watering and syringing of the plants.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Verbenas, Tropæolums, Petunias, &c., require a rich, loamy, well-drained soil. If the soil is very light apply cow-manure, and if it is too heavy add a good proportion of leaf-mould. The plants are short-lived on hot, sandy soils. The variety Miss Willmott is of lovely pink colour. Verbena venosa is a grand autumn-flowering plant, but must be given the best treatment possible. Tropæolums of the Vesuvius type require similar treatment. Petunias require a sunny position and moderately rich soil. Koniga variegata should not be planted in very rich soil, or the variegation may disappear. K. maritima minima is a good plant for the forming of a groundwork below other plants.

Dahlias and *Salvia patens* raised from seed, cuttings or tubers may now be planted in mixed borders, or the Dahlias may be planted in a quarter devoted to Dahlias. The ground must be deeply dug and liberally manured. Afford a substantial stake to each plant and secure them at once by ties. Salvia patens has the defect of dropping its flowers on poor soils, therefore requires considerable manure.

China Asters and *Stocks* require moderately rich soil. Preserve as much soil as possible about the roots when transplanting them. The single-flowered Aster sinensis is a favourite for cultivation in borders and for cutting, as the stalks are of good length.

Alonsoa Warscewiczii and other varieties of Alonsoa that were pricked out in cold frames are ready for planting. They are suitable for borders and for covering ground under large plants, such as Hydrangea paniculata grandiflora.

Phlox Drummondi requires full exposure to sun, and will flower over a long period if afforded rich soil.

Nymphæas.—Now is a good time for planting Water-Lilies. The pond should be made about 1½ to 2 feet deep and be well exposed to the sun. Secure the plants in baskets, working some good loam in firmly amongst the roots. Then drop the baskets into the desired positions. Clear out all water weeds. Aponogeton distachyon, Hydrocharis Morsus-ranæ, Peltandra virginica, and Sagittaria variabilis are other water plants suitable for present planting.

Seeds to Sow.—Lobelia cardinal isand L. syphilitica can be sown now in pans containing light fine soil. Cover the seed thinly, and place them in a temperature of 60° or so. Both varieties are capital plants for the bog-garden. Seeds of Campanula pyramidalis and Humea elegans may be sown.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

The Fig.—To prevent overcrowding the trees should be freely disbudded at this season, rubbing off with the finger and thumb young shoots which will not be required. The leaves being of large size, much space is needed between the shoots in order that the leaves of one shoot may not shade those of another, otherwise there will be only a poor crop next year. "Stopping" will also need to be carried out. When a shoot has made five or six perfect leaves pinch out the points, and the resulting outgrowths from this pinching should produce next year's crop, except in some cases where the earlier shoots will form small fruits, which will not come to maturity this year; these may afterwards be removed entirely. Trees in restricted rooting areas and growing in calcareous soils will need considerable feeding immediately the crop of fruit is formed. In properly constructed borders and where the drainage is perfect, up to the time the fruit commences to ripen alternate waterings may be given of diluted liquid manure-water from the farmyard, and of a chemical mixture composed of three parts of superphosphate of lime and one part of nitrate of potash, applied at the rate of 2 oz. per square yard. During the time the trees are actually ripening their fruits too much moisture would cause the fruits to split, and the flavour of them would be impaired.

Gooseberries.—Where large fruits of the Lancashire varieties are required, a considerable quantity of the smaller fruits, useful at this season for preserving in bottles, should be gathered. Mulch the ground about the bushes, and afford water to the roots according to requirements. The individual fruits may be increased in size by the employment of capillary attraction, which is practised by the competitive prize cultivators in Lancashire. [These growers affix a piece of lead or stone weighing ½ oz. or more to the corolla on the end of the berry. They also wind one end of a woollen thread around the stem of each fruit, the other end being placed in a bottle or basin of water or manure-water. ED.] The caterpillars of the Gooseberry Sawfly may be removed by hand-picking. Hellebore powder or tea should only be applied at this season if the attacks are serious.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Runner Beans which have been raised in pots or boxes should now be planted out, affording to each plant a stake, which will support it until fresh roots are made, and other sticks are applied. Climbing plants grow most quickly when they find early means of support. When the work of planting has been completed afford a good watering, and repeat this when it becomes necessary to do so. Seedlings in the open should be thinned until the plants are 9 or 10 inches apart from each other

Tomatos should now be planted, preferably against a warm wall, and each plant kept to a single stem, pinching out the side growths as soon as they appear. The soil in which they are to be planted should be somewhat poor, but when the plants have set a good crop of fruit they may be fed freely with advantage.

Turnips.—Sow seeds on a north or east border, a cool position being most suitable after this date. If the Turnip fly is troublesome dust the plants with dry wood-ashes, when the revolving sprayer cannot be applied. The wood-ashes will also act as a good fertiliser.

Small Salads.—Maintain a constant supply by sowing seeds at frequent intervals. Radishes soon become soft and spongy in hot weather. Mustard and Cress in like manner soon become useless, whether sown indoors or in the open. To have them in use together the cress should be sown two days earlier than the Mustard.

Coleworts.—During early autumn, winter, and spring these are amongst the most useful greens or small-headed Cabbages, being very hardy. They may be planted much closer together than Cabbages are put. The variety London Rosette is the one usually grown, but the hardy green Colewort, when sown at the end of June or in July, will continue to grow well into the winter, and may be planted at 1 foot apart each way.

Asparagus-beds.—Plants which have come into bearing this year for the first time should now be allowed to develop their growths, and thus make good crowns for affording a crop next season. The Asparagus-manure supplied by Messrs. Willis Bros., Harpenden, if used according to directions, at the rate of half a pound to the square yard, when cutting is finished, and again in the autumn, will be found to considerably increase the vigour of the plants.

THE APIARY.

BY CHLORIS.

Metal Dividers and Foundation.—Last autumn a shopkeeper invited me to inspect a crate of sections which he had purchased just as it had

FIG. 153.—METAL DIVIDER.

been taken from the hive. He had been endeavouring to get a good section out without damage to it or its companions, but had failed. He now asked me to give him a little assistance. No one would believe how tightly they were sealed in with propolis, and to add to this no separators had been used. After a good deal of trouble we got the sections out; but what a messy task it proved! Honey everywhere, but only three or four sections were really fit for sale. The quality of the honey left nothing to be desired, but for the sake of saving a few coppers the contents of the crate had been spoiled. The appearance of the sections left much to be desired, and appearance goes a long way when one desires to sell an article.

Best Kind of Separators to Use and their Price.—There are three kinds of dividers on the market—1, wooden; 2, tin; 3, perforated zinc. Those of wood are cheapest as far as prime cost is concerned, but they are not durable, so they cannot be considered economical, although they cost but a halfpenny each. Those of tin or perforated zinc are about a penny each, are slotted, very durable, as with care they will last years.

Foundation.—When fitting up sections use full sheets of extra thin "Weed" foundations, avoiding all cheaper makes as you would poison. Weed foundations cost about 3*s.* 2*d.* per lb., but if you have preserved your own wax the makers will convert this into super foundation at 1*s.* per lb. It is penny wise and pound foolish to use starters in place of full sheets.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JUNE 12—Bank Holiday.
THURSDAY, JUNE 15—Linnean Society Meets.
FRIDAY, JUNE 16—Royal Botanic Society, Lecture. Gardeners' Royal Benevolent Institution, Annual Festival Dinner at Hôtel Metropole.

SALES FOR THE WEEK.

WEDNESDAY NEXT—
Palms, Begonias, Ferns, Geraniums, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.
FRIDAY NEXT—
Fruit and Market Garden, with Residence, Lodge, Two Cottages, Glass, &c., well planted, at Laindon Hills, Essex.—The Nurseries, Wick, Littlehampton, 8 Acres, 10 Greenhouses, Model Block of Buildings, 3 Cottages, fully stocked.—Freehold Estate, 9½ Acres, 15 Greenhouses, Outbuildings, &c., Orchard well planted, at Chigwell Row, Essex. Sale at The Mart, E.C., by Protheroe & Morris at 2.—Orchids in large variety, at 67 and 68, Cheapside, by Protheroe & Morris, at 12.30.
(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —60·5°.
ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, June* 7 (6 P.M.): Max. 55°; Min. 47°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June* 8 (10 A.M.): Bar., 30; Temp., 60°. *Weather*—Dull.

The Sale of Poisonous Compounds used in Agriculture, etc.

A DEPUTATION waited on the President of the Board of Agriculture on the 24th ult., to complain of the monopoly which "chemists" have as regards the sale of these substances. At the deputation Mr. RICHARDS is reported to have spoken as follows:—

Mr. G. H. RICHARDS, manufacturer of XL-All Insecticide, said: "In 1892 I experimented with nicotine, and found it was a very valuable insecticide. I then saw one of the large manufacturing chemists, Messrs. THOMAS WHIFFEN, and approached them to see if they could manufacture nicotine in this country. After some delay they obtained permission to manufacture nicotine from tobacco in bond. I then introduced nicotine insecticides to horticulturists and the trade generally, and they found them superior to anything else, and they put them in their catalogues. I have now 2,500 agents selling these insecticides, and it sometimes happens that one of these agents is dropped upon by the Pharmaceutical Society for selling these preparations. I may say that until these insecticides were proved to be so successful, the chemists took little or no notice of the nurseryman selling them, but as soon as they saw the insecticides were successful, they urged upon the Pharmaceutical Society to take up prosecutions, and these have been going on for the past two or three years. Last year I introduced an insecticide to the Hop-growers in Kent, and though it is a little more expensive, the Hop-growers who have used it say that it will save them a considerable amount of money, as one or two sprayings is equal to many sprayings with other insecticides."

From the same source we learn that the President, in replying to the deputation, made the following amongst other remarks:

"The only thing you ask for is that the monopoly that the chemists have got should not go on, but that others should be allowed, with proper safeguards, to sell these sheep-dips and other things. You will remember that at Sir HERBERT MAXWELL'S Committee there was evidence given from this Board by Mr. CRAWFORD, and he said plainly that the Board of Agriculture was of opinion there should be no monopoly as regards the sale of these preparations for use in agriculture, such as weed-killers, sheep-dips, &c., where such articles contain poisons in the Schedule of Pharmacy Act, 1868. That was the view taken by this Board then, and I am in favour of that. I think it is wrong that there should be a monopoly in important things like sheep-dips, which, as Mr. CONNELL has said, are wanted so much in Scotland, and will be wanted much more in the future. I think other people should have the right to sell them with proper safeguards. But I would say this, some regulations are necessary for the protection of the public from these poisonous and dangerous compounds, and I think the person who sells them should have a licence from the local authority, necessitating that they should be sold in the same condition as received from the manufacturers, the bottles and packages to be unopened and to have some indication as to their contents. I think that is a safeguard that ought to be given to the public, and I do not think there would be the slightest damage to anybody concerned. As regards a Poisons Bill, I believe there is a Bill on the lines as recommended by Sir HERBERT MAXWELL'S Committee—I believe it is in preparation now. Mr. FITZROY, of the Privy Council, is here now, and I will take an early opportunity of speaking to him on the matter, so that we may do what we can to push it forward."

No amount of legislation can entirely prevent careless, stupid, or wicked people from obtaining, distributing, or making improper use of these poisonous substances; but in the interests of the public it is, as the President remarked, most desirable that every reasonable precaution should be taken to ensure against accident. The sale of poisons, like that of firearms or explosives, needs to be fenced in with precautionary restrictions. We cannot say that up to the present the precautions have been adequate. Insecticides, ant-killers, weed-killers, and similar substances are sent to us, and they are advertised habitually, without the slightest indication of their poisonous character. All such compounds or substances, intended for use in agriculture or horticulture, should be distinctly labelled POISON, and the name of the seller should be attached to each package, large or small. If these and other obvious precautions were taken, and the law strictly obeyed, there would be no reason why the nursery and seed trade should not be licensed to sell POISONS. The deputation assured the President that the precautions above mentioned were actually taken.

BERLIN BOTANICAL GARDEN (see Supplementary Illustration).—The new botanical garden in Dahlem, a few miles south of the town of Berlin, is about 100 acres in extent. It was started about ten years ago on a treeless, undulating site, miles away from factories, and since then over £250,000 have been spent on its construction, whilst probably as much more will be required to complete it. Dr. ENGLER, under whose direction the work is being carried out, has turned to good account the undulating, almost hilly character of the ground by constructing miniature ranges, which are said to be faithful imitations of the Pyrenean, Scandinavian, Carpathian, Balkan, Caucasian, and Himalayan groups, each group being planted as naturally as possible with the vegetation peculiar to it. The arrangement of rocks, gullies, slopes, swamps, &c, is most ingenious, and where the climatic conditions are favourable the plants are most satisfactory. The Rocky Mountains, the plains of California, the South African veldts are also represented, as are the high elevations of China and Japan. In the summer, geographical groups of plants in pots and tubs are arranged to represent the characteristic floras of tropical and subtropical regions, such as Central America, Australia, the Canary Islands, &c. It will be seen that the scheme of the garden is a most ambitious one. Generally the effect is pleasing as well as instructive, but, as is to be expected, some of the groups cannot possibly be made to look well. Two of the most successful hits of alpine gardening are represented in the Supplementary Illustration. Time is needed to enable Dr. ENGLER and his staff to make a selection of plants suitable for the purpose, and at the same time capable of cultivation in the conditions provided. No such attempt at geographical gardening has ever been made before, and we heartily congratulate all concerned on the success of the scheme so far as it has gone.

LINNEAN SOCIETY OF LONDON.—There will be a meeting on Thursday, June 15, at 8 P.M., when the following papers will be read: 1, "Biscayan Plankton, Part VI., Colloid Radiolaria," by Dr. R. N. WOLFENDEN, F.L.S., &c.; 2, "Biscayan Plankton, Part VII., Mollusca," by Dr. P. PELSENER; 3, "Longitudinal Nerves and Transverse Veins in Bamboos," by Sir D. BRANDIS, K.C.I.E., F.R.S., &c.; 4, "Some Indian Undershrubs," by Sir D. BRANDIS, K.C.I.E., F.R.S., &c.; 5, "Notes on a Skeleton of the Musk Duck, Bizuria lobata," by Mr. W. P. PYCRAFT, A.L.S., &c.; 6, "Note on the genus Widdringtonia," by Dr. MASTERS, F.R.S. Exhibitions: "Arum maculatum in relation to Insects" (with lantern-slides), by Rev. J. GERARD, S.J., F.L.S., &c.

THE FROSTS ON MAY 21 AND 22.—We have received several additional letters describing the injury done to garden crops, especially in the Midland Counties, on May 21 and 22. Mr. W. MILLER, Berkswell, Coventry, whose letter, written on May 21, was published in our issue for May 27, states that had he waited until the next day he would have had to relate damage of a much more serious nature. Mr. J. W. MILES, Blenheim Gardens, Woodstock, states that 4° Fahr. of frost was registered in that garden at 5 feet above ground, and 8° Fahr. of frost on the ground line. Considerable injury was done. A letter from Mr. WORSLEY, Isleworth, published on p. 362, speaks but poorly for a good fruit season.

PRESENTATION TO MR. HENDERSON.—Mr. HENRY HENDERSON, gardener at Cromarty House, Ross-shire, having been appointed estate manager to Mrs. BALFOUR, of Dawick Stoho, was recently entertained at the Cromarty Arms Hotel, when a presentation was made to him.

PRESENTATION TO MR. J. G. WESTON.—Mr. J. G. WESTON, who has been gardener to Lord DUNCANNON, Bessborough, Piltown, Ireland, for the past eight years, has lately removed to Eastwell Park, Kent, where he has been appointed gardener to H. J. KING, Esq. Before leaving Bessborough Mr. WESTON was presented with an illuminated address and a pair of silver flower-vases by the heads of departments on the estate, and other presentations were made by friends in the locality. Mr. WESTON gained his experience at such well-known and efficient garden establishments as Hatfield, Childwickbury (St. Albans), and Mentmore. He was inside foreman for three years at Childwickbury, and for three years and a half was foreman at Mentmore. Those who were present at the Gardeners' Dinner in 1903 may remember the tribute Lord DUNCANNON then paid to his gardener, Mr. WESTON, who had carried out many improvements in the gardens at Bessborough, and won distinctions at the fruit show held at Cork in 1902, and other horticultural exhibitions.

Presentation to Mr. Leonard Sutton.—On the 26th ult. the members of the Reading and District Gardeners' Mutual Improvement Association visited the Reading University College Gardens, and were escorted through the departments by Mr. Chas. Foster. We have on previous occasions referred to the excellent condition of these gardens under Mr. Foster's management, and to the superior vegetable and other crops that are raised there; it is not surprising therefore that the 150 members of the Association were much pleased with all they were shown. Occasion was taken of this meeting to make a presentation to Mr. Leonard Sutton, President of the Association. The presentation was a silver centre-piece, suitably inscribed, and accompanied by an illuminated address. The address was designed to represent the four seasons of the year, Spring being represented by Star Cinerarias, Summer by Gloxinias, Autumn by Chrysanthemums, and Winter by Star Primulas. At the foot was a water-colour drawing of Hill Side, the residence of Mr. Sutton. In the wording of the address the presentation was described "As a slight and very sincere token of our great respect and appreciation of your [Mr. Leonard Sutton] kind services as President [of the Society] since January, 1902," &c. Appended were the names of 200 subscribers. Mr. Sutton had no previous knowledge of the presentation, and in a few words expressed his great surprise and gratification. Speeches were also made by Mr. A. W. Sutton, Mr. Stanton, Mr. Powell, Mr. T. Neve, Mr. W. Barnes, Mr. H. G. Cox (Secretary), &c.

"Botanical Magazine." — The plants figured in the June number are the following:—

Nepenthes Rajah, Hook. fil., t. 8017. — Discovered by the late Sir Hugh Low, and introduced into Messrs. Veitch's Chelsea nurseries by Mr. Burbidge. See *Gardeners' Chronicle* (1881), ii., p. 493, fig. 91.

Erica lusitanica, Rudolph, t. 8018. — See E. codonodes in *Gardeners' Chronicle* (1877), p. 463, f. 70; and (1896), i., p. 487, t. 74. Naturalised at Lytchett Heath, near Poole, Dorset, where it reproduces itself by seed, so that, according to the Hon. Mrs. Evelyn Cecil, between one and two acres of ground are covered with thousands of bushes.

Rhabdothamnus Solandri, A. Cunningham, t. 8019.—The curious New Zealand Gesneread, figured from Mr. Gumbleton's garden in *Gardeners' Chronicle, March* 11, 1905, p. 146.

Lycaste Locusta, Reichenbach fil., t. 8020.—See *Gardeners' Chronicle* (1879), i., 524. Flower-segments green, lip of the same colour with a white fringed border. The stalk of the pollen-masses bears on each side at the base a narrow, deeply-cleft process, the significance of which is not apparent. Native of Peru.

Bowkeria Gerardiana, Harvey, t. 8021. — See *Gardeners' Chronicle* (1904), ii., 398, with figure, under the name of B. triphylla.

Cypripedium Chamber-Leeanum. — The system adopted in naming plants of hybrid origin sometimes leads to odd combinations, as in the case of the hybrid obtained by the late Edward Pynaert by fertilising C. Chamberlainianum with the pollen of C. Leeanum. Written without the mark of hybridity (×) the reader might well imagine the name was misspelt.

Annuals. — The second pamphlet of the "One and All" garden series, edited by E. O. Greening, is entitled *Annuals*. Information about this large and useful class of plants is always useful, and the paper before us is illustrated. Mr. T. W. Sanders is responsible for the letterpress. The pamphlet has already reached its second edition.

Flowers in Season.—Messrs. James Veitch & Sons send us from their Combe Wood Nurseries a large selection of cut specimens of flowering shrubs, among which we note Styrax Obassia, a handsome shrub with large white, pendulous, bell-shaped flowers, and bold foliage; Osteomeles anthyllidifolia, a Rosaceous shrub with a terrible name, with elegant pinnate foliage like that of a Sanguisorba, hoary on the under surface, and with terminal corymbs of white Cratægus-like flowers; Chionanthus retusus, an Oleaceous shrub with shining foliage, and loose, pendulous panicles of elegant white flowers with narrow petals; Cornus Kousa, a Japanese species with large white or pink bracts surrounding the flowers; numerous varieties of Philadelphus, double and single, including "Manteau d'Hermione," "Boule d'Argent," P. grandiflorus, &c.; Magnolia Watsoni, handsome alike in foliage and flower, the latter with a fragrance so powerful as to render it unsuitable for indoor decoration; M. tripetala, M. parviflora, M. Soulangeana, Carpinus cordata, with handsome foliage and hop-like spikes of female flowers, together with other rarities and beauties too numerous to be recorded.

The "Eckford" Testimonial.—The contributions to this fund up to the evening of Saturday, June 3, amounted to the sum of £38 15*s*.

Eremurus.—Madame Olga Fedtschenko has lately described, in the *Bulletin* of the Boissier Herbarium (tom. iv., 1904, p. 771), three new species of this genus which have been collected in Central Asia. Madame Fedtschenko herself collected some of the species, and cultivates some ten of them in her garden at Olguino, near Mojaïsk, prov. Moscow. The three new species above alluded to are E. Korshinskii, E. comosus, and E. lactiflorus; of the last mentioned an illustration is given.

The Pear Midge.—We have already published information on this subject in the *Gardeners' Chronicle*, and we now note that a pamphlet has been issued on the Life-history of the Pear-midge (Diplosis pyrivora), by Walter E. Collinge. The publishers are Messrs. Cornish Bros., Ltd., Birmingham.

The Pagoscope —Some time ago we called attention to this instrument as an indicator of the probable occurrence of frost even at a time when the thermometer is several degrees above the freezing-point. We advert to the subject again for the purpose of suggesting to the manufacturers that the water-cistern is too shallow, and that it is placed on the hinder side of the instrument, instead of in front, where it would be more accessible. If it were attached to a post, and not against a north wall, this objection would not apply.

A "Country-in-Town" Exhibition.—A very full attendance gathered at the first meeting to consider the proposal to hold an exhibition in the East End, intended to demonstrate what can be done towards the conversion of London into a garden city, or, at all events, a city of gardens. The meeting was held in the council room of the Agricultural and Horticultural Association, Long Acre, with Canon Barnett in the chair. Letters of hearty approval from many representative men and women were read by Mr. Edward Owen Greening, who acted as convener of the gathering. Mr. Joseph Fels, who has given the free use of a farm to the "unemployed" committee, sent with his approval an official report of a successful association in Philadelphia which takes in hand vacant lots of land in that city pending their requirement for building purposes, and converts them into gardens, some beautiful, and some profitable. It was resolved to hold an exhibition during the second week in July at the Whitechapel Art Gallery, kindly lent by the trustees for the purpose. The exhibition will include models, photographs, and designs of roof-gardens, streets and frontages beautified with trees and house climbers, forecourts and back-yard gardens, waste-grounds converted from barrenness, window-boxes, climber-clad porches, archways and screens, small greenhouses and summer-houses, rockeries and grottoes, suburban allotments, railway-stations and embankments rendered pleasant with shrubs and flowers, and views of towns at home and abroad where successful floriculture has been made to brighten the life of cities. The Hon. H. A. Stanhope was elected President. About twenty-five names were nominated for the first council, and a working executive of ten elected, with Canon Barnett as Chairman, and Mr. E. O. Greening as Vice-Chairman. Mr. Campbell Ross and Mr. E. O. Greening were elected Honorary Secretaries.

Guides on Sale at the Royal Botanic Gardens, Kew.—In compliance with a request from the Director, we have pleasure in publishing the following particulars in reference to the publications issued at Kew, the prices of which have in most cases been reduced:—

Key Plan and Index to the Royal Botanic Gardens, Kew. 6th ed. 1904. Price 2*d*. By post 2½*d*.

Official Guide to the Museums of Economic Botany. No. 1: Dicotyledons and Gymnosperms. [Under revision.]

Official Guide to the Museums of Economic Botany. No. 2: Monocotyledons and Cryptogams. 1894. Price 4*d*. By post, 5*d*.

Official Guide to the Museums of Economic Botany. No. 3: Timbers. 2nd ed., revised and augmented. 1893. Price 3*d*. By post, 4*d*.

Official Guide to the North Gallery. 5th ed., revised and augmented. 1892. Price 4*d*. By post, 5½*d*.

Hand-list of Trees and Shrubs grown in Arboretum [excluding Coniferæ]. 2nd ed. 1902. Price 10*d*. By post: Inland, 1*s*. 2*d*.; Foreign and Colonial, 1*s*. 5*d*. Part II. [1st ed..] Gamopetalæ to Monocotyledons. 1896. Price 8*d*. By post, 10½*d*.

Hand-list of Coniferæ grown in the Royal Gardens. 2nd ed. 1903. Price 3*d*. By post, 4½*d*.

Hand-list of Trees and Shrubs [2nd ed.] and Hand-list of Coniferæ [2nd ed.] in one volume, cloth boards. Price 1*s*. 7*d*. By post: Inland, 1*s*. 11*d*. Foreign and Colonial, 2*s*. 2½*d*.

Hand-list of Ferns and Fern Allies cultivated in the Royal Gardens. [Under revision.]

Hand-list of Herbaceous Plants Cultivated in the Royal Gardens. 2nd ed. 1902. Price 1*s*. 9*d*. By post: Inland, 2*s*. 2*d*.; Foreign and Colonial, 2*s*. 6½*d*. Cloth boards, price 2*s*. 6*d*. By post: Inland, 2*s*. 11*d*.; Foreign and Colonial, 3*s*. 3½*d*.

Hand-list of Orchids Cultivated in the Royal Gardens. 2nd ed. 1904. Price 8*d*. By post, 10*d*.

Hand-list of Tender Monocotyledons cultivated in the Royal Gardens. 1897. Price 8*d*. By post 10½*d*.

Hand-list of Orchids [1st. ed.] and Hand-list of Tender Monocotyledons, in one volume, cloth boards. Price 1*s*. 6*d*. By post, 1*s*. 10½*d*.

Hand-list of Tender Dicotyledons cultivated in the Royal Gardens. 1899. Price 1*s*. 8*d*. By post: Inland 2*s*.; Foreign and Colonial, 2*s*. 1*d*. Cloth boards. Price, 2*s*. 2*d*. By post: Inland, 2*s*. 6*d*.; Foreign and Colonial, 2*s*. 7*d*.

Mycologic Flora of the Royal Gardens, Kew. 1897. Price 4*d*. By post 5*d*.

Money Orders to be made payable at the Kew Post Office to W. Watson, Curator, Royal Botanic Gardens, Kew.

Guide-books Received.—We notice on our table the Great Eastern Railway Company's *Tourist Guide to the Continent*, edited by Percy Lindley. The book is illustrated and contains maps, and several new features are introduced, making this edition still more interesting than those preceding it. We should suggest that the reprinted letterpress be revised on the occasion of the publication of the next edition: there is, for instance, no longer a "comfortable little Hôtel Tête d'Or" in the Rue de Lille at Ypres, nor has there been one for some few years past.

—— The London and South-Western Railway forward an official *Illustrated Guide and List of Hotels, Boarding Houses, Apartments, and Business Houses*, that should prove very useful to intending travellers in the direction indicated. A map accompanies the publication, which treats of many beautiful and interesting localities.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

APRIL AND MAY FLOWERS IN THE SOUTH-WEST.—The disastrous gale of the last day of April (which blackened all the young foliage) and the drying, easterly winds and absence of rain experienced for some weeks were adverse to vegetation, but nevertheless spring flowers have afforded a bright display. Clianthus puniceus, on a south wall, has been a blaze of crimson, and its white variety has also flowered well. Neviusia alabamensis, which was much written about some twenty years ago, but is now rarely met with in gardens, produced its curious flowers, entirely lacking petals, and with crowded white stamens set in green bracts. The single Kerria, far rarer than its double variety, has borne its orange-coloured flowers and Rhodotypos kerrioides its white blossoms. Among the other flowering shrubs that have been in bloom during the past two months the most noteworthy have been Veronica Hulkeana, at its best in mid-May, a plant over 5 feet in height and 7 feet across, growing against a wall, and bearing over 200 flower-sprays, some of them 2 feet in length. It was a perfect cloud of lavender, a most beautiful sight. A bush of Dimorphotheca Ecklonl, 4 feet in height and 5 feet through, which has been unprotected in the open for the last two winters, is now charming in the sunshine with its countless white, violet-scented flowers. Olearia nitida is so completely covered with its clusters of white, Hawthorn-like blossoms that scarcely a leaf is visible, and is a very showy shrub; but O. argophylla, also in bloom, suffers by comparison. Solanum aviculare is bearing the first of its lavender-purple, golden-centred flowers, 2 inches across, to be followed by yellow, egg-shaped fruits; and S. crispum has been smothered in bloom for the past three weeks. Weigela (Diervilla) Conquete is a fine variety, bearing pale-pink flowers quite 2 inches in diameter. Another very pretty shrub is Deutzia kalmiæflora, which has borne its flesh-coloured, rose-edged blossoms in profusion. Helianthemum formosum, formerly Cistus, is daily expanding its bright-yellow, maroon-blotched flowers, and the rare Cistus ladaniferus maculatus (true) has opened its great white claret-spotted blooms fully 5 inches across. Of Calceolariss the charming C. violacea and C. Burbidgei are now in flower. Towards the end of April the beautiful pale sulphur-coloured Gladiolus tristis was in bloom. The scent emitted by the blossoms at night is delicious. It increases rapidly by bulblets, and also by seed, which is freely produced. In Mr. Archer-Hind's garden I noticed hundreds of seedlings coming up around the old clumps. In a noted Cornish garden I have seen this Gladiolus nearly 5 feet in height, but with me it rarely exceeds 3 feet. Ixiolirion montanum has been lovely for the past fortnight. It is an improvement upon I. tataricum, which is growing close by. Its flower-spikes reach a height of 28 inches, while those of I. tataricum rarely exceed 18 inches. Its flowers are larger and more freely borne, twelve often being carried on the same scape, while I. tataricum seldom bears more than six, and is a fortnight later in flowering. The Sparaxis and Ixias have been very gay, S. Fire King, scarlet with yellow eye, being especially brilliant. Homeria collina has been lovely, and Camassia Leichtlini, over 4 feet in height, has had a telling effect with its ivory-white flowers, while the curious Feather Hyacinth (heliotrope-blue) imparts a pleasing colour to the border. Rosa xanthina, syn. R. Ecæ, is bearing its yellow flowers; enormous clumps of Libertia formosa, 5 feet in height and over 6 feet through, are holding aloft hundreds of white flower-wands; Ranunculus myssanus has been very bright, and Rehmannia angulata is bearing its deep rose-coloured Gloxinia-like blossoms. Bushes of Agathæa cœlestis have been blue with flower for many weeks, and will bloom well into the winter, as will Erodium pelargonifolium, which here is in flower for nine months out of the twelve. Linum narbonense has commenced to show its clear blue colour; Anthericum liliastrum giganteum, its spikes of pure white blooms, the first of the Day Lilies; Hemerocallis flava is in flower, and the earliest of the Peach-leaved Campanulas, Backhouse's variety, has opened its great white bells. This fine plant unfortunately proves to be of tender constitution, scarcely increasing at all, being very different in this respect from the vigorous, semi-double C. Moerheimi, another excellent variety. Of dwarf plants Androsace lanuginosa, over 3 feet across, is smothered in blossom, and Æthionema pulchellum hard by is blooming freely. Phlox divaricata is beautiful with its grey-blue flowers, and other dwarf Phloxes, such as the Bride, Vivid and nivalis are very pretty. Antirrhinum glutinosum and A. asarinum, hanging over rocks, are displaying their white-and-sulphur flowers, and the Sun-Roses, especially the double crimson, are very bright. Early in April Shortia galacifolia was charming and is now followed by Ourisia coccinea holding dozens of its bright scarlet flower-spikes, and by the Ramondias, growing in the chinks of the rocks, over which Arenaria balearica spreads a tracery of green, spangled with countless tiny white stars; and A. montana hangs its larger flowers. Anemone ranunculoides has borne its yellow blossoms, the orange Lithospermum hirta and the deep-blue L. prostratum are in full flower; the dwarf Aster Stracheyi, earlier and larger than A. alpinus, is in profuse bloom; Dianthus Emilie Paré is crowded with salmon-pink blossoms, and a large patch of the pretty Daisy Alice is covered with dozens of its quilled blooms. Viola cucullata alba was at its best three weeks ago; but Sisyrinchium bermudianum is in full flower, and Morisia hypogæa is bright with its yellow blossoms, and in a damp spot Claytonia sibirica is flowering. Arctotis aureola robusta, growing at the top of a retaining wall, is bearing a number of deep orange flowers nearly 4 inches across, and A. aspera arborescens, close at hand, is also in bloom, as are Gazania longiscapa, 3 feet across, brilliant in the sunshine, Ajuga Brockbanki, and the little night-scented Stock, Hesperis tristis. Of Saxifragas, Guildford Seedling has been fine, and S. Macnabiana, S. longifolia, S. pyramidalis, and others are in flower. Tropæolum pentaphyllum has opened its first blooms; and three annuals, that invariably spring up from self-sown seed—Collomia coccinea, Omphalodes linifolia and Calceolaria mexicana—are coming into bloom. *S. W. Fitzherbert, Cornwall.*

THE WEATHER AND THE FRUIT CROPS.—The month of May, fine enough from a meteorological point of view, proved to fruit-growers one of the most disastrous months in my memory. The strong southerly gale of May 1 irretrievably bruised and twisted the fruit-stems of the better sorts of Pears, and the drought, hot sun, cold winds, and arid air, which prevailed through the rest of the month, wrought sad havoc among Plums and Cherries. As a result it is now certain that in this district there will be a shortage of all the best kinds of large fruits, although common Apples promise well. Among small fruits the prospect is not so bad. Strawberries and Raspberries will be generally small, although the former may be a large crop. Currants of all kinds promise well, as is also the case with the Loganberry. In general the fruit crops will not be appreciably better than they were in 1903, which was one of the worst years on record in West Middlesex.

Table of Averages (Normal Crop being estimated as 100).

Wall Peaches, Nectarines, and Apricots ...	120
Orchard Peaches, Nectarines, and Apricots ..	5
Wall Pears and Plums	5
Orchard Pears (dessert)...	5
Orchard Pears (common sorts)...	40
Orchard Plums (dessert)	10
Orchard Plums (common sorts)	25
Orchard Cherries...	5
Wall Cherries (Morello)...	90
Orchard Apples (dessert)	50
Orchard Apples (cooking)	120
Orchard Quince	140

A. Worsley, Mandeville House, Isleworth, Middlx.

A DRY MAY.—On May 1 I registered 0·08 inch of rain; on the 2nd the same amount was recorded, and on the 3rd it was 0·12 inch—a total of 0·28 inch. From then until the end of the month we had twenty-eight consecutive rainless days, when not a trace could be found in the gauge. On June 1, 0·02 inch was recorded; the same on the 2nd; on the 3rd 0·01 inch, and 0·02 inch on the 4th; while at the time of writing all promise of the much-needed downfall seems to have failed us. This is only 0·35 inch for 35 days, and upon all the lighter soils the outlook is most serious. Some growers in this district will commence gathering Peas in a few days, and it is apparent the crop will be a very short one, though a considerable acreage is devoted to this vegetable in the Vale of Evesham. The heavy soils show less effects of the drought where they have been thoroughly cultivated, but even upon them the strain is beginning to tell severely upon both fruits and vegetables. For cleaning foul land the season is an ideal one, but all spring-planted trees are passing through a great ordeal. Surface cultivation, mulching, and even watering have had to be resorted to in many places. *R. L. Castle, Evesham, June 3.*

—— Since writing the preceding remarks the long-desired rain has reached us. We have had a steady continuous downpour, which has already exceeded half an inch. The rain has improved prospects greatly. *R. L. C.*

SCHIZANTHUS WISETONENSIS.—For making an effective as well as an economical display in the greenhouse during the spring and summer seasons, there are few plants that can compare favourably with this. It is invaluable for decorative purposes, especially to the small amateur gardener, as from a pinch of seed sown in the early part of the year plants can be easily grown that will give a very charming effect for a long period. In the horticultural tent at the Somerset Agricultural Show, held at Bath on May 9, Messrs. James Garaway & Co., of Clifton, exhibited a magnificent group of hybrids, in producing which the variety wisetonensis had evidently been largely used. Not only were these plants well grown and of good bushy habit, but the individual flowers were larger and rounder than those of the variety mentioned, while the colours were exceedingly varied, and exquisite in tone, varying from purple-and-gold, mauve, rose, pink, and creamy-white. I understood that Mr. W. H. Bannister, of Ote House Gardens, Westbury-on-Trym, was the fortunate hybridist. If so he is to be congratulated. *T. Challis, Wilton House Gardens, Salisbury.*

EREMURUS.—Three years ago, I think, Mr. Wallace, of Colchester, gave me the tuber of an Eremurus which he considered to be a form of E. Bungei, but which from its early flowering he proposed to call E. Bungei præcox. The plant is now well established with me. So far as I can see it differs in no specific way from E. Bungei, and yet it flowers regularly very early, at about the same time as E. robustus. The name, therefore, seems quite justified. It is a grateful addition to the garden, and may serve as the means of giving us interesting hybrids. *M. Foster, Shelford, June 5, 1905.*

THE KEW GUILD.—I observe that in the report of the dinner of the Kew Guild, Mr. Watson, the Curator of the Royal Botanic Gardens, is stated to have suggested that the energies and influence of the Guild should be "exerted on behalf of the less fortunate of professional gardeners, and in such a manner that their legitimate grievances might be remedied." Had I been present I should certainly have raised my voice against the Guild doing anything of the kind. I gave my approval to the formation of the Guild in 1893 in a letter which has frequently been described as its charter. I did so because I thought that it would "have the effect of consolidating the *esprit de corps* which already exists amongst our young men," and I did not doubt that this would be "of great benefit to the establishment." I think my expectation has been realised, and it is for that reason that I view with great regret a proposal that the Guild, to use its own words, should "dabble in horticultural politics." This is departing widely from its original purpose, and would, I am sure, affect its interests injuriously. The Guild from its start has never had an official character. It is a purely domestic, I might almost say a family affair, confined to those who have been attached to one

establishment. Its annual gathering I have always insisted was of a purely private character, having for its principal object the opportunity of bringing together old but often widely scattered friends, and giving the younger generation of Kew men the opportunity of seeing and making the acquaintance of the veterans. Such gatherings are common in the Army and the Universities, and their charm and value lies in their purely private character. That in the case of the Guild was destroyed when the practice began of reporting what passed in the Horticultural Press. As this seemed to me to be a breach of confidence, it precluded my being present at the dinner this year. It appears to me to be little short of absurd for those who have been connected with one establishment to arrogate to themselves the task of taking charge of the interests of the gardening profession at large. I am quite sure that Kew men would resent it if the attempt were made by those connected with one of the large horticultural firms. In my opinion it is peculiarly improper in the case of a Government establishment. Persons in Government employ have to serve under Ministers who hold widely differing political opinions. The recognised discipline of the service precludes its members from engaging in active political movements, or from airing their political sympathies. The proposed action would be embarrassing to the branch of the Government responsible for the administration of Kew, and would, I think, provoke hostility to it elsewhere. It would also, I think, be injurious to the interests of Kew men. I do not think that it would be possible to bring the scattered units of the gardening profession under the control of anything like a trades-union. If it were, I think anyone would be shy of engaging a gardener who had at his back an organisation proposing to interfere between employer and employed. I should be sorry to see the Kew certificate regarded rather as a danger-signal than as a recommendation. No one is, or has ever been, more anxious to raise "the status of gardening" than myself. But this must be done by raising the standard of competence. When the gardener is worth more he will get more. He must learn that diligent professional study and its intelligent application will in the long run land him in a better position than mere adherence to rule-of-thumb practice. *W. T. Thiselton-Dyer, Kew.* [The proceedings at the first annual meeting of the Guild, as well as of all subsequent meetings, were reported in the Press. ED.]

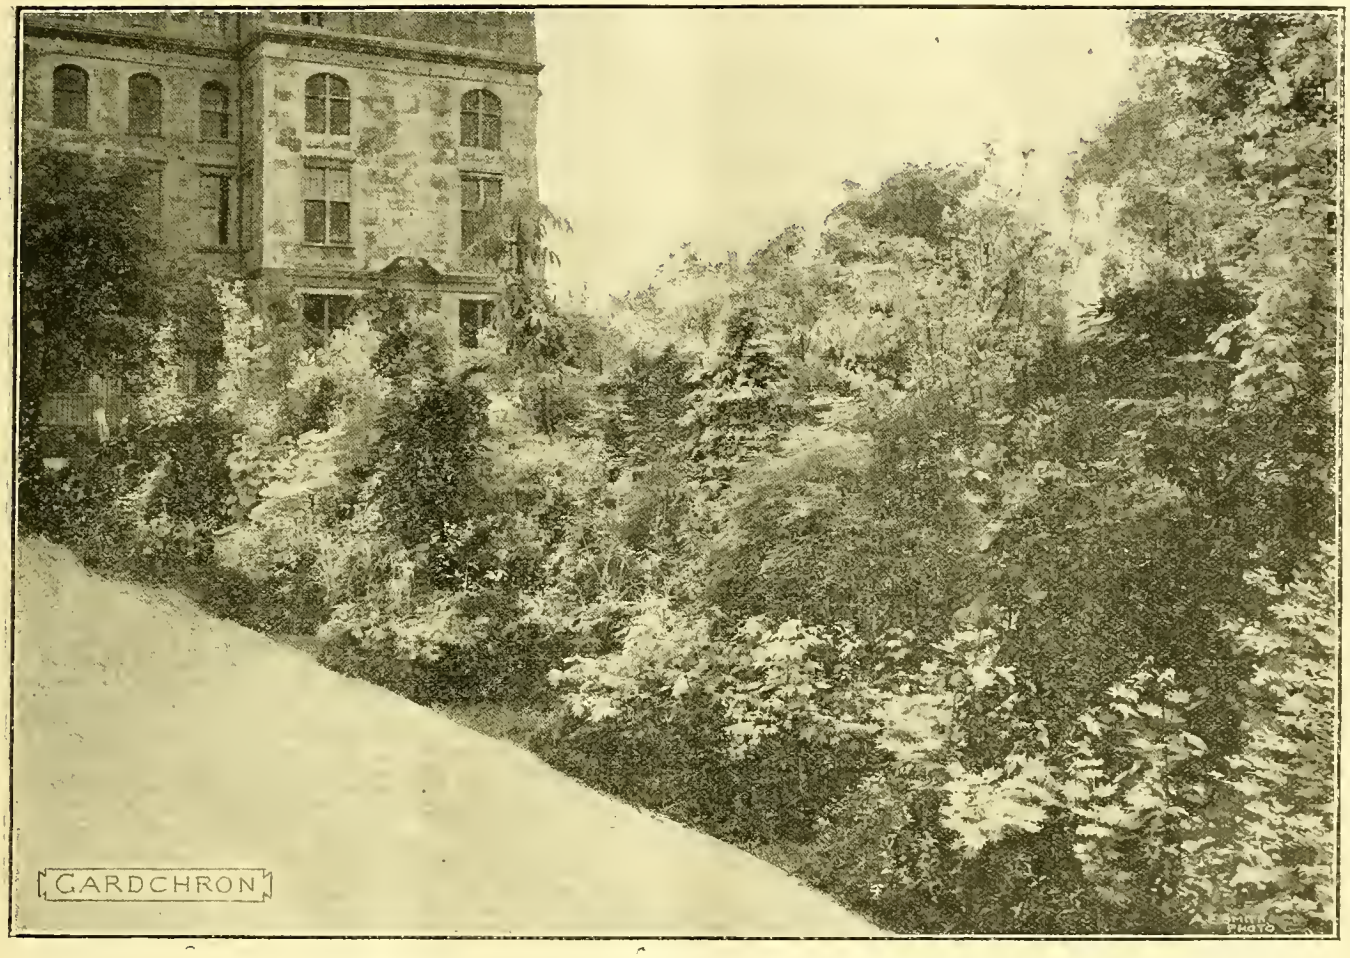

FIG. 154.—VIEW OF MESSRS. CRIPPS' ACERS AND OTHER PLANTS EXHIBITED AT THE TEMPLE SHOW AND AWARDED THE VEITCHIAN GOLD CUP FOR THE MOST GENERALLY INTERESTING EXHIBIT. (*See ante, p.* 350.)

MANURE-WATER AND PEACH-TREES.—I think that had Mr. Ward read my article on this subject with more attention than he seems to have done, he would not have penned that sentence (see p. 324) relating to the cause "of short-lived, bare, unproductive, and stunted Peach-trees that are frequently met with." Moreover, how can he assert that "this condition of the trees is put down to every cause but the right one"? My knowledge of Peach-culture in this country is not so extensive as to enable me to define a cause in every individual case, neither can Mr. Ward, without making an investigation and being afforded an account of the course of treatment pursued for a number of years by perhaps different gardeners. In my article I distinctly stated the necessity of affording sufficient moisture to the border in the period March to September. Mr. Ward begins to apply water a month earlier, but that is a matter of little moment. The Peach-borders Mr. Ward alludes to, presumably those at Longford Castle, he says faced south, south-west, west, and even east; and further on he states that the borders were hard, and faced southwards! Most of us would suppose the border of an east wall to slope eastwards, and that of a west one to slope westwards. Now a south-west border, getting the rainfall from the wettest quarter, would receive enough of the natural rainfall, not to speak of snow, to satisfy the needs of the Peach or any other trees planted on that aspect, excepting the soil were light, shallow, or very porous, when water might be demanded early in the spring and at intervals during the summer. Much would depend on the locality, the aspect of the garden, the part of the country, whether south, east, west, or north, which are matters that I touched upon briefly, which every sensible gardener would naturally take note of, and to which he would mould his practice. As for the rain only wetting the surface of a border, that state of things would not occur if the crust were kept in a loose, friable condition by occasionally pointing it over an inch or two deep with a digging-fork. I have always made use of stout planks laid in a row about 3 feet from the wall, and by this means I have kept the soil from being unduly consolidated. Most gardeners know that a lightly or uncropped tree will run to wood as a rule, if it be healthy, and to afford such a tree extra feeding is one way of increasing the evil of gross shoots and consequent unfruitfulness. Why induce grossness at all, and then use the knife for its reduction? As for my advice with regard to the use of spare manure-water, your correspondent errs in stating that I advised its use on various crops in the autumn, winter and spring, for in point of fact no season was specified. *F. Moore.* [Enough has been said on this subject. ED.]

