NOVELTIES OF 1904.

ORCHIDS.

HOME-RAISED hybrids steadily gain ground over newly-introduced species, and the best evidence of their popularity is to be found in the fact that the majority of awards made by the Orchid Committee of the Royal Horticultural Society have during the past year been given to such hybrids. The production of such a wealth of floral beauty as that already evolved by the hybridist has been an eminently good work, whereby not only has each section of Orchids dealt with been recruited by flowers having great variety of form and colour, but, by intercrossing, the duration of the flowering season, and especially that of autumn and winter, has been prolonged.

From the Right Honourable Lord ROTHSCHILD, Tring Park (gr., Mr. A. Dye), came two of the finest species of the year, viz., the wonderful Angræcum infundibulare, which received a First-class Certificate (the first award made at the new Hall), and the beautiful Angræcum Rothschildianum, which was given an Award of Merit. Fine hybrids from the same garden were Lælio-Cattleya × Dominiana, L.-C. × Martineti, and Cattleya × Patrocinii, all distinguished as Tring Park varieties.

From his very extensive botanical collection the Hon. WALTER ROTHSCHILD received Botanical Certificates for Restrepia leopardina rosea, R. aspasicensium, Cryptophoranthus Lehmanni, Masdevallia Burbidgeana, Saccolabium gracile, and others.

Captain G. L. HOLFORD, Westonbirt, Tetbury (gr., Mr. Alexander), whose collection is one of the best cultivated, received awards for Cypripedium × aureum Œdippe, a very massive flower; C. × triumphans magnificum and C. × Niobe Westonbirt variety, a model flower, finely coloured, and which was awarded a First-class Certificate. Also the graceful Cymbidium × Ballianum, the bright rose-coloured Lælio-Cattleya × Digbyano - Mossiæ Westonbirt variety; and Cattleya × Iris Westonbirt variety.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), great in fine spotted Odontoglossums, has shown many promising varieties of that class, but nothing approaching the beauty of his O. crispum Cooksoniæ. The awards fell to Odontoglossum crispum Clive, O. c. Harold, O. c. Sibyl, O. c. Kinlesideanum, and O. c. xanthotes Cooksoniæ, grand additions to blotched-flowered class; O. × ardentissimum Cooksoniæ, heavily marked with claret-purple; and O. × Andersonianum Crawshayanum. Mr. Cookson also received awards for Cypripedium × W. R. Lee Oakwood variety, and C. × Dom Carlos, a very distinct hybrid between C. Godefroyæ leucochilum and C. Lawrenceanum.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), whose collection contains many remarkable varieties, and who has the most complete collection of hybrids in which Cypripedium Fairieanum has been used directly or indirectly, in the country, is credited with awards for Cypripedium × Wellesleyanum (bellatulum album × concolor), the finest of the class, with the yellow colour and purple spotting of C. concolor; C. × King Edward VII., a very stately C. Rothschildianum and nitens magnificum cross; Lælia anceps Schroderæ var. Theodora, Lælio-Cattleya × bletchleyensis Mrs. Francis Wellesley, and Cattleya labiata Mrs. Francis Wellesley, both charming, delicately-tinted flowers.

Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White), has, as usual, flowered a number of interesting novelties in species and hybrids during the past year. Three of the most remarkable of the species were the singular leafless trailer with showy yellow and purple flowers, Vanilla Humbloti; the elegant little Gomesa Binoti, and the handsome purplish - crimson Sobralia Ruckeri, for which a First-class Certificate was awarded, May 17. One of the best of the hybrids was Cypripedium × Sanderiano-selligerum, shown at the last meeting of the year.

H. T. PITT, Esq., Rossiyn, Stamford Hill (gr., Mr. Thurgood), the owner of some of the best and most valuable spotted Odontoglossums, adds to his already long list of honours in that class with Odontoglossum crispum Prebendary Bevan, a fine purple-spotted flower; O. c. xanthotes Snow Queen, pure white with a few orange-coloured spots; and O. cirrosum Pittianum, a very large form, which secured a First-class Certificate. Also Cattleya Warscewiczii Rosslyn variety, of one shade of rose-pink.

G. F. MOORE, Esq., Bourton-on-the-Water (gr., Mr. Page), the exhibitor of the record group for which a Gold Medal and the Lindley Medal was given, secured awards for Cypripedium × aureum virginale, C. × Graceæ "W. H. Page," C. × Thompsoni, C. × Miss Blanche Moore, and C. insigne sythetense gigantcum, all fine flowers; also Cattleya × Portia Chardwar variety and Lælio-Cattleya × Pallas magnifica.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), the Odontoglossum specialist, has for his best of 1904, Odontoglossum × waltoniense rosefieldiense, a pale-yellow flower with some brown blotches; O. crispum Venus, a noble variety of the typical class, and O. crispum Theodora, finely blotched with red - purple. Better than any of these however is the beautiful O. crispum De Barri, shown March 9, but kept in reserve until perfected.

J. WILSON POTTER, Esq., Croydon (gr. Mr. W. H. Young), scored with the finely spotted Odontoglossum crispum Rosendale and O. Uro-Skinneri splendens.

Sir FREDERICK WIGAN, Bart. (gr. Mr. W. H. Young), among other good things, produced Lælio-Cattleya × Constance Wigan, a pretty bright yellow flower, with reddish-rose markings on the lip. And other amateurs have contributed to the garden gains of the year.

F. W. MOORE, Esq., the Curator of the Royal Botanic Gardens, Glasnevin, Dublin, has done much to sustain the interest in botanical Orchids at the Royal Horticultural Society. At the first meeting he was awarded four Botanical Certificates, and others were obtained at subsequent meetings, some of the most interesting subjects, such as Bulbophyllum Hamelini and B. Weddelli being illustrated in the *Gardeners' Chronicle*, and references will be found in the appended list of plants illustrated.

NURSERYMEN.

Messrs. SANDER & SONS, of St. Albans and Bruges, have been highly successful, and have received Awards for some of the best Orchids of the past year. Their magnificent Cypripedium × Fred K. Sander is considered the best C. bellatulum cross yet raised, and their C. × Helen II. var. Fascinator and the other forms of the same batch are fine acquisitions. Other remarkable and showy hybrids credited to be firm are Lælio-Cattleya × Hy. Greenwood var. Imperator, a finely-coloured and very large flower; L.-C. × Luminosa "The Mikado," L.-C. × Mme. M. Fournier var. W. H. Young, L.-C. × Martineti Sunrise, L.-C. × eximia Sanderæ, L.-C. × crispo-brosa, all remarkably fine; Cattleya × G. W. Law-Schofield, C. × triumphans, the pretty white C. labiata "Miss Kate Brazier," Cypripedium callosum Sanderæ "Hye's variety," a better flower than the old form, and with more white in the petals, and Zygopetalum × Gottianum, one of the darkest in colour. During the past year Messrs. SANDER & SONS have successfully imported many desirable Orchids, by far the best of which is Cymbidium Parishii Sanderæ, a noble ivory - white flower with labellum heavily marked with violet-purple.

Messrs. CHARLESWORTH & Co., of Heaton, Bradford, have been among the most successful exhibitors of the past year. Their certificated plants of the year are mainly fine forms of hybrids which the firm have previously shown. Of these two

very handsome examples were given among a host of other fine hybrids staged by Messrs. Charlesworth at the last Temple Show, viz., Lælio-Cattleya × Fascinator King Edward VII., and L.-C. × Canhamiana, Rosslyn variety. L.-C. × Haroldiana magnifica, is finely coloured; L.-C. × Digbyano-Mossiæ Queen Alexandra, the first pure white hybrid of L. Digbyana; L.-C. × Cappei Charlesworthii, L.-C. × Myra Charlesworthii, and L.-C. × Illustris, distinct and good. The beautiful and prolific batch of Cattleya × Iris, already honoured with awards, produced three additional good novelties in C. × Iris aurifera, "Prince de Piedmont," and "Fascinator." Other good novelties certificated to Messrs. Charlesworth were Cattleya × F. W. Wigan superba, C. × Rosa Leemann, and Odontoglossum crispum xanthotes Charlesworthii, by far the best of its class in the form of its flowers, their clear white, and the attractive arrangement of the light-yellow spotting, which is the only colour in the flower.

Messrs. JAS. VEITCH & SONS, Chelsea, have for their best Dendrobium × Thwaitesiæ, Veitch's variety, the largest and finest Dendrobium of its class, with clear buff-yellow flowers having a purple disc to the lip; Sophro-Cattleya × Saxa, and Lælio-Cattleya × Mona, two pretty hybrids; and their importations being Cymbidium Wilsoni and other interesting Orchids.

Other good Orchids of the year were Odontoglossum Pescatorei Kathleen, of Messrs. MCBEAN; Cattleya labiata reedleyensis, and C. l. Mrs. G. H. Muller, of Messrs. HUGH LOW & Co.; and Cattleya Mossiæ alba, Tracy's variety, and the fine Cypripedium × Tracyanum, of Mr. H. A. TRACY.

CONTINENTAL NOVELTIES.

M. CHAS. VUYLSTEKE continues to be the best supporter of Continental interests at the Royal Horticultural Society's shows. This year he staged at the Temple Show a number of very pretty hybrid Odontoglossums, several of which obtained awards, and with them × Odontioda Vuylstekeæ (O. Pescatorei × Cochlioda Noezliana), one of the most remarkable and beautifully-coloured hybrids ever raised.

M. A. A. PEETERS, of Brussels; M. JULES HYE DE CROM, M. BERANEK, of Paris (Cypripedium × Rolfei superbum), and Mr. OTTO BEYRODT, of Marienfelde, Berlin, also showed good novelties, the Cattleya Warscewiczii Madame Melanie Beyrodt being the most beautiful "white gigas," with rose-crimson lip.

The Marquis DE WAVRIN, Chateau de Ronsele, Ghent, also showed some novel hybrids flowered in a remarkably short time.

The following new and rare Orchids have been illustrated in the *Gardeners' Chronicle* in 1904:—

Aërides crispum, August 20, p. 134.
Angræcum infundibulare, Supp., August 20.
Bulbophyllum Hamelini, August 20, p. 124.
Bulbophyllum Weddelli, December 3, p. 382.
Calanthe discolor, June 18, p. 389.
Coryanthes speciosa, August 13, p. 106.
Cymbidium Parishii var. Sanderæ, May 28, p. 338.
Cymbidium Wilsoni, March 5, p. 157.
Cattleyas (Mr. McBean's), Supp., May 7.
Cattleyas (Rothschild's), Supp., February 27.
Cypripedium × F. K. Sander, Oct. 29, p. 307.
Cypripedium × Rolfei superbum, Dec. 10, p. 399.
Cypripediums, winter-flowering, April 2, p. 213.
Cypripedium insigne Oddity, Dec. 24, p. 444.
Cynorchis purpurascens, April 9, p. 227.
Dendrobiums, hybrid, March 26, p. 197.
Dendrobium × melanodiscus gloriosum, April 2, p. 219.
Dendrobium nobile virginale, June 4, p. 357.
Dendrobium × Thwaitesiæ Veitch's variety, April 23, p. 274.
Dendrobium Williamsoni, May 28, p. 341.
Dendrobium bellatulum, August 13, p. 114.
Epidendrum elegans, January 30, p. 66.
Hæmaria Dawsoniana, June 18, p. 387.
Lælia purpurata Queen Alexandra, June 4, p. 363.
Lælio-Cattleya × bletchleyensis Ruby King, Supp., February 6.
Odontoglossum crispum de Barri, March 26, p. 196.
Odontoglossum crispum Boltoni, July 16, p. 34.
Odontoglossum × ardentissimum Cooksonæ, April 23, p. 260.
Odontoglossum Pescatorei Kathleen, April 9, p. 228.
Odontoglossum Pescatorei, five varieties, February 27, p. 131.
Odontoglossum, group of spotted, April 23, p. 261.
Odontoglossum × Vuylstekei vivicans, Jan. 2, p. 3.
Odontoglossum × waltoniense rosefieldiense, May 21, p. 331.
Odontoglossum nebulosum Gurney Wilson, June 4, p. 356.
Odontioda × Vuylstekeæ, June 4, p. 360.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

ACANTHUS PERRINGI, *Siehe.*

I DISCOVERED this beautiful new species in 1903 in the Cappadocian Anti-taurus, and have so far propagated it as to be now able to place it on the market. It grows on cliffs, in dry, chalky loam, and in barren places at a height of from 5,000 to 6,000 feet above sea level. The winter climate is extremely cold, the snow often lying from three to four months. The handsome spike of flowers makes its appearance about the end of June. In England the plant should be grown upon rockeries where it can have the necessary dry situation. The roots are creeping and form rhizomes. Leaves sessile, from 5 to 6 inches long, lancet-like, tapering, often deeply toothed and notched, and set with spines. Stem clothed with short hairs. The plant is from 1 to 1½ foot high, and is almost entirely covered with large, handsome, decussate, rosy-red flowers. The bracts are large, ovate, pointed, and sharply indented. They are provided with spines. The bracteolæ are narrow and lanceolate. The upper sepal is entire, broadly ovate, nearly as long as the corolla; the lower one is also broad but smaller, and bi-partite above. The inner sepals are very narrow and lanceolate. The corolla is bright rose-coloured, with three lobes. The bracts and sepals are silvery-green streaked with rose-colour. The plant is closely allied to Acanthus Dioscoridis, according to Boissier's description. The differences are that the leaves of Acanthus Perringi are grey-green instead of bright green. The stem is very short and the leaves sessile. The stem leaves are extremely broad and arranged in an oval, not a circular form. They are somewhat broader than the root-leaves. The bracts are broad and ovate; the lower sepal is broad and not narrow or linear in shape. *W. Siehe, Mersina, Turkey-in-Asia.*

POTATOS.

UP-TO DATE.—The reputation of this well-known variety has lately been assailed in some quarters, but with us we find it still one of the most desirable varieties, for out of nine distinct kinds grown under field culture this one has given most satisfaction as regards weight of crop, disease-resisting capabilities, and edible qualities when cooked. After all considerations, it is the soil that is the determining factor with regard to flavour in a Potato. In localities situated even a few miles apart, one often finds that a particular Potato that is giving satisfaction in the one district is a failure in the other district; but to condemn a variety as worthless and only fit for pigs, as one or two correspondents have recently done, is, to my mind, too sweeping an assertion. I am forwarding half-a-dozen tubers of Up-to-Date to be tested when boiled or baked. Not only are they of excellent quality now, but they will be equally good up to the month of May. *J. Mayne, Bicton Gardens, Devonshire, December.* [Excellent. ED.]

QUALITY OF COOKED POTATOS.

The interesting cooking tests to which Potatos were recently subjected by Messrs. Dobbie & Co. at Marks Tey, Essex, and which showed the Scotch tubers generally to be inferior in quality to those from Lincoln and Essex, open up some interesting themes for enquiry, first, as to whether tubers of varieties that ripen later do really become drier and of better quality when cooked two or three months after lifting than they are at the time of lifting. As to this matter we have no assured tests by which to guide us. Generally it is held that such is the case, and it is much to be hoped that the Scotch varieties subjected to the cooking test on the 13th ult. be again tried with Essex tubers six weeks later. Seeing that we need Scotch tubers for consumption from January onward, to defer such a further test till the spring is certainly undesirable. As Mr. Cuthbertson is as deeply interested in Scotch tubers as in those grown in Essex, the fullest reliance may be placed in his trials. But a further subject for enquiry may be found in the connection, if any, between the comparatively greater sappiness of Scotch Potatos, as the Essex trial seems to have evidenced, and their undoubted greater strength and robustness as seed tubers when planted in the south. There seems to be no fact in relation to Potatos that is more assured than is the one that Scotch-raised tubers give far better growth and crops south than South-of-England-raised tubers do. Do Potatos become more starchy prematurely down south than they do in the north, and is starchlessness more promotive of growth than is sappiness? Were that the case we in the south should find second-growth tubers, always more sappy or watery than first-growth tubers, to make much the best seed. Why Scotch-grown tubers generally produce the best growth and crops southwards is so far an unsolved problem. *A. D.*

Of the many exhaustive tests of Potatos recently made in various directions, the cooking tests conducted by Mr. Cuthbertson are probably one of the most valuable series yet issued. Too often it seems to me, and more especially in recent years, has it been taken for granted that, given a heavy weight per acre and a large and often unhandsome tuber, the necessary quality is also present. Yet it is a curious thing to note in connection with this most recent test, that no mention is made of a variety which is admitted to be the finest quality Potato extant, and which is making a better price on the London markets than any other variety, and this not on account of any [illegible]ing, but because of the demand by that expert judge "the cook." I refer to Langworthy, which is now selling at

from 20s. to 30s. per ton more than can be obtained for other ware. The following extract from the letter of a large grower in Scotland is interesting:—"Notwithstanding the amazing cheapness of Potatos, my 'Langworthy' is selling in London at this moment at 90s. per ton. I cannot understand why growers should potter away with gross bulky tubers when this fine Potato is still at its best." And those English growers who know something of this variety will fully endorse this remark. Amongst other varieties one notices that the record of "Factor" is uniformly good, and maintains its reputation as an excellent all-round Potato. The demand for Scotch seed of this (Langworthy) and Chas. Fidler, which also maintains a good place in this test, is increasingly great, and points to a tendency on the part of growers to secure top returns by having the best. Many samples of Langworthy from the district from which my Scotch cargoes are drawn (Dunbar) are, as a matter of fact, making £5 per ton and over at the present time on the London markets. *R. W. Green, Wisbech, December* 23.

BOOK NOTICE.

LANDSCAPE GARDENING. By Samuel Parsons, Junr. (London: C. P. Putnam's Sons.)

THE intention of this book (written primarily for the denizens of the United States) is "to stimulate interest in an inexpensive style of landscape gardening by enunciating a few fundamental principles, and giving an account of some well-laid-out grounds." The laying out of the "lawn," or, as we should say, the garden, and the construction of roads and paths, form the subjects of the earlier chapters. Roads and paths are considered as necessary evils, and really the roads leading to the house concern the architect and the engineer as much as the gardener; the smaller by-ways, however, come strictly within the province of the gardener, who should know how to dispose them to the best advantage, and specially how to avoid their unnecessary multiplication and frivolous and worrying turns and twists. The appropriate trees and shrubs then come under review, the author of course studying the "environment" as it is manifested in the northern and eastern United States. In the Morningside Park, New York, for instance, a whole hillside is systematically planted, on account of their rich colour in autumn, with White Dogwood, Cornus florida, Andromeda arborea, Liquidambar, Scarlet Maple, Rhus Osbeckii, &c. At other points groups of spring-flowering or of summer-blooming trees are arranged so that the beauties belonging to each season are brought into prominence.

The author further considers the question of massing trees and shrubs in some situations, and in others of placing them apart where their distinctive features may be seen unencumbered by surrounding trees.

The remarks on pruning are eminently judicious, and the directions for the treatment of slopes, the formation of rockwork, the proper use of herbaceous plants are replete with hints which the gardener may profitably consider. The selection of trees and shrubs for particular purposes is both extensive and appropriate. It indicates how large a choice is offered to the connoisseur and at the same time shows the restricted area from which the ordinary gardener gets his material. The remarks on bedding-out plants and their proper use are sensible and devoid of exaggeration, and the details, relating alike to small surburban gardens, town squares, and large parks, may be read with great profit.

The book is well printed, has a good index, and is copiously illustrated. Some of the illustrations are new, but others are old friends which have done duty in other publications. We may strongly commend the book to the notice of our readers.

LILIUM GLEHNI.*

THE illustration of Lilium Glehni at fig. 1 has been prepared from a plant which I found growing on the railway embankment near Asahigawa, in the centre of Hokkaido (Yezo), on July 17, 1904.

In a paper by Dr. K. Miyabé and the Rev. John Batchelor in the *Transactions of the Asiatic Society of Japan*, vol. xxi., p. 231, this plant is said to be known to the Ainos as "Umbairo," and to be used extensively for food. The bulbs are washed, pounded in a mortar, and the finer part of the flour (called "irup"), after drying, is made into gruel, with millet or rice. The coarser part is boiled, pounded, and when rotten made into large cakes. The plants as I saw them were usually 4 to 5 feet high, with six to eight flowers or less, but the specimen figured was exceptionally fine, and had twenty-four flowers of a pale-yellow with reddish streaks.

In the same district, on wooded slopes, and generally in deep shade, I found Lilium avenaceum, which is a much handsomer plant, with two to eight flowers on a stem, like those of a small Tiger Lily; but the bulbs are so fragile and brittle that they are very difficult to collect, and, though also eaten by the Ainos, are rarely cultivated in Japan. These were the only Lilies I saw in the island of Hokkaido, though L. dahuricum is also common on sandy beaches and river banks in some localities.

Lilies do not seem to be by any means so common or generally distributed in Japan as I had supposed. The only species I saw growing wild were L. auratum, L. tigrinum, and L. cordifolium, of which L. Glehni appears to me to be hardly more than a northern variety, and a slender form of tigrinum, which I take to be L. Maximowiczii. The bulbs of tigrinum are commonly used as food, and when baked or boiled are not at all bad eating with a little salt and butter.

I was rather disappointed with the wild flowers of Japan on the whole. There are some fine terrestrial Orchids which are difficult to collect in a condition to send to England, and would be difficult to cultivate. Almost the only very desirable plant that I saw which I have not had in cultivation was Shortia uniflora, which was very abundant in the dense shady forest of Sciadopitys verticillata and Thujopsis dolabrata, in one place in the Central Alps at about 3,000 feet elevation. Though the flowers are larger than those of Shortia galacifolia, they seem to be much less freely produced (at least in the shade of the

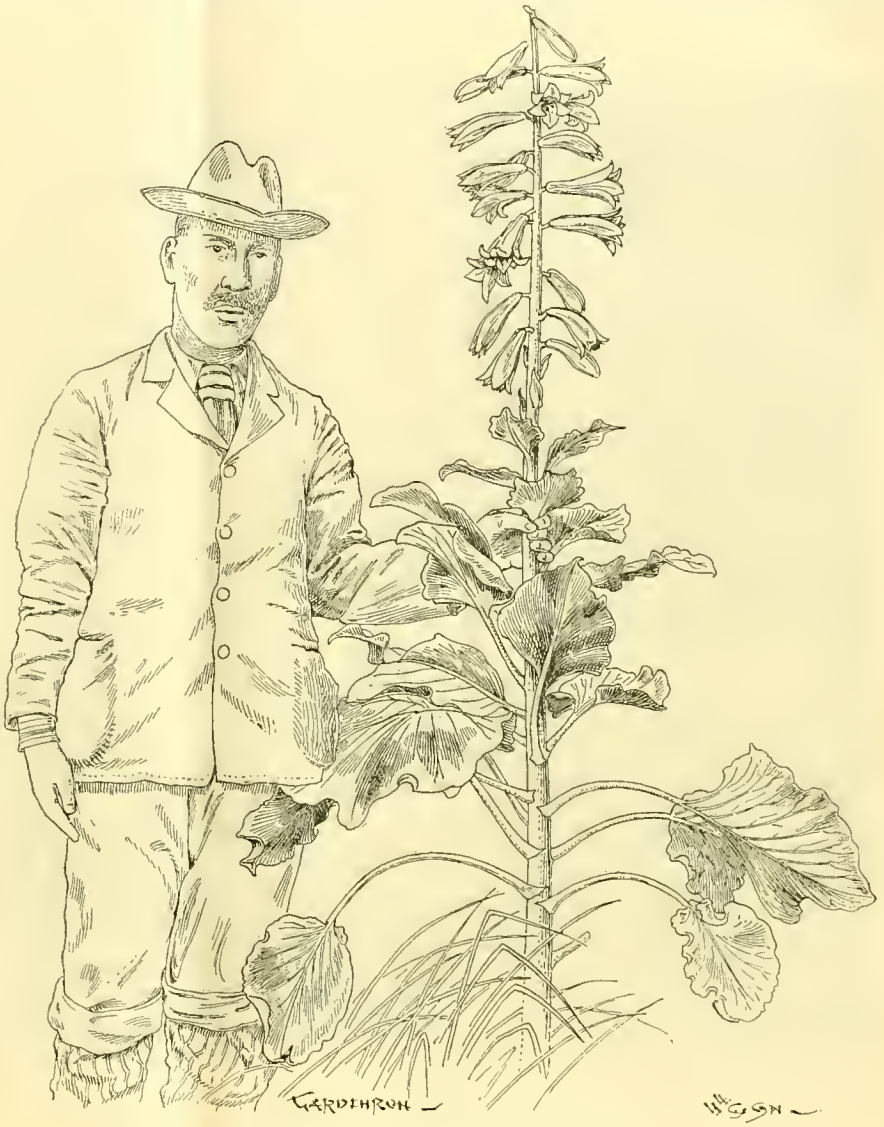

FIG. 1.—LILIUM GLEHNI, FROM YEZO.

* *L. Glehni*, Schmidt, *Reis. Amur*, 187.

forest), where the plant formed large spreading tufts. Schizocodon soldanelloides, which grows abundantly higher up, is probably the most interesting of the Alpine plants, and the occurence of Diapensia lapponica, found on the Yatsu-ga-take by Mr. Atkinson is very interesting. Conandron ramondioides, which I saw on wet sandstone rocks in the Kisogawa Valley, at about 2,000 to 3,000 feet, is also a very curious and beautiful plant, and is easy to grow in pots in a cold greenhouse, as it goes completely to rest in winter. Plants sent me from Japan five or six years ago have increased considerably in size. Alpine plants, though cultivated to some extent by a few amateurs in Japan, are not long-lived in gardens owing to the tropical heat of the summer, and are not so numerous or varied as in the Alps, Himalayas, and the Altai mountains, or on Mount Tacoma in Washington, which I visited on my way back to St. Louis in August. *H. J. Elwes, Colesborne.*

FORESTERS' DIARY. — Webster's *Foresters' Pocket Diary and Note-Book* has been issued by W. RIDER & SON, 164, Aldersgate Street. It is a most convenient little publication, containing in addition to a diary just the sort of information that the busy man wants, whether in the woods and nurseries or at the desk. An index further helps the reader to find what he wants.

HORTICULTURE IN SOUTH AFRICA.

A BEAUTY SPOT IN THE TRANSVAAL.—"Where, in the name of goodness, is Irene?" you ask. "A beautiful name; but is it also a beautiful place?" Irene, I may say, is a sometime notable spot in the Transvaal, on the direct road between Johannesburg and Pretoria, near to the latter place. It stands on the Rand high veldt, at a lower altitude than the Golden City, and is some 5,000 feet above mean sea-level.

A beautiful name "Irene" certainly is, and a very beautiful garden also, seeing that the Transvaal as a whole cannot by any means be called beautiful. Grand and awe-inspiring, with a wonderfully fertile soil, the high veldt, the goldfields of South Africa, is now denuded of all its indigenous woodlands, and is chiefly a waterless and dusty waste, except in the river-beds around Zeerust and Potchefstroom. A notable place, Irene, because here dwelt the late A. Hugo Nelmapuis, a founder, if not the finder, of the Transvaal Goldfields, called the Rand (Witwatersrand or White Waters Reef). Here, then, at Irene, Mr. Nelmapuis, the pioneer of the Gold Reef, built his house, and desired to lay out his grounds in a well-watered valley—at that time, when gold was first discovered, a treeless and a barren veldt waste.

The house was easily designed and erected where funds were plentiful; but not so easily were the grounds to be laid out and planted. Mr. Nelmapuis being then in Europe, looked around to find, if possible, a suitable landscape-gardener, and hearing that a clever young German was then at the Orchid nurseries of Messrs. Sander, St. Albans, who had received his earlier experience in the French gardens and nurseries, sent for him, and finding him efficient, with ideas of his own, engaged Mr. Fuchs and despatched him at once to the scene of his future work in the Transvaal, to begin the laying out of the grounds at Irene.

Mr. Fuchs amusingly refers to his work and

FIG. 2.—THE GARDEN STAFF AT "IRENE," TRANSVAAL.

wages when Mr. Nelmapuis, fortunately for both, found him at the St. Albans nurseries. He was there, he says, receiving 14s. per week, and his living cost him 19s. Probably his wage was larger than he could have got in the French gardens and nurseries, but not so his living, which is provided at a less cost on the Continent than in England. But the serious part of the business was that he was spending in England 5s. per week more than he earned, so a change as quickly as possible was certainly desirable, although I have no doubt that the English practice Mr. Fuchs obtained was more than worth the 5s. weekly loss.

Irene then arose under Mr. Fuchs's skilful work, and became in a few years a Paradise, as trees and plants where water is in the Transvaal grow and thrive very quickly, a

five-years' Transvaal growth being equal to an English growth (even in Devon or Cornwall) of twenty or more years, as witness the recent wonderful covering-up of the Johannesburg suburbs, which only five or six years ago were but bare veldt, a barren and desolate land indeed.

But the Irene estate as Mr. Fuchs left it some ten years ago was magnificent. Irene is now in other hands, and it has, I regret to say, much degenerated, being used as a semi-nursery, badly managed, as half nurseries and half pleasure-grounds generally are, neither the one nor the other being made the best of. Mr. Nelmapuis, alas! died too soon, and the family having left for Europe, Irene was sold, and Mr. Fuchs left in order to establish his present prosperous business in Johannesburg at the Rand Nurseries and the Henwood's Arcade Floral Depot. He is undoubtedly

FIG. 3.—MR. FUCHS DIRECTING THE KAFFIR "BOYS" IN THE GARDENS AT "IRENE," TRANSVAAL.

the Rand Decorator, and as much sought after by the wealthy magnates of the Rand for decorative work as he is esteemed by them, for all his work is of a high class, and he well deserves success.

Mr. Fuchs is a bachelor, and lives at his villa at the nurseries of some 200 acres in extent, beyond Sansouci, and dispenses hospitality there with a free and generous hand. Mr. Fuchs had the honour to present personally a bouquet of Transvaal Orchids to Mr. and Mrs. Chamberlain on the occasion of their visit to Johannesburg in 1903 (see *Gardeners' Chronicle*, March 21, 1903, p. 179, fig. 75); and the late Colonial Secretary and his charming wife drove out to see Mr. Fuchs's nursery, and were delighted with what they saw. It was on that visit that Mrs. Chamberlain said to Mr. Fuchs, "And you surely do not always intend to remain without a wife in this lovely spot?" "But, Madam, I am too happy and busy here, and too well looked after by Madam my housekeeper to desire to alter my mode of life," was Mr. Fuchs's answer. *Alfred Chandler, F.R.Met.Soc., F.R.H.S.*

NURSERY NOTES.

PLANTS IN BLOOM AT MESSRS. J. VEITCH AND SONS.

As the years advance so do the species of plants, mostly of recent introduction, which come naturally into flower at this "dead" season, or are made so to do under a régime of forcing after suitable preparation. One form of this is retardation in cool chambers, as in the case of Lily of the Valley and Lilac.

Taking the cool show house first on the occasion of a visit paid to the nursery on Monday, December 19, I found it very gay with Camellias, small plants of about 2 feet in height each carrying from three to six flowers of mostly large size, which is unusual in small young plants. One of the more conspicuous is the old C. Chandleri elegans, a flower of more than ordinary size, fairly full, light rose in colour mottled with white; also Baronne Lequay, white striped with rose colour; imbricata Madame Hovey, and other favourite varieties (the foliage of these plants was all that could be desired). Among other plants in bloom were the comparatively new Lindenbergia grandiflora, a species having an almost continuous flowering habit and numerous yellow flowers of the same tint as that of Celsia cretica; Salvia splendens, many specimens of Daphne indica rubra, some choice Cyclamens of the grandiflora type; beautifully-flowered neat examples of Azalea indica as globular-headed standards of 1½ ft. to 2 ft. high, including the favourite Deutche Perle, the best for bringing into bloom at this season, and several Ericas, viz., melanthera, hyemalis, and gracilis; Roman Hyacinths, Lily of the Valley, nicely bloomed; Christmas Roses showing some few flowers, and giving promise of a good succession; some finely-fruited small specimens of Aucuba japonica vera, and one pyramidal-trained plant covered with fruits just ripening of Cratægus Pyracantha Lelandi. A few Tree-Carnations added colour but not discernible fragrance to the whole.

The warm show, otherwise rockery, house afforded specimens in fine flower of Jacobinia (Justicia) coccinea, J. chrysostephana with showy orange-coloured flowers, Reinwardtia tetragyna, Caraguata ligulata splendens (the bracts of a vivid scarlet tint), Euphorbia (Poinsettia) pulcherrima, and the rich purple-flowered Lasiandra.

It was noted that the warm-house plants generally are grown at this season, and indeed always, at a lower degree of temperature than was at one time considered by cultivators advisable, with the advantages of more endurable conditions for those inspecting or working among them, greater freedom from insects, sturdier growth, and a lessened coal bill.

The Codiæum (Croton) house contained an admirable assortment of highly coloured plants of sizes suitable for table adornment and indoor use generally where small things are desirable. A grand lot of Aspidistra lurida variegata was remarked. One of the transformed pits of old time, now a commodious span-house, was filled with "table plants," including well-grown and coloured examples of Dracænas, such as Flamingo, Mayii, Prince Manouk Bey with narrowish, erect leaves of a deep red tint; the showy norwoodiensis Jamesi, with narrow leaves of a reddish-crimson tint, a variety of Australian origin, and others.

In another similarly reconstructed house were a capital lot of Eucharis amazonica now beginning to open their flowers; of Aralia Veitchii gracillima, A. leptophylla, reticulata, and other species of these graceful plants suitable for table uses, &c. The singular-looking Urceolina aurea and several specimens of Nægelia exoniensis, whose showy scarlet flowers make it so valuable as a decorative plant at this season, were observed. Of Pandanus Veitchii numerous small examples occurred in this and other houses. It is a plant that is very generally in use, as are also the varieties of Rex Begonias.

The more noteworthy varieties of the winter-flowering section of Begonia consisted of Agatha, resembling in general aspect the better known Gloire de Lorraine, but having larger and richer-coloured flowers, and more compact in habit. The blooms last well, and withstand London fogs better than any other variety. Mrs. Heal, one of the finest of this section, was observed in some quantity, possessing a height of 2 to 3 feet, robust, with almost orbicular leaves, and very stout stems. The peduncles carry from five to seven and nine flowers each, 3 inches in diameter, of a fine carmine touched with scarlet. Some of the plants observed had been in bloom since early October. Winter Cheer, another of this section, was observed splendidly in flower, the trusses massive, and consisting of numerous scarlet flowers of about 3 inches in diameter. The plant grows and flowers well in 5 and 6-inch pots. Winter Perfection, a bright rose-pink-flowered variety, has charming semi-double flowers of the same size as the last named. It is a sturdy, erect, free-flowering, beautiful variety. Julius has flowers of a faint pink shade suffused with white, resembling those of a double Nerium Oleander. Ensign has a rosy-crimson flower, and the habit of growth of Winter Cheer. Those of the above-named varieties were struck from cuttings taken in August last. Plants of Coleus thyrsoideus, 3 feet in height, and each main growth terminated with a spike of bright blue flowers, were struck in July. Some plants of Moschosma riparium were smothered with their white, Spiræa-like spikes of flowers. Plants of Epiphyllum truncatum in variety coming into bloom were noted.

Of Javanico-jasminiflorum hybrid Rhododendrons I noted Cloth of Gold, golden-yellow

flowers in bold trusses; Princess Beatrice, pale yellow suffused with pink: Mrs. Heal, the only pure white variety; Princess Alexandra, white with a faint blush tinge; Hercules, a large flower of a deep yellow tint; and Little Beauty, red flowers, small growing, excellent for forming sprays.

In the Orchid-houses the following were noted in bloom—Cypripedium insigne Harefield Hall variety, C. Hitchinsianum, C. Spicerianum, C. Prospero, C. Sedeni, Lælia Olivia × = L. crispa × L. xanthina, the flowers forming a pleasing combination of primrose and pink tints; Lælio-Cattleya Proteus, a cross between L. cinnabarina and Cattleya amethystoglossa; L.-C. luminosa = Lælia tenebrosa and Cattleya aurea; L.-C. Bryan, a cross from C. Gaskelliana and L. crispa, a fine large truss, the lip of rare brightness, the flower coming out splendidly under artificial light.

The stock of Lælias, Vandas, Cattleyas Trianæ and labiata, now housed in the once show greenhouse, are looking the picture of healthy vigour; but nothing was noted in flower among them. *F. M.*

FRUIT REGISTER.

APPLE ANNIE ELIZABETH.

I AM forwarding you examples of this excellent late-keeping Apple, taken from the fruit-room at Wentworth House to-day. You will observe the flesh is extremely solid, and for market purposes should be one of the best varieties, being of suitable size and of good appearance. Mr. H. E. Edwards, gr., Wentworth House, Mill Hill, N.W., speaks very highly of this Apple. As grown ordinarily on the northern heights of Finchley, it proves a good cropper, the fruits are of useful size, and keep good for a very long time. The flesh is excellent when cooked. If kept till March the fruits are not at all unsuitable for dessert purposes. *Stephen Castle, December* 19. [Six excellent specimens of this well-known Apple accompanied the above letter. ED.]

I send you herewith a few fruits of Apple Cornish Gilliflower. They are from orchard-grown trees on grass, and the fruits find great favour with my employer, as also do Cox's Orange Pippin, Adam's Pearmain, Braddick's Nonpareil, Old Nonpareil, Sturmer Pippin, and Allen's Everlasting, with Devonshire Quarrenden and Lady Sudeley for consumption early in the season. Another good early variety that one scarcely ever sees mentioned out of Cornwall is Lucomb or Pince's Seedling, ripening about the same time as Lady Sudeley. King of Tompkin's County succeeds well with us, and in most seasons is grandly coloured, but, like King of Pippins, Wyken Pippin, Blenheim Pippin, Allington Pippin, and Worcester Pearmain find, but little favour here as dessert varieties. *Philip R. Murton, The Gdns., Penrose Helston, Cornwall, December* 21.

[The large fruits of Cornish Gilliflower have a rough exterior that is not specially inviting in a dessert Apple, but the flavour is very good indeed and distinct from that of most other varieties. The flesh is very firm and not juicy. Probably the fruits would have been even better a fortnight earlier. ED.]

PEACH SNEED, OR EARLIEST OF ALL,

is figured and described in the *Revue Horticole* for December 16. This is an American variety which ripens its fruits one or even two weeks earlier than any other variety.

"THE HORTICULTURAL DIRECTORY FOR 1905."—As this is the forty-sixth annual edition it is not necessary to do more than mention the fact, as all business men will, like ourselves, know of its value from daily use.

The Week's Work.

[At the beginning of a new year, we have, in accordance with our usual practice, made certain changes in our weekly Calendar. Our object is to lay before our readers each week practical directions written by men of acknowledged pre-eminence in their several departments, and who are in actual practice. In our present issue it will be of interest to give the portraits of those who have kindly consented to write the Calendar for the present year. To those who have retired we tender our thanks for the services they have rendered. ED.]

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Peas.—By a proper selection of varieties and careful cultivation the natural season of this favourite vegetable may be extended by two months at least. No time must be lost before sowing seeds. Fill some 4-inch pots with old potting soil, and sow at least five Peas in each pot. Use sufficient pots to provide plants for the supply under glass, and for planting-out in the open border in March. Those to be forced under glass should be put near to the glass in heated pits, admitting air whenever practicable to do so, and those for planting-out in March may be placed in cold frames. The varieties we have found best here for this purpose are Chelsea Gem, and of taller varieties Sutton's Giant, Veitch's Early Marrow, and Edwin Beckett, handsome podded varieties. Last season I formed a very favourable opinion of Carter's May Flower. At the same time as sowing the seeds in pots we make our first sowing, weather permitting, in the open garden upon a south border previously prepared. The variety used is Exonia, which grows 3½ feet high. The drills are made of sufficient depth to allow of some leaf-soil, wood-ashes, stable-droppings, old potting-soil and soot, all mixed together and in dry condition, to be put into the drill before and after the seeds are sown. The drills are made about level with this compost, and are then covered with the ordinary soil taken from the drills. When sowing at this season we employ double the quantity of seeds we should use in spring, and if considered necessary the plants are thinned out subsequently.

Onions.—Immediate preparations should be made for this crop by deep cultivation and liberal applications of manure. If this be done no change of soil will be necessary, for during the last ten years I have grown Onions on the same ground, and yet get bulbs from 2 to 3½ lb. in weight. But in order to secure this object the seeds must be sown now, and for this purpose we use clean pots 3 inches in diameter. These are filled with light, moderately rich soil made pretty firm, and a few seeds are dropped in the centre of each pot. The pots are then placed in a temperature of 50° to 55°, and kept near to the glass. The best variety for this purpose is a well-selected variety of Ailsa Craig. Magnum Bonum and Crimson Globe should be grown for supplying variety. When seeds are sown in the open garden during March, I find Veitch's Main Crop to be the best variety. This variety may also be sown now in boxes, placed in cold frames, and transplanted in the spring.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pot Vines will now be in various stages of growth, and the details in their cultivation must be given attention at the proper time. Especial care has been necessary recently owing to dense fogs and other adverse climatic conditions, but satisfactory progress will have been made if the excellent advice given by my predecessor in the Calendar in the *Gardeners' Chronicle* for 1904 has been faithfully followed. In gardens where fruit is required at an early date, light and rich top-dressings of good fibrous loam with some approved Vine-manure added should be given the Vines as soon as the Grapes have been thinned, and a temperature of 68° may be maintained at night in mild weather, especially in houses where some covering can be placed over the roof-lights to conserve the heat. Excessively high temperatures, however, must be avoided until the fruit is set, as nothing would be gained by trying to hurry the Vines during the early stages of their growth. See that tepid water is supplied to the roots as often as required, occasionally substituting for the clear water some weak liquid-manure. Keep the atmosphere moist, but avoid damping the floors too frequently in dull or wet weather, rather add fresh fermenting material where this is used, and if it be turned repeatedly this will help to keep up the necessary degree of moisture. Those Vines which are now approaching the flowering stage should be afforded a temperature of 65° at night, which may vary a few degrees more or less according to the condition of the weather. A rise by day of 10° or 15° with sun-heat may be permitted. Admit a little air for a short time on all favourable occasions, but prevent cold draughts. The atmosphere should be slightly dryer during the time the Vines are in flower, and it will be necessary to tap the rods lightly in the brightest part of the day in order to distribute the pollen. Tie the shoots into position as they increase in length, stopping them at two joints beyond each bunch, and removing those shoots that will not be required for supplying the necessary degree of shade. Later Vines that have only just commenced to grow must be watered with extreme care. Cease to syringe them as soon as the buds have broken evenly into growth, but supply the necessary moisture by damping all other available spaces in the house.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

A good Beginning.—During the last weeks of the old year we have had one of the worst visitations of fog that has occurred in my Orchid-growing experience. The effects of this will be disagreeably apparent for a long time to come. It is at such periods that the suitability or otherwise of the houses and compartments used for Orchid cultivation is proved. Too many beginners, on deciding to form a collection, utilise ordinary plant or Cucumber houses, without paying much regard to the necessary conveniences for providing efficient ventilation, atmospheric moisture, and good light, and then if a fair amount of success is not

attained, the venture ends either in disappointment or in the discharge of the *employé*. A skilful grower may contrive to grow his plants under adverse circumstances, but give him suitable houses, erected in the best position obtainable, and he alone is then to blame if the very best results are not secured. There are, however, one or two circumstances which are beyond the cultivator's control, such as local and climatic conditions, and these will to a large extent influence the growth of his plants. Orchid-houses should be erected on the south side of a high wall, or in such a position as will afford protection from northerly winds. They should be compact, and run from the north to the south, so that the plants on each side may share in the daily sunshine. The houses should be of moderate height only, and have a roof-angle of about 45°. Ample means of ventilation are necessary both in the walls and roofs. Sufficient water-pipes should be provided to furnish the requisite degree of warmth without having to unduly heat the pipes. That atmospheric moisture may be fairly constant and arise naturally from the floors, these should be made of coke-breeze or suitable refuse from the stokeholes. Any brickwork needed inside should be constructed with good porous bricks, using as little cement as possible. Tanks for the collection and storage of rain-water are needed, but if they extend beneath the stages any distance they should be covered over, excepting here and there for dipping a supply from. Double stages are almost always essential, the lower one to be covered with moisture-holding material, and the upper one, 4 to 6 inches above, made of laths an inch or so apart. With houses combining the foregoing essential characteristics, a good beginning will have been made.

Temperatures, &c.—During the shortest days much work other than cleaning cannot be undertaken, and so long as the temperatures are properly regulated, water intelligently afforded to such plants as need it, and the requisite degree of humidity maintained in the atmosphere, the plants should pass satisfactorily through the dull season. As a guide the following figures should be approximately maintained during this month and February, always allowing the temperatures to decrease when severe frosts or cold winds prevail, and raising them proportionately during mild weather: *Stove or East Indian-house*, 65° by day, 60° by night; *Cattleya and Mexican-houses*, 60° by day, and 55° by night; *Intermediate-house*, 58° by day, and 53° by night; *Masdevallia-house*, 55° by day, and 50° by night; *Odontoglossum-house*, 53° by day, and 48° by night. These are temperatures to be promoted solely by fire-heat, and a considerable rise may be allowed during the daytime when arising from solar-heat.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to the Countess BECTIVE, Underley Hall, Westmoreland.

Improvements.—This is a suitable time of the year to make alterations and improvements. The flower gardener will have his notes of successes and failures obtained last summer to refresh his memory and aid him in his endeavour to secure improvement. In all departments this is most likely to result from simplicity of arrangement, and an endeavour to copy Nature in her most pleasing features.

Fencing.—See that the fence enclosing the flower garden is proof against vermin. If galvanised-wire-netting is used, and requires replacing with new, it may be well to know that instead of burying it 9 inches in the usual way it is quite as satisfactory to bend at right angles about three-quarters of a foot, and fasten level with the ground with wooden pegs a yard or so apart. The wire soon embeds itself in the grass, and does not rust for many years.

Shrubberies.—Press forward with the grubbing and blasting of roots, trenching, wheeling, and all similar operations in readiness for the planting season. Shrubs for winter effect are now at their best, and when planted in the best manner are very satisfactory. On a sunny bank a group of Rubus biflorus (the Whitewashed Bramble) is very effective associated with Picea pungens glauca, Cryptomeria elegans, Cotoneaster frigida (well berried), and Cornus sanguinea, with Bamboos for a background. Pinus sylvestris aurea is the brightest of the golden-coloured shrubs. Golden Hollies, Taxus fastigiata aurea, T. baccata aurea, Cupressus Lawsoniana Smithi, Retinospora plumosa aurea, and Diplopappus chrysophyllus (Cassinia fulvida) follow in the order named.

Transplanting Shrubs.—When regulating shrubberies there are always some specimens worth moving, and good-sized trees with proportionate balls can be easily transplanted with every prospect of success by using a mason's bogie in lieu of a transplanting machine. Prepare the ball, say 3 feet in diameter, then have four stout boards a little longer than the width of the bogie, and secure these well underneath the ball at front, back, and sides by wooden blocks and bricks at each corner, bearing in mind the width of bogie. Keep the tree perpendicular, raise each corner alternately, and undermine the ball. Now that the boards have got the weight, prepare an inclined path, and run the bogie underneath; reduce the pillars till the bogie has its load, then with levers and a steady pull the tree will be raised out of the hole. Having decided on a position in which to replant the tree, make a hole and path, run the bogie down, block up the boards to relieve the bogie, then lower the ball of the roots to the proper level, ram good soil underneath, take away blocks and boards, use friable soil amongst the roots, and the tree will be firmly and expeditiously planted.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant, Oxon.

Even in the winter months there is much work to occupy the attention of the grower of hardy fruits, such as tree planting, manuring, pruning, staking, nailing, training, and the destruction of lichen and insect pests by spraying, &c. Each of these operations will be given attention in this column in due course.

Planting Fruit-trees.—This is one of the most important items in successful fruit cultivation. Where it has been delayed in some localities owing to frost and snow, the work should be proceeded with as expeditiously as possible immediately the soil is found to be in such a condition that it can be satisfactorily worked. A great many failures in fruit growing are the result of stunted growth, canker, &c., that follow "slip-shod" planting. It will pay well to do this work thoroughly and skilfully. The natural conditions of the site and soil are the first considerations. In some low-lying gardens where there are no practical means of draining, effective measures should be taken to prevent the roots growing down into a cold and wet subsoil. A quantity of broken bricks, lime-rubble, slates, or concrete placed at the bottom of not too deep a hole, and well rammed together, will answer this purpose. Where the subsoil consists of chalk, the foregoing remarks are also essential, otherwise if the roots are allowed to descend into the chalk a sickly-looking tree will result, and it will need to be lifted and replanted. Before proceeding to plant the tree trim all damaged roots by making an upward cut, and from the apex of each root new roots will grow. If the soil at the time of planting is in a rather wet condition, a quantity of old potting soil and burnt refuse should be worked well amongst the root-fibres, the main roots being laid out at right angles from the tree and covered at varying depths, making the whole firm by means of treading with the foot, and filling up with the staple soil, leaving it rough and untrodden on the surface. In all cases it is of the utmost importance to secure the trees to a stake, and in the case of wall-trees to so fasten them that they cannot be blown about. It is best to plant to the stake, and there is then no risk of injuring the roots by driving the stake in after planting. There is sure to be a natural settlement of the soil, and the trees should not be secured finally until this has taken place. Do not bury the roots more deeply than they were when growing in the nursery, the mark of which will be seen on the stem of the trees. Where a plantation of cordon Apple-trees on Paradise-stocks is contemplated for supplying large fruits for exhibition purposes, they may be advantageously planted on slightly raised mounds, allowing a space of 4 feet between the rows, the intervening space to be heavily mulched with manure in the summer time. Instead of staking each tree, two wires strained to supports at either end is all that is necessary for making the trees secure.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Necessity for Light.—At this time of the year, when fog and dull sunless weather are so frequent, too much importance cannot be attached to the admission of all the light obtainable for plants, whether grown for their foliage or for flowers. This can only be done by keeping the glass and woodwork of the houses thoroughly clean and sweet.

Stove containing fine Foliage Plants.—Maintain by fire-heat a temperature of 65° by night with a rise of 5° by day, but allow the temperature to fall a little lower in very severe weather in order to avoid heating the pipes excessively. Keep plenty of moisture in the atmosphere by damping the floors and the surfaces between the pots, &c., but use the syringe sparingly over the plants during very dull weather. Little or no advantage is gained by commencing to propagate plants too early in the season, but where specimen Codiæums (Crotons) are required propagation may now be proceeded with, selecting only strong healthy plants for this purpose. The method known as "ringing" is the best. Care should be taken in this operation not to cut deeper than the rind in taking out the ring of bark, also in tying the moss round, for the wood being very brittle it is easily broken and the advantage this method should possess is then lost.

Stoves with Flowering Plants.—At this season the utmost care is required in the watering of plants particularly of those that require a warm temperature to develop their flowers perfectly. Keep a moderately dry atmosphere and a temperature of 60° by night. Only under the most favourable conditions should air be admitted to the house, and only sufficient then to allow the damp air to escape. Begonia Winter Cheer, B. Ensign, B. Mrs. John Heal and others of this type having flowered, steps should be taken to ensure them a thorough rest. Gradually withhold water from the roots as they show signs of resting, but on no account allow them to become dust-dry, and for this reason they should always be under the eye of the man in charge. They must not be placed where the temperature falls below 55°.

APPOINTMENTS FOR JANUARY.

MONDAY,	JAN. 9	United Hort. Ben. and Prov. Soc. Com. Meet.
FRIDAY,	JAN. 13	British Gard. Assoc. Meeting at Swansea.
SATURDAY,	JAN. 14	Ann. Dinner Soc. Franç. d'Hort. d'Londres, Café Royal 6.30 P.M.
MONDAY,	JAN. 16	British Gard. Assoc. Meeting at Cardiff. Birmingham and Mid. Counties Gard. Mut. Imp. Assoc. Ann. Meeting.
WEDNESDAY,	JAN. 18	Brixton and District Hort. Soc. Ann. Meeting.
THURSDAY,	JAN. 19	Linnean Soc. Meet. Gard. Roy. Ben. Inst. Ann. Meet. and Elect. of Pensioners at Covent Garden Hotel, at 3 P.M.; Ann. Friendly Supper at 6 P.M.
TUESDAY,	JAN. 24	Roy. Hort. Soc. Coms. Meet. Nat. Rose Soc. Com. Meet.
FRIDAY,	JAN. 27—Roy. Bot. Soc. Meet.	

SALES FOR THE WEEK.

MONDAY, JANUARY 9—
Hardy Border Plants, Roses, Azaleas, American Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 o'clock.

WEDNESDAY, JANUARY 11—
Continental Plants, 2,400 Roses, Fruit Trees, &c., at 67 & 68, Cheapside, E.C., at 12 o'clock. Enormous consignment of 3,800 cases of Japanese Liliums, including 147,640 L. auratum, 147,480 L. sp. album and rubrum, 100,000 Palm Seeds, 50,000 Tuberoses, and a great variety of other Bulbs, at 67 and 68, Cheapside, E.C., at 3 o'clock 14 Greenhouses, Piping, Boilers, and Stock, at the Hollisfield Nursery, Firs Lane, Winchmore Hill, by order of Mr. C. E. Town, at 12 o'clock. By Protheroe & Morris.

FRIDAY, JANUARY 13—
Rhododendrons, North American Plants, Gladioli, Spiræas, &c., at 67 and 68, Cheapside, E.C., at 12 o'clock; Imported and Established Orchids, at 67 & 68 Cheapside, E.C., at 12.30 o'Clock; by Protheroe & Morris.

For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —36·4°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 4 (6 P.M.): Max. 50°; Min. 46°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 5 (10 A.M.): Bar., 29·8: Temp., 49°. Much rain.
PROVINCES.—*Wednesday, Jan.* 4 (6 P.M.): Max. 49°, West Coast of England; Min. 45°, East Coast of Scotland.

Sir Joseph Hooker.

THE retirement of Sir JOSEPH HOOKER from the Editorship of the *Botanical Magazine* affords us an opportunity of presenting to our readers a portrait of this distinguished botanist. The history of the Magazine was written in our columns by Mr. HEMSLEY,* so that it is not necessary to enter into details concerning it. It must suffice to recall that it was established in 1787, and was edited by Dr. (afterwards Sir WILLIAM) HOOKER from the year 1827 to 1865. For some years before he came to Kew the Magazine was edited by Dr. HOOKER at Glasgow. At that time his personal influence ensured the introduction to the botanic garden of that university of numerous rare and interesting plants which were figured and described by the Professor. On his removal to Kew in 1841, Sir WILLIAM HOOKER continued the editorship till his death in 1865, when he was succeeded by his son, Sir JOSEPH HOOKER. For a continuous period, therefore, of seventy-seven years botanists and gardeners have been indebted for the illustration and exact description of rare or interesting plants to father and son. The boon that has thus been conferred on botanists and gardeners is beyond computation, and is certainly not the least of the innumerable services that have been rendered to science and horticulture by Sir WILLIAM and by Sir JOSEPH HOOKER.

The very characteristic illustration that we give as a Supplement to this issue was taken from the portrait by HERKOMER in the possession of the Linnean Society. Another portrait hangs on the walls of the Royal Society.

* See *Gardeners' Chronicle*, vol. i. (1887), beginning at p. 345; vol. xix. (1896), p. 389; vol. xx. (1896), p. 651; and vol. xxxi. (1902), p. 289.

The New Year.

IT is much easier to write of what is past than of what is to come. In the one case we have a solid basis of fact; in the other we have in some measure to rely on the unstable foundation of the imagination. Nevertheless the past in many ways governs the future, and enables us to anticipate coming events. Everything points to the success of the Horticultural Hall. All the Committees were enabled to meet in the new rooms on Tuesday last, and the Lindley Library is in process of rearrangement. The commodiousness and bright appearance of the exhibition hall command universal approbation, and the show, though small, was excellent in detail, and gave full promise of successful fortnightly meetings for the present year. Let us hope that in the near future the cost of the new building, which is so useful to the Fellows, will be defrayed, and that the Trustees of the Lindley Library may be afforded an income a little less beggarly in amount than that which is at present available. In the meantime we record with great gratification the fact that Baron Sir HENRY SCHROEDER, in addition to his former munificence, has undertaken to defray the costs incident to the removal and reinstatement of the Library. The Library, which has had a chequered career since it was purchased by the committee of the great International Horticultural Exhibition and Botanical Congress of 1866, will now be housed and arranged in a manner consistent with its value and importance. It occupies the topmost floor of one wing of the new building, and is fitted up with oaken shelves, projecting cases, tables and other requirements, so that at last there is more than a prospect that the Society will be in a position to offer to the Fellows facilities for study and research far greater than it has previously been able to do.

One of the most important horticultural events of the present year will in all probability be that of the Royal Caledonian Horticultural Society, which will hold a great International Horticultural Exhibition in Edinburgh from September 13 to 15.

On this occasion we may expect to see a grand collection of fruit, as the prizes offered will doubtless ensure a brisk competition. We are pleased to note that an attempt is to be made to render these exhibitions more generally useful to horticulture by encouraging exhibits calculated to promote the advance of scientific horticulture. Thus we see that exhibits are requested illustrative of any new or improved method of cultivation, or any new application of scientific facts to practical purposes. This opens up a very large field, including as it does the results of hybridisation and cross-breeding. Too much must not be expected from this section in the first instance, but as a means of infusing variety into the stereotyped arrangements of an ordinary flower-show it should be welcomed quite independently of its prospective benefits to practical horticulture.

The Royal Horticultural Society will hold its usual exhibitions in the Temple Gardens and at Holland House, also a great show of British-grown fruit, and another of Colonial-grown fruits, in addition to the ordinary fortnightly meetings. The Society's examinations in horticulture will be held as usual, and it is expected that the new gardens at Wisley will be so far modified as to afford facilities for the resumption of the old Chiswick trials.

The National Rose Society, the National Chrysanthemum Society (whose dates of exhibitions at the Crystal Palace are not yet fixed), the Potato Society, the Sweet Pea Society, and all of the other special societies, will continue to hold exhibitions; and the provincial horticultural societies have already announced that exhibitions will be held at Shrewsbury, York, Newcastle, Manchester, Wolverhampton, Hanley, and other places.

It is satisfactory to know that a larger number of the special Societies than heretofore will hold their exhibitions in conjunction with meetings of the Royal Horticultural Society.

The British Gardeners' Association has arranged to hold meetings in various parts of the country with the view of enlightening local gardeners as to its aims and purposes. It is hoped that there will be a large accession of members now the New Year has dawned.

The Almanac which we issue with the present number shows how numerous are the fixtures for the present year. We cannot make it complete, for several of the societies have not yet fixed their dates of meeting, and some of the dates are liable to revision. Nevertheless we trust it will be found serviceable as a reminder to our readers, and will act as an incitement to them in future to keep us posted in local events.

Upon the whole the year 1905 promises to be one of satisfactory activity, though it is not likely to be distinguished by such important events as marked the Centenary of the Royal Horticultural Society last year.

"THE JOURNAL OF THE KEW GUILD."—As an excellent illustration of what may be effected by co-operation and good fellowship we may call attention to the Kew Guild, an association of those who are or have been connected with Kew at some portion of their career. The annual Journal, which contains letters from old Kewites in every part of the world, is most interesting even to those who have not been so fortunate as to have passed through Kew. The present number, in addition to business details, contains an account of the annual dinner, presided over by Mr. WATSON, a function that becomes annually of increasing importance. The Himalayan-house is the subject of a notice, together with an excellent illustration of the rock-pool constructed in it. The letters from old Kewites in various parts of the world, to which we have already alluded, are so interesting as to excite the envy of editors. We are pleased to see as the frontispiece to the present part a portrait of our valued friend and correspondent, Mr. N. E. BROWN, an acute and painstaking botanist, to whom we have very often been indebted for valuable assistance, and who has contributed numerous descriptions and illustrations of interesting plants to our columns.

"THE BOTANICAL MAGAZINE."—The January number, which inaugurates a new series (the fourth), now appears under the editorship of Sir WILLIAM T. THISELTON-DYER. Little alteration has been made in the appearance of the magazine, beyond a few changes in the type, the name of "CURTIS" even being retained on the title-page as a survival. The plants figured are:—

Cadalvena spectabilis, Fenzl., t. 7992.—A noble-flowered Ginger-wort from Tropical Africa. The flowers are bright yellow. Mr. C. H. WRIGHT furnishes the technical details relating to it. The species flowered at Kew.

Cotyledon elegans, N. E. Brown, t. 7993.—A Mexican species described by Mr. N. E. BROWN, and readily distinguished by its inflorescence, which bears two flowers only. Kew.

Phyllostachys nigra, Munro, t. 7994. — This Bamboo is considered by Dr. STAPF to be synonymous with P. Henonis, P. Castillonis, and P. boryana. It is a native of China and Japan.

Swainsona Maccullochiana, F. Mueller, t. 7995. —A handsome leguminous plant with purplish Pea-like flowers in long racemes. It is a native of N.W. Australia. Kew.

Vanilla Humblotii, Reichb. f., t. 7996.—A very handsome yellow-flowered species from the collection of Sir TREVOR LAWRENCE. It is a native of Madagascar, and was originally described in our columns in 1885, vol. i., p. 726.

"THE GARDEN MAGAZINE" is the title of a journal to be published by DOUBLEDAY, PAGE & Co., New York, on January 14, and to be devoted to all branches of gardening. It seems strange that whilst trade journals have so large a circulation in the States and are so well conducted, yet there seems no public in America for a gardening journal that is not exclusively commercial. The proprietors of the *Garden Magazine* are evidently intending to make a public, and we hope they will succeed.

CATTLEYA LABIATA.—Mr. (afterwards Sir WILLIAM) HOOKER was the first to flower this Orchid in 1818, at Halesworth, Suffolk, the plant having been received from its discoverer, Mr. SWAINSON.

GASPARD BAUHIN'S HERBARIUM.—One of the works undertaken by PYRAMUS DE CANDOLLE was the investigation of the herbarium of GASPARD BAUHIN. GASPARD or KASPAR BAUHIN was born at Basle in 1560, and died in the same city in 1624. His herbarium has since 1802 been in the possession of the University of Basle, and it was in the year 1818 that PYRAMUS DE CANDOLLE first devoted himself to its study, giving special attention to the synonyms of the plants named in BAUHIN'S celebrated *Pinax*. The revision was, unfortunately, never completed, but sufficient progress had been made to induce M. CASIMIR DE CANDOLLE to publish the results of his grandfather's investigations on the synonyms of the plants mentioned in the *Pinax*. These are now issued in a convenient booklet, entitled *L'Herbier de Gaspard Bauhin*, which comprises the textual reproduction of all the determinations made by the elder DE CANDOLLE in his copy of the *Pinax*. Appropriate prefixes and a portrait of PYRAMUS DE CANDOLLE accompany the volume.

"A GARDENER'S YEAR."—We have on more than one occasion called attention to the serviceable nature of Mr. RIDER HAGGARD'S notes in the pages of the *Queen* on gardening, and now learn that the notes are to be issued in book form under the title, *A Gardener's Year*, with twenty-six illustrations. This work is not a text-book, but a record kept throughout the year of the various operations carried on in a Norfolk garden of moderate size, in which a good many varieties of fruit-trees, flowers—including Orchids—and vegetables are grown. It also treats incidentally of matters kindred to their cultivation. The author hopes that it may please those readers to whom such things are of interest, and at the same time convey a certain amount of useful information which may help towards the establishmant of a successful garden. The book is to be published by Messrs. LONGMANS & Co.

SAHARANPUR BOTANIC GARDEN. — This garden, with which are associated the names of FALCONER, ROYLE, and more recently of DUTHIE and others, is now under the management of Mr. LEAKE.

TOO MUCH POTATO!—At the recent "cooking test," the judges were called on to taste and deliver judgment on no fewer than sixty-seven samples. How did they do it? Sixty-seven different pots were made use of for cooking the tubers. Where did these pots come from? Who cleaned them after the feast? Some of the samples of each variety came from Essex, some from Lincolnshire, and some from Scotland, and it was remarked that the flavour of those grown in Essex was superior to that of those grown in Scotland. Among those noted as excellent were Up-to-Date, The Crofter, Dalmeny Hero, Charles Fidler, Duchess of Cornwall, Sim Gray, Highlander, Twentieth Century, and Dobbie's Favourite.

A SOCIAL GATHERING IN THE NORTH.—A large attendance of *employés* and friends of Messrs. DOBBIE & Co., Rothesay, met in the Public Hall, Rothesay, on Friday, December 23. Councillor FIFE presided, and was supported by his partner, Treasurer BURNIE. Among others present was Mr. JAMES DOBBIE, founder of the firm. The hall was beautifully decorated with greenery and cut flowers, the catering being in the hands of Mrs. JOHNSTON, Victoria Restaurant. The evening's entertainment included singing and dancing.

"WILLING'S PRESS GUIDE."—This publication is always welcome, and the present, thirty-second, annual issue seems even fuller of information than were its predecessors. It contains, as most readers know, a list, with addresses, of all the periodical literature of Great Britain, tables arranging these publications according to their subject matter, and other particulars concerning them. Appended are lists of the principal Colonial and foreign journals, and a variety of general information. *Willing's Press Guide* is obtainable from 125, Strand, W.C., and from 162, Piccadilly, W.

VANISHING PLANTS.—The *Gardeners' Chronicle* for December 17 contains an interesting letter from Dr. PEREZ, of Teneriffe, relating to Statice arborescens, Broussonet. It is much to be regretted that the number of species dying out from their original habitat is increasing. Dr. PEREZ speaks of a species peculiar to Teneriffe which, he tells us, is all but extinct owing to unknown causes, but found a refuge in two small islands, where it is likely to be extirpated by the goats. There would be less cause for regret if this curious and characteristic species were really, as the *Index Kewensis* states, identical with S. fruticans, Webb, which may, it seems, still be found near Bueno Vista, Teneriffe. But if Boissier's monograph (*Prodomus*, De Candolle, vol. xiii., p. 636) is to be believed these two species, though allied, differ first in their size (the leaves are three times smaller), which I am aware is not a reliable botanical characteristic, then in the stem, which has the branches unprovided with wings; in the bracts, which are hairy within and with less spreading tips, and so on. The species being then distinct, and Teneriffe and the Canaries being classic ground for Statices of the nobilis group, which seems to be of ancient creation, it is important to try to preserve these floral treasures in their habitats. Dr. PEREZ tells me that he cultivates the Teneriffe Statice; will he let me suggest a proposal which the Association for the Protection of Alpine Plants seeks to encourage in Switzerland, that of the creation *in situ* of an enclosure or sanctuary well fenced from the attacks of goats and rabbits. The spot should offer as nearly as possible the conditions of the plant's home, and the barriers must be strong. This little garden or enclosure must be protected by some local political or scientific authority, and the natural propagation of the species must be assisted by every means known to horticulture. Dr. PEREZ, who still possesses some specimens of this vanishing type, could perhaps plant some of them in some such position, and thus contribute to the preservation of an interesting species that would otherwise become extinct. To those who consider me as holding Utopian views, I would recall two facts recorded in the *Gardeners' Chronicle*. Psiadia rotundifolia, Hook., once abundant in St. Helena, is now only represented by a single specimen, which was figured February 11, 1888, and a regret expressed that it was the last of its race. It is interesting as being the only shrubby Composite in that island which has survived to this time. On the other hand, Mr. A. D. WEBSTER, in *British Orchids*, pp. 41—44, speaks of the distribution in Ireland of Spiranthes Romanzoviana, Cham., whose only European habitat is on the coast of Bantry Bay, near Castletown, in the South of Ireland. In 1844 BABINGTON foretold the approaching disappearance of this plant, which is interesting as being the only Orchid known which forms the flower-buds for the next year before the fall of the current year's leaves, suggesting to this botanist that it formed bulbils in the axils of its leaves as does Lilium bulbiferum. The plant has been so sought by collectors and uprooted by natives, that in 1887 Mr. WEBSTER wrote in the *Bulletin de l'Association pour la Protection des Plantes* (1888, p. 24), that it might be considered to have disappeared, with the exception of some cultivated specimens at Kew and in Dublin. There is, it is true, a Romanzoffia, closely allied to it, which the *Index Kewensis* considers to be identical, and which is found in North America. BENTHAM, and after him LINDLEY, considered the two to be distinct. *Henry Correvon, Chêne-Bourg, Geneva.*

SOFT-ROT OF CALLA.