FLORISTS' FLOWERS.

EARLY-FLOWERING CHRYSANTHEMUMS.

THE early-flowering Chrysanthemums as a section may be said to have commenced with the introduction of two varieties of the Chusan Daisy—the forerunner of the Pompon type—by Mr. Robert Fortune in 1846. They were considered by growers of the large-flowering varieties to be too small to command attention; but their merits as pot-plants were soon recognised as the varieties increased, and by 1869 the late Mr. John Salter catalogued fifteen varieties blooming from June till October.

The late Mr. William Piercy, of Forest Hill, who took great interest in the early-flowering section, held that such a group was necessary if the Chrysanthemum was to be of any service in the garden, the November varieties being in great danger of having their blooms destroyed by frost before they were well expanded. An old yellow variety named Drin Drin proved to be early-flowering, and this with a dozen or so others, apparently of Continental origin, formed the earliest group of such precocious varieties.

A remarkable advance was made when in 1879 the late Mr. Robert Parker discovered, during the summer of that year in a lady's garden in Wales, the well-known and still popular variety Mme. C. Desgranges. Mr. Parker was given two plants of it, which he increased and was able to distribute the variety. It was regarded as of French origin, and was believed to have been raised by Mons. Boucharlat. Then soon followed its sports—George Wermig (yellow) and Mrs. Burrell (primrose). George Wermig appeared the very next summer after the introduction of Madame C. Desgranges, and with remarkable simultaneity it was found to have sported in six other places. Later in time George Wermig threw a deeper yellow sport, which received the name of Mrs. Hawkins. The adoption of the Desgranges section for decorative and market purposes led to the introduction of other early forms, and now the list of those which bloom in September and October is a very long one. Continental and home raisers have vied with each other in the production of acceptable varieties, while notable additions have resulted in the character of sports.

May is the month in which it is advised that the early Chrysanthemums be planted in the open for garden decoration. But if this work has not been already carried out, anyone interested in them will still find the best results are secured by making a plantation of a selection of varieties, so as to afford an opportunity for comparison. The plan adopted by Mr. William Sydenham at Tamworth is a very good one. He has a series of beds, 12 feet or so in length and about 4 feet in width; these beds run out at a right angle from a main walk, and each bed contains three or more varieties, planted in threes or half-dozens. There is of course a narrow path between each pair of beds. As Mr. Sydenham is an early-Chrysanthemum specialist, he has an extensive collection of varieties; and as in planting-out he observed an alphabetical arrangement, he had varieties of tall growth and later in flowering in juxtaposition with those of quite dwarf habit and early to bloom; the effect as a whole was confusing, and the tall growers hid from view the dwarf, compact plants.

If the soil in which the plants are to be placed has not been previously dug over and manured, it should be deeply loosened and some well-decomposed manure worked into it. Many of the dwarf early-flowering September and October varieties are of a free-branching growth, and the plants should have ample space in which to develop; 3 feet apart each way is not too much.

Some of the best dwarf varieties which bloom in August, September, and October, will be found in Bobby (white with pink lines), Carrie (deep yellow; a perfect gem), Goacher's Crimson (bright chestnut-crimson), Doris Peto (pure white), Horace Martin (deep yellow), Jimmie (crimson-purple), Kitty (a very pleasing shade of pink), Mme. Marie Masse (lilac-mauve), Market White (white), Mrs. A. Willis (yellow, striped red), Mrs. Mollinson (bright bronzy-yellow), Mytchett Pink (pink), Mytchett White (white), Norbet Puvrez (golden salmon), Polly (deep orange and amber), and Satisfaction (ivory-white). The foregoing vary in height from 1 foot to 3 feet.

Among the Pompon varieties are several which bloom as early as June, and in July and August; they are generally dwarf and make charming bushes heavily laden with blossom, so free are they generally. *R. D.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

MAY 23.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair), Rev. W. Wilks, M.A., Professor Boulger, Dr. M. C. Cooke, Messrs. Saunders, Güssow, Worsdell, Massee, Douglas, Worsley, Holmes, and Chittenden (Hon. Secretary).

Shoots of Yew injured.—Dr. COOKE reported that the injury to these shoots, shown at the last meeting, was due to the interference with the proper performance of their functions by the presence of a complete covering of the alga, Pleurococcus vulgaris, on their upper surface.

Diseased Cucumber Leaves.—Mr. MASSEE reported that the leaves sent to the last meetiog by Mr Terry were attacked by the fungus Cercospora melonis, Cooke.

Raspberry Moth.—Mr. SAUNDERS reported on some shoots of Raspberry in which the buds had failed to grow:—"The buds on the Raspberry were attacked by the caterpillars of a small moth, the 'Raspberry-moth' (Lampronia rubiella) (see fig. 118, p. 288). Any of the canes which are badly infested should be cut out at once and burned; if only a few buds are affected they should be picked off and treated in the same way; in doing this however be sure that the grubs are not left in the cane. The moths lay their eggs in the flowers of the plants, and the young caterpillars make their way into the core of the fruit, where they do not appear to do any harm. Later on they let themselves down by silk threads, or crawl down, to the stool of the plant, where they hide among dead leaves or rubbish in cracks of the soil, or in some inequality in the bark of the canes, &c. Each then spins a thin silken cocoon round itself, and in this position passes the winter; in March, earlier or later according to the season, they leave their winter quarters and crawl up the canes and make their way into the base of the buds. When fully grown they form a chamber in the pith of the cane, in which they become chrysalides, from which the moths emerge in about three weeks. During the winter the stools should be thoroughly cleaned, and all rubbish, dead leaves, &c., carried away and burnt. They should then be earthed up, which should prevent any caterpillars still in the stools from ascending the canes, the bases of which should be painted with a thick solution of paraffin emulsion as a further safeguard."

Scale on Cotoneaster.—Mr. SAUNDERS also reported on insects on Cotoneaster sent by Mr. Bunyard: "These are badly attacked by the 'Mussel-scale' (Mytilaspis pomorum), and to a less degree by the 'brown Peach-scale' Lecanium persicæ var. sarothamni). I should cut out as many of the infested branches as can be spared, and then towards the end of May and again early in June spray with paraffin emulsion, taking care that the insecticide reaches the back of the shoots that are against the wall; another spraying might be given with advantage about the middle of June. The particular reason for spraying at this time of year is to destroy the young insects as soon as they begin to leave the shelter of the scale of their mother, and to find fresh quarters for themselves. If it were not an evergreen plant, I should recommend spraying with a caustic alkali-wash in the course of the winter, but a good spraying with paraffin emulsion then could not be otherwise than beneficial, and it would prove more efficacious if the plant were protected by a mat afterwards, to prevent the insecticide being washed off by the rain."

New Primulas. — The following newly-introduced Primulas from Western China were exhibited by Messrs. J. VEITCH & SONS:—Primula vittata, Bureau et Franchet; P. deflexa, Duthie; P. nivalis farinosa, Schrenk; and P. Cockburniana, Hemsley. On the motion of Dr. MASTERS, seconded by Mr. DOUGLAS, a Botanical Certificate was unanimously awarded to P. Cockburniana, a Chinese species bearing flowers of an orange-colour, reminding one of the colour of Hieracium aurantiacum, quite a novel colour in Primroses.

Double-coloured Spathe in Richardia Elliotiana, and quite distinct in colour from any previously known Primrose.—Mr. BATCHELDER, of Ipswich, sent photographs of a plant bearing a second spathe completely coloured yellow, unlike those usually exhibited, where the second spathe has usually a large yellow blotch.

Seeds from Caucasus.—Mr. S. HOGG sent seeds of Lablab vulgaris and Staphylea colchica, requesting the names.

Diseased Potatos.—Mr. Z. GRAY, F.R.H.S., sent Potato tubers badly affected by the black scab disease, which has spread so much in this country lately.

Laurel leaves injured.—Mr. SAUNDERS showed some leaves of Laurel, each of which contained large numbers of holes. Dr. Cooke undertook to examine them.

Phyllocactus.—Mr. WORSLEY showed several fine forms of Phyllocactus, and remarked upon the difficulty there is in fixing the origin of the garden Cacti. It appears that two very unlike species are sent out under the name Phyllocactus crenatus, one having scales up to the base of the flower, the other having a long naked ovary. Garden forms appear to show very little trace of the latter character. It was decided that at a future meeting the question of the origin of these forms should be brought forward.

Cereus amecaensis.—Mr. WORSLEY also showed a flower of this very fine white-flowered species from Mexico.

BRITISH GARDENERS' ASSOCIATION.

JUNE 1.—The first annual meeting of the members of the British Gardeners' Association was held in the Memorial Hall, Farringdon Street, London, E.C., on the above date. Dr. M. T. Masters, F.R.S., presided, and there were upwards of sixty members present. It was generally agreed that the attendance would have been greater if the meeting had been held on the previous day, as many of the country visitors to the Temple Show had returned, and the exhibitors were busy at the time packing their plants for transmission home. Dr. Masters congratulated the Association on the progress that had been made during the year. He felt every confidence that the objects of the Association were good, therefore the members should not feel discouraged, for eventually those objects would triumph. They sought to benefit themselves, but would rigorously refrain from injuring others.

Mr. Geo. Gordon, Chairman of Committee, then moved the adoption of the following report, which was seconded by Mr. W. Dallimore, supported by Mr. E. F. Hawes and Mr. K. Drost, and carried unanimously.

REPORT OF THE COMMITTEE OF SELECTION.

AT a public meeting of gardeners held in the Essex Hall, Strand, on June 1, 1904, it was resolved to form a British Gardeners' Association on the lines indicated in the prospectus, and a Committee of Selection was appointed to conduct the work of organisation. This Committee consisted of the following gentlemen:—Messrs. Gordon, Curtis, Divers, Drost, Jordan, Pearson, F. K. Sander, J. Weathers, G. H. Clack, W. P. Wright, R. J. Frogbrooke, Witty, Lawson, Leech, Cadman, Close, Brooks, Newberry, T. H. Candler, Isbell, Taylor, Hales, T. Winter, W. J. Bean, Stocks, and Watson. The Association is greatly indebted to the Horticultural Club for permission to use the Club Room at the Hotel Windsor for Committee meetings. After a year's operations the Association has developed slowly but steadily in the direction generally desired. Twenty-eight public meetings have been held and addressed by delegates from the Committee in horticultural centres throughout England and Wales. The result of these meetings has been in many cases the formation of a branch of the Association, and further development in this direction only awaits the stimulus of the Executive Council. The number of members enrolled up to May 25 was 632. These are distributed throughout the country as follows:—England, North, 131; England, South, 332; Wales, 98; Scotland, 48; Ireland, 16; Colonies and abroad, 7; total, 632. [Not National distribution:—There are, for example, many more Scotch members than the above table indicates.]

It is interesting to note that by far the majority of the members at present are employed in private gardens, whilst only very few of the many thousands engaged in commercial gardening have as yet joined. This is no doubt largely due to the difficulty of making the Association and its aims known to these men; and also, it is to be feared, to the opposition some nursery-

men have shown to the Association, an opposition which has gone so far as to forbid their *employés* to take any part in the movement. It is to be regretted that not a few head gardeners have displayed the same kind of antagonism to the Association, evidently from a belief that its operations would interfere with them in the control and management of their charges. The exact classification of the gardeners who are now members is as follows:—Head gardeners, 273; single-handed gardeners, 33; foremen, 121; journeymen, 107; curators, park superintendents, lecturers, pressmen, 36; nurserymen and nursery foremen, 50; disengaged, 12; total, 632.

The expenses incurred by the Committee in the work of promotion have been almost covered by donations received for the purpose. In addition to the meetings held the Committee have distributed a large number of pamphlets, application forms, and rules, but the have found poor results arise from the distribution of printed matter alone. The firmly-rooted belief of the majority of gardeners that association and co-operation can do nothing to improve their condition or raise the status of their calling cannot easily be shaken. It is evident that only when this Association has demonstrated its capacity for usefulness will the great body of professional gardeners actively support it. To do this effectively funds are urgently needed. The Committee, therefore, appeal for the liberal support of those who are in a position to afford it. If £1,000 could be obtained it would enable the Executive Council to commence operations on a scale that would command respect, and the British Gardeners' Association would then, undoubtedly, in a short time, take its place among those excellent organisations which in this country have done and continue to do so much for the industries they represent. An office in London and a paid Secretary must be provided before any satisfactory advance can be looked for. Up to the present the donations promised amount to £81.

Is it possible that amongst the wealthy patrons of horticulture there is not one who is sufficiently in sympathy with its workers and the effort now being made to better their condition to induce him to advance the amount required to start us? Four thousand members would mean £1,000 in subscriptions and registration fees, and surely these would be forthcoming in a short time if only the Association could make a strong effort from a position of security.

Amongst those who have been most active in the promotion of the movement in the provinces special mention should be made of Mr. H. A. Pettigrew, Cardiff; Mr. W. Hall, Sunderland; Mr. W. L. Deedman, Birmingham; Mr. A. Gaut, Leeds; Mr. G. Carver, Leeds; Mr. A. G. Chalice, Plympton; Mr. D. Bliss, Swansea; Mr. J. Coutts, Killerton; and Mr. C. Girdham, Altrincham.

The support accorded to the movement since its initiation by the horticultural press has been most gratifying. This alone should satisfy doubters as to the necessity for an Association, and the genuineness of the present effort. Many employers, amongst them the Right Hon. J. Chamberlain and Lord Windsor, have expressed their sympathy with the movement, and their belief in its power for good. Mr. Chamberlain wrote:—

"*Highbury, Moor Green, Birmingham.*

Sir,—I am desired by Mr. Chamberlain to acknowledge the receipt of your letter of January 20, and to say that he cordially approves of the proposal to establish the British Gardeners' Association, and cordially wishes it success.

Yours obediently, J. Wilson.

W. Watson, Esq."

The want of faith amongst the gardeners themselves is a most deplorable element, but it has to be overcome, and there is every reason to believe that it will disappear as the objects of the Association become better known.

The election of an Executive Council was conducted in a manner calculated to give general satisfaction, the following circular letter and list of candidates being posted to every member of the Association. The list included thirteen private gardeners, so that members preferring an Executive composed of private gardeners only could have their choice. It is significant that no one selected private gardeners exclusively. The voting paper is reprinted below, the elected candidates being marked with an asterisk. Only 362 voting papers were returned. *June* 1, 1905.

"ELECTION OF EXECUTIVE COUNCIL.

DEAR SIR—The Committee of Selection, having decided to proceed to the election of an Executive Council in accordance with the directions stated in the prospectus, beg to submit herewith a list of members who are willing to serve on the Council. They all reside within a short distance of London and are therefore in a position to attend the meetings. You are invited to mark in the list the names of the twelve candidates you prefer, and, for your votes to be recorded, you must return it to me before May 20. In addition to the twelve members thus elected each branch will have direct representation upon the Council.

A public meeting will be [was] held in the Memorial Hall, Farringdon Street, E.C., on Thursday, June 1 (last day of Temple Show), at 8 P.M. W. WATSON."

CANDIDATES FOR EXECUTIVE COUNCIL.

Members of the Present Committee.—*T. H. Candler, Foreman, Warley Place, Great Warley; *G. H. Clack, H. G., Putney Park, Putney; *W. E. Close, Superintendent of Parks, Fulham; *C. H. Curtis (*Gardeners' Magazine*), 68, Whitestile Road, Brentford; R. J. Frogbrooke, Superintendent of Parks, Leyton; *G. Gordon (*Gardeners' Magazine*), Priory Road, Kew; *J. Lawson, H. G., Horticultural College, Swanley; *R. Hooper Pearson (*Gardeners' Chronicle*), 40, Brocklebank Road, Earlsfield; *W. Taylor, H. G., Tewkesbury Lodge, Forest Hill; *W. Watson, Curator, Royal Gardens, Kew; *J. Weathers, Horticultural Instructor, Pymmes Park, Edmonton; *T. Winter, Superintendent of Parks, Marylebone.

Other Members Willing to Serve.—C. F. Bailey, H. G., Angley Park, Cranbrook; J. O. Clarke, H. G., The Poplars, Avenue Road; J. Clark, Foreman, Messrs. J. Waterer & Sons, Bagshot; *W. Dallimore, Foreman, Royal Gardens, Kew; H. O. Etherington, Messrs. J. R. Box & Son, West Wickham, Kent; J. Fulton, H. G., Grims Dyke, Harrow Weald; E. F. Hawes, Superintendent, Royal Botanic Gardens, Regent's Park; P. J. Lucking, H. G., Hopedene, Holmbury St. Mary, Dorking; W. McKechnie, H. G., The Mole House, Hersham, Walton-on-Thames; M. McKiernan, Foreman, Waddesdon, Aylesbury; G. Nottage, H. G., Mill House, Bourne End, Maidenhead; C. Taylor, H. G., Ormeley Lodge, Ham Common; F. T. Woodfield, H. G., The Grange, Nether Street, Finchley.

Only twelve names must be marked.

(*The asterisk* (*) *signifies the successful candidates.*)

Mr. J. Weathers, in the course of a few remarks, emphasised the fact that the Association would not become a mere trades-union, and hoped that no one would be misled into thinking that ordinary trades-union methods would ever become the policy of the British Gardeners' Association.

Mr. J. Harrison Dick moved a vote of thanks to the Committee, which was accorded; and on the proposition of Mr. W. Watson a vote of thanks was passed by acclamation to the Chairman. It was fitting that the meeting should terminate with an acknowledgment of the generous and disinterested efforts Mr. Watson has made on behalf of the objects of the Association, he having done very much more work than any other person. On the proposition of Mr. Jordan (Hyde Park), a hearty vote of thanks was therefore accorded him.

SOCIÉTÉ NEERLANDAISE D'HORTICULTURE ET DE BOTANIQUE.

AT a meeting in May of the above Society at Amsterdam, the Floral and Botanical Committee made the following awards:—First-class Certificates for—1. Iris × Juno, new plant, obtained from seed by M. P. W. VOET, nurseryman, of Overveen, near Haarlem. Flowers grey tinged with violet, veined with brownish-purple; of good form. 2. Iris × Pollux, from the same exhibitor. Flowers violet mixed with grey and black, of good form and very floriferous. 3. Cineraria hybrida nana alba, from Messrs. SLUIS & GROOT, seedsmen, of Enkhuyzen. Flowers pure white, plant dwarf and compact. 4. C. hybrida (of Cactus form), from the same firm. Flowers variously coloured, petals narrow, prettily curved; the plant dwarf and decorative. 5. Rhododendron hybridum Aalsmeer's Roem, new plant staged by M. K. MAARSE DZN., junr., nurseryman, of Aalsmeer. Flowers deep rose, very floriferous and hardy. 6. Trollius Fire Globe, a new seedling raised by Mr. H. J. DE LANG, nurseryman, of Oogstgeest. 7. Phaius Blumei Sanderianus, staged by M. C. J. KIKKERT, of Haarlem. Flowers brownish-yellow, lip purple-and-white. 8. Lælio-Cattleya Hycana, from M. H. C. HACKE, of Baarn. Flowers rose-coloured, lip dark-purple, form excellent. 9. Lælia purpurata maxima, from M. J. G. BALLEGO, nurseryman, of Leyden. An excellent variety, with larger flowers than the type.

A Certificate of Merit was awarded for—1. Odontoglossum Adrianæ Ashworthianum, from M. H. C. HACKE. Flowers yellowish-white spotted with brown.

Botanical Certificates for—Lælia Latona, from M. C. J. KIKKERT, amateur, of Haarlem. Flowers orange-yellow, and lip purple. Alopecurus lanatus, from M. H. D. WILLINK VAN COLLEN, of Breukelen. A very dwarf plant, greyish-white and downy.

A Bronze Medal was given for a collection of hybrid Cinerarias from Messrs. SLUIS & GROOT, and Honourable Mention accorded for a collection of Odontoglossums in flower from M. E. A. LEHMAN, of Amsterdam, and for Cypripedium barbatum from M. F. T. BLÖTE, of Leyden. *A. J. Van Laren, the Secretary.*

ROYAL BOTANIC.

JUNE 7, 8, 9.—The summer horticultural exhibition of the Royal Botanic Society took place on the above dates. The weather on the opening day left much to be desired, the skies being overcast and threatening. Fortunately, however, the rain kept off, and the public attendance was fairly satisfactory. The exhibition was an advance on that of the previous year, and embraced some excellent exhibits. The show was very comprehensive, for in addition to excellent groups of plants and fruits, there were to be seen the best and latest devices in hot-water heating systems, spraying-machines, irrigators, lawn-mowers, rustic summer-houses, glass structures, garden furniture, and a hundred-and-one sundry articles of garden utility. Exhibits of Roses were a feature, hardy plants were shown extensively, and the exhibit of Messrs. RIVERS & SON'S fruit-trees was in the best possible condition; indeed, we doubt if they have ever been shown better.

Messrs. WM. PAUL & SON, Waltham Cross, showed excellent Roses in pots and baskets. The variety Spencer, H.P., was in first-class condition. Pillar varieties were freely represented, including the handsome Lady Gay and the Farquhar, which somewhat resembles the last-named, the trusses being as floriferous as that variety, but individual flowers are rounder in shape (Gold Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, exhibited a choice display of Roses, admirably staged, and occupying the end of one of the large tents. Standard and trained varieties of such kinds as Dorothy Perkins, Crimson Rambler, mixed with such beautiful kinds as Conrad F. Meyer and Ulrich Brunner (Large Silver-gilt Medal).

Some nice cut Roses were displayed by Mr. G. PRINCE, Longworth, Berks. Boxes contained good examples of many of the better-known varieties, such as Bessie Brown, Maréchal Niel, Comtesse de Nadaillac, &c. (Silver-gilt Medal).

Mr. CHAS. W. BREADMORE, Winchester, exhibited vases of Sweet Peas and plants of Nicotiana Sanderæ (Large Silver-gilt Medal).

H. T. PITT, Esq., 57, Stamford Hill, London, N. (gr., Mr. F. W. Thurgood), put up an excellent group of Orchids, among which Odontoglossums were a feature. A new Lælio-Cattleya, L.-C. Martinetta, was prominent. The lip is an intense purple colour crowned with cinnamon-rose-coloured petals. Some of the more notable plants were Odontoglossum Wilckeanum, O. Pescatorei, O. Ruckerianum, choice forms of O. crispum, &c. (Gold Medal).

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., staged a mixed group, having Gloxinias, Roses, Stocks, herbaceous flowers, Carnations, Verbenas, &c (Silver-gilt Medal).

Mr. JOHN R. BOX, West Wickham, staged a batch of herbaceous Calceolarias (Silver Medal).

Messrs. T. S. WARE, Ltd., Feltham, Middlesex, showed a very pretty group of hardy plants and flowers staged on the ground. The background was furnished with "pillar" Roses in pots and tall spikes of Eremurus. The front was arranged in the form of three "bays." An adjoining table was also furnished by Messrs. WARE with a collection of hardy flowers and tuberous-rooting Begonias (Gold Medal).

Each end of one of the principal tents was occupied with a group of Caladiums, staged respectively by Messrs. PEED, of West Norwood, and by Messrs. LAING, of Forest Hill. Messrs. PEED'S group contained well-grown plants. Messrs. PEED also displayed a large collection of Gloxinias (Gold Medal).

Messrs. JOHN LAING & SONS, Forest Hill, London, N., showed some excellent Caladiums. The foliage was not of large size, but the colours and shadings were nicely developed. The best varieties were Alcibiades, Triomphe de Comte, Madame Hubert Koechlin, Madame Groult (very handsome). The same firm also filled a long table in the conservatory with an excellent collection of tuberous-rooting Begonias. The variety Sir Howard Vincent is a remarkably handsome "scarlet;" White Lady is a commendable "white." Single varieties were freely represented (Gold Medal).

Messrs. W. & J. BROWN, Stamford and Peterborough, exhibited a collection of greenhouse plants comprising Heliotropes, Pelargoniums (among which the "Cactus" type was prominent), Verbenas, Roses, Statices, &c. Statice Bonduelli (yellow) is a nice plant (Large Silver Medal).

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, showed a mixed collection of plants, having Carnations, Caladiums, Nicotiana Sanderæ, Epacris, Ferns, Metrosideros floribunda, &c. Of Carnations, Liberty, a large scarlet "tree," is a new variety. Some good Orchids were shown. Cypripedium grande was excellent; a large plant of Cymbidium Lowii was prominent (Gold Medal).

Messrs. WATKINS & SIMPSON, Tavistock Street, Covent Garden, London, exhibited a miscellaneous collection of greenhouse plants (Silver-gilt Medal).

Mr. R. RASSMUSSEN, Eastville Nurseries, Waltham Cross, exhibited Petunias and Sweet Peas (Silver Medal).

Messrs. BARR & SONS, King Street, Covent Garden, London, exhibited a large display of hardy flowers, including Lupines, Irises, Pæonies, Gladioli, Poppies, Pyrethrums, &c. On the opposite table Messrs. BARR displayed a large collection of dwarf trees in fancy china pots (Gold Medal).

Messrs. WM. CUTBUSH & SON put up a very artistically-arranged group of Carnations relieved with small Palms and Maidenhair Ferns (Large Silver-gilt Medal).

Messrs. GEO. BOYES & Co., Aylestone Nurseries, Leicester, exhibited border, tree, and Malmaison Carnations (Silver Medal).

Messrs. SANDER & SONS, St. Albans, exhibited their new hybrid Nicotianas, the colours of which are so greatly admired.

Messrs. REAMSBOTTOM & Co., Alderborough Nurseries, Geashill, King's Co., Ireland, brought a collection of Anemones of the St. Brigid and other varieties (Silver Medal).

Messrs. JOHN WATERER & SONS, Ltd., Bagshot, Surrey, are making their usual display of Rhododendrons. The flowers were in first-class condition, and were a feature of great attraction. The whole is displayed under one huge roof, and can be viewed without discomfort (Large Gold Medal).

The long corridor was entirely occupied with groups of ornamental foliage plants, relieved here and there with a number of flowering subjects, such as Rhododendrons, Roses, Clematis, &c. Mr. DAVID RUSSELL, Essex, staged two large banks of these plants, having Maples, ornamental Conifers, coloured Oaks, Elms, Beech, Vitis, &c. The design was in good taste, and finished with a pleasing edging of Euonymus latifolius and moss (Gold Medal).

Mr. L. R. RUSSELL, Richmond, Surrey, showed ornamental trees and shrubs, staging the plants on both sides of the walk. Maples, Ivies, Elders, Oaks, Hollies, Aralias, Euonymus, and similar subjects comprised the collection; Olearia Hastii, Ceanothus, Clematis, &c., occupied the foreground (Large Silver-gilt Medal).

Mr. A. R. UPTON, Guildford, Surrey, staged a collection of alpines and hardy plants (Silver-gilt Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Woking, Surrey, displayed some good hardy plants and cut flowers. We noticed Cistus formosus and Rubus xanthocarpus. Such subjects as Irises, Lupines, Oriental Poppies, Aquilegias, Pyrethums, &c., comprised the main features (Large Silver Medal).

Messrs. R. H. BATH, Ltd., Wisbech, showed a large batch of herbaceous flowers, Irises, Pyrethrums, Poppies, Liliums, Gladioli, &c. (Silver-gilt Medal).

Mr. AMOS PERRY, Winchmore Hill, London, N., exhibited a collection of hardy plants, Irises, Liliums, Papaver orientale, Incarvillea Delavayi, Ostrowskia magnifica, Saxifragas, Eremurus, &c. Phlox ovata was noticed flowering in a pan (Large Silver-gilt Medal).

Messrs. WALLACE & Co., Kilnfield Nurseries, Colchester, showed many excellent hardy and border plants. Heucheras were a feature. Papaver bracteatum was represented in many choice varieties, among which was one with an immense flower of an unique colour, which can best be described as a very pale shade of salmon. To mention the many other beautiful things would require more space than is at our disposal, but we may include Plantago maxima, a new species, not unlike a small Eremurus himalaicus. Heuchera Kilnfield White has large racemes of creamy-white-coloured flowers. Iris pallida Junonia and I. p. dalmatica are two good Irises. Pentstemon glaber cyananthus is a new "break," the flowers of which approximate to a gentian-blue colour (Silver-gilt Medal).

Messrs. T. RIVERS & SON, Sawbridgeworth, staged a collection of fruiting trees in pots. The plants were arranged in the beds of the great conservatory, and showed well amongst the background of tall Palms &c. Peaches, Nectarines, Plums, Grapes, and Cherries were included in the collection. Foster's Seedling and Gradiska Grapes were shown well trained on stands. A plant of Sturt Plum was loaded with fruit, while the fruits of Guigne Annonay Cherry were hanging in clusters. The newly-certificated Peach Peregrine was exhibited in a basket (Gold Medal).

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed Cucumbers, Melons, and Tomatos. The new Cucumber Delicacy was prominent (Silver-gilt Medal).

Mr. GEO. HOBDAY, Market Place, Romford, displayed Rhubarb from the open with petioles of immense proportions.

Colonial produce was shown by the AGENT-GENERAL FOR WESTERN AUSTRALIA, who staged examples of cereals grown in that Colony, some very tempting-looking Apples, and views of fruit-farms, vineyards, cattle-ranches, &c. (Silver Medal).

The ROYAL BOTANIC SOCIETY showed a great number of economic plants, such as produce rubber, fibres, coffee, drugs, food products, &c.

THE AGRICULTURAL SEED TRADE ASSOCIATION.

MAY 29.—The twenty-fifth annual dinner of the above Association was held on the foregoing date at the Holborn Restaurant. Members from all parts were present, also several Colonial friends. The Chairman, W. Caldicott, Esq., J.P. (Worcester), in proposing the toast of the evening, "Success to the Agricultural Seed Trade Association," said:—The decline of agriculture is a very serious thing; there has been a decline of something like 2,000,000 Wheat acreage during the last ten or twelve years, which means a loss to the National Revenue and also the profit accruing from same. It has driven labour from villages to already overcrowded cities. Speaking more as regards the toast of the evening, he was reminded that this Association had just passed its twenty-fifth anniversary. If it did nothing else—there is the settling of disputes by arbitration by its members, sufficient in itself to commend it to all gentlemen who are not members. There is one thing it does, that is the settling of disputes at a minimum of cost and a maximum of good feeling. It is a costly thing to go to law over a small matter. It might cost more than the seed is worth. By being a member of this Association differences of opinion can be settled at a minimum of cost by experts and at the same time keep good friendship. There is one thing I should like to draw the attention of all gentlemen here—that is early buying. Some firms are only too anxious to rush in and buy to make a nominal profit of 3s. or 4s. irrespectively of the harm done to immature markets. I would suggest that they should hold off until stocks accumulate, then help themselves to get in at the bottom, not at the top.

SCHEDULES RECEIVED.

HANLEY HORTICULTURAL FETE, to be held in the Hanley Park, on Wednesday and Thursday, July 5 and 6, 1905.

NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY'S Annual Exhibition, to be held in the grounds of the Arboretum, Nottingham, on Wednesday and Thursday, July 12 and 13, 1905.

WINCHESTER HORTICULTURAL SOCIETY'S Autumn Show, to be held in the Guildhall, Winchester, on Tuesday and Wednesday, November 14 and 15, 1905.

TRADE NOTE.

MR. C. D. WISE has resigned the management of the Toddington Orchard Company, and his resignation will take effect from June 24 next. Mr. Wise will be succeeded by Mr. C. S. Martin, who for some years has held the post of assistant-manager.

MARKETS.

COVENT GARDEN, June 7.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

Hardy foliage (various), per dozen bunches	3 0– 4 0	

REMARKS.—Indoor Strawberries are still arriving. Next week there will be plenty from Southampton. This week the trade has not been so good for them as was expected. The wet weather and the coming holidays account for this. Good consignments of Cherries from France are still arriving; also a few Strawberries in baskets. There are plenty of English Figs on the market, mostly from Worthing, and the prices are good, considering the quantities available. Pines are a little cheaper, owing to the slow trade.

POTATOS.

Dunbars, 80s. to 90s.; various, home-grown, 60s. to 70s. per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

POT PLANTS.

THERE has been a very good trade done in pot plants during the past week, though owing to the rain some plants did not clear quite so well on Tuesday or Wednesday mornings. Good flowering plants for use in decorations are in demand, and there is a large trade being done in bedding plants. The supplies continue to be abundant. Ivy-leaved Pelargoniums were never seen in better condition. Souvenir de Chas. Turner, Madame Crousse, and Galilee are the varieties most extensively grown, the last-named being the most effective. Show Pelargoniums are now very good, and zonal Pelargoniums are remarkably well flowered plants, the most showy variety of all being that of Raspail, which might be described as a blaze of colour. Fuchsias are abundant; it is remarkable that it is chiefly the older sorts that are grown. Royal Purple is one of the best dark varieties seen, and Avalanche still remains a favourite. Ballet Girl is the best double white-corolla'd variety. Lady Heytesbury remains as one of the best. Spiræas (Astilbes) are plentiful. Some fine plants of the variety S. astilboides floribunda are seen. Of Hydrangeas those of H. Hortensia having blue flowers make the highest prices. The hot weather has not been good for Verbenas, and these are hardly equal to the plants sold a little earlier in the season. Mignonette is very good. Rhodanthe continues to be plentiful, but the quality is not consistently good. The yellow-flowered Marguerite Etoile d'Or is much better this season than usual. There are some good dwarf plants of Lilium Harrisi, but the cut flowers of L. longiflorum being plentiful the plants do not sell well. Verbena "King of Scarlets" is now very fine, and there are also some good specimens of a purple variety. There are still some fine plants of Erica ventricosa magnifica and E. v. rosea; E. Cavendishii is still procurable. Boronia heterophylla is good. Ferns, Palms, and other ornamental foliage plants vary but little in price. They are not quite so prominent now that so much space is required for flowering plants.

CUT FLOWERS.

The demand for cut flowers is fairly good, and for choice material prices are inclined to advance. Much of the surplus, however, which is usually cleared out by hawkers, has been left over, because several days were wet, and this morning at closing-time much remained unsold. Good Roses and Carnations have sold much better they they did recently. Iceland Poppies are more than plentiful. Liliums are advancing in price. Lilium speciosum superbum is very fine, but there are no good flowers of L. auratum at the moment. Imported flowers are practically finished for the season. *A. H., Wednesday, June 7.*

THE WEATHER.

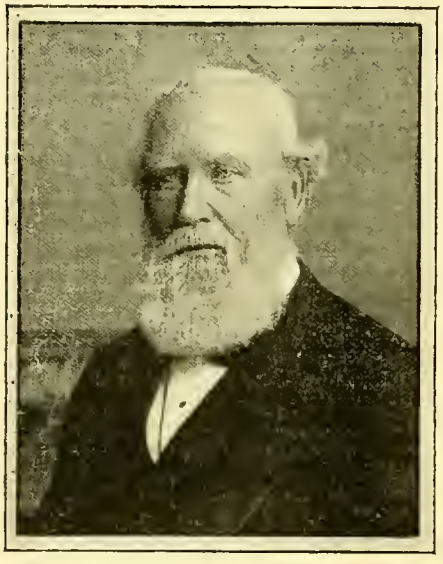
Obituary.

D. S. THOMSON.—We have to record the death, on Tuesday morning last, of Mr. David Stewart Thomson, head of the firm of Messrs. D. S. Thomson & Sons, Wimbledon, Surrey, nurserymen, seedsmen, and florists. Deceased, who was in his ninetieth year, was probably the oldest member of the trade, and throughout his career Mr. Thomson won the esteem of the members of the trade and of gardeners generally. He was upright in all his dealings, commercial and otherwise. Mr. Thomson was born in the vicinity of Stirling, N.B., but more than half a century ago he purchased the famous fruit gardens, as they were then, at Wimbledon from the family of James Paxton (brother of Sir Joseph Paxton), who possessed them previously.

Mr. Thomson soon commenced to establish the present nurseries, and made landscape gardening a special feature of his business. Later Mr. Thomson secured the freehold of nearly 50 acres of good land between Wimbledon and Raynes



THE LATE D. S. THOMSON, WIMBLEDON, AGED 90.

Park, which he abundantly stocked with trees and shrubs, and other species of hardy plants. A description of this nursery will be found on reference to our issue for November 8, 1902.

Deceased leaves two sons, William Stewart Thomson and Henry David Thomson, who have both taken active parts in the management of the business for some years past.

ANSWERS TO CORRESPONDENTS.

BAMBOOS: *A. B.* and *Lord Mt. E.* It is the habit of most of the species to die after the plants have flowered. From the description furnished of your plants it appears unlikely that those which have flowered will again become ornamental, and the best thing to do will be to clear them away.

CATERPILLARS ON IVY: *J. H. Edwards.* Caterpillars or larvæ of a species of Tortrix Moth, closely allied to the Rose tortrix. Spray the Ivy with Paris-green, at the rate of 1½ oz. to 20 gallons of water. Get it in the paste form, and use with great care, as it is poisonous. Keep the water agitated during the process of spraying, as the substance is a heavy mineral and has a constant tendency to settle to the bottom of the vessel. Spray at once, as the caterpillars are nearly full fed, and if necessary repeat the spraying after a week has elapsed. You could also considerably reduce the pest by sweeping the Ivy with a fly-net when the moths appear.

CORRECTION. In the report of the Temple Show, on p. 346, col. 1, our reporter inadvertently referred to an exhibit of Tree Carnations shown by Messrs. R. H. Bath, Ltd., Wisbech, as having come from Mr. M. Prichard.

DICHROIC THORN: *Sir R. P.* The occurrence of trusses of red and white flowers on the same branch is interesting, but not unique.

GLOXINIA: *Warwick.* The Gloxinia is good, but not remarkable. The climber is Mandevilla suaveolens. The other plant we do not recognise. Send when in flower.

LONDON CLAY AND VEGETABLE CULTURE: *H.J.S.* London clay, being of a sticky, retentive, and cold nature, requires to be broken up to a depth of 3 feet at least. This is best accomplished by what is generally termed trenching, which means opening a trench 3 feet in width and the same in depth, and wheeling the excavated soil to the other end of the ground, or where the work is to finish. The next piece to the same width is then marked off, and the soil from this area put into trench No. I. Before this is done, however, the trench should be well lined with London stable-manure, and the soil, whilst being put into the trenches, should be mixed well with road-scrapings, sand, ashes, lime-rubble, and the shortest of the droppings from the manure. If the subsoil is very poor, it should be allowed to remain at the bottom of the trench, but even then it needs to be intermixed with the ingredients named above. Clay so treated will become much more fertile than formerly. Frequent digging is one of the most important and necessary operations for bringing such soil into a fertile condition, the consequent exposure to the weather allowing a freer access to air, heat, and sun. By thoroughly trenching the soil 3 feet deep good drainage is generally secured.

MUSHROOMS: *C. A. B.* We cannot determine from the specimens you send the reason of their failure. We should advise you to make a fresh start. Clear out the old material, thoroughly cleanse the structure, and syringe the woodwork and other surfaces with a rose-red solution of permanganate of potash, after which proceed to make the new beds.

NAMES OF PLANTS: *A. C.* Collomia coccinea.—*T. S.* Pyrus torminalis, Wild Service tree, the berries of which are bletted like Medlars.—*H. R., Norfolk.* Maxillaria tenuifolia.—*T. W., Glamis.* 1, Allium moly; 2, Ornithogalum arabicum.—*A Reader.* We are unable to name such an incomplete specimen. Send when in flower.—*Japonica, Durham.* 1, Dendrobium Parishii; 2, D. crystallinum.—*A. M. K.* Cœlogyne nitida.—*Felix.* 1, Bulbophyllum Careyanum; 2, Maxillaria lepidota; 3, Oncidium barbatum.—*R. A.* 1, Adiantum caudatum; 2, A. concinnum; 3, Asplenium bulbiferum; 4, Cheilanthes elegans; 5, Pteris tremula; 6, Selaginella Wildenovii.—*Woking.* Styrax officinalis.—*Mrs. S.* Styrax officinalis.—*W. P., Stroud.* Cynoglossum officinale, belonging to the Boraginaceæ.—*F. G. G.* Scilla peruviana.—*F. S.* Syringa Emodi.—*W. S. S.* 1, Carex acuta probably; 2, Parietaria officinalis.—*F. L.* 1, Alchemilla vulgaris; 2, Cornus sanguinea; 3, Citrus triptera; 4, Griselinia littoralis; 5, Polygala vulgaris; 6, Cytisus sp. or hybrid.

PEACH: *Dr. G. G.* The fruit has fallen prematurely because there has been imperfect stone formation. We are unable to say definitely what may have caused this, but in the cultivation of stone fruits it is necessary to assure oneself that a certain amount of lime is present in the soil.

PEACH LEAVES: *T. G.* The injury to the leaves has been caused by scorching or scalding. Employ more ventilation and examine the glass in the roof of the house to see if there are any faults that have the effect of focusing the rays of the sun. There is no fungus disease present, and we do not think the water is to be blamed.

PELARGONIUM: *R. W. R., Usk.* The Pelargonium cuttings were too long and old. They were planted too deeply and possibly over watered. As to the Narcissi it will be better not to force them a second year, but to grow them on in the open and let the bulbs well ripen.

PENNY SEED PACKETS: *The Cape.* We cannot enumerate special firms. Scan our advertising columns.

POTATO: *J. T. S.* We will report on your specimens in another issue. The granules you see are enlarged cells, not starch grains, though they may contain some.

SHAPES FOR USE IN THE TOPIARY GARDEN: *A. C.* You will be able to obtain these on application to some of the garden sundriesmen. See our advertising columns.

THINNING APPLES: *Southern Grower.* No hard-and-fast rule can be laid down with respect to the thinning of Apples or other fruits. Characteristics of particular varieties have to be considered, also the conditions of culture, and the nature of the soil in which the trees are growing. Much also depends on the number of fruits which set and their distribution throughout the tree. If Peaches are recommended to be thinned until there is only one to the square foot or half foot, and through bad setting parts of the tree are devoid of fruit at all, the cultivator, being unable to rearrange his fruits, would permit some of them to remain closer to each other than would otherwise be done, because the total amount of fruit left to be perfected would not be more than the tree is capable of ripening. So with Apples if a tree has set only a poor crop, then in instances where several fruits have set in a particular truss it may be advisable to leave such unthinned. Apple-trees worked on the Crab stock and growing vigorously may be more heavily and more continuously cropped without impairing the constitution of the tree than can a tree worked on the Paradise stock. Trees that are thoroughly well nourished would naturally perfect a heavier crop than others that are merely pruned annually and the ground about them kept clean. For every Apple left upon a single truss of a large fruiting variety, such as Peasgood's Nonesuch, two or even three fruits may be left of smaller fruiting varieties, such as Beauty of Bath, Worcester Pearmain, and Cox's Orange Pippin. The general effect of well-considered thinning is not only to increase the size of the fruits, but it also has a great influence on the production of good colour and quality. It tends also to promote regular bearing. Fruits which have been properly thinned have the highest market value, being much more profitable than a larger quantity of inferior produce would be. Our Calendar writers endeavour to be as explicit as possible, but, as we have shown, they cannot advise you as to the exact number of fruits that should be left on a particular tree, unless they saw that tree. After stating the reasons for thinning, and the principles that underlie the carrying out of the work, the teacher must leave the rest to the judgment of the operator.

TOMATOS: *F. C. B.* You have probably afforded too much food, and an excess of water and heat, for the plant to perfect its flowers, which have been cast off before fertilisation.

WALLFLOWERS: *B. and B.* The specimens you send have been planted too deeply. The earth has covered about 6 inches of the main stem and branches. When so planted there is nothing for the plant to do but for the outer covering of the stems to assume the nature of the covering of the root and send out roots nearer the surface. Failing that the bark dries, and the plant also. Some plants are capable of adapting themselves to these unnatural circumstances better than others, but deep planting is bad as a rule.

THE SPECIES OF MECONOPSIS.

[*We are pleased, in view of the great interest now attaching to the genus in horticultural circles, to lay before our readers a brief account of the Asiatic species of Meconopsis from the pen of the recognized authority on the subject, Lieut.-Col. D. Prain, Indian Medical Service, Director of the Royal Botanic Garden, Calcutta.* ED.]

THE interest that has lately been taken in the genus Meconopsis, owing to the successful introduction and exhibition of some Chinese species quite worthy of the attention they have received, will remind gardeners that there are a number of Indian species of this genus. Some of these are quite well known in cultivation, others have been introduced to European gardens from time to time, but have failed to persist. Still others have not yet been added to our European garden lists.