SINCE the short note on p. 410, a correspondent (p. 466) has intimated that the same disease was observed in this country four or five years ago. It seems to have been first noticed in the United States about five or six years ago, but attention has been specially directed to it by a report issued by the Department of Agriculture* during 1904. Probably the same disease was known to a limited extent in New Jersey in 1893. The Callas are found rotting off at or just below the surface of the ground, the decay sometimes extending down into the corm, sometimes upwards into the leaves, and frequently in both directions. Occasionally the disease seemed to start in the edge of the leaf-stalk, in the flower-stalk, or in some underground part of the corm, though as a rule it started at the top of the corm, just above but near the surface of the ground. The disease was worse and spread most rapidly in houses where the Callas were grown in solid beds.

When a diseased corm was cut open, it was found that there was a distinct line between the

* Bulletin No. 60, *A Soft-Rot of the Calla Lily*. By Dr. C. O. Townsend, June 30, 1904.

healthy and diseased portions of the corm. The healthy portion was firm and nearly white; the diseased part had a decidedly brown colour, and was soft and watery. When the disease extends upwards into the leaves, it is the edge of the petiole that first becomes involved, the affected part becoming slimy without at once losing its green colour. As the disease progresses towards the centre of the petiole, the edges of the leaf become pale, then brown. Pale spots, turning brown, then appear in other parts of the leaf-blade, and finally the whole leaf becomes brown and dead. Frequently the disease develops so rapidly that the leaf rots off at the base and falls over before it has time to lose its green colour. When the disease attacks the flower-stalk the flower turns brown, and the stalk, without having decayed more than a fraction of an inch, eventually falls over. When the disease works downwards through the corm it reaches the roots, which become soft and slimy within, while the epidermis remains intact; eventually the slimy contents dry up, and only the dead skin of the roots remains. When the disease begins below the surface of the ground, the lower portion of the corm frequently rots away, causing the plant to fall over, without any previous indication of disease.

If the conditions for the development of the disease are unfavourable after the corms are affected, the softened spots will dry down and become darker in colour. In these spots the disease may remain dormant until the conditions are favourable for its further development. In this way the disease is carried over from season to season, and it may be transported.

Examination has proved that the cause of disease is a minute organism of the Bacteria kind, which has been called Bacillus aroideæ, which need not be described here, of which artificial cultures have been made, and healthy plants have been inoculated therewith, producing the disease as well as in some other plants. This organism occupies the intercellular space in the host and dissolves the layers that connect the cells, causing the affected tissue to break down into a soft slimy mass. It is able to attack a large number of raw vegetables, and is capable of producing soft-rot in many of our useful plants, such as Carrot, Potato, Turnip, Radish, Cabbage, Cauliflower, and such green fruits as Tomatos, Eggplant, and Cucumber. Care must therefore be taken not to throw any decayed or partly decayed Callas, or the soil from a bed in which Callas have decayed, to any place where the vegetables above mentioned are to be grown.

It does not attack tree-fruits readily, and hence is not likely to produce fruit-rots. Its growth is not affected by diffused light, but direct sunlight will kill the organisms when isolated in from five to fifteen minutes.

The successful treatment of diseased plants in the bed was considered impracticable, and preventive measures had to be resorted to. It is safe therefore to state that the soft rot of the Calla may be prevented or held in check sufficiently for all practical purposes by changing the soil every third or fourth year, depending upon the number of cases of rot that appear, and by exercising due caution in selecting only healthy plants for the bed. Diseased corms may be detected even in the dormant state by examining for discoloured spots, but it is safer to start the plants in pots, even after the corms having discoloured areas have been rejected, to ensure getting as few diseased plants as possible in the beds, since some corms are so slightly affected that the disease is not easily detected in the dormant state. *M. C. C.*

PUBLICATION RECEIVED.—*Trade Press List* (American), 50, Central Street, Boston, Mass., U.S.A.

ASPARAGUS SPRENGERI IN FLOWER.

I SEND you a photograph of a spray of Asparagus Sprengeri taken when the plant was in full flower. This plant is 7½ feet in length, and the upper portion 3¾ feet in width. The aroma of the flowers is very pronounced and delicious, especially in early morning, and resembling that of Peaches when very ripe. The flowers are a great attraction to bees. The species is worthy a place in every conservatory and is most effective when planted with Asparagus deflexus in hanging baskets. The flowers of the latter species are not conspicuous, but when the plant is studded with scarlet berries intermingled with the feathery foliage, it is very attractive. Both species are native of Zululand.

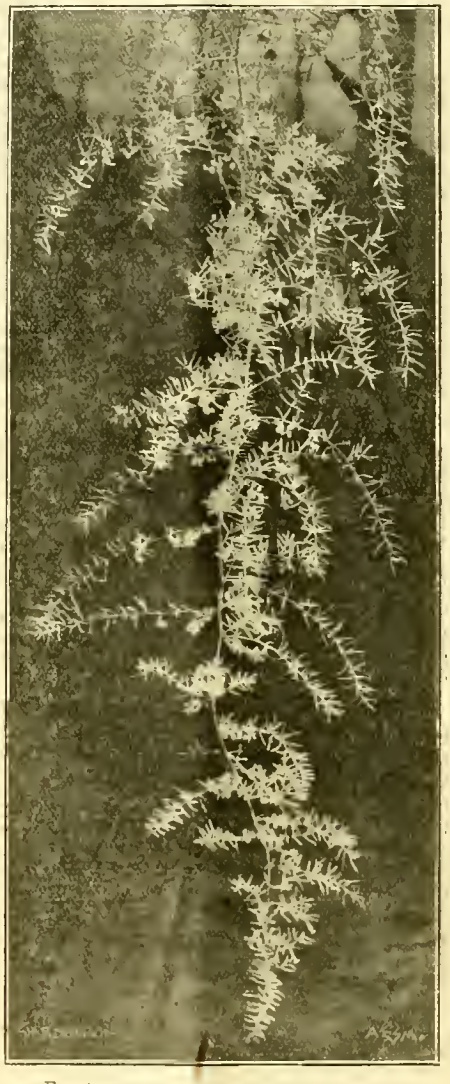

FIG. 4.—ASPARAGUS SPRENGERI IN FLOWER.

Asparagus Sprengeri was discovered by J. Medley Wood, Esq., of the Natal Botanic Gardens, Durban, growing in the kloofs, where I am told it grows luxuriantly, hanging in festoons, and forming an imposing sight. Mr. Wood forwarded specimens to Italy, to see if it was already in cultivation, but heard nothing further until it was introduced as Asparagus Sprengeri by Mr. Sprenger, nurseryman, Naples, Italy. I think a word of praise is due to Mr. Wood for introducing such a valuable plant, also for other introductions, such as Cyrtanthus O'Brieni, Ceropegia Woodii, &c. I may say the plant of A. Sprengeri was put into the basket, which is 12 inches in diameter, from a 7-inch pot. The photograph was taken nine months later, and serves to show how rapidly the plant grows. *W. Thorpe, Gardener to J. M. Collett, Esq., Hillfield, Gloucester.*

FOREIGN CORRESPONDENCE.

NOTES FROM JAPAN.

THE GENUS ANEMONE.—Among early spring flowers is the delicate Anemone Hepatica. I like this charming species, and cultivate many wild varieties of various colours. They flourish in a cool, windy place, as is general with all Anemones. The winter sunshine causes them to open into unexpected beauty, and they continue in bloom for a long time. It may be said that this Hepatica has two different forms, one with sharply-pointed lobes to the leaf, the other obtuse at the tips, as is seen in the wild specimens. These may be collected in the same mountainous region far from Tokyo.

Besides this Hepatica there are other species of the genus Anemone which prefer woodlands and hillsides, with rich light soil and partial shade. They are not generally known in our nurseries. I will here enumerate the names only of the species I know; they are as follows:—A. altaica, Fischer; A. cernua, Thunberg; A. gracilis, Fischer; A. flaccida, Fr. Schmidt; A. japonica, Siebold et Zuccarini; A. Keiskeana T. Ito.; A. nikoensis, Maximowicz; A. Reddeana, Regel; A. stolonifera, Maximowicz.

ADONIS DAVURICA.—There are only two species of the genus Adonis known in Japan—A. davurica, Ledebour, and A. villosa, of Ledebour. The wild species I have occasionally met with in mountainous and northern regions. It blooms freely, and the beautiful flower is yellow in colour and prefers sunshine, and is afterwards gradually hidden away under the surrounding foliage, which forms a good shady situation for it. Bearing this natural aspect in mind our successful cultivators imitate the natural conditions and so acclimatise it in our gardens. The common form of the plant was brought last year into our market by professional florists. These plants are admired by us, and grow well in pots in the early, pleasant days of the year. There are many garden hybrids and varieties which are raised from seedlings. Some of them are less beautiful than is the common one, but they are appreciated by those who like rarity and novelty. *K. Hagiwara, Tokio.*

TREES AND SHRUBS.

THE HANDLING OF SEEDLINGS.

THE raising of plants from seed is usually an easy matter, as it is only a question of providing the proper conditions of heat and moisture necessary for germination to ensure a fair crop of seedlings if good seed is used. It is when the seedlings have become large enough to require transplanting that the greatest difficulty arises. As there are so many individual wants to satisfy, it becomes a matter of forethought to ensure that each different class of plant shall be grown under the conditions and in the soil best suited for it. It may be argued that seedlings of hardy trees and shrubs are hardy, and able to look after themselves if kept clear of weeds, but in practice this is not the case by any means, as like other classes of plants some are quick-growing and easy to cultivate, others are slow of growth and require constant attention, while some are either easy or difficult subjects according to whether their requirements are properly understood or not.

Those that can, to a certain extent, be left to look after themselves are chiefly forest and

underwood species, such as Horse Chestnut, Beech, Pine, Sycamore, Spruce, Larch, Alder, Quick, &c., though in the case of some of these a certain amount of knowledge is required to know where to plant them, as it is utterly wrong to plant Larch or Sweet Chestnut, for instance, in low damp ground where they are liable to be cut by spring frosts; or Spruce on a poor stony hillside where it cannot grow. The Douglas Fir and Silver Fir are quick-growing plants that require a rather poor dry soil, as if planted in strong ground they make long weak leaders, which spoil the shape of the plants in after years; a long leader in a young state meaning so much bare stem when the plants get older. Spruce, Larch, Beech, Oak, &c., require good deep ground where they can grow quickly, as the faster they grow the better and "kinder" plants they make.

The greatest difficulty with seedling hardy trees and shrubs arises when we come to deal with purely ornamental plants, many of which require careful handling to ensure properly-shaped and well-rooted specimens afterwards. Probably the common Holly is the worst, as it requires constant attention to keep it in proper condition for removal, strange though it may seem that an indigenous plant should give more trouble than many exotics. Seedling Hollies require to be transplanted annually for the first three or four years after being taken from the seed-bed, at the end of which time they will stand and keep well rooted for two years. The following plants, Arbutus, Cytisus, Genista, Magnolia, Photinia, Ulex, Abies grandis, Cedrus, Tsuga Mertensiana, and in fact the majority of Conifers, must be transplanted annually for at least two years after leaving the seed-bed, or they will get coarse-rooted and at least fifty per cent. of them will die after transplantation if left longer than a year without being moved. Sequoia and Libocedrus especially must be shifted every year until they are in permanent quarters, for they grow fast and make long thick roots if left for two seasons, the cutting off of which will either cause the death of the plant or else cripple it so much that it takes two or three years to recover.

An attempt to avoid the trouble of handling many subjects that are difficult to transplant is made in many instances by growing them in pots; but this system cannot be too strongly condemned, as pot-culture is ruinous to most hardy, ligneous plants, especially those which ultimately form trees. There are three plants that cannot be handled successfully in the open ground, and they are Cratægus Pyracantha, Garrya elliptica, and Quercus Ilex, none of which I have ever been able to transplant with success, for even if they do not die, the upper part of the plant dies away, and instead of growing larger it gets smaller and weaker year by year. Excepting these three species there is practically no plant that cannot be handled successfully in the open ground. To grow Coniferæ, such as Abies, Picea, or Pinus, or any which make large trees with age, in pots, is a great mistake, as the roots take the shape of the pot, and rarely, if ever, get away freely when planted out. To have plants in pots seems to have become the rage this last two or three years, but plants from the open ground are far preferable, if they have been properly transplanted and kept in good order for removal. *J. C., Bagshot.*

PEAR PASSE CRASSANE.

In our issue for December 24, Mr. Geo. Woodward, in his article, "Pears for Christmas and After," referred to the variety Passe Crassane in the highest terms of appreciation, and described it as a winter Doyenné du Comice (fig. 5). We have since received some specimens of the Pear from Mr. Woodward, and are disposed to agree fully with his estimate of its merits. The fruits are now at their best, but some of them, Mr. Woodward informs us, will keep in good condition until March.

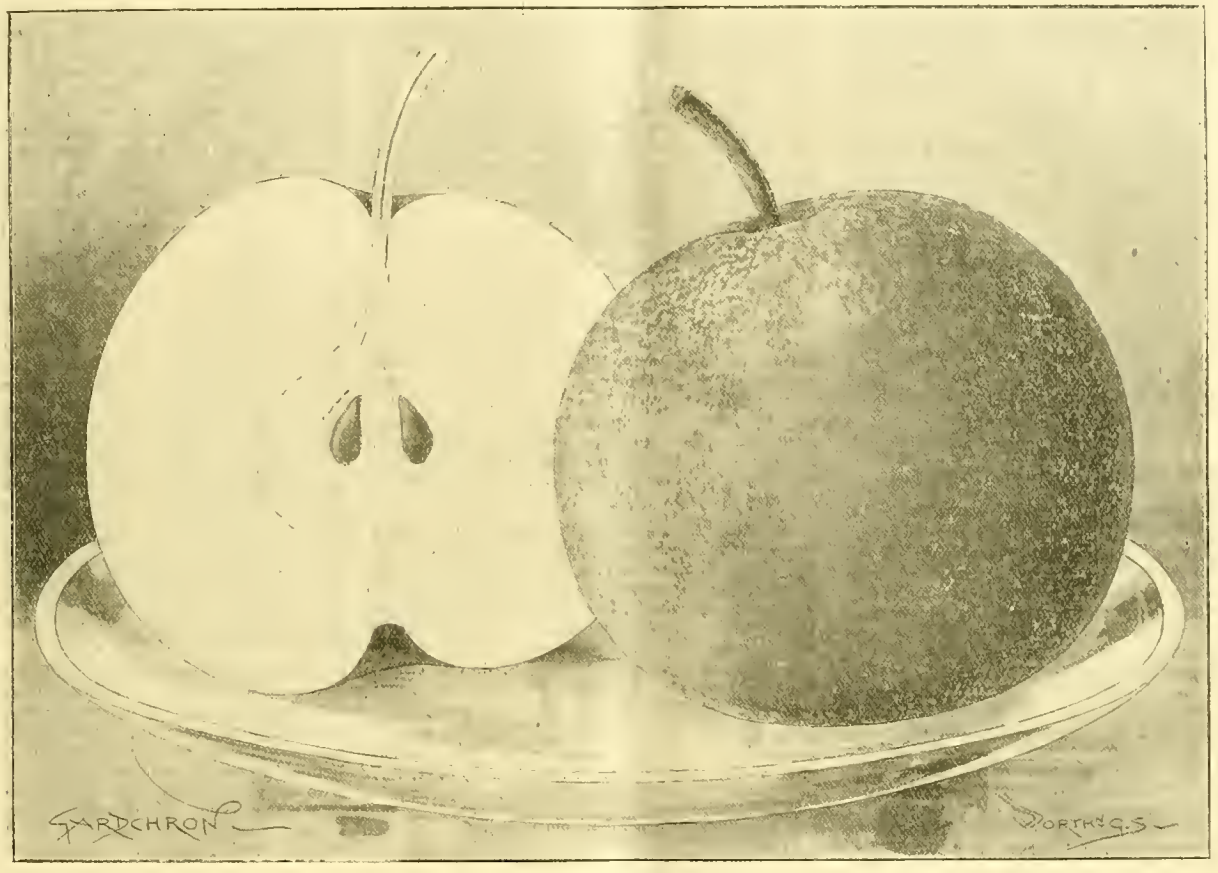

Fig. 5.—Pear Passe Crassane.
(From specimens supplied by Mr. Geo. Woodward.

FLORISTS' FLOWERS.

NEWER VARIETIES OF PENTSTEMONS.

For some time past I have taken a deep interest in Pentstemons, selecting the best named sorts and growing them as well as I can; and as every season adds to my list of varieties, making a final selection is a matter of considerable difficulty. This season I am growing a batch of varieties introduced by Mr. Forbes last year; and for the benefit of those interested in Pentstemons I have noted a few of those most desirable. Crimson Gem is perhaps one of the most effective varieties in existence. The colour is dazzling crimson-scarlet, the throat broadly margined with cinnamon. Emile Rodigas is the brightest scarlet Pentstemon I know, a distinct advance even upon Lord Lister, Phryne, or George Howe. The throat is pure white, and the bells fully 2¼ inches in diameter. The habit of growth and strength of the flower-spike are all that could be desired. Miss O. Inglis is not quite so large in the bells as some, but

point of colour it is distinctly pleasing. The bells are rosy-scarlet-coloured, and the throat white, margined and striped with rose-colour. Marcel Dubois reminds one much of Talma; in colour it is blush-white margined with rose, paler than in the case of Talma. It produces a vigorous flower-spike, and in every way is desirable. Jules de Lerne is of sturdy growth, producing a large spike of carmine-coloured flowers with pure white throat. R. Heywood Thompson has deep-rose-coloured bells, and a white throat, margined with pale rose, flushed and striped with purple. Dr. Barrie is purple-crimson or of deep-claret colour, a fine spike with bells 2½ inches in diameter. Henry Parr is rose-coloured, with a white throat margined and splashed with scarlet, of vigorous growth, producing a long spike of well-formed flowers. Marconi has rosy-crimson bells and white throat, veined and spotted with crimson and margined with rose colour. Edwin Beckett has the outer part of the bell of rose colour, fading to pale rose; the throat is white, veined and splashed with purple and scarlet. Commandant Jouve grows fully 3 feet high and produces a compact spike of huge bells of a purple claret colour, the white throat is margined crimson. M. Deherain is of dwarf growth with rosy-crimson bells, bordered with red, throat veined with white. Daniel Bellet has rose-coloured bells and a white throat, which is pencilled with crimson and margined with chocolate colour. C. R. Fielder is of a rich rose colour, but the white throat is margined with chocolate colour. The plant produces a fine closely set pyramidal spike of flowers. Lord Rothschild is of rose-pink colour, and the throat is veined and margined with crimson. John Jennings has bells 2 inches in diameter, of rose colour; the throat is white, margined with crimson. Miss Talbot has rich dark crimson bells and pure white throat. *E. Molyneux.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

FOSSIL PLANTS.—Your correspondent "M. A." (December 24, p. 452) gives the names of some plants still to be found growing in recent formations of the post tertiary system, which also flourished in the coal measures of the carboniferous system of the Deutozoic life period. The names of plants mentioned by "M. A." are the Mare's-tails, Equisetums and Ginkgo biloba; I always prefer its synonym, Salisburia adiantifolia, as being by far the prettier, and certainly the most easily-pronounced name. Might not "M. A." also have included in his list that of Taxodium distichum as a present-day continuation plant of the carboniferous formation, as we read of its roots being found at great depths in the under-class of the Cypress swamps of the Mississippi valley, just as stigmaria—the roots of Sigilaria—are found in the under-clays of the coal measures? And are not our Araucarias, Cycads, and some forms of the present period but a continuation also of the flora of the carboniferous life period? Many fine avenues and isolated specimens of Araucaria are to be met with throughout the country, succeeding best on dry soils, and where the thermometer does not fall very low. Some handsome specimens of Taxodium distichum are also to be met with; a very fine tree of it may be seen in the park at Combe Abbey, which I measured with an Abney level in 1887; its height then was 75 feet, and circumference at 3 feet from the ground 11 feet 6 inches. The same tree measured by J. C. Loudon in 1843 was 47 feet high, and diameter of trunk 2 feet 3 inches. There is a large specimen at Asbury Priory, the seat of F. A. Newdigate, Esq., M.P.; but unfortunately during that ever-memorable and destructive hurricane of Sunday, March 24, 1895, a large piece was broken from off the top of it. Loudon, in his *Arboretum*, gives a list of the localities where Taxodium may be seen, also of when planted, their height, and diameter of both "top" and "butt." This tree thrives best in moist places. "M. A." incidentally remarks that Salisburia adiantifolia makes an admirable tree for town or street planting. Would he kindly give some information as to where it may be seen in this position? and also whether he could give any information where in this country the Ailanthus glandulosus, or Tree of Heaven, may be seen as a street or town tree? [We know of specimens of each in the environs of London. ED.] Why the Ailanthus should also be known by the synonym of "Tree of Heaven" I am at a loss quite to understand. Is it because it grows so tall? But have we not trees in this country which tower heavenwards by many feet higher than the Ailanthus? We need only mention such trees as the Elm, Douglas Fir, the Lombardy, and the Black Poplar; all of them are quite as entitled to be "trees of heaven" as the Ailanthus. At present the choice of trees for town planting seems to be chiefly confined to two species, viz., Platanus orientalis and varieties of Tilia or Lime tree. Surely some other trees might be found quite as suitable and certainly quite as handsome as either of the above! During a short spell of dry weather the Lime-tree drops its leaves and looks seedy for the remainder of the season, and added to this it gets the credit of being the cause of much of our dark-coloured and unwholesome honey. When our scientists, who are now busy with the enterprise of ridding our large towns of smoke and fog, have succeeded, we may then see our streets ornamented with a choice collection of fine trees. I should like to see the Ailanthus more generally planted as a town tree; it retains its graceful foliage until the arrival of the first frost, when shade from the sun is no longer necessary, and being a tall grower it would form a high canopy over the street, thus rendering unnecessary the cutting away a portion of the tops of trees which intercept the view. This sort of treatment may be seen all the way up the Rhine, especially where the boulevards of towns run parallel with the river. The residents must have shade, and they must also have a view of the river and of the opposite bank. Where such enchanting scenery exists as is to be found there, the view ought never to be impeded or obscured—no, not even by a single twig. *W. Miller, Berkswell, January 2, 1905.*

SPIRÆA BILLARDI. — According to Zabel's classification of Spiræas this is a variety of S. Menziesii ×, a hybrid between S. Douglasi and S. salicifolia. It belongs to the sixth (Euspiraria) section of the genus, of which the well-known S. Douglasi is a typical example. The list of this section is as follows:—

S. difformis (alba × corymbosa), S. d. var. effusa, S. d. var. typica, S. d. var. subincisa.
S. salicifolia and vars.
S. Menziesii (Douglasi × salicifolia), S. M. var. triumphans, S. M. var. pseudo-Douglasi, S. M. var. angustifolia, S. M. var. eximia, S. M. var. ovalifolia, S. M. var. macrothyrsa, S. M. var. Billardi, S. M. var. Lenneana.
S. Douglasi.
S. pallidiflora (Menziesii × tomentosa).
S. tomentosa.

Zabel, however, made nearly as many varieties or hybrids as he grew plants, so that it is a difficult matter to know the differences between some of them. There is really very little distinction between the above varieties of S. Menziesii. *J. C., Bagshot.*

EFFECTS OF RECENT FOGS ON PLANTS AT KEW.—Last month will be remembered at Kew as one in which an exceptional amount of damage was done to indoor plants by fog. Nothing like it has been experienced here since the winters of 1889-90 and 1890-91, when fogs proved so injurious, not only near London, but in other parts of the country, as "to cause dismay to all interested in horticulture, and gave rise to a general feeling that something ought to be done." This led to an investigation, at the instance of the Scientific Committee, of the "Effects of Urban Fog upon Cultivated Plants" by Prof. F. W. Oliver, and his report was published in the *Journal of the Royal Horticultural Society*, vol. xiii., 1891, and vol. xvi., 1893. He found that the injury to plants caused by fog in the neighbourhood of large towns was due to the presence of various poisonous vapours, particularly sulphurous acid, which come chiefly from coal smoke. These poisons cannot be kept out of plant-houses except by contrivances which are not practicable, and we are therefore reduced to the very indifferent expedient of maintaining a comparatively low temperature and a dry atmosphere in the houses whilst the fog is upon us. It is doubtful if these conditions serve to mitigate the ill-effects of fog. At any rate, we have suffered terribly at Kew, notwithstanding the precautions taken to lessen the effects. Sulphurous acid could not be kept out of the houses, whilst over everything outside, including the glass, there was deposited a layer of what might be called a mixture of tar, oil, and soot, which has stuck hard, darkening the houses, and no doubt doing much damage to outside vegetation. The gardener in the country knows nothing of these difficulties, but it is to be hoped that he does not overlook them when he inspects the work of his less fortunate brethren. Up to the middle of December the indoor collections at Kew were healthy and flourishing, although a few delicate Orchids, such as Calanthes and Dendrobium Phalænopsis, and some greenhouse plants, particularly Begonias and Acanthads, were injured by the fogs of November 14 and 15. But the dense, dirty fogs experienced from December 19 to 27 were most destructive to many kinds of plants. In the Palm-house the leaves fell as thickly as they do out-of-doors after a frost in October, and it was almost as bad in the Temperate-house. Winter-flowering plants were stripped of their flowers and buds, whilst such genera as Coleus, Moschosma, Euphorbia, Reinwardtia, Bouvardia, Jacobinia, Aphelandra, Salvia, Eupatorium, Poinsettia, Echium, Tecoma, Begonia (tuberous and evergreen sections), Brunfelsia, Luculia, Solanum, Piper, Codiæum (Crotons), Ipomæa, Panax, Clerodendron, and Bougainvillea were in most cases reduced to bare sticks. Even the Acacias in the Temperate-house suffered, and such sturdy shrubs as Coffea, Gmelina, Barringtonia and Cæsalpinia were severely hurt. The climbers under the roof of the Palm-house were on the whole the greatest sufferers, due probably to the poisonous vapours being thickest nearest the glass. A list of the genera that suffered most numbers 118, exclusive of Orchids. In the Orchid-houses all the flowers and buds of Angræcum, Phalænopsis, Calanthe, Catasetum, Dendrobium, Lælia and Cattleya were destroyed. So far as my observation goes plants in the open-air are not affected by fog in the same way as those under glass. No doubt they are injured by the greasy-sooty deposit on their leaves and stems, but sulphurous acid does not cause the leaves to fall off at once as it does the leaves of shrubs grown under glass. *W. Watson, January 4, 1905.*

COLOUR IN APPLES.—I think that moisture plays an important part in producing colour. In writing of moisture, I mean the natural rainfall, not artificial watering, although trees copiously watered during the summer will, other conditions being favourable, produce highly-coloured fruit. I do not refer to such Apples that colour well in any season, such as Worcester Pearmain, Gascoyne's Scarlet Seedling, Mère de Ménage, &c., but to such Apples as Cox's Orange Pippin, Ribston Pippin, Boston Russet; and, among cooking Apples, Tower of Glamis, Alfriston, &c. The sun plays an important part in bringing out the colour, but some soils will produce a higher and more intense colour in both Apples and Pears than others. Is this due to the presence of iron in the soil? The most striking example of moisture producing colour which I have ever noticed was during the past summer, after the heavy rains we had in the month of July—4 to 5 inches. One could almost see the colour deepen day by day, not only in fruit, but in other things. Some Dracæna-leaved Beet, that was quite green, assumed a blackish-crimson colour a day or two after the rains, while it was also most noticeable in other root crops. Gravenstein is a good-flavoured Apple, but, like many other good things, it is very sparingly produced here. I could have shown good fruits of September Beauty at the Royal Horticultural Society's show, but put up Mabbott's Pearmain instead. I have never had Cox's Orange Pippin of such superb colour as they are this season, while the flavour is exceptionally good. I staged them twice in open competition; on both occasions there were over thirty-five entries, but they were

far ahead of the others in colour and finish. Lady Sudeley has with me been much deeper in colour than usual this season; it is a grand early Apple to gather as required from the tree, and it is almost too large for dessert. *T. H. Slade, Poltimore Gardens, Exeter.*

LILY OF THE VALLEY. — Mr. Vrengdenhill, Haarlem, Holland, says, *Gardeners' Chronicle*, December 31, p. 466, "There seems no reason why they [flowers of the Lily of the Valley] should not be crystallised with sugar for sweetmeats." He does not seem to be aware that the Lily of the Valley is harmful in all its members, the flowers being the most dangerous part. The *Revue Horticole* published some time ago an account of the poisoning of a brood of fowls by the decaying flowers of the Lily of the Valley. Only the parent birds survived, and one out of ten chickens. *George Henslow (Rev.), Drayton House, Leamington.*

THE EPHEDRAS—JOINT-FIRS.—The members of the peculiar genus Ephedra, which look like the remains of some prehistoric vegetation, and bear strange resemblances to the Equisetums and Hippuris in form, are rarely seen in gardens, except where scientific collections of plants are grown; yet for rockeries or dry situations some of the species are useful, attractive with their bright red fruits, and graceful in habit. They are not difficult to grow, and are readily increased by layers. One of the most beautiful is the Himalayan E. Gerardiana, which grows freely, but does not usually exceed 18 inches or 2 feet in height. The stems and branches are slender, terete, suggestive of the smaller Equisetums, or a miniature Cytisus præcox; but there is a slight glaucous tint which adds to its beauty. E. nebrodensis is a much more vigorous species, reaching 2½ or 3 feet, and bearing a strong resemblance to the common Horsetail. Both these Ephedras thrive in any ordinary soil which is not too wet; and their resemblance to the Equisetums is confined to the form of the growths. The twenty or thirty species known are interesting also for their geographical distribution, for Europe, North and Central Asia, North Africa, North and South America, all include representatives. In Loudon's time it was suggested that some of these plants might be grown in dry regions as a soil-covering, in place of the grass of moist climates; but I am not aware that any extensive experiments have been undertaken in that direction. *R. L. C.*

CARNATIONS GLACIER AND MRS. S. J. BROOKS. —The original stock of Glacier I obtained from Messrs. Wm. Cutbush & Son when it was first offered. On changing situations about two years ago, I brought cuttings of Glacier with me. I found here Mrs. S. J. Brooks, which I was informed was also obtained from Messrs. Wm. Cutbush & Son. How is it that the two varieties are alike? I cannot take advantage of the kind offer of Messrs. Cutbush to show me the two varieties growing in their nurseries, but should be pleased to accept flowers and foliage of the two varieties. *Henry Butcher, Whcatley Park Gardens, Doncaster.*

THE CULTURE OF EUCHARIS (see vol. xxxvi., p. 412).—The most successful cultivator of these plants I have known used only hard water for them. Mr. Hambly, the gardener in question, was for some twenty years head gardener and steward to Chas. Aldenburgh Bentincke, Esq., and grew a largo number of these plants in big specimens that to my certain knowledge occupied the same pots for ten years, and were flowered never less than twice, and often three times, each year; and further, the great leathery and robust foliage was distinct testimony that the strain upon them was not unduly great. The *modus operandi* as adopted by Mr. Hambly was as follows:—Immediately the flowers were cut for the decoration of the mansion or town demesne a much less quantity of water was afforded to the roots, and gradually the supply was withheld until the plants flagged somewhat, when they were transferred to an ordinary greenhouse temperature in winter, and to the Peach-house in summer. At the time of removal they were immersed in a tank and thoroughly saturated. The plants received no further supply of water until the leaves hung limp over the pot, and after this process had been repeated three times they were plunged to the rim in new tan in the stove. Hot-water pipes ran through the central bed, and a very high temperature was maintained, to which the plants invariably responded by producing a wealth of flowers. Fibrous loam only was used in top-dressing, with an occasional dose of liquid-manure prepared from sheep and fowl droppings, commencing from the time the flower-spikes made their appearance. *Walter H. Aggett.*

TREE CARNATIONS AT WORTH PARK, CRAWLEY, THE RESIDENCE OF MRS. MONTEFIORE.—A fine collection of these plants is now in fine flower at Mrs. Montefiore's residence. The plants are strong and vigorous, perfectly clean, healthy, and well-grown specimens. One large span-roofed house contains several hundred plants arranged on a high central stage quite close to the top of the house, sloping down to the path, facing all round, forming a lovely bank with scarcely a pot visible. There are also side benches filled with dwarf-growing varieties. It is a charming arrangement and will form a delightful picture all through the winter. The following sorts are grown in large quantities: Winter Cheer, Lady Carlyle, Mme. Franco, William Robinson, La Neige, Duchess of Devonshire, and Worth Park Favourite, a fine red variety raised by Mr. Allen, the head gardener. Large quantities of cut flowers are required during November and December. Two houses contain "Malmaison" Carnations in healthy condition, and just coming into flower; Churchwarden and Lady Ulrica are splendid in size and colour. Carnations are quite a feature. Several other houses contain Begonia Gloire de Lorraine, Coleus thyrsoideus, zonal Pelargoniums, and Chrysanthemums. It is a fine range of glass, and one house is allotted to each class of plants. Late Grapes have been excellent this season, especially Muscat of Alexandria and Black Alicante. *R. H. H.*

RIPENING WOOD-GROWTH ON NORTH WALLS. —When comment is made on the ease with which the shoots of the Morello Cherry ripen or mature on a north wall, it should be remembered that the shoots of this Cherry are invariably of a nature that admits of hardening or ripening under cool conditions as easily as the wood of Pears. Plums or Sweet Cherries will ripen on east or west walls, and very often the more tender wood of Peaches and Nectarines on south walls. It is true that some Pears and Plums will produce good fruit and ripen wood on north walls, but only in warm seasons and in Southern localities. I have seen Victoria fruiting finely on a north wall at Hackwood Park, Basingstoke, and in that way keeping up a long succession of fruit; but the finest fruit and crops, taking the average of years, are on east walls. In such a hot garden as that of Syon House, Middlesex, it is easy to understand Mr. Wythes' advocacy of the utilisation of north walls for certain Pears, but it must not be forgotten that even though little or no sunshine might fall on the trees, yet there the great heat absorbed by the brickwork on sunny days on the south side must serve to warm the wall on the north side materially, and in that way help to the maturation of the wood. A solid wall of brickwork once well heated by the sun parts with that warmth slowly, and trees on both sides of the wall greatly benefit. Even in Lancashire no doubt the same sun influence through the wall tends to the same end that is found in the South. *A. D.*

DAHLIA THE MIKADO.—I note on p. 455 of the last volume that amongst the National Dahlia Society's list of Dahlia novelties (for) of 1904 there is a single-flowered variety called "Mikado." A year previously this name was given to a novelty from the firm of H. Kohlmannslehner, Britz, Berlin, and as I am agent for this firm I beg to bring the matter before your readers to prevent any error. "Mikado" (Kohlmannslehner) was described and illustrated in *Die Gartenwelt*, vol. viii., p. 24, as one of the best novelties of its year. The flower very much resembles a "Chrysanthemum," and if this name had not already been given to a recent variety the raiser would have adopted that name. The thin tubuliformed florets, which are twisted and incurved, are of dark cherry-red colour. The flower is in size a little larger than "Red Rover," and very free-flowering, and was given the highest Certificate from the German Dahlia Society. Enclosed please find a copy of the issue of *Die Gartenwelt* in question, which contains the rules adopted by the German Dahlia Society. *Frank Koehler, London.*

CUCUMBER DISEASE OR "SPOT."—In reply to Mr. Owen Thomas's request with regard to the Cucumber disease or "spot" (Cercospora melonis) (December 24, p. 438), which has caused such severe damage and involved such enormous financial losses to the growers during the past ten years, I venture to give the results of several experimental trials of remedies which have been made at a large market-growing establishment in this neighbourhood, extending over the past four years. The proprietor has been a Cucumber-grower on a large scale since 1860; he first noticed the disease six years ago, since which date it appears to be getting worse and worse. Unless some remedy is quickly found the growth of this crop on an extensive scale is doubtless, as Mr. Owen Thomas says, a doomed industry in England. From systematic observations by the proprietor he became convinced that the disease was not caused by imperfect root action, neither by soil, manure, nor water. In the immediate vicinity of the nursery it was observed that many garden flowers and wild plants were attacked by a similar leaf-spot disease; it was thought therefore that the fungus germs were conveyed into the houses from outside. Several specimens of these diseased leaves were conveyed to the Rothamsted Experimental Laboratory, and the fungus was cultivated, with the result that it was found to be of quite a distinct character from that of the Cucumber leaf-spot. Preventive trials were set on foot in the year 1901. In the first year cow-manure was mixed with sulphur and applied to the hot-water pipes without any beneficial result. For the second crop an application of flowers-of-sulphur and quicklime was used; this also proved of no avail in stopping the disease. In the second year (1902) a Bordeaux-mixture was sprayed on to the plants as a preventive before there was any appearance of the disease, and was carried on at intervals through the summer. The spots, however, multiplied rapidly, spreading through all the leaves of every house, causing the plants to wither and decay. No disease could be found on the roots. In the third year the remedy as recommended by the Board of Agriculture was tried, using a solution of Potassium sulphide (liver-of-sulphur), 2 ounces to 3 gallons of water, adding 2 ounces of soft-soap. The solution was sprayed on to the plants, wetting every part, both the upper and the under surfaces of the leaves, and thoroughly drenching the soil. Again, a failure to stop the disease was the result. At the end of the season the whole of the surface-soil was wheeled out of the houses, and to the subsoil was applied a dressing of ammoniacal liquor. One ton of liquor was given to each 150-feet house for the purpose of killing any fungus germs that might be lurking in the soil or on the woodwork of the houses. So strong was the ammonia gas given off that it discoloured the paint on the woodwork and killed all insect life, but it did not prevent the appearance of the "spot" disease in the following season, even although new surface soil was employed. In the fourth year (1904) the disease was first seen as early as March 23. Commencing on March 25 the disease was kept in check by spraying the plants with a solution of sulphate of copper, using 1 ounce of copper to 36 gallons of water every fourth day. This eventually had the effect of drying up the plants so that they became extremely susceptible to the attacks of red spider, and it was impossible to keep these pests under. The remedy in this case was considered as bad as the disease. A preparation of cupram was also tried—½ pint of strong liquid ammonia was added to 2 quarts of water in which was dissolved 1 ounce of carbonate of copper. This blue fluid was further diluted with 12 gallons of water and sprayed on to the plants. But as this preparation could not be used after the fruit began to form it was useless in preventing the disease attacking the young foliage late in the season. In each of the

four years it was found that the hotter the weather the more virulent was the disease. Every time a crop of Cucumbers was finished the woodwork of the houses was washed with a solution of sulphate of iron, 2 oz. to a gallon of water. Sulphate of iron has also been applied as manure. Varying quantities of sulphate of potash have been given as manure. The houses have further been vaporised with sulphur, using Richards's lamps of the largest size, twenty-four lamps to each 150-feet house; the lamps were kept going for two hours. All these experimental trials have so far proved of no avail in arresting the leaf-spot disease. It seems, therefore, that so long as Cucumbers are grown under the present "highly forced" conditions of moisture and heat no remedy can be found, because what kills the disease will also kill the plant. *J. J. Willis, Harpenden.*

DANÆ RACEMOSA = RUSCUS RACEMOSUS = LAURUS ALEXANDRINA (ALEXANDRIAN LAUREL OR BAY).—(See enquiry on p. 468).—"Supposed to be the plant with which the ancients crowned their victors and poets. The stalks of this, being very pliable, may be easily wrought into coronets for this purpose, and the leaves of this plant having a great resemblance to those which are represented on the ancient busts, seem to confirm this opinion." The above is quoted from Miller's *Gardeners' Dictionary*. In Potter's *Antiquities of Greece*, vol. i., p. 446, of the Olympian Games it is stated: "the original [game] was only a race . . . the victor was crowned with an Olive garland, which was not composed of the common Olive branches, nor the natural product of that country, but brought from the hyperborean Scythians, and planted near Olympia, where it flourished, though not after the manner of other Olive trees, but spreading out its boughs more like a Myrtle. . . . Garlands given to victors in these games were always composed of it, and it was forbidden under a great penalty to cut it for any other use." Of the Pythian Games it is recorded that "Aristomenes was crowned with Laurel that flourished upon Mount Parnassus, but at the first institution of these games the victors were crowned with garlands of Palm or of Beech leaves." In the Nemean Games the victors were crowned with Parsley. Parsley was the conquering ornament of the Isthmian sports, but garlands of Pine-leaves were likewise used, and afterwards the use of Parsley was discontinued. Another quotation of interest is from the *Treasury of Botany*, above the well-known initials "M. T. M.":—"Under the common name of Laurel many very different plants are met with in gardens; but Bay or Noble Laurel (Laurus nobilis) is the only one which is properly so called. . . . It is one of the plants called Daphne by the ancients. The branches of this plant were likewise used to form the crowns placed on the heads of the heroes of antiquity, and on the statues of the gods; hence, perhaps, the name, from *laus* (praise), and also the specific name, 'noble.'" Seeing that the revival of the Olympian Games, according to Callimachus, took place about 828 B.C., it is not surprising that there is some difficulty in determining the particular plants used then by the ancient Greeks for making the crowns or garlands for distinguishing the heroes of the Olympian Games. *John E. Jefferies, Oxford.*

AUDIT OF CHRYSANTHEMUMS.—This as given by Mr. H. S. Kemp on p. 453 is very interesting but hardly correct in the statement that the various positions are obtained by the number of times shown. Should it not be "by the number of times mentioned in the reports given by certain papers"? It is well known that compared with many varieties not mentioned, Madame Carnot, Mrs. Mease, and Mrs. Bryant have been shown in noteworthy form, scarcely at all, and from some important shows were entirely absent. They were met with much less frequently than Miss Olive Miller, Ethel Fitzroy, and Sensation. In some large exhibitions these have each appeared in good form more than the minimum number of times mentioned (twelve). I made notes of the number of exhibits certain varieties appeared in the three most important shows in the kingdom—Crystal Palace, Birmingham, and Edinburgh. Bessie Godfrey was shown in sixty exhibits at the first-named, and forty at Edinburgh; F. S. Vallis almost as many; Mafeking Hero was in five of the six exhibits in the most important class, besides twenty-five others in the same show. It also appeared twenty-seven times at the Crystal Palace, and about the same number at Birmingham. Henry Perkins was shown in excellent style more often than Mrs. Mease, and among novelties I noted Souvenir de Madame Benson and Mrs. C. Beckett more than four times. H. S. Silsbury is without doubt the finest novelty of last season, but I believe others will prove superior to those honoured by inclusion in the best six. *W. J. G.*

THE TRAINING OF YOUNG GARDENERS. — It is not surprising that someone has been impressed by the remarks of "J. G. W." on p. 411, and no doubt Mr. C. Buckland feels somewhat relieved after giving us his little story on p. 453 about the smart young foreman who had never touched a spade to use it. This man must have received his training in some very funny gardens, for even in the glass department the spade is indispensable; and I venture to say that whilst Mr. Buckland was looking for the specimen to suit his purpose, he might have easily found a dozen foremen who would have been only too pleased to discuss with him the proper use of the spade in the way of trenching, root-pruning, planting, &c. Young gardeners of to-day are often called upon to take over the charge of gardens that have drifted into a most deplorable condition, which points plainly to the fact that amongst the old school there were a great many who not only despised the use of the spade and hoe, but in many other ways were very inefficient. *W. C. R.*

—— On p. 453, "W. C. R." takes exception to remarks of mine in a former issue; but I think it would have been more appropriate to point out a little more clearly the particular remarks which, in his opinion, "have no foundation." Naturally no one expects that all will agree with any one statement made, but I have had confirmation of my views from friends and also from total strangers. After over twenty years' experience in medium-sized and large gardens I again say most emphatically that a great many young gardeners are deficient in many branches of outside work. But here let me say that I do not think it is a case of being "too particular," as I have generally found, if put to them properly, that they are usually anxious to have a turn at all branches of the profession; but I think that in the training of young gardeners too much is made of the glass department. With reference to the remarks of "W. C. R.," "that almost the whole of our summer bedding, as well as many other flowering plants, &c., are the produce of this [the glass] department," and the allusion lower down to the "reductions of labour in gardens," where such reductions have unfortunately been made, I would say that much labour is practically wasted in the production of huge quantities of Pelargoniums, Alternantheras, Iresine, and such-like tender plants, to the exclusion of many beautiful and quite hardy perennial plants, which are not utilised nearly as much as they might be, and which do not require much room and attention under glass, at a time of the year when the labour thus saved may be put to very good use in the outside departments in getting work generally in a forward condition for the busy months of spring and early summer. *J. G. W., Bessborough.*

JASMINUM PRIMULINUM.—Mr. Mayne (p. 441) remarks that this species is "said to be quite hardy." It is certainly true that when Messrs. Veitch distributed it they said, "It is hardy in this country, and at our Coombe Wood Nursery has resisted 16° frost on a north wall." Unfortunately I cannot bear testimony to its hardiness, as a fine plant on a sheltered west wall here was killed to the ground in November, when we registered 25° frost. This plant was in full growth when the frost came, and had I anticipated such severe weather I should have taken care to have had it adequately protected. It is disappointing to find that this species will be unsuited for this part of the Midlands, as its free and graceful growth and floriferous habit make it a most desirable wall plant. The severe frost coming so suddenly did a great amount of damage in this neighbourhood (which is rather low lying), and I am a little surprised to find that a large old plant of Buddleia globosa, 10 feet high, has been killed to the ground. *Arthur R. Goodwin, The Elms, Kidderminster.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

JANUARY 3.—The first meeting of the Committees of this Society in 1905 was not accompanied by a large display of exhibits. This is nothing unusual in the month of January, but in the old Drill Hall the smallness of the display was not so apparent as in the new and more spacious Hall in Vincent Square. Visitors on Tuesday last were more impressed with the size and light appearance of this building than they had been hitherto, yet there were several very handsome groups of Cypripediums and other Orchids, also of ornamental foliage and flowering plants.

The ORCHID COMMITTEE recommended two Botanical Certificates and four Awards of Merit to novelties; the FLORAL COMMITTEE an Award of Merit to a variety of Chrysanthemum; and the FRUIT AND VEGETABLE COMMITTTEE Awards of Merit to an Apple and a Pear. At a meeting held in the afternoon forty-two new Fellows were elected.

Floral Committee.

Present: H. B. May, Esq., in the chair; and Messrs. C. T. Druery, Jas. Hudson, Jno. Green, Jas. Walker, Geo. Nicholson, J. A. Nix, H. J. Jones, G. Reuthe, Chas. E. Shea, C. R. Fielder, Chas. Dixon, W. Howe, H. J. Cuthush, R. C. Notcutt, Chas. E. Pearson, Geo. Paul, W. P. Thomson, E. H. Jenkins, and W. J. James.

A number of vases was shown furnished with flowers of a white Japanese Chrysanthemum named Lady Belper, shown with long stems, there being three, four, and five flowers on each stem. The flowers came from Lord BELPER'S garden near Derby (gr., Mr. W. H. Cooke), who stated that the variety is an Australian seedling. Flowering so well at this late season it is valuable.

Messrs. H. CANNELL & SONS, Swanley, staged flowering plants and sprays in vases of Moschosma riparium. The inflorescences were pleasing and well developed (Cultural Commendation).

Messrs. W. WELLS & CO., Ltd., Earlswood Nurseries, Redhill, Surrey, displayed some vases of Chrysanthemums, principally of "single" and "quilled" varieties.

Messrs. HUGH LOW & CO., Bush Hill Park, Middlesex, staged three baskets of a pleasing variety of Cyclamen named "Low's Salmon," also vases containing varieties of these flowers, and plants of Asparagus medeoloides.

Messrs. WM. CUTBUSH & SON, nurserymen, Highgate, N., set up a collection of alpine plants, backed with a number of small shrubs—Conifers, Pernettya in fruit, Daphne mezereum, Eupatorium Weinmannianum, and similar plants suitable for the rock-garden. Iris Histrio, I. sophenensis, I. Vartani, and I. Heldreichi were exhibited in flower (Silver Banksian Medal).

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, staged an excellent collection of greenhouse plants, Ferns, Azaleas, Primula obconica, P. kewensis, Daphne indica alba, Erica melanthera, Eranthemum pulchellum, &c. Many choice specimen Ferns were introduced into the group, the whole of which was arranged with excellent taste (Silver Flora Medal).

Messrs. JAS. VEITCH & SONS, Ltd., King's Road, Chelsea, set up a number of greenhouse plants, Coleus thyrsoideus, Moschosma riparium (flowering well in small pots), Jacobinia chrysostephana, and several baskets of the winter-flowering Begonias, B. Agatha, Julius, &c. Gesnera (Nægelia) exoniensis was shown with the inflorescences about to open, the handsome foliage being not the least decorative character of the plants (Silver Banksian Medal).

A handsome group of plants of Euphorbia jacquiniæflora was displayed by Mr. Beckett, gr. to Lord ALDENHAM, Elstree. This old garden plant was plentifully flowered, the sprays being very bright in appearance, and well set off by a number of Palms, Ferns, &c., introduced into the group for effect (Silver Flora Medal).

AWARD OF MERIT.

Chrysanthemum Market Gold. — This is a rich golden-yellow-coloured decorative or Japanese variety,

which from its habit is considered to be valuable for market purposes.—Shown by Lord ALDENHAM, Elstree (gr., Mr. Beckett).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), J. Gurney Fowler, De B. Crawshay, J. W. Potter, Francis Wellesley, Jeremiah Colman, W. Boxall, J. W. Odell, W. H. Young, H. A. Tracy, A. A. McBean, G. F. Moore, R. G. Thwaites, H. T. Pitt, J. Charlesworth, H. Little, and F. W. Ashton.

There was a far better show of Orchids than the inclement weather seemed to foreshadow, and the meeting was remarkable by reason of the extraordinarily fine group of magnificently-grown specimens of Orchids from the famous collection of Captain G. L. HOLFORD, C.I.E., Westonbirt, Tetbury (gr., Mr. Alexander), for which the Society's Gold Medal was awarded, and the Lindley Medal for excellent culture voted. The group, which extended the whole length of the central staging of one side of the Hall, was composed principally of large specimens of the best varieties of C. × Lecanum, C. insigne, and other handsome Cypripediums, the specimens bearing in the aggregate some 500 flowers. Among the best noted were C. × Leeanum Holford's variety, a dark-coloured and finely marked form with twenty flowers; C. × L. giganteum, with twenty-four and sixteen flowers; C. × L. Westonbirt variety, with fourteen flowers, and other forms equally good. C. × J. Hewes bore eleven large blooms, C. × nitens superbum, fifteen, and several forms of C. × aureum and C. × Sallieri from five to ten flowers. Among the rarer specimens of Cypripediums noted were several very massive forms of C. × Hera, the best of which were the new and fine varieties "Marion" and "Joan," both handsome flowers and finely marked; C. × Actæus langleyense was a pretty light-coloured hybrid which had previously received an award; C. × Alcibiades (Lecanum giganteum × Mons. de Curte), a bold flower of good quality; C. × Scipio (Sallieri Hyeanum × Mrs. Tautz), an improvement on C. × Sallieri aureum; and good examples of C. × Charlesianum, C. × Fascinator, C. × Tityus (six flowers), and the best forms of C. insigne. The centre of the well-arranged group was made up of good specimens of Oncidium tigrinum, Lælia anceps, L. a. Sanderiana, L. a. Amesiana, and a few good Odontoglossum crispum; and at intervals were fine specimens of Lælia autumnalis, one specimen of the large and finely-coloured "Westonbirt" variety having seven spikes, bearing together twenty-three flowers of bright scarlet colour; on the front row were several good specimens of Sophronitis grandiflora.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver Flora Medal for a good group in which the main feature was Lælio-Cattleya × Charlesworthii, about thirty plants of it, some of them with several strong spikes being used, their bright coppery-orange coloured flowers with ruby-purple labellums giving a very bright effect. With them were a plant of the pretty L.-C. × Andromeda with primrose-yellow flowers with claret-coloured labellums; several good Odontoglossum crispum; O. × Hallio-crispum, several of the pretty white-and-rose Trichopilia suavis, &c.

Mr. J. CYPHER, Cheltenham, secured a Silver Flora Medal for a remarkably good group of rare Cypripediums, all exceptionally well grown and flowered. The group included a selection of the best forms of Cypripedium insigne, C. × Lecanum, C. × aureum, and other winter-blooming kinds. Specially noteworthy were C. insigne "Harefield Hall," C. i. Sanderæ, C. i. Sanderianum, and C. i. Oyama, the last-named being a singular and beautiful variety of the C. i. Bohnhoffianum class in which the spotting is suppressed and the peculiar pale rosy-brown colouring disposed in close reticulation and tinting. Others noted were C. × aureum, Lambianum, like C. a. Surprise, but with an emerald-green tint; C. × Phœbe, C. × Mme. Jules Hye, C. × Tityus, C. × Swinhurnei magnificum, Trichopilia suavis, varieties of Lælia anceps, and good Masdevallia Schroderiana.

Messrs. SANDER & SONS, St. Albans, staged a small group in which were a good example of Cypripedium Rothschildianum, a pretty light form of C. × Helen H., C. × Lucienianum, C. × aureum virginale, and two other good varieties of it; C. × exquisitum (exul × insigne Chantini), and a very remarkable form of C. insigne, with the ground colour of C. i. Bohnhoffianum, but with a rose-flush and rose-coloured spotting running into the white upper half of the dorsal sepal.

JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), showed cut spikes of Lælia anceps Mrs. Jeremiah Colman, a good and richly-coloured flower; L. a. alba, and a strong-branched spike of Calanthe × Wm. Murray.

Messrs. HUGH LOW & Co., Enfield, showed Cattleya Triane Alpha, a good variety with broad, crimped petals; Cypripedium × Mrs. Tautz, C. × Prewetti, C. × nitens, Ball's variety; C. × Madame Geo. Truffaut, and other Cypripediums.

G. F. MOORE, Esq., Bourton-on-the-Water (gr., Mr. Page), showed Cypripedium × Amy Moore (Sallieri aureum × insigne maximum), a large yellowish flower distinctly spotted, and with a white tip to the dorsal sepal; and C. × Leeanum Fowlerianum.

FRANCIS WELLESLEY, Esq. (gr., Mr. Hopkins), sent Cypripedium insigne Hopkinsianum, Lælia anceps Amesiana Wellesley's variety, and two others (see Awards).

FIG. 6.—DENDROBIUM TRIFLORUM (CYMBIDIOIDES).
(Awarded a Botanical Certificate on Tuesday last.)

AWARDS OF MERIT.

Cypripedium × *Memoria Jerningaliana*, from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins). A noble hybrid of unrecorded origin. The flowers have the massive form of some of the

darkest C. × aureum, but with a thicker texture and other characters suggestive of one of the hybrids of C. Drurii, perhaps C. × Winnianum, being one of the parents. There is a charming undulation to the segments of the flower, and altogether it has a novel and attractive appearance. The dorsal sepal is pure white with a small purple base from which ascends some stout emerald-green rays, the middle of the sepal having a broad purple band. Petals and lip honey-yellow tinged with purple-brown, the margin of the lip being clear yellow, and the surface of the flower very glossy.

Cypripedium × *westfieldiense* (Lecanum superbum × Pollettianum), from FRANCIS WELLESLEY, Esq. (gr., Mr. Hopkins).—A fine flower with large white dorsal sepal with a small green base, the greater part of the white area being covered with lines of bright rose irregular spots. Petals and lip yellowish, heavily tinged with dark mahogany-red.

Cypripedium × *Alcibiades* (Lecanum giganteum × M. de Curte), from Captain G. L. HOLFORD, Westonbirt (gr., Mr. Alexander).—Flower large and of fine substance, the showy white dorsal sepal having rich purple markings.

Dendrobium Phalænopsis Chardwar. var., from G. F. MOORE, Esq., Bourton-on-the-Water (gr., Mr. Page). Flowers of perfect shape and of a bright magenta rose colour.

BOTANICAL CERTIFICATE.

Dendrobium triflorum, from F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin. The plant often found in gardens named D. cymbidioides. The spray sent had seven cream-white flowers with red and yellow markings on the lip (see fig. 6).

Acrides Ortgiesianum, from F. W. MOORE, Esq., Glasnevin. A species with greenish-white flowers, slightly marked with rose. Originally described by Reichenbach, in the *Gardeners' Chronicle*, 1885, p. 501.

CULTURAL COMMENDATION

to the Rt. Hon. Lord ROTHSCHILD, for a magnificent eight-branched inflorescence of Phalænopsis Aphrodite, with nearly fifty flowers.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (Chairman); and Messrs. Jas. Cheal, Jas. Gibson, S. Mortimer, Alex. Dean, Ed. Beckett, H. J. Wright, J. Willard, W. Poupart, Geo. Kelf, and Owen Thomas.

Mr. B. ASHTON, Lathom Gardens, Ormskirk, exhibited tubers of a large, flat-shaped Potato, named Earl of Lathom.

Some large cooking Apples of a seedling variety, named Lord Belper, were shown by Mr. W. H. Cooke, gr. to the Right Hon. Lord BELPER, Derby. The fruits were deeply ribbed.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, exhibited fruits of a small-sized Pear named Winter Williams, raised from a cross between the varieties Williams' Bon Chrétien and Beurré Bachelier. It is remarkable for possessing a flavour identical with that of Williams' Bon Chrétien in September. The same firm exhibited fruits of an Apple named G. Wythes, obtained from a cross between the varieties Peasgood's Nonesuch and Cox's Orange Pippin. The fruits are of moderate size, round shape and good colour. The flesh is soft and the flavour moderate.

W. SHUTER, Esq., 22, Belsize Grove, Hampstead (gr., Mr. J. Armstrong), exhibited a dozen bunches of Black Alicante Grapes. The fruit could hardly be regarded as well finished, this fact being undoubtedly due to the proximity of the gardens to the Metropolis.

AWARDS OF MERIT.

Apple Fenn's Wonder. — This is a large kitchen variety, the fruits of which are slightly ribbed and very highly coloured on one side, and only less so on the other side. It would probably make a good market Apple.—Shown by the Earl of STRADBROKE, Henham, Wangford, Suffolk (gr., Mr. T. Simpson).

Pear Santa Claus.—Ripe fruits of a Pear bearing this name were shown by Col. BRYMER, M.P., Ilsington House, Dorchester. The fruits were of moderate size, and suggestive of Beurré Diel, but had not the "grittiness" usually present in that variety. Santa Claus is said to have come from Belgium about thirty years ago, and as this name has only now been given it, the variety may still be known in Belgium under another name.

GARDENERS' DEBATING SOCIETIES.

WARGRAVE GARDENERS'. — The last meeting of 1904 was held on Wednesday, December 21, when Mr. J. Bothy, gardener to the Rev. H. M. Wells, of Scarlets Park, gave an interesting exhibition of lantern slides and photographs of beautiful plants and views of various gardens in the neighbourhood. A short description was given of each view as it appeared on the screen. A number of Chinese views was also shown, from the negatives taken by Mr. R. Wells, who spent some time in the Far East. These were very interesting, as they gave good ideas of the Chinese methods of tillage, &c. Mr. Robbins showed some good stalks of Brussels-Sprouts.

BATH AND DISTRICT GARDENERS' SELF-HELP AND DEBATING.—The fortnightly meeting was held on the 23rd ult., the subject for discussion being "The Cultivation of the Potato, its Diseases, &c. The debate was opened by Mr. Waters, who gave details of the history and culture of Potatos. Attention was directed to the famous Northern Star variety, and some remarkable personal experience with it were related. Mr. Sparks gave some useful observations on spraying as a preventive of disease. A suggestion that the Society should procure a sprayer next year, and lend it to the members at a small charge, was very favourably received. There was a good display of Potatos at the meeting, no fewer than thirty-two varieties being sent by Messrs. J. C. Wheeler & Son, nurserymen, Gloucester, who, in addition, sent two varieties of Onions and a collection of Primulas. The treasurer, Mr. O. G. McLaren, announced a presentation of gardening books to the Society given by a gentleman who wished to remain anonymous. Sixteen new members were elected, making the total number of members 118. *T. P.*

EGHAM AND DISTRICT GARDENERS'.—At a meeting of this Society, held on December 21, a paper was read by Mr. G. Baskett, of Wood Lea, Virginia Water, on "The Rose Garden." Mr. Baskett, after referring to the history of the Rose, gave detailed information with regard to selecting the most suitable site, the formation, soil, planting, and arrangements of the Rose-garden; the most suitable varieties of Roses to grow, and the best methods of pruning the various species of Roses. A discussion ensued in regard to draining "other than water-logged soils;" also as to the advisability of earthing dwarf Roses as a protection during severe weather.

REIGATE, REDHILL AND DISTRICT GARDENERS'.—The fortnightly meeting was held on Tuesday, December 20, Mr. W. P. Bound occupying the chair. The subject for debate was "Successes and Failures during 1904." The discussion was led by Mr. Herbert, of the Gardens, Nutfield Court. There were about eighty members present, of whom a number took part in the proceedings. Mr. Herbert was able to report many successes. Crops of fruit were undoubtedly good, not only in this district, but almost everywhere in the country; the quality was also exceptionally good. Vegetables were in no way lacking in merit; reports of splendid crops were generally noted. The Onion-fly had been troublesome in some districts. Celery was generally good, the Celery-fly being less noticed than in 1903. Peas were also good: the variety The Gladstone was highly spoken of for late cropping. The Chairman strongly advocated trenching as a means of preparing ground. *C. L.*

SCHEDULES RECEIVED.

INTERNATIONAL EXPOSITION of the Société d'Horticulture de Genève from September 6 to September 12, 1905, at Geneva.

CULTURAL MEMORANDA.

SOLANUM JASMINOIDES.

THIS very desirable greenhouse climbing plant is easily propagated by cuttings from the young growths, these being inserted in efficiently crocked 3-inch pots filled with a compost consisting of three parts light sandy loam and one of leaf-mould, plunged in a gentle bottom-heat, watered, and kept close until rooted, when they should be potted off singly into 3-inch pots and grown on in the usual way. Young plants may also be raised from seed sown thinly in pots, afterwards treating the seedlings as indicated above. Some time ago the writer saw in the lofty and elegant conservatory attached to Watermouth Castle, near Ilfracombe, a plant of this white and sweetly-scented greenhouse perennial in grand flower; the flowering shoots, hanging loosely and gracefully from the roof, were very effective.

ENQUIRY.

MYROBALAN PLUM. — Can any reader of the *Gardeners' Chronicle*, who has planted the Myrobalan Plum for hedging purposes, tell me if it is a good substitute for Quick (Thorn)? Nurserymen are reluctant to give much information concerning it. Any hints on its culture, etc., will be gratefully received. *Reader.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BOOKS: *Journeyman. Elementary Botany*, by Percy Groom. It can be obtained from our Publishing Department.

BRITISH GARDENERS' ASSOCIATION: *J. C., Headingly, Leeds.* Your request for rules and particulars of this Association has been forwarded to the Secretary, Mr. W. Watson, Kew Road, Kew.

FERNS: *E. B.* The appearances are those caused by thrip. Weak tobacco-water may be used and frequently repeated. The atmosphere of the house is probably too dry.

HOLY THORN: *Nuneham.* You are doubtless referring to what is popularly known as the Glastonbury Thorn, an early-flowering variety of Cratægus oxyacantha, known as C. oxyacantha præcox in gardens. It is popularly supposed to have sprung up at Glastonbury from the "staff" of Joseph of Arimathea, and to produce its blossoms on Christmas Day.

NAMES OF FRUITS: *C. H. W.* Glout Morceau.—*S. B., Thrapston.* Kindly send other specimens, as your last consignment, and those of some other Correspondents, appear to have been lost in the post, doubtless owing to the press at Christmas, and to the confusion caused by the fog.—*G. H.* 1, Tower of Glamis; 2, London Pippin; 3, Herefordshire Pearmain.—*F. E. Fecar.* 1, Minchull Crab; 2, Whiting Pippin; 3, Claygate Pearmain; 4, Court of Wick; 5, Bramley's Seedling; Pear, Nouvelle Fulvia.

NAMES OF PLANTS: *T. B. A.* Thunbergia laurifolia.—*E. B.* 1, Ornithogalum laoteum; 2, Veltheimia viridifolia.—*S. H.* Begonia ricinifolia, manicata; Polypodium glaucum; Adiantum formosum; the large frond with small pinnæ, Adiantum decorum.—*A. S.* Oncidium sphacelatum; Phalænopsis Schilleriana, and Cattleya Percivaliana.—*A. B. C.* 1, Azalea indica alba plena; 2, A. indica alba; 3, not recognised; 4, A grass, not recognised; 5, Selaginella denticulata of gardens; 6, Eupatorium micranthum [ligustrinum].—*G. H.* Ilex dipyrena. —*J. M.*—Salvia leucantha; Dianthus superbus.

SPRUCE GALLS: *T. R.* The work of an insect (Chermes) allied to that known as American blight. It is very common, but we are unable to suggest any "cure," beyond removing the affected shoots in spring and burning them.

TREE FERN: *N. P. J.* Without making an examination of the plant, which you describe as having grown for thirty years in your conservatory, we cannot definitely say what has caused it to droop. You state, however, that the roots are contained in a wooden tub, and that it is possible that the plant was neglected during the period that elapsed between your head-gardener's death in July and the appointment of his successor in October. If the roots were allowed to suffer from drought this would naturally cause the young fronds to droop, and if the check was sufficiently severe they will wither entirely. But Tree Ferns have a wonderful amount of vitality, and your specimen will most likely develop fresh fronds although it loses all those that have developed. Do not disturb the roots at present, but let the plant be given care for a time in the same conditions as heretofore, and await the result hopefully.

COMMUNICATIONS RECEIVED.—H. S.—J. H.—A. B.—W. H. S.—F. C.—G. T.—Fred. Burvenich, Ghent—W. J. W.—Jason—J. S.—J. G. W.—H. W., Trevince—A. D. H.—W. W.—Exhibitor—W. F.—J. C.—S. A.—Constant Reader—Mr. T., Worsley—G. J. I.—H. A. Pettigrew—J. S.—J. D. C.—H. E. C.—De B. Crawshay—J. B. L.—N. S.—H. & S., Germany—T. Humphreys—J. V. & Sons.

THE MANURING OF LAWNS.

ITS EFFECT IN DESTROYING WEEDS

NO question is more frequently asked than that involving the demand for information as to how to improve the grass of a lawn, of a tennis-court, or a golf-green; how to get rid of moss, or to eradicate Plantains and Daisies; how, in fact, to obtain a smooth, elastic turf of grass instead of an exiguous and miscellaneous collection of weeds. There are various nostrums for the purpose, but the plain and simple recipe of putting on manure nearly always meets with objections. People who load up their beds and borders with manure, though but a small crop be taken off every year, yet seem to suppose that a lawn mown once a week during the growing season will support itself, and that the grass will be produced out of nothing. In many of our suburban gardens also the lawn had a bad start, the thinnest of turf has been laid over a mixture of harsh subsoil and builder's rubbish, all the good soil having been piled up on the borders when it has not been sold to a neighbouring gardener. Yet still the prejudice against manure holds. "It will make the grass too coarse;" "It will bring too much Clover," are the arguments. Instead, some magic liquid is sought which will kill Daisies, Dandelions, and Plantains at a touch, and leave the grass to flourish unharmed.

Putting on one side the unlikelihood of ever obtaining rank grass on such a soil as lies beneath the majority of our lawns or golf-greens, the mere fact of the constant cutting and rolling would prevent any of the coarser grasses from getting a foothold. The particular plants we see in a piece of mixed herbage like a lawn represent the survivors of a great competitive struggle for existence in which only those plants persist that are adapted to their environment. And in this case the main factor in the environment is the recurrent rolling and close cutting. Grasses, like Cocksfoot or Meadow Foxtail, with an upright tufted habit, are badly suited by the conditions and are easily supplanted by seemingly much weaker creeping grasses, like the Poas or the dwarf Fescues.