These "Poppies" arrange themselves in a few natural groups, which are easily distinguished. There is first of all the group "Aculeatæ," which takes its name from M. aculeata, of the North-western Himalaya, a species quite familiar to English gardeners. Another member of this group is M. horridula, known also in one of its forms as M. racemosa; this is really a Tibetan species, which only overflows into the higher Himalayan valleys along the southern border of Tibet. Though it has been over and over again introduced to European gardens, little success seems to have attended its cultivation. This is not surprising, considering the natural conditions of its existence, and it may be doubted whether any, save those who are in charge of the really alpine gardens in Central Europe, can hope to raise the species successfully. The last member of the group, M. sinuata, which is the representative in the eastern Himalaya of M. aculeata, has not yet been raised in Europe.

More familiar than the "Aculeatæ" group is the group "Robustæ," which takes its name from M. robusta, a yellow-flowered species from Kumaon. This has been frequently introduced to European gardens, and possibly now exists in more than one collection, though if so it would appear to be somewhat readily mistaken for M. paniculata, another yellow-flowered species which extends from Central Nepal to

FIG. 157.—MECONOPSIS GRANDIS AS FLOWERING IN THE EDINBURGH BOTANIC GARDEN. (*Reduced one-half.*)
Colour of flowers dark blue, with markings and suffusion of purple. Size of flowers, 5 inches in diameter.

Bootan. Both species, as references to the literature of the subject will show, have been mistaken for M. nepalensis, a red-flowered species which considerably resembles M. paniculata in externals. This species was apparently known in English gardens before 1830, but had so completely disappeared from cultivation till it was re-introduced by Sir George King, and flowered by the late Mr. Wilson at Weybridge, about twenty years ago, that when it was successfully raised anew it was not recognised, but was taken for a red-flowered form of M. Wallichii. This last species is possibly the most familiar member of the Robustæ group; owing to the pale, somewhat washed-out-purple colour of its petals it is perhaps the least beautiful. But if one may judge from the material available, the finest member of the Robustæ group is M. superba, a white-flowered species from Bootan, which it has not yet been possible to introduce to European gardens.

The "Primulinæ" group takes its name from M. primulina, a species from Bootan and Chumbi, with nodding, blue flowers. This species, which has not yet been introduced to European horticulture, is the only Indian member of its group. In China the group is represented by M. Henrici (sometimes also known as M. principis), which has apparently been introduced to European gardens; and by M. Delavayi, which, like M. primulina, does not seem to be yet known in cultivation.

The group in which most interest is being taken at present is the group "Grandes," which takes its name from M. grandis. There are two distinct sub-groups within the Grandes—viz., one composed of species with one-flowered, leafless scapes, the other including species whose several-flowered scapes bear leafy bracts. Of the former sub-group India claims but one species, M. simplicifolia, which has long been familiar to European gardeners. It is a native of the Eastern Himalaya, but extends thence into Southern Tibet. The other species of the sub-group are East Tibetan or West Chinese, and of these the most striking is M. punicea, which lovers of Poppies had an opportunity of seeing at the recent Temple Show (see *Gardeners' Chronicle*, Oct. 22, 1904, fig. 130). The sub-group, with leafy bracts on the several-flowered scapes, includes two species only; one of these is M. integrifolia, the yellow-flowered species, whose recent introduction has been so warmly and so deservedly welcomed (see Supplementary Illustration to the *Gardeners' Chronicle*, October 1, 1904); the other is M. grandis, from which the group takes its name. This has been in cultivation now in England for a number of years, but as it apparently has the bad taste not to care for the atmosphere of London, it has not provoked so much remark as M. integrifolia [see fig. 157. Mr. Harrow, to whom we are indebted for the photograph, tells us that a plentiful supply of seedlings has been raised in the Edinburgh Botanic Garden. ED.] M. grandis is to be met with in Western Sikkim, towards the head waters of the Rangiet river, not far from the Nepalese frontier. It appears, however, only to occur in the vicinity of the huts occupied in summer by graziers, who say that it is not really a native of Sikkim, but that it was brought thither from Nepal. There would appear to be two forms of the species, because some of the specimens are stated by native collectors to have had red or purple flowers; others are said to have had the flowers blue.

The first European to note the colour of the flowers was Professor Gammie, of Poona. As he found them to be very deep blue, and as native observers are often quite unintentionally misleading recorders of colour "very deep blue" is given in the original

account of M. grandis as its colour. It has, however, turned out, as is often the case, that both observations were correct, although the majority of those who have flowered M. grandis have found the flowers to be blue. The late Mr. Thompson, who was the first to flower the species in Europe, happened to succeed with a plant whose flowers were described by him as "vinous-purple," and not blue.

The last group of Indian species is the group "Bellæ," which is represented by a single species, M. bella, the most beautiful member of this interesting genus. It is a native of Eastern Nepal, and has not yet flowered in Europe so far as is known. [In the Edinburgh Botanic Garden are several seedlings derived from seed obtained in the Calcutta Botanic Garden, some of which it is hoped will flower this year. ED.] It differs from the other species in having finely-divided foliage like that of a Corydalis, and in affecting the faces of steep cliffs, into the crevices of which its thick root-stocks penetrate horizontally. *D. P.*

NEW OR NOTEWORTHY PLANTS.

KALANCHOE MAGNIDENS, N. E. BROWN (*n. sp.*).*

THE genus Kalanchoe appears to be well represented in Africa, whence of recent years many very fine species have been introduced, but the present novelty cannot be said to possess much beauty, as its flowers, although numerous, are small and not showy, of a light salmon colour; it was sent to Kew in 1904 from Uganda by Mr. T. Dawe.

KALANCHOE ANGOLENSIS, *N. E. Brown* (*n. sp.*).†

This is rather a pretty species with broad-petalled, bright yellow flowers, differing from those of all other species known to me in the great variability of the number of the corolla-lobes, which vary from four to seven in different flowers open at the same time on the same inflorescence. As this tendency to vary by increasing the number of parts of the corolla (four being the normal number of lobes throughout the genus) is a perfectly natural one, it points to the possibility of a double-flowered form being obtained from it by careful selection; and if this could be effected, a new race of decorative plants would be the result. The flowers, however, do not remain open more than two or three days, but being numerous make a very fair display, and are about two-thirds of an inch in diameter. This species was discovered in Angola by Mr. John Gossweiler, the Curator of the Botanic Garden at Loanda, who sent seeds of it to Kew in 1903, from which the plants that flowered in February of this year were raised. *N. E. Brown.*

* *Kalanchoe magnidens, N. E. Brown* (*n. sp.*).—Plant 2½ feet or more high, quite glabrous in all parts; the stem, leaves and calyx are green, with a scarcely perceptible glaucous bloom. Leaves with a petiole ¼—1 inch long, and a blade 2—3½ inches long, ¾—2¼ inches broad, the lower elliptic-ovate; the uppermost oblong or lanceolate-oblong, all obtuse, broadly cuneate at the base, with usually three (rarely four) large, obtuse distant teeth on each side. Inflorescence laxly branched, the ultimate cymes compact, ½—1½ inch in diameter, nine to twenty-five flowered. Pedicels 1—3½ lines long. Sepals ¼ inch long, nearly 1 line broad, lanceolate, acute. Corolla four-lobed, light salmon coloured; tube 5—5½ lines long; lobes ¼ inch long, nearly 1 line broad, lanceolate, very acute, recurved-spreading. Stamens included, inserted in the throat of the corolla-tube; anthers blackish. Hypogynous glands ¾—1 line long, subulate, yellowish. Carpels included, gradually tapering into the styles, green.

† *Kalanchoe angolensis, N. E. Brown* (*n. sp.*).—Stem about 3 feet high, ½ inch or more thick at the base, clothed with a spreading pubescence. Leaves opposite, fleshy, brittle, the lower about 4 inches long and 2 inches broad, the upper gradually smaller, oblong, elliptic-oblong or lanceolate-oblong, obtuse or subacute, recurved and concave beneath at the apical part except the three to four upper pairs, channelled along the middle of the rest of the leaf on the upper side; midrib prominent and rounded beneath, somewhat thinly covered on both sides with a very short, spreading, and rather indistinct pubescence, dark green, shining. Cyme terminal, compound, 3—4 inches or more in diameter, flat topped, with the main branches 1—1½ inch long, pubescent, green. Bracts 1—2 lines long, subulate, pubescent. Pedicels ½—1½ line long, pubescent, green. Calyx divided to the base into 4—5 lanceolate, acuminate lobes, ½-inch long, about ¾ line broad, pubescent, light green. Corolla-tube ½ inch long, obtusely 4—7 angled at the enlarged base, light green, pubescent; limb ¾ inch in diameter, with 4—7 widely-spreading lobes 3—3½ lines long, 1½—2 lines broad, oblong, very obtuse, with a terminal awn ½ line long, rich bright yellow, slightly darker at the centre, pubescent on the back. Stamens in two rows, included, glabrous: filaments ⅔ line long. Hypogynous glands 2 lines long, filiform, acute, yellowish-green, glabrous. Carpels included, lanceolate, tapering into slender styles ¾—1 in. long, green.

FORESTRY.

THE LOCUST TREE.

I THINK we are not so far behind about the Locust tree as Mr. Booth (see p. 246) and some others would have us believe. If they had a thousand acres of it ready for disposal, what would they do with it? At what size, for what purposes, and at what price, could they dispose of it? I venture to say that it would prove a drug on their hands. It makes good posts, and for such purposes it might be grown as tall coppice, but as a timber tree it has neither height, bulk, nor good colour, and is often broken by gales. The Locust tree has been known long enough and well enough in this country and on the Continent to prove its value, yet it scarcely enters the lists.

FIG. 158.—RHODODENDRON "SAPPHO": FLOWERS WHITE WITH MAROON BLOTCH.

RHODODENDRONS.

As supplementary to the illustrations of Rhododendrons published in our last issue, we now reproduce two photographs, figs. 158 and 159, which show the varieties Sappho and Lady Godiva flowering well in a garden in the North-east of Ireland. Though these varieties are not so expensive or choice as Pink Pearl or Doncaster, they are nevertheless valuable. Sappho is one of the best known and most effective in the section having spotted or blotched flowers. In a garden or in an exhibition such as that held at Paris quite recently, Sappho, by its distinctness and effectiveness, stands out very prominently; and if Messrs. Jno. Waterer & Sons have this variety in their collection now on view at the Royal Botanic Society's Gardens, Regent's Park, visitors will be sure to see and admire it. The flowers are white, and the blotching is of deep maroon colour. Lady Godiva, shown at fig. 159 is also a good variety, the flowers being white blotched with yellow.

BOOKS RECEIVED.—The following books are upon our table, and we hope to make further notice of them as our space permits:—*How to Make and Manage a Garden*, by William F. Rowles; *Greenhouses; How to Make and Manage Them*, by W. F. Rowles. Both books published by C. Arthur Pearson, Ltd., Henrietta Street, W.C.—*Homeland Handbook to Lynton, Lynmouth, and the Lorna Doone Country*, Mr. J. E. Morris. Homeland Association, Bride Lane, Fleet Street, E.C.—*Mittheilungs-Berichte und Abhandlungen*, "Flora" zu Dresden, 1903-4, Franz Ledien, H. Burdach, Königl. Sächs. Hofbuchhandlung, Dresden.—*Economie Forestière*, Tome 2me, G. Huffel. Paris: Lucien Laveur, 13, Rue des Saints-Pères.

If I wanted a marketable substitute for the Locust tree, its equal or superior in every respect, I would choose the common Laburnum, which produces such beautiful wood—hard, heavy (over 50 lb. to the cubic foot when dry), and almost indestructible, taking a polish like glass (both heart-wood and sap-wood, the former a deep rich brown and the latter bright yellow, both clearly defined at their edges). A beautiful slab of this wood was exhibited in the Forestry section at the Park Royal show last June. It is much used for making small articles, and is, I believe, nearly all imported from abroad. It is often seen on shop counters as a string-box, where it stands tugging at, being heavy.

We have plenty of good trees of known quality for cropping purposes, but to get heavy and saleable crops is the problem. To put a new tree on the home market is not easy, and that is the main obstacle to selling the Douglas Fir at present. To timber merchants who are neither botanists nor foresters, it is simply a Spruce worth 2*d.* or 3*d.* a foot standing in the wood, and it is only by judicious trimming and lotting to show its colour and quality that as yet the price of Larch can be got for it, but by the time it is plentiful it will be better known.

The time a tree takes to grow, its uses and the extent of the demand for its timber, are the factors that constitute its value to the planter. I

should be sorry to advise anyone to plant either Locust or Walnut extensively, while they had other well-known and better croppers at their disposal. It is rather curious that advocates of the Locust-tree do not plant it more extensively themselves, seeing how long and favourable their opportunities have been.

I may be wrong, but the longer I live the more I discount the opinions as to the value of timber trees of those foresters and owners who are not also acquainted with the timber trade and its demands.

Fig. 159.—Rhododendron "Lady Godiva": flowers white with yellow blotch.

Outside the "trade" the ignorance on this head is profound. Locally and generally everything depends ultimately on the demand and the variety of uses to which any timber can be put. Fancy-woods under planking dimensions usually go as oddments at timber sales and fetch a low price.

Reverting to Cobbett, can those of your readers who profess to know most about the Locust-tree tell us what became of Cobbett's plantations? He raised and distributed great quantities of the tree; stated that in sixty years it would be as common as the Oak in England, and extolled it so much that it was planted to an unprecedented extent. It cannot be said, therefore, that the tree was not tried. What has become of the plantations? Planters stuck to the Larch after trial, but neither the precept nor the practice of Cobbett appears to have established a belief in the Locust-tree. I may say here that I am looking at this subject from an economic forestry point of view, as I understand your correspondents are doing, and I ask, Will it pay to plant the Locust-tree?

There is one tree that I have an increasingly favourable opinion of, and that is the Deodar Cedar. Dr. Masters says its resemblance to the Larch is striking botanically, and the same may be said of the timber, only it is closer in the grain, heavier, and of a deeper colour. It is one of the finest of Conifer timbers, I should say, and I have seen it growing of such good dimensions, and in so many parts of Britain on dry upland situations, as to think that it might be made one, at least, of the substitutes for the Larch. I do not go by heavily branched garden specimens, but by what I have seen of it in plantations, where it is always clean and timber-like, and not much behind the Larch in height. There are many trees of this description in the woods at Newstead Abbey, near Nottingham, belonging to Lady Chermside. *J. Simpson.*

Extra-Tropical Forestry.

In the *Agricultural Journal of the Cape of Good Hope* for January 1905 was the commencement of a series of articles on "South African Forestry," by Mr. D. E. Hutchins, which are of great interest. The native trees, it appears, are from various causes ill suited to the requirements of the forester or to the local exigencies. It is therefore necessary to select for planting suitable trees from other countries. Cheapening of timber is necessary to diminish the present high cost of construction, and something needs to be done to stop the efflux of £1,500,000 now paid annually for timber imported into the Colony.

South Africa, we are told, has long been notorious for the high cost of living, and among the items of this expensive living the most conspicuous is house-rent. Whether one builds one's house oneself or rents it, the result is always the same—an enormously high rental. In many cases as much rent is paid per month in South Africa as would procure the same house for a year in England. The reason for this excessive cost of house-building is the dearness of timber and of labour. When all timber has to be brought a distance of 6,000 miles or more from the northern hemisphere it is easy to see why house-building must be costly."

Extra-tropical climates, as defined by Mr. Hutchins, fall naturally into three divisions, and within these three divisions the trees are generally interchangeable. Thus a Mediterranean tree may be expected to succeed at the Cape (S.W.), California and S.W. Australia or *vice versâ*, but not a summer rainfall tree in a winter rainfall climate. Extra-tropical climates characterised by winter rains are found in the Mediterranean region, in Persia, and as far east as Afghanistan, at the Cape (S.W.), in California, in S.W. Australia, in Mid-Chile.

Summer rains prevail in South Africa exclusive of the S.W. district, Mexico, the highlands of Central America, Yunnan, Mid-China, and Korea, Himalayas, Abyssinia, Argentine (N.), and the highlands generally in tropical latitudes.

All-the-year-round rains occur in Japan, the Gulf States of North America, Mid-Argentine, and Southern Chili, New Zealand and Tasmania, and the equatorial highlands. The presence or absence of technically valuable forest is governed by a minimum rainfall of 20 inches; while the successful selection of the technically valuable species depends primarily on the amount and distribution of the rainfall.

COLONIAL NOTES.

Botany and Forestry of the Transvaal.

The Annual Report for 1903-4 of the Transvaal Department of Agriculture contains the following details, furnished by Mr. Jos. Burtt Davy, on the Division of Botany and Agrostology:—"This Division has been very busily engaged in the work of seed and plant introduction, large quantities of seeds of almost every kind have been obtained from different parts of the world, and an elaborate series of tests are being made with them upon the various experimental grounds, and a large number of samples of varieties, which appear particularly promising, have been distributed to farmers for trial and report. These co-operative experiments are much appreciated, and will serve the double purpose of eliciting information and bringing the Department more closely into touch with the farmers.

In addition to the above, investigations have been conducted as to the merits of various native plants likely to prove of economic importance, including veld grasses. Attention has been paid to poisonous plants, which are the cause of heavy mortality amongst stock in some localities

and at certain seasons of the year; many seeds and plants have been identified, and a number of specimens collected for the herbarium. Numerous plant diseases have also been investigated. An assistant for seed and plant introduction was appointed early in the year, and two or three lads have been admitted to the Division as pupils.

Rust and other diseases are very prevalent and troublesome, and the services of a first-rate plant pathologist are needed to undertake this branch of the work. Provision for the post has been made upon the estimates, and it is hoped that before long an officer will be appointed."

In the Division of Forestry the assistant chief forester, Mr. C. E. Legat, reports that:—

"The Transvaal is sadly destitute of trees, and in some districts one may travel for many miles without seeing either a bush or a tree of any kind. At the present time the whole of the timber required by the railways and for building purposes, together with a large quantity of mining timber, has to be imported from oversea at an enormous expense. The value of last year's imports amounted to — manufactured wood, £195,060; unmanufactured, £721,990. Trees are also required for ornament, for shelter against cutting winds, for fuel and ordinary farm use, and for the protection of the water supply.

The soil and climatic conditions are favourable to the growth of trees, and there is apparently no reason why suitable selected varieties should not do well here. Accordingly the Division is taking active measures to amend matters, and has already performed an immense amount of good work. Steps have been taken to preserve such small areas of natural bush and forest as remain.

At five convenient centres sites of from 1,000 to 6,000 acres have been selected for permanent plantations, and at these places nurseries have been established for the dual purpose of providing trees for the plantations and for selling them at low rates to farmers and others.

A central nursery for the raising and sale of trees has also been started near Pretoria. Tree seeds have been obtained in quantity and are supplied to farmers at cost price.

Our hearty thanks are due to Mr. Hutchins, Conservator of Forests, Cape Colony, for a valuable report upon forestry in this Colony and for the advice and assistance he has so frequently and ungrudgingly given us.

Last year 1,753,824 trees were raised and 921 lb. of seeds sold, and it is hoped and expected that during the coming year operations will be greatly extended. Also 127,265 trees were distributed to the public and to various Government institutions during the past season, and there are now 1,676,499 trees in the nurseries ready for distribution."

Begonia Gloire de Lorraine in South Africa.

It is very surprising to find this Begonia so little known amongst the gardening community here. In Cape Colony the plant is, I believe, grown by two or three individuals, but the only nurseryman who grows it is Mr. E. Brett, of Port Elizabeth, and his stock is small. From what I gather it appears to be somewhat difficult to manage. Like many other little-known plants with a reputation for stubbornness, it was coddled to death. Both of the varieties Turnford Hall and Caledonia have been imported at various times, but my personal experience was at first disappointing, till at last perseverance won. Turnford Hall is practically unknown here, excepting of course from accounts found in the horticultural papers. Gloire de Lorraine with me is given no artificial heat. Cuttings root readily in a cool frame or on a greenhouse shelf, and plants will grow in an unheated pit or frame without the slightest trouble. When better known I predict a great future for this Begonia in South Africa. *Colonial, South Africa.*

New South Wales.

We note the publication of Vol. II., Part 4 (Part XIV. of the complete work), of *The Forest Flora of New South Wales*, J. H. Maiden. It contains descriptions and illustrations of Owenia acidula, Eucalyptus stellulata, Casuarina glauca, and Ficus Henneana. Part 5 of this volume contains Acacia melanoxylon, Eucalyptus coriacea, Casuarina Cunninghamiana, and Atalaya hemiglauca.

Part VI. of *A Critical Review of the Genus Eucalyptus*, J. H Maiden, contains plates and descriptions of Eucalyptus amygdalina, E. linearis, and E. Risdoni.

The Barbados Banana Industry.

The rapid development of the Banana industry in Barbados has hardly received the attention it deserves from the neighbouring colonies. Originated in a modest and tentative way by the Imperial Department of Agriculture, the shipment of Bananas to England is proving eminently successful, and there is every prospect that the trade will soon rank as a permanent and well-established industry in the island. At a critical time, when sugar prices had declined to a ruinous figure, Sir Daniel Morris conceived the idea of making small trial shipments of Bananas to the United Kingdom by the Royal Mail steamers. At the recent Intercolonial Agricultural Conference in Trinidad, Mr. J. R. Buvell, describing the progress of the industry, mentioned that from January 1 to October 31 last year about 8,012 single bunches and 3,656 single bunches in double crates had been exported from the island; and Mr. Foster Alleyne, who gave some statistics connected with his personal experience of the enterprise, stated that the Bananas shipped from one of his estates, numbering 700 bunches altogether, netted no less a sum than 1s. 2*d.* per bunch, or approximately £40 altogether. Another Barbados planter realised about £30 last year on an acre under Banana cultivation.

As to the average net profits secured by the planters, the report of a Committee of the Barbados Agricultural Society, recently published, records that notwithstanding loss on certain shipments, when a forced sale of the fruit had to be made, the net return to the planter was about 1s. per bunch. At the last Agricultural Conference, indeed, Sir Daniel Morris claimed, on the authority of experts in England, that the Barbados fruit was the "finest that reached the United Kingdom." The Barbados Banana industry, given favourable shipping conditions in the future, seems tolerably well assured. This is no small achievement to accomplish in a year or two, especially when we bear in mind that the Banana industry of Jamaica was firmly established only after twenty-five years of difficulties and disappointments. *Demerara Daily Chronicle, April* 19, 1905.

FOREIGN CORRESPONDENCE.

THE APPLE CURCULIO (ANTHONOMUS QUADRIGIBBUS, SAY).

This insect, which is found over most of the Northern United States and Southern Canada, has been committing depredations on the Apple-crop of South-eastern Nebraska for nearly twenty years. It is not an introduced insect, but before the advent of cultivated fruit attacked the wild Crabs and Haws, and in some localities it still prefers these wild fruits to the cultivated ones. In the older orchards, however, it has turned its attention to tame Apples and Pears, and has become a very injurious insect, and one difficult to control.

The insect itself is a "snout beetle" or weevil, of a rusty-brown colour (sometimes ashy on the thorax), from 3 to 5 millimetres long, with the wing covers broadening from the shoulders backward, and each is provided with a pair of conspicuous humps. The beak protrudes somewhat horizontally, and cannot be folded under, being in the female as long as the body, in the male only half as long. According to our present knowledge the life-history of the Apple Curculio is as follows:—It is single brooded, wintering in the mature state, while all the changes from the egg to the adult are carried on in the fruit. The female beetle in late May or early June bores a hole in the fruit as deep as her beak is long, and much enlarged toward the end, while the opening still remains just large enough for her beak to enter. Into this cavity she immediately deposits the egg, an oval yellowish body about a millimetre in length and a little more than one-third as wide, an operation consuming about five minutes. As soon as the egg hatches the larva makes for the core of the Apple, where it feeds, producing much reddish excrement, and after about a month becomes fully grown. It is then a soft, white, legless grub about $\frac{1}{2}$ inch long, with a hump-backed, much wrinkled body. Unlike the Codlin-moth and the Plum Curculio, this insect does not cause the fruit to fall. The larva remains in the fruit, and after a final moult assumes the pupa state. Another moult after two or three weeks brings on the adult beetle, which cuts a large hole and makes its way out. The adult beetles begin to appear about the third week in July, and continne coming out through much of August, since the period of egg-laying is somewhat extended. In addition to the harm done by the maturing insects in the Apple, their feeding punctures produce irregular knots and swellings which stunt and deform the fruit as well as greatly aid in the spread of the "Apple-rot" fungus by catching and affording entrance for the spores. Moreover, the Curculio attacks the young trees and kills them by drilling them full of holes in rows running lengthwise of the stem.

Remedies.

The known remedies for the Curculio are few, and apparently of little avail. Sprayings such as will destroy the Codlin-moth have scarcely any effect on it, although they probably do some good by preventing feeding and oviposition. Jarring the trees and collecting the fallen beetles on a sheet are only moderately successful, as the beetle is so disinclined to drop that this method can never prove of great value. Destroying the infested fruit by picking it while the insect is therein would, of course, prove beneficial; also all fallen fruit should immediately be removed, as in combating the Codlin-moth. A tobacco decoction is said to prevent injury if applied to young trees, but this has not been well proven. *Lawrence Bruner.*

[This insect belongs to a distinct genus called Tachypterus. This generic name, however, is preoccupied, and in a forthcoming list of the Coleoptera of New Mexico the insect is called Tachypterellus quadrigibbus. *T. D. A. Cockerell.*]

Campanula persicifolia.

About thirty forms of Campanula are cultivated in gardens, and these differ considerably in form, size, and duration, some being biennials, but most of them perennial. All are more or less beautiful for the size and abundance of their flowers, the typical colour being blue, but varying from white to violet, pink being the most uncommon colour. Of all these the most desirable for its beauty and easy cultivation is the Peach-leaved variety, a perennial to be found growing wild throughout the woods of France, but also frequently cultivated. In its natural condition it has but few slender stalks about 3 feet long with long and narrow leaves below, headed by a cluster of pale blue bell-shaped flowers. When cultivated it produces white flowers and also double

blue and white flowers. However, it is from seed chiefly that this Campanula is capable of the most improvement, not only in the shape and colour, but also in the size of the flowers. When one sees the clumps of two years' growth from seed, with often twenty to thirty stalks bearing heads of a dozen flowers as large as a claret glass, and compare it with the same flower in its wild state, we are amply repaid for our trouble, and may reckon this the Peach-leaved variety among the most beautiful of our garden plants. It is a fine example of what can be done in increasing the growth and strength of the plant by the sowing of the best seed, and shows how capable of improvement are many of our common wild flowers which we tread thoughtlessly under our feet.

wards be put in a nursery and finally planted-out in the autumn, or better still in the following spring, at a distance of one foot apart. *J. J. Dunnington-Jefferson*, 15, *Rue Delamore, Boulevard Montparnasse, Paris.*

KEW NOTES.

Ceropegia fusca, *Bolle.*—This species is now flowering in the succulent-house. It is one of the most distinct plants of this extraordinary genus, most of the species of which are natives of South Africa, having slender, trailing growths. C. fusca is a native of the Canaries, and is arborescent in its growth. The plant has leafless, fleshy stems, about 18 inches in height, with a grey lepidote surface. The internodes vary greatly in length, some of them are only an inch long, while others are fully 2½ inches in length. The growths are constricted at the nodes, at which points the clusters of flowers are produced. They are of a light red-brown colour (those of C. dichotoma, also a Canarian species, are yellow); the corolla tube is 1½ inch in length; the lobes are very acuminate and slightly spreading. There are two seed-pods on the plant, which are subulate in form and 6 inches in length, though not quite fully developed.

Cirropetalum robustum, *Rolfe.*

This genus is represented in the Kew collection by about forty species, all of which are more or less beautiful. The majority are small in structure, only a few having large growths and flowers. C. robustum, from New Guinea, is one of the largest species grown at Kew, and one of the most showy. It was introduced into cultivation by Messrs. James Veitch & Sons, of Chelsea, and was illustrated in the *Gardeners' Chronicle*[1] in 1895, ii., fig. 116. The plant now in flower has monophyllous pseudo-bulbs, the largest leaf being 14 inches in length by 3½ inches in breadth, the stout flower-scapes, produced from the base of the pseudo-bulbs, are from 4 to 6 inches in length. The largest inflorescence on the plant now flowering in the warm Orchid-house has fourteen blooms, each of which measures 3½ inches from the apex of the dorsal sepal to the tip of the connate lateral sepals. They are of a tawny-yellow colour, the prominent lip being of bright, glossy ruby-red.

Fig. 160.—Group of Sarracenias exhibited at the Temple Show by Mr. A. J. Bruce, Chorlton-cum-Hardy.

The very fact that the plants are natives of our soil makes them more easy of cultivation here. The white variety is easily grown from seed, and remains particularly true to its type; and an exceptional variety exists in "Morheimi" (see illustration in *Gardeners' Chronicle*, June 30, 1900, fig. 135), which has double white flowers much larger in size than any of those of the kinds already mentioned, and they are produced on long, stiff stems. This newer variety has already been much admired at several flower-shows, but so far it has not been easy to reproduce the variety by seed, so that it must be increased by sub-division and cuttings, which is best done in the spring. For the plain blue and white varieties it is best to depend upon seed. The seed should be sown in May or June in a frame without heat or in a sheltered spot in the open-air, but very little depth of soil must be allowed above the seed. The plants should after-

× Philageria Veitchii, *Masters.*

This is a very interesting hybrid now flowering in the cool Fernery (No. 3). It is, as the name indicates, a hybrid between Philesia and Lapageria, and was raised by Messrs. Veitch, of Chelsea, many years ago (see *Gardeners' Chronicle*, March 16, 1873, figs. 119 and 120). There are but few plants in cultivation, probably this is due to the fact that it is rather a slow grower, and that horticulturally it is not so useful a plant as the Lapageria, which parent it more closely resembles. The Kew plant is one with branched flexuose growths some 6 feet in length, with leaves that vary greatly in size, the largest being about 2 inches long by ¾-inch in width. The Lapageria-like flowers are solitary or in pairs; they are deep red in colour, the inner segments are about 2 inches long, and broadened at the apex; the outer segments are only half the length of the inner ones, and have an acute apex. *W. H., June 6.*

BOOK NOTICE.

GARDEN COLOUR. London: 29, Bedford Street, J. M. Dent & Co. New York: E. P. Dutton & Co.)

A volume divided into four sections, one for each season of the year, and treated of by the following authors:—Spring, by Mrs. C. W. Earle; Summer, by "E. V. B."; Autumn, by Rose Kingsley; and Winter, by the Hon. Vicary Gibbs. Notes and water-colour sketches are furnished by Margaret Waterfield. This is one of those handsome, we may say sumptuous, books on gardening of which we have of late years seen so many. The collaborators have done similar work before, and their writing, as far as its style goes, will be familiar to our readers. It is not to be inferred, however, that the matter of *Garden Colour* is not original. On the contrary this book is in praise of gardens, according to the several authors, and it is based upon two considerations. The first of these is that long ago propounded by Lord Bacon, that "in the royal ordering of gardens there ought to be gardens for all months of the year, in which severally things of beauty may be in season;" and the second proposition is that arrangement of groups and individual plants according to their habits, forms and colours is most desirable. The beauty of appropriateness should never be overlooked, indeed, should form the first consideration.

The object of the book is to "illustrate the value of artistic massing of colour, a skilful grouping of one variety of plant, and to suggest an ideal for the garden lover of to-day—pictures in flowers changing from day to day and month to month."

The object thus defined is well carried out, and we must not complain if other and equally important aspects of gardening are purposely left on one side. A garden is or should be something more than a picture, for if harmonious colouring be the sole object, why not go back to coloured stones and brightly-tinted fragments of glass, as in a cathedral window. Indeed the illustrations to the book show that the charm of a garden is by no means dependent simply on well-balanced harmony or striking contrasts of colour. A picture on the one hand is lifeless—it may and does excite sympathy and kindle emotions, but itself is dead. The whole garden, on the other hand, is alive. Its inmates are living beings toiling and struggling each in its own way to fulfil its destiny under the conditions in which it is placed.

Love for picturesque effect is certainly enhanced by the study of plant-life and the investigation of the great drama enacted under our eyes, and it is certainly not lessened by accuracy. This is a quality which is somewhat missing in the volume before us. Thus the beautiful blue-flowered Coleus, lately introduced by Messrs. James Veitch & Sons, is here named "Coleus Thyrsoidens." Capitals are used throughout in the most erratic fashion. Thus we have "Crocus Etruscus, C. Biflorus, C. Chrysanthus, Tulipa Sylvestris, T. Reflexa." "Mittallia" represents what is generally known as Nuttallia. We should have supposed this to have been a misprint, but that it occurs more than once. "Felicité Perpetué; Ranunculus amplexicaules, R. Acris, Oreocoma Candoblii," and very many more such dissights show that the proofs have not been so carefully read as they might have been. These are matters of minor importance in a book of this character, but they are disfigurements nevertheless, and engender a distrust of the value of the subject-matter, a distrust which is not in reality justified.

The illustrations are of unequal merit—some are very beautiful and truthful, others are of an impressionist nature, requiring the aid of the legend before one can decipher what the artist intended to convey.

When we say that Rose-culture is the subject of an article by Mr. George Mount, and that Mr. Vicary Gibbs's excellent paper on "Trees and Shrubs for Autumn and Winter Effect" is reprintsd from the *Journal of the Royal Horticultural Society*, it will be admitted that the text of the book varies in quality, as do the illustrations.

The book is handsomely got up, well printed, and provided with an index, in which the names of the plants, though by no means always correct, are not so frequently misspelt as they are in the text. It would be a work for the drawing-room table if the display of books in that way were still in vogue; and it would make a charming present to a garden-lover, as affording a profusion of useful hints and suggestions.

RUBBER.

THE following extract is taken from Mr. Eugène André's *A Naturalist in the Guianas* (Smith, Elder & Co.), and reviewed in our columns September 17, 1904, p. 197:—

Of rubber, two kinds are shipped, true rubber, the product of trees of the genus Hevea, and Balata rubber, obtained from the order Sapotaceæ, the principal source of supply being Mimusops balata. The true rubber, or rather india-rubber, is similar to the article exported in such large quantities from Pará in Brazil, and like the Brazilian product it comes from considerable distances in the interior. Whereas india-rubber has been known to science for quite a length of time,* and has been put to commercial uses for more than half a century, it is only within the last decade that an extensive trade in Balata gum has sprung up, although so far back as 1857 Professor Bleekrod called attention to its value as a substitute for guttapercha.† The tree producing this gum is one of the largest of forest-trees. Its timber is exceedingly hard, heavy and durable, and is of a fine claret colour. It is found all over the West India Islands and in Venezuela, being particularly abundant in the Guianas, where the preparation of Balata gum has become within the last four or five years a very important industry. Unfortunately the method employed to obtain the gum is sure to lead to the destruction of this industry, which, if conducted on intelligent principles might constitute a permanent source of wealth to the countries where the Balata tree is found in the forests. It is almost impossible to exercise any control over the gum-collectors in the vast expanses of forest where their operations are carried on, so that they are at liberty to work in whatever manner they choose, and they have in consequence adopted the method which gives the least labour and the biggest return. Instead of judiciously tapping the trees, the gum-collectors throw them down, and then, by scoring the bark of the trunk and branches, they secure all the sap they can, which they then boil and cast into rough moulds. Sometimes the gum is brought to market in the shape of large blocks. The experienced trader, who has learnt that these blocks may contain heavy stones or other materials not valuable as gum, is very careful in dealing with this class of merchandise. Like most hard-wood trees, the Balata is of very slow growth. Those giants of the forest, recklessly destroyed in a few short hours, have taken hundreds of years to attain their full development. In ten or fifteen years there will not be, it is to be feared, a single Balata-tree in the districts where gum is being obtained by the destructive system in vogue amongst the collectors. What is most to be regretted in the wholesale destruction of these trees is that the very valuable timber they might supply is allowed to remain and rot on the ground. Of course the reason for this is that in most cases the trees are found in the depths of the forest, far from any road, so that the dragging out of logs of this heavy wood would be an undertaking too costly to leave any return on the outlay."

* Torquemada, in his *De la Monarquia Indiana*, published at Madrid in 1615, says: "There is a tree which the Indians call Ulequahuitl. It is held in great estimation and grows in the hot country. It is not a very high tree; the leaves are round and of an ashy colour. This tree yields a white milky substance, thick and gummy, and in great abundance."

† *Journal of the Society of Arts*, October 9, 1857.

SMALL FRUITS IN FOREIGN CATALOGUES.

ALTHOUGH many of the kinds and varieties of small fruits found in gardens in this country are much appreciated on the Continent, there are others which from a variety of reasons are much grown and liked for culinary and dessert purposes there which are comparatively unknown in England.

Taking that useful fruit the Red Currant, mention may be made of the variety Pomona, which produces very long "straps" or bunches, measuring sometimes 15 cm. each, with from twenty-seven to thirty even, middle-sized berries. The bush is a most prolific cropper, and the variety is of American origin. The Red Seedless ripens late in the summer, greatly extending the Currant season, rendering it an excellent variety for growing on the north aspect of walls and on north borders. The fruit is not really destitute of seeds, but these are scarcely distinguishable when eaten, and in consequence of this feature, and its handsome, dark red tint and pleasant flavour, it is well adapted for preserving whole in preference to all other varieties. Red Currant Star of the North likewise possesses very long bunches and berries of middle size, and the bush has great cropping powers. A new American introduction.

Of Raspberries, the varieties grown are chiefly those we grow here, the exceptions being Shaffer's Colossal (see *Gartenflora* for 1891), with very large purple fruits. The variety is a cross between a red and black American Raspberry. The plant is very productive, and makes no suckers. In flavour it is inferior to our red and yellow varieties. Other excellent and productive Raspberries are Von Türcks, a heavy bearing, early variety, good as a market fruit; Vorster's Grosse, fruits very large and dark-red in colour, an excellent dessert fruit; and Double-bearing, from Feldbrunnen, in size very large, in colour red, and of great productiveness in the autumn. The growth is extremely vigorous, and the fruit-crop is not influenced much by periods of drought, thereby making the variety very valuable for field culture. It is of German origin.

Under Brambles (Blackberries), mention may be made of Newman's Thornless, the fruit of which commences to ripen at the end of the month of August. It is black and rather large. The plant is pretty productive and almost destitute of thorns. Another thornless variety, the identity of whose origin is not known with certainty, is met with in some lists. The shoots are said to carry on an average 100 fruits each, and with heavy manuring the crop can be increased from four to sixfold.

Among numerous novelties in Strawberries, note should be made of Deutsch-Evern, which is distinguished by its great earliness, heavy cropping, and magnificent colour. The fruit is of middle size, and of a fine, mild flavour, and the flesh very firm, making it an excellent marketing variety, as it bears transport without injury, a matter of great importance with Raspberries, Strawberries, and Blackberries.

Of varieties of the Strawberry there is nothing better than those we possess, although for field

cultivation for market purposes the following are highly commended in German lists—viz., König Albert von Sachsex, Kaiser's Sämling, Gartenінspektor A. Koch, and Belle Alliance. In alpine varieties Belle de la Parraudière, with shining red fruits of a large size for an alpine, and capital flavour; Belle de Montrouge has its fruits surrounded by a leaf-like calyx, and is a continuous bearer; of this there exists a white-fruited variety. There are two without runners, viz., Busses, white and red-fruited, an abundant cropper, and of excellent flavour; Holland's Glory is a large red-fruited variety, 4 cm. long and 2 cm. broad, very juicy and fragrant. Schöne Anhalterin has very large carmine-red fruits, which colour thoroughly to the point. The flavour is delicious, and the plant a great bearer.

There are two species of edible Sorbus cultivated in Russia and eastern Germany and Austria which are likely to find acceptance in this country as compôte fruits, one being the Russian S. Aucuparia rossica, whose fruit, of the size of culinary Peas, is preserved in immense quantities in the conserve factories at Kieff. The process consists of covering the fruit with sugar in the dry state and exposing it to dry cooking. When finished, the fruit is packed in canisters and small boxes for sale, export, &c. The fruit has a pleasant, sweet-sourish taste, combined with a slight bitterness and astringency.

Sorbus Aucuparia moravica has scarlet-coloured fruits, which make wholesome, enjoyable compôtes, and are also employed in wine manufacture. The berries are a little larger than the Russian variety, but in flavour they are considerably more astringent. *F. M.*

THE FERNERY.

A CURIOUS FERN PEST.

At this season of the year, when Fern-fronds are uncoiling, I frequently find that the tips of the fronds of Athyrium and Blechnum, and rarely of other species, suddenly flag as if for want of water. One or two on a plant suffer in this way, the rest being unaffected. This flagging affects only the upper portions, say 3 or 4 inches, and to the naked eye no cause exists; but on holding the midrib up to the light and examining it with a lens, a slight discolouration is seen at the point where the flagging begins, and on splitting open the midrib it is seen that the central vein is cut through, a brown stain showing at the point of severance. If left alone the top withers entirely, and a small maggot, or usually two, is hatched from a deposited egg or eggs, and commences to eat its way downwards, growing as it proceeds, until eventually the entire core of the frond-stem becomes eaten away and is replaced by brown dust, while at the lowest portion of this one or two maggots about ¾ inch long, and of a pale bluish tint, will be found prior to their emergence when full grown. Curiously enough, although this pest attacks Ferns under glass, I have never yet been able to detect the egg-laying fly at work or even hovering about; nor so far have I been able to ascertain what it is like, which I should very much wish to do, as it is a great nuisance where it prevails. It is my practice now to pinch off the affected tips about an inch below the wound immediately they flag, thus, of course, removing the eggs and preventing to that extent a further generation of flies; since if the frond be left, these flies will inevitably emerge later on from the very base of the frond-stem, unless, as I conceive is possible, the maggots emerge and assume the chrysalis stage in the soil, appearing as flies the following season. This seems the more probable, as I do not find fronds attacked except in the spring, and only when they have nearly uncurled, completed fronds remaining untouched. This, coupled with the softness of the young tissues of the two species of Ferns named, indicates too that the fly has no power of piercing matured and tougher tissues. *C. T. D.*

ODONTOGLOSSUM CRISPUM "RAYMOND CRAWSHAY."

Our illustration (fig. 161), taken from a plant of this fine variety exhibited by De B. Crawshay, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), at the Royal Horticultural Society, April 4, 1905, shows in its perfected condition a flower of a variety which has been much admired for its perfect shape and rare colouring. The variety was exhibited in an early stage of development, May 7, 1901, when it was given an Award of Merit. It was again shown in perfect condition at the Royal

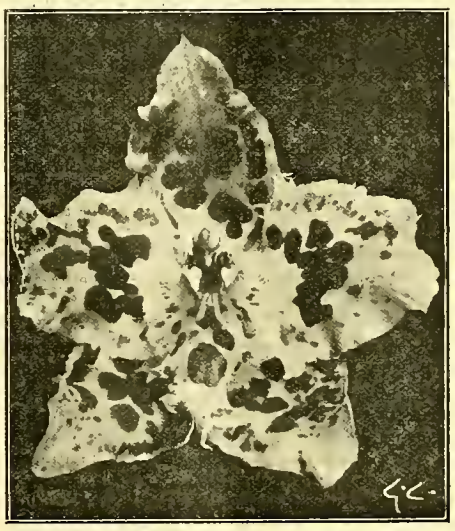

FIG. 161.—ODONTOGLOSSUM CRISPUM "RAYMOND CRAWSHAY."

Horticultural Society, November 12 in the same year, when a First-class Certificate was accorded. The reverse of the segments is tinged with purple, and the beautiful spotting is of various tints of orange-red colour shaded with rose.

PLANT NOTES.

STREPTOSOLEN JAMESONI.

This showy plant, with its masses of orange-coloured flowers, succeeds best when allowed a position quite near to the glass roof, where its long, pendulous shoots with their terminal flower-heads are shown to the best advantage. Here it is planted in quite a small border at the warmest end of a span-roof greenhouse, the main growths being trained to within a foot of the glass, to which we attribute our success in flowering it so successfully. The glass is lightly shaded when the flowering period arrives, and it remains in beauty for a period of quite six weeks. When the flowers are over the plant is cut hard back, as is done in the case of Bougainvillea glabra, and like that plant it pushes forth many shoots, which require to be well thinned out in order that the remaining growths may receive the maximum amount of light. These new growths must be allowed to grow unchecked, and must not be subjected to pinching or stopping; in fact, the treatment should be identical to that given to Bougainvillea glabra. The plants must be frequently watered and not allowed to become dry; when in active growth especially they require liberal applications of manure-water. No stimulant should be given during the week before pruning, but it should be applied for some weeks afterwards, and until the new shoots are making headway. At that stage a little of the surface soil should be removed with a pointed stick, and fibrous loam and leaf-soil, with a little bone-meal and sand, substituted. The plant should be syringed twice daily up to the end of September; this will ward off thrip, the only insect we have noticed to attack this plant.

Serviceable little plants to flower in April can be had by inserting cuttings during May and by standing them in a close propagating-box in a north aspect, shifting them when nicely rooted into 2½-inch pots, and eventually into 48's. Let the plants be fully exposed to the sun until frost threatens, they should then be removed to quite a light position, out of the reach of danger from frost. We train our plants with a single stem, but I see no reason why three shoots should not be encouraged by nipping out the point of the shoot a week or ten days after the first potting is accomplished. For summer bedding the plants proved a failure here. It would be interesting to hear of any reader who has been successful with them in this respect. *James Mayne, Bicton Gardens, Devonshire.*

ARENARIA MONTANA.

This Sandwort, sometimes known as A. grandiflora, was especially attractive in May on the rockery, where it is quite at home. Its large snow-white flowers with yellow anthers are very attractive, produced as they are quite freely. As an edging to a path creeping over rough stones or at the front of the herbaceous border, with a few stones piled up where the growth can creep over, it is a desirable plant, and quite one of the best of May-flowering Alpines.