Plenty of manure and rich soil, so far from encouraging the big coarse grasses, really gives the finer ones a much better chance, for the coarse grasses have long, spreading roots which can range deep for their food, whereas the finer grasses are wholly dependent on the surface soil, and will quickly exhaust it should its richness not be maintained by manuring. But this thesis and the all-important question of the nature of the manure to be used can best be illustrated by an examination of the grass experimental plots at Rothamsted. [The results of the experiments made at Rothamsted were first published in the "Philosophical Transactions" of the Royal Society, and were contributed by Dr. Gilbert and Dr. Masters, a summary of which is published in *Plant Life* by the last-named writer.] There, nearly fifty years ago, twenty plots, most of them half an acre in area, were marked out on the old grass-land of the park near the house, a particular scheme of manuring for each plot was adopted, which has been repeated year by year ever since with practically no alterations. The effects of this long-continued manuring in particular directions is now instantly visible in the class of herbage carried by each plot, and a walk by them in the springtime is pregnant of lessons not only for the farmer and grazier, but for the gardener who has lawns and paddocks to manage. The plots look as though they were strips of land transported from different counties, so varied is the vegetation they carry; one is all flowers, another is wholly dark green grass, a third seems to be all Clover, a fourth is white with the Parsley-like flower of the wild Chervil, yet no seed has ever been sown, the differences have all arisen from the manuring. The Rothamsted plots are laid up for hay every year, and though at first sight this may seem to prevent one from deriving much information from them as to the management of lawns, it will soon be seen that the same principles apply in one case as in the other.

The plot to begin with is the one that has been without manure the whole time; the herbage is scanty, as might be expected, rarely much more than ankle deep even at hay-time, but the fact that strikes one most is its varied composition. All sorts of flowering plants are to be seen; Hawkweeds, Ribwort Plantain, Hard-heads, Cowslips, Scabious, Speedwell, Bird's-foot Trefoil, catch the eye most prominently; the grasses are poor and stunted, among them the pretty Quaking Grass (*Briza media*) is the most prominent. In winter time there is plenty of moss to be seen all over the plot. A complete botanical analysis made in 1903 showed that only 52 per cent. of the herbage by weight consisted of grasses, the Clovers and other leguminous plants made up 8 per cent., while the remaining 40 per cent. consisted of miscellaneous species or weeds. The variety of the vegetation is to be seen in the fact that forty-seven different species were identified in the herbage from this plot. Examine now, by way of contrast, some of the plots lower down the field which receive a complete manure containing nitrogen, phosphates, and potash, but in which the nitrogen predominates. At once there is a big crop of strong-growing herbage, which has yielded on an average 2, 3, and even 3½ tons of hay per acre over the whole period of forty-seven years. But the character of the herbage has been even more strikingly altered than its amount; the forty-seven species have been reduced to twenty, or indeed practically to four on the most heavily manured plot of all, and these species are all grasses—the Clovers and the weeds have been crowded out. If we turn to the plot on which, instead of nitrogen, a purely mineral manure containing only phosphates and potash is supplied, we see another great change; the Clovers predominate—red and white and the allied Meadow Vetchling—and the grasses only occupy a subordinate position. In some seasons the leguminous plants will make up more than half of the herbage at haytime. On another plot we may see the effect of applying superphosphate and sulphate of ammonia without any potash; we have an exclusively grassy herbage, with not a particle of Clover and very few weeds. The grasses also are all shallow-rooted kinds, more than half of the whole consists of Sheep's Fescue, Sweet Vernal Grass being also abundant; very much the kind of vegetation, in fact, we want to see upon a lawn. The shallow-rooted nature of the grasses is due to the fact that the manures used are such as are arrested by the soil close to the surface, consequently the shallow-rooted species gain an advantage. If instead we employ nitrate of soda, which sinks down with the rain, deep-rooted grasses like Soft Brome grass are favoured and become prominent in the herbage.

Without going into details we may draw the following lessons from the Rothamsted plots:—

1. Weeds, moss, and a varied herbage indicate poverty of the soil. In rich soil the grasses will crowd out everything else; in poor land the weeds can beat the grasses.

2. Nitrogenous manures encourage the grasses and depress the Clovers.

3. Mineral manures and particularly potash encourage Clover and allied plants.

4. Of the nitrogenous substances ammoniacal manures encourage shallow-rooting, nitrate of soda the deeper-rooting grasses.

Let us apply these principles to practice. Lawns that are intended for use as tennis-lawns, bowling-greens, putting-greens, should be made up of grass only; Clover wears too easily, gets slippery in the evening, has a different "pace," and is less true. Consequently manures containing much potash, or lime which acts as a liberator of potash in the soil, should be avoided. A mixture of superphosphate (three parts) and sulphate of ammonia (one part), at the rate of ¼ lb. per square yard, is about the best manure where the soil is loamy with a sufficiency of lime; but on thin sands and gravels, or on heavy sour clay, such a manure is rather too

acid; it is better then to use a good Peruvian guano, perhaps the best of all manures for producing fine grass, or a mixture of nitrogenous fish guano with some bone-meal. Soot also is good, but soot is a manure supplying nitrogen only, and must be accompanied by some phosphate. Where the presence of Clover does not matter, as on lawns not used for games, the fairway of a golf-green, the outfielding of a cricket-field, a more general manure containing potash will grow a closer sward. A good all-round mixture should contain four or five per cent. of nitrogen, twenty of phosphates, and six to eight of potash; this, at the rate of ¾ lb. per square yard, will grow excellent grass.

Damp low-lying lawns, or putting-greens that are evidently sour and suffering from lack of lime, must be dressed with a little ground-lime or with basic slag, at the risk of encouraging a free growth of Clover for a season or two; otherwise the sourness will spread, and the herbage will begin to die in patches; the Clover that results may be troublesome at first, but will gradually give place to good grasses. So far we have spoken only of artificial manures, because they are most easy of application; they only need to be sown early in the year (February is perhaps the best month), and allowed to wash in. But on many sandy and gravelly soils perhaps the best treatment is to cover the lawn late in the autumn with a good coating of well-rotted dung, best of all from an old Mushroom-bed, and leave it there to wash in until the grass begins to grow in the early spring, when it can be swept off. The grass benefits from the humus thus introduced, as well as from the more direct plant-food; the shelter also provided by the manure for the springing grass is valuable.

In any case the great thing is to bear in mind that grass cannot be grown out of nothing; it is only by growing a lot of grass and keeping it constantly cut close, that we can establish the mat of old roots under the sward, which gives on the one hand the delightful feeling of life and elasticity, and on the other the recuperative power after wear, characteristic of the best turf. *A. D. H., Rothamsted.*

HARDY PLANTS.

GUNNERA SCABRA MAJOR.

FINE as is a well-grown specimen of the typical Gunnera scabra, with its large and handsome rough leaves, quite tropical in their effect, it shrinks into comparative insignificance when seen alongside its descendant—G. scabra major. This is a truly noble plant, reminding one in its grand dimensions of the magnificent Gunnera manicata, but with a rugged grandeur not possessed by G. manicata, though the latter is taller and makes a larger plant. This greater form of G. scabra originated, I believe, with Mr. T. Smith, of Daisy Hill Nursery, Newry, and as seen growiug there it was remarkably fine. It is an improvement upon the type, and well worthy of a place in the grounds of those who appreciate such striking plants. By a pond or in the wild garden by some moist spot it would be perfectly at home. It is, however, all the better for some shelter from strong winds, as one has seen the leaves of the typical plant, sturdy as they are, wrenched off by a severe gale when in a comparatively exposed position. *S. Arnott.*

WIDDRINGTONIA WHYTEI.

THIS tree, known in the vernacular as the Milanji Cypress, was originally found at an elevation of 10,000 feet, on Mount Milanji, in Nyassaland (35°—36° E. long., 16° N. lat.), by Mr. Alexander Whyte. It was alluded to in the *Kew Bulletin* (1892), p. 121, and was described in detail by Dr. Rendle in the *Transactions of the Linnean Society*, May, 1894. The tree is destined to be of great importance as a timber tree in subtropical countries, if it can be adequately protected against forest fires and reckless felling. Like so many of its allies, the tree is remarkable for the varying forms of its foliage. Thus in the adult stage the leaves are small, deltoid, and closely appressed to the branch; other leaves are more elongate, linear-lanceolate, and spreading at the tips. In the seedling condition, and in what we may call the Retinospora stage, the leaves are about 1 inch long, glaucous, distinctly linear, and spreading. Of such character were the leaves furnished us by Mr. Medley Wood (see *Gardeners' Chronicle*, August 18, 1894, p. 19), and from Kew (see *Gardeners' Chronicle*, June 16, 1894, p. 746). See fig. 7, B.

Now Mr. Bartlett, of the Pencarrow Gardens, Cornwall, sends us specimens showing on the same branchlet all three of the forms of leaves just mentioned, but in the specimen figured, only two forms are shown on the one branchlet (fig. 7, A), whilst the other (fig. 7, B) bears the long primordial leaves characteristic of the Retinospora stage. The specimen at Pencarrow is between 7 and 8 feet in height, and is planted out in summer and removed under glass in winter. Other plants of the same

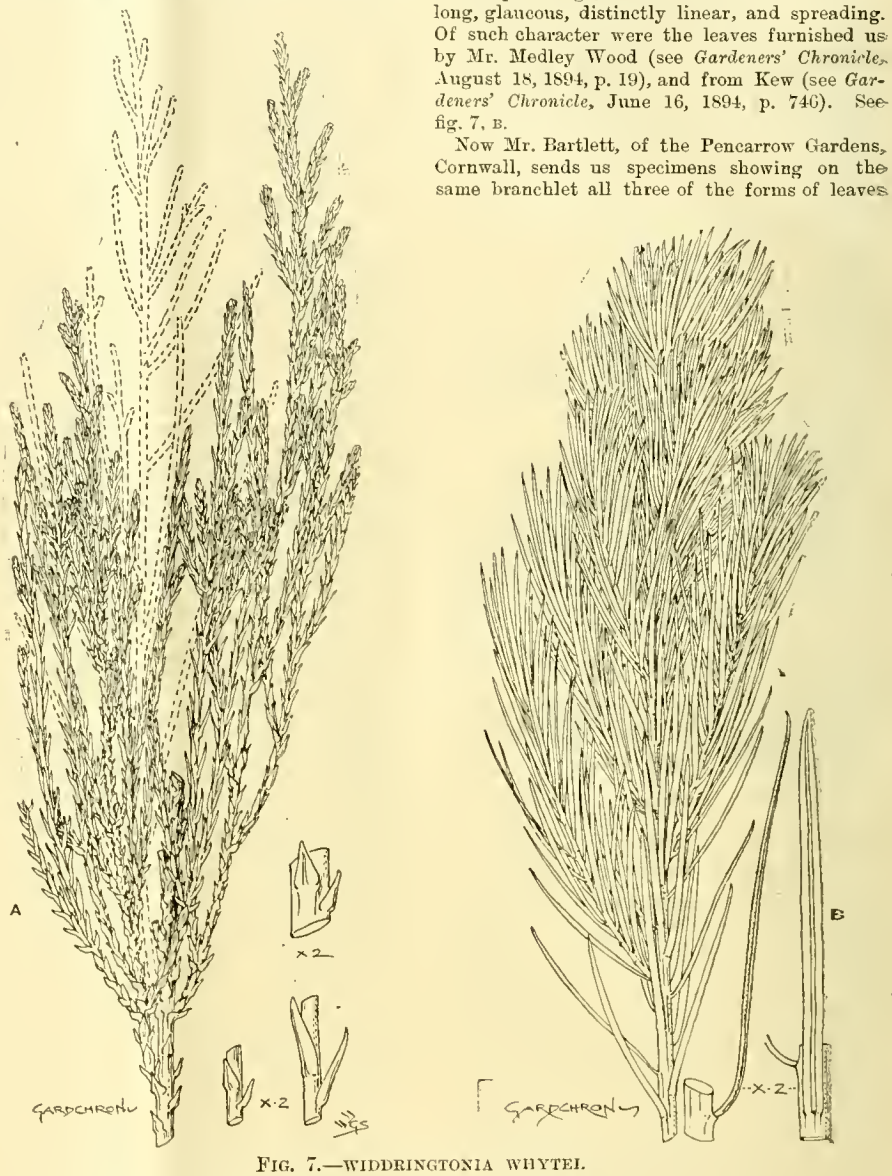

FIG. 7.—WIDDRINGTONIA WHYTEI.
A—Branch showing two forms of the adult foliage; B—Showing the primordial Retinospora-like leaves. The detached leaves of each form are shown as magnified 2 diameters.

species (see *Gardeners' Chronicle*, March 21, 1903) have been planted out, and passed the last winter without injury. Mr. Bartlett's specimens also

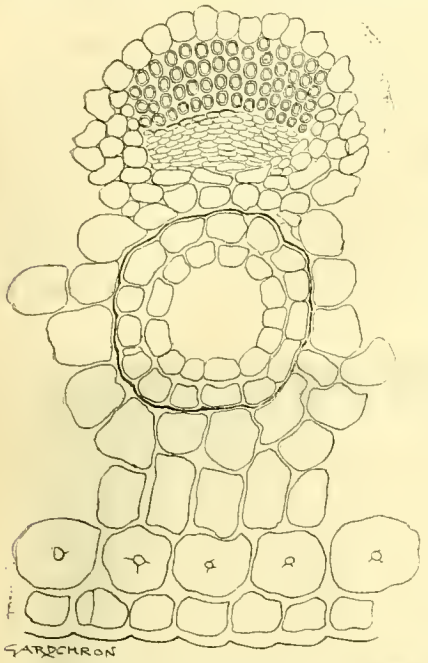

FIG. 9.—WIDDRINGTONIA: DIAGRAM OF SECTION OF LARGE LEAF, B, MORE HIGHLY MAGNIFIED. For references see fig. 8.

showed the male catkins, which are as described by Dr. Rendle.

It may be added that a cross-section of a primordial (Retinospora-like) leaf (fig. 8) shows it to

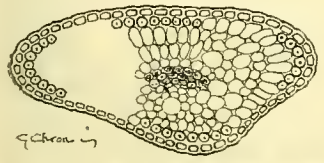

FIG. 10.—WIDDRINGTONIA: DIAGRAM OF SECTION OF SMALL-SIZED LEAF.

be transversely oblong, rounded at the two extremities, with the midrib prominent on both surfaces. Beneath the outer skin or epidermis is a single layer of hypoderm or strengthening cells, S.T.; the

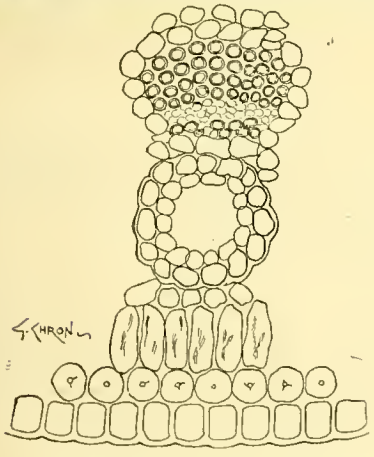

FIG. 11.—WIDDRINGTONIA: SECTION OF SMALLER LEAF, MAGNIFIED. The structure and references are as in fig. 8.

central cylinder is elliptic, surrounded by a bundle-sheath or endoderm, and with a single fibro-vascular bundle, with the wood or xylem, XY., above, and the bast or phloëm, Ph., beneath. A solitary resin canal, R.C., traverses the cellular tissue of the leaf between the hypoderm and the central cylinder. The structure of the adult foliage is essentially similar (figs. 10, 11).

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUMS AT ARDDARROCH.

I AM often told, "These crispums, as you call them, must be magnificent and far finer when they are at home on their native tree than in cultivation. Why do you not go out to South America to see them?" I might induce a smile of incredulity on some faces if I replied, "I can see them better grown under cultivation by going to Arddarroch." It will not make people smile when I tell them it is far easier to visit the plants there, but it would make them smile, with a good broad grin of satisfaction, did they have the good fortune to see the 300 plants in Mr. R. Brooman White's No. I. house, that have been grown there for periods of various duration extending to twenty and a half years, the oldest one having been purchased at Sir W. Marriott's sale, May 20, 1884. They are plants in pots ranging from 48's (5 inches) to many of 12 inches in diameter. The "specimens" are grand indeed, and have immense bulbs, some as large as 6 inches high by 2½ across the widest part, and 1⅜ thick. There are dozens which carry four years' leaves most of them having two leaves to a bulb, and many have three; and here and there you find a plant with five years' leaves, a rare occurrence in most collections an unknown one in a great many. These leaves are not puny and soft things of pale green, but are magnificent straps of foliage whose depth of colour leaves nothing to be desired. The "tipping of leaves" here is absent, and from what cause I shall hope to show later. One Odontoglossum Andersonianum has three spikes upon one giant bulb, one spike having seven branches, each spike being thicker than an ordinary lead-pencil. Being at a dull time of year there were few in bloom, but I have so often seen the greater portion of them that I can say without any exaggeration that sixteen blooms on a spike is a common occurrence, and I know of nineteen without a branch—blooms, too, of grand substance and variety, for no "poor var." is kept in No. I.

The first idea that will occur to many people is possibly, "This is the result of some manuring." It is the result of absolutely no manuring of any sort whatever, either liquid or solid; such treatment is neither allowed nor needed at Arddarroch. The compost that Mr. Perfect uses is peat, sphagnum, and Oak-leaves in equal thirds, chopped finely and mixed. The Oak-leaves are collected when they fall, and left heaped on the ground, being used as and when required, but not in a state of rottenness, when all nourishment has left them; the sounder the leaf the more there is for the plant to feed upon. Bracken-roots are used for drainage, and then the plant is settled into the compost, the surface being of sphagnum. I do not say live sphagnum, for it does not die easily at Ardarroch.

Plenty of air is given at all or any time, for it is never so cold that the plants may not have some with beneficial results. Watering is largely done by Nature here, for the position of the house is ideal. It is placed north and south, a span-roof, whose general dimensions are 40 by 10 by 9, with two side stages, under which are two stages of Loch Long finest gravel, the path being covered by a larger size of the same; it contains three rows of 4-inch pipe on each side, has "Hit and Miss" side ventilators, also top ditto; spray pipes for use in hot weather are also in it and on the roof.

The position, partly in the ground, is one of its great points. On one side is a bank 7 feet high, the south end being also "banked" by the continuation of the slope of the hill. In the house is a 14-feet well of beautiful mountain water, softer than most rain-water, and from the natural slope of the hill the water percolates under the house, thus continually maintaining a most advantageous moisture. Sphagnum grows all over the mountains around. Loch Long is 100 feet below, and the climate is perfect; and above all Mr. Brooman White and his grower (Mr. Perfect) are always eager to take advantage of and utilise Nature's beneficent endowments.

To enumerate and describe the other branches of Orchid culture may rest for another time; it is enough to take Odontoglossums now, of which there are six houses more (and another building) full to repletion of unbloomed plants selected from all the best importations. This 25,000 plants should give some good results in blooming. Some exceedingly fine varieties should make their appearance, for if character means anything then the only question is time, which will bring its own reward that will be richly deserved, and hope unsparingly given.

The plants I have described constitute a most beautiful houseful of Odontoglossums, the names of some of which ma form a fitting termination to this article:—

O. crispum
Angela
Arddarroch var.
Aurora
album magnificum
Erin
Geraldine
Mrs. Brooman White
North Star
Rosa
Starlight
Sunlight
xanthotes White's var.
Aimée
Eileen
Diana
Peetersii
Trianæ Reine des Belges
Mariæ

O. „dersonianum
Arddarroch var.
obstupefaciens

O. Rückerianum
egreginm (from "Tantz" collection).
Mrs. Brooman White

O. Wilckeanum
White's var.
splendens
albens

O. Hallii Charlesworthii
loochristiense Arddarroch var.
elegans Pollett's var.

And a great many very fine crispums (rosy and nn spotted) which are nnmbered, not named.

De B. Crawshay.

NEW OR NOTEWORTHY PLANTS.

MALORTIEA TUERCKHEIMII, U.D.

AMONGST the dwarf Palms the genus Malortiea contains some noteworthy species. Some time ago I received from Guatemala a specimen of a new species of this genus, which is in more than one respect of great interest. This dwarf Palm has a height of about 16 inches, and bears upon its thin stems, which are only 1½ lines in thickness, a crown of fifteen leaves, which more closely resemble those of a Geonoma than those of a Malortiea. Whilst the leaves of M. simplex and M. Koschnyana are of a bright green, those of M. Tuerckheimii are dull green. The blade of the leaf of the new species is traversed on each side of the midrib by nineteen veins, which are directed forward at an acute angle; the blade itself is folded somewhat between the veins. But whilst the blade of the leaf in Geonoma is more or less bifid at the apex, in this species the apex is not bifid. It is cuneiform, about 6 inches long and 2 inches broad. The petiole is short, about 1 inch long. The margin of the blade is crenate, the crenules diminishing in size upwards and being very regular. The plant was detected near Cobán in Guatemala at an altitude of 4,500 feet above the sea-level by the German Consul Baron von Tuerckheim.

The Central American States are perhaps the richest district in Palms of the globe. Certainly there are a great many Palms as yet unknown, and I have no doubt that among them are representatives of new genera. Importers of novelties might still find here a quantity of new and rare plants. *Dr. Udo Dammer, Dahlem.*

EXPERIMENTAL CULTIVATION.

(Continued from p. 398.)

MANURES FOR SPECIAL CROPS: STRAWBERRIES:—The results of manurial experiments with Strawberries are often conflicting and puzzling, but the increased value of a larger or earlier crop is so considerable that they are worthy of all the attention which can be devoted to them. Though much work has been done there is ample room for further investigation, indeed some experiments should be repeated in other soils and situations in order to test the conclusions arrived at. Experimenters are naturally always eager to start original lines of investigation, but quite as useful work might be done by following up what others have commenced when the work has been performed in a systematic manner, and the records of results are at command. The more frequently a well-designed experiment in cultivation can be repeated, the more valuable do the observations become, and the greater the probability of arriving at reliable averages, with the elimination of errors due to local conditions.

With Strawberries such repetition is especially necessary, for the varieties are numerous, and these behave differently in varied soils and positions, the consequence being that records are often divergent or even contradictory. My own experiments in the manuring of Strawberries were commenced about sixteen years ago, and I have had the opportunity of studying the matter on five widely different soils. The work of others in a similar direction has also received close attention, but we have still much to do before any conclusive results of general application can be recorded. The physical condition of the soil has more influence on the variable results than the chemical composition as determined by ordinary analysis; and this fact is being generally recognised in connection with other crops.

RUNNERS IN POTS AND OPEN SOIL.

As regards Strawberries, there is another variant which materially affects results, namely, the method and time of preparing the runners for planting. I have seen as much difference between plants of the same variety layered into pots and those rooted in the open soil, as between two varieties differing in strength and productiveness. The difference is sometimes observable for several years, and is quite as marked as that which follows extremes of manurial treatment. If experimental plots are made up of plants which differ so much at the start, it is not surprising that the results are divergent.

Again, the earliness of rooting the runners has a bearing upon the matter, for the early, strongly-rooted plants will be in a different state from those obtained late in summer, and possibly weak or stunted. This will to some extent influence the after behaviour of the plants whatever their manurial treatment may be, and is a source of error in the conclusions if plantations are formed indiscriminately of both.

PLANTING.

A point requiring attention also is the condition of the soil and the nature of the weather at the time of placing-out the runners in the plots. If in one portion of an experiment Strawberries are planted in soil moist with warm rain, and the weather is dull for a few days afterwards, these plants have all in their favour for healthy progress; but if from any cause it is impossible to complete the planting under these conditions, and it is finished under a glaring sun in a dry soil, and with the aid of the water-can to keep the plants from perishing, a serious difference may be expected in the behaviour of the plants.

These are not imaginary difficulties, for I have known cases where cultivators inexperienced in experimental work have conducted trials of Strawberries, both for manurial tests and other objects, without due attention being paid to such initial differences, and with consequent confusion of the issues.

In experiments organised and conducted by myself, I have always preferred to rely upon Strawberry-runners layered in the open soil at the earliest possible time after fruit-gathering, and planted-out under the best weather conditions. Besides this, the plants should be assorted and equalised as far as possible by rejecting the weaklings; and it simplifies the work if only one variety be taken at a time until some general results are obtained, when a collection can be tried.

STABLE MANURE *v.* ARTIFICIAL MANURES.

The principal practical object in manurial experiments with Strawberries is to ascertain whether the large amounts of stable or farmyard-manure can be profitably reduced or dispensed with by the addition or substitution of chemical or artificial compounds. Where stable manure has to be purchased at a cost of £9 to £12 per acre, the prospects of the grower in a bad season are not encouraging. But under the best conditions the expense is a heavy one, and if that could be reduced by half on an area of 100 acres, it would mean a substantial addition to the grower's income.

The comparison of heavy and light dressings

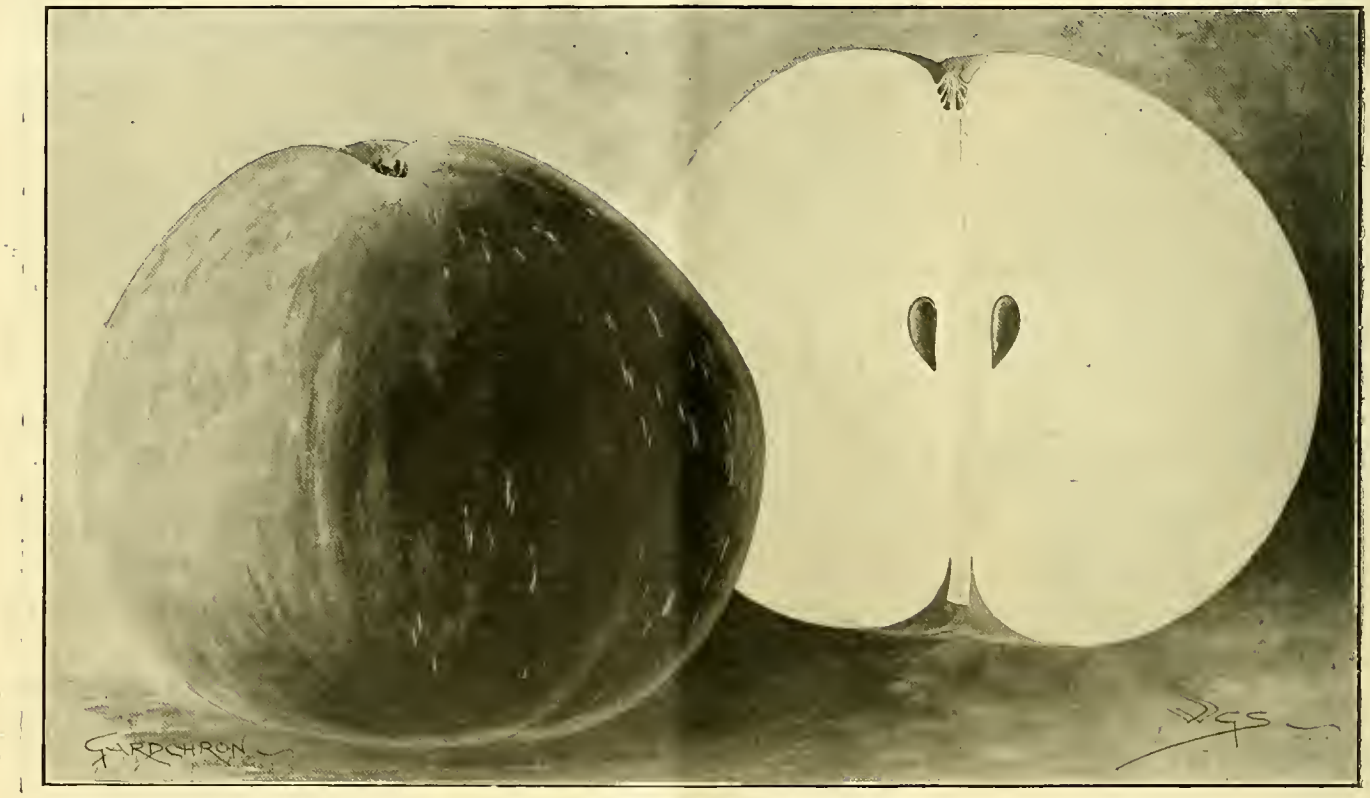

FIG. 12.—NEW CULINARY APPLE "FENN'S WONDER,"

Which obtained an Award of Merit at the Royal Horticultural Society's meeting on January 3, being shown by the Earl of Stradbroke (gr., Mr. T. Simpson)

(See also report of the meeting on p. 16 of our last issue.)

of manure have therefore taken this form, the amounts given being per acre:—

A. 30 tons of stable manure.
B. 20 tons of stable manure.
C. ,, ,, plus phosphates and potash.
D. ,, ,, ,, ,, plus nitrate.
E. 10 tons of stable manure.
F. ,, ,, plus phosphates and potash.
G. ,, ,, ,, ,, plus nitrate.
H. No stable manure, but phosphates and potash.
I. ,, ,, plus nitrate.

The phosphates, potash, and nitrate are calculated to supply the essentials of 10 tons of manure in C and D, of 20 tons in F and G, and of 30 tons in H and I, so that chemically all the plots are on an equal basis. From a scientific point of view it would be desirable to add to these a plot receiving no manure, but practically it is not essential, as growing Strawberries without manure can only give satisfactory results under exceptional circumstances in special soils As repeatedly stated the duplication of the plots is very desirable.

RESULTS.

The chief object of these notes is to indicate the lines of experimental work, and the discussion of results would occupy too much space. But as indicating how greatly the soil characters affect such experiments, it may be briefly stated as three examples that in a very light soil I found the stable manure in the heavy dressing (A) gave considerably the best results, notwithstanding the extra cost. In a heavy soil D gave the most profitable returns, taking into consideration the expense, and in a medium fertile loam the advantage was slightly in favour of G. But it is not merely a question of total weight of crop, the actual money value depends mainly upon the size of the fruits and their earliness. In this matter I have never found artificial manures alone give as satisfactory results as stable manure supplemented by a complete mixture of minerals and nitrogenous substances in moderate quantities.

Experience differs, and it must be stated that Dr. Dyer has deduced from his experiments that the addition of chemical manures to a light dressing of dung resulted in a marked and profitable earliness. He has recorded that in 1898 the variety President, "on the plot dressed only with light dung, gave the enormous crop of 4 tons 4 cwt. per acre. When this dressing was supplemented by chemical fertilisers, including 2 cwt. of nitrate of soda, the total crop was only increased to 4 tons 7 cwt. per acre. But in the first few days of picking we gathered from the chemically manured plot nearly 700 lb. more fruit per acre than from the dunged plot, and during this time the market value of the fruit picked was at least twice that of the fruit picked during the succeeding days." This is worthy of further examination, and it is an example of how difficult it is to generalise in outdoor experiments, as the conclusions arrived at are not supported by my own observations. It must also be borne in mind that earliness alone is not sufficient, as it is possible to obtain an early crop of very small and almost worthless fruits, and the advanced "market price" would not avail for comparison in such a case, as I have proved by both growing and selling the crops.

POTASH SALTS.

A peculiar circumstance in the Hadlow experiments is that the use of potash salts for Strawberries has been discontinued, because "in every case the potash plots were so markedly inferior in yield and the development of the plants appeared to be so unsatisfactory as compared with that of the plants on the non-potash plots, that we resolved to withhold potash salts in future." I have tried potash in various forms in conjunction with phosphates, but usually found that on heavy soils (such as that at Hadlow) the former was without any appreciable effect, and it was only when excessive quantities of kainit or muriate of potash were used that ill-effects were noted, and these then took the form of real injury to the plants. It would be interesting to know what form of potash was employed in the particular instance named by Dr. Dyer, as I have not observed any injury follow the use of sulphate of potash in ordinary dressings; on the contrary, in medium and light soils, a distinct advantage has been gained. *R. Lewis Castle.*

(To be continued.)

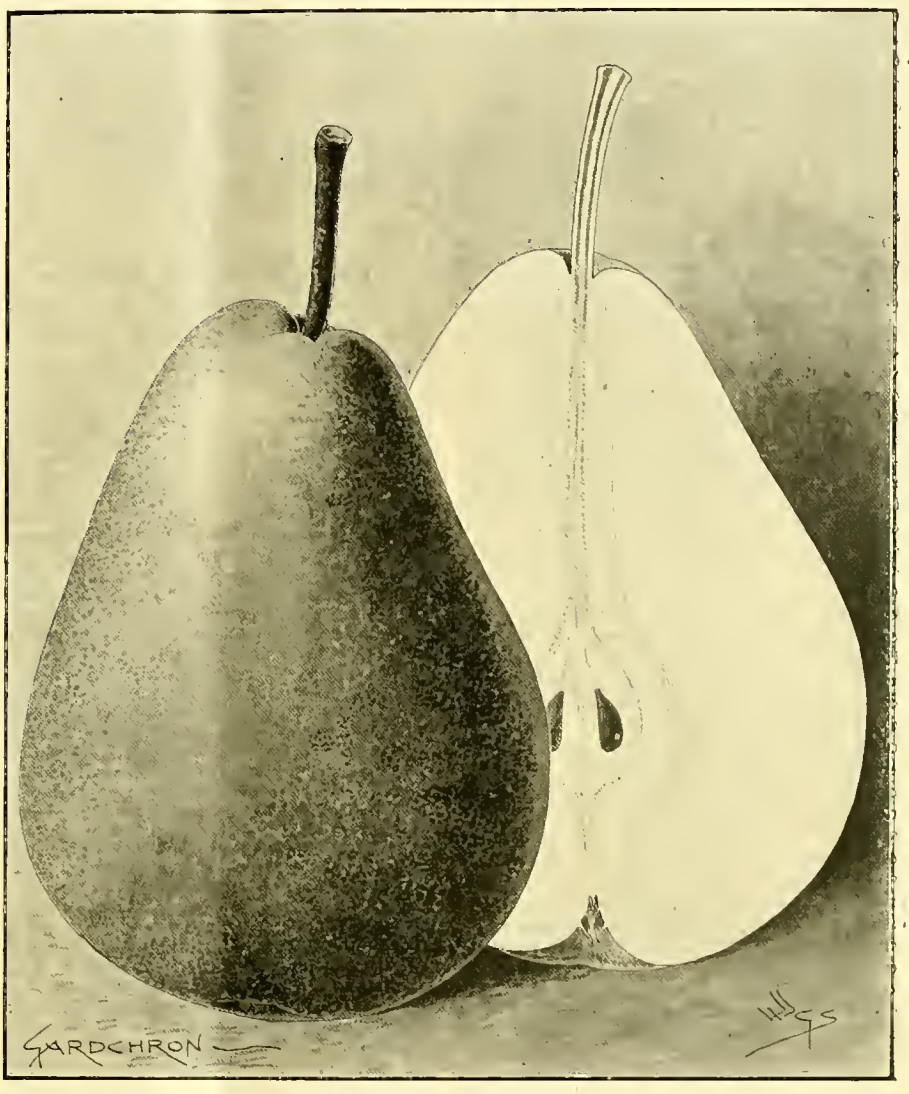

FIG. 13.—PEAR "SANTA CLAUS."