TRILLIUM GRANDIFLORUM ROSEUM.

This is a fine companion plant to the variety T. grandiflorum, so well represented on p. 308. The warm-pink or pale-rose hue on the flower is so pleasing a contrast to the pure white of the type, and flowering as they do simultaneously, they make a bright display on the rockery in April or the early part of May. *E. M.*

AGAPETES MACRANTHA, *Hook., f.*

This plant, like many other hardwooded greenhouse subjects of early introduction, is now seldom seen in cultivation, although it is a charming plant when in flower, and is one of the best garden plants of the Vacciniaceæ. It forms a loosely-growing shrub with smooth, leathery, lanceolate leaves. The flowers are produced in early spring on the older wood in clusters of three or four. The five-ribbed tubular corolla is 2 inches in length and ¾ inch in diameter, measuring about ½ inch across the month. When fully developed the five lobes are well reflexed. The flower is stiff and wax-like, of a pale rose colour, beautifully veined with claret-coloured markings. The plant was introduced about fifty years ago by Mr. Veitch, of Exeter, who raised plants from seeds gathered on Kola Mountain, Moulmein, by Thos. Lobb. It is figured in the *Botanical Magazine*, t. 4566, under the name of Thibaudia macrantha. Plants were sent to the Cambridge Botanic Garden some years ago by Mr. W. B. Latham, at that time Curator of the Birmingham Botanic Gardens, who cherished many worthy plants that are now not often seen in cultivation (see *Gardeners' Chronicle*, January 19, 1901, p. 47).

HETEROTOMA LOBELIOIDES, *Zucc.*

Of the four or five existing species of Heterotoma, H. lobelioides is the only one in general cultivation. It is a native of Mexico, and is known as the "Bird Plant" on account of the shape of the flowers somewhat resembling that of a bird. The plant is a herbaceous perennial, and grows to a height of from 1 to 2 feet. The leaves are pale-green, broadly ovate, and have an irregularly-

serrated margin. The flowers are borne on loose racemes at the extremities of the shoots. The tube is of a purple colour, with the upper half yellow. The plant is not nearly so well known as its merits entitle it to be, for when grown in pots it makes a charming decorative subject for either the conservatory or the greenhouse. It commences to flower in March, and keeps in good condition for at least two months. Cuttings are easily rooted, and if these are given the same treatment as is allowed to other soft-wooded greenhouse plants they will not fail to give satisfaction. It is also worthy of a trial out-of-doors, and may prove to be hardy. Lobelia laxiflora, one of its allies, and also native of tropical America, has been doing well out-of-doors here, planted against the wall of a greenhouse, for some years past. *E. J. Allard, Botanic Garden, Cambridge.* (See figure in *Gardeners' Chronicle*, August 1, 1885, p. 137.)

HARDY PLANTS.

VANCOUVERIA HEXANDRA.

A NEAR ally of the Epimediums, the Vancouveria has much of the elegance which characterises the majority of these attractive and valuable plants. That it is far less often seen than they is a little surprising; for it has a character of its own, and is worthy of cultivation even where the Epimediums are well represented. Its scarcity cannot be due to any want of natural increase, as it runs freely at the roots, and once established it grows so vigorously that it may even become a troublesome subject if planted in an unsuitable place. Yet it is only when seen in a bold group, or better still in a mass, that the Vancouveria shows its true beauty. This beauty does not lie in the brilliancy of its flowers or a bold and effective habit. On the contrary, its flowers, which are simply yellowish-white, are not such as invite the eye of a casual looker. They are small, of a yellowish-white colour, but their singularly pretty form will please and hold the attention of the true lover of flowers. Nor is its character a bold one, for it forms a group of graceful leaves and slender stems only from 6 inches to a foot high. These leaves are however of beautiful form, and in colour a lovely green shaded with purple, and in themselves most delightful. Although the Vancouveria can be cultivated in sun as well as in shade, it yet prefers a rather shady position and a peaty soil, with a fair amount of moisture in summer. It is easily divided, and the underground offsets which it makes so freely can be taken off to increase the stock.

The running character of Vancouveria hexandra, which is the only member of the genus in cultivation, makes it necessary to give its position due consideration. A good place for it is by the side of a pond; but it must not be hidden by grosser vegetation. A better position would be that at the base of a good rockery. Here it would receive the benefit of the water which drains from above, and, given a fair space, it will be long before it requires to be kept within narrower bounds than it would desire. This species, although introduced as far back as 1827, is not common, either under its true name or under the synonym of Epimedium hexandrum. *S. Arnott, Carsethorn-by-Dumfries, N.B.*

PLANT PORTRAITS.

CYPRIPEDIUM (1) AURIFERUM, (2) ALBERTIANUM, (3) MME. JULES HYE, (4) ELMIREANUM.—*Revue de l'Horticulture Belge*, May.

CATTLEYA WARSEWICZII.—*Gartenwelt*, May 6.

ANGELONIA INTEGERRIMA, Sprengel.—A Pentstemon-like perennial from Paraguay. *Gartenflora*. May.

APPLE CELLINI.—*Bulletins d'Arboriculture*, May.

The Week's Work.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Planting Broccolis and Kales.—On stiff, retentive soil the work of planting proved very difficult during the dry weather in May, especially on ground that had not been well prepared previously. But after the rain of the past week the work can be done with a comparatively small amount of labour and with better results. Broccoli, like all other Brassicas, delight in a rich, heavily-manured soil, but those intended to stand through the winter must not be planted in such conditions. A moderately rich, stiff soil will answer the purpose better, and with a fairly loose surface to plant in nothing further is necessary. If the position is an open one, is well drained, and has some shelter from the north, so much the better. Allow spaces of 3 feet between each plant in the row and a similar distance between the rows also. No greater mistake can be made than that of putting the plants too thickly together, for weakly plants are injured by the first sharp frost. The system of drawing deep drills in which to place the plants has something to recommend it because during the time they remain open they are good receptacles for water, and as the drills are gradually filled in when the plants become established, the additional soil about the roots and stems affords greater protection and support to the plants.

Brussels-Sprouts—The present weather being so favourable for this work, the main plantation of Brussels-Sprouts should be made if the plants have not been already planted. No winter Greens surpass this vegetable for general usefulness and quality. Plant the Sprouts at distances of 2 feet 6 inches to 3 feet each way. The same remarks apply to Asparagus and Cottager's Kale (Veitch's Exhibition and Carter's Welsh Kale), both of which are useful and ornamental.

Purple Sprouting-Broccoli.—A good plantation of this is one of the most useful vegetables in season during an early spring which follows a severe winter. Continue the planting of all green crops as the plants become of a sufficiently large size. If the plants have been subject to clubbing in previous years, let the ground be given a good dressing of air-slaked lime previous to planting.

Parsley.—Attend to the thinning and planting of this crop. It is seldom that an over-abundance of Parsley is found in the garden.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cattleya Warscewiczii (*gigas*).—This glorious summer-flowering Cattleya should be repotted or resurfaced as soon as new roots are seen to emerge from the base of the developing growths. To induce this plant to flower regularly, it is essential that moderately dry conditions obtain at its base until the flower-sheaths appear. When repotting is carried out, retain as few of the old leafless pseudo-bulbs as reasonably are needed. Let the pots or pans be furnished to two-thirds of their depth with crocks, placing them edgewise, and fix the plant in position with good fibrous peat and a little sphagnum-moss. Stage the plants in the lightest and warmest part of the Cattleya-house, and until the new roots are growing freely in the fresh materials apply only very little water, but afterwards and until the resting period begins a good supply will be needed. Moisture sometimes collects beneath the sheathing bracts of the young growths, and causes them to turn black. Where this occurs carefully strip the sheaths back, and dust the parts with powdered charcoal or sulphur to prevent decay or rot. Cattleya Dowiana and its variety aurea, also the hybrid C. × Hardyana, need similar conditions and treatment to those afforded C. Warscewiczii. If the roof of the house is some little distance from the stage, plants of the above are better suspended. New surface materials may be afforded soon after growth commences, but repotting should be deferred until new roots emerge from the base of the growths. A very generous supply of water is needed when the plants are rooting freely, but at other times infrequent and somewhat meagre supplies will be sufficient.

Cattleya Warneri.—Plants of this need rather dry treatment until the flowering period arrives, as they seldom emit roots before that event. It is most successfully cultivated when planted in suspended baskets or pans that have ample drainage, applying a thin layer of peat and sphagnum-moss about the roots. Much water is needed only when the plants are rooting freely. Plants of C. labiata, now fast developing their growths, need careful management during changeable weather or injury may overtake them; too much moisture in the air or at the base, in conjunction with a falling temperature, often proving fatal. This species needs moderate shade during the bright hours of the day, and a considerable degree of heat to develop its growths.

Odontoglossum citrosmum.—When the plants have flowered apply fresh surface materials or afford new receptacles as each case requires. The best results are obtained when they are grown in baskets, though if leaves be introduced into the compost pans are preferable. When putting them into baskets place a large crock or two on the bottom, and fill in with good, lumpy peat and sphagnum-moss. If using a mixture containing leaves, employ more drainage material and surface with peat and sphagnum moss in the ordinary way. Suspend the plants in the Cattleya or intermediate-house, and in either case apply sufficient water to keep the materials moist. Those plants in baskets naturally need more frequent supplies than those in the leaf-mixture. When the pseudo-bulbs are perfected, a long rest in dry conditions should follow. The cool-growing Odontoglossums should be allowed a rest when the flower-spikes have been removed by keeping the plants dry at the base, so long as excessive shrivelling does not occur in the pseudo-bulbs.

FRUITS UNDER GLASS.

By F. JOBDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pines.—Fruits of early-forced Queens, which should now be colouring, have had a very favourable time during May, the sun's heat alone having produced a temperature of 90° to 95° after closing time. Discontinue the use of all manures. Maintain a steady bottom-heat, increase the amount of ventilation, and gradually reduce the supply of atmospheric moisture in order that the fruits may be of good colour and high flavour. Should too many fruits be ripening concurrently, remove some of the plants to a cooler house before they have fully ripened their fruits. At the same time remove and pot any suckers that are of sufficient size for the purpose. The fruits will have better flavour and colour if they are allowed to ripen in an atmosphere that is not very moist. Later plants that are swelling their fruits should receive twice weekly alternate supplies of farmyard liquid manure and guano-water applied liberally. Maintain sufficient atmospheric moisture by damping all available spaces in the house, and by syringing the beds and bases of the plants with weak guano-water. Damp the plants lightly overhead with clear water, but do not cause much water to fall on the crowns of the fruits. Give ventilation freely, especially during the early hours of the day, and allow a small amount of ventilation during the night, opening the ventilators for this purpose at about 7 P.M. Shade the plants lightly during the middle of the day for a few hours to maintain a good colour in the fruits, and prevent the plunging material about the base of the pots becoming dry by applying copious waterings, being careful to see that the water is sufficiently warm for the purpose.

Successional Plants.—The earliest of these will now be well advanced in growth and should be given alternate waterings of weak guano water, liquid manure, and soot-water. Keep the night temperature about 5° lower than is maintained for fruiting subjects, and encou-

rage the plants to make sturdy growth. Plants that are required for autumn and winter fruiting should be allowed somewhat drier conditions, and be given increased ventilation, so that they may have a short rest before their fruits appear. Examine younger plants, and afford them the same careful attention as is recommended for older ones. Repot the plants before they become root-bound, or they will suffer a check, which may cause them to fruit prematurely. Suckers should be potted when sufficiently developed, and the pots plunged in a brisk bottom-heat, where the plants may be shaded from bright sunshine. A bed of leaves placed in an old pit will form a suitable place for plunging these young plants. It will be necessary to keep the atmosphere close for a time.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Grafted Fruit-trees in this locality are rather backward in making growth owing to the want of rain we have experienced. Attention must be given in order to prevent the ligatures from cutting into the bark as growth proceeds. In districts where the union between scion and stock is already complete, and this can generally be determined by the amount of growth the scion has made, these ligatures may be carefully removed. The growth from each graft should be effectively secured to a stake to prevent its being blown out by the wind, the stake used being one that is long enough to support the growth as it increases in length. In cases where the graft has not been successful, a single shoot may be induced to grow from the stock below the graft. This will be sufficiently strong to bud during the coming season. All growths appearing from points below the grafts on young stocks should be removed, but in the case of old trees that have been headed down, a few shoots appearing round about the scion will be useful to encourage root-action, and increase the flow of sap, but they should be removed gradually after the scions have commenced to grow freely.

Morello Cherries.—If the crop is too abundant, those fruits which are hanging towards the wall may be removed, and the bunches of fruit be judiciously thinned by means of a pair of scissors. If there is a trace of black aphis, apply a solution of soft-soap in soft-water, or one of the prepared extracts of Quassia, afterwards giving the trees a thorough syringing with the garden-engine, which will clear away the remains of all flowers and other refuse likely to form lurking-places for insect-life.

Sweet Cherries.—The earliest varieties of this class, such as Guigne d'Annonay, Bigarreau Jaboulay, Early Rivers, Frogmore Early Bigarreau, and May Duke, are now beginning to change colour on walls. The last-named variety is used more for culinary purposes than for dessert. Examine the trees in case there are black or green-fly on them. If these pests are allowed to spread at this season, they will spoil the ripening fruits by the adhesive substance deposited on them. It is rather late to use Quassia-extract for cleansing purposes on trees with the fruit changing colour, as the liquid might impair the flavour of the fruit. Therefore apply a good washing with soapy water used with force through the syringe or garden engine, afterwards washing this off by clear water also from the garden engine. Securely net the trees from the attack of birds. Keep the roots of the trees in a uniformly moist condition by artificial waterings when these are necessary.

Strawberries.—The rains during the last week have proved a salvation to this crop, and as the forward fruits were then half grown, a slight dressing of artificial manure will improve them in size and colour, besides causing the later fruits to become larger in size. Strawberries should now be protected from birds, and large plantations may have a light framework erected over the beds upon which the netting can be placed. The fruits can then be gathered more conveniently than is the case when the nets are placed directly on the plants, and such a structure is, moreover, a more efficient protection from birds.

Disbudding should be continued while growth is soft, doing the work periodically until all the thickly-placed shoots throughout the trees have been removed, and pinching the points out of those which will be retained as spurs. This work will be necessary for a few weeks longer in the case of cordon Apple and Pear-trees, for although these are worked on the dwarfing stocks, they make a large amount of growth, necessitating considerable thinning and stopping, if the use of the pruning-knife later is to be dispensed with and the tree is to be kept in a well-balanced and fruitful condition. Care should be taken that the trees are not denuded of much growth at one operation.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Salpiglossis and *Dianthus.*—Salpiglossis requires a light but rich soil in a sheltered and sunny place. Dianthus Heddewegii and Zinnias require fully-exposed situations.

Herbaceous Plants. — When the flowers of Pyrethrums have faded, in order to induce the plants to flower again in autumn, cut off the old leaves and stalks and apply a good mulch, affording water when necessary. Doronicums, Oriental Poppies, and Potentillas can be treated similarly. Gaillardias raised from seed may be planted now in warm, well-drained soil. Fritillaria imperialis, F. meleagris, and other bulbous plants will have sufficiently ripened their growths that they may safely be cut away. In order to fill up bare places plant Paris Daisies, Nicotianas, Cannas, and other quick-growing subjects. Cyclamen hederæfolium raised from seeds sown where ripened are now fit to transplant. Prepare a piece of gritty ground enriched with leaf-mould, and prick out at a few inches apart. With a little care they will make flowering root-stocks in two seasons. Platycodon grandiflora sown early requires to be planted in nursery-beds. Sow seeds of Myosotis for supplying plants to fill the beds in autumn.

Carnations infested with green-fly should be syringed with a reliable insecticide distributed by means of an Abol syringe.

Annuals. — Half-hardy annuals may now be safely planted—Arctotis grandis, Nemesia strumosa, Schizanthus, Solanum Balbisii, and others. Afford the plants good soil, and provide them with shelter from winds. The earliest sown hardy annuals will soon require to be thinned. Let this work be done on a dull morning. Some of the quick-growing annuals, such as Nemophila insignis, may still be sown.

Climbing Plants require frequent attention in regard to the tying of growths, &c. Many plants are growing in sheltered nooks about buildings and need frequent applications of water from the hose-pipe. If red-spider should gain a footing it must be fought vigorously by means of one of the insecticides, such as Spidacide or Niquas. Half-hardy climbers, such as Cobœa scandens, Mina lobata, Maurandyas, Nasturtiums, and Solanum jasminoides may be planted. Afford them liberal treatment. They are suitable for planting against walls, on pergolas and in other places.

Store Plants.—Select strong plants of favourite strains of Lobelia erinus, dwarf Heliotropes, Tropæolums, Ageratums, &c. Plant them in 5 or 6-inch pots, and place them in the reserve ground. Do not allow them to flower. By pinching the growths a few times they will make sturdy stock plants for another season. If tall Ivy-leaved or other Pelargoniums are used for pillars, &c., pot on the required number and grow them for another season.

Packing Flowers will be an every-day occurrence. Cut the flowers in early morning (evening is next best time), and place them loosely in water for a few hours in suitable receptacles in a cool shed. Have proportionate boxes for size and quantity, and moisten the insides. Line the boxes with packing and tissue-paper. If practicable, pack one kind of flower in a box by itself; but if the flowers are mixed put the heaviest in the box first. Pack firm enough to prevent the blooms shaking during transit. Avoid cutting flowers when they are full of rain-water.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Chrysanthemums.—Early-rooted cuttings that were potted into 6-inch pots as advised in a previous Calendar will now be ready for transplanting into the pots in which they will flower. Preparations should be made at once for this work to be carried out. Do not make too free a use of artificial manures of any description when preparing the compost. Better results will be obtained by judicious feeding at a later stage. In mixing the compost use six barrow-loads of good fibrous loam, one of old mortar-rubble, one of spent manure from a Mushroom-bed, two pecks of charcoal, one peck of bone-meal, together with just sufficient silver-sand to keep the whole porous. These ingredients should be mixed well together. See that the pots are thoroughly cleansed before they are used. Drain them well with pieces of broken pots, charcoal, or clinkers, rather than with ground-bones. If the weather is dull for a few days after the potting has been done, the plants will have a good chance of getting established quickly, otherwise shading from the sun's rays will be necessary. This can be done by placing them under the shade of a wall or hedge for a few days, when they may be removed to their summer quarters.

Herbaceous Calceolarias.—Sow seeds to produce a batch of plants that will flower early next spring. The seeds should be sown in rotten leaf soil which has been passed through a fine-meshed sieve, and an equal quantity of silver-sand mixed together. Fill a pan to within 2 inches of the rim with suitable drainage material, on which place some coarse leaf-mould and the compost described above on the top of this, filling the pan to the brim, then press firmly down with a piece of flat wood and sow the seeds thinly. Carefully press them gently into the soil, but add no fresh soil. Place the pans underneath a hand-light near to a wall, where the sun's rays cannot reach them. The compost should be sufficiently moist when used that water will not be necessary until the seeds have germinated.

Humea elegans.—For raising early plants sow seeds now in old potting soil in a warm temperature.

General Remarks.—Give attention to cuttings of various plants as they are removed from the propagating-frame, separating and potting those that are two or more in a pot before they become too thickly rooted.

THE APIARY.

By CHLORIS.

Ants.—Some of my friends say that this season the honey is being consumed by ants as fast as the bees bring it in. This, I am convinced, is an error. The bees require a great deal of honey to raise brood, and the honey flow little more than meets this want. The true cause, in my estimation, of ants seeking a home in hives is the warmth of the cluster, and it will be found when the bees become strong they will turn the lodgers out. This is always supposing the bees to be stronger than the colony of ants. I have known cases where the ants have been in the ascendant and the bees themselves have been compelled to turn out.

Method of Destroying Ants and their Nests.—Take a stout stake and make a fairly large hole into the nest, then pour in kerosene oil. If the nest be on a lawn, be careful not to spill any on the grass or it will destroy it. This done, plug up the hole with anything handy, or take a kettle of boiling water and pour the contents down the hole. When you have ridded the hives of the pest, place the feet of the stands in saucers filled with water, or better still, oil. Another method is to run a trail of oil (kerosene) round the hives, and this will act as a barrier.

AMERICAN NUT JOURNAL. — Among the numerous trade journals that we receive from the other side of the Atlantic is one which is devoted exclusively to the interest connected with the cultivation of Nuts—Chestnuts, Pea-nuts, Pecan-nuts, Butter-nuts (Juglans cinerea), Brazil-nuts, Pistachio-nuts, and others. It is published every month at Petersburg, Virginia.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JUNE 20 { Royal Horticultural Society's Committees meet. / National Rose Society's Committee meet.

WEDNESDAY, JUNE 21—Yorkshire Gala, York (3 days).

FRIDAY, JUNE 23 { Royal Botanic Society, Lecture, and Meeting at 4 P.M.

SALES FOR THE WEEK.

TUESDAY NEXT—
Sale of the whole of the Established Orchids in variety, at Park Hill, Kenilworth, by Protheroe & Morris, at 12.30.

WEDNESDAY NEXT—
Palms, Plants, Ferns, Begonias, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY NEXT—
Cattleya Schröderæ, Odontoglossum crispum, from Messrs. Sander & Sons, and others, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —61·6°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, June* 14 (6 P.M.): Max. 70°; Min. 55°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June* 15 (10 A.M.): Bar., 29·8; Temp., 69°. *Weather*—Bright sunshine.
PROVINCES.—*Wednesday, June* 14 (6 P.M.): Max. 60°, Norwich; Min. 57°, N.E. Scotland.

British Gardeners' Association.

THE British Gardeners' Association is just one year old. The isolation of gardeners, their lack of cohesion, the absence of co-operation among them, their "want of faith," have been noted and deplored for many a long year. Those who know the facts have been and are surprised that the social position and remuneration of gardeners (we are not speaking of exceptional cases) are by no means adequate to the lengthened training, the forethought and intelligence required of them. The position accorded to the gardener is not adequate when compared with that meted out to some of his fellow-servants from whom less is expected, or as compared with that accorded to the superior artizan. Head gardeners who have risen to high positions do not always sufficiently recognise the laudable aspirations of those in the ranks, and do not do all they might to encourage young men in their desire to better their condition. Individual character and self-help are, of course, the most important factors, but a helping hand at certain stages of a man's career is almost equally important. This helping hand the Association is devised to supply. In some quarters disappointment is expressed at the fact that on May 25 the members of the Association only numbered six hundred and thirty-two, a very small proportion of the gardeners of the country. For our own part, bearing in mind the great difficulties incurred in rousing gardeners to a sense of their responsibilities in this matter, and in getting them to co-operate, the adhesion of over six hundred members in the first year is by no means unsatisfactory. An association of this character cannot leap into position all at once. It must grow, evolve, adapt itself to circumstances. Prudence, caution, and a due regard for the opinions of honest objectors must characterise its management. Given these, the objects of the Association are so well calculated to benefit the profession that we can but look forward with confidence and hope.

The objects of the Association are to facilitate the selection of the competent and the honest and to "rogue" or at least to ignore those who are not worthy of the name of gardeners. Employers at the present time, when they cannot avail themselves of the personal experience of trustworthy friends, have to depend on the recommendations of the trade, or the hazardous experiment of the advertising columns. Head gardeners have no formal guarantee that the candidate for an appointment possesses the qualifications which he ought to have to fulfil the duties of his office. Such a guarantee the Association will, when it gets into working order, be able to offer. Some, mindful of the tyranny which has been occasionally associated with trade-unionism, and detesting the infringement of the liberty of the individual that sometimes fetters the best men and forces them to remain in a position of mediocrity, have failed to give in their adhesion to this Association. But it is not the bad features of an evil system of trade-unionism that the Association desires to copy, but that helpful co-operation which, whilst encouraging and developing the self-respect of its individual members, secures the recognition of the rights of others.

CYMBIDIUM RHODOCHEILUM (see Supplementary Illustration).—This fine species was introduced by M. G. WARPUR, a Belgian collector, in 1900, and first flowered in The Royal Gardens, Kew. It was doubted whether the plant would be amenable to cultivation, but the fact that it has been successfully grown was proved by the specimen exhibited by J. BRADSHAW, Esq., The Grange, Southgate, at the Royal Horticultural Society's meeting on May 10 last. A First-class Certificate was unanimously voted for the specimen; which was greatly admired on account of its stately habit and distinct colour. The sepals and petals are yellowish-green, but the petals are spotted with dark purple, the front and sides of the labellum being of bright rosy-red colour. It requires to be grown in a warm-house, and should be afforded an abundance of moisture and shade during the summer. We are indebted for our illustration to Messrs. W. BULL & SONS, Chelsea.

THE ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held in the Society's Exhibition Hall, Vincent Square, on Tuesday, June 20, when a lecture will also be delivered by the Rev. Professor HENSLOW, V.M.H., on "The Plants of the Bible," which will be illustrated by lantern-slides.

—— We are reminded by the Secretary that the Society's Summer Show, which for the last few years has been held at Holland Park, will this year be held in the grounds of the Royal Military Hospital, Chelsea, on Tuesday, Wednesday, and Thursday, July 11, 12, and 13, the arrangements for which will be similar in all respects to those in force at the Society's shows at the Temple. The Chelsea site is ten minutes' walk from Victoria Station, and less than five minutes from Grosvenor Road and Sloane Square. Omnibuses run along the sides of the estate from all parts, including Liverpool Street, Clapham Junction, Walham Green, Shepherd's Bush, Holloway, and other outlying parts of the metropolis. Copies of the schedule may be obtained on application to the Secretary, Royal Horticultural Society, Vincent Square, S.W.

FLOWERS IN SEASON.—To Mr. LINDSAY, of Murrayfield, Midlothian, we are indebted for flowers of Veronica Hulkeana, a New Zealand shrub with oblong-obtuse, crenate leaves about ¾ inch long, tapering at the base into a short stalk, and bearing much-branched, elongated, pyramidal clusters of pale lilac flowers. A variety, also sent, has denser, less-spreading clusters, and somewhat darker flowers. V. Fairfieldi × has much shorter flower-clusters, and is considered to be a hybrid between V. Hulkeana and V. Fairfieldi. Pentstemon Menziesii, with small (⅔ inch long), somewhat fleshy, oblong leaves tapering at both ends and slightly toothed at the margins, bears its numerous glowing crimson flowers in clusters at the ends of the branches. Each flower is about ¾ inch long. Growing in a mass the effect must be magnificent.

HORTICULTURAL CLUB.—Mr. D. B. CRANE will read a paper, on the 20th inst., on the "Beauty of the later Developments of the Pansy, and Dr. STUART's work in hybridising the Violas to produce garden flowers for massing." The paper will be illustrated with flowers of the principal varieties.

RHODODENDRONS AT THE ROYAL BOTANIC GARDENS, REGENT'S PARK, N.W.—Messrs. JOHN WATERER & SONS, Ltd., Bagshot, Surrey, opened their annual exhibition of Rhododendrons on Thursday, June 8, and it will remain on view throughout the present month.

THE YORKSHIRE GALA.—The floral *fête* in connection with the York Gala will be held in Bootham Park, York, on Wednesday, Thursday, and Friday next, June 21, 22, and 23. Prizes to the amount of £700 will be awarded, and a good show is anticipated.

VIENNA CONGRESS.—The Botanical Congress in connection with the International Botanical Meeting in Vienna is taking place from June 11 to 18. Associated with the Congress, an exhibition has been organised in the Schönbrunner Orangerie. This includes a historical section, a collection of modern appliances for the assistance of research and instruction, and a horticultural section. The exhibition will remain open from June 11 to 25, but it is proposed to close the botanical division on the 18th of this month.

POTATOS.—The Honourable A. H. T. de Montmorency, of Carrickmines, Co. Dublin, exhibited some well-matured and large Potato tubers at the Temple Show, the varieties being Royal Kidney, Sir John Llewelyn, Snowdrop, and his own variety, The Scout. They were grown, we are informed, in a house built specially for Potato-culture, in which there is no bottom-heat either from the employment of hot-water or manures, and only sufficient surface artificial heat is used to ward off frost. As it is by the heat of the sun they are brought to maturity, the roof having a certain pitch which collects all the heat and light, they are quite like Potatos grown in the open, and have no appearance of having been forced. He also secured the award of Cultural Commendation on December 14, 1904, for a dish of new Potatos grown from some tubers that he exhibited at the Temple Show in the previous May.

THE GARDEN CITY. — The Garden City, which is gradually rising at Letchworth, within an hour's journey of King's Cross, was seen on the 31st ult. in an interesting stage of development by members of the Worshipful Company of Gardeners, by whom it was visited. Already about a thousand persons are settled on the estate, which covers 3,800 acres; and in course of erection for a prize exhibition next month are eighty or ninety cheap cottages. Amongst builders not only in the district, but also in various parts of the country, great interest is being taken in this cheap cottage exhibition, for prizes of the total value of £600 or £700 are being offered for the five that are adjudged the best. The whole principle of the scheme is to get manufacturers and others there with their workpeople. In order to attain this end, the rents of the cottages have been fixed as low as 5s. a week, ample accommodation being provided on the most approved plans. It will be gathered from what has been detailed that considerable progress has been made with the city during the eighteen months that the Company has had possession of the estate. Exceedingly useful work has also been done in providing employment and accommodation under the auspices of the Mansion House Committee for 300 of the unemployed. The last of these men left the estate about a week ago, and the buildings which they occupied will be brought into use as administrative offices for the Cheap Cottages Exhibition. A pleasant feature of the proceedings during the afternoon was the naming, by Mr. OSMAN, Deputy-Master of the Gardeners' Company, of an open space to be used as a park, and known as Howard Park, in honour of the founder of the city. When asked what the visitors thought of the city, Mr. OSMAN said they were extremely pleased with it. He specially noted the fact that the houses and cottages were substantially built, with good spaces between them, and he added that he thought the exceptionally low rents would make them very attractive. In any case he feels that the city is bound to succeed, and that it will return to those who are financially interested in it moderate dividends. In the evening the Directors of the Garden City Company were the guests of the Gardeners' Company at a dinner given in town. Mr. MERVYN E. MACARTNEY gave a lecture on "Garden Architecture," illustrated by lantern-slides.

A NEW ALPINE FLORA.—We note the appearance of *Alpenflora*, die verbreitetsten Alpenpflanzen von Bayern, Tyrol und der Schweiz, by Dr. GUSTAV HEGI, Privatdozent und Kustos am k. Botan-Garten, Munich, and Dr. GUSTAV DUNZINGER, also of Munich. The book contains brief descriptive letterpress of the chief species and varieties of alpine plants, and a great number of coloured plates. It should prove useful to the many tourists who, in summer and early autumn, visit the mountainous districts mentioned. The publication issues from J. F. LEHMANN'S Verlag, Munich.

TREES.—Messrs. HUTCHINSON & Co., Paternoster Row, will shortly publish the first number of an important new work on "British Trees," by Mr. REX VICAT COLE, to be completed in thirty fortnightly parts at 1s. net each. The author, who is a member of the Royal Society of British Artists, has made a long and careful study of his subject, and his notes have been modelled to their present literary form by Miss DOROTHY KEMP. The work will contain 250 drawings by the author, many of which are from his pictures that have been exhibited at the Royal Academy and elsewhere. Besides the general edition there will be a limited issue at twice the price.

THE BIOLOGY OF MELAMPYRUM. — M. L. GAUTIER contributes to the *Comptes Rendus* for May 22 a paper on the biology of Melampyrum pratense (yellow Rattle). This plant is remarkable as being semi-parasitic. The causes that determine its habitat have long been imperfectly known. Melampyrum shows a special preference for the terminal ramifications of the roots of Beeches. A mass of fungus mycelium is frequently attached to the roots, and to this also the parasite appears to attach itself. Melampyrum pratense, according to our author, is especially found in soils rich in humus, wherein it seems to seek for those fungoid growths which, according to FRANK, form the greater part of the humus of our forests, as in Fontainebleau, where the leaves fall abundantly, and the "mycorhiza" find it correspondingly easy to develop. The Beech, which is there abundant, has its roots infested by the mycelium filaments of the humus; the suckers of Melampyrum pratense attach themselves to these in preference to any other roots, and ally themselves intimately with the mycorhiza of the tree. If these "mycorhiza" are considered as taking a part in the nutrition of the plant it is not difficult to conceive that the Beech, better armed than neighbouring plants for the struggle for existence, turns the nutritive substances of the soil to its advantage, and that Melampyrum pratense has thus every inducement to fix its suckers into such a powerful absorbing apparatus. The abundant humus rich in hyphæ, the neighbourhood of the Beech or of another species to the mycorhiza as a consequence may therefore be considered as factors highly favourable to the parasitic habits of Melampyrum pratense, and as justifying its selection of its habitat.

CULTIVATION OF AZALEAS IN DRESDEN — Mr. P. J. SCHENK, in a recent issue of *Le Jardin*, describes the method of cultivating Azaleas as practised in Dresden, which is different from the plan usually adopted at Ghent. In Dresden, "Azaleas are often grafted on Rhododendron Cunninghami. At the end of July or the beginning of August the grafts are placed in a house where all the openings are closed with wood-shavings. The house is shaded by means of wide boards, which are also used to cover it at night. The air of the house is kept moist by frequent waterings. In addition to being grafted, the shoots of the Azalea plants which are cut off are struck as cuttings in low boxes placed under the stages on a heap of sawdust; this sawdust serves in winter to cover the great wooden houses called 'Japans,' where grafted plants two or more years old are planted on the stages. The ungrafted Azaleas are also propagated by cuttings at the same time as the cuttings which are to serve as stocks next year. All these cuttings are pricked out in the same low propagating frames when rooted, and are wintered in the same houses in which the Azaleas in pots are kept, and in the corridor which connects a whole series of low houses. They are planted then in spring in mixed compost in an open house called 'Grundkasten.' The plants do not leave this until the grafting time. The grafted plants in the houses are freed from the ligatures which join the grafts to the stocks as soon as new growth is evident. At the end of June, when the oldest plants are removed from the 'Japans' the grafts that are now about a year old take their places. They remain in the 'Japans" for about a year, then are planted in the 'Grundkasten' during the summer, and are replaced in the 'Japans' for the autumn. In the third year after grafting they are transplanted in the 'Grundkasten' for the last time, as Azaleas three years old are usually potted at the beginning of September, unless they are not strong enough or unless they are destined to make great bushes of several years' growth. The plants in pots winter in the temperate houses, and in summer are placed in full sun under simple wooden erections that are easily covered in bad weather and which afford shade when the sun is too powerful. It is here that Azaleas form their flower-buds. To encourage this they are sprinkled several times daily, and after July are given but little shade. In September the purchasers arrive, and the plants are sent out about the 15th of the month. The following are some of the differences between the Belgian and the Dresden plants:—The Ghent grower trains his plants so as to make fine, symmetrical heads; the Dresden grower prunes them to check overvigorous growth and to favour the formation of flower-buds. Thus the latter obtains plants of loose and informal habit. The varieties of Azalea employed are the following: A. phœnicea, especially used for standards; A. concinna, only employed to form small plants, as it grows slowly at first and only vigorously after three or four years. This variety is certainly the best for grafting for wholesale purposes. The third Azalea preferred in Dresden is a hybrid called Hexe, raised by crossing A. amœna Forsteriana with A. hyb. Duc Adolphe of Nassau. Hexe is not merely used as a stock, but is also grown for fine plants for trade purposes; it is apt to produce too many shoots on the stem, and consequently is more or less covered with knobs. The sorts chiefly cultivated in Dresden and the neighbourhood are Deutsche Perle, Talisman, Apollo, Simon Mardner, Sigismond Rucker, Emma, Président Comte Oswald de Kerchove, Hélène Theleman, Professeur Wolters, Vervæneana, Eggebrechtii, Impératrice des Indes, Frau Hermann Seidel, Madame Van den Cruyssen, Niobe, and Sakuntala."

"TREES AND SHRUBS."—The fourth part of this valuable publication, edited by Professor C. S. SARGENT, has been issued. It consists of illustrations and descriptions of new or little-known ligneous plants, prepared chiefly from the collections in the Arnold Arboretum. The plants figured in the present number include numerous Maples, such as Acer truncatum, Oliverianum, sinense, Wilsoni, erianthum, flabellatum, caudatum, Davidii, urophyllum, tetramerum, barbinerve, and Francheti, thus including various species collected in China by HENRY, WILSON, and others. A conspectus of the East Asiatic species with differential characters is supplied by M. REHDER. Three species of Parthenocissus are mentioned — P. quinquefolia (better known as Ampelopsis hederacea), dumetorum, and Texana; three of Rhododendron—amœnum, sachalinense, japonicum; two of Arctostaphylos—virgata and vestita; two of Pinus—Altamirani and Pringlei (both of Mexican origin); Malus Zumi, Dracæna americana from Guatemala, and Oroxylum flavum.

ANTS AS GARDENERS.—According to a recent number of *Nature*, the April issue of *Himmel und Erde* (Berlin) contains an illustrated popular account of the "flower-gardens" made by ants in the crowns of trees in Amazonia and Peru, as discovered and described by Mr. E. ULE. These "gardens," or perhaps we might rather say "baskets," are shown in various stages of growth, from the time when the plants are just budding until the long slender leaves of Streptocalyx angustifolius, which appears to be the favourite species, are fully developed. All the plants cultivated appear to have very minute seeds or spores, which seem to be sown by the ants in their nests.

"HOW TO USE NITRATE."—A pamphlet under this title has been issued by G. SPEET & Co., 30, Coruhill. It contains a lecture by Dr. BERNARD DYER on the application of artificial manures, and a large number of valuable hints as to the application of this fertiliser. For hay crops a mixture of one part of nitrate of soda, two parts of superphosphate, and two parts of kainit, is recommended. For 1 acre the "parts" may be reckoned as so many hundredweights.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.—In the number for May, 1905, the following plants are figured:—Ænia polystachya, Bentham et Hooker; Epidendrum dichromum, Lindley; E. variegatum, Hooker; E. Lambeauanum, De Wildeman; Odontoglossum crispum var. Luciani, Hort.; Cypripedium Chamber-Leeanum, Rolfe; C. callosum-Charlesworthii, Hort.; C. Hera var. Gillianum, Rolfe; C. Orion Veitch; Dendrobium crassinode, B. et R.; D. chlorostele var. Juno, Hort.; Vanda cœrulescens var. Boxallii, Reichenbach; Megaclinium Fuerstenbergianum, De Wildeman. We note that a large Gold Medal was awarded to this publication by the International Jury at the late Paris Exhibition. This useful publication is illustrated and published by M. GOOSSENS, Avenue Walkiers, 68, Auderghem, Brussels.

EXPERIMENTS WITH FUNGOUS DISEASES.—Mr. ERNEST SALMON is continuing his cultural experiments with "Biologic Forms of the Erysiphaceæ." He had previously shown that it was possible to infect with the fungus leaves that under ordinary circumstances are immune.

"We see, then," says he, in a recent paper in the *Annals of Botany*, "from the results of experiments, that not only mechanical injuries, such as wounds from cuts, bruises, attacks by slugs, &c., but also injuries due to the action of narcotics and heat, cause a leaf to become susceptible to a 'biologic' form of a fungus to which it is normally immune. . . . It is obvious that mechanical injuries quite similar to those produced by cutting, bruising, &c., described in the experiments, are constantly being inflicted on plants in nature—by animals and by frost, hail, wind, &c. In the case of cereals the agricultural operation of rolling seedling plants causes a number of leaves to be torn or bruised. An experiment carried out during the last spring demonstrated that bruised places on leaves produced by rolling are rendered susceptible in the same way as those caused artificially by pressure in the experiments mentioned. At the beginning of last May he collected from a field of young Barley which had just been rolled a number of bruised leaves. The soil of the field was stony and 'steely,' and in the operation of rolling about 30 per cent. of the leaves had been bruised more or less severely. Ten of these injured Barley-leaves were placed in a Petri dish on damp blotting-paper, and each inoculated over the bruised cells with conidia taken from Wheat leaves. On the fourth day several of the leaves bore at the inoculated place numerous small straggling mycelial patches, and on the seventh day these patches, in the case of four of the leaves, bore several little tufts of a few clustered conidiophores. A number of saprophytic fungi were now growing vigorously at the injured places, and stopping the further growth of the Oidium. . . . In the hypothesis already advanced to account for the susceptibility shown by leaves injured by a cut or burn, it was assumed that in consequence of the vitality* of the leaf-cells being affected by the injury, either the protective enzymes or similar substances normally present are destroyed or become weakened, or the production of them by the protoplasm is interfered with in the cells in the neighbourhood of the injury. This hypothesis may still be advanced to account for the same susceptibility being shown when leaves are injured by the action of alcohol, ether, chloroform, or heat, since it is known that protoplasmic functions are temporarily inhibited by anæsthetization, and that a high temperature may partially or entirely inhibit the process of the secretion of an enzyme or ferment. Attention may be directed to the fact that these cases of the loss of immunity, brought about by causes which affect the vitality of the leaf, find their exact parallel in the recorded instances of induced susceptibity in animals to certain diseases caused by bacteria. The decrease of vitality caused by fatigue, action of drugs, abnormal food, or environment, has been proved to induce susceptibility to certain bacteria in the case of animals which are immune under normal circumstances. . . .

1. Susceptibility can be induced not only by the various kinds of mechanical injury, but also by such interference with the normal functions of the cell as follows the application of anæsthetics and heat.

2. The conidia of the first generation produced on leaves of a strange host-plant previously subjected to the action of alcohol, ether, or heat, retain the power of infecting their original host, and do not acquire the power of infecting normal leaves of their temporary host."

* Until our knowledge of the physiology of the cell has progressed further, it is necessary to use the general term vitality to express the sum of the individual physiological processes at work in the cell. External factors which affect the normal balance in the working of the individual physiological processes increase or decrease the vitality of the plant.

MONMOUTHSHIRE EDUCATION COMMITTEE.—Mr. W. J. GRANT reports on the three months' work between January 23 and April 25. In addition to instruction in various branches of farming, horticultural lectures and demonstrations have been given at various places in the county. A course of twelve days' practical instruction in the management of hedges has been given, and also suggestions as to the improvement and extension of fruit crops. The rainfall for the first three months of the year was no less than 9·65 inches below the amount in the corresponding period of the previous year.

OVER-SEA SUPPLIES: MAY.—The Trade and Navigation Returns for the past month continue to show an upward movement. The value of the imports is placed at £46,832,967, as against £44,780,098 for the same period last year—or an increase of £2,052,869. The exports also show a large increase. The value for last month was £27,252,693, against £24,332,089 for the same period in 1904—an increase of £2,920,604. The value of those imports in which we are particularly concerned will be found summarised in the following table:—

IMPORTS: DESCRIPTION OF PRODUCE.	1904.	1905.	Difference.
	£	£	£
Class I. — Cereals, and other field crops — Wheat, Barley, Oats, &c.	5,601,335	5,712,141	+110,8.5
Class II.—All other food cultures — Tea, Coffee, Fruit, &c.	4,337,740	3,933,199	−404,541
Class III.—Used in manufactures — clothing, household goods, &c....	6,845,135	7,491,802	+6·9,467
Class IV. — Miscellaneous — including seeds, flowers, &c.	1,468,861	1,531,336	+62,475
Values of Produce...	18,253,072	18,671,278	+418,206

The value of the fresh flowers imported last month shows a decrease of some £381 as compared with May, 1904—£17,319 against £17,703.

Our fruit and vegetable imports table is as follows:—

IMPORTS—MAY.	1904.	1905.	Difference.
Fruits, raw—	£	£	£
Apples	160,442	152,899	−7,543
Apricots and Peaches	192	1,792	+1,600
Bananas	148,992	157,091	+10,099
Cherries	64,353	42,589	−23,784
Gooseberries	1,307	1,020	−287
Grapes	4,698	5,379	+681
Lemons...	35,539	31,648	−3 891
Nuts—Almonds ...	23,201	19,095	−4,106
Others used as fruit	32 538	45 742	+13,204
Oranges...	235,715	131,416	−104,299
Pears	3,318	4,461	+1,143
Strawberries	5,612	8,800	+3 188
Unenumerated ...	12,028	15,047	+3 019
Vegetables, raw—			
Onions ... ...bush.	134,869	110,963	−23,906
Potatos ... ... cwt.	364,209	299,129	−65,080
Tomatos ... ,,	115,589	99,247	−16,342
Unenumerated ,,	57,543	55,043	−2,500
Totals ...	1,400,145	1,181,341	−218,804

Since the issue of our last "Oversea" notes, the Cape fruit supply season has closed—1153 packages having to be added to the totals previously recorded. There is promise of an increased importation of Apples. The value of the dried fruit imported last month shows a decrease of £15,328 as compared with the figures for the same period last year—£9,949 as against £25,277; and here it is worth noting that the demand for the fruit is stated to be gradually contracting. Attention may be called to the not improbable increase in the acreage devoted to Potato-culture in this country consequent on the proposed substitution of Potato-spirit for petrol in the propulsion of motors.

"MY NEW ZEALAND GARDEN."—By a Suffolk Lady (London: Elliot Stock, 62, Paternoster Row, E.C.). The garden here described is certainly very different to the more or less formal plantations familiar in England. Shrubs and trees that are tender or but half-hardy in this country grow luxuriantly in New Zealand, and the "Lady's" garden is adorned with what are, in one sense, wild flowers. Written unconventionally and with no little humour, the book makes pleasant reading, and an apologetic preface disarms criticism even as to grammatical errors and mistakes in plant-names. The following extract is illustrative of the writer's general style:—"Among New Zealand Coniferæ, Dacrydium cupressinum (the Rimu or Red Pine) in its young state excels all the family in beauty. An irregular green fountain might roughly help to describe it. Its pendulous branches coming out from the central stem and falling all round, from the top to the ground, have rather that effect. These branches, which are about the thickness of thin rope, are covered with scales of a brilliant green; they are always looked upon as the handsomest forest trees, and although they are very pretty almost from their cradle, about 12 feet high is the prettiest size; and I believe they are rather stationary in growth at about that age, as if trying to prolong their most beautiful stage. The wood of the Rimu is very satisfactory, and is used almost exclusively for building in this locality." The careless writing may be partly excused by the good spirits with which the "Lady" sets about her tasks, be they literary or manual. She desires a beautiful garden, and obtains it by thought and labour; she wishes to describe it pleasingly, and succeeds in spite of digressions and of too rapid a pen. We can commend the full-page photographic illustrations, showing us various nooks and corners in the garden and their inhabitants. Amongst other things the "Lady" narrates an interview with the famous globe-trotter, Mr. BARR. There are incidental notes on New Zealand plants which increase our oft-expressed wonder why our colonial friends are so anxious to imitate European customs, when they have such beautiful flowers at their own back doors.

"ANOTHER HARDY GARDEN BOOK."—By HELENA RUTHERFURD, Ely (New York: The Macmillan Co. London: Macmillan & Co.). The title seems to suggest that this is in some way a sequel to the writer's former book, *A Woman's Hardy Garden*, though it sounds like an exclamation that still another addition should be made to the numerous volumes already penned on this subject. The pages before us claim to chronicle only the result of personal experiences in raising vegetables, fruits, and flowers, and is not intended as a dogmatic treatise. The many amateurs whose gardens are an ever-new delight to them will read their fellow-enthusiast's pages with much sympathy. "Go out into the country, O ye flat-dwellers of the city," says she; "have a few rods, if no more, of your own ground about you, and till it and tend it; the flowers you raise will be sweeter and more beautiful to you than any displayed in florists' windows, and no vegetables that can be bought will compare in flavour with those you will raise yourself." From this encouraging beginning we are led on to share the writer's confidences concerning her various crops, and how she tended them and advises others to tend them. The whole is pleasant reading, with evidence of good spirits on every page. We must not forget to praise the pretty but not flattering photographic illustrations of special flowers and

of groups of them, and of nooks taken in the author's garden by Professor C. F. CHANDLER. They might well, most of them, be illustrations made in an English garden, though really representing scenes at Meadowburn Farm, on the further side of the Atlantic. With few exceptions the gardening hints are quite applicable in England also.

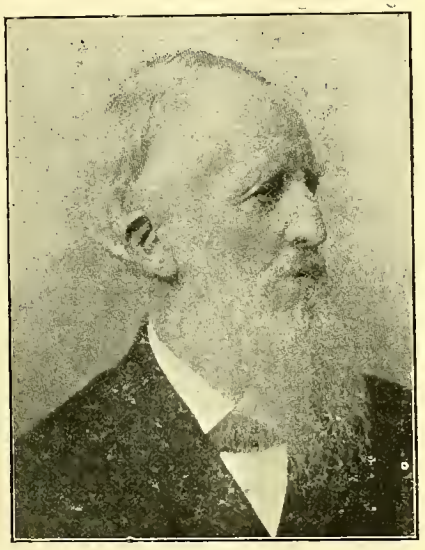
DEATH THROUGH THE FALL OF A BRANCH IN KENSINGTON GARDENS.—The death of a young lady last week, caused by the fall of a large decayed branch from a tree in Kensington Gardens, should afford a lesson to those critics who are ever ready to complain when the authorities charged with the responsibility of keeping public parks or forests, have reason to prune or fell aged trees. It is most necessary in places to which the public have access that trees of large size, and particularly Elm-trees, should be examined frequently, and that measures should be taken to ensure safety for those who may walk beneath them. Even when all possible care is taken, as it is in the London parks, accidents cannot altogether be avoided.

INVESTIGATION OF PLANT DISEASES IN GERMANY.—The Department of Plant Diseases of the German Agricultural Society has recently been transferred to an Imperial Institute. In 1889, at the instigation of Professor KÜHN, of Halle, the German Agricultural Society resolved to form a section which would be concerned with the investigation of the diseases and insects that attack crops. By the summer of 1891 the section had established communication with twenty-one local stations distributed throughout Germany. These consisted, for the most part, of the State experimental stations, though some were of a private character. The work of investigation and the distribution of information was carried out without any subvention from the Society. The first Report was issued in 1893, and a volume has appeared annually since that year. The first Report contained 106 notices of attack, whereas the number in the twelfth Report was 3,904. At the present time some forty local stations are affiliated with the central Society. A book entitled *The Protection of Crops against Diseases and Insects* was issued free to members of the Society in 1892, and 22,000 copies have been distributed. The work, having somewhat outgrown the resources of the Society, has now been taken over by the Biological Department of the Imperial Board of Public Health, and considerable extension is contemplated. The various States of the Empire have been approached by the Imperial Home Office with a view of securing the support of their research stations, and cordial co-operation has been promised. A central institute, fully staffed and equipped, will be established in each State, Province, or group of Provinces, and each central institute will have subsidiary institutes or stations affiliated with it. The latter will consist largely of local colleges, agricultural schools, experimental stations, and the like. Finally, each of these subsidiary stations will be associated with local collectors, chiefly farmers, gardeners, and foresters, of whom it is proposed to appoint about 1,000 for the Empire. The information supplied by the collectors will, in the first instance, be transmitted to the subsidiary institutes, from which it will be passed on to the central institutes, to be finally issued in an Annual Report to the Board of Public Health. Applications for advice will for the most part be dealt with by the subsidiary institutes, only the more difficult problems being investigated by the central institutes. *Cited from the Journal of the Board of Agriculture.*

CATALPA.—Professor SARGENT, in 1889, published an account of a hybrid Catalpa known as C. "J. C. Teas," and supposed to have originated from a cross between C. Kæmpferi and either C. speciosa or C. bignonioides. Latterly Professor PENHALLOW has studied the anatomy of the wood in this and other species, and has published an account of them in the *American Naturalist* for March, 1905. We cannot enter into the details, important as they are, but they show that C. speciosa is not one of the parents, but that C. "J. C. Teas" is the result of a cross between C. Kæmpferi and C. bignonioides, as suggested by SARGENT. The dominant characters of the hybrid as expressed in the anatomical structure are those of the Japanese parent.

MR. J. MEDLEY WOOD.

MR. J. MEDLEY WOOD, the Director of the Botanic Gardens, Durban, is one of our oldest correspondents and the leading authority on Natal plants. He has lately celebrated his golden wedding, and we should like to associate ourselves



J. MEDLEY WOOD,
Director of the Botanic Gardens, Durban.

with his fellow-countrymen in thanking him for all he has done for the botany of Natal and in congratulating him on this most interesting occasion.

THE ROSARY.

ROSE DOROTHY PERKINS.

THIS new R. Wichuriana hybrid was beautifully shown by Messrs. Cannell & Sons at the Horticultural Hall, Vincent Square, S.W., on May 9 last, the three plants staged being literally crowded with tender, rosy-salmon-coloured blossoms.

The proper season for flowering is June and July and onwards in minor degree until the month of September. The plant is a strong grower, and even in pots, as observed on this occasion, the growth was robust, so that it is a capital variety that may be employed for forming pyramids and weeping examples, or as a hedge, a wall covering, or a pillar plant. The flowers are semi-double and fragrant. *F. M.*

RAMBLER ROSES.

Some Roses of this class, new in commerce, were noted at a recent meeting of the Royal Horticultural Society. Notably were Anna Rübsanien, having semi-double pale-pink blossoms; Ernest Grandpierre, with double white blossoms, and central petals of primrose tint; Non Plus Ultra, of a deep bright purple colour; Waltham Bride, a hybrid variety having white blossoms; Wedding-Bells, an almost single-flowered Rose of a pink colour; and Taunusblümchen, a blossom of a deep pink tint. All of these appear to possess features which make them desirable acquisitions to the Rose-garden proper, or for forming pyramids, pillars, and fences in the flower-garden and pleasure-garden. As forced plants in cold conservatories, worked high on tall Dog-rose stocks so as to show up above other subjects, especially Camellias out of bloom, Orange-trees, and New Holland plants, to which Roses appear in pleasing contrast, they may be greatly recommended. Some possess fragrance, and all are very floriferous. I do not consider their beauty to be enhanced by close training, rather the reverse. *F. M.*

ÉTOILE DE FRANCE.

This new Hybrid Tea Rose, which was distributed last autumn by J. Pernet-Ducher, of Lyons, promises to be a valuable variety. The colour of the flowers is crimson with a darker centre, being just what is required in this class. The habit of the plants is vigorous and the foliage good. I have not seen many aphis on our solitary plant. The flowers, which are just opening, are of the much-desired pointed form, and of good substance. I think the variety will make a good Rose for market-growers; the buds come singly, and the shoots have very few thorns. *Chas. Page, Dropmore Gardens, Bucks, June 6.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM PURPURASCENS.

THE two plants of this fine Odontoglossum included in the special sale of rare Orchids at Messrs. Protheroe & Morris's Rooms on Thursday, June 1, "by direction of Sir Trevor Lawrence, Bart., V.M.H., K.C.V.O., for the benefit of a charity," realised 150 gs. and 120 gs. respectively. The charity will thus be benefited substantially by the liberality of the donor, and by the appreciation of good Odontoglossums by his fellow-orchidists.

The sale throughout was very successful, although the extremely high figures attained at the previous Tuesday's sale were not reached, a good number of Odontoglossums ranged from 50 gs. to 100 gs., and some over, and the Cypripodiums fully sustained their values. *J. O'B.*

CYPRIPEDIUM BARBATUM.

There is no Cypripedium that flowers more profusely than C. barbatum, and for supplying flowers for cutting it is second only to C. insigne. I have recently cut over 230 flowers from twenty plants growing in 7 and 9-inch pots. The flowers last so well when cut, that one is apt to get tired of them before they fade; but this monotony can be avoided to a certain extent by varying the mode of arranging them in the glasses every few days. Though rather sombre in colour they never look commonplace. The plants can be grown very easily in the intermediate-house. They require considerable water at all seasons as they are never at rest. Repotting should not be done except when the plant becomes too large for the pot. *W. W., N. B.*

LAW NOTE.

A MEETING of the creditors of Thomas Horsman, seedsman and nurseryman, of Bradford and Ilkley, was held at the office of the Bradford Official Receiver (Mr. C. L. Atkinson) on June 7. According to the statement of affairs, it appeared that the bankrupt had been in business for thirty-one years on his own account. The liabilities expected to rank were £2,113, and the assets were estimated to produce £388, leaving a deficiency of £1,725. The bankrupt made no offer to his creditors, and Mr. Edgar A. Mitchell, accountant, was appointed trustee, with a committee of inspection.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from p. 357.)

THE HOME OF THE CHINESE PRIMULA.

[*The history of the introduction, and subsequent discovery of the habitat of this favourite garden plant were described and illustrated in these columns, see "Gardeners' Chronicle," January 2, 1892, p. 13, and the issue for April 26, 1902, pp. 269, 270, and 271.* ED.]

THE distribution of the plant is remarkably local. The length of the Ichang gorge is roughly 15 miles. The cliffs are of limestone, and exceedingly precipitous. It is on the tiny ledges and niches on the face of these vertical cliffs that the plant is at home. The accompanying illustrations (figs. 163, 164) show the habitat fairly well, but unfortunately they do not show the height of the cliffs, which are often several hundred feet sheer. But though the plant occurs sparingly throughout the length of the gorge, it is only at the entrance nearest to Ichang, and more especially in the lovely San-yu-Tung glen, that it is really abundant. Outside this gorge and the glens which pierce it, I only met with it in one other locality, and on similar limestone cliffs one day's journey north of Ichang. The plants grow fully exposed to the sun, and without a drop of water for months together. They evidently live on the accumulated humus chiefly derived from their own decaying leaves. One wonders at the plant existing, much less thriving, under such arid conditions.

In January, February, and early March, the face of these cliffs is dotted all over with thousands of plants—one mass of delicate mauve-pink flowers, and the fragrance is delicious.

The plants vary from 3 to 9 inches in height, according to situation. The leaves are very small. The scapes have often two or more whorls of flowers. I have counted as many as twenty scapes to one plant with over a hundred flowers open at the same time! The flowers often measure 1½ to 1¾ inch in diameter, which rather astonished me. The colour is a pleasing soft mauve-pink with pale yellow eye. In the shade the colour is a little lighter, but I never succeeded in finding an albino. Considering how the colour has varied under cultivation one is rather surprised to find the "shade" so constant in the wild plant.

The petals are deeply emarginate, and the flowers are, of course, heterostyled. In company with many other cliff plants, the peduncles and pedicels after flowering become "positively geotropic." This insures the safe depositing of the seeds in the niches and ledges of the cliff.

It is interesting to compare the long-cultivated plant with the typical spontaneous one. The new class of Primula, called "stellata," I think, is very near the typical form. I know nothing of the origin of this "class," but if a product of cultivation derived from the long-cultivated plant, it constitutes a remarkable "throw-back." Perhaps it is the result of cultivating the spontaneous plant from seeds, and if so, there is nothing remarkable about it. If my memory serves me rightly the Kew plants were lost after flowering.

In colour, size, shape and substance the florists' flower has diverged widely from the type. In the "fern-leaved" forms we find a remarkable deviation from the typical leaf. In short the only thing that has remained constant is the perfume. But what has been gained in size and colour has been lost in grace and beauty. The spontaneous plant is, to my mind, far more graceful and beautiful than the florists' flowers growers have striven so hard to produce.

As I wrote this my view was of a white cliff nearly 200 feet high, where thousands of plants one mass of flower were revelling in warm sunshine. It was a picture to make the heart glad, and it is a great pity all lovers of this favourite flower cannot enjoy such a sight.

ICHANG TO KIATING.

April 25, 1903.—We left Ichang last night, crossed the river, and tied up for the night at An-an-Miao, a village opposite the upper end of Ichang city. At 5 A.M. this morning, with much noise, we unmoored and commenced our journey of 800 miles.

With a strong fair wind to aid us we made good progress. At 7 A.M. we were off San-yu-Tung and entered the Ichang gorge, last of the stupendous chasms the mighty Yang-tsze has cleft for itself. In these gorges the river is reduced to half its usual breadth, and the water is in consequence very deep. In their soundings the two British gun-boats, on their first ascent to Chungking, found over sixty fathoms of water off San-yu-Tung. This at low-water season! In summer the water in the gorges is often 80 to 100 feet above its winter-level. At such times all traffic through the gorges is suspended.

This gorge is about 15 miles long. The cliffs are of limestone, turreted and castellated, culminating in grotesque forms and shapes. Though the cliffs of this gorge are not so precipitous as they are in the others, the scenery is not one whit the less grand and awe-inspiring. All the gorges afford such wild and wondrous scenery that neither pen, pencil, brush, nor camera can adequately portray it, and it is very much a matter of opinion as to which is finest. I shall ever remember my first view of the Ichang gorge. It was after a heavy fall of snow. The day was dull but clear, and the cliffs, covered with snow, stood out in solemn grandeur. To-day the cliffs are alive with lovely flowers, shrubs, and herbs in the wildest profusion. Truly a sight for the gods!

As we sailed rapidly through this wondrous scene I stood on the deck of the boat lost in admiration of the things around me. Flowers of every hue met the eyes and gladdened the heart—a grassy bank one mass of the lovely Primula obconica; a cliff, in every niche of which nestled Corydalis thalictrifolia, with its erect racemes of yellow flowers; a waterfall, beneath which hundreds of Iris japonica luxuriated; the rocks, drenched in spray, were green with Adiantum Capillus-Veneris var.; the crags themselves alive with masses of Cæsalpinia sepiaria, Rosa moschata, Spiræa dasyantha, Wistaria sinensis, Polygala Mariesii, and other such favourites. And so we journeyed on, every hundred yards revealing some fresh aspect.

At 10 A.M. we reached the Customs' barrier at Ping-shan-Pa, a tiny village romantically situated in the heart of the gorge. Our papers having been duly examined and initialed we proceeded. About a mile above this picturesque village the river takes a right-angled turn. At this bend, and near the middle of the river, is a large and dangerous rock, designated "Sleeping Pig." Rounding this difficulty, we soon come in view of the "Needle of Heaven," an isolated pillar-shaped peak of limestone, perhaps a thousand feet high. At 1 o'clock we were opposite to the lovely village of Nanto, nestling amidst orange-groves, with a huge precipice culminating in curiously-fringed overhanging peaks on the opposite bank. We were now clear of the gorge, and the river in front was strewn with boulders. Looking back I noted that a temple crowned the highest peak visible. This is Ching-kan-Shan, "Diamond Hill," alt. 2,800 feet.

FIG. 163.—PING-SHAN-PAI, WHERE THE CHINESE PRIMULA GROWS WILD.

At 4 P.M. we moored for the night at Wang-ling Miao, 30 miles above Ichang. This is a small village on the right bank, possessing a fine temple, and is a noted mart for Bamboo ropes. These ropes are made from the split culms of Phyllostachys mitis, plaited, and soaked in lime-water. These ropes possess enormous strength, and are used for pulling the boats up-river.

In many places during the day the currents were very strong, and in the gorge we crossed many dangerous-looking eddies. Just below our mooring we crossed the first rapid—a small affair called Chin-shui-Tan, "Clear Water Rapid." One of the chief floral features of the day was Aleurites cordata. This plant is highly valued for the oil which is expressed from its seeds. The oil is known as "Wood-oil," and is an important article of commerce, its principal use being varnish for boats. In the *Index Floræ*

Sinensis, vol. ii., p. 433, a footnote states that the oil is sometimes known as "Ningpo Varnish." This is a mistake. The tree itself averages 10 to 15 feet in height, flat-headed, with large cordate leaves, and unisexual flowers, white with brown striæ. It thrives in rocky places, and is particularly abundant in these parts.

During the day I noted some eighty-four distinct species of plants belonging to seventy genera. They were made up as follows:—19 species of shrubs, 13 species of trees, 44 species of herbs, and 8 of Ferns. Out of the 44 species of herbs 29 may be designated "weeds of cultivation" in the broad sense of the term. Out of the 84 species no fewer than 21 are valued in England from a horticultural standpoint. Apart from those already mentioned the following made the gayest display:—

Daphne Genkwa, Linum trigynum, Sophora viciifolia, Azalea indica, Loropetalum chinense, Symplocos cratægoides, Paulownia imperialis, Rosa lævigata, Deutzia discolor, Rehmannia rupestris, Mazus pulchellus, and Rosa Banksiæ.

On the cliffs hereabout a peculiar kind of chamois is common, and so also is a species of muntjac. The former haunt the inaccessible limestone cliffs; the latter the more open but rocky ground.

April 26.—The barometer fell during the night, and rain fell heavily at 9 A.M., forcing us to tie up. We restarted at 1.30 P.M., and by 2.30, with the aid of thirty extra trackers, we got safely over the Tatung, last of the major rapids of the Yang-tsze.

It continued to rain more or less the whole of the day, but the crew worked till 5.30 P.M. We moored for the night a short distance below the Tung-ling rapid.

From Nanto to here the Chinese call the river Ta-cha-Ho—"River of Dregs." This is a most appropriate name, since for the whole distance the banks are strewn and the stream impeded with enormous boulders—granite chiefly. In the high-water season this is one of the worst reaches on the river.

The country hereabouts opens out considerably, and is largely under cultivation; Peas, Beans (broad), Vetches, Barley, and Opium are the principal crops. The people seem strangely indifferent in regard to the Barley crop. If the season is late and the ground required for Rice or Cotton, they plough-in the Barley as manure.

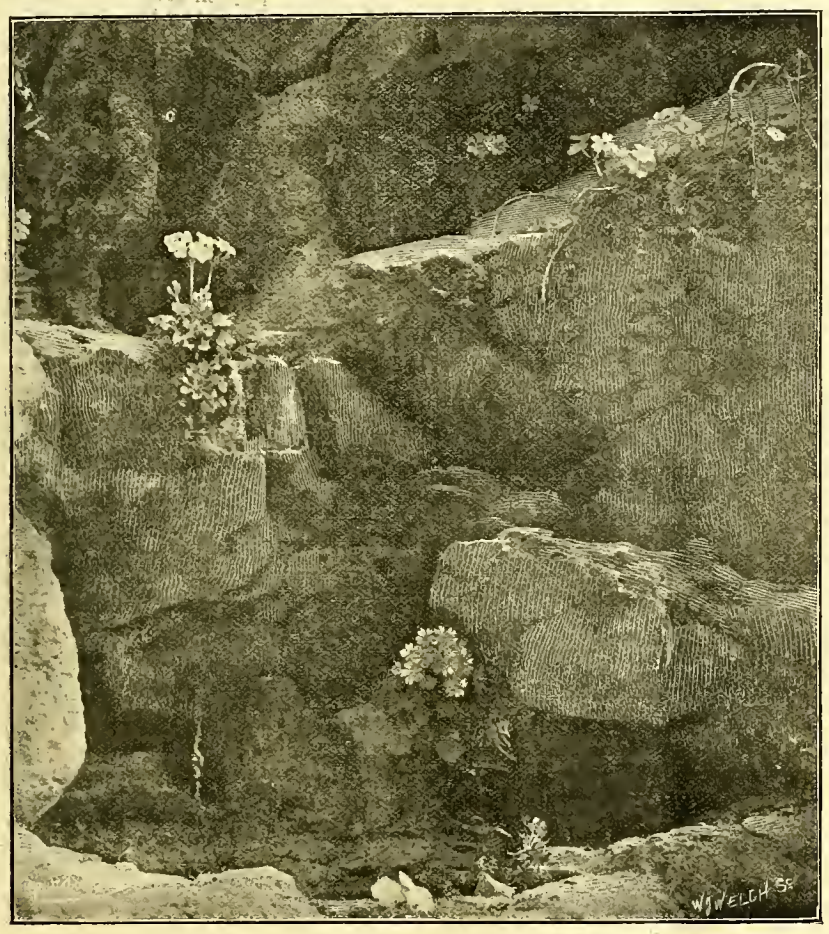


Fig. 164.—PRIMULA SINENSIS AT HOME.

I noticed much less Opium cultivated hereabouts than formerly. This, I gather, is due to the heavy tax imposed on the growers. The tax was first instituted in 1902, and amounts to 64·00 taels per picul of crude Opium. The result is seen in the almost total absence of this crop from places where formerly it was largely grown. (This tax threatened to ruin the culture of this crop, and has since been repealed.)

Innumerable groves of Bamboo were the feature of the day. The higher hills were clad with Pine and Scrub Oak, Liquidambar formosana is a very common tree to-day. Rain and the nature of the country combined did not admit of much botanising. I merely noted a few weeds of cultivation, Styrax japonicum (small bushes), Rosa indica (planted on a tomb), and Cedrela sinensis, the shoots of which are eaten.

At the Tatung rapid the legumes of Gymnocladus chinensis were for sale. These pods are about 4 or 5 inches in length, thick, and dark-brown in colour. They are used as soap in many parts of the Yang-tsze Valley.

April 27.—We started soon after 6 A.M. and reached the Tung-ling rapid at 7 A.M. At dead low-water a broken reef of rock stretching right across the river makes this an extremely difficult and dangerous place. A huge rock divides the channel of the river and stands sentinel at the gate of the Niu-kan gorge. It was on the above-mentioned reef that, in December, 1900, the ill-fated German steamer struck on her maiden voyage and sank in twenty minutes. She still lies at the bottom of the river, and is likely to remain there.

Opposite the village of Tung-ling and on the south bank are two or three coal adits. The output is small and the quality very inferior. Having crossed this dreaded rapid in safety we entered the Niu-kan or Lukan gorge. The Ox-liver gorge, for such is the meaning of the Chinese name, obtains this appellation from a projecting mass of limestone which bears a fanciful resemblance to that anatomical organ. This gorge appeals to one as one of the wildest of all. It is only about 5 miles long. The cliffs are for the most part sheer, and often 2,000 feet high. In one or two places the upper parts are well-wooded. Chionanthus retusus is common on the cliffs. This plant, well-known but little cultivated, is one of the handsomest of all flowering trees or shrubs. Here it forms bushes 4 to 8 feet in height, and is nothing but a mass of flower. Given a rocky and very sunny place it ought to thrive in England much better than it does.

The first of the three rapids, called Hsin Tan, was reached at 10.15 A.M., and we were over at 10.45 A.M., when a heavy downpour brought matters to a standstill. At 2 P.M. we restarted and sucessfully crossed the remaining two. Rain now recommenced, and we were forced to moor for the night. These rapids are not bad at this season of the year, but in the dead low-water they are considered with one other the worst on Upper Yang-tsze. I crossed them in March, 1901, when they were truly foaming cataracts. The loss of life and cargo yearly at these rapids is terrible.

Ficus infectoria occurs here, the most eastern-most place where I have met with it. In Szechuan it is the commonest of trees, and usually shelters some shrine or temple. It is practically an evergreen, the young leaves unfolding almost as soon as the old ones have fallen. Lycium chinense, Myricaria germanica, and Distylium chinense are common fluviatile shrubs here.

The village of Hsin Tan is much scattered, and is noted for its inkstands. These are made of a kind of graphite, in which iron pyrites are embedded. The workmanship is often very artistic. A shifting population of trackers, boat chandlers, and retired junk owners make up the population of this romantically situated village.

April 28 we were delayed by a strong head-wind; it was 8 o'clock ere we started through the Mitsang gorge. This is only about a couple of miles long, and is really a continuation of the Niu-kan gorge. The hills open out a little at the Hsin Tan, but there is no break in the range of hills as with the other gorges. The cliffs in this gorge are very high and steep—in one place fully 2,000 feet sheer. These vertical cliffs are for the most part bare, but in places Chionanthus retusus is conspicuous. With much hard sculling and shouting we reached the middle of the gorge, where it is possible to track for a short distance. Very soon the tracking path came to a finish, and we took our trackers on board again. The head-wind continued to annoy us, and it was with

the utmost difficulty and great relief to all that we get clear of this gorge.

From the head of this gorge to the town of Kui the river is one long succession of rapids and races. Many reefs of rock stretch across the river, jutting out at nasty angles, and rounding these is a very difficult task. In our passage through this dangerous reach we passed a couple of junks wrecked—an ominous sign. Having crossed the two nasty rapids opposite the town of Kui, we moored for the night. At these rapids we pressed native trackers into service, and they were dissatisfied with the remuneration made. Thinking to appease them, I gave another hundred cash. This only increased the hubbub, thanks to the presence of a couple of women. They began quarrelling among themselves, and it was fully an hour ere all was quiet.

The head-wind and strong current made it a very heavy day. The poor, patient, bullied trackers were quite tired out. Poor fellows, a dog's life seems preferable to such as theirs! Nothing to live for except their rice, and to earn this they have to work like beasts in the field. Their sure-footedness is simply marvellous; they walk easily where one would think a chamois could scarcely move. Flowers are everywhere abundant. The variety is great, but all are common around Ichang. Roses—R. lævigata, R. moschata, R. microcarpa, and R. Banksiæ are everywhere; I never saw them finer. On one branch of R. lævigata I counted fifty fully-expanded flowers, some of which measured 4 to 5 inches in diameter. Pistacia chinensis was a common tree to-day. It often occurs in small groves with tombs beneath its shade. It attains a large size, being often 40 to 60 feet in height, and with a correspondingly thick trunk and large, spreading branches. At all seasons it is a strikingly handsome tree, and in late autumn vies with Sapium sebiferum in the richness of its crimson tints. The wood is valued for its toughness, and makes the finest rudder-posts for junks. The young shoots are eaten in the same way as those of the Cedrela sinensis.

On the cliffs opposite Kui Spiræa Thunbergii occurs. It is quite common in the Wushan gorge, but I did not find it nearer Ichang than here. It grows in the niches of the rocks where there is little soil or moisture. It is the first of all the Spiræas to flower, and is now in ripe fruit. I first gathered it in flower here in early March, 1901.

Ever on the look-out for something to satisfy the "inner man," I to-day bagged a cock pheasant and a species of partridge. The latter has red legs, and is much larger than the common English bird. It frequents stony places on the hillside. I presume it is merely the ordinary "red-legged partridge," but, whatever its name, I found it excellent eating. *E. H. W.*

TREES AND SHRUBS.

FLOWERING CHERRIES.

On the occasion of the meeting of the Royal Horticultural Society on May 9 there were several varieties of flowering Cherries shown which are as yet comparatively rare in gardens, and have certain points to recommend them to planters. One of these is Cerasus (Prunus pseudo-Cerasus) J. H. Veitch, exhibited by Messrs. Paul & Son, Cheshunt. The plant flowers abundantly in the manner of C. Watereri, which is like C. Sieboldi, and it carries tender rose-coloured blossoms. C. J. H. Veitch, as shown, had blossoms rather larger than either, but its chief recommendation is its earliness in flowering, exceeding C. Watereri in that respect. The same firm likewise staged C. (Prunus) Padus flore-pleno, with small, white blossoms numerously produced, making it an effective lawn or foreground shrubbery standard. *F. M.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

FLORAL AWARDS. — With reference to the Editorial article in the issue for May 27, relating to Floral and Fruit Awards, may I be permitted to say, as one of the Floral Committee, and speaking I am sure for most of its members, that financial considerations have very little to do with the decisions arrived at, except in so far as merit is or should be correlated with value. I have been a member of that Committee now for a good many years, and the conception of its main motive in my mind is the recognition of improvement and of novelty if the latter involves advance in or gain to our floral wealth. In making these awards, consideration is undoubtedly given to the practical value of the plants concerned for horticultural purposes, as certainly should be the case with a Committee elected by the Royal Horticultural Society. Hence a plant such as cited, a Welwitschia or a Rafflesia, would quite conceivably not be honoured with an Award, though it would probably be referred to the Scientific Committee to be dealt with on botanical lines. The odour alone of the Rafflesia would disqualify it on practical grounds. In the Floral Committee the award of a Botanical Certificate which is occasionally made implies that a plant is botanically interesting but not horticulturally, and this being so I am at a loss to understand the alleged inappropriateness of the award of a First-class Certificate to Meconopsis integrifolia, which was at once seen to be highly interesting from both points of view—a fact which to my mind was peculiarly appropriately recognised by the two awards of the Scientific and Floral Committees. Botanical interest and horticultural value are by no means necessarily associated, and I maintain that it is the latter which the Floral Committee are bound in duty to the public to keep in the forefront. It must not be forgotten that the Royal Horticultural Society's Committees are practically the elected judges of what the horticultural public should obtain. These awards are published far and wide as indications of novelty or improvement. The First-class Certificates are reserved for something better than the comparative "commonplace" step-by-step improvements to which Awards of Merit are given. Hence the Meconopsis award could not, to my mind, "lower it to the category of the commonplace," but, on the contrary, lifted it out of it, so far at any rate as the verdict affected public knowledge. Turning now to such valuable introductions as Primula Cockburniana, we have in this plant undoubtedly the starting-point for a wonderful series of fresh tints in the already rich Primula family. The colour is altogether novel—a rich orange-scarlet. As seen, however, at its first *début*, the new colour was the sole charm of the plant exhibited, and to my mind the Committee would have stultified itself by giving it a First-class Certificate without having an opportunity of seeing it when better developed, while an Award of Merit to such an acquisition would indeed have lowered it to the level of the commonplace. Its horticultural value, in point of fact, remains to be established, though its botanical value is beyond all doubt, and was appropriately recognised in the proper quarter by the Scientific Committee. The implication that the Society's credit was saved by the Scientific Committee, while the Floral Committee failed to do so, is hardly fair in view of the circumstances; its botanical value was *in esse*, its horticultural only *in posse*. To my mind it would be a salutary rule for the Floral Committee not to issue Botanical Certificates, but to refer plants which they consider worthy of such to the Scientific Committee. This would obviate the slur which now practically attaches to such certificates when given by the Floral Committee, whose province is a different one. *Chas. Druery, V.M.H., F.L.S.* [Our correspondent, from his point of view, is quite justified in his remarks: but few know better than he that the outlook of the Royal Horticultural Society is, or should be, much more catholic, and the action of its Committees at once more discriminating in some points, and less restricted in others. However valuable a First-class Certificate may be for commercial purposes, it has, to some extent, lost its significance to those plant-lovers or fruit-growers who are not in the trade, by reason of the frequency with which it is given. The "Botanical Certificate" is held in low estimation by the trade, mainly, we take it, because the plants thus honoured are not effective enough to be used for purposes of decoration, or, as the phrase goes, because they are not "garden plants." What seems to be wanted is a "Special Certificate," to be awarded by any of the Committees or by the Council to such plants as from any cause whatever possess special merit. Had such a special award been made to the Meconopsis or to the Primula, or to both, it would at once have been seen that these plants possessed an interest beyond that attaching to the ordinary run of plants to which First-class Certificates are awarded. As it is, the Meconopsis was relegated to the ordinary pass-list instead of to the honour-list, whilst the Primula, in some ways of even greater interest, was not recognised in any way by the Floral Committee, either in Vincent Square or at the Temple. We know, of course, that there were reasons for this—valid enough in existing circumstances, but giving rise to an anomaly which a special award would have obviated. The Council already take it upon themselves to make such awards, independently of the Committees and the judges who are restricted by regulation or custom, and they might with advantage have done so in the present instances. ED.]

GARDEN PATHS.—I can assure Miss Turnor that I never criticise an article without having due regard to facts. Miss Turnor says, in the fourteenth line from the bottom, p. 226, when writing of roads—not paths—"It will improve the wearing quality of the road if this last layer is lightly coated with tar." Again, Miss Turnor says, p. 342, "Gravel requires constant raking and rolling." Such an assertion only displays a further want of practical knowledge of the subject. Gravel properly laid should never be sufficiently loose to enable a rake to be employed. If gravel is laid with water while being rolled, and is of a binding nature, no trouble after it is "set" is experienced. A broom to remove leaves or refuse of any kind only is needed before rolling, which should be sufficiently attended to. Miss Turnor says, "the road should be excavated 2 to 4 feet deep, according to the nature of the soil." Assuming then it is excavated 3 feet deep, rough stones are laid at the bottom one-third the depth—1 foot. Now this leaves a depth of 2 feet to be filled with "granite, flint, or slag," as quoted by Miss Turnor, p. 342. This is the point to which I still take exception, not only on account of the cost, but of the utter waste of material. If this top space, 2 feet, is not to be filled up, will Miss Turnor say what is the ultimate finish of the road? In treating of smaller paths Miss Turnor says "there is no need to excavate so deeply, but gives no depth; now, she says, on p. 342 18 inches is the usual depth, but 2 feet is generally ample. I should think it is! Who would think of making an ordinary garden path, where there is no wheeled traffic, 1 foot deep, let alone 2 feet? Unfortunately I have never had the chance to get granite for paths—very few gardeners have to any extent. Flints picked from the land cost 5s. per load here, and 1s. for breaking, and this is purely an agricultural district, in which flint-stones abound. Certainly we cannot get materials at such low prices as Miss Turnor quotes, thus my criticism of the unnecessary outlay. Miss Turnor certainly advised the excavation to be 4 feet deep, and if she did not intend to fill it up I would ask again, How is the road to be finished? *E. Molyneux, Bishop's Waltham.*

EREMURUS FOR LARGE BEDS.—For grouping in large beds against a background of Holly, Laurel, Coniferæ, &c., there is much to recommend the beautiful and stately Eremurus as an early-flowering plant. Comprising quite a variety, and extending as they do in their native state from Asiatic Russia to the Himalayas, they only require a little protection from spring frosts, otherwise they are perfectly hardy. We have a bed of eighteen plants, planted in the gardens here, December, 1903, the varieties used being E. himalaicus and E. robustus, which I consider two of the best. Last year these plants

threw one spike each about 6 feet high; to-day (June 2) they are again almost in full flower, each plant throwing at least two spikes, the tallest of which, although not finished growth, measures 8 feet 4 inches in height, and fully 12 inches in circumference at the flower base, while the very smallest measures over 4 feet in height. They are planted in a rather heavy soil, but get no stimulants of any kind. When the young crowns begin to move early in March I top-dress with about 9 inches of sharp sand. Again, about the beginning of April they appear for the second time, when we use 9-inch pots for a protection at night only, or during severe frost. When they become too tall for the pots to be used I place a few Spruce and Birch branches upright in the bed, which is all they require until the flower-spikes are ready for staking, and when in full flower they amply repay the small amount of labour bestowed upon them, as without doubt they are at present the finest feature of the garden. *H. MacFadyen, The Gardens, Cuckfield Park.* [Two good photographs were obligingly sent, but as we have frequently published similar illustrations there is no necessity to do so on the present occasion. ED.]

DORMANCY OF INSERTED ROSE-BUDS.—In July 1903, I inserted three fine buds from "Mme. Pernet Ducher" in three vigorous shoots of a half-standard stock of Rosa lucida. They remained plump and fresh-looking throughout the rest of 1903, through the whole of 1904, and up to the month of April of the present year, when every one of them began to grow vigorously. Since then a rose-grub in each of them ate out the heart. Subsequently two of the three have rallied and have produced grand, healthy growing shoots. One would be glad to know of any similar case of suspended growth of inserted rose-buds. *G. Paul, F.R.Met.Soc., Harrogate, June 10, 1905.*

TULIPA SUAVEOLENS AND T. PRÆSTANS.—On perusing the article contributed by Mr. G. B. Mallett, it strikes me that he evidently overlooked my note on T. præstans which appeared in your issue of June 6, 1903, p. 364. What also surprises me is that Mr. Mallett, who refers to the plate 839 of the *Botanical Magazine*, apparently has not taken the trouble to inspect that plate, or he would have seen that the Tulipa suaveolens of Roth is nothing but the old Dutch red, yellow-margined, sweet-scented Duc Van Tholl Tulip, and not the tall, scarlet, many-flowered Central Asiatic Tulip, which he is writing about. He will also find a fine-coloured plate in *Redouté les Liliacées*, t. iii. The description he gives of T. suaveolens is also inaccurate; it applies in reality to my T. præstans. If any description of the old, universally-known Duc Van Tholl Tulip (T. suaveolens, Roth) was wanted, why not have given the right description, taken from the original source (see Roth's synopsis in *Neue Annalen der Botanik*, vol. iv., p. 44, or Baker's *Revision of the Genera and Species of the Tulipeæ*). Even such an easily accessible book as *Nicholson's Illustrated Dictionary of Gardening* publishes an engraving of the true T. suaveolens, and describes it as the Duc Van Tholl Tulip. If further authentic proof be wanted that Tulipa suaveolens, Roth, really represents the Duc Van Tholl Tulip, I may here cite the following phrase taken from Mr. Baker's description of Tulipa suaveolens: "In hortis diutissime culta sub nomine 'Duc Van Tholl' (see *Revision of the Genera and Species of the Tulipeæ*, by J. G. Baker, *Journal of the Linnean Society*). The original dried specimens of Tulipa suaveolens of Roth, a German botanist who lived near Bremen in the early part of the last century, are preserved in the Oldenburg State Museum. I have examined them, and they clearly and unmistakably represent nothing but the old Dutch Duc Van Tholl Tulip, the bright yellow margin of which in the dried specimens, which are now nearly a hundred years old, shows as clearly as if the flowers had been dried a few days ago only. It is also evident that the said German botanist, Herr Roth, could not possibly have described the Central Asiatic Tulip which Mr. Mallett is discussing, as at that time Central Asia was a *terra incognita* for European botanists. This point settled, I would once more ask Mr. Mallett to turn for further information respecting the T. præstans to my article in these columns above cited. It is most unfortunate that Dr. Regel, always so keen in botanical matters, made the error of referring this Tulip to Roth's T. suaveolens, with which it has absolutely nothing in common. In fact no two Tulips can be more widely different in bulb, foliage, flowers, and every other botanical character than are the T. suaveolens (*i.e.*, the old Dutch dwarf and sweet-scented Duc Van Tholl), and the tall, many-flowered Central Asiatic Tulip which Dr. Regel mistook for Roth's T. suaveolens by prematurely describing it from a poor, badly-dried herbarium specimen. With all possible reverence for the memory of so great an authority as Dr. Regel, I cannot imagine why we should persist in perpetuating so obvious an error as has been committed in the present case, the more so as I hold written proof from Dr. Regel's son (Dr. Albert Regel, of St. Petersburg), that his father, on becoming better acquainted with this particular Tulip, became fully convinced that it needed to be described as a new species. These facts have induced me to rename Dr. Regel's Tulip, and distribute it as Tulipa præstans, now that Messrs. Van Tubergen have obtained an abundant supply of it through their Bokhara collector. That the strain lately obtained by the Messrs. Van Tubergen differs in time of flowering, &c., somewhat from the first importation of this Tulip obtained by Dr. Regel from his collector, now about twenty or twenty-five years ago, I readily admit, but that both belong to the same species, which I have called T. præstans, is also absolutely certain. A Tulip collected in a valley will have an earlier time of flowering than one which occurs at high altitudes, and it may in course of time also have assumed a variation in colour, &c.; but if both present the same botanical characteristics it would be foolish to establish two species. During the present season there have been in flower in Messrs. Van Tubergen's nursery considerable breadths of the Bokhara Tulips, T. præstans, T. Fosteriana, and T. Tubergeniana, three perfectly distinct species, but the variation in each of these is often extreme. If there be any real need to offer the T. præstans of Regel's distribution under a different name from the one now being sent out by Messrs. Van Tubergen, there is no better way I think than to call the one T. præstans Regel's variety, and the other T. præstans Tubergen's variety. The principal thing is that the name T. suaveolens, Roth (the old Dutch Duke Van Tholl), should altogether be dissociated from the totally different T. præstans. *John Hoog, Haarlem, Holland.*

THE KEW GUILD AND GARDENERS.—I may say that a similar proposal to that reported in the Press was made at the first annual dinner in 1900, and since then I have discussed the question with a great many members of the Guild, the majority of whom express themselves in favour of some united action being taken to improve the very unsatisfactory conditions under which gardeners are now working. As the Guild from its start has never had an official character, but is an absolutely independent body, it is difficult to see how the "proposed action would be embarrassing to the branch of the Government responsible for the administration of Kew. Moreover, the majority of the members are at present in no way connected with Kew, and it is not merely as a society of Kewites that the Guild may act, but as a society in which every branch of the profession without exception is widely represented. And to show that we do not "arrogate" to ourselves this task, I hope the day is not far distant when other organisations will join their forces to those of the Guild in a common effort to improve the position of gardeners both socially and professionally. I gather from the concluding remarks of his letter that Sir Wm. Thiselton-Dyer considers that the remuneration of gardeners is at present commensurate with their ability. That being so, the latter must be about equal to the skill of an ordinary labourer. Everybody knows, however, that it is to the gardener that we owe such magnificent displays as are seen at the Temple Show, Kew, and elsewhere, and some people know what a high order of intelligence is required to produce these displays. As to gardeners applying themselves to diligent professional study they will only be able to do that when they receive a living wage and are free from the care of supporting themselves and families on what is often a mere pittance. *Old Kewite.*

—— The word "politics" has been defined as "the science of government," and it seems to me there can be no such thing as "horticultural politics" at present, because we have a profession without any government, and that is the one great fault which requires remedying. If we can only get the profession properly combined and organised, existing evils can be remedied. But when Sir W. T. Dyer goes on to say "When the gardener is worth more he will get more," he is under a wrong impression altogether. The law of supply and demand governs the gardener's wages. We have at present a supply many times greater than the demand, and I am constantly hearing of good men who cannot get situations; while there are several hundreds applying for every situation they can hear of, there is no chance of the average gardener getting more wages. On the contrary he is sure to get less as time goes on. By all means let the gardener study the science of his profession, but pay him a reasonable wage to enable him to do this and to do his profession justice. I, too, am strongly opposed to trade-unions, but I have not yet heard of one in any of the professions, and gardeners ought certainly to keep above those tactics. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

—— In last week's issue of the *Gardeners' Chronicle* Sir W. T. Thiselton-Dyer's letter states that when the gardener is worth more he will get more. As to diligent study and its intelligent application, those who have studied hard and work hard in putting their knowledge into practical form think themselves fortunate to be able to get 30*s.* a week for giving some one else the use of it. Now he is told that when he is worth more he will get more. I think the principal cause of low wages is that the gardening profession is overcrowded, like a good many more callings. If a situation is advertised and over a hundred gardeners apply for same there is sure to be one man among the applicants who will take the same at the lowest offer under sheer necessity, on the principle that "half a loaf is better than no bread." No one can blame a man for making sure of half a loaf. Surely a gardener who has to grow anything that is wanted from a Pelargonium to an Orchid, and from a Radish to a Tomato, Cabbage to Asparagus, a Gooseberry to a Melon, is worth as much as a road-sweeper, who gets as much for working six days as a gardener does for working almost the whole seven (counting Sunday work), beside an hour or two in the evening if extra busy. Yet he cannot command his value owing to overcrowding. Any society founded for the betterment of gardeners should be supported by gardeners throughout the Kingdom if they wish to improve matters at all. I have had nineteen years' practical experience, and my pay is now £1 a week, and a building called by courtesy a "cottage." Well, my wife, self, and family of three cannot live on air, and get our family clothed free. I have to hand over 17*s.* 6*d.* a week for household expenses. This leaves me the princely sum of 2*s.* 6*d.* a week—3*d.* *Gardeners' Chronicle*, 6*d.* club money, 3*d.* insurance for children, there then remains 1*s.* 6*d.* for clothes, boots, visits to shows to see anything fresh in the horticultural world, and a holiday in summer as well. I hope that I shall soon be estimated at a little higher value in my employer's opinion, for, like Oliver Twist, I want more. *W.*

VANISHING SPECIES.—The article signed "P." in the *Gardeners' Chronicle* for January 28 concerning Statice fruticaus interests me greatly, as it is an additional proof that the species is dying out, and has not now power of increase sufficient to enable it to survive. That it crosses with other species is in favour of Darwin's theory that cross-fertilisation may be a necessity of plant-life. It is well known that he remarked that most flowers were fertilised by pollen from others of the same species, and that matters were so organised that the flowers attracted the insects most helpful to this crossing. Further, that anemophilous species

are fertilised by the agency of the winds in conveying the pollen from plant to plant. In young subjects with full powers of spreading this crossing is less essential than in old and weak ones, where it is absolutely necessary. Thus is explained the case of the well-known Psiadia rotundifolia from St. Helena, which, as I said in a recent note in the *Gardeners' Chronicle*, does not yield fertile seeds because only one plant of the species exists which forms few or no seeds capable of germinating. It is so with other plants also. Certain Campanulas, especially C. Allionii, one of the most beautiful types of the genus, is old and local, yields but little seed, and when grown as a solitary plant these seeds germinate badly or not at all. The plant must be grown in colonies to yield fertile seed. It is the same with C. petræa, a rare plant with yellow flowers found in a valley of the Maritime Alps, growing on one particular hill, but which also grows some hundred miles away in the Italian Tyrol, where it is always very local. The young and vigorous C. excisa, on the contrary, I notice extends from the Simplon Mountains to those of Saas, then to those of the Val Anzasca even to Tessin; from the Bietschorn, near Belalp, that is to say, on the right bank of the Rhone, near Binn, then to the other side of the river, to Piedmont, in the Graian Alps, and which is also found on Mont Cenis, and doubtless elsewhere. This plant produces seed abundantly even in the case of an isolated specimen. In our garden of the Linnæa it has over-run the Willmott and Berkeley rockeries, the paths, the Grosvenor rockery, and now grows down among the stones over 60 feet from the summit. It is quite otherwise with C. Allionii, which, owing to its stoloniferous nature, grows in sturdy clumps, but does not increase spontaneously as the Linnæa, which now, as there are several specimens of it, yields an abundance of seed. A species, like an individual, has a limited existence. Like all other earthly things, it has a beginning and an end. Geological study reveals that species appear, and then at varying periods disappear. Aged and decreasing species are interesting, and should be protected by those who but too often assist in destroying them. *Henry Correvon, Floraire, Geneva.*

TEMPLE SHOW.—I have waited for an outburst in the Press against the bad ventilation of the tents, but excepting for a few passing remarks no point has been made of this great failing. The ventilation [or the want of it], as all visitors to the show will agree, was terrible, quite spoiling the pleasure of a visit, for the one idea of the majority of the public on entering the tents (as the passing remarks and personal experience will testify) was to get out again as soon as possible. As this must act against the popularity of the show, as well as against the business done by the exhibitors, it is to be sincerely hoped that the Council will take some steps to alter this for the future. It surprises me that more has not been said on the subject, but possibly the wish not to grumble at the arrangements of an excellent Society has made others hold their hand. *J. C. L.* [This complaint should have been sent to headquarters. Ed.]