Said to have been introduced from Belgium thirty years ago. Recommended an Award of Merit when shown by Col. Brymer, M.P., at the Royal Horticultural Society's Meeting on January 3.

(See report on p. 16 of our last issue.)

FLORISTS' FLOWERS.

THE HOLLYHOCK.

I was pleased to read the remarks of "R. D." on the Hollyhock at p. 415 of the last volume. It is a pity that this noble flower is not cultivated more extensively. Doubtless the fungoid disease alluded to by "R. D." is greatly to blame for this neglect of one of the most noble of autumnal hardy garden flowers. It is easily raised from seed, and not only so, but the seedlings are as a rule but little inferior to the varieties from which the seed has been obtained, and some of them superior. I have been an admirer and cultivator of the Hollyhock for more than half a century, and can well remember the seedlings sent to Scotland from the garden of Mr. Charles Baron, of Walden, a worthy shoemaker and keen florist. The Hollyhock was his favourite flower, and the varieties produced flowers of small size, but up to the florists' standard of a high, perfect centre, although lacking in guard petal. Later, about 1854-5, a very fine set of seedlings was sent out from Paul's nurseries, Cheshunt. I well remember how impatient we were to watch the unfolding of the blossoms; no such flowers had been previously seen in Scotland. The finest of them were Beauty of Cheshunt (rosy-red), Glory of Cheshunt (yellow), Lizzy (peach colour), White Globe (the best white variety up to that time), &c. Probably the raising and culture of Roses was more attractive to the Cheshunt firm, and the stately Hollyhock was relegated to the background. At this time there was quite a different type of Hollyhock grown in Scotland, though the raisers of them were not much known; but I well remember seeing both the types grown in Lord Rosslyn's garden at Dysart, in Fifeshire, under the care of

the late Mr. John Laing. This excellent cultivator and good florist conceived the idea of crossing the two sections, the English type of medium size with a high centre and scarcely any guard petal worth mentioning, and the Scotch with large flowers, as much across as a tea-saucer, and with a small centre, the guard petals an inch wide all round. It was a great treat to me to visit this garden, and to see Mr. Laing at work amongst his flowers; everything in the garden was well grown, but he surpassed everybody in Hollyhocks and Chrysanthemums. Unfortunately he gave up his work at Dysart, and started a nursery at Forest Hill in company with Downie and Laird, of Edinburgh. Many splendid varieties of Hollyhocks were raised at Forest Hill—none were better; but unfortunately for the science of horticulture a nurseryman must grow plants that will pay, and probably owing to the Hollyhock not being a profitable plant to grow, or from the ravages of disease, or both combined, Mr. Laing gave it up, and found Begonias and other things more suitable.

The fungoid disease and other pests may be successfully dealt with if taken in time. When the Carnation-rust first appeared, the cultivators of this charming flower were frightened out of their senses; but we know now that it is not to be dreaded. Any collection can be cleaned however bad it is by examining the plants once a week and carefully cutting off the diseased parts and burning them. Some of the plants may look frightful scarecrows, with scarcely a bit of foliage left, but better no leaves at all than diseased ones. I have treated the Hollyhock fungus in the same way, and with success. I bought a collection of what were supposed to be clean plants from Scotland when I came to Bookham, but I found they were not, and the leaves were badly attacked by the end of the flowering season. As soon as the flowers had passed away I cut down the stems as near to the surface of the ground as I could, cut off every leaf, dug the plants up, and dipped all the parts that had been above ground in a solution of soft-soapy water and sulphur. They were subsequently potted into 8-inch pots, and wintered in a cold frame. One would have thought that this drastic treatment would have been enough to get rid of the disease. The plants were put into a greenhouse to make growth early in the new year, and as soon as the growths were ready they were propagated, either by root-grafting or by cuttings, and the leaves were clean and healthy until they were planted out, but the disease appeared, and I kept it down by cutting off the diseased leaves. It was of no use however, for within a short distance of my plants was a row of single varieties smothered with disease. Here was my trouble. I could have conquered the fungus, but I had no power to interfere with other people's gardens. If this or any other very infectious disease in plants is to be stamped out, it must be done on the same principle as hydrophobia was stamped out by muzzling the dogs, or as swine fever or the murrain in cattle is stamped out. There are no diseased Carnations near me, and I can easily keep my plants clean, and just as readily may the Hollyhock disease be stamped out in a country garden outside an infected zone.

Red-spider is troublesome in some gardens, but it can easily be destroyed by syringing in the morning or at night in hot weather.

Propagation by seed is the easiest and a very satisfactory way to grow Hollyhocks. The seed should be sown in May; if it is sown earlier the plants are likely to make an attempt to flower in the autumn of the same year, and this is not desirable. Old plants of the best-named varieties are not hardy enough to stand some of our winters, but unflowered seedlings seldom suffer. They can be planted where they are to flower in July or August at least a yard apart. They need rich well-manured soil, and a mulching of decayed manure on the surface is very desirable.

The flowering of named varieties may be prolonged by propagating plants from eyes which can be obtained from the lateral growths during summer; these growths have generally more flower-buds than leaf-buds, but a few of the latter will be found at the base of the growths. These can be cut out, and planted in small flower-pots; and if treated similarly to Vine-eyes, each one of them planted separately, and plunged in very gentle bottom-heat, or in a spent Cucumber-frame, they will succeed. When the young plants are well established repot them, and winter them in cold frames. Cuttings or root-grafts are struck in spring in a propagating-house; they are plunged in bottom-heat, and if potted in fairly moist soil they should not receive any water until roots are formed. These will be the latest to flower. *Jas. Douglas.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Orchids Resting.—Most pseudo-bulbous Orchids are in a state of rest during winter, when the climatic conditions are most unfavourable. Absence of light cannot be altogether remedied, but the glass can be kept clean to admit as much as is available. The enervating effects of the use of much fire-heat should be compensated by judicious damping of the surfaces in the house and by ventilation, always refraining from employing more fire-heat than is necessary to maintain the desired temperature. The application of water to the roots of the plants is probably the most difficult duty to fulfil, as so many things have to be considered, including the size of the receptacle, the nature of the potting material, the habit of plant, and the weather at the present time and in the immediate future. Deciduous Orchids will naturally need water less often than those having leaves, but in neither should an unnatural degree of shrivelling be permitted, and the time to give water in sufficient quantity and no more is just when the older pseudo-bulbs approach the shrivelled state. On no account should pseudo-bulbs made in the two previous seasons be allowed to shrivel, or the tips of the leaves may suffer. The above remarks apply more particularly to Cattleyas, Lælias, Lælio-Cattleyas, and Dendrobiums. In the case of Odontoglossums, Oncidiums, Vandas, &c., one's judgment has to be guided more by intuition than by ocular observance. If such plants as Vandas are kept too long without water loss of the lower leaves will follow, and again, if kept equally long in a wet state, the disease known as "spot" may attack and disfigure them. A few days or even a week's drought will not affect large plants, but small plants having less potting material at their base may not remain absolutely dry for so long a time, and the giving of water to these is attended with less risk, as they sooner become dry again. A fine day should always be taken advantage of to examine each plant and supply water or not as may be judged to be desirable. During unfavourable weather afford water in small quantities only to those that are on the verge of suffering from drought. Except in the case of some Cypripediums, it is best not to wet any of the leaves, because it might lodge in the sheathing-bracts and cause injury. All water used for applying to the roots of Orchids should be heated to the same temperature as that obtaining in the house. Immersion of the receptacles to the surface of the potting material should not be practised during winter.

Miscellaneous. — During foggy weather less damping should be done so that the atmosphere inside may become comparatively dry. The temperature should be well below the maximum though when the outside atmosphere is fairly mild, the set standard may be maintained. During frosty weather, or when cold winds prevail, some kind of covering should be employed on those roofs easy of access, with the double purpose of conserving heat and preventing the formation of ice on the inside, for this would afterwards melt and cause "drip" on the plants beneath. Flower-spikes will now be appearing on many Odontoglossums, so that means of capturing any slugs or snails present should be adopted. Nothing is so efficacious as seeking for them at night by the aid of a lamp when the weather is moist.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant, Oxon.

Mulching. — Generally speaking, all newly planted trees should be mulched with long strawy litter. This is the more necessary in cold districts, so that the young roots which start growth in the spring and are very tender may not be killed by severe frost.

Pruning Fruit-trees.—Complete the pruning of fruit-trees as early as possible, excepting Peach-trees and newly-planted trees of any variety. When pruning, try to secure an equal balance of top growth and root-action. Cut out all useless shoots, so that one shoot when in foliage will not injure its neighbour by overcrowding. It must be borne in mind that all stone fruits dislike the use of the knife, especially the Apricot. Many growers treat Apricot-trees too generously, plant them in too rich a soil, thereby causing them to make strong soft growth; subsequently these growths are pruned hard back, and "gumming" is the result, or worse still a branch dies, and finally the tree also. Plenty of broken bricks, mortar rubble, and old plaster should be incorporated with the soil when planting Apricot trees, and they will then be likely to produce firm, short-jointed wood. It is best to prune Apricots in the autumn directly the leaves turn colour or fall; then the cuts will partially heal over before the sap descends. If the shoots were pinched back in summer to the fifth leaf they can now be shortened back, leaving two or three buds, and the extending shoots, which have still some amount of wall space to cover, should have one-third of their length removed. In the case of old trees whose spurs have become of some considerable length, and whose flowers do not have the same amount of protection as those near to the wall, they should be shortened back where possible to a growing shoot, failing this, a dormant bud, which will eventually furnish a growth. This rejuvenation of the spurs should be done gradually, employing a period of two or more years for each tree. Apricots may be grown successfully on low walls, training-in each season new shoots, and removing a corresponding number, but always avoiding overcrowding. The foregoing remarks apply equally well to Plum, Sweet Cherry, and Pear-trees trained in the shape of fans. Where young fan-trained trees are making strong growths 3 to 4 feet in length, it is imperative that these should be shortened by one half, always selecting a well-placed bud at the end of each shoot. A portion of the resulting shoots will be required for extending and furnishing the wall. In the case of trees with horizontal branches prune back the leading shoot to 12 inches, leaving a good growth bud at the top and one on either side for furnishing the next pair of branches. The leading shoots on other parts of the tree should not be pruned very severely, the object being to obtain fruit-spurs from the dormant buds rather than new growths. In all cases remove the fruit-trees entirely from the walls, destroying all the old shreds and ties. Where there is any evidence of scale or other insect-pests, wash the trees with Gishurst compound, using a partially worn painter's brush. Any holes in the brick-work where insects may hibernate should be stopped with cement. All walls should be wired where practicable; the initial cost is but small compared with the labour saved in tying and cleansing the trees, besides which leaf, branch, and fruit get a freer circulation of air round them. Where buttresses make it somewhat

awkward to wire walls, instead of straining wires over these, cut out joints between the bricks by means of an old rough saw, to allow the wires a free course, afterwards "pointing" the buttresses with cement.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Seakale.—The crowns should now be lifted and stored in the open ground with each crown standing in a perpendicular position, and covered with soil to their full depth, adding any light material as a protection over the whole. The thongs should be cut in lengths of 5 inches, with the cut at the lower end slanting, tied in bundles of 50, and plunged in the soil to keep them from shrinking. We grow this vegetable on the same ground with success for a number of years, but deep cultivation must be practised. Rich manure is seldom required and salt I do not use or recommend. Crowns of moderate size produce the best flavoured Seakale. To keep up a constant supply place the necessary number of crowns in heat every ten days. Put them in any place of darkness containing a flow-and-return hot water-pipe, and cover the crowns standing perpendicularly with screened leaf-soil to the depth of 4, 5 or 6 inches, whichever length should be preferred. Keep the material damp, and as soon as the tips of the Kale appear above the soil cut them with about 1 inch of the old crown attached.

French Beans.—Veitch's Early Favourite is a suitable variety for sowing at this season. The seeds should be sown in pots 7 inches in diameter, using plenty of drainage material and a soil composed of light loam, mixing with it a little dry stable manure. The seed should be planted about an inch deep. Only sufficient space need be left in the pot for watering purposes. This plan is preferable to the practice of adding new soil to the plants as growth develops. The soil when sowing should be in a moist condition so that water will not be needed until the seedlings appear. In establishments where sufficient space can be provided the climbing varieties of French Beans give very satisfactory returns if cultivated in boxes. A temperature of 55° to 60° is sufficient.

Hot Beds.—Attention must now be directed to the formation of new and the re-lining, as the material settles down, of previously formed hot-beds, upon which further remarks will be made next week.

Horse-radish should be planted in a deep, rich, and well-drained soil that was well manured and trenched 2 feet in depth last season. The cuttings (12 inches in length) should be planted in rows 2 feet apart, allowing 1 foot between the plants in the row. Remove all the side rootlets and eyes from the cuttings, and plant them in a slanting position, using a crowbar with which to make the holes; this reduces the tendency of the roots to branch. Another system is to use single crown-buds with 2 or 3 inches of the stem attached. These may be dropped in holes 1 foot in depth made with the crowbar.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Figs require much water at the roots and moisture in the atmosphere, as they are subject to attacks from red spider, and attention to this detail is a dominating factor in the work of successfully forcing them into fruit. It may not be absolutely necessary when the earliest trees are grown in pots to plunge them in a steady bottom-heat of 75° to 80°, but where this can be given them so much the better, for under such conditions the atmospheric moisture can be more easily maintained when the weather prevents the syringe being freely used. The work of damping and syringing must not, however, be neglected, and the roots must be kept in a moist condition by applications of weak liquid-manure applied at a temperature of 80°. Trees started in November may now be afforded a night temperature of 60°, and by day with sun-heat this may be increased to 75°, but a little air may be admitted in favourable weather when the temperature in the house has risen to 70°. Introduce later pot plants to warmth, or close houses containing trained trees, and afford them a night temperature of 50° to 55°. Have all the woodwork and glass in later houses cleaned; afford top-dressings to the trees, and make all ready for starting, but do not re-pot any of the trees at this season, rather give rich top-dressings of good loam, mortar rubble, wood-ashes, and bone-meal, the compost being made very firm.

Fruiting Pines.—Get the Pine stove in readiness for the earliest plants of the Queen variety by thoroughly cleansing the woodwork and white-washing the walls. An early start must be made in order to obtain ripe fruits in May and June. Put fresh leaves or tan into the pit, and allow it to settle down before plunging the pots into this material. The bottom-heat should range from 85° to 90°, and when it has fallen to 90° the pots may safely be plunged. Some judgment is necessary in selecting the plants for forcing. Choose those having the thickest stems and a number of small leaves in the centre, as these are generally most likely to show fruit before making fresh growth. Remove a few of the lower leaves from the stems and any loose soil from the roots, then afford the plants a top-dressing with rough fibrous loam, with a little bone-meal and soot added, firmly ramming this round the collars of the plants. Plunge the pots 2 feet apart, and if the bottom-heat is under control and not allowed to exceed 90° the pots may be plunged to the rims and the material pressed closely round, but if the heat is likely to rise much higher the pots must be plunged loosely until the heat becomes less. The plants having been rested, and the roots kept dry for a time, a thorough application of clear water must be given at a temperature of 80°. Cover up the pits at night in order to economise fire-heat and preserve moisture. A temperature of 65° at night, and 80° by day with sun-heat, with a little air for a short time at 75°, will be sufficient to commence with. Keep the evaporating-pans on the hot-water-pipes filled with water, and provide additional atmospheric moisture by occasionally damping the paths and all available spaces in the houses.

Plants for Succession will require to be kept for some time yet in a bottom-heat of 70° to 75°, and an atmospheric temperature at night of 58° to 60°. Do not allow the plants to become dry at the roots, and exercise special care in respect to those that are plunged near to the hot-water-pipes, as these are more likely to suffer from drought.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Herbaceous Border.—In choosing the position for making a border of herbaceous plants, several conditions must be given consideration. There must be a good background, some shelter from prevailing winds, but nothing that will shade the plants from the sun, or big trees whose roots would rob the soil of its richness. It should not be too near to the residence, but be used as a connecting link between the useful and ornamental departments, or in front of a shrubbery having a serpentine foreground. Such a border loses half its charms if planned with mathematical precision. Having settled the situation and the width of the border, which may vary from 3 to 8 yards or so, commence to trench the ground at one end, working into the staple soil quantities of manure, leaf-soil, loam, old potting-soil, and vegetable refuse, making when finished a border 2 to 3 feet deep. This will deplete the store of compost, but the gardener must console himself with the old adage that "it is not lost what a friend gets." I strongly advise having a border for producing effect in spring and early summer, and another for effect in late summer and autumn. Many bulbs and strong-growing perennial flowering plants being more suited for the wild garden may be omitted when planting these borders. For a border intended to be at its best in the latter part of July and onwards, it is advisable to employ the choicest plants only. Avoid planting one variety at recurring intervals, but have prominent specimens standing out, then lays of pleasing combinations of foliage and colour, irregular shaped masses of one kind dovetailed into another. Let there be no overcrowding, but a circumspectness that can only be obtained by a knowledge of the plants, and practice. The background can be made to add lustre to the flowering plants by planting in it trees of distinct and effective colours, such as Pinus koraiensis, Cupressus Triumph of Boskoop, C. Lawsoniana var. Allumi, Salix regalis, Prunus Pissardi, Populus aurea, Yews, Hollies, &c.

Rosary.—Prune and tie in hardy Roses on bowers, pillars, and pergolas. These are generally of the Ayrshire Rambler and Wichuriana types. Cut out all stunted and weak growths, and tie in the remaining growths 6 ins. apart. This pruning will cause the bowers to have a naked appearance, but the plants will flower more profusely for it in summer. Amongst the best of the rambling, trailing, and climbing varieties are Turner's Crimson Rambler, Dorothy Perkins, Auguste and Alberic Barbier, François Foucard, René Andry, one of the very best, and Elisa Robichon. Protect tender varieties with bracken and Fir branches.

Propagating Department.— Peruse the seed catalogues, and send your order early. Obtain stocks of pots and sundries. Prepare the propagating-house by getting ready a good hot-bed in addition to the hot-water-pipes. Induce stock plants of Heliotrope, Trepæolum, Lobelia erinus vars., Ageratum, Verbenas, and Agathæa cœlestis to make growth. Sow seeds of Begonias in pans, covering them with a sheet of glass till germination has taken place.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Conservatory or Coolhouse, with Flowering Plants.—Keep this structure as bright and gay as possible. The recent fog has had a bad effect on many plants that would otherwise have done service for a considerable time. Defects must be made good. Admit air carefully, but lose no opportunity of doing so on all favourable occasions. See that the creepers on the building are tied neatly together, and let tidiness generally be a feature.

Plants for Early Forcing that were potted and plunged in ashes some time ago will on being placed in heat commence to grow readily. Amongst the most useful are Spiræa Thunbergii and S. confusa, Staphylea colchica, Lilac Charles X., Madame Lemoine, and Viburnum plicatum. Azaleas, whose buds are plump and prominent, may be put in the forcing-house, and be syringed frequently. Batches of the earliest Tulips and Narcissus should from time to time be placed in heat to produce a succession of flowers according to requirements.

Hippeastrums (*Amaryllis*).—Flowering bulbs that were well ripened and have rested should be examined, and any that are showing their flower-sheaths should be turned out of their pots, the soil carefully removed from the bulbs, and the bulbs repotted. A compost consisting of three parts good turfy loam, one part of decayed leaf-soil, one part of broken lime-rubble, and a 6-inch potful of Thomson's "Plant Manure" to each barrowload of the compost, together with sufficient silver sand to keep the whole porous, will be suitable. The plants should be placed in a stove temperature if early flowers are wanted; they may be syringed lightly, but not watered until root action has commenced. Seeds also may now be sown thinly in pans or pots, and lightly covered with finely sifted potting soil. If the soil is watered before the seeds are sown, no more water should be required until the seeds have germinated. Place a sheet of glass over the pots to prevent drip or insects from disturbing them, and plunge the pots to the rim in a mild bottom-heat.

Gloxinias.—For an early batch a few of the corms which show signs of activity may be repotted. Reduce the old ball of soil by means of a sharp pointed stick, and put them into pots according to the size of the corms, using a compost of turfy peat and loam in equal proportions, with a little silver-sand. The soil should be moderately moist when used, and no water will then be required until a good start into growth has been made. Syringe the plants overhead in favourable weather.

Cinerarias, Primulas, &c.—Remove any decayed foliage on plants in cold frames, and allow a circulation of air to pass between them on all favourable occasions.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	JAN. 16	British Gardeners' Association Meeting at Cardiff. Birmingham and Mid. Counties Gardeners' Mutual Improvement Association Annual Meeting.
WEDNESDAY,	JAN. 18	Brixton, Streatham and Clapham Hort. Soc. Ann. Meeting.
THURSDAY,	JAN. 19	Linnean Soc. Meet. Gard. Roy. Ben. Inst. Ann. Meet. and Elect. of Pensioners at Covent Garden Hotel, at 3 P.M.; Ann. Friendly Supper at 6 P.M.

SALES FOR THE WEEK.

MONDAY, JANUARY 16—
Hardy Border Plants, Gladiolus, Spiræas, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

WEDNESDAY, JANUARY 18—
Azaleas, Aspidistras, &c., from Belgium: Roses, Carnations, &c., at Protheroe & Morris' rooms, at 12.

FRIDAY, JANUARY 20—
Greenhouse Plants, Iris, Hollyhocks, &c., at 67 and 68 Cheapside, E.C., at 12 o'Clock, by Protheroe & Morris.—Great sale of Orchids, by order of Messrs. Sander & Sons, at Protheroe & Morris's Rooms, at 12.30.

For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —36·9°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 11 (6 P.M.): Max. 49°; Min. 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 12 (10 A.M.): Bar., 30·1; Temp., 44°. Weather—moderate degree of sunshine.
PROVINCES.—*Wednesday, Jan.* 11 (6 P.M.): Max. 48°, Dover; Min. 44°, North of Ireland.

The Importance of Spraying.

THE value of spraying as a means of checking fungous and insect pests on crops is now widely acknowledged, and the Cornell University (Ithaca, N.Y.) has lately published Bulletins dealing with the subject. The following general directions are as applicable in our orchards and gardens as they are in America:—

"It should be remembered that in all cases success is dependent on the exercise of proper judgment in making applications. Prevention in the case of fungous diseases should be the watchword. Plant diseases are rarely cured, but they can frequently be prevented. Know the enemy to be destroyed, know the remedies that are most effective, and apply at the proper season. Be prompt, thorough, and persistent. Knowledge and good judgment are more necessary to success than any definite rules.

Spraying is an insurance. Spraying is no longer an experiment. It is an accepted practice, as tillage, pruning, and fertilizing are. It may not be necessary to spray every year, but the farmer should be prepared to spray every year. In case of doubt spray. See that pumps and rigs are in working order before ploughing time comes. Order your materials. 'Be ready.'

There is no one best pump or nozzle. There are best devices for particular kinds of work, depending on the size of the plants to be sprayed, the kind of spray to be used, the extent of the operations. Get a good pump, one that works easily and smoothly, and is strong enough to make a fine spray when two lines of hose and four nozzles are used, if it is designed for field work; it is economy in the end. Look over the horticultural papers for advertisements of spraying outfits, and write for circulars. Power pumps are becoming more popular each year."

As regards spraying for wild Mustard (Charlock), Mr. J. L. STONE remarks that:—"Wild Mustard growing with Cereals or Peas can be destroyed with a solution of copper sulphate, without injury to the crop. A 3-per-cent. solution (about 10 lb. to the barrel, or 40 gallons of water), at the rate of 40 to 50 gallons per acre, gives very satisfactory results."

Mr. JOHN CRAIG contributes to the Bulletins information concerning dust or dry powder sprays, and remarks that:—

"The labour and expense of applying dust sprays appear to be less than for sprays in liquid form. Six applications of dust spray were practically not more effective on Apples than two applications of Bordeaux-mixture, nor did they cost more. Dust or powder sprays should be applied in the early morning or late afternoon. Damp, not wet, conditions of atmosphere and of the tree are desirable, if not essential. The powder must be strictly dry. Thoroughness of application is as necessary as with Bordeaux-mixture. Finally, it does not seem that, at the present time, there is any good reason why an orchardist who has reasonably level ground and available water supply, and who is equipped with pumps for the application of liquid spray, should discard these, or even introduce the dry spray method. Under special conditions it certainly has advantages, but the conditions demanding the employment of dry sprays are usually lacking in the fruit districts of New York."

MR. CHAMBERLAIN'S GARDEN (see Supplementary Illustration).—In our issues for November 26 and December 3, 1904, we published several very interesting views of Mr. CHAMBERLAIN'S garden at Highbury, near Birmingham. As a Supplement to this present issue a further picture is given from the same garden, illustrating the new part of the pleasure-grounds, which has been planted with an exceedingly choice collection of trees and shrubs. It will be seen that the planting has been done in a very informal manner, but each species has been given a position either of isolation or of association with others as was best suited to its characteristics. The surface of the ground throughout this part of the garden is covered with grass, which is mown occasionally with scythes; and winding, grass-covered paths, kept closely mown with machines, serve to guide one through the miscellaneous assortment of beds and isolated specimens of trees and shrubs. The effect is good, and upon a cursory glance at the picture we might imagine the view to be one in the Royal Gardens at Kew.

EUCALYPTUS.—The fifth part of Mr. MAIDEN'S *Critical Revision* contains descriptions and illustrations of E. stellulata, E. coriacea and E. coccifera, the latter a Tasmanian species, which has proved hardy in some parts of southern England.

LINNEAN SOCIETY.—The next general meeting of the Society will be held on Thursday, January 19, 1905, at 8 P.M. Exhibition: Rev. T. R. R. STEBBING, M.A., F.R.S., Sec.L.S.—Specimens of notable and little-known Crustaceans, chiefly exotic. Discourse: Dr. A. HENRY, F.L.S.—Botanical collecting. Paper: Dr. W. G. RIDEWOOD, F.L.S.—"On the Cranial Osteology of the Families Osteoglossidæ, Pantodontidæ, and Phractolæmidæ."

"KEW GUILD JOURNAL."—We are requested to state that in compliance with numerous requests by those interested in Kew and Kewites, a few copies of the Journal are this year available for purchase by non-members of the Guild. Applications for copies should be made to the Secretary (W. N. WINN), Royal Botanic Gardens, Kew. Price 1s. per copy; by post, 1s. 2d.

THE HOLLAND HOUSE SHOW.—We greatly regret to hear, from an official source, that there will be no exhibition of the Royal Horticultural Society in Holland Park in the ensuing summer.

PHYLLOXERA.—M. G. CANTIN reports to the Academy of Sciences, Paris, that lysol is destructive to the winter egg of the Phylloxera. The cuttings of the Vine were steeped before planting in a one-per-cent. solution of lysol. In spring, before the pruning is done, the Vine is sprayed with lysolated water at the strength of 4 per cent.

"THE ANTIQUARY."—For twenty-five years this magazine has faithfully chronicled the progress of archæological research, and has critically reviewed the antiquarian work of the time. With the present year the *Antiquary* appears in slightly different guise, the first number of a new series being in a newly designed cover, and containing an additional sheet of eight pages. We hope our contemporary will still continue to increase in popularity, of which this commencement gives good promise. It is published by ELLIOT STOCK, Paternoster Row.

VILMORIN MEMORIAL. — The total amount received now amounts to 30,439fr. (=£1,217+), contributed by 2,710 subscribers. Mr. HARRY VEITCH has forwarded £5, which will be included in the next list. A large proportion of the subscribers hail from the United States.

WOBURN FRUIT FARM.—The fourth report of the proceedings at the Duke of BEDFORD'S fruit farm at Ridgmont, near Woburn, has been published by EYRE & SPOTTISWOODE. It deals with the physical and chemical characters of the soil and then records the results of the manurial experiments on Strawberries, Gooseberries, Currants, Raspberries and Apples. It is very curious to note that whilst in other crops manure, whether natural or artificial, produced an increase, no such increase is observable in the case of Apples. In a future issue we hope to reproduce some portion of this interesting report, the results in which show more conclusively than ever the necessity for the grower to undertake experiments on his own soil during a period of several years. The experiments need not be either extensive or elaborate, but the results would be more valuable in practice than any obtained elsewhere under different conditions.

NICOTIANA SANDERÆ.—This hybrid between N. affinis and N. Forgetiana has conquered the horticultural world. It has been figured in our own columns, in *Flora and Sylva*, in the last issue of *The Garden*, and in the *Revue Horticole*, and we know not what other periodicals. From what we saw of it on a large scale at Bruges last autumn we are decidedly of opinion that its reputation is not greater than its merits demand. There are many colour variations not yet in commerce. It is a half-hardy annual, which may be treated like the China Aster.

LOUIS LUBBERS.—We regret to have to announce the death of this gentleman, who was known to many of our readers as the former Curator of the Brussels Botanic Garden, and a regular attendant at the principal horticultural meetings in Belgium. M. LUBBERS was in the seventy-third year of his age, and had been the recipient of many honours.

MANCHESTER BOTANICAL GARDENS.— The following is an extract from the *Manchester Evening News* for January 5:—"A deputation headed by Mr. JOHN BOWDEN, Treasurer of the Royal Botanical and Horticultural Society of Manchester, and Mr. Alderman GIBSON, waited upon the Lord Mayor of Manchester to-day with an offer to hand over the Botanical Gardens at Old Trafford to the city on the understanding that the obligations at present incurred by the management would be met. The LORD MAYOR while viewing the proposal with favour, was not, of course, in a position to make a definite reply but he promised that he would report to the proper quarter. He thought the Council would be pleased to secure at a nominal price an open space of such great value and beauty. The alternative, he understood, was that the estate would go into the hands of the builders, as, owing to the changed condition of the neighbourhood, it was no longer possible to maintain the gardens without financial loss. Time was when the Botanical Gardens at Old Trafford were among the most popular, as they were in many respects the most beautiful of the resorts of Manchester, Lancashire, and Cheshire people. An older generation will remember the crowds that were in the habit of flocking to the famous flower shows that were held from time to time. No more charming gatherings were held throughout the year. Their fame spread throughout the North of England. Then the famous Jubilee Exhibition was built round the gardens, of which the gardens themselves were the gem, the haunt every day in the week and every evening of thousands of delighted citizens. For many years it has been apparent that the gardens, on their old basis, could not be continued. Money was lost every year, largely owing to the changes in the Old Trafford district from the residential point of view. Not long ago there was a feeling that the Stretford Urban District Council should acquire the gardens, but a poll of the ratepayers being taken on the question, the majority voted against the project. The gardens, it will be remembered, are a mile beyond the city boundary.

GRAFTING CHRYSANTHEMUMS.—In the *Revue Horticole* M. GASTON CLEMENT recommends that notch-grafting should be practised on Chrysanthemum frutescens, especially the varieties known as Countess of Chambord and Golden Star (Étoile d'Or). The most favourable season for the operation is from February to April. The grafted stocks are kept in a propagating-frame for about three weeks, and then gradually hardened-off.

A FAMOUS CAMELLIA TREE.—The famous Camellia tree, well known to tourists, in the hot-house of the English garden of Pillnitz Castle, near Dresden, is reported to have been seriously damaged by fire. The tree is 27 feet high, 300 years old, and was originally brought from Japan. It was presented by the Empress ANNE of Russia to the Elector FREDERICK AUGUSTUS II. in 1739.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We would remind our readers that the sixty-sixth Annual General Meeting of the members and subscribers of this Institution will be held at the Covent Garden Hotel, Southampton Street, Strand, London, W.C. (adjoining Covent Garden Market), on Thursday, January 19, 1905, at 3 P.M., for the purpose of receiving the report of the Committee and the accounts of the Institution (as audited) for the year 1904; electing officers for the year 1905; and for the election of eighteen pensioners on the funds. The chair will be taken by HARRY J. VEITCH, Esq., Treasurer and Chairman of Committee. The poll will open at 3.15 o'clock, and close at 4.30 o'clock precisely, after which hour no voting papers can be received. The annual Friendly Supper will be held at the same place after the Annual Meeting at 6 P.M., when EDWARD SHERWOOD, Esq., will preside.

STOCK-TAKING: 1904.—It will be necessary to give a very brief synopsis of the Trade and Navigation Returns for the month of December, before setting forth in brief review the total record for the year 1904. The imports for December are valued at £52,845,366, which, compared with the same period of 1903 (£52,319,618), shows an increase of £525,748. The exports also show an increase—£28,072,134, as against £24,612,503 for the same period in the preceding year — an increase of £3,459,631. By the way, it may be worth noting here that among the latest arrivals of fruit in December were two consignments of Peaches from the Cape, some sixty packages in all.