THE CALANDRINIAS.—Not a few beautiful hardy annuals do not put in an appearance in our gardens, probably for want of being sufficiently known. There are several species and varieties of Calandrinia, though not more than three or four find a place in seed catalogues. These are C. discolor, a South American species, producing bright magenta-coloured flowers in a long raceme; the blossoms open in July and August under sunshine, but the bloom is successional during that period. It is recommended that the seeds be sown in pots so that they can be transplanted direct to the open ground. The soil should be dry and fairly light, and the position should be a sunny one. C. grandiflora is the finest and showiest of all; the flowers are large and of a rosy-purple colour, and the plant has thick, glaucous leaves. It should be planted in good loam, on a sunny position; it blooms earlier than C. discolor, and continues in flower until the autumn. C. speciosa is smaller-flowered, but produces large racemes of magenta-crimson blossoms; under the sunshine they expand fully. The plants should therefore occupy a sunny spot, and the soil be fairly dry. It is a prostrate-growing form, and does well for rockwork and other raised spots. There is a white variety also. C. umbellata is a dwarf form, and partly perennial in character, the plants are of low, tufted growth, and should be sown in light stony soil, or in a sandy loam with which some peat has been mixed. It succeeds best when sown in small pots in the autumn, kept in a cold frame during the winter, and put out in the open at the beginning of May. *E. D.*

TREATMENT OF PLANTATIONS WITHOUT REGULAR THINNING.—I was able to look through every part of my 6-acre plantation lately with my son, who is in the India Forest Service. I think the state of the trees is as near perfection as possible, and there is no Larch disease. He, with German forest training and with seventeen years' experience in Indian forests, differs from me. He objects to the openings which I have made. I think the openings have allowed a circulation of air among the trees day and night by the difference of temperatures in the openings from the parts where leaf canopy is fairly preserved, enabling the trees to absorb more carbonic acid gas as the air passes the leaves, and so promoting tree-growth from the greater amount of carbon deposited as the sap descends. His advice has been very valuable, first, as to branching the forest trees in 1892 and in 1897, as to cutting out long, thin Larch from the thick parts between the 20 feet cuts that were made in May, 1895, and under-planting with Beech and Silver Fir. The thick parts of Larch have been thinned to the present date, so that Larch are now 8 feet apart, and most of the ground is under-planted with Beech and Silver Fir. We only found one dead Larch in the field part this year. Before a 20-foot cut was made thirty, and sometimes forty, Larch died in one acre of Larch in a year. There is room for about 300 trees under the other trees, and I hope to put in some Douglas Firs where the trees are tallest, as they do very well for under-planting and grow faster than Silver Firs. *Henry Rogers, Plymouth.*

A CURE FOR MILDEW ON CUCUMBER-PLANTS.—It does not appear to be known by cultivators that the grafting of Melon and Cucumber-plants on to stocks of the Vegetable-Marrow enables the plants to resist that fatal disease mildew in the winter season. The Marrow-seeds are sown on the stations where the future Melon or Cucumber-plants will grow, and seeds of the latter are sown singly in small pots elsewhere, and when large enough the plants are inarched on to the stocks, their roots and the tops of the Vegetable-Marrows being removed after the union is complete. I have considered this procedure would probably impart such vigour to our present-day Cucumber-plants as to produce immunity to the "spot" disease now so prevalent on the plants under glass. So as to enable the Vegetable-Marrow plants to attain a good size before being inarched, the seeds should be sown a fortnight before those of the Melons or Cucumbers. *F. M.*

SOCIETIES.

LINNEAN.

JUNE 1.—Professor W. A. HERDMAN, F.R.S., in the chair.

Mr. H. E. H. SMEDLEY, F.L.S., exhibited models of restorations of some extinct Dinosaurs, Ceratosaurus, and Diplodocus, also of Ichthyosaurus, Plesiosaurus, Scelidosaurus, and Stegosaurus.

On behalf of Mr. J. F. Waby, F.L.S., the General Secretary exhibited two photographs of a Palm, Corypha elata, which had been previously mentioned. At the General Meeting of June 18, 1903, photographs were shown of two specimens of equal age; one had flowered normally, fruited and died; the other, instead of flowers, had thrown up a secondary central growth of leaves. The information now sent completes the record; the survivor in its turn had flowered and died, the inflorescences being developed from the secondary crown of foliage. On being cut down it proved to be 68 feet in height, diameter at base 3 feet 6 inches; diameter at base of secondary growth 1 foot 10 inches. The secondary growth itself was 4 feet in height, and the height of the spadix an additional 20 feet, 5 feet of this being bare stem, the remaining 15 feet crowded with twenty-nine huge branches. The crop of fruit numbered over 51,000 and weighed half-a-ton, most of the fruits being abortive.

Mr. C. B. CLARKE remarked that though this Palm grew in the Calcutta Botanic Garden, he had never noticed this abnormal behaviour, though branching in Palms occurred in many species.

The General Secretary exhibited sundry rarities from the books and manuscripts of Linnæus, especially three which had been lost sight of owing to their having been placed among the manuscripts which remained unbound. Each exhibit was explained, with the circumstances attending its production, and its special interest indicated.

The President remarked that in spite of what had been done in bringing to light certain items in the collections of Linnæus, doubtless much yet remained to be discovered, and instanced the fact of his exhibiting the artificially produced pearls from the Linnean Cabinets. He suggested that possibly among the Linnean manuscripts there might yet exist some documents still not utilised which would throw light upon the procedure adopted by Linnæus as regards pearl-mussels.

The last item was a paper by Mr. R. N. RUDMOSE-BROWN, communicated by Mr. W. BOTTING HEMSLEY, F.R.S., F.L.S., on "The Botany of Gough Island.—Part II. The Cryptogams, exclusive of the Ferns and Unicellular Algæ."

GARDENERS' DEBATING SOCIETIES.

ADDLESTONE, CHERTSEY AND OTTERSHAW GARDENERS'.—The usual monthly meeting was held at Addlestone on Tuesday, June 6. The President, H. Cobbett, Esq., was in the chair, there being a very good attendance of members present, and the exhibits included a group of Hydrangeas from Mr. F. Norris; a collection of Sweet Peas from Mr. T. Culver; and a small collection of Sweet Peas and Royal Sovereign Strawberries from Mr. T. Stevenson. Awards were given in each case. A lecture on the various methods of propagation was given by Mr. Sturt, gardener to L. Cohen, Esq., Round Oak, Englefield Green. A discussion followed, in which several members joined. *T. S.*

BOURNEMOUTH AND DISTRICT GARDENERS'.—At the meeting held on June 5, Mr. C. Pearce, Astney Firs Gardens, in the chair, a paper on "Hybrid Rhododendrons" was read by Mr. C. Nippard, Ashton Court Gardens. A long discussion followed, after which the reader was heartily thanked for the information imparted. A fine collection of Calceolarias was exhibited by Mr. E. T. King, Higham Gardens, who was awarded the Society's Certificate of Merit.

EGHAM AND DISTRICT GARDENERS'.—At the last meeting of this Society, Mr. W. Swan in the chair, Mr. Peerless read a paper on "The Gloxinia." The essayist explained in detail the best method of cultivation, from raising seeds until the flowering stage, which proved a most interesting and instructive paper, and was much appreciated by the large number of members present. Mr. Brown, of Cooper's Hill College, exhibited specimens of injurious insects which he had himself collected, and offered some remarks on the haunts and peculiarities of these garden pests. Mr. Sturt, Round Oak, Englefield Green, exhibited a group of plants of Calla Elliottiana. Mr. Lingwood exhibited seedling varieties of Begonia in flower. They were raised from seeds sown in January. Through the generosity of a few ladies and gentlemen of the neighbourhood, the committee were enabled to open a library at this meeting, which should prove very useful to the members for reference and for obtaining information generally. *T. J. W.*

Obituary.

COLONEL WILLIAM GEORGE WEBB.—We regret to have to record the death, on Wednesday last, of Colonel Webb. Colonel Webb was the elder son of the late Mr. Edward Webb, a glass-manufacturer in the Stourbridge district, and was born in 1843. Like his father he engaged in the glass trade, but ultimately left it, and in conjunction with his brother, Mr. Edward Webb, the present High Sheriff of Worcestershire, he successfully developed the well-known seed business at Wordsley with which their names are identified. Deceased was Member of Parliament for the Kingswinford division of Staffordshire. Colonel Webb was a magistrate for the county of Stafford, and his title of "Colonel" was due to his long association with the South Staffordshire Volunteers. He married a daughter of Captain Broughton Pryce, and leaves three sons and two daughters.

ENQUIRY.

JIMSON WEED.—Can any reader inform me what plant is meant by the term "Jimson Weed"? It is said that all kinds of insects have a great objection to the smell of this weed. Where is it usually found growing; in damp or dry places? *J. E. P.*

Watercress, per doz. bunches.	0 5-	0 6

REMARKS.—Indoor Strawberries are nearly past; the few that are still arriving are making an average price of 3*d.* to 6*d.* for seconds, and 1*s.* to 1*s.* 6*d.* for best. There are plenty of ripe Bananas on the market, but there is no demand for them, owing to the sudden drop in the price of Strawberries. English Tomatos are very plentiful, and prices for these will probably fall during the week. Cherries are very abundant and cheap. Trade on the whole is good.

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 60*s.* to 70*s.* per ton; seed in variety.

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Vegetables: Potatos, 2*s.* 2*d.* to 3*s.* 6*d.* per cwt.; Jerseys, 12*s.* to 13*s.* do.; St. Malo, do; Turnips, 1*s.* to 1*s.* 3*d.* per dozen bunches; Cucumbers, 1*s.* 9*d.* to 3*s.* per dozen; Onions, foreign, 3*s.* 6*d.* to 4*s.* 6*d.* per bag; Parsley, 4*d.* to 6*d.* do.; Lettuces, 6*d.* to 8*d.* per dozen; Cauliflowers, 2*s.* to 3*s.* 6*d.* do.; Cabbages, 4*d.* to 6*d.* do.—Fruit: Oranges, Valencias, selected, 21*s.* 6*d.* to 30*s.* per case; do., inferior, 9*s.* to 14*s.* 6*d.* do.; Apples, Tasmanian, 8*s.* 9*d.* to 12*s.* per case; do., Western New York State, 16*s.* per barrel; Bananas, 5*s.* to 8*s.* 6*d.* per crate; Tomatos, Valencia, 8*s.* to 9*s.* 6*d.* per case.

EDINBURGH.—Fruit: Oranges, Valencias, 18*s.* 6*d.* to 25*s.* per box; Grapes, English, 2*s.* to 2*s.* 6*d.* per lb.; do., Belgian, 1*s.* 4*d.* do.; Lemons, Palermo, 7*s.* 6*d.* to 16*s.* 6*d.* per box; Apples, Australian, 12*s.* to 14*s.* 6*d.* per box; Bananas, 5*s.* 6*d.* to 10*s.* per bunch; Nuts, 18*s.* 6*d.* to 40*s.* per cwt.; do. Barcelonas, 35*s.* to 36*s.* 6*d.* per bag; Figs, 9*d.* per dozen; Walnuts, Italian, 6*s.* 3*d.* per stone; Dates, 15*s.* 6*d.* per cwt.; Tomatos, Teneriffe, 5*s.* 6*d.* to 6*s.* 6*d.* per box; do., Guernsey, 5½*d.* to 6½*d.* per lb.; do., English, 7*s.* to 7*s.* 6*d.* per stone; Onions, Egyptian, 5*s.* 6*d.* per cwt.; Carrots, 2*s.* do.; Gooseberries, English, 3*d.* per lb.; Potatos, Maltese, 13*s.* per cwt.; do. Canary, 13*s.* 6*d.* to 14*s.* 6*d.* do.

DUBLIN.—Vegetables: Cabbages, York, 3*s.* to 8*s.* 3*d.* per load; Cauliflowers, 1*s.* to 1*s.* 3*d.* per doz.; Parsley, 1*s.* 6*d.* to 2*s.* per bag; Parsnips, 2*s.* 6*d.* to 3*s.* per cwt.; Salad, 2*d.* to 3*d.* per doz.; Onions, Tripoli, 3*d.* to 5½*d.* per bunch; Rhubarb, 1*s.* 3*d.* to 2*s.* 10*d.* per dozen; Turnips, white, 6*d.* to 8*d.* per bunch; Carrots, 8*d.* to 9*d.* per dozen; Potatos, 2*s.* 4*d.* to 3*s.* 4*d.*; Selected Main crop, 3*s.* 6*d.* to 3*s.* 8*d.* per cwt.

COVENT GARDEN FLOWER MARKET.

GROWERS complain of a falling off in trade, but this I think refers chiefly to the sale for bedding plants. The wet weather last week was a great hindrance, and the Whitsuntide Holidays always interfere with trade. Large supplies still come in. Crimson Rambler Roses are very good, and are obtainable in various sizes. There are also a few plants of the variety Dorothy Perkins, and H. P.'s of various sorts, but in these it is rarely that anything very good is seen. Fuchsias are plentiful, and there are some good standards coming from several growers, the prices for these vary from 2*s.* 6*d.* to 5*s.* each. Show Pelargoniums are now very good, but dwarf plants possessing good foliage do not realise more than 12*s.* per dozen. Ivy-leaved varieties are good, and sell moderately well. Zonal Pelargoniums, except single-flowered white varieties, are considerably overdone, many being unsold at closing time. Marguerites are fairly plentiful, but dwarf plants which are freshly in flower are rather scarce; many now seen have grown tall and thin. Yellow-flowered plants are very good, and rather lower in price. The yellow Chrysanthemum segetum, both double and single, are very showy, and the dwarf plants of these, also good Mignonette, sell fairly well. Lobelia is not so much in demand, and it must be very good to realise an appreciable price. There are still a few Intermediate Stocks coming in, but they are not now wanted. Calceolarias are very good; the very best "yellows" make 6*s.* per dozen, but many are sold at much lower prices. Herbaceous Calceolarias have been very good, but they do not sell very quickly. Hydrangeas are plentiful. H. paniculata is not very good, and the best plants sell well. H. Hortensia and H. Thos. Hogg vary in price but little. Ferns are selling better, but the trade for these will soon fall off. Good Codiæums (Crotons) with well-coloured foliage are in demand, especially the larger-sized plants. Well-coloured Dracænas would also sell well.

CUT FLOWERS.

Some sorts are now getting a little short. Lilium longiflorum is dearer; also the best Roses. We are now getting flowers of the variety General Jacqueminot and others from the open ground, but many of the flowers have been damaged by the bad weather. Carnations are plentiful, except good white varieties. The varieties of Souvenir de la Malmaison are just now at their best. Iceland Poppies are coming from all quarters. Hardy flowers of various sorts are overabundant. Lily of the Valley and Eucharis have advanced in price. Gardenias are not quite so plentiful as they were, but Stephanotis is more abundant. Sweet Peas are over pleutiful and some are sold at very low prices. The Spanish Iris are abundant and good and commaud fair prices. The double white Daffodils still hold out, this morning there were large quantities of good fresh blooms. Gypsophila elegans in white and pink varieties is now coming in from the open ground and is much cheaper. Orchid bloom is not so pleutiful. *A. H., Covent Garden, June* 14.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending June 10, 1905.

JUNE 4 TO JUNE 10, 1905.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	Wet Bulb.	Highest. DAY.	Lowest. NIGHT.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending June 10, is furnished from the Meteorological Office:—

"The *weather* continued very fine and dry in all the more northern and north-western parts of the Kingdom, but in the south east and south the conditions after Sunday were extremely dull and wet. At most stations rain was experienced every day, and many of the falls were unusually prolonged. Thunderstorms were experienced at Dungeness quite at the beginning of the period, and at Tunbridge Wells, Epsom, and London on Saturday.

"The *temperature* was below the mean generally, especially during the afternoons. The highest of the maxima recorded on Sunday ranged from 72° in England, S., and 70° in England, E., the Midland Counties, and Ireland, N., to 64° in the Channel Islands, and to 61° in Scotland, N., but later in the week the highest readings were not much above 60° anywhere,

and often below it. On Tuesday nearly all the maxima over the southern counties of England were about 52°, while at Shaftesbury the thermometer only touched 49°. The lowest of the minima were registered on rather irregular dates. They ranged from 31° in Scotland, E., and England, N.W., and 35° in England, S.W., to 45° in England, E., and to 48° in the Channel Islands. At Southport a thermometer exposed on the grass fell as low as 31·6° on the nights of the 8th and 9th.

"The *rainfall*.—Scarcely any rain fell in Ireland, Scotland, and the North of England, but in England, S. and E., the fall was excessive, the respective totals for the week being six times and five times as large as the mean. In the Channel Islands the fall was more than twice the mean amount. The heaviest falls within the 24 hours were generally measured on the morning of Tuesday; at Dungeness there was 1·96 inch, and at Southampton 2·48 inches, while at Canterbury 1·95 inch was measured at 10 P.M. on Monday.

"The *bright sunshine* was abundant in several of the Northern districts, but very deficient in the South. The percentage of the possible duration ranged from 49 in Scotland, W., 48 in England, N.W., and 43 in Ireland, N., to 25 in the Channel Islands, 16 in England, E., to 10 in England, S."

THE WEATHER IN WEST HERTS.

Exceptionally Heavy Rainfall.—After eight cold days the weather became much warmer on the 13th inst. During the cold period in question the days were, as a rule, very cold, but not so the nights, which were only slightly colder than is usual at this season. The ground temperatures are rising, but the soil is still rather cold, the reading at 1 foot deep being about 1° lower, and at 2 feet deep about 2° lower than is seasonable. Rain has fallen on eleven of the last sixteen days, and to the total depth of 2¾ inches —equivalent to nearly thirteen gallons on each square yard of surface in my garden. Of that quantity 6½ gallons have come through the bare soil percolation gauge, and nearly one gallon through the gauge on which short grass is growing. The latter is the more remarkable of the two as the percolation through that gauge usually ceases altogether some time in May, and does not start again until late in the autumn. The weather has lately been very gloomy for a summer month. For instance, during the last nine days, the average duration of sunshine has been only 1¾ hour a day, which is as much as four and a half hours a day short of the average for the time of year. Four days out of the nine were altogether sunless, and on two others the sun shone for less than half an hour. During the same nine days the wind remained light and the direction persistently some point between north and east. The mean amount of moisture in the air at 3 P.M. was as much as ten per cent. in excess of a reasonable quantity for that hour. *E. M., Berkhamsted, June* 14, 1905.

[*For actual temperature and condition of barometer at time of going to Press, see p.* 378.]

ANSWERS TO CORRESPONDENTS.

ANTELOPSIS: *Shotlands.* The Vine has been killed by a fungus, traces of which are very obvious. It will be better not to plant another in the same soil.

CLIANTHUS DAMPIERI: *F. G. G.* This species, known as the Glory Pea, is admittedly a difficult plant to cultivate in pots. In some of the south-western counties, where the climate is sufficiently warm, the species, and particularly C. puniceus, grows and flowers very well, and under such circumstances occasions much less trouble than when grown as a plant in a greenhouse. It will, however, be useful to you to remember that it is imperative to observe two rules—one being that the plant must be kept free from red-spider, a pest to which it is peculiarly liable, and the other that the roots must not be injured when repotting is carried out in March or April, after the growths have been pruned back. Some cultivators knock the bottom from the pot in which the plant is growing, and afterwards transfer the remainder of pot and soil into one of larger size. Some loamy turf, containing plenty of root-fibres with a little leaf-soil, silver-sand and charcoal added, is a suitable compost for use in potting. Pull the turf into pieces with the hands. Perfect drainage is necessary, and an abundant supply of water may then be afforded during the time the plants are most actively growing. It has been found that this plant succeeds better when grafted on to Colutea arborescens than it does when on its own roots. The late M. Marc Micheli, of Geneva, sowed seeds of C. Dampieri in February, and as soon as the cotyledons were sufficiently expanded for the operation to be possible, the terminal bud of the stock (Colutea arborescens) was removed and replaced by that of Clianthus Dampieri. It was found that union was soon effected, and the plants commenced to flower in June or July. On such a stock the Clianthus becomes a perennial greenhouse flowering plant. At the Ghent Show two years ago, a group of plants so treated occasioned the greatest surprise and admiration. An illustration of one of M. Micheli's grafted plants was given in the *Gardeners' Chronicle*, June 29, 1901, p. 419. See also the issue for January 19, 1901, p. 44.

CONTRIBUTION: *X.* Your article was in course of preparation for insertion, but as a similar note on the same subject from your pen has now appeared in other papers, there seems to be no reason for publishing it also in these columns.

CUCUMBERS DISEASED: *E. W.* We find no trace of fungus disease and can only suggest a check as being the cause of the young fruits dying at their tips. Be careful in affording water—too much or too little is alike injurious. Prevent cold draughts from reaching the plants. Do not overdose them with artificial manures. The water applied to the roots or used for syringing the plants should first be warmed to the temperature of the house in which the plants are growing.

CUCUMBER PLANT: *J. D.* The powdery substance is Reticularia lycoperdon, one of the slime fungi. It is not a parasite, and will do no injury. If necessary the mass of spores can be sprayed or blown away.

CURRANTS: *A. T. S.* See next week's issue.

DELPHINIUM: *J. F.* We cannot find the maggot, but from what you say we have no doubt he is the culprit. Manure would do no good. Better burn the plants and get a fresh stock, taking care not to plant them in the same soil.

EVERGREEN TREES FOR A SCREEN: *G. J. Jones.* Any of the following trees will answer your purpose:—Pinus Laricio (Corsican), P. L. nigricans (Austrian), Pseudotsuga Douglassii (Douglas Fir), Thuya gigantea (T. Menziesii and T. Lobbii), and Picea excelsa (Norway Spruce). Planting should be done in autumn or spring.

GRAPE SPOT: *G. C.* and *E. H.* Due to a fungus called Gloeosporium ampelophagum. Spray with liver-of-sulphur, ½ oz. to a gallon of water.

HYDRANGEAS: *Ponica.* It is generally supposed that the blue colour in Hydrangea flowers is due to the presence of iron in the soil. You may therefore apply small quantities of sulphate of iron in solution, and note the result. It has been stated recently that applications of weak alum-water when the plants commence to grow are more effective than the iron. By dissolving the alum in a small quantity of hot water, afterwards diluting it with cold water, this method may be tried with very little trouble.

LONDON PARKS: *C. A., Cork.* Applicants for employment in the Royal Parks, Central (Hyde, St. James's, Regent's, &c.), should apply to the respective Superintendents, who will (if there is a vacancy) furnish the applicant with a form to be filled up and sent to H.M. Office of Works. A personal application at the various Superintendents' offices at 10 A.M. is preferable. For admission to the London County Council's Parks, apply to Col. Sexby, General Superintendent of these parks, at his office, 11, Regent Street, W. We know of no such stipulations as you suggest.

MANURE-WATER AND PEACH-TREES: *W.* We have received a further letter from Mr. Ward on this subject, in which he repudiates the construction put by Mr. Moore upon his previous references to the aspects of walls, and of the borders sloping from them. It is not necessary to continue the discussion further.

NAMES OF FRUIT: *E. B.* If you send Peach or other soft fruits to be named it is imperative that two specimens be sent. These should be gathered just before they are quite ripe, and be packed very carefully in soft material, and in a wooden box that cannot be broken or crushed in the post. Do not post at the week-end, when delay may be reasonably anticipated.

NAMES OF PLANTS: *J. R.* Cercis siliquastrum (Judas-tree).—*G. P.* Piptanthus nepalensis.—*W. B. K.* Choisya ternata.—*G. B.* Pyrus intermedia.—*Miss E. W.* Spiræa chamædrifolia.—*J. A. F.* Tropæolum tuberosum.—*B., Wolverhampton.* Scilla amœna.—*T. A. F.* Tropæolum tuberosum.—*Sir A. H.* 1, Asphodelus ramosus; 2, Dactylis glomerata variegata; 3, Veronica pinguifolia; 4, Phyteuma spicatum; 5, Tiarella cordifolia; 6, Delphinium species, probably D. cashmerianum.—*Formosa.* 1, Masdevallia ignea; 2, M. triaristella; 3, Pleurothallis rubens; 4, Selaginella Wildenovii.—*Japonica.* Odontoglossum citrosmum album, and two of the ordinary rose-tinted forms, the darker one being exceptionally good.—*E. C.* Oncidium sphacelatum.—*W. F.* Cotoneaster affinis.—*H. W.* Iris sibirica.—*C. L. L.* The single Clematis is C. (Atragene) alpina; the double one is perhaps C. John Gould Veitch. The appearance of the Palm-leaves is probably the result of defective or injudicious watering. —*A. S.* 1, Alyssum calycinum; 2, Cerastium tomentosum; 3, Alium Moly.

PEACH MILDEW: *W. R.* The fruits and leaves are attacked by the fungus that causes Peach mildew (Oidium leuconium). Remove and burn all diseased fruits and leaves, and dust the healthy ones with flowers-of-sulphur.

PEAR LEAVES: *W. P.* The blistered appearance is caused by the Pear-mite (Eriophyes piri), a microscopical insect by no means uncommon. Destroy all fallen leaves by burning.

POTATO: *J. T. S.* The Potato that failed to grow is dead—that is, the protoplasm in the cells is coagulated. How this came about it is impossible to determine from the specimen. In the second tuber the eruptions are not due to enlarged starch grains, but to cells of the rind that have divided rapidly owing to the presence of moisture, warmth and light.

RASPBERRY CANES: *K. & S.* We observe that the tops of the canes are dead, and assume the cause of this to be something connected with the roots. There is no appearance of disease of any kind, and it may be that the plants have suffered from drought at a particular time. Are the roots in a healthy condition, or do they show any sign of injury from the strong chemical manures you have applied to the soil?

RHODODENDRONS: *Shortlands.* See that the drainage is perfect, and apply leaf-mould or peat, but no manure.

SYRINGING GRAPES: *E. M. L.* It is not customary to syringe Vines after the berries have been thinned. You can obtain the amount of atmospheric moisture necessary by frequently damping the surfaces in the house and by keeping the troughs which are fixed on the water-pipes filled with water or weak manure-water.

TOMATO: *Norfolk.* The condition of the fruits is due to excess and consequent granulation of one of the constituents caused by lack of potash in the soil. Apply small doses of sulphate of potash, but do not use kainit. The amount of solid residue per gallon of the water you use is most unusual.—*W. D.* Apply small quantities of sulphate of potash, and if subsequently you notice any decay in the fruits send us further specimens.

WEEDS ON GARDEN PATHS: *G. C.* Dress the paths with carbolic acid [POISON], mixing 2 to 3 oz. of acid to each gallon of water; or apply a sprinkling of finely-ground rock-salt occasionally, brushing in each application with a new birch or ling besom. The salt is much less dangerous and yet effective. In applying salt or any other weed killer take care not to let any get on to live edging, as Box, turf, &c. If you use the vitriol (sulphuric acid, POISON), you must dilute it by adding at least four times as much water as acid.

YEW: *A. T. S.* The result of the puncture of an insect, Ceccdomyia taxi.

THE PINK.

HAPPENING to take up a volume of *Gossip for the Garden* for 1856, I found therein some remarks upon this pretty, sweet-scented garden flower. I write "sweet-scented" advisedly, for it is well known that some Carnations are not sweet-scented, although I never yet found a Pink that lacked perfume, or that was not hardy enough to stand out-of-doors all the year round; but what is noticeable in most of the papers written upon the Pink was the apparently fixed idea that exhibitions of Pinks were essential to the very existence of the flower. There is no doubt that exhibitions give a considerable impetus to the growth of any flower, and such displays are very desirable, and do good in many ways; but when they become absolutely essential to the very existence of any class of garden flowers, it shows a sad falling-off in the taste of the flower-loving public. I well remember meeting, amongst others of the good old florists, at an exhibition of "The Metropolitan Floral Society," the late Mr. John Keynes, of Salisbury. I believe he pawned his watch to purchase his first collection of Pinks, and he stated at the meeting that he remembered the time when seven exhibitions of Pinks were held in Salisbury in one year. The florists at that time would look on one class of Pinks only, the "laced" varieties. There were three distinct shades of colour—purple, red, and black, but they never could make an exhibition of flowers that the general public cared to visit. Single flowers spread out on home-made stands, carefully dressed, can give no idea of the beauty in the garden of the plant when furnished with a hundred or more flowers and buds standing well above the silvery foliage, with the dew sparkling on every leaf and bud on an early morning in June. Moreover, for garden purposes there is no need to confine ourselves to "laced" Pinks, nor do I find any amateurs who grow the plants for their beauty in the garden, or for their sweetness as cut flowers in the house, very anxious to possess them. The pure white varieties are the most popular, and next, those that are white but with a slight rose or red tint in the centre of the flowers. Besides a collection of named Pinks much interest and instruction are to be derived from the raising of seedlings. I had a year or two ago a bed filled with a thousand plants, and for six weeks or more when the plants were in flower it was a source of great interest to me. There might have been 10 per cent. of them single or slightly passing into the double-flowered state, not more, but out of the thousand there were of good laced Pinks not more than a dozen.

The same remark applies to Carnations. You may raise a thousand flakes and bizarres, or rather, to put it correctly, a thousand seedlings from flaked and bizarred varieties, and not have six good enough to pass the critical examination of the florist. With Auriculas it is even more difficult; it seems almost impossible to raise a perfect flower from the florist's standpoint. The eye is too pale, the paste is too thin, the outline is not circular, and the body colour—oh, the body colour! it is never right. There is the standard of excellence in these which for want of a better term we must designate florist's flowers, and of course in the eyes of the florist these difficulties have to be overcome; but in the course of selection many beautiful plants quite outside the florist's standard may be selected and grown as "garden plants," and it cannot be denied that many of these are more valued than those that strictly conform to the florist's standard.

I am not decrying the true florist's type of the Pink, the Carnation, or the Auricula. I prize them highly, and fully appreciate the good work that has been done in the past by the florists who selected their flowers carefully and dearly loved them, but one never will get the amateur gardener to be tied down by square and rule. Every one of them has his own ideas as to "standards of excellence." There are ten growers of fancy and self-coloured Carnations where there may be one cultivating flakes and bizarres. "Want of education or bad taste," say the florists. Let it pass.

> "He that complies against his will
> Is of the same opinion still."

We may as well pass on to our Pinks. They are easily grown and easily propagated. I ought to know. The Pink and Pansy were my favourites even as a schoolboy; I have grown them and loved them for more than half a century. In those early years I had no frames, not even a glass light, but I took "pipings" the first wet day in July (the plants flower later in Scotland than in the South); they were simply dibbled into fine soil about 3 inches asunder, and I lost very few. I did not understand layering at that time, but it is a good plan to propagate some from layers. The small, wiry slips should be taken as "pipings" or cuttings. They ought to be planted-out where they are to flower in September. The Pink is nearly allied to the Carnation, and requires very similar treatment; but avoid pot culture if you want the "lacing" to be richly coloured and well defined. Growth under glass will give nice clear, clean flowers, but it will in some instances cause the lacing to disappear altogether.

To obtain a bed of good plants, Pink seeds should be sown in March; they germinate quickly in a hotbed of which the temperature is not excessive. The steam from manure might kill the young seedlings, therefore the violent heat should be past before any seed is sown of any kind. Prick the plants out into boxes as soon as the seedlings are large enough, and place the boxes in frames until the plants have started into growth. If they are planted out on a bed of deep, rich soil in June or July, they will make full plants to flower the following season in June. It is a waste of time to sow seed that has not been saved from the best named varieties. Even if the seed is saved from the best laced varieties comparatively few will give laced flowers, showing very clearly that it is not the normal characteristic of the Pink. The wild plant is self-coloured and fringed, so that the florist sets himself the difficult task of first obtaining by cultivation a double flower, which is also fringed; but he does not like a fringed or notched petal, and works until he has a variety with smooth or plain-edged petals. The self-colour must also be destroyed, and a white ground is obtained, but on the white ground has to be painted a rose, red or black colour, and this in a certain way, a daub of colour in the centre, and a band of the same colour running round the petals, leaving a white margin, and another space of white between the band of colour and the central blotch.

All this has been obtained from a very plain, simple wild flower of a rose or purple colour. We must therefore grant a meed of praise to the patient workers who have done so much for our enjoyment. In the process of selecting the seedlings every flower that has perfectly laced qualities should be set aside to be grown next season. There may be half a hundred growths at the base of the stems which may either be rooted as layers or taken off and struck as "pipings"; these, when well rooted, may be planted out in the open garden to produce a display of flowers next season. Besides the laced flowers the amateur will look for self colours, and especially for those with a blotch of colour in the centre of the flowers; besides, some of the seedlings with quite single flowers are admirable; but unfortunately they have the fault of being fugacious in character; but to make amends the plants produce them in profusion. *Jas. Douglas.*

TREES AND SHRUBS.

HYBRID LARCH.

IN the *Transactions of the Royal Scottish Arboricultural Society*, vol. xviii., 1905, p. 62, mention is made of a hybrid Larch, a cross between the Japanese L. leptolepis and the European L. europæa, the Japanese species having been the female parent. No further information is given, and we are left in ignorance whether the cross was a natural or an artificial one, by whom it was effected, and of other details which would be of particular interest.

FIG. 165.—PRIMULA VITTATA, A CHINESE SPECIES: COLOUR OF FLOWERS MAGENTA SHADE OF PURPLE.

PRIMULA VITTATA,

Bureau and *Franchet.*

THIS species was first discovered by Prince Henri d'Orleans in 1890 in the neighbourhood of Talien-lu. Pratt also met with it in the same region about the same time. Messrs. Bureau and Franchet described it in the *Journal de Botanique*, v., 1891. The plant was introduced into the Veitchian nurseries by their collector, Wilson, who describes it as being common in bogs and marshes on the Tibetan border, between 9,000 and 10,500 feet. It flowered in an open border in Messrs. Veitch's Coombe Wood nursery in May last, and was exhibited before the Royal Horticultural Society on May 23, when it received an Award of Merit.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM SEIDELIANUM.

I OBSERVE at p. 355 a note by Mr. J. O'Brien respecting Dendrobium Seidelianum, Rchb. f., of which my Dendrobium Loddigesii is given as a synonym, and it is said that both names appeared on the same date. In July, 1887, I had to compare a dried specimen of a Dendrobium sent from China by Mr. C. Ford, and discovered that it agreed with the plant figured in 1833 in Loddiges' *Botanical Cabinet* (t. 1935) under the name Dendrobium pulchellum, although it was not the original D. pulchellum, of Roxburgh. I also discovered that Reichenbach had further included the well-known D. Devonianum as a variety of the same species. The consequence was that I wrote an article on the question, pointing out the confusion, and re-naming the Chinese plant D. Loddigesii (*Gardeners' Chronicle*, 1887, ii., p. 155). On the day that the article appeared the following note was published in the *Gardening World*:—

"*Dendrobium Seidelianum.*—This is a fresh name attached by Professor Reichenbach to the well-known D. pulchellum (Roxburgh), which is quite a distinct thing from the old garden plant, as may be seen by Roxburgh's drawing kept at Kew. *J. O'B.*"

This note puzzled me greatly, for if the facts were as stated, D. Seidelianum would be a synonym of D. pulchellum, Roxb., but I afterwards found that they had been reversed. In a note in the third volume of *Lindenia* (p. 8), Reichenbach briefly remarked that he had given to D. pulchellum of Lindley the name of Seidelianum, in honour of M. T. J. Seidel, of Striesen-Dresde. This, however, does not help us much, for the D. pulchellum of *Lindl. Gen. and Sp. Orch.*, p. 82, is simply D. pulchellum, Roxb., as Lindley himself states, though he afterwards wrote it D. pulchellum, Lindl., adding the synonym D. Devonianum, Paxt., and citing Loddiges' plate as belonging to the same species (*Journ. Linn. Soc.*, iii., p. 12). How he came to make such a series of mistakes I cannot explain, but merely point them out. As to the name D. Loddigesii, which has been accepted for over eighteen years, there is no reason in priority or anything else why it should be set aside in favour of D. Seidelianum, which by the way is only now clearly defined for the first time. *R. A. Rolfe.*

CATTLEYA MOSSIÆ NALDERIANA.

It is interesting to find that this distinct variety, described many years ago, is still in cultivation, and that its peculiar characteristics are unchanged. A plant has flowered in the collection of Mrs. Mount Batten at Mornington Lodge, West Kensington (gr., Mr. Yorke). The sepals are pale greyish-rose with purple margins. The petals have a feather-like band of silver-white up the middles, the rest being bright rose-purple with a slight silvery tint between the veining. Lip rose-purple with a reddish-orange base, and lighter orange patches on each side of the tube, and with a lavender-coloured crimped margin. C. M. Courtauld's variety, Rchb. f., which is described in *Gardeners' Chronicle*, June 2, 1888, p. 681, is allied to Nalderiana, but it is remarked that no others of the section are known. *J. O'B.*

NEW OR NOTEWORTHY PLANTS.

ARACHNANTHE ANNAMENSIS, *Rolfe, n. sp.**

A STRIKING species of Arachnanthe has appeared among the Annam importations made by Messrs. Sander & Sons through their collector Micholitz, and has just flowered with Mr. F. W. Moore at the Glasnevin Botanic Garden. It is one of a number picked out of this importation by Mr. Moore, and until it flowered was thought to be a species of Trichoglottis. On flowering, however, it proves to be very different. When I first saw a flower I thought it belonged to the old Arachnanthe moschifera, on account of the general shape and markings, but on comparison it proves to have a very different lip, and the leaves are also much more elongated. This, however, is its nearest affinity, and the lip is just as delicately mobile, responding to the slightest movement, like some species of Bulbophyllum or Cirrhopetalum, though very different in shape. Mr. Moore states that the plant is stiff and erect, about 18 inches high, and the inflorescence sent to Kew is over a foot long, and bears six flowers. They are just as large as in A. moschifera, and resemble some huge yellow spider, very heavily barred with red-brown, the resemblance being increased by the falcately-curved petals and lateral sepals. It is a very striking addition to a small but very remarkable genus. A. moschifera, Blume, the "Spider Orchid," was figured in the *Gardeners' Chronicle* on October 13, 1894, p. 435. *R. A. Rolfe.*

* *Arachnanthe annamensis*, Rolfe.—A stout, erect plant about 18 inches high. Leaves somewhat recurved, linear-oblong, somewhat bilobed at the apex, coriaceous, 11 inches long by an inch broad, bright green. Inflorescence over a foot long, six-flowered in the upper half. Bract ovate-oblong, obtuse, 5 lines long. Pedicels 14 lines long, suffused with light pink. Flowers much resembling Arachnanthe moschifera in shape and appearance. Dorsal sepal sub-spatulate-oblong, sub-acute, over 2¼ inches long by 5 lines broad at the apex, very heavily barred with red-brown on a yellow ground. Lateral sepals spatulate-oblong, sub-obtuse, falcate and approximate at the apex, 1⅞ inch long by 7 lines broad at the apex, coloured like the dorsal. Petals spatulate-oblong, sub-obtuse, strongly falcate, 1⅛ inch long by ⅓ inch broad at the apex, coloured like the sepals. Lip mobile, strongly 3-lobed, about 10 lines long. Side lobes triangular, acute, incurved, and nearly meeting at the apex, over ½ inch long, light yellow striped with red-brown, the basal angle lilac. Front lobe fleshy, compressed and keeled, with an oblong auricle over a line long on either side of the base, bifurcate at the apex, the lower tooth short and fleshy, a line long, the upper subulate, acute, sub-erect, 3 lines long; base of the front lobe light yellow, rest red-purple; crest consisting of an erect, oblong, dorsally-compressed callus, 2 lines long, situated at the base of the front lobe, and terminating in a short, acute tooth at either angle, while with a few purple spots at the apex. Column very stout, 5 lines long, lilac-purple in front and at base behind, reddish-purple at the apex. Native of Annam. *R. A. Rolfe.*

BOOK NOTICE.

AUTHOR AND PRINTER.

A BOOK whose sub-title explains its intended uses as a "Guide for authors, editors, printers, correctors of the press, compositors, and typists; with full list of abbreviations. An attempt to codify the best typographical practices of the present day." The compiler is Mr. F. Howard Collins, who has arranged in alphabetical order the most commonly used words, expressions, and abbreviations, and shows their correct spelling, the way in which they should be divided into syllables at the end of a line and the beginning of another. The sizes of paper and of type are given, the methods of punctuation explained, and a great variety of miscellaneous information afforded. We think many who are considered, or think themselves, fairly correct in their use of words will experience some surprise, when looking through this book, to see how commonly and unconsciously they make mistakes. How often, for instance, do we meet with the expression *double entendre* as applied to something with a twofold meaning. The book before us reminds us that the correct phrase is *double entente*, and so with many similar cases.

Amongst the abbreviations we meet with *G. Chr.*, as denoting the title of this Journal, but for telegraphic purposes the abbreviation is *Gardchron.*, written as one word; V.M.H. finds no place in the abbreviations, though its meaning is well known to our readers. The capital initial letter in Gardenia, Fuchsia, Ficus, Rhododendron, Geranium, and similar cases is omitted, though in most botanical books the capital is retained for generic names; "ab incunabilis" seems hardly correct. We might extend incidental notes of this description to almost any extent; indeed, we do not recommend readers or writers who are pressed for time to do more than confine themselves strictly to the search for the particular entry they require. The temptation to read on and on is very great, and in the circumstances we have named must be resisted. As this is really a great compliment to the book we need say nothing more in its praise. Authors, editors, and proof-readers will find it indispensable. It is published by Henry Frowde.

THE MONTAUBAN HYBRID ORANGE.

IN the year 1894 M. Armand Bernard, in his garden near Montauban, fertilised the scented flowers of a tender variety of Orange, having large fruits with pollen from Citrus triptera. The object he wished to attain was the production of a hardy Orange with edible fruits. From this artificial fertilisation he raised several hardy hybrids, all different from sorts already in cultivation, and all bearing spines. Some of the young plants resembled the male, others the female parent.