We come now to the year's over-sea trade, which figures for the enormous sum of £852,180,021. If this be compared with the figures for 1903 (£833,400,397), an increase of £18,779,624 will be seen. To distinguish: the imports value for last year was £551,362,124; for 1903, £542,600,289—an increase of £8,761,835. As to

EXPORTS,

the figures for last year were £300,817,897; for 1903, £290,800,108—an increase of £10,017,789. The summary section of the Returns has all its wonted value. It is as follows:—

IMPORTS.	1903.	1904.	Difference.
	£	£	£
Articles of food and drink—duty free	114,093,078	112,098,747	−1,994,331
Articles of food & drink—dutiable	114,001,215	115,168,574	+1,167,359
All other Imports...	214,505,996	224,094,803	+9,588,807

Again, the value of the flowers, plants, &c., imported last year was £242,454; this compared with 1903 (£248,689) shows a decrease of £6,235. The following table of fruits and vegetables imported speaks for itself; some of the figures are well worth noting:—

IMPORTS.	1903.	1904.	Difference.
Fruits, raw—	Cwt.	Cwt.	Cwt.
Apples	4,569,546	3,771,781	−797,765
Apricots and Peaches	9,578	13,465	+3,887
Bananas—bunches ...	3,087,518	3,910,511	+822,995
Cherries	110,192	260,830	+150,638
Currants	76,419	117,352	+40,933
Gooseberries	34,312	76,215	+1,903
Grapes	684,084	853,572	+169,488
Lemons...	978,318	989,296	+10 978
Nuts—Almonds ...	157,156	153,015	−4,141
Others used as fruit	791,281	706,065	−85,216
Oranges...	6,176,752	5,853,253	−324,499
Pears	271,518	542,624	+271,106
Plums	594,626	493,984	−100,642
Strawberries	32,644	34,524	+1,880
Unenumerated ...	688,873	654,765	−34,108
Vegetables, raw—			
Onions ... ...bush.	8,619,919	8,291,814	−328,105
Potatos ... ... cwt.	9,150,202	10,003,267	+853,065
Tomatos ... ,,	1,071,927	1,134,697	+62,770
Unenumerated ,,	396,784	457,491	+60,707

The value of the twelve months' imports of dried fruit was £1,849,683; for the preceding year, £2,116,717—a decrease of £267,034.

The value of the timber of all descriptions brought to our ports last year was £15,505,625. Compared with the figures for 1903 (£18,192,519), this shows a decrease of £2,686,894. The denudation of some of the principal timber lands still continues, we believe; and as there are no nurseries the result may easily be foretold. A few words as to

EXPORTS.

The total for the year is placed at £300,817,897; for 1903, £290,800,108 — an increase of £10,017,789. There is nothing to be gained by endeavouring to account for this or that rise or fall—the figures must stand for themselves.

NATIONAL POTATO SOCIETY.—Arrangements are not concluded, but it is probable that the exhibition will be held on November 22 and 23 at the Royal Horticultural Hall, Vincent Square.

"PIGS FOR PROFIT."—This is No. 10 of *The Profitable Farm and Garden* Handbooks (148 & 149, Aldersgate Street, E.C.), and should be consulted by everyone who keeps pigs or who proposes to do so. The instructions are plainly and simply written and the illustrations of samples of some of the best breeds give additional value. So useful an animal is the pig to large and small farmers that the least they can do is to learn how to keep the creature clean and comfortable.

THE BRITISH GARDENERS' ASSOCIATION.—We are informed that a meeting to consider the advisability of forming a local branch of the Association was held in the Co-operative Hall, Ipswich, on Wednesday, January 4. Mr. J MORGAN, of the well-known firm of THOMPSON & MORGAN, presiding over a large and representative gathering of local gardeners. In the course of his address, Mr. W. E. CLOSE, a member of the Committee of Selection and a former resident in Ipswich, dwelt particularly upon the benefits which would result to employers from the establishment of a reliable source for the supply of thoroughly competent and trustworthy gardeners. He strongly urged the establishment of a local branch, and asked all those who cared for the uplifting of their profession to at once become members. After a well-maintained discussion a resolution approving the programme of the Association and the formation of a local branch was carried unanimously. Mr. E. G. CREEK, of Westerfield House Gardens, Ipswich, agreed to undertake the duties of local secretary. There was a British Gardeners' Association meeting at Reigate on January 10, and others will take place at Swansea, on Friday, 13th; at Cardiff, in the Town Hall, on Monday, 16th; at Birmingham, on February 13; in the Isle of Wight on a date to be arranged, and at other places.

OUR CONTEMPORARIES. —The New Year's number of the "GARDENERS' MAGAZINE" is a special number, containing numerous illustrations, and a variety of information from grave to gay. Mr. ODELL's article on Gourds should induce gardeners to grow these highly interesting plants. Mr. GORDON's article on the evolution of the Cabbage is very interesting as showing the plastic nature of Brassica oleracea. The Almanac reminds us in its first item that taxes are due—a painful if accurate beginning. Let us hope that the practical directions which our contemporary gives may be the means of supplying a fund from which these painful though necessary requirements may be met.

"THE GARDEN," which now enters the ranks of the penny papers, has a good coloured illustration of Nicotiana Sanderæ, an almanac, and numerous illustrations. Prizes are offered by Mr. GINNS to young gardeners for answers to certain questions relating to hardy trees and shrubs.

"THE JOURNAL OF HORTICULTURE" opens the New Year with a New Year's message from the veteran, "D. Deal." Amid other matter there is an interesting article on the vineyards near Montreux. The writer does not tell us what

number of francs he had to pay as a fine for looking at the Vines. Our own experience is that a fine, of small amount, it is true, is threatened for entering a vineyard, much more for touching a leaf.

"THE GARDENER" is full of practical notes and varied information. We note articles on hardy trees and shrubs which indicate a desire to bring under the notice of the public the great variety, interest, and beauty there is in these subjects. But the public is very capricious, and if the taste does not run in that direction, it is hard indeed to force it. The articles on Grape Culture, by Mr. TAYLOR, are of great interest.

"GARDEN LIFE."—In this periodical, under the head of "Gardening Experiences," is an interesting letter from Captain HANCOCK, in which he records his experience with Solanum Commersoni, which he finds to be immune to disease, and to thrive in an actual swamp.

"AMATEUR GARDENING" has a coloured plate of Cypripedium insigne, and directions for cultivating this popular Orchid. The contents are varied, and serviceable to amateur gardeners.

"THE GARDENING WORLD," now published at 2*d*., has a supplementary plate of the new Pillar Rose Maharajah. Articles, paper and print are alike good.

"GARDENING ILLUSTRATED" is filled with matter specially interesting to amateurs, and its illustrations in the current number include good representations of Magnolia Lennei, Rose "Sulphurea," and Gladiolus "Mrs. F. Field." The Answers to Correspondents occupy a considerable share of the available space.

APPLES.—So much interest has been excited in our Apple Census (see our volume for 1904) that we are induced to put the results in another form. It will be remembered that the 198 voters were distributed through every part of Great Britain and Ireland. They included not only gardeners, but nurserymen and growers of fruit for market, and therefore the conditions under which the trees are growing are very varied. Each voter naturally recorded his own individual impressions, and took into consideration not only flavour but cropping qualities, liability to canker, and suitability to local conditions and requirements. The total number of varieties mentioned was 89 in the case of kitchen Apples, and 102 in that of sorts grown for dessert. Of these, only the first six in each section were numerically important. There can, therefore, be no question as to the general opinion as to the merits of the twelve Apples mentioned. The others which were enumerated in our columns are evidently very good in some few places, but were a very long way behind the selected twelve in the opinion of the large majority of voters:—

DESSERT APPLES.

COX'S ORANGE	about	82 per cent.
KING OF THE PIPPINS ...	,,	64 ,,
WORCESTER PEARMAIN...	,,	51 ,,
RIBSTON PIPPIN	,,	47 ,,
BLENHEIM PIPPIN ...	,,	35 ,,
IRISH PEACH	,,	31 ,,

The percentage of votes for all the other varieties was very much smaller.

KITCHEN APPLES.

LANE'S PRINCE ALBERT...	about	59 per cent.
WARNER'S KING	,,	55 ,,
LORD SUFFIELD	,,	42 ,,
ECKLINVILLE SEEDLING.	,,	41 ,,
BRAMLEY'S SEEDLING ...	,,	36 ,,
DUMELOW'S SEEDLING ...	,,	34 ,,

As in the case of dessert Apples, the percentage of votes for the other varieties mentioned was very much less.

A GARDENERS' CRICKET CLUB.—The annual supper and concert of the Anguloa Cricket Club, which was organised over twenty years ago, and consists entirely of *employés* of Messrs. SANDER & SONS, was held at the Crown Hotel, St. Albans, on Saturday, January 7. During its history many gardeners throughout England have been associated with the club; and the cricket clubs of Kew Gardens and of Messrs. PROTHEROE & MORRIS are its most formidable opponents. The chair was taken by Mr. F. K. SANDER, and a pleasant evening resulted. The Hon. Secretary reported the club's finances as being most satisfactory, and showing a considerable improvement on those of previous years.

THE RAINFALL AT ROTHAMSTED IN 1904.

ACCORDING to the records from the rain gauge at the Rothamsted Experimental Station, Hertfordshire, constructed fifty-two years ago, and one-thousandth part of an acre in dimension, standing 2 feet above the surface of the ground, and being about 420 feet above sea-level, we find that the total rainfall for the year 1904 amounted to nearly 25 inches. This is 3 inches less than the average record for this district extending over the past fifty years, and 13¾ inches less than fell in the twelve months of the previous year, 1903.

The following table shows the rainfall of each month for the past year at Rothamsted, with the average amount of rainfall for each month of the previous fifty years, and the difference of 1904 above or below the average:—

Rainfall at Rothamsted, Herts, for each month of the year 1904, the Total for the Year, the Average Rainfall of fifty Years, 1853-1902, and 1904 above or below the average.

Months.	Rainfall, 1904.	Average rainfall of fifty years.	1904. Above or below the average.*
	Inches.	Inches.	Inches.
January	3·50	2·35	+ 1·15
February	3·44	1·79	+ 1·65
March...	1·58	1·78	— 0·20
April	1·25	1·86	— 0·61

August	2·15	2·65	— 0·50
September	1·60	2·50	— 0·90
October	1·37	3·09	— 1·72
November	1·67	2·58	— 0·91
December	2·48	2·31	+ 0·17
Yearly total ...	24·92	28·00	— 3·08

* The sign in the last column (+) signifies above the average, and the sign (−) below the average.

The above figures show that the yearly total of rain, frost, and melted snow, of which latter there was but a very small quantity, in the past year amounts to 24·92 inches, against an average of 28 inches for the previous fifty years, showing a deficiency of a little more than 3 inches. As 1 inch depth of rain represents 101 tons of water on each acre of land, the results show that there is a deficiency of water amounting to 311 tons per acre to our underground water-supply.

Leaving out the months of January and February, we find that the remaining ten months of the past year of 1904 show a deficiency of rainfall amounting to nearly 6 inches, compared with the average of the past fifty years of these same months, which is equivalent to a loss of water on each acre of land in this district of 133,029 gallons. It is seen that the four months of January, February, July, and December have each given an excess of rain compared with the average, while the eight remaining months have each yielded a deficiency.

So much depends in the realisation of the gardener's hopes upon the degree of humidity in the atmosphere, and the amount of moisture contained in the upper layers of the soil, that the rainfall of any particular period is necessarily a matter of much interest to the horticultural community. From the above figures it can be readily seen that 1904 was decidedly dry, and that the month of June gave 1½ inch of rain deficient, which is one-half the total deficiency of the year. An old adage says, "A dripping June puts all things in tune"; the dryness, therefore, of the past month of June may perhaps account for the stagnation which occurred in the growth of several of the outdoor crops at that period—in fact in many districts the crops did not appear to recover their normal growth throughout the season; and the cereal crops, and more especially Wheat, was the worst that had been harvested since the year 1879, although previous to the month of June there was such a capital promise.

Root crops and Potatos also suffered considerably from the deficiency of rainfall during their early growing period.

Owing to the fact that there was a large excess of water in the soil remaining in the lower depths from the previous year's (1903) heavy records, which totalled up to nearly 38¾ inches, being 10 inches in excess of the average yearly fall, the deeply-rooting fruit trees and shrubs did not suffer from the 1904 drought, and the result was an abundant crop of most kinds of fruit. *J. J. Willis, Harpenden.*

BOOK NOTICE.

"THE BOOK OF TOPIARY."

SUCH is the rather awkward title of a little book written by Mr. C. H. Curtis, of the "*Magazine*," and Mr. Gibson, the head gardener at the famous garden at Levens. It forms one of the series of handbooks of practical gardening edited by Mr. Harry Roberts, and is published by Mr. John Lane. It is not quite clear where Mr. Curtis's participation ends—it might, on a first glance, be thought that the three introductory pages, which alone are signed by him, constituted the sum of his work, but such an idea is dissipated by the statement that he had been invited to contribute a historical account of the art of Topiary. In any case the first forty pages or so form a very interesting and readable preface to the practical advice given in later chapters by Mr. Gibson. There is no disputing about matters of taste, and in gardening there is room for the most varied opinions. Where a solitary specimen or a garden of clipped Yews has been handed down to us from our forefathers by all means let us preserve it and them as curiosities and historical documents. In a public garden like that at Versailles or at Kew, for instance, we expect to see examples of all possible styles of gardening, and on this account the clipped Yews and Hollies near the Palm-house at Kew may be tolerated even where admiration is not possible.

But when it comes to private gardens and modern imitations of what is ugly and unnatural we think that while full liberty of using the shears as he pleases should be conceded to every man, those whose duty it is to lead the public taste or to set an example of what is beautiful and true should have equal liberty to express their opinions without being "pitied." The very same writer who made use of the word just quoted, which is repeated on the title-page of this little volume, expresses himself more charitably in another passage quoted on p. 12. "I confess"—it is Mr. Shirley Hibberd who is speaking—"that I should never care to adorn my garden with topiary or with carpet-bedding, but I hope always to be cautious in making declarations in respect of such matters, that I may not appear to despise another man's pleasures or vainly desire to set up a standard of my own in opposition to the delightful variety that is ensured by the free exercise of individual taste and fancy."

It is indisputable that, in spite of the fact

that foliage is a very inappropriate medium for the representation of animals, statuary, or architecture, the fancy for these strange productions is at present extending, and no better guide for their management can be had than Mr. Gibson, who has charge of the very remarkable examples at Levens, of which illustrations have been given in our columns. The Yew is the tree that is most often treated in this fashion, but its relatively slow growth constitutes an objection to its use. In some cases the tree lends itself to "artistic" treatment, but those who remember the Yews in Mr. Dixon's wood at Leatherhead will realise how much more interesting the extraordinarily diverse natural forms of the trees in that place are than any that have been artificially manipulated. Still, for those so minded, these particular Yews offer suggestions for artificial treatment which could readily be adopted. Evergreen trees are mostly made use of for this purpose, and Thuya gigantea would lend itself well to these grotesque distortions. Every fruit-grower knows how espalier trees can be made to assume almost any shape that may be desired.

So, too, natural seedlings often occur which the gardener may utilise in this way. We have daily in view a Hawthorn of considerable size which in shape is a perfect umbrella with an unbranched stem and a dome-shaped head. It came up as a seedling, and soon manifested its tendency to grow into an "umbrella-tree," a tendency which has been fostered, though in truth it needs nothing but the removal every spring of a few branchlets, which by their upward tendency would, if not removed, soon spoil the shape of the tree. There is one advantage that the topiary art has, it ensures adequate treatment of the hedges. Whatever may be said in disparagement of the strange devices dear to the topiarist, no one will object to the formation and maintenance in an appropriate position of a good hedge, and the man who can keep a peacock or a giant in good order may be trusted with the management of a Yew or Holly-hedge.

Mr. Gibson's directions and his recommendations as to what should be grown in association with these curiosities are excellent and clearly expressed. So we can thoroughly recommend the little book, not only to those who have to create or manage these topiary gardens for themselves but also to those readers to whom the history of garden fashions and caprices offers attraction, and who read for diversion if not for practical purposes.

CYPRIPEDIUMS.

THE three Cypripediums, of which an illustration is given at fig. 14, were grown in the collection of W. Duckworth, Esq., of Flixton, near Manchester (gr., Mr. H. Tindall), and were exhibited at the meeting of the Manchester and North of England Orchid Society on December 15, 1904, when they were awarded a Gold Medal.

Plant No. 1 to the left is C. × Leeanum giganteum, and bore twenty-one flowers, every flower being perfectly formed, and the leaves rich and vigorous.

FIG. 14.—THREE WELL-FLOWERED CYPRIPEDIUMS.

No. 2 is C. insigne Sanderæ, in the centre, and was very beautiful with twelve fine flowers, the condition of the plant generally being excellent. No. 3, to the right, is possibly the finest specimen of C. insigne Harefield Hall variety extant, possessing fifty or more growths, and occupying a pan 15 or 16 inches in diameter. The number of flowers on this plant was thirteen, and it is possible that next season the plant will carry two dozen flowers.

All orchidists who saw these three plants exhibited agreed that it would be a hard matter to match them for beauty and excellence of cultivation. The owner, Mr. Duckworth, was honestly proud of his productions, one of his ideals being to make every plant in his collection a "specimen." Many converts to "specimen" growing were made on December 15, 1904. *P. W.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE GARDENERS' BENEVOLENT.—The need for this institution is shown in the voting paper just issued to subscribers, on which there appear the names of no fewer than fifty-six applicants for pensions. Seeing that the fund admits of the election of but eighteen candidates, the chance of election on the 19th inst. for those who have not already a good number of votes to their credit is small. Sad it is to find so large a number of applicants. Out of the entire number forty-seven have been subscribers for few or many years, or are the widows of subscribers. No fewer than thirteen candidates have now upwards of 2,000 votes to their credit, and no doubt many of these regard their election as safe. Two have already enough and to spare of votes to elect them on last year's voting basis. One having over 4,000 votes has been a subscriber for thirty-five years, and has been a thrifty man in other directions. In a second case a candidate is the widow of a subscriber for thirty-four years, and has now over 3000 votes to her credit. There are many similar cases in which long periods of annual subscriptions of one guinea are in time of old age and need being repaid by large numbers of votes accruing automatically from these subscriptions. What an object-lesson is thus presented to young gardeners who now ignore the Institution, not so much that subscribing a guinea yearly is so great a financial difficulty, as that old age seems so remote that there is ample time to see about providing for it. Pity indeed is it that such should be the case! There cannot be found anywhere a wiser or a safer investment than an annual subscription to the Gardeners' Benevolent. Blessed is the man who in old age may never need its aid. Wise is he who in any case does make such provision, for who can foretell what time may bring to any of us? The premium is indeed small in comparison with the benefits. *D.*

BRITISH GARDENERS' ASSOCIATION.—It is gratifying to be assured by those who are active in the promotion of this Association that it is steadily growing, some head gardeners, who at first held aloof, being now keen to get it established. There is, as was stated some time ago in your columns, every prospect that it will grow and adapt itself gradually to circumstances, and prove beneficial alike to employer and employed. Those employers who believe that a well-managed garden is worth paying for, will not hesitate to pay a reasonable rate of wages for intelligent, trained gardeners recommended by this Association; indeed, it is known that in many private gardens, especially in the North of England, the rate of pay and hours of labour are better than those prescribed by the Association. We are forced to measure the value of work by the wages of the workers and to respect the worker according to the amount of his earnings. Judged by this standard a gardener is lower in the scale than an ordinary mechanic for the simple reason that his labour does not realise as high a price. But every one conversant with the matter knows how unreasonable this state of things really is. Gardening is an occupation which should make some demand on the gardener's self-respect. He should not suffer violence to his feelings by working for a lower rate of pay than is reasonable and fair. In the words of J. S. Mill, he should show a "determination to preserve an established standard of comfort." This question of wages is worth consideration because some gardeners have expressed doubts as to the wisdom of the Association interfering with it. We know that the scale recommended is reasonable, and we also know that employers recognise the value of a standard that is put forward by a body of men who are actuated, we are convinced, by worthy motives. The Association will serve a useful purpose by acting as an employment registry office. Employers can apply to it with confidence for competent, trustworthy men, whilst the members, if treating themselves, will be supported by the standard terms set forth by the Association, and the feeling that the Association is behind them. There must always be prominent in the mind of the gardener who thinks of the future that to-morrow may see him out of employment. Hitherto the nurserymen have supplied many gardeners with situations, but their interests are not those of the gardener, and when a low rate of pay is offered the nurseryman does not feel called upon to exert himself in favour of more reasonable terms, but sends a man at the price named. The result is too often most unsatisfactory to all concerned. The Gardeners' Association will be in a position to bargain for the best interests of its members and of the would-be employers, as by means of its branches scattered all over the kingdom it will be in possession of information as to situations and men that will enable it to fit the place with the right men. It cannot hope to provide situations for all gardeners, but it can take such steps as will assure those who are successful in the competition for situations of a fair return for their labours, and by choosing men of as high a standard in skill and capacity as can be obtained employers will be satisfied. Such an arrangement cannot fail to react on the men. The young man, knowing that he cannot get a good situation by offering to accept lower pay than the standard, will exert himself to get into the good books of the Association by acquiring technical skill and intelligence and by keeping his character unspotted. In this way as high a standard rate as is possible may act as a stimulus to the whole class and lead to a correspondingly high quality of work. That horticulture would gain by raising the status of the workers is quite clear from the fact that it would attract greater intelligence and capacity. Trades with a high standard, such as the cotton-spinners and engineers, draw to themselves the pick of the young men, and the unregulated trades have to put up with the inferior labour that remains. It will be difficult for the Association to maintain any effective control over entrance to the profession, but it can insist on boys being put through a definite course of practical instruction in the work. It may also be in a position to prevent unscrupulous gardeners from taking on too many boys and turning them adrift as soon as they begin to ask journeymen's wages. *Head Gardener.*

CHRYSANTHEMUM MRS. SWINBURNE, AND SPORT.—I enclose a flower of Mrs. Swinburne, and one of a beautiful yellow sport from that variety, which has been named Mrs. George Beech. The flowers were from late buds. Mrs. George Beech was a root-sport of two plants bought in last year; one came with three beautifully rich yellow flowers, exactly in form like Mrs. Swinburne; the cuttings from this plant were propagated in the usual way, and all have come true this season. To get these varieties in flower for the November shows the growths must be stopped at the end of April, but natural first-crown buds will be grand for the December shows. An Award of Merit was gained by Mr. H. J. Jones for flowers of Mrs. Swinburne at one of the Royal Horticultural Society's meetings. *Exhibitor.* [The yellow flower appears to be similar to that of Mrs. Swinburne, except in colour. ED.]

THE CENSUS OF DESSERT APPLES. — In looking over the very valuable tabulated note which appeared in the *Gardeners' Chronicle*, November 5, p. 315, I was not a little surprised to find that the old favourite Wyken Pippin received only seven votes as against 100 for the Worcester Pearmain; the former is a winter Apple, the latter an autumn one. The flavour of the Wyken Pippin is far superior to that of the Worcester Pearmain, but what the latter is short of in flavour is made up in colour, which in my opinion is its only recommendation. In the window of a first-class fruiterer's shop in Birmingham, I saw the Worcester Pearmain making a grand show: it was ticketed 3*d*. per lb. No other Apple in the window was priced so high. Being so poor in flavour I am afraid it will eventually have to take an inferior position. In the Midland counties and perhaps more especially round hereabouts, the Wyken Pippin is in great favour, being considered amongst farmers the best of all amongst dessert Apples; but it also will, I fear, have to take a back seat when such Apples as Cox's Orange Pippin, Adam's Pearmain, and many others become better known. Of the Wyken Pippin a fairly truthful tradition is generally believed in in this neighbourhood, namely, that this Apple was originally brought from somewhere in the Netherlands by Admiral Craven, who was an early member of the present Craven family of Combe Abbey, and planted by him in his garden at Wyken Manor, near Coventry. This tree was blown down, and its "butt" was brought to Combe whilst I was there. There is also in this neighbourhood another Apple, viz., the Temple Pippin, whose history unfortunately is not so well known. It is an excellent cooker and keeps well, and is much thought of hereabouts. Adjoining this parish is the parish and church of Temple Balsall; whether the Apple originated there I cannot say, but a good many people are of that opinion. If anyone knows of the whereabouts of its origin perhaps he will kindly let us know. *W. Miller, Berkswell.*

ASPARAGUS SPRENGERI (see illustration in last issue).—Plants of this species have flowered frequently and abundantly with us, but never before have the fruits developed in such numbers as they have this season. I am forwarding some sprays bearing fruits, also some sprays of A. decumbens in flower. *A. Munro, The Gardens, Ilton Court, Chepstow.* [Excellently berried growths of A. Sprengeri, and well-flowered growths of A. decumbens. They are certainly well adapted for growing together in baskets. ED.]

CUCUMBER-DISEASE.—There is no sure cure known but that of cupric sulphate, more commonly known as blue vitriol; and infinite care has to be taken in its use as a preventive. If the following directions are carried out strictly by some trustworthy man, who will take the greatest care that his hands are free from cuts or sores, he may be successful. Procure cupric sulphate from some reliable firm, and have it reduced to powder before buying it, as the means of doing this are not always handy in a market nursery, and when powdered it is more easily dissolved. Procure a wooden pail, or better, an earthenware pan, that will hold 4 gallons, and put into it 2 ounces of cupric sulphate; then add a small quantity of water, and stir with a stick until well dissolved; then fill up the pail with water, and well stir the whole. To a 2-gallon can of water put half a pint of the solution, and stir until well mixed with the water, when it will be ready for use. One canful will at first be sufficient for four plants, but as the plants grow larger one canful will be needed for three plants, and should be applied at least twice a week. The cans which are used should be well washed out as soon as the work is finished, as the solution would soon eat into them. *C.* [See Mr. Willis's note on the subject on p. 13 of our last issue. ED.]

THE ROYAL HORTICULTURAL SOCIETY'S VEGETABLE SHOW.—The announcement in the *Gardeners' Chronicle* Almanac (the only one, also) that it was proposed to hold an exhibition of vegetables at the Horticultural Hall on September 12 next, caught the eyes of some of our leading vegetable growers, who were alarmed, on the ground that, wishing to be at the great International Exhibition at Edinburgh the next day, they could not possibly exhibit on the 12th at Westminster. I was by them invited to urge the postponement of the vegetable show on that account, and on representing this fact to the Secretary (the Rev. Mr. Wilks), that gentleman readily accepted the next possible meeting for the show—October 24. On September 26 the National Rose Show takes place, and on October 10 the great show of British fruit is held, hence October 24 is the earliest available date. Will all vegetable growers or exhibitors please to note this new date? *A. Dean.*

THE BOARD OF AGRICULTURE AND GARDENERS.—I should like to draw the attention of the gardening public to a new departure on the part of the Board of Agriculture. This consists of the issue by them at a purely nominal price of the first 100 of their well-known leaflets, bound. The leaflets are the work of the highest authorities, and principally deal with the ills and evils which beset those "on the land." They range from that Gargantuan ill—income tax (certainly one of the biggest to those whom it attacks), through such

visible evils as the Daddy Longlegs, to such comparatively invisible foes as the Black Currant Bud Mite. Very nearly all the leaflets will be found of interest to the gardener, and as the result of a rough count I should say that 80 out of the 100 intimately concern him. Several of them I regard as being likely to be of the highest value to the market grower. I will give a selection of their titles, thinking that this may be the means of many growers writing for the book :—"Grading and Packing Fruit and Vegetables," "Red Spider," "Root-Knot Disease in Cucumbers and Tomatos," and "Cucumber and Melon Leaf Blotch." In several instances the use of potassium sulphide, commonly known as liver-of-sulphur, in solution as a spray as a fungicide is commended. I can give personal testimony to the value of this, but so far as my experience goes potassium sulphide is by no means in very general use. Having thus very briefly and partially indicated the value the volume possesses to horticulturists, it remains to tell how it can be procured. This any interested person can do by sending an unstamped application, with 6*d.*, to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, S.W.; and he or she will do well to at the same time ask for the remaining leaflets of the series (unbound). The latest of these is, I believe, No. 116, which deals with the "Sleeping Disease of Tomatos." The relations of the Board to its public—what it does do and what it might do—is a very interesting subject, but this I will not enter upon on this occasion. I hope that the issue of this valuable work at a nominal price is but the prelude to other issues, and I can point out to the Board a concession on their part which would be very grateful to gardeners. It is a considerable reduction in the prices of the Kew *Hand-Lists*, the prices of which are at present by no means nominal. "*Jason.*"

DAHLIA THE MIKADO.—In reference to my note on p. 13 concerning the Dahlia "Mikado," I may add that there is still a third variety in the trade called "Mikado." It has single flowers, and the colour is golden yellow at the points, and the base of the florets and the remainder red. It grows about 4½ feet high. Of course, it is an old variety, but still is offered in catalogues for 4*d.* or 5*d.* each root. *Frank Koehler.*

MYROBALAN PLUM. — (See enquiry in last week's *Gardeners' Chronicle*, on p. 16).—The Myrobalan Plum is much superior to the Thorn for hedging purposes, that is as regards quickness of growth and impenetrableness of fence. It also makes a pretty hedge if trimmed annually, as all hedges should be. Within the last seven or eight years I have supplied and superintended the planting of thousands of the Myrobalan Plum for hedging purposes, and they have formed good living fences within a space of three years from the time of planting, The plants will grow almost anywhere and under the most ordinary conditions. But the more favourable the conditions are regarding soil and method of planting, the quicker and better will be the results obtained within a given time. The ground (pasture land) was simply dug a spit deep and from 15 to 18 inches wide, and the planting was proceeded with in the process of digging, the plants being set 6 inches apart zig-zag in the row, the soil being trodden more or less according to the nature and condition of the soil at the time of planting to make it firm round the roots. Assuming the planting to be done in late autumn or early spring, the plants should be cut down to within about 15 inches of the ground twelve months from the time of planting in order to insure a good foundation and a thick and impenetrable hedge within as short a space of time as possible. *H. W. Ward, Rayleigh.*

—— I planted several thousands of the Myrobalan Plum when in Scotland, but found it no substitute for Quick there. Hares and rabbits are also very fond of the plants, which require rich soil to grow well. *Geo. Duncan.*

FOSSIL PLANTS.—I read Mr. W. Miller's letter on p. 12 with much interest. In it reference was made to "fine avenues and isolated specimens of Araucaria imbricata to be met with in various parts of the country." The only fine, or anything approaching fine, avenue of the Araucaria I have seen was observed at East Dean Park, Lord Wimborne's place near Bournemouth, some years ago. The trees appeared to be quite at home in the light dryish soil characteristic of Bournemouth generally, and the warm sheltered position which they occupied. The finest specimens I have seen are growing in the vicarage grounds at Alderbury, near Salisbury, the rectory grounds at Rayleigh, and in a cottage garden at, or near, Ightham, near Sevenoaks, all the trees being located in somewhat favourable positions as regards soil, and sheltered from north and east winds. Regarding Taxodium distichum, there are two good specimens growing in the grounds at Longford Castle near the waterfall, and within a couple of dozen yards of the rivers Avon and Ebele. One specimen is considerably larger than the other, and I should say is now over 100 feet in height, and of good girth of trunk. There is even a finer specimen than this to be found growing on the bank of a tributary to the river Test, in the grounds at Broadlands, Romsey. This is the finest tree of the kind it has been my good fortune to see in any part of England, Ireland, or Scotland. All the trees of the deciduous Cypress named, it will be observed, are growing in moist situations, as mentioned by Mr. Miller. *H. W. W.*

NOVELTIES OF 1904.

(*Continued from p. 2.*)

Stove and Greenhouse Plants.—The finest new plant of the year has been the gorgeous ruby-crimson Gloriosa Rothschildiana, introduced from Uganda, and shown from the Right Hon. Lord Rothschild's gardens, Tring Park (gr., Mr. A. Dye). This was the only plant to which the Floral Committee awarded a First-class Certificate out of the large number of beautiful specimens exhibited at the last Temple Show.

Nicotiana Sanderæ has been shown by Messrs. Sander & Sons in quantity. The elegant plants bear showy flowers of various shades of magenta, rose, and crimson, with an occasional white form, and for which a First-class Certificate was awarded at the Royal Horticultural Society's meeting on May 3, 1904. It is an ideal garden plant, as it may be grown from seeds freely, and used either as a greenhouse decorative plant or for planting in the flower-garden, for massing in beds or for occasional clumps in the herbaceous borders or shrubberies. Other good plants of the year shown by Messrs. Sander were Clerodendron myrmecophilum, Alpinia Sanderæ, and a number of very handsome hybrid Begonias between B. Socotrana and B. Rex, two of the best being B. Mrs. H. G. Moon and B. Fearnley Sander.

Messrs. Jas. Veitch & Sons, Chelsea, continue to improve their fine strain of perpetual-flowering Begonias of the "Winter Cheer" class, and in the pretty dwarf floriferous Begonia Washington they have the best of "bedders." From their famous strain of Hippeastrums, H. Ronda was certificated, and the firm is credited with the handsome new Nepenthes "F. W. Moore," and their Eupatorium vernale is one of the most useful species for the supply of flowers for cutting.

Various other useful plants in this and other classes will be found enumerated in the list, to be published next week, of good plants illustrated in the *Gardeners' Chronicle* during 1904.

Tuberous Begonias.

These beautiful plants have been brought to such a high state of perfection by the several firms cultivating them, that it has become difficult to secure superior novelties. But although the awards are few, Begonias have never been seen in greater excellence than last year. The best of the certificated varieties were B. Argus (double crimson-scarlet), B. Avalanche (double white), and B. Lady Curzon (salmon-red), all of Messrs. Blackmore & Langdon, Twerton, Bath; B. Mr. W. H. Edwards (double blush-white), of Messrs. T. S. Ware; B. Canopus (fringed double yellow), of Messrs. B. R. Davis & Sons; and B. Margaret Gwillim (large double yellow), of Mr. A. Ll. Gwillim.

Ferns.

As with most other classes of plants, the interest centres in the "decorative" kinds. Pteris Hilli and P. Binotii, of Messrs. J. Hill & Sons, are very useful additions; Pteris Sumnersi, P. cretica capitata, and Lomaria Mayi, of Mr. H. B. May, Edmonton, are graceful plants likely to be grown in quantity for market; and Cyrtomium falcatum Butterfieldi, of Mr. P. T. Butterfield, Waltham Cross, is a graceful variation of a useful species.