The first hybrid flowered in 1903. The flowers were white, scented, resembling those of C. triptera, but narrower. The fruits were from 2½ to 3 inches in diameter, larger than those of C. triptera, but with a thicker rind. The fruit so far is too dry to be palatable. The first hybrid, shown at fig. 166, has been named Armand Bernard, and is on its own roots. In habit it has a slender stem, having grown up among other plants and remained etiolated. The specimen survived 12° of frost, but the drought of 1904 caused it to drop

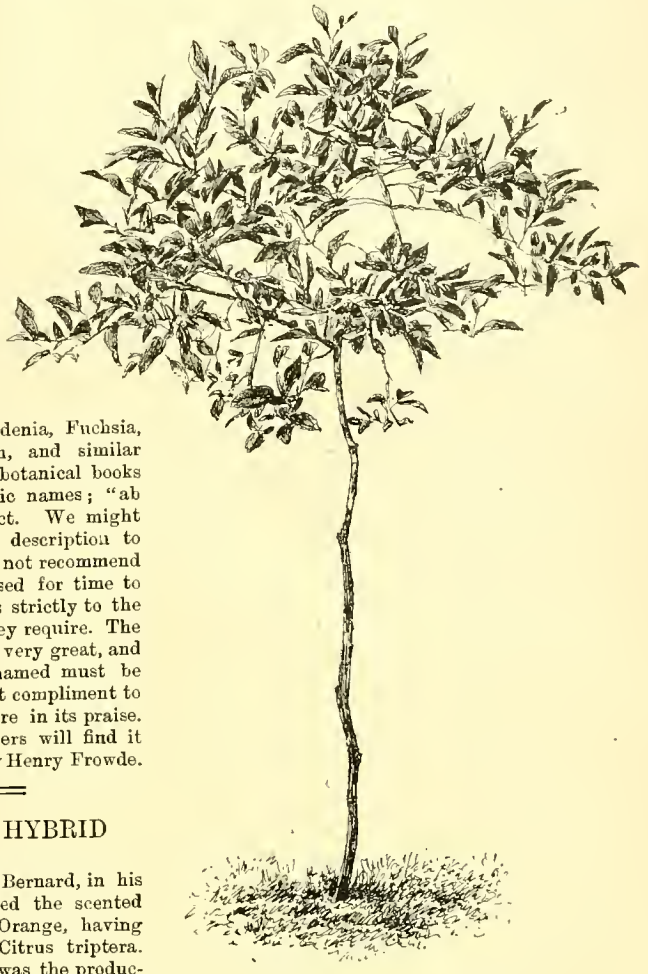

FIG. 166.—HYBRID ORANGE.

FIG. 167.—LEAVES OF HYBRID ORANGES. (SEE TEXT.)

many leaves. A branch of the tree grafted on Citrus triptera and kept in the coldest and dampest place in the garden survived 14° of frost without losing its leaves. Other plants of the hybrid having some trifoliolate leaves with winged petioles, and others trifoliolate leaves with bare petioles suffered no injury from the frost. On the other hand certain hybrids with entire leaves were injured by 12°, and died from 14° of frost, while the fruits hung frozen to the trees. Such extreme temperature is rare, so that the new hybrid may be considered hardy in the ordinary climate of France. Those plants that differ most from C. triptera are least resistent. Their entire leaves (fig. 167, c) are like those of the ordinary Orange C. aurantium; the trifoliolate leaves being, as before observed, mostly evergreen and hardy (see fig. 167, A, B). There seems every reason to hope that hardy evergreen Oranges with edible fruit will soon be brought into cultivation. *E. A.*

[This Orange is the subject of a coloured figure in a recent number of the *Revue Horticole*, and to its editor, M. André, we are indebted for the opportunity of giving the accompanying illustrations. ED.]

THE ROSARY.

WILD ROSES AT KEW.

WHEN I term the Roses now growing so luxuriantly near the pagoda in Kew Gardens, "wild," I mean to convey the idea that they are growing wild rather than under ordinary garden culture. A special reason for drawing attention to these Roses just now is that about the end of the month the bulk of them will be in glorious bloom. The broad dell in which they are growing is near the pagoda, and as it will soon be one of the most interesting as well as beautiful objects in the Gardens, it would be a misfortune for any lover of Roses to miss it. Ample evidence of late has been furnished that Rose-growing in gardens is now less limited to Teas, H.T.'s, and similar large-flowered or exhibition varieties and that what are commonly termed garden Roses are very popular. The Rose dell at Kew furnishes a fine illustration of the semi-wild manner in which these Roses should be grown, and the Kew authorities merit special thanks for furnishing so large and beautiful an example, and specially so because it is in a spot where everyone may see it. Entering the Gardens from the Richmond Gate, the dell is to be found immediately to the right of the pagoda. It was originally slightly excavated, the soil being used to help form broad raised banks, and these banks are now almost throughout covered *en masse* with Roses. The dell is some 100 yards long, and the grass footway 12 feet wide. It is partially winding, and seems to be an ideal place for forming a semi-wild rosary.

Some few varieties have been flowering for two or three weeks, notable amongst them being Paul's Carmine Pillar, rich in bloom and in colour, and a pretty pink, cluster, very free-growing Rose, The Dawson, a sort of preliminary to Dorothy Perkins, which was many years ago raised from crossing Rosa multiflora with General Jacqueminot. The "General" is not there, but just across the broad grass walk that runs so finely all up the gardens, is a big clump of R. multiflora with its almost bramble-like small white flowers. A big clump of the old Amadis is also in full bloom. Crimson Rambler is a huge mass but not yet open, neither is Dorothy Perkins, though in luxuriant growth. Among others may be noted Rosa moschata, R. blanda, Fellenberg, R. lutea (only recently planted, but which will in time be a brilliant feature), R. spinosissima, Maude's Triumph, South Orange Perfection (both much alike and of Wichuraian origin), Jersey Beauty, and R. Wichuraiana, as an edging. There are many lesser-known varieties, all of which should be seen by those who, having space and a slightly shaded position, would like to grow Roses in this semi-wild form, as Roses evidently like to be treated. The planted banks on either side of the dell vary in width from 15 to 30 feet, and on their raised surface in some places old tree stems and stools have been placed, as over such objects these free-growing Roses delight to ramble. No doubt another year some newer varieties, inclusive of the beautiful Lady Gay, will be added to the collection, for Kew evidently likes to be up to date, a detail of management which merits all praise. There are other garden Roses growing just across the broad grass walk, but these have been treated as border plants. The dell Roses now are a revelation of what Roses can be. *A. D.*

COLONIAL NOTES.

JAMAICA.

THE May number of the *Bulletin of Agriculture* is mainly taken up with the subject of Cotton and its cultivation, but there is also an excellent article on the Raffeisen Agricultural Banks, by means of which cultivators can borrow on easy terms, the money being supplied by other cultivators on the co-operative principle, and safeguards being afforded against loss or fraud.

THE MALAY STATES.

In the March number of the *Agricullural Bulletin of the Straits Settlements* Mr. Ridley identifies the "Kumus" timber, so highly prized by the Malays, as Shorea ciliata, one of the Dipterocarps. It furnishes excellent timber for railway sleepers and house construction.

TRANSVAAL DEPARTMENT OF AGRICULTURE.

The Annual Report of this Department for 1903–4 is now published. The division of Botany and Agrostology, under Mr. J. Burtt-Davy, has been busily engaged in seed and plant distribution. Attention has been paid to poisonous plants, pasture plants, weeds; plant-diseases have been investigated, and many specimens collected for the herbarium. As regards the Forestry division, Mr. C. E. Legat mentions the great lack of trees and shrubs, which are much needed, not merely for timber but for ornament, shelter and fuel. Active measures are being taken to amend matters. The division of Horticulture will in future pay much attention to the question of fruit culture. The area under crops has been much increased; the produce on the whole was very good, and the harvest the best for years. Mealies, Kaffir Corn, and Potatos were the principal crops sown. An evident disposition to test new crops was manifested. The Report is, on the whole, entirely favourable.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Long-stemmed Cattleyas of the C. guttata type, C. bicolor, C. granulosa, C. Schofieldiana, C. intermedia, C. Harrisonæ and C. Loddigesii, are not amongst the easiest of Cattleyas to manage, but they are deserving the most careful cultivation. Members of the first four species need the warmest and driest position afforded in the Cattleya-house, and the rooting materials should be kept moderately dry until roots appear at the bases of the new growths. At this period fresh surface material may be applied, and should any plants have overgrown their receptacles repot them. Use clean pots and half fill them with drainage material. For placing about the roots use good turfy peat two parts, and sphagnum-moss one part, adding a small portion of Oak-leaves as the work proceeds, and surfacing with chopped sphagnum-moss. When the plants are making roots keep the materials and surroundings moist, but, should dull weather prevail, carefully avoid wetting the new growths. Free ventilation is essential, together with a good share of light and natural heat when obtainable, but draughts should be prevented. C. intermedia, which is often imported along with Lælia purpurata, may be grown under similar conditions to that species, a central position in the house suiting it well, but as it possesses more slender pseudo-bulbs a less protracted drought should be permitted during the resting period. A liberal supply of water and atmospheric moisture is needed when the plants are growing actively, and any needful potting should be done as soon as the flowers are past, for then new roots appear. C. Harrisonæ and C. Loddigesii are almost identical, yet culturally C. Loddigesii appears to enjoy a higher temperature than its ally. These two species thrive well if decaying leaves are included in the compost, though in that case extreme care in watering is necessary. Let repotting or resurfacing be done when new roots are expected from the young pseudo-bulbs. A long dry rest is needed after root-action has ceased.

Cool-growing Dendrobiums. — A very pretty sight is a well-flowered plant of D. Falconeri, when fixed in a small pan and allowed to hang downwards. The plant should be suspended near to a ventilator, in a position of moderate shade, where it can be syringed several times each day during growth. A high temperature is needed during day, but at night with ventilation the plants like a low temperature. The hybrid D. Venus also grows in a cool intermediate temperature, but should not be given a position near to the ventilator. Afford water in abundance during growth if the plants are in baskets having only a small quantity of material about the roots, but allow moderately dry conditions when growth has ceased. D. Jamesianum, D. infundibulum, and D. longicornu, each of which produces good white flowers, succeed well in baskets suspended in a cool, well-ventilated house that is not heavily shaded. Having now done flowering the plants will make growth, and may be syringed several times during the day; when root-action occurs keep the base well moistened. Extremes of heat with free ventilation at night appear to suit these plants during the summer months. D. Cambridgeanum also grows best under similar conditions, though, if anything, much drier surroundings are advisable when the plants are at rest. D. Kingianum thrives when suspended near to the roof glass of the cool house, and needs very few direct waterings, except just when rooting freely. Atmospheric moisture alone will keep the plant in proper condition throughout the winter.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Creeping Plants.—Frequent attention is needed to prevent the growths of vigorous creepers becoming entangled, and every opportunity for tying-in or cutting-out as the case requires must be taken. A little time spent each morning before the sun becomes too powerful may keep the work well in hand. Among some of the very vigorous growers, such as Passiflora quadrangularis, P. edulis, Vitis Voinieriana, Hexacentris mysorensis, Solanum Wendlandi, &c., grown in temperate houses, a good deal of thinning out is very necessary, and the work should be done frequently, for otherwise the plants quickly get out of hand. Heavy syringings overhead with clear water, or better still the use of a hose-pipe for the purpose, will be necessary to keep the plants free from red-spider and other pests, and a weekly fumigating with XL-All Compound is also very beneficial. Solanum Wendlandi, when grown together with Passiflora racemosa, is very effective, but is subject to attacks of mite, and frequent syringing with Quassia-extract should be given to counteract the evil. An examination should be frequently made for slugs among Lapagerias, and strong growths proceeding from the base of these plants should be protected with a band of cotton-wool, which

needs to be replaced when it has become wet. Lettuce-leaves laid down towards dusk, and examined later with the aid of a lamp, afford the best method of capturing the slugs. Give the plants a good soaking of diluted liquid from the farmyard once a week.

Cassia corymbosa.—When once established, this plant makes very vigorous growth and fills a large space. Its bright golden-yellow-coloured flowers are produced in abundance, and for a cool greenhouse or corridor are very effective. It should be planted out in a rich compost of loam, leaf-soil and silver-sand. The present is a good time for planting.

Zonal Pelargoniums.—Cuttings rooted in spring for flowering during the winter months should be ready for potting into 5 or 6-inch pots. Before plunging the pots to the rims in ashes, fully exposed to the sun during the summer, they should be stood in a cool frame for a week, by which time they will have begun to root into the new soil.

Cinerarias and Primulas.—Pot off young plants as soon as they are ready and place them in cool frames under a north wall or hedge where they can enjoy the benefit of full light free from the sun's rays.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Aster acris.—The staking of this blue Starwort must be done carefully in order to obtain the best effect. Apply plenty of sticks, and "sling" some of the shoots between the supports. A little time and patience will be well repaid by a mass of colour, which has been aptly termed a "poem in flowers."

Hollyhocks need liberal cultivation, and will then be less liable to disease. Destroy any infected foliage, and encourage the plants to grow by affording them abundant waterings, and by working the Dutch-hoe frequently in dry weather to help to conserve moisture and check weeds.

Pinks may now be propagated by "pipings." Prepare a frame and put into it some sandy soil, also a layer of sand on the surface. Choose sturdy growths three or four joints long, and dibble them in firmly. Afford water. Keep the atmosphere close and provide shade from bright sunshine until the "pipings" have made roots, then gradually inure them to exposure.

Liliums.—In affording supports to these, be careful to thrust them into the soil at a good distance from the stem, in order to avoid injuring the bulbs. Apply a top-dressing of rotten cow-manure over the roots, and afford copious waterings during dry weather.

Sweet Peas require to be watered in dry weather; and if the plants need a stimulant, mix a pinch of sulphate of ammonia or nitrate of soda to each canful of water, or apply weak liquid from the farmyard. Do not allow water that contains manure to touch the foliage.

Shrubberies.— Apply the dutch-hoe over the ground amongst shrubs. If any Conifers have lost their leaders tie a strong stick to the stem, and having selected a likely shoot to form a new leader tie it to the stick. Encourage this leading shoot to grow as quickly as possible by taking away the points of other adjacent shoots. Remove cones that may be forming on young trees of Abies nobilis, &c.

Wall Gardens are now at their best, and require frequent waterings. The following are some of the plants in flower:—Antirrhinum glutinosum, A. sempervirens, Campanulas, many Dianthus neglectus, D. plumarius annulatus, and others; Erodium Manescavi, E. macradenium, E. chamædryoides, Geranium in variety, Helianthemums, Heuchera sanguinea, Hippocrepis comosa, Linums, Linaria anticaria, Onosma tauricum, Thermopsis montana, Verbascum densiflorum.

Miscellaneous.— Wallflower and other seed-beds will require frequent waterings in dry weather to assist in the germination of the seeds. Aster Thomsoni should be propagated now, also Androsace lanuginosa. Sow seeds of Meconopsis integrifolia.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Celery.—The earliest plants will now be growing rapidly. Promptly remove any suckers that appear. Place round each plant in good time a piece of matting, in order to retain them in their natural form and prevent the outer stems and leaves from falling away, with the result that they would eventually have to be removed because of their broken and damaged appearance. If Celery is required for show purposes in August, careful attention is necessary in the matters of watering and feeding and to keeping the plants free from insect pests. Finely-powdered lime is the best preventive of damage by slugs, and should be applied early in the season and freely. The plants need not be earthed-up until six or seven weeks before the crop is required for use, but the work must be done carefully, and brown-paper collars applied from the ground-level to the extreme tips of the centre growth, closely surrounding these collars with fine soil to keep the stems in perfect darkness, which is so important in the production of well-bleached and tender Celery. Weak liquid-manure may be easily applied to the roots by placing a drain-pipe at intervals in a perpendicular position between the plants, into which the water can be poured. This may be done conveniently even when the ridge of soil has been fully formed, and it is essential always to guard against dryness at the roots.

Cauliflowers.—In planting Cauliflowers at any season it should be remembered that dryness at the roots is a cause of the production of premature "buttons" in place of well-developed specimens. Where the appearance of mulching is not objected to great advantage may be derived from it. The kind of material to use will depend in a measure upon the condition of the soil. Rich soil may be covered with short grass from the lawn, or any grass cut before the seeds develop. Mulching occasions very little trouble compared with that of watering, and the results from the mulching are even better, for if the ground is allowed to crack, the escape of moisture is considerable. Upon poor soil apply litter or fresh droppings from the stables. Before applying a mulch use the hoe freely amongst Beans, Peas, Globe Artichokes, &c.

Lettuce.—Make frequent and small sowings, and as soon as the plants are large enough to handle thin them out to the desired distance apart, which will vary according to the size of the variety. The best results at this season are secured irrespective of variety without transplanting. Sow the seeds in rich soil in order that growth will be free and of a succulent nature.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Extension of Wall-trees.—If previous directions as to disbudding and stopping have been carried out, the shoots which have been left for extension will have made considerable growth, and should be secured by nails or ties, bestowing trouble with them that they may be trained perfectly straight and parallel with the shoots above and below them. Any weak shoots should be allowed to grow naturally for a time, only tying-in those which are very strong, and stopping these when they have made from 12 to 18 inches of growth. On trees which are making but moderate growth the shoots may be tied-in their full length. The system of extension necessary to the training of the Peach, Nectarine, and Morello are the same. Shoots growing from the base of the old wood should be trained-in where required. Such shoots will furnish fruit-bearing wood where the trees are disposed to become bare.

Pears and Plums.—Extension shoots upon some horizontally-trained trees, as for instance Beurré Dubuisson, Marie Louise, and Williams' Bon Chrétien, &c., may be allowed to grow their full length without fear of the back buds becoming dormant, but upon other varieties the leading shoots may be stopped when 15 to 18 inches long. In the case of horizontally-trained trees which are extra vigorous, stop the leading shoot when 12 inches long; this will force the three top buds into growth; two of these may be trained at right angles to form another tier of branches, with the leading shoot to be trained upright as before. By this means a tier of branches will be formed this year, which in the usual practice would not be the case until next season. Trees now growing in the open but which will be trained should have all the superfluous growths cut clean away, and a foundation made for the tree to be trained on by driving three upright stakes firmly into the ground close to the tree, and tying to these three or more light Bamboo-cane "traces" in an horizontal position. To these the shoots may be firmly tied, securing them from time to time as growth proceeds.

American Blight.—Where old Apple orchards in close proximity to fruit plantations are infested with this pest it is always sure to cause endless trouble. If the blight is present it can always be found about the buds of last season's "worked" trees, or about the callused parts of trees grafted this spring. Gishurst Compound Soap used with sweet-oil well rubbed into the affected parts will destroy the pest. When the foliage is infested the above insecticides applied by means of a syringe will be effective after repeated use.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Peaches and Nectarines. — Syringe vigorously each day those trees which have been cleared of fruit. It is essential to keep the foliage clean in order to secure the proper maturing of the wood for affording next season's crop. Ventilate the houses to the fullest extent, and if the roof-lights can be removed so much the better. Keep the trees thoroughly well supplied with water, and apply liquid-manure to old trees or others that require extra feeding. Pressure of work in other departments at this season is sometimes the cause of fruit-trees being overlooked when the fruits have been gathered, and the soil about the roots becoming too dry the flower-buds fall from the trees at a subsequent period. American varieties, such as Alexandra, will succeed better if afforded a light shade to prevent the wood from getting over-hard, especially in houses of which the supports are of iron, or in the case of trees the foliage of which has become thin from the attacks of red-spider or other causes. Keep houses which contain ripe fruit moderately cool by free ventilation day and night. Examine the trees daily when the fruits are cool, gather carefully all that are ripe, and place them on a soft surface in a cool well-ventilated fruit-room until required for use.

Succession trees should be syringed twice daily, the first operation being carried out shortly after six o'clock in the morning. If the roots are inside the house afford them an abundance of water and liquid manure over the mulch previously recommended. Ventilation must be employed liberally by day and by night. Expose to the sun's rays any fruits which are approaching to a state of ripeness.

Late trees.—Tie down the shoots and keep the laterals pinched, allowing fully 6 inches of space between each shoot. Then thin out the fruits, and apply a mulch of good stable manure over the borders inside and out. Ventilation and watering are just as necessary for these trees as for earlier ones. Elevate all pendent fruits by placing pieces of lath under them. If it is necessary to retard the crop, let it be done now by much ventilation, rather than later by having to shade the trees.

Newly-planted Trees should be carefully trained and any gross shoots stopped to obtain a proper balance of growth. Employ another light fumigation if green-fly has not been thoroughly exterminated.

JAPANESE HORTICULTURAL SOCIETY.—The May number of the Journal of this Society is an elegant production, containing articles on Tulips, Peaches, Psilotum triquetrum, &c. Paper and print are excellent, but we are not in a position to judge of the merits of the articles.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JUNE 26—Isle of Wight Rose Society's Exhibition at Ventnor.

WEDNESDAY, JUNE 28—Richmond Flower Show. Southampton Flower Show (2 days).

THURSDAY, JUNE 29—Colchester Rose Show.

FRIDAY, JUNE 30—Royal Botanic Society. Lecture.

SALE FOR THE WEEK.

TUESDAY NEXT—
By Protheroe & Morris, the whole of the Greenhouse Plants, Bay Mare, Van, Carts, Tools, and Effects, at Bedford Nursery, Haverstock Hill, at 12 o'clock.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —62·4°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, June* 21 (6 P.M.): Max. 71°; Min. 57°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June* 22 (10 A.M.): Bar., 30·4; Temp., 73°. *Weather*—Fine, with bright sunshine.

PROVINCES.—*Wednesday, June* 21 (6 P.M.): Max. 71°, E. Coast of England; Min. 53°, N.W. Coast of Scotland.

The New Chiswick.

BEARING in mind the history of the Royal Horticultural Society in this the beginning of its second centenary, we are inclined to think that for once fortune has "come with both hands full," for were not the Hall and the garden both secured in one year? Well may the Society say, "Fortune and I are friends." A tablet in the Lindley Library records the generosity of Baron Sir HENRY SCHRÖDER; a portrait in the new Council-room at Wisley reminds us of the munificence of Sir THOMAS HANBURY. The foundations having been securely laid, it is for the successors of these two benefactors to make the most of their advantages, to supply deficiencies, and to bring the Society abreast of modern requirements. A visit to Wisley at this season will show that the Council is alive to its responsibilities in these matters.

The new garden is a little difficult of access, but is delightfully situated. Doubtless in time the journey will involve a smaller expenditure of time and money than is now necessitated. Be that as it may, visitors are already numerous. The drive from Weybridge on a June morning, across heaths and commons glowing with the bright flowers of the Broom, and adorned with the stately blooms of the Foxglove, through leafy woods and endless plantations of Scotch Pines exhaling delicious fragrance, is a thing to be grateful for. Traces of the frost on May 22 were everywhere visible on the Oaks, and specially on the Sweet Chestnuts grown as coppice wood. Rhamnus frangula, by the way, a tree that one does not often see, is here abundant and unhurt by the frost. In the woods children were met laden with sacks. Curiosity being raised as to the contents of these receptacles, enquiry was made, when the answer came "Co-nies." Evidently the "feeble folk," usually so called, were not intended, but Pine cones, collected for fuel! It was some time before we realised what the word pronounced in two syllables meant! But we are lingering in the woods, which is not unnatural, seeing that the garden is actually in the woods. The original enclosure is, with great appropriateness, left as it was in the time of its former proprietor, the late Mr. G. F. WILSON. It occupies a sheltered ravine, the sides of which are densely wooded, whilst the centre is diversified by low mounds and undulations clothed with an endless variety of shrubs and herbaceous plants.

In a comparatively open space is a newly-formed rockery in full sun, and at the bottom of the slope is a pool crossed by a rustic bridge, filled with aquatic plants, and bordered with Japan Irises, Primula japonica, P. rosea, Ferns, and other plants adapted to the situation. The noble foliage of the Gunnera had been injured by the May frost, but the damage was speedily concealed by new growths. Elsewhere are other pieces of water covered with brilliant Water-Lilies and Villarsias. The flash of the kingfisher may be seen as he darts across the surface of the water. No sound of intrusive "motor" is to be heard, but the croak of the bull-frogs and the call of the cuckoo are not bad substitutes. More melodious sounds are emitted by the nightingales and other songsters, for whose safety and convenience provision is made. In the wood which borders the central ravine Rhododendrons, Azaleas, Camellias, Kalmias, Bamboos, Tree Ferns, New Zealand Flax, and flowering shrubs in great variety are met with. Towering up among these are patches of Lilies, such as L. Szovitzianum, L. rubellum, and the noble shafts of L. giganteum. Beds of hardy Cypripediums, of Ixias, of Shortia, of Epigæa, of Vacciniums and Pernettyas, and other choice subjects cluster at the base of the trees, and give no sign of their exotic origin. In spring Narcissi, Scillas, Muscari, and other bulbous plants by the thousand are to be seen, and Cyclamen in their season. In another quarter the eye is attracted by the profusion and beauty of the Tree Lupins in varied colours.

It is, however, quite impossible to do more than generally indicate the nature of the contents of this garden, and to show that at all and any season there will be found much to interest and charm the plant-lover. Generally on visiting a garden one endeavours to see what was the purpose which the designer had in view, what particular requirements, decorative, scientific, or utilitarian, are provided for, what individual tastes and fancies indulged in. In this case it is not a garden in the ordinary sense—there are no lawns, no flower-beds, no terraces, not many walks. It is not even a "wild" garden as commonly understood, but a wood in which clearances have been made here and there, and stocked throughout with the most select, the most interesting, and the most beautiful hardy plants. These are allowed to grow, not in any definite order, but where they can best establish themselves. Imagine the rock-garden at Kew transferred to the middle of the pleasure-grounds, and some idea may be formed of the general character of the original garden at Wisley. This is the pleasaunce, as our forefathers would have called it. It recalls remembrances of the Wilderness Walk at Chiswick, which half a century ago was such a delightful feature of that historic garden.

The mention of Chiswick reminds us that Wisley is destined to replace that old experimental garden so rich in memories, so dear in its associations. There are at Wisley, besides the "garden of plants" that we have mentioned, acres to spare in every aspect, with soil varying from a very light sandy loam to stiff clay, with an adequate water supply and an unpolluted atmosphere which fogs of the London type do not penetrate. Here then there is space for trial-plots for an experimental garden, for plantations of fruit trees, for an arboretum, for a research station. Associated with the trial-plots should be selections of the acknowledged best standard types of vegetables and fruits, correctly named, for purposes of instruction and of comparison with novelties, real or reputed.

The desirability of an arboretum is enhanced by the fact that the climatal conditions at Kew are becoming less favourable year by year, so that it is necessary to consider and, so far as possible, provide for contingencies some decades ahead.

As to the research-station, that, too, we look on as imperatively necessary. The Council is pledged to its formation; but, seeing how much it has in hand, and how much remains to be done, we must possess our souls in patience. In the meantime the ever-increasing losses from plant-diseases, and the endless questions of practical importance that turn up regularly, many of which could be solved in a properly-equipped station with a competent director, will, we trust, stimulate the Council to carry out its expressed promises at as early a date as possible.

In the meantime substantial progress has already been made. A commodious dwelling-house for the Superintendent, with a convenient council-room, has been erected. Other residences have been built for the staff. Seven span-roofed houses, running north and south, 100 feet long and most of them 30 feet wide, and three rows of pits, have already been constructed. These are eventually intended to be used as Peach-houses, Vineries, and for other purposes. They are substantial structures, admirably light, and with adequate provision for ventilation and heating. The whole is heated by a horizontal tubular boiler, with a second to be used in case of emergency. This part of the work was carried out by Messrs. KINNELL & Co. Some of the houses are at present used for Tomatos, one of which, "Carter's Sunrise" by name, is remarkable for its prolific habit. Another house is occupied with pot-Figs, thus carrying on the old Chiswick tradition. Veitch's Chelsea manure is found very effectual in promoting the root-growth of Figs, as was evidenced by specimens shown us.

A stone causeway runs in front of the the houses for their whole length. These stones have been trodden by generations of gardeners, for they formed the pathway on either side of the great vinery at Chiswick.

From lack of space, assuredly not of material, we must stop, not before offering our congratulations to the Council on the excellent progress that has been made by Mr. WRIGHT and his staff. A fine opportunity is before them, and there is every appearance that the fullest use will be made of it.

The Gardeners Royal Benevolent Institution.

Once again we are privileged to record a successful Festival Dinner in aid of this most deserving Institution, a sum of £2,100 having been obtained for the relief of aged or infirm gardeners who are no longer able to follow their calling, and who are consequently in necessitous circumstances.

We have urged again and again that it is necessary for gardeners themselves to look to it that the amount contributed to the Fund in the form of annual subscriptions shall be increased in order that the Institution may become less dependent upon results obtained, mainly from outsiders, by special efforts such as the Festival, which source of income must always be more or less uncertain. But as the need for relief increases year by year it is likely that even when the subscriptions have been largely augmented there will always be a deficiency to be made good by special means of some kind or other. The Institution is, therefore, deeply indebted to such liberal and sympathetic patrons as the Duke of Westminster and others who preside at these annual dinners and contribute to the funds. As the Chairman pointed out in his speech at the dinner, the annual liability amounts to £4,000, and we know that it is impossible even with this expenditure to elect all the candidates who are deserving of assistance.

The dinner held at the Hôtel Métropole on June 16 was the sixty-sixth festival, and the Duke of Westminster, who presided, was supported by a large company of well-known horticulturists. On his Grace's right hand was Sir Walter Smythe, and on his left Mr. Harry J. Veitch, Treasurer and Chairman of the Executive Committee, whose successful efforts on behalf of the Institution last year when he presided at the annual festival will be remembered gratefully for a long time to come.

Amongst the company present we noticed Messrs. A. W. Sutton, Leonard Sutton, W. Robinson, A. McKellar, W. Y. Baker, Geo. Monro, W. Barr, P. Rudolph Barr, Geo. Barr, P. Blair, N. F. Barnes, O. Thomas, W. Iceton, W. Crump, H. Williams, Geo. Norman, H. J. Cutbush, W. Cutbush, W. A. Bilney, J. Douglas, J. Walker, Geo. May, H. B. May, J. H. Veitch, Geo. Paul, J. Poupart, J. Assbee, H. Rides, W. Atkinson, Geo. Bunyard, G. H. Cuthbert, P. Kay, J. McIndoe, J. Hudson, J. Sweet, W. R. Alderson, &c.

The Duke of Westminster, in proposing the toast of the Institution, said that he was very gratified to be able to accept the invitation to be present, more especially as his grandfather had been President of the Institution for a period of twenty-one years. He said the charity was well worthy of practical sympathy. It had for its object the relief of those over sixty years of age who had formerly been employed in the different branches of horticulture, and also of their widows, who might, from old age or sickness, find themselves in distress and poverty. It now had on its pension list the names of over two hundred persons—one-hundred-and-twenty men in receipt of £20 a-year, and about ninety women receiving £16 a-year, making an annual liability of about £4,000, which had to be raised by voluntary contributions. We saw and enjoyed the results produced by the gardeners' industry, and few could be more fortunate in that respect that he was at his home in Cheshire. But the life of the gardener was not literally a bed of Roses. Nor were his gains great. He was a skilled workman who gave an infinite amount of pleasure to the community at large by his labour and ingenuity, and yet his wages compared very unfavourably with those of skilled workmen in other branches of industry. He thought that it was Charles Dickens who said that gold and silver were well known to gardeners, not as a lining to their pockets, but by the colours of their fruits and flowers. Few gardeners could afford to lay by from their wages a sufficient sum to enable them to meet the rainy day or the inevitable advent of old age. He therefore commended the charity to their notice, confident that when its objects were more generally known further generous contributions would be forthcoming.

Mr. H. J. Veitch, the Treasurer, responded. He said that including those elected in January last, there were now two-hundred-and-fourteen pensioners on the books, being seven more in number than at any previous time. At the last election thirty-two unsuccessful candidates remained, of whom some were blind and ten were more than seventy years of age. To meet the pensions alone a sum of about £4,000 a year was required, while the assured income was only £900 and the anticipated income from subscriptions £1,600. Of the pensioners now on the funds, two were over ninety years of age, fifty-nine over eighty, and one-hundred-and-ten over seventy. The whole expenses of management are paid out of the income from invested funds, therefore all contributions made now are available for purposes of relief. The Auxiliaries were doing excellent work, as might be inferred from the fact that he had been handed a cheque for £90 from the Worcester branch that night. Speaking of the Victorian Era Fund, Mr. Veitch said that £160 was awarded from this fund last year. The Samaritan Fund was doing excellent service in providing temporary relief for candidates for election who were not subscribers. He deplored the losses by death the Institution had sustained, and mentioned the name of Dean Hole, who always supported the cause "by his eloquence, seldom equalled and never surpassed."

Sir Walter Smythe proposed the toast of "Horticulture in all its Branches," which was responded to by Mr. Geo. Paul.

The Chairman's health was proposed by Mr. Arthur W. Sutton, who in the course of his speech related some interesting details respecting the Duke's efforts to provide farms for such of the Cheshire Yeomanry who chose to remain in South Africa after the close of the war. His Grace bought twenty thousand acres of land, built suitable homesteads upon it, and has since sent out an expert in fruit culture to teach the settlers, and some of his best thoroughbred horses to improve the breed of horses there. He has also built a home for himself there, so that he can visit his tenantry from time to time. In replying to this toast, His Grace said that Mr. Sutton had mentioned the lost jewels. As the gentlemen present were gardeners he might say that the jewels were "planted" in a field near Cambridge, and that they "came up" wonderfully quick.

As we have stated already, the amount of the contributions exceeded £2,100. The principal donations are announced in our advertisement columns.

National Chrysanthemum Society.—We are asked to state that the annual outing is fixed for Monday, July 17. The arrangements for the day consist of a water-trip from Staines to Windsor, &c. The programme sets forth that the party will be conveyed from Paddington to Staines by Great Western Railway, the train leaving at 9.55 a.m. One of the largest launches on the river will take on board the company at the Bridge House landing-stage. The water journey to Windsor will occupy about two hours. Dinner will be served in the Victoria Hall of the White Hart Hotel at 1.30 p.m. It was hoped that a visit might have been made to some portion of the Frogmore Gardens during the afternoon, but owing to extensive alterations no orders to view are being issued this year. In lieu thereof, arrangements have been made for drives through Windsor Park, the vegetation of which will be seen at its best. Tea will be served in the White Hart Hotel, Windsor, at 5 p.m., and the launch will start on the return journey to Staines soon after six o'clock. The return train will leave Staines at 8.55. The charge for the day is 10s. 6d. Tickets can be obtained from the Secretary, Mr. Richard Dean, 7, Marlborough Road, Ealing.

The "Henry Eckford" Testimonial.—The contributions to this Fund up to the evening of June 17 amounted to 812 shillings.

The Richmond Horticultural Society.—We are informed by the Secretary, Mr. W. J. Cook, that the annual show to be held on Wednesday next promises to be a successful event.

Paris Exhibition.—A Gold Medal was awarded to *Le Jardin* and to the *Dictionnaire Iconographique des Orchidées* of M. Goossens, of Brussels.

Edgar Sanders, the "Dean of Chicago Horticulture."—We often have occasion to note the frequency with which men of British origin have come to the front in American horticulture. We suppose in time American-born cultivators will naturally displace them, but even so many of them will be of British extraction. In any case it is pleasant to read of the success of our countrymen. Among them none is more respected than Mr. Sanders, who began his career at Felbridge Park and Tilgate House in Sussex. He was a member of the Stoke Newington and Clapton Gardeners' Society as early as 1846, and belonged to mechanics' institutes when he could not find gardeners' clubs. After "five weeks' tossing" he landed in New York in April, 1853, and soon obtained occupation enough to save money sufficient to purchase land near Chicago in 1857. Here he started as a nurseryman and florist, and in 1867 established the first "flower-store" ever opened in Chicago. In spite of a disastrous fire in 1871, he continued his business, entered public life, and rendered good service to the municipality. In America he followed his old habit of founding or of attending horticultural clubs and societies, was the first President of the American Association of Nurserymen, and was for a long time connected with the *Florists' Exchange*. He records, or the *American Florist* does for him, that "he always dabbled some as a scribbler," a colloquialism that would hardly pass the editor's scrutiny on this side of the ocean! His early effusions were sent to the *Gardeners' Chronicle*, and he still remembers how proud he was to see his name in

print. Since that time he has been almost continuously connected with the American Press, though we are sorry to say that he, like so many of his associates, seems to think that once they have crossed the Atlantic that their communications will not be welcomed here—at any rate, we see them rarely.

THE GHENT QUINQUENNIAL OF 1908.—Our friends at Ghent have already announced that they are preparing to celebrate, in April, 1908, the hundredth anniversary of the foundation of the Société Royale d'Agriculture et de Botanique. May their enterprise and forethought be as fertile in result as their previous efforts have been! We cannot say more.

THE BARNHAM FRUIT INDUSTRY AND THE RAILWAY COMPANY.—We take the following extracts from the *Fruit, Flower and Vegetable Trades' Journal* of June 10:—"There has grown up at Barnham during the last twenty years a considerable horticultural trade. On about 160 acres of land there are employed about 120 hands, taking in wages about £5,000 per annum, and producing about £15,000 annually. Under agricultural treatment the same land would probably employ two men, pay about £84 in wages, and produce, at the outside, £1,000. When we come to facilities for markets we find, if some new rules are observed, that the local grower will have in the future to dispatch his produce for through conveyance for the northern markets [at 11.20 A.M. each day. The foreign producer, shipping to Southampton, can have his produce put on the same markets by a train leaving Southampton at 5.15 P.M. What these six hours mean to packers of delicate perishable produce only those connected with the trade know. What they mean in £ s. d. I shall state later. The 'hub of the universe' to the market grower is Covent Garden. Well, we find that to ensure our produce being delivered there for the early market on the following day we have to dispatch at 12.18 P.M. on the previous day. Thus to reach a market 65 miles off we have to send off sixteen hours before the market opens, though the foreigner can have his goods conveyed from Dover, Newhaven, or Southampton in at most twelve hours, and sometimes in as little as five. It is not uncommon for produce reaching Covent Garden in the afternoon of the day of packing to make £8, £10, and even more per ton than the same produce the following morning. It is practically impossible for us to put our goods on the market on the day of packing, thanks solely to local railway conditions. Owing to the competition of the northern lines for our traffic, we can actually (at present) dispatch goods from Barnham hours later than we can to Covent Garden, and still reach the northern markets in time. Foreign produce passing through the 'Sunny South' must be competed for by railway companies. Consequently it is well treated. Home produce (severely handicapped by the foreign), which keeps English homes, enriches the nation, and employs the population on the land, not being competed for, can, it seems, be treated with neglect."

A PINETUM AT NORWICH.—A local journal contains details of a plantation which "is really a magnificent pinetum such as few towns possess." It runs parallel to the old city wall in its course along the chapel field. The selection of trees, representing forty-five varieties, has been made by the Superintendent, Mr. J. WARD, who has caused labels containing details as to the names, native country, uses, &c., to be affixed to the trees.

PRESENTATION TO MR. HERBERT T. KING, OF COGGESHALL.—At Coggeshall, recently, a presentation took place, the recipient being Mr. HERBERT T. KING (head of the firm of Messrs. JOHN K. KING & SONS, Royal Seed Growers, of Coggeshall and Reading), on his forthcoming marriage with Miss ELLA MARIE ROSA CRINDLAND, of Westbury-on-Trym. The presentation took place in one of the large seed warehouses of the firm, which had been prettily decorated with flags, &c. The presentation had been subscribed to by all the *employés*, nearly 100 of whom were present; many from the seed farms at Great Tey and Chappel being unavoidably absent. The proceedings were of the most gratifying character.

"THE MUNICIPAL PARKS, GARDENS, AND OPEN SPACES OF LONDON. . . ." By Lt.-Col. SEXBY. (ELLIOTT STOCK.)—We welcome a "cheap edition" of this particularly interesting book. It is well written, well illustrated, and full of matter that appeals to the born cockney, the London resident, and his visitors the country cousins. It deals with the parks and gardens under the control of the London County Council, but does not include the parks belonging to the Government or to the City of London. Many a Londoner will be surprised at the number and extent of his gardens, and at the varied historical associations connected with them. As we have already called attention to the original edition we need now only remind the reader that a new edition is at his service.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.—The contents of the "Jubilee" volume of Transactions published this year are particularly interesting. In addition to articles relating to the history of the Society and to the progress of Forestry in general, there are detailed accounts of the visits of the members of the Society to France, where various State forests were inspected. German Forestry also occupies a considerable part of the volume. The contents are so varied that no extract would convey an adequate idea of them. We must content ourselves with calling the attention of those of our readers interested in the subject of Forestry to this publication, in the full assurance that they will find much of interest in its pages.

THE "GARDENERS' CHRONICLE" OF AMERICA.—This is a newly-established journal, devoted to the interests of amateurs and their gardeners, published in Jersey City at ten cents per copy, and adopted as the official organ of the National Association of Gardeners, the objects of which are to "unite in one body for mutual and benevolent benefit and protection all professional gardeners of good moral character." Full details are given as to the objects and management of the Society, details which might profitably be studied by the promoters of the analogous British Society. The journal is well got up. We wish our namesake every prosperity.

PUBLICATIONS RECEIVED.—*Sugar-Cane Experiments in the Leeward Islands.* Report on Experiments at Antigua and St. Kitts, 1903—4. Part I., Experiments with Varieties of Sugar-Cane. Part II., Manurial Experiments. Issued by the Imperial Department of Agriculture for the West Indies.—From the New Hampshire College Agricultural Experiment Station, *Bulletin* 119, Forestry. I., The Value of Native Pine Seedling; II., Experiments; Digging, Packing, and Transplanting; III., Comparative Expense. Wild Seedlings, *versus* Nursery Purchased Stock. By F. Wm. Rane.—Board of Agriculture and Fisheries (Whitehall Place, London). *The Pine Sawfly*—We have received the following Leaflets from the Board of Agriculture and Fisheries, and our readers will note that the subjects therein treated have been repeatedly described and illustrated in our columns also. Leaflets 131, *Apple and Pear Scab*: No. 132, *Slugs and Snails*: No. 133, *Powdery Mildew of the Vine*: No. 134, *Apple Culture*: No. 135, *Mange in Cattle*: No. 136, *The Bulb Mite*; No. 137, *Potato Scab*: No. 138, *Pine Weevils*.—New Hampshire College, Agricultural Experiment Station. Bulletin 119, *Forestry*, by F. W. Raue.—From the Ontario Agricultural College Macdonald Institute: Bulletin 142, *Outlines of Nature-Studies*, by William Lochhead.—United States Department of Agriculture. Farmers' Bulletin No. 221, *Fungous Diseases of the Cranberry*, by C. L. Shear.—Michigan State Agricultural College Experiment Station. *Observations of Nodules on the Roots upon the Composition of Soy Beans and Cowpeas* by C. D Smith and F. W. Robison.—From the United States Department of Agriculture we have received, from the Bureau of Plant Industry, Bulletin No. 74: *The Prickly Pear and other Cacti as Food for Stock*, by David Griffiths; and Farmers' Bulletins, No. 213: *Raspberries*, by L. C. Corbett, and 215, *Alfalfa Growing*, by A. S. Hitchcock.

CHESFIELD, HAMPTON WICK.

[SEE SUPPLEMENTARY ILLUSTRATION.]

CHESFIELD is one of those beautiful residences found on the margin of the river Thames sufficiently far removed from the bustle which goes on nearer the great city to ensure perfect quiet and freedom. Many of us are familiar with the lovely scenery on the Thames above Richmond; indeed, the beauty may be said to commence earlier with the peerless gardens at Kew, whose grounds are bounded on the north by the river's margin. The view in our Supplementary Illustration could easily be taken to represent a spot in some extensive woodland through which the pleasing stream in the foreground had made its way past jutting rock and over fallen crags. In reality the Beech and other trees shown on the left of the picture stand on the margin of the river's bank, which is included in the grounds of Chesfield though not shown in the illustration. Beautiful as the spot appears in our picture it seems even more so when visited, on a glorious summer day—a day on which the river was gay with merry-makers, and on which the cool retreat of the shady glen could be appreciated. The stream is an outlet of the water originally brought by Cardinal Wolsey to supply the Palace at Hampton Court, and is thus historically interesting. No doubt even in those distant times the banks were beautiful with native flowers and gay with bird life. Even now a stray kingfisher frequents the spot, and it is occasionally the haunt of the coot and hern, while the moorhen is a not infrequent visitor. The present owner, H. Trengrouse, Esq., has taken pains to conserve the wild fowl, and is endeavouring to establish a colony of wild ducks on the stream. The banks have been planted with suitable subjects, and of these not a few are species of British Ferns, the spot being an ideal one for these shade-loving plants. Osmunda regalis appeared quite at home, and was represented by many large specimens that looked the picture of health; so, too, did the Hart's-tongue, some of which were "crested" forms; the Male Shield Fern and the Lady Fern, the Spleenwort, Ceterach, and many others. Even the common Rush (Juncus communis) found a place, and many another British water and bog plant were included—the Water Iris (I. Pseudacorus the Willow Herb, Nymphæa lutea, Lycopodium clavatum (although this last-named was not doing well), Lysimachia vulgaris, the Meadow-sweet (Spiræa Ulmaria), Figwort (Scrophularia nodosa), &c. In addition to these Alpine and hardy plants have been freely planted, and each jutting piece of rock-work forms a suitable pocket for a patch of Aubrietia, Arabis, Campanula, Veronica, Saxifraga, &c. Even the Ivy-leaved Toadflax (Linaria Cymbalaria) has not been overlooked, and is as effective in appearance as its exotic neighbours. Bamboos have been planted at intervals and are doing well, while the dwarf Conifers seemed now at their best with their new season's growths. Water-Lilies find a place in the stream in company with Nuphar luteum.

The rustic bridge shown in our illustration has recently been substituted for one of stonework, and from this spot the view is delightful. Near by is an elevation constructed of stonework that harmonises with the other rock-work, all of which has been designed and built by Messrs. Pulham in good taste. This structure is approached by tiers of stonework that have afforded scope for planting, and the best use has been made of the opportunity. Ferns are luxuriating, and an admirable selection of alpine plants furnishes the numerous "pockets" made for their reception.

The view from this point of vantage is exceedingly good. Beneath, landwards, is a small fruit garden, somewhat too shaded by the taller trees to furnish the best results, still there

were indications of fairly good crops of fruit. Across a well-kept and extensive lawn stands the mansion, a well-appointed residence built on an elevated terrace.

The view from this terrace is exceptionally good, and terminates in a stretch of the river Thames.

The grounds around are well furnished with trees, and borders of shrubs lend additional beauty. A very good specimen of Cedrus atlantica was noticed, just now at its best, with its young glaucous growths. A number of flower-beds have been formed at the foot of the terrace on which the house stands; these have just been furnished with their summer occupants, and will later on form a pleasing feature seen from the house. In one of the beds by the residence a large specimen of New Zealand Flax (Phormium tenax) is throwing up a fine inflorescence. Several Rhododendrons were in bloom, but the dry weather in May adversely affected the flowering of the majority of these shrubs.

The kitchen-gardens are well filled with vegetables, and several good flower-borders are now bright with herbaceous flowers, while there are several glasshouses, including a stove, vinery, greenhouse, and a range of Melon, Cucumber, and Tomato houses. The plants in the stove and greenhouse contain many reminiscences of their owner's visits abroad. There are Ferns, Osmunda sp., Thalictrums, &c., from the Falls of Minnehaha, and a fine specimen of the Papaya-tree (Carica Papaya) that is flowering at the present time. Of the remaining plants in the houses we may say there is a mixture of many things—Orchids, Ferns, Selaginellas, Begonias, Primulas, Gloxinias, Tacsonias, Passifloras, Cobea, Tydeas, &c.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

MECONOPSIS GRANDIS AND M. RACEMOSA.—Dr. Prain's valuable notes on the species of Meconopsis solve a mystery which has been bothering me a good deal. I have several times flowered M. grandis from seed kindly sent me some years ago by Dr. Prain. Unlike all other members of the genus in cultivation, save M. cambrica, M. grandis is a true perennial. It increases, however, very slowly, and though I have not watched sufficiently closely to be certain, I am inclined to think that flowering and seed-bearing one year involve absence of flowering the following season. But what has surprised me has been the wide disparity in the quality and colouring of the flowers. To such an extent does this reach that I have found it difficult to believe that they could come from a single species. Dr. Prain's note now makes it clear that the difference is a perfectly genuine and natural one, and in no respect due to the artificial conditions of culture here in England. The difference is a most remarkable one, and seems to extend beyond the flower colouring. Of five plants which bloomed here this spring, four had flowers of the vinous purple colour, correctly described by my old friend, the late Mr. Thompson, of Ipswich, and approximating in shade to that of the true M. nepalensis. In these four cases the plants were, and are, small, and the flower-stalks on which the blooms were borne were only a few inches high. This form is to my thinking quite without merit. The fifth plant, however, amply compensated for the disappointment occasioned by the other four. I am not going to try my hand at word-painting. It is quite enough to say that it is very beautiful indeed. Mr. Elwes happened to be here just before the petals dropped, and had the opportunity of seeing its fine iridescent blue. But the interesting point is that it differed from its fellows not only in the colour of its flowers, but in the size of the plant and in the great development (1½ to 2 feet) of the flower-stalks. Is it possible that the flower-colour is not fixed, but varies with the healthiness of the plant? I have a pan of seedlings raised from a plant which bloomed last year with particularly fine blue flowers. It will be interesting to see whether they all come true. I am glad to say that M. racemosa, which seems to have been a difficulty when previously introduced, does well here, flowering freely both out-of-doors and under glass. It is only a biennial, but it makes good seed which germinates readily. The flowers vary greatly. At their best they are of a very fine blue colour. *Arthur K. Bulley, Cheshire.*

MECONOPSIS GRANDIS.—I am pleased to see such a good illustration of the fine Meconopsis grandis in the *Gardeners' Chronicle* for last week; but, excellent as it is, a photograph cannot well do justice to a plant of so much beauty as this Meconopsis. I have seen it in bloom two years in succession in Edinburgh. Mr. Harrow is attempting to hybridise the species with some of the Papavers. *S. Arnott, Sunnymead, Maxwelltown, Dumfries.*

A USE FOR THE LABURNUM.—Mr. Simpson's reference to the Laburnum, p. 307, reminds me of a set of chairs that Mr. Ross, who for many years was dominie (schoolmaster) of an Aberdeenshire parish, used to be very proud of. They were made by himself of Laburnum wood, in his leisure hours, and were beautifully marked and polished. The wood I understood was procured from a fine row of trees that once grew by the side of the main road (where many still grow) about midway between Peterhead and Fraserburgh, and some four miles from the sea coast. *T. Coomber, The Hendre Gardens, Monmouth.*

FOREIGN SMALL FRUITS.—In the course of the interesting and suggestive notes upon this subject on p. 374, mention is made of several which I had under cultivation for seven or eight years, and it may therefore be worth while to record my experience. Raspberry Shaffer's Colossal, which has proved very satisfactory in America, was one of the varieties tried in the expectation that it might give some favourable results, but we never succeeded in obtaining more than a few fruits, which in quality fell far short of the praise bestowed upon them in the United States. In other respects it corresponded exactly with the description furnished by Professor Card. It is very strong in growth, the canes reaching 6 or 7 feet in height, of a proportionate thickness, bright purple in colour, well clothed with good foliage, and one of the most distinct of this group of Rubus. But though grown in several different soils, heavy, medium, and light, with and without stable or artificial manures, the plants rarely flowered well and still more rarely ripened their fruits. It is said to have originated near Scotsville, in Munroe County, New York, about 1871, and is considered "one of the most productive Raspberries known—an excellent canning variety, in quality not far behind the red Raspberries, and with a richness not possessed by them." Another Rubus included in the notes referred to is Newman's Thornless, which is classed amongst the hybrids between R. nigrobaccatus and R. villosus, amongst which Wilson Junior is also ranked. One American grower has stated that "it produces few thorns and fewer berries," which has been fully confirmed in my experience, with the addition that it throws up an enormous number of suckers. It will grow in almost any soil or situation, but its value as a fruit-yielding plant is insignificant compared with that of the common Blackberry or the useful R. laciniatus. Amongst the German Strawberries named in the notes is Koenig Albert von Sachsen, which has appeared in some British lists as King Albert. This I grew for some years, and a more worthless variety it would be difficult to find as regards its behaviour in this climate. The fruits are very pale in colour and amongst the softest known to me, for when ripe they could scarcely be gathered without crushing, and if a couple of pounds were placed in a basket the lower ones were always reduced to pulp. There are few of the American or Continental varieties of Strawberries which bear favourable comparison with British-raised seedlings, under the conditions prevailing here. The most satisfactory of the former that I have grown is Crescent Seedling, though the fruits are small and pale in colour, but they are produced in great abundance under good cultivation. Of the less well-known French varieties, Dr. Morère, La Constante, and Edouard Lefort have proved the best, taking all points into consideration. *R. Lewis Castle.*

SOCIETIES.

THE ROYAL HORTICULTURAL.*

JUNE 20.—There was a very fine display of plants and flowers at the ordinary fortnightly meeting of the Committees held on Tuesday last. Orchids were exhibited largely, and so many novelties were shown that the ORCHID COMMITTEE recommended awards including two first-class Certificates, four Awards of Merit, and four Botanical Certificates.

The FLORAL COMMITTEE recommended nine Awards of Merit to various new plants. Many interesting and effective groups of plants and flowers in season were contributed by members of the trade, very few being from amateurs. The Committee recommended as many as seventeen Medals.

No award to a novelty was made by the FRUIT AND VEGETABLE COMMITTEE, and there were few exhibits.

In the afternoon 140 new Fellows were elected, and a lecture on "Plants of the Bible" was delivered by the Rev. Professor Henslow.

It may be mentioned that arrangements have now been made by which visitors to these meetings will be able to obtain tea in the Hall between the hours of 3.30 P.M. and 5.30 P.M. The attendance on Tuesday last was rather less than usual, probably owing to the race meeting at Ascot.

Floral Committee.

Present: W. Marshall (Chairman), and Messrs. H. B. May, R. Dean, W. J. James, W. P. Thomson, W. Cuthbertson, Chas. E. Shea, R. C. Notcutt, Chas. E. Pearson, Chas. Jeffries, Geo. Gordon, Chas. Dixon, W. Bain, C. R. Fielder, C. J. Salter, J. T. Bennett-Poë, Ed. Mawley, J. W. Barr, C. T. Druery, Geo. Nicholson, Jas. Walker, F. Page Roberts (Rev.) E. T. Cook, E. H. Jenkins, Geo. Paul, H. J. Jones, R. W. Wallace, R. Hooper Pearson, Chas. Blick, J. Jennings, and W. Howe.

Petræa volubilis.—A plant of this Verbenaceous twining plant was shown by Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. Bain). The plant was in a 10-inch pot, and some of the racemes of purple flowers were produced from the old wood, and others on young growths several inches in length (Cultural Commendation).

Awards.

AWARDS OF MERIT.

Aster sub-cæruleus.—An exceedingly effective perennial Aster, which grows about 20 inches high. The flowers are 2 inches across, of perfect form, and bright mauve colour with yellow disc. The leaves are described as being somewhat similar to those of A. alpinus, but rather broader and more hairy. A. sub-cæruleus has been grown very recently in nurseries as A. diplostephioides, but this latter species has a purple centre in the disc, and is exceedingly difficult to cultivate, whilst A. sub-cæruleus appears to be very free, and a first-rate garden plant in every way. Shown by Mr. AMOS PERRY.

Impatiens Holsti.—A species resembling I. Sultani, but having vivid flowers of nearly scarlet colour. Suitable for cultivation in a greenhouse, and perhaps for bedding out-of-doors in warm weather. Shown by Messrs. H. CANNELL & SONS, Swanley.

Hemerocallis corona.—This variety of the Day Lily was raised by Mr. YELD, York, from H. flava and H. aurantiaca major. The flowers are golden, almost orange-yellow in colour, and many are produced on the cymose inflorescences. It is a good and very effective garden plant.

Iris "Neptune."—A very fine variety raised by Mr. GEO. YELD, Clifton Cottage, York, one of the parents

* Owing to the publication of the Index and the pressure on our space we are compelled to hold over our remarks on the details of the general exhibits until next week's issue. ED.

being I. pallida. The flowers have large, broad, blue-coloured standards, and purple falls veined over a white ground at the base. From Mr. GEO. YELD.

Herbaceous Pæony "Her Grace."—A very fine double flower of very commendable form, and in colour a bright, pure shade of pink.

Herbaceous Pæony "La Fiancée."—Of almost equal good form to that of "Her Grace," but pure white in place of pink. Both varieties were shown by Mr. R. H. BATH, nurseryman, Wisbech.

Rodgersia pinnata alba.—Some flowering growths of this new Rodgersia were shown by Messrs. JAMES VEITCH & SONS, Chelsea. They bore large panicles of pure white flowers, which would make the plant a very effective dwarf shrub for planting on the banks of streams and in similar places (see note on the species Rodgersia in *Gardeners' Chronicle* for August 23, 1902, p. 131).

Streptocarpus "Royal Purple."—A variety with large leaves and strong inflorescences, some of which bore six large flowers of vivid royal-purple colour, having lines of deep brown colour in the throat. Shown by Lord ALDENHAM, Elstree.

Sweet Pea, Henry Eckford.—A variety with flowers of salmon scarlet colour, being a distinct shade. Two, but sometimes three flowers are produced on a spike. Shown by Mr. H. ECKFORD, Wem.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, W. H. Young, W. Boxall, H. J. Veitch, H. Little, A. A. McBean, T. W. Bond, G. F. Moore, H. T. Pitt, W. H. White, R. G. Thwaites, J. Charlesworth, J. Douglas, J. Colman, and R. B. White.

Awards.

FIRST-CLASS CERTIFICATE.

Sophro-Lælia × lata Orpetiana, from Captain G. L. HOLFORD, C.I.E., Westonbirt.—A charming and floriferous variety which had already received an Award of Merit. Flowers bright magenta-crimson with yellow base to the lip. The three little plants shown had each two fine flowers.

Lælio-Cattleya × King of Spain (? L.-C. × Digbyano-Mossiæ × C. Warneri).—A grand flower in shape, size, and colour, excelling a good C. Warneri, the broad, fringed lip being a specially fine feature. Sepals and petals light rosy-lilac; front of lip bright crimson-purple, disc yellow with purple markings at the base.

AWARDS OF MERIT.

Odontonia × Lairesseæ (Miltonia Warscewiczii × Odontoglossum crispum).—A very remarkable hybrid raised by M. A. DE LAIRESSE, Avenue de Comte, Sclessin lez Liège, Belgium. It closely follows Miltonia Warscewiczii, but is enlarged in all its parts. Flowers white, with the lower two-thirds of the segments tinted and blotched with rose, a similarly coloured marking being also in the labellum; crest yellow.

Cattleya Mendeli Pittiæ, from H. T. PITT, Esq., Stamford Hill.—Sepals and petals nearly white, the lip having a clear rose marking on the front lobe. The two flowers on the spike were not alike, the one having the colouring more diffused than the other.

Epidendrum × radico-vitellinum (radicans × vitellinum), from Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. H. White).—A singular hybrid, with ascending leafy stems, similar to E. radicans, and heads of numerous orange-coloured flowers more nearly like those of E. vitellinum.

Epi-Lælia × vitell-brosa (E. vitellinum × Lælia tenebrosa), from Sir TREVOR LAWRENCE, Bart.—A rather showy hybrid with erect spikes of many flowers each about two and a half inches across, and with the bronzy tint seen on L. tenebrosa. The whole flower strongly indicates the other parent, E. vitellinum.

BOTANICAL CERTIFICATE.

Brassavola Perrini, from Sir TREVOR LAWRENCE, Bart.—A fine old species with white fragrant flowers.

Cirrhopetalum guttatum, from Sir TREVOR LAWRENCE, Bart.—A pretty species from the Himalaya allied to C. maculosum. Flowers cream colour spotted with purple.

Bulbophyllum radiatum, from Sir TREVOR LAWRENCE, Bart.—Inflorescence slender, surmounted by several flowers with narrow white segments.

Epidendrum pterocarpum, from Sir TREVOR LAWRENCE, Bart.—A small species with brownish sepals and petals and whitish lip, the expanded side lobes of which are striped with purple.

CULTURAL COMMENDATION

To Mr. W. H. WHITE, Orchid grower to Sir TREVOR LAWRENCE, Bart., for a fine specimen of Brassavola Perrini.

To Mr. H. G. LUCKHURST, gr. to Sir JOHN EDWARDS-MOSS, Bart., Henley-on-Thames, for a large and finely-flowered Lycaste Deppei.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (Chairman), and Messrs. Jos. Cheal, W. Bates, S. Mortimer, A. Dean, E. Beckett, Geo. Kelf, H. J. Wright, G. Reynolds, F. Q. Lane, J. Jaques, J. McIndoe, G. Norman, Owen Thomas, A. H. Pearson, and H. Parr.

A collection of ten dishes of Apples in as many varieties was shown by the GOVERNMENT OF WESTERN AUSTRALIA, as well as samples of various seeds and grains. The Apples were of such good appearance that the Committee recommended a Silver Knightian Medal.

Several seedling Melons were shown for certificate, but none was considered to be sufficiently good to warrant an award being made.

Mr. ED. BECKETT, Aldenham House Gardens, contributed a dish of British Queen Strawberries.

The Lecture.

The Rev. Professor HENSLOW delivered a lecture on "The Plants of the Bible," which he illustrated with a fine series of lantern-slides. He pointed out that about 120 plants were mentioned in the Bible, which could be grouped according to their use as Textile Materials; Medicinal, Edible, and other Herbs; Plants used in the Arts; Flowers; Odorous Resins, Spices, and Perfumes; Fruit, Timber, and other Trees; and Desert, Field, and Water Plants. Of the textile plants, Flax was used for lamp-wicks as well as for fine linen, but Cotton was only once mentioned in Holy Writ. The herbs included Mint, Rue, Dill, Cummin and Coriander, and bitter herbs, under which latter he quoted the description by Josephus of the method of extracting Mandragora, which, as well as being an imaginary charm against demons and a real medicine, was believed to shriek and drive anyone mad who tried to pull it up and who heard it shriek. A trench was therefore dug round the root, and a dog tied by the tail to the crown of the plant; then the dog would pull it up, but die in the effort.

Camphire, Madder, and Saffron were among the plants used in the arts. The lecturer pointed out that very few plants were mentioned in Scripture for the sake of their flowers only, and they were largely of the Lily or Rose tribe. Of esculent herbs, Lentils formed the substance of Jacob's pottage, and Beans, Gourds, and Garlic were used as vegetables. Egypt still grew the same varieties of Wheat as of old, and Barley, Rye, and Millet were also found mentioned. The odorous resins and perfumes were used principally for making incense and holy oil, including frankincense, myrrh, balm of Gilead, spikenard, and calamus. Among the fruit-trees the Vine, Pomegranate, Almond, Olive, Fig, and Apple were mentioned; and Cedars, Firs, Cypresses, Oaks, Poplars, Ebony, Box, and Myrtles were almost all the timber-trees referred to in the Bible. Most of the desert plants appeared to have been thorny or spinescent, and Nettles, Thistles, Tares, and Cockle were some of the field weeds. The water-plants included the Bulrush or Papyrus; this was the most important, and was not only used for making the first paper, but also for baskets and boats, including probably the ark of Moses.

YORKSHIRE GALA.

JUNE 21, 22, 23.—The forty-seventh exhibition of the York Gala took place as usual in the Bootham Field, York, the weather at the opening being dull and threatening for rain, but in the afternoon there was bright sunshine. The large spacious tents were as usual well filled with a varied collection of plants, cut flowers, fruit and vegetables. These exhibits on the whole were generally considered to be above the usually high standard of the York shows. One of the judges remarked that he had been a regular exhibitor at York for forty-five years, and he considered this to be the finest exhibition (especially of hardy cut flowers) ever seen in that city. There was a large number of visitors during the afternoon.

ORCHIDS

were above the usual average at this exhibition.

Messrs. CHARLESWORTH & Co., Bradford, Yorks, had the only non-competitive trade exhibit, and made a very effective display. The plants were all well grown, and consisted principally of Cattleyas and Lælio-Cattleyas, among these being C. Mossiæ Reineckiana, C. Mendeli Princess Margaret (a pale, uniformly-coloured variety, and very distinct), several very fine varieties of L.-C. Fascinator, L.-C. Aphrodite, and L.-C. Canhamiana; L.-C. Phœbe (with beautiful, richly-coloured lip), Cattleya Fernand Denis (a fine distinct hybrid between C. gigas × C. Aclandiæ), Brasso Cattleya purpurato-Digbyana (very fine), nice plants of Miltonia vexillaria, M. Roezlii alba, Cypripedium niveum, Tricopilea Galleottiana, &c. (Silver Floral Medal).

For a table of Orchids arranged for effect, Messrs. CYPHER, of Cheltenham, won 1st prize, having an excellent exhibit, including such well-known species as Cymbidium Lowianum, Thunia Bensoniæ (a splendid dark variety), long arching spikes of Odontoglossum crispum, Oncidium varicosum, also Brassavola Digbyana, Phalænopsis Rimestadtiana, Miltonia vexillaria, Cattleya Mossiæ, richly-coloured Masdevallias, Epidendrums, &c. Mr. J. ROBSON, Bowden, Manchester, also set up an excellent group composed chiefly of fine spikes of Odontoglossum crispum, good varieties of Cattleya Mossiæ, and various Cypripediums.

For ten Orchids in bloom (distinct), Mr. CYPHER was 1st with finely flowered plants of Epidendrum prismatocarpum Veitch's var. (the plant carried thirteen fine spikes), Miltonia vexillaria with about seventy flowers, Lælia grandis tenebrosa, Lælio-Cattleya Martinetti, Cattleya Lawrenceana with thirteen blooms, also a finely-grown plant of Cypripedium Curtisii, &c. W. P. BIRKINSHAW, Esq., West Hill, Hessle, was a very close 2nd, only one point, as judged, being the difference; he had excellent plants of Cattleya Mossiæ Wagnerii, with six fine flowers, C. Mendeli, C. gigas (very fine), Lælio-Cattleya Eudora alba, a large pan of C. Euryalis with about two dozen flowers, also a well-grown Cattleya Mossiæ with sixteen flowers.

For six Orchids in bloom Mr. BIRKINSHAW was 1st with well-flowered plants of Miltonia vexillaria, L.-C. Amelia, C. Mossiæ Reineckiana, C. M. Wagnerii, &c. Mr. CYPHER was a close 2nd.

For three Orchids in bloom Mr. BIRKINSHAW was again 1st, also in class 26 for three new or rare specimen Orchids in bloom. These included L.-C. Martinettii nobilior, one of the richest-coloured varieties yet seen; this plant was deservedly awarded a First-class Certificate.

For six Orchids, single specimens, Mr. BIRKENSHAW was 1st, having L.-C. Roehlingiana, a beautiful hybrid between Lælia purpurata and Cattleya Gaskelliana, one of the finest Orchids in the show. The single specimen Orchid class brought seven competitors, the best being Oncidium spacelatum. 2nd, Dendrobium thyrsiflorum with thirteen spikes, only four being open. Had the others been fully developed this lovely specimen would undoubtedly have secured the 1st prize.

PELARGONIUMS.

The display of zonal Pelargoniums was very bright and attractive. The class for six plants, distinct (open), brought a keen competition, the 1st prize going to Mr. H. PYBUS. His Lady Buchanan and Mrs. Newdigate were excellent examples of good culture. 2nd, G. LEE, Esq.

A class for four zonal varieties brought superbly-trained specimens over 5 feet across. Classes were also provided for six double-flowered zonal varieties and for three Ivy-leaved Pelargoniums.

GROUPS OF PLANTS.

The groups of ornamental and miscellaneous plants, artistically arranged, were quite a feature of the show. Numerous were the visitors around these groups, and it was interesting to hear their remarks of admiration of the gardeners' skill in making such excellent floral displays. 1st prize was awarded to E. B. FABER, Esq., M.P. (gr. Mr. W. Townsend). This group was composed chiefly of Roses, Carnations, Liliums, Orchids, Crotons, Hydrangeas, Gloxinias, Coleus, Dracænas, these species being very cleverly intermixed with various Ferns and Asparagus. 2nd, Messrs. W. ARTINDALE & SONS, High Street, Sheffield, who were very close competitors, the group being perhaps a trifle more heavily arranged than the former but in other respects it was equally good. The 3rd prize went to JAS. BLACKER, Esq. (gr. Mr. Curtis).

Class 2 of miscellaneous groups was also well competed for. Mr. W. VAUSE, Leamington, was 1st, the beautifully arranged group consisted largely of Crotons (well coloured), white Liliums, Gloxinias, &c. 2nd, Messrs. R. SIMPSON & SONS. 3rd, Mr. G. COTTAM.

Mr. JAS. ARCHER won 1st prize for hardy Ferns. These consisted of fine specimens of Lastrea grandiceps, Adiantum pedatum, Osmunda cristata, Polystichums, &c.

HARDY CUT FLOWERS.

These were equal to anything seen at the shows in the Temple Gardens, London. Messrs. HARKNESS & SONS sent a magnificent collection, which was greatly admired by everyone, their Pæony Faust, a new variety of a curious salmon-carmine colour, being very fine; also double Pyrethrum Mont Blanc, Papaver nudicaule (yellow), Hesperus matronalis purpurea plena and the variety alba, lovely Foxgloves, Pyrethrums, Gaillardias, numerous fine Iris, Liliums, &c., made a grand display. The 2nd prize collection came from Messrs. G. GIBSON & Co., Bedale, and included Inula oculus Christi (very fine), Papaver Marie Studholme, the salmon-carmine Poppy. Double Pyrethrum Godiva had splendid blooms. Delphiniums, &c., made an excellent floral display. 3rd, J. D. HUTCHINSON, Esq.

Eighteen bunches of Pæonies: Messrs. HARKNESS & SON were 1st. There were several fine collections of Sweet Peas.

Mr. J. WOOD, Hardy Plant Nurseries, Boston Spa, had a pretty rockwork arrangement with a small pond of water in which were several aquatic plants in full growth. J. NICHOLSON, Esq., was 1st for alpine plants; and T. NICHOLSON, Esq., 2nd.

For twenty alpine and herbaceous plants, Mr. W. PYBUS was 1st with Lupins, Mimulus, Funkias, &c.—a very good exhibit. 2nd, S. HARDCASTLE, Esq., with Pyrethrum Mont Blanc, Campanula aggregata, Sedums &c.

STOVE AND GREENHOUSE PLANTS.

For nine stove or greenhouse plants (Orchids excluded) in bloom, Messrs. CYPHER were 1st, with splendid examples of Bougainvillea Cypherii, Stephanotis floribunda, Pimelia diosmæfolia, &c. Mr. WM. VAUSE was a good 2nd. Mr. CYPHER was 1st for six stove or greenhouse plants; Mr. VAUSE being 2nd. Mr. CYPHER was again 1st for three stove and greenhouse plants, showing excellent specimens of Erica Cavendishiana, Statice profusa, and Hedaroma tulipiferum; Mr. VAUSE 2nd; and Messrs. R. SIMPSON & SONS 3rd. Mr. CYPHER was 1st for six ornamental fine foliage or variegated plants. His examples of Phœnix rupicola, Croton mortefontainensis, Kentia Belmoreana and Kentia australis being of excellent culture. Messrs. CYPHER again were placed 1st for a single greenhouse plant in bloom, with a grandly-flowered specimen of Pimelia diosmæfolia. Mr. CYPHER was also 1st for a specimen stove plant with a beautiful specimen of Ixora Williamsii with about seventy fine heads of bloom (a noble plant).

For six stove and greenhouse plants, THOS. DIXON, Esq., was 1st, showing Bougainvillea Sanderiana (very fine).

For twelve bunches of cut flowers, Lady BATTYE WRIGHTSON was 1st with Anthurium Andræanum (very fine), Malmaison Carnations, Lælia purpurata, Odontoglossum crispum, Swainsonia albiflora, Stephanotis floribunda, &c. 2nd, Mrs. WHITEHEAD, who had fine examples of Vanda suavis, Cattleya Mossiæ, Lilium candidum, Verbena Miss Willmott, &c. 3rd, J. D. ELLIS, Esq., M.P.

The best collection of eight plants of tuberous Begonias came from Mr. F. STYAN, who had fine varieties and well-grown plants; 2nd, Mrs. LLOYD.

For eight Gloxinias Lady HAWKE was 1st; and Mr. JAS. SUNLEY, 2nd.

Calceolarias were well shown by W. TOWBRIDGE, Esq., and Mrs. RICHARDSON, who won 1st and 2nd prizes respectively.

For four Calceolarias W. TOWBRIDGE, Esq., was 1st; and Mr. F. DEAN, 2nd.

There were seven splendid groups of Carnations in competition, the Earl of HARRINGTON being placed 1st. 2nd, M. F. MUDDLETON, Esq., Highfield, Ripon. 3rd, Messrs. ARTINDALE & SONS. 4th, Mr. JOHN ROBSON.

FRUITS AND VEGETABLES.

Decorated Table of Ripe Fruit, not to include more than fourteen, nor fewer than ten dishes.—The 1st prize was won by the Earl of HARRINGTON (gr., Mr. Goodacre), who had a fine lot of fruit and flowers well set up, which was awarded 116 points. Black Hamburgh Grapes were good in form and colour. Other fruits were Melon Countess, a good Queen Pine, Early Rivers' Nectarine, Lady Sudeley Apple, and Royal George Peach. The decorative flowers used were Odontoglossum crispum, scarlet Schizanthus with long sprays of Selaginella. The Hon. E. L. WOOD, Temple Newsam, near Leeds (gr., Mr. Dawes), was 2nd with ninety-nine points. Peaches Abec and Gros Mignonne, and Nectarines Lord Napier were very fine here. 3rd, Mr. C. E. SIMPSON, York.

Collection of Ten Dishes.—The 1st prize was won by the Earl of HARRINGTON with a similar but not quite such a fine lot as before. 2nd, the Hon. E. L. WOOD.

Six Varieties.—The Earl of LONDESBOROUGH was 1st (gr., Mr. McPherson), his best dishes being Muscats and Black Hamburghs, and a fine seedling Melon. 2nd, Lady BEAUMONT, Carlton Towers (gr., Mr. Nichols), who had good Buckland Sweetwater and Black Hamburgh Grapes, with a good dish of Noble Strawberry, &c.

For Four Varieties (excluding Pines), Lord ST. OSWALD (gr., Mr. Easter) was 1st. Exeellent Black Grapes were the leading feature. 2nd, Earl of HARRINGTON.

The best Pinecapple was shown by the Hon. E. L. WOOD, the variety being Queen.

For three bunches of Black Grapes, which was a strong class, Lord HINDLIP, Hindlip Hall, Worcester (gr., Mr. Bayley), was 1st with a very fine trio, though many people thought that the 2nd prize lot was superior. 2nd, Mr. J. JOHNSON, Boston Spa, with a well-finished lot of Black Hamburghs.

For three bunches of White Grapes, which as shown were not quite up to average, the Lady BEAUMONT won 1st prize, having nice dishes of Buckland Sweetwater.

Peaches and Nectarines made a splendid show. The Marquis of NORTHAMPTON, Castle Ashby (gr., Mr. A. B. Searle), had the best exhibit of six Peaches in excellent fruits of the variety Hale's Early.

The best exhibit of six Nectarine fruits was shown by Col. HARRISON BROADLEY, Welton House, Brough, with a very exquisite dish of Lord Napier. 2nd, the Marquis of NORTHAMPTON; and 3rd, T. CORBETT, Esq., Impney, Droitwich (gr., Mr. Jordan), who had a grand dish of Early Rivers, which might have been placed higher.

There was a very fine lot of Melons. The Earl of LONDESBOROUGH had the best scarlet-fleshed variety; and Lord DERAMORE (gr., Mr. Goodall) was 2nd. For a green-fleshed fruit, Lord ST. OSWALD was 1st; and C. THELLUSSON, Esq. (gr., Mr. Chuck), 2nd. The Earl of LONDESBOROUGH had the best white-fleshed variety.

Figs were very good, the best coming from the Earl of FEVERSHAM (gr., Mr. Williams), who had a capital dish of the variety Brown Turkey.

The best Cherries were shown by W. A. H. BASS, Esq., Byrkley, Burton (gr., Mr. Neshit), who had a good dish of Early Rivers.

Strawberries made an excellent show, the Earl of LONDESBOROUGH winning 1st prize; and Mr. J. HOLMES, Bootham, York, 2nd prize.

For Tomatos, F. A. SAMUELSON, Esq., Thirsk (gr., Mr. Brotherston), was 1st, having a fine dish of Best-of-All. 2nd, Mr. J. JOHNSON, with the variety Comet.

Among vegetables, the Earl of LATHOM won 1st prize in both classes, for which prizes were offered by Messrs. WEBB & SONS and Messrs. SUTTON & SONS. These were a very creditable show. 2nd prize in both classes went to Sir R. W. BULKELEY, Bart., Baron Hill, North Wales (gr., Mr. Bolton). The whole of the exhibits were very good. For Messrs. SUTTON'S prizes Lady BEAUMONT was 3rd.

NON-COMPETITIVE GROUPS.

It is usual in most large horticultural exhibitions nowadays for these to form the main portion of the show. This was particularly the case at York this year. The entrance tent was filled with exhibits of this class. Taking them as they appeared to the visitor, on each side were two nice exhibits mainly Japanese Acers and Euonymus put up artistically by Messrs. E. P. DIXON & SONS, of Hull. Next eame Messrs. BACKHOUSE & SON with a large mixed group having a background of Palms fronted by Carnations, dwarf Roses, Cannas, &c. Following these was Messrs. WALSHAW'S well-arranged group; Miss Willmott Verbena and Lord Roberts Heliotrope stood out prominently. At the end was a group of Carnations put up by Mr. A. DUTTON, Iver, Bucks, the flowers being borne on long stems. Notieeable among these were Enchantress, Fair Maid and Harry Fenn. Messrs. KENT & BRYDON, Darlington, had a splendid group in which Rhododendrons, Lilium Harrisi, Lily of the Valley, and Skimmia japonica were the strong features.

Messrs. R. SMITH & CO., Worcester, had a large and very fine exhibit, mainly eut flowers of choice and showy herbaceous plants. On the eentre table in this tent, Messrs. CUTBUSH & SONS, Highgate, put up a very fine exhibit. Dorothy Perkins Rose and a splendid lot of Carnations, both of "Malmaison" and perpetual-flowering varieties, were well arranged, and made a leading feature. At the further end was a small rockery on which were growing some of the choicer alpine plants. The background was formed of Eremuri in variety, Lilium Henryi, L. Orange Queen, to which must be added a fine collection of Nymphæas and other water and bog plants. Messrs. WEBB & SON, Wordsley, Staffordshire, had a magnificeut show of Gloxinias and Sweet Peas.

Messrs. PEED & SONS, Norwood, put up a grand lot of Gloxinias. Messrs. R. H. BATH, Ltd., Wisbech, showed Pæonies, Iris, and other hardy flowers; and Messrs. CLIBRAN & SON, Altrincham, were well to the fore in exhibiting hardy flowers.

Messrs. BLACKMORE & LANGDON, Bath, created quite a sensation with their splendid double and single Begonias. Messrs. WOOD & SONS had a large exhibit of their well-known sundries. Mr. R. SYDENHAM had a table of Carnations arranged on his well-known rustic stands. Messrs. W. ARTINDALE & SONS, Sheffield, made a gay show with their Violas and Pansies. Messrs. W. & J. BROWN, Stamford, had a fine exhibit of zonal Pelargoniums, Verbenas, and Heliotropes.

Messrs. DOBBIE & Co., Rothesay, exhibited Sweet Peas and Violas, the Sweet Peas being grand. Messrs. DICKSONS, Chester, and Messrs. WALLACE & Co., Colchester, had a fine lot of Pæonies and other choice hardy flowers. Mr. PRINCE'S Oxford Roses were one of the best features in the show; Irish Anemones from Messrs. REAMSBOTTOM & Co., King's County, created much interest.

GOLD MEDALS

were awarded to Messrs. CUTBUSH & SONS, Highgate; Messrs. J. BACKHOUSE & SONS, York; Messrs. R. SMITH & SONS, Worcester; Messrs. WALLACE & Co., Colchester; Messrs. KENT & BRYDON, Darlington; E. P. DIXON & SONS, Hull, with a premier award to Messrs. CUTBUSH & SONS.

FIRST-CLASS CERTIFICATES

were awarded to G. YELD, Esq., Clifton Cottage, York, for Iris Neptune, I. Prospero, and Hemerocallis corona; also to Captain HOLFORD, C.I.E., Westonbirt, Gloucestershire (gr., Mr. Alexander), for Sophro-Lælia × lata Orpetiana; and to Mr. BIRKENSHAW, for Lælio-Cattleya Martinettii nobilior.

REMARKS.—Southampton Strawberries are the predominant feature in the market, there are also large quantities of this fruit arriving from Kent. While the Strawberry season is at its height other fruits, such as Grapes, Oranges, and even Tomatos are neglected by buyers. The last consignment of Tasmanian Apples has arrived, and for such varieties as Sturmer Pippin and Stone Pippin there is keen competition. Red Currants are seen. These are packed in flat baskets with handles, and are sold at an average price of 5s. per basket. Trade on the whole is brisk, and for really good produce there is a ready market.

POTATOS.

Dunbars, 80s. to 90s.; various, home-grown, 60s. to 90s. per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

THE turn of the season is apparent in the market; in fact some growers have already finished with spring-flowering plants. Prices vary but little. Show Pelargoniums are very good in quality and fairly plentiful; among the Ivy-leaved varieties many are of indifferent quality; the same may be said of "zonals." Yellow Marguerites are more plentiful: white Marguerites are also abundant; some of these are drawn, and too tall for many purposes. The yellow Chrysanthemum segetum is also plentiful and good. Mignonette sells fairly well. Plants of Lobelia are well flowered, but there is not much demand. Calceolarias are not over plentiful, but sufficient are obtainable to meet the demand. Fuchsias are of very good quality, but the trade for these is slow, and large quantities are sold at closing time to hawkers at small prices. Rhodanthe is over-abundant. Hydrangea Hortensia with single heads of well-coloured flowers are still arriving. The variety Thos. Hogg is not extra good. H. paniculata grandiflora varies considerably in quality, in many plants the flowers are not well developed. Rambler Roses continue plentiful. The varieties Dorothy Perkins and Crimson Rambler are equally good. There are also some fairly good H.P.'s and other dwarf sorts. Tuberous Begonias do not sell well. Verbenas are plentiful, but the weather is too hot for them to last in condition. Some growers are now filling their stands with Ferns, but trade in these is not very brisk. Palms are selling slowly. There is a small demand for extra-large bright-coloured foliage plants. The best trade for small bedding plants is now over, although large quantities are still coming to the market. I find some growers still have a quantity for disposal.

CUT FLOWERS.

Many Roses cut from the open ground show the effects of the late bad weather. Best flowers are not plentiful. Good blooms of Mrs. J. Laing with long stems have realised as much as 6s. or 7s. per dozen. Carnations are plentiful, and best flowers sell for good prices. Lilium longiflorum continues plentiful, but other Liliums are not so abundant. Few good Callas are seen. Irises of various sorts are abundant; some very good Japanese varieties are obtainable. Best quality Lily of the Valley is not over-plentiful, but smaller spikes are abundant and cheap. Iceland Poppies are over-plentiful, and can be purchased in the streets. Herbaceous Pyrethrums and Paeonies are abundant. Sweet Peas are plentiful, but good prices are maintained for best quality flowers. Large supplies of Grasses and hardy foliage arrive, also Asparagus, Smilax, and other choice foliage. Hardy Fern fronds are now good. *A.H., June 21.*

Obituary.

JAMES ADAMS.—The death has occurred, at the early age of fifty-seven years, of Mr. James Adams, who for the past sixteen years has acted as general foreman in Regent's Park, and whose labours, especially in connection with flower-garden work, are so well known. He was a master of his craft, and previous to coming to Regent's Park served at Kensington Gardens, Hampton Court and Battersea Park. His death occurred on June 15, at the Lodge, Broad Walk, Regent's Park, and he was interred at Finchley Cemetery on the 21st inst. *A. D. W.*

ANSWERS TO CORRESPONDENTS.

BEGONIAS: *W. G.* It is bad practice to syringe the flowers, which do not absorb the water, but which are likely to be damaged by it.

CARNATION: *L. E. A.* Your plants are attacked by the fungus Helminthosporium echinulatum. The pest vegetates between the membranes of the leaf and cannot be destroyed without injuring the leaves. Remove and destroy by burning all leaves that are affected, and burn even the plants themselves if their condition seems hopeless.

FIGS: *C. E. L.* Without seeing specimens we surmise that the check has been due to the low temperatures at night.

FOXGLOVE: *A. J. W. D.* and *R. W. Llewelyn.* Several of the terminal flowers have run together into a cup. It is not uncommon and has often been illustrated in our columns. It comes true from seed.

GALLS ON TWIG: *A. T. Shaw.* The woody galls are the work of a species of Cecidomyia, but in the absence of the perfect insect it is impossible definitely to fix the species.

GLOXINIAS, &c.: *H. G. K.* The leaves are attacked with mites. Steep the leaves in Tobacco-water. The Vine leaves show lack of nourishment and vigour. Fumigate your house well.

GOLD-FISH: *W. J. S.* They can be purchased in Covent Garden Market from Mr. Robt. Green, whose address is The Bedford Conservatories and Aviary, Central Avenue, Covent Garden Market, London.

LILY OF THE VALLEY: *R. B.* The plants are attacked by a fungus (Botrytis) causing collar rot. The most certain means of arresting the disease would be to remove the scattered diseased patches and mix the soil with quicklime. Remove as much of the surface soil as possible during the winter, and replace by fresh soil mixed with flowers-of-sulphur.

MAGNOLIA: *H. B. W.* The leaves have been scorched when wet with dew.

NAMES OF PLANTS: *F. E. G.* The specimen you send is a Fern, and the yellow portion is not made up of flowers in the true sense as you take them to be. It is Botrychium lunaria (Moonwort). The lower branch is the sterile portion, and the upper, with yellow, globular spore-cases, the fertile portion. With regard to the small thrips which infest the fronds of Pteris which you forward, some of the Pteris are much more liable to the attack of these insects than others; but in all cases their presence points to a too dry atmosphere in the house in which they are grown, or to some other unsuitable condition in their culture. Fumigation causes as much damage to Pteris as do the thrips, and immersion in weak insecticide is a better remedy. In bad cases the old fronds should all be cut off and burnt, and let the new come up.—*D. & Sons.* Astrantia major.—*R. H.* Rosa sinica Anemone.—*F. R. B.* Varieties of Azalea pontica.—*E. V. B.* Prunus Padus (Bird Cherry).—*E. F. G.* Sprekelia formosissima (Jacobæa Lily). It belongs to a section of Hippeastrum.—*Volvox.* 1, Oncidium sarcodes; 2, Odontoglossum Lindleyauum.—*R. G. H.* Barbarea vulgaris, a native plant.—*J. M. F.* Olearia stellulata.—*J. M.* Berberis Darwinii. *P. O. K.* The flowers are of seedling varieties of Pinks, which it is impossible to determine.—*H. R. T.* The Iris flowers arrived in poor condition, and it is impossible to verify them. They are possibly a batch of seedlings between I. germanica and I. olbiensis, or it is possible they may be from old strong plants, and the flowers only half of their natural size. It is impossible to affix names to them.—*J. S., County Tyrone.* 1, Tecoma jasminoides; 2, Trachelospermum (Rhynchospermum) jasminoides; 3, Jasminum undulatum; 4, Bignonia speciosa; 5, Aërides crispum; 6, Carpenteria californica. —*S. P.* 1, Cratægus tanacetifolia; 2, Scilla peruviana; 3, Casuarina species.—*H. M. G.* 1, Cotoneaster frigida; 2, C. Simonsi; 3, not recognised; 4, Ailanthus glandulosa; 5, Euonymus latifolius; 6, Pyrus Aria. —*R. W. R.* Lonicera Ledebourii.—*Tydia.* 1, Rhododendron ferrugineum, the alpine Rose of the Swiss mountains; 2, Xanthoxylum alatum. *A. J. A., Leeds.* 1 and 4 next week; 2, Sparmannia africana; 3, Prunus Padus.—*D. W.* 1, Veronica Teucrium; 2, Robinia Pseudoacacia; 3, Geranium pratense; 4, Clerodendron fœtidum; 5, Magnolia Lenné; 6, Cratægus coccinea.—*C. A. B.* Taxodium distichum; Magnolia cordata.—*R. H.* 1, Pyrus intermedia; 2, Ulmus campestris; 3, Symphoricarpus racemosus (Snowberry). — *W. G. G.* Phacelia grandiflora so far as we can tell from the bad specimen sent.—*W. S.* Oncidium pulvinatum. — *F. G.* Photinia serrulata.— *W. S.* Carex, next week; the other is Rumex crispus.—*Sir H. A. H.* 1, Aquilegia leptoceras var. chrysantha; 2, Anchusa italica; 3, Lilium Szovitzianum; 4, L. pomponium (yellow variety); 5, Celsia cretica; 6, Euphorbia Lathyris [Caper spurge]; 7, Dracocephalum grandiflorum.

ORCHID-LEAF: *T. H. S.* Next week. The Rose is affected with the Rose-rust [Phragmidium]. Spray with Bordeaux-mixture. See *Gardeners' Chronicle*, 1904, May 28, p. 352.

PÆONIES: *Count F. L. C.* The disease is caused by a fungus [Botrytis]. You might try spraying with Bordeaux-mixture and the other means described in the *Gardeners' Chronicle*, August 13, 1898, p. 124, fig. 32.

PEACH: *W. R. C.* Shot fungus. We are afraid it is too late to do anything now but burn the affected leaves and fruits. Try spraying with liver-of-sulphur, ½ oz. to a gallon of water. —*W. C.* Before deciding upon your Peach please let us know if it is large or small-flowered. This is important. Your packing is excellent, and the fruits arrived in good condition.

PEARS: *A. C.* The fruits are attacked by the Pear-midge. See figure in *Gardeners' Chronicle*, May 20 of the present year, p. 315.

PHLOX: *G. B.* We often see this peculiar growth, but are unable to assign a cause for the atrophy of the leaves. Perhaps it is due to the attacks of insects.

RASPBERRIES: *A. Y.* The flowers are not "set," or fertilised—perhaps from the absence at the proper time of bees or other insects.

TOMATOS: *W. B. R.* The fruits are affected by the "black spot" fungus. Remove all that are similarly affected and burn them.—*E. F. C.* Your plants appear to be affected with the "sleepy disease," due to the growth of a fungus in the interior of the plant. Turn out the soil and start afresh.

WORMS IN SOIL: *Case Bros.* The sample of soil had completely dried up during transit, and the worms you refer to were dessicated, and we could find no trace of them, but from the description you give of the galled roots, it is highly probable that the disease is due to eelworms (Tylenchus). If you will send us a fresh lot of soil, together with a sample of the infected roots, we will have them examined.