Miscellaneous Bulbous Plants, &c.

The best Hippeastrum certificated during the year is H. Snowdon, the finest white of the best "florists'" shape, which received a First-class Certificate when shown by the raiser, Mr. Fielder gr. to Mrs. Burns, Hatfield, on April 19.

In the Nerine Bowdeni, shown by Messrs. Robert Veitch & Son, Exeter, is exemplified the remarkable occurrence of a new Nerine with pink flowers, better than any imported before; and H. J. Elwes, Esq., Colesborne, Andoversford, who now takes the lead in raising hybrid Nerines, had two pretty new varieties in his group shown October 18, viz.—Nerine Lady Ffolkes and N. Miss Shelley, both having delicate pink flowers, and both were accorded Awards of Merit. At the same meeting similar awards were made to ten new Chrysanthemums, additional varieties of Chrysanthemums securing awards for novelties also at other shows.

Hardy Flowers.

A welcome new set of hybrid Iris × Regeliocyclus was shown by Mr. C. G. Van Tubergen, junr., of Zwanenberg, Haarlem, on May 17. Eight of the most beautiful received awards. Other worthy novelties have been added to the genus, notably the Iris Lorteti alba and I. Haynei, for which Messrs. W. Cutbush & Sons, of Highgate and Barnet, received awards.

Messrs. Kelway & Sons, Langport, continue to improve Pæonies, Gladioli, and other showy flowers for which they are famous, and have improved the qualities of each class. Mr. James Douglas, Edenside, Great Bookham, has been successful with Auriculas and Carnations, in the latter being joined by Mr. Martin R. Smith and others. Various other worthy novelties were exhibited, some of them already certificated, and others (as with the grand Meconopsis of Messrs. Jas. Veitch & Sons) reserved for that honour in the coming year.

Narcissus.

The Daffodil shares with the Iris the distinction of being the Orchid of the open-air garden, and embraces some of the most beautiful and graceful flowers, well improved by the gardener's efforts. Miss Willmott, Great Warley, is one of the best cultivators, and has one of the finest collections. Of the best novelties in this class Narcissus Great Warley (a lovely flower nearly 4 inches across), N. Warley Scarlet (with orange-scarlet cup), N. Zenith (white with flat orange-scarlet corona), N. Flag of Truce (white), N. White Ensign (white with lemon-yellow corona), and N. Count Visconti (canary-yellow), have secured awards. Mr. A. Kingsmill's best was N. Bennett-Poë; Messrs. Barr & Sons', N. Elvira, N. Henry Vilmorin, N. Pyramus—all Awards of Merit. N. Surprise was shown by Messrs. Pope & Son.

Potatos.

These have occupied much attention, and the list of illustrations given during the past year gives references to some of the best. The introduction of new varieties raised from seeds is

an important work which should be encouraged, as apart from any consideration as to the better quality of the new varieties when compared with the old, there is no doubt that the introduction of such newly-raised varieties offers the best means of combating the dreaded Potato disease.

The relative merits of the different varieties of Apples and Pears have also been gone thoroughly into, and attempts made in our own columns to indicate the very best. Most of those considered the best are not new, but being the best they have been illustrated, and the figures will be found in the *Gardeners' Chronicle*.

(To be continued.)

POTATOS.

EARLY CULTURE IN CORNWALL. — From a Cornish contemporary we note that the market gardeners in the Penzance and Marazion districts have almost finished taking in their supplies of seed Potatos of the early varieties for the coming season, and of which many tons have been daily put on the shelves for sprouting for some weeks past. The varieties chiefly in demand this year are the Duke of York and the British Queen. The first-named is generally recognised as being the very earliest to mature for market purposes, and the Queen is the favourite to follow in succession. Myatt's Ashleaf, which, until the introduction of the Duke of York, was the earliest general cropper, is still favourably regarded by many growers, although the quantity sold is much less than formerly. The recent varieties, of which so much has been written, and for which such high prices have been paid in Lincolnshire and elsewhere, have not yet taken any general hold on the West-country grower, although this season a few of the newer varieties, disease-resisting and otherwise, are being tried on many farms. There have been many enquiries for May Queens, and a few parcels have been secured and quickly disposed of, whilst several lots of the variety Sir John Llewelyn have also been distributed. Prices for the ordinary kinds, although somewhat high, are considerably below those of last year, and towards the end of the season have become somewhat firmer, due probably to the fact that the demand is equal to the supply. The bulk of at least early seed Potatos comes from Lincolnshire, which is the premier Potato-growing county in England. An enormous amount of capital is being laid out in seed, and it is to be hoped that next season will be more remunerative than the last, when low prices were realised for the early crops after the first few days' lifting.

Obituary.

ARTHUR W. WADE.—We regret to announce the death of Mr. A. W. Wade, who immediately previous to his death was in the employ of Messrs. Caldwell, nurserymen, of Knutsford, Cheshire. Mr. Wade met his death by falling from his bicycle when riding towards his home at Knutsford, on the evening of January 2. He died unconscious a few hours after the accident had occurred. Previous to entering the service of Messrs. Caldwell, Mr. Wade was for some time foreman in the herbaceous department at Messrs. Clibrans'. He had also filled a similar position with Messrs. Wallace & Co., of Colchester. Mr. Wade was once employed at Kew, which gardens he left in March, 1891. Deceased, who was thirty-six years of age, leaves a widow and young family.

JOHN R. STIRLING.—The many friends of Mr. John R. Stirling, late head gardener at Buckingham Palace, will hear with regret of his death, an event which took place rather suddenly on December 17 at the little village of Ryme, in Dorsetshire, whither he had retired on the receipt of a pension after twenty years in the Royal service. Deceased commenced his gardening career in the early sixties at Petworth, continuing at two or three of the leading places in the South of England. Four years as foreman at Enville Hall followed, after which he went to South Wales as gardener to Lord Swansea. In 1882 he received the appointment at Buckingham Palace, and remained there nearly twenty years, earning the esteem of all with whom he came in contact, alike from his high personal character and his gardening abilities. When shortly after the death of Queen Victoria considerable alterations were made as to the upkeep of the Palace gardens, Mr. Stirling retired on a pension to a remote Dorset village. He has unfortunately not lived long to enjoy his well-earned rest. He leaves a widow but no family. *E. L. B.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 3.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair), Dr. Cooke, Professors Boulger and Church, Rev. W. Wilks, Messrs. Saunders, Bowles, Shea, Worsley, Odell, Gordon, and Chittenden (Hon. Secretary).

Henslow Testimonial.—Dr. MASTERS reported on the progress made towards the completion of this. The subscriptions, confined to members of the Committee, amount to about £40 at present.

Diseased Carnations.—Mr. SAUNDERS reported concerning the Carnation plants sent to the last meeting that he could find no trace of eelworms or insects present; and Dr. COOKE wrote: "The plant examined gave no evidence of fungus attack, but the root was completely rotted with moisture. All the mischief evidently arose from mistakes in cultivation, and this is sufficient to account for the result."

Fungus on Agapanthus Stem.—Dr. COOKE reported on this, specimens of which were brought to the last meeting by Mr. Worsley: "The black elliptical and elongated spots on the dead stems are merely indications of the common saprophytic mould, Cladosporium herbarum. Being kept in a damp atmosphere for two or three days, every spot was velvety with the threads and covered with the spores."

Oranges attacked by Scale.—Respecting the Oranges from Seville badly attacked by scale, Dr. COOKE reported: "There was not the slightest trace of Fumago or Capnodium, or even of fungus or fungus mycelium of any kind, except Penicillium glaucum, which soon made its appearance and produced a plentiful crop."

Pear Diseased.—Mr. SHEA showed a Pear which had several brown decayed spots in the flesh, but seemed quite normal externally. Dr. COOKE undertook to report upon it at the next meeting.

Spots on Phyllocactus.—Diseased specimens of Phyllocactus shown by Mr. WORSLEY were referred to Mr. SAUNDERS and Dr. COOKE.

Germination of Sechium edule.—Mr. ODELL showed specimens of the curious fruits of this plant, known as the Chaco or Chocho, containing germinating seeds. The plant belongs to the Cucurbitaceæ, and the fruit is a pepo, containing only one seed. The seed germinates within the "pepo," and is inseparable from it. Numerous roots are produced on germination, and the stem grows out through the fruit wall, which subsequently becomes woody, while the cotyledons remain behind in the fruit. Some discussion took place as to the fate of the radicle, which appears to be of very limited growth. The fruit is used like the Marrow in the West Indies and in the United States of America. (See fig. in *Gardeners' Chronicle*, Dec. 22, 1900, p. 459.)

Big-bud in Hazel.—Buds of the Hazel attacked by the bud-mite were referred to Mr. SAUNDERS, who undertook to report upon them. (See also fig. 15.)

Plant for Naming.—Mr. J. R. BAKER, of West End, Southampton, sent some branches under the name of Thuya Lobbi. This naming was confirmed by Dr. MASTERS, T. Lobbi and T. gigantea being garden names for the true T. plicata.

Diseased Beech.—Mr. D'OMBRAIN sent specimens, which Dr. COOKE kindly undertook to examine and report upon.

Variety of Douglas Fir.—Dr. MASTERS showed a curious short-leaved form of the Douglas Fir which came up among a batch of seedlings in Holland. It was at first thought to be a hybrid of that species with Tsuga Sieboldi, but a transverse section of the leaf at once showed it to be a true Douglas Fir.

NATIONAL SWEET PEA.

WE are informed that it has been arranged to hold the 1905 exhibition in conjunction with the Royal Horticultural Society at Vincent Square, S.W., on Tuesday, July 4. Upwards of £90 are offered in money prizes, and Messrs. Sutton & Sons are presenting a Silver Challenge Cup, value fifteen guineas, in Class 1, the Society giving the winner a Gold Medal as a permanent memento of success. The schedule will be in the hands of members by the 14th inst. The *Sweet Pea Annual* will be published one week later, and will be sent free to members. Full particulars on any matter connected with the Society will be gladly furnished by Horace J. Wright, 32, Dault Road, Wandsworth, London.

HORTICULTURAL CLUB.

JANUARY 3, 1905.—The usual monthly dinner of this Club was held at the Hotel Windsor, on Tuesday, the 3rd instant, when Sir John Llewelyn, Bart., took the chair, and a good muster of members and guests assembled to hear the subsequent chat, rather than lecture, of Mr. Joseph Cheal, entitled "Talks on a Journey to Egypt and Syria," illustrated by numerous lantern slides. Unfortunately, the generally dry and desert character of the region traversed by Mr. Cheal detracted inevitably to some extent from its horticultural or botanical interest, but this element was by no means altogether absent, since the celebrated home of the Lebanon Cedars was visited; and some very interesting photographs were shown in this connection, while Mr. Cheal remarked that the generally-received idea that but few remained in the original habitat of these magnificent trees was erroneous, since many thousands still remain on the Lebanon slopes in the district he visited, and many also in another and distant one. The chief enemy to the trees appears to be the goats, which destroy the seedlings; and although steps are said to have been taken by the Turkish Government to protect them, these steps are too much on the vague and uncertain Turkish lines to be of much avail.

Some specially interesting slides illustrated the culture of the Mulberry-tree in the silk-producing districts. Here the mountain slopes are covered with rudely-built terraces constructed of alternate banks of stone and beds of soil, in which the trees are grown in rows, and kept cut so hard back as to be little more than standard bushes. The white Mulberry appears to be the prevalent kind, only a few of the red variety being grown for dessert purposes.

The Date Palm is another and very important staple, and it has been said that a single Palm will support a man by its produce; it must however be borne in mind that the needs of the man in question are orientally meagre. Locust trees, a splendid specimen of the Banyan [?], antique and weird Olive trees, huge Opuntias with pseudo-leaves as big as tennis-bats, Bougainvilleas of most luxuriantly rampant growth, steeple-like Cupressus, and an extremely curious tree called the Cucumber tree, with long Cucumber-like but hard and leathery fruits, suspended on 6 to 8 feet stalks, all figured on the screen, intermingled with oriental landscapes and scenes embracing camels, Arabs, ancient rock inscriptions, primitive ploughs, native methods of irrigation, cookery, &c., culminating in a swarm of locusts, covering the ground and the herbage thereon, like a veritable insect blizzard. An interesting fact in connection with the extremely rude methods of irrigation in vogue, consisting of wooden wheels with loosely attached earthen jars suspended by rough cordage, was that several attempts had been made to improve this by modern machinery, but all in vain, for the reason that no facilities existed for the inevitable repairs of ironwork, while the primitive apparatus could be always and immediately repaired on the spot by the natives themselves at comparatively little expense. Some views of Jerusalem and other places mentioned in Holy Writ were also shown, and as Mr. Cheal's visit was connected with some mission work in Syria, he was able to accompany their exhibition with many interesting remarks. No discussion followed the lecture, since Mr. Cheal had invited those present to make any desired remarks as he proceeded; and this was done.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 5.—The first meeting of the new year brought together a nice collection of plants.

Messrs. J. CYPHER & SONS, Cheltenham, had a magnificent group, consisting principally of well-grown Cypripediums, hybrids and species. A pretty feature of the group was a mass of well-flowered Trichopilia suavis. There was also a good plant of Cypripedium insigne var. Luciani (Silver Medal).

G. W. LAW-SCHOFIELD, Esq., Rawtenstall (gr., Mr. Skill), exhibited a collection of Cypripediums, among which were two fine varieties of C. × Euryades, viz., C. × Euryades var. splendens and C. × Euryades var. magnifica. C. × aureum var. Surprise was also worthy of note.

W. THOMPSON, Esq., Stone (gr., Mr. Stevens), exhibited a grand plant of Odontoglossum × Mulus with eight large spikes of flowers, a fine example of cultivation, for which a certificate was given.

Messrs. SANDER & SONS, St. Albans, exhibited Cypripediums, &c.

Messrs. A. J. KEELING & SONS were awarded a Bronze Medal for a group in which were some distinct hybrid Cypripediums.

Messrs. H. LOW & Co., Enfield, staged Cypripedium × Minos Young's variety, C. × macrochilum, and others.

Messrs. COWAN & Co., Ltd., Gateacre, staged some good Odontoglossums, including O. × crispo-Harryanum, O. × Wilckeanum, and O. × loochristieuse (Vote of Thanks).

Mr. D. MCLEOD, Chorlton-cum-Hardy, exhibited several plants, including a fine form of Cypripedium × trimmphans and C. × Euryades var. (Vote of Thanks).

Mrs. S. GRATRIX, Whalley Range (gr., Mr. Cypher), exhibited the only plants to which awards were made —viz., Cypripedium × The Czar, a cross between C. insigne var. Sanderæ × C. Sallieri var. Hyeanum; and C. × General Stössel (parentage unknown), a good hybrid, quite distinct; both received Awards of Merit.

The following awards were made at the meeting on December 15, 1904.

FIRST-CLASS CERTIFICATE.

Cypripedium callosum Sanderæ Jules Hyes var., from Mrs. S. Gratrix.

C. Leeanum corunna triumphans, from Mrs. Ardern.

Lælia-Cattleya Donuii, E. Ashworth, Esq.

Cypripedium Arthurianum pulchellum, from A. Warburton, Esq.

AWARD OF MERIT.

Cypripedium mirabile barbatum naurum × callosum, from T. Statter, Esq.

MEDALS.

W. Duckworth, Esq., Gold Medal.
W. Laverton, Esq., Bronze Medal.
J. C. Cowan & Co., Silver-gilt Medal.
Messrs. Sander & Son, Bronze Medal. *P. W.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JANUARY 9.—At a meeting of the Committee held on Monday evening last, Mr. Curtis in the chair, twelve new members were elected and one nominated. Fifteen members have received sick benefit during the past month, the amount of sick pay being £36 18*s.* The usual grants were made to members on the Benevolent Fund. A grant of £5 was also made to a member in distress who had recently lost his wife.

GARDENERS' DEBATING SOCIETIES.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.—The annual general meeting of the above Association was held at Warburton's Hotel, Newport, on Saturday, January 7. Dr. Groves, B.A., J.P., presided over a good attendance of members. The Hon. Secretary, Mr. A. Kime, read the report of the Committee and the balance-sheet, which were considered satisfactory and were adopted. In addition to the Association being numerically stronger than last year, after all expenses are met, there is a substantial balance left in the hands of the Treasurer. The retiring officials were cordially thanked for their past services. Dr. Groves was unanimously elected Chairman and Treasurer of the Association; Mr. R. A. Sutton was elected Hon. Auditor; Messrs. Kime and Snook, Hon. Secretary and Assistant Hon. Secretary respectively. The retiring Committee was elected *en bloc*, with the exception of Mr. Snook for the Shanklin district, who is succeeded by Mr. J. H. Silsbury. A unanimous vote of thanks was accorded the Editor of the *Gardeners' Chronicle* for kindly inserting reports of the Association's meetings. Several new members were elected. Mr. Wm. Tee will lecture on "Carnations" at the next monthly meeting.

BECKENHAM HORTICULTURAL.—At the first gathering of this Society held in the New Year, a paper was given by Mr. P. Waterer on "Decorative Chrysanthemums." Mr. A. J. Baker, K.C.C., occupied the chair. The paper dealt with the methods necessary for producing a number of medium-sized blooms, rather than the usual three of exhibition size as generally grown. Mr. Waterer's method of cultivation is to pinch the shoots twice during the season. Some varieties he advocated disbudding to one bud on each shoot, while on other plants he retained three or four buds, according to which plan gave the best results. A pleasing basket of Chrysanthemums of the variety Robert Morgan, intermixed with Freesias, staged by the lecturer, was much admired. *F. W. P.*

EGHAM AND DISTRICT GARDENERS'.—At the meeting of this Society held on January 3, an interesting paper was read by Mr. Brown, assistant in the Botanical Department of Cooper's Hill College, on "How Botany Helps us." The essayist invited his hearers "in thought," to take a general walk round, pointing out in passing through the various departments how the science of botany assists one to master many difficulties that arise from various failures of growth, and to understand the many diseases plants are subject to. The lecturer advised the more general study of botany by our younger gardeners. A discussion took place on some of the diseases that are met with in the immediate district.

CROYDON AND DISTRICT HORTICULTURAL.—The annual meeting of the above Society took place on Tuesday evening January 3, Mr. J. Gregory presiding. The following officers were duly nominated and elected:—President, Mr. J. J. Reid, Coombe Lodge, Croydon; Chairman, Mr. M. E. Mills; Vice-chairman, Mr. W. Beotley; Treasurer, Mr P. F. Bunyard; Hon. Sec., Mr. H. Boshier, 62, High Street, Croydon. The names of Messrs. A. C. Crowley and N. Waterall were added to the list of vice-presidents. Messrs. W. Tyrell and W. Veners were appointed to serve on the Committee *vice* Messrs. W. Beotley and W. Harris. Mr. Bunyard formally presented the Treasurer's report for the year ended December 31, 1904, from which it appeared that the receipts amounted to £52 18*s.* 3½*d.* and the expenditure to £51 1*s.* 11½*d.*, there was thus a balance in hand of £1 14*s.* 4*d.* The Treasurer's report was adopted. The Secretary's annual report gave a most satisfactory statement of the condition of the Society, and recorded success in all the Society's undertakings. The proceedings closed with votes of thanks to the Chairman and the officers, special reference being made to the services of the Hon. Secretary, Mr. Harry Boshier.

THE REDHILL, REIGATE AND DISTRICT GARDENERS'.—This Society held its fortnightly meeting on January 5, Mr. W. P. Bound in the chair. The lecture on this occasion was given by Mr. W. Blackwood, who took for his subject "The Cultivation of the Tomato." After briefly touching on the introduction of the Tomato, Mr. Blackwood devoted attention to the practical side of the question, giving much valuable information on raising the seedlings, and the best means of obtaining thoroughly strong and healthy plants. January, February, March and August were the most suitable months for sowing the seed and by making successional sowings the cultivator would have little difficulty in maintaining a good supply of fruit for the greater part of the year. The lecturer also dealt with the questions of temperature, soil, manures and diseases to which the Tomato is subject. A discussion followed. *F. C. L.*

TRADE NOTE.

WE are informed that Mr. J. E. Sadler, late of Messrs. J. Backhouse & Son, of York, has been appointed traveller for the northern district, representing Messrs. Wm. Wood & Son, Ltd., Royal Horticultural Specialists, Wood Green, London, N.

Answers to Correspondents.

APPLES: *R. W. P. & Sons.* Many thanks for your communication. The census showed that there is an overwhelming agreement in regard to the best half-dozen varieties, as you will see on reference to the percentages given on p. 26 of this issue. At the same time we are aware that in particular gardens, owing to peculiarities of soil, altitude, or degree of shelter, the results obtained from certain varieties will not be exactly the same as the average results, even in the same neighbourhood. We quite agree with your appreciation of the varieties Dumelow's Seedling and Lord Suffield, and their inclusion in the best half-dozen can hardly surprise any fruit-grower, notwithstanding the liability of Lord Suffield to attacks from canker. The fruits of Maltster you have kindly sent us show that the season of this culinary Apple does not usually extend beyond the close of the year. It is grown chiefly in Nottinghamshire, where the trees grow freely and bear abundantly.

BEECH-TREES DYING: *W. J. W.* In the absence of specimens we suspect that the white downy appearance on the trees is due to an insect, the Beech-aphis, Chermes fagi. This is a common pest on Beech-trees, and is very frequently associated with canker. Spraying with petroleum emulsion is advisable where practicable.

BUD VARIATION: *X. Y.* We know of no means of inducing bud-variation, but insect-punctures will and do induce malformations. There is no separate work on bud-variation, but you will find much information in Darwin's *Animals and Plants under Domestication*, Masters's *Vegetable Teratology*, and a special article in these columns in 1891, January 10, 17, 24, and February 21.

CARNATIONS: *Correspondent.* We do not know the composition of Wagner's Solution for use in the culture of Carnations.

CINERARIAS: *T. B. A.* If you will cut through the collar of your plants from above downwards you will see a cavity formed by the grub of some insect. You must keep watch and try to ascertain what the insect is.

CURRANT BUDS: *E. S.* Your inference is correct; the shoots are badly infested with the Currant-bud mite, which causes the buds to have a swollen appearance. We should advise pruning the bushes very hard back, removing the soil

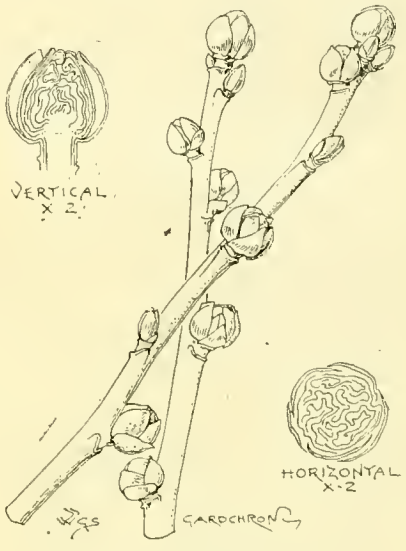

FIG. 15.—SHOOTS OF THE BLACK CURRANT AFFECTED WITH BUD-MITES.

from the surface beneath, and encouraging new growth by the addition of a suitable mulching of manure. Unless the plantation is young, however, grub the trees and replant on fresh ground.

GRAFTING HOLLIES: *H. E. C.* If the green-leaved Hollies you intend to use as stocks are as high as you wish your variegated standards to be, do not graft them, but in June or July insert buds of your variegated varieties either in the main stem or in the laterals of the stocks. If the stems are of moderate stoutness insert two or three buds in each, or if they are put in the laterals then put one bud in each, pushing the shield close down into the angle made by the lateral with the main stem. Bind the stem around the inserted bud closely with budding-cotton, and smear a thin layer of grafting-wax over the tie. The grafting of Hollies is not a very certain means of propagating them, and should only be done to obtain dwarfs or pyramids, and then the grafts should be made close to the ground, while after the tie and wax has been put on, it is better to draw the soil in a ridge round the grafts to make sure of their growing. This should be done in April and May, when the stocks are just beginning to grow, and it is better to cut the scions a month before and to bed them in the soil till wanted. If properly done, and yours is a "Holly soil," it will take about three years for the plants to make respectable heads; but this period may be shortened by good cultivation and the use of manures. Wateriana (gold), Queen (silver), and Handsworth's Silver-striped are among the best varieties to make standards, and the Weeping Holly in both green and variegated varieties is very suitable for this method of cultivation.

HAIR EEL: *C. R. F.* The specimen you send is a good example of Gordius aquaticus, belonging

to the Annelida class, possessing very simple structure. This is the commonest species of Gordius in Britain, of which the popular name is Hair-eel; and a notion still prevails in many parts of the country that it is nothing else than a horse-hair, which has somehow acquired life by long immersion in water. Gordii are extremely common in the River Thames.

LYCASTE SKINNERI VARIETIES: *J. B.* The flowers form a most interesting set of eight very fine and distinct varieties of this beautiful Orchid. These are L. S. alba, a fine pure white form; L. S. Lady Gladys, similar to alba, but with a slight blush tint; L. S. armeniaca, blush-white, with slight copper-coloured tint on the lip; L. S. Enchantress, a large blush-white; L. S. Beauty, rose-pink, with white labellum bearing bright rose-coloured markings; L. S. Amazon, a magnificent large flower; and two others, the one a dark form with fine crimson spotting on the lip. A flower of a very fine dark Cymbidium Tracyanum, and large blooms of three forms of Odontoglossum × Harryano-crispum, also accompany the Lycastes, all indicating a very high state of cultivation.

NAMES OF FRUITS: *W. H. S.* 1, Bess Pool; 2, Court of Wick; 3, Brownlees's Russet; 4, Winter Red Streak; 5, Reinette de Canada; 6, Ross Nonpareil.—*J. R. B.* Pear decayed. Apples, 1, Tower of Glamis; 2, Minchull Crab. —*W. E. H.* 1, Flower of Kent; 2, Brown's Seedling; 3, Augustus Pearmain.—*A. McAslam.* Cornish Aromatic.—*Thrapston.* 1, Dumelow's Seedling (Wellington); 2, Cox's Orange Pippin; 4, Scarlet Nonpareil.—*A. B.* Lord Lennox.—*H. Smart.* Beurré Sterckmans.—*J. H., Staffs.* Hollandbury.—*J. T. S.* Your Apple was too far decayed for us to identify the variety.

NAMES OF PLANTS: *J. H. H.* Pleroma macranthum.—*J. A. C., Eastbourne.* Æschynanthus speciosus.—*B., Essex.* Cymbidium Tracyanum. —*F. G. B.* Dendrobium Phalænopsis and Oncidium tigrinum. The Dendrobium is a warm-house plant, but the Oncidium will grow with the Odontoglossum in a cool-house. — *A. C. F.* Cupressus (Retinospora) obtusa and Picea Morinda, small undeveloped specimen.— *F. C.* Phyllanthus nivosus.—*Japonica.* 1, Cymbidium giganteum; 2, Lælia anceps; 3, 4, 5, 7, all forms of Oncidium tigrinum; 6, Restrepia striata; 8, Odontoglossum Rossii majus, a very pretty form of it.—*V. M.* 1, Brassavola tuberculata; 2, Aspasia lunata; 3, Odontoglossum Lindleyanum; 4, Oncidium flexuosum; 5, O. sphacelatum; 6, O. crispum.—*W. D. D.* We are unable to name the Chrysanthemum.

PEACH-TREES PLANTED IN ROWS ACROSS THE HOUSE: *W. H.* You had better put one trellis across the house, and see first how a tree against this trellis will succeed in your Northern locality. If your garden were situated in the South of England, where there is a greater degree of sunshine, we should have no hesitation in advising you that the system would be satisfactory. At Buxted Park, near Uckfield, in Sussex, Mr. Prinsep, the gardener there, planted years ago a house 32 feet long and 18 feet wide (same width as yours) in this manner, and the results he obtains are excellent, the crop being in his own opinion heavier than could be got from trees on the roof and upon the back wall only. The house at Buxted has a "hip," or three-quarter-span roof, and trees are cultivated against the back wall, just as under the common system of planting. Then instead of having trees along the front of the house, there are seven rows of trees proceeding across the house from the path near to the wall to the front. The trees are trained to upright trellises, and 4 feet spaces are allowed between each row of trees. As we stated in our issue for November 22, 1902, p. 373, the system appears to be one that might be adopted with advantage in gardens of moderate size and convenience, providing the locality is a sunny one, where the outdoor crops usually ripen early. In colder or in northern districts, and in extra wide houses, it might happen that parts of the trees would not perfectly mature the wood. See also *Gardeners' Chronicle*, November 29, p. 401; December 6, p. 422; and December 20, p. 463, all in 1902.

PEAT SOILS: *J. D. C.* Peat soils contain an over-abundance of organic matter, and are therefore generally rich in what is called acid humus, in which it is well known our cultivated plants do not flourish. But if basic bodies, such as lime, wood-ashes, peat-ashes, &c., are added to the peat soils, they are changed gradually into ripe or mellow humus, and lose the acid properties; then it not only becomes fertile, but increasingly so when it has been subjected to fermentation, which is greatly hastened by the application of liquid animal manure. Peat soils are generally very poor indeed in all alkaline salts, of which lime and phosphoric acid are the most important, since these have been in great part washed out by the water which covered the peat deposits. We recommend an application of a mixture of superphosphate (high grade—say 37 per cent. phosphate) and quick-lime in equal proportions, to which may be added a little sulphate of potash, and apply this at the rate of 10 oz. per square yard of soil. Wood-ashes and soot mixed together are excellent fertilisers for peat soils. Basic slag may also be used with advantage at the rate of 8 to 10 oz. per square yard. Use liquid-manure much more abundantly for culinary vegetable crops than for flowering plants. The six hardy flowering annuals we recommend for the peat soils are Godetia (Lady Albemarle and Duchess of Albany), Clarkia elegans rosea, Mignonette, Schizanthus grandiflorus oculatus, Sweet Sultan in various colours, and Nemophila insignis. We strongly recommend you to plant Primula japonica, which is one of the finest of the strong-growing species, and succeeds well in the bog-garden or by the side of a stream or lake. The seeds of this species should be sown as soon as ripe. When once sown it seeds itself, and the young plants come up in hundreds, when they may be transplanted. They die down in the winter and remain dormant until the following spring.

RICHARDIA (CALLA) GRANDIFLORA [ÆTHIOPICA]: *J. M.* No doubt your plants are affected with soft rot. Try to scoop out the diseased portions and apply a weak solution of carbolic acid or Condy's fluid.

SEEDLING ORCHIDS: *T.* The first step is to get good, well-matured seed capules, and these are most successfully ripened if the plants bearing them are suspended near to the glass of the roof or placed on a shelf in a house having an intermediate temperature. The fruits take a long time to ripen, and when fully matured the seed capules of such plants as Cattleyas should be cut off, placed in strong paper or calico bags, and put on a shelf in a rather dry atmosphere to complete the last stage. When the seed-vessels split, the seed should be sown, or as much of it as is required, the remainder being kept dry for future use. The surface of the potting material of any other established Orchid which does not require drying off is a very good place to sow seed of Cypripediums and some other Orchids. But if it is intended to raise seedlings in large numbers, it is best to have a rather roomy glass-covered case, arranged in a moist and warm part of the house. In this case, previously prepared pots should be arranged on which to sow the seeds, and the seeds sown when ready, and the crosses duly recorded. Various materials are used for sowing the seeds on. Some prepare pads of sphagnum-moss covered with coarse calico, or material like Orchid-house shading; others use blocks of peat. Some use for Cattleyas, &c, pans of broken crocks with peat and charcoal on the surface, others discs of wood. When the arrangements are successful, the seedlings show signs of vitality by germinating in a few weeks, or it may be months. It appears that the seedlings will enter on the first stage on almost any material, but they often die off unaccountably afterwards. The object should be to get as many seedlings as possible into thimble-pots, four or five in a pot. The seeds should be sown on a previously-moistened surface, and they should not be allowed to get dry. A sprayer is the best means of keeping the pots and material moist.

VANILLA CULTURE: *M.* Considering the relatively small demand, the facility and cheapness of transit of the native pods, and the heat and expense requisite to grow the plant here, we do not think it would be profitable to embark in its culture in the Channel Islands. Try it on a small scale at first, in order that you may be able to form some idea of the risk involved.

VINE MILDEW: *W.* A correspondent who at our request made trial of Campbell's Patent Vaporiser was thoroughly satisfied with the result, and recommends its use in glass-houses in which Grape-Vines, Peaches, Cucumbers, Roses, Chrysanthemums, and similar plants are grown. The principle consists in heating the sulphur in a vessel having a funnel-shaped outlet, the tube of which is loosely closed by a pyriform hollow glass ball, which rises or falls according to the pressure of the hot sulphur vapour inside, thus allowing of the passage of the sulphur vapour, but at the same time preventing the entrance of hot air into cylinders where it could set fire to the heated sulphur.

WIRING CONCRETE WALL FOR TRAINING MORELLO CHERRIES: *J. S.* The oak posts should be let into the ground 2 feet flush with the face of the wall and close up to it at each end, the soil being rammed firmly about them. This done, mark the positions of the several wires on both posts at 6 inches apart, commencing 1 foot from the ground-line. Then drive the 3-inch galvanised wrought-iron driving-eyes quite 2 ins. into the posts at the points indicated thereon. Strain a line from end to end, beginning at the bottom eyes, and then mark off the positions of the several holdfasts at 5 feet apart on the wall, repeating the operation until the positions of the supports for the top wire are indicated. These positions should be arranged so that the holdfasts will alternate in each succeeding row. They should be driven quite 2 inches into the concrete wall, which, it will be found the galvanised wrought-iron driving-eyes will pierce under the influence of due force. This will dispose of the expense and labour involved in plugging the wall as you have suggested. No. 14 gauge galvanised wire will answer your purpose in every respect. Having cut the necessary series of wire into lengths of, say, 162 feet 6 inches each, secure the ends of the individual wires to the holdfasts provided for them in the post at, say, the west end, and then thread them through the series of "driving-eyes," and secure to "screw-tightener," which pass through eye of holdfast driven into the post at the east end of wall and tighten up to the necessary degree of tightness. Owing to the great number of small branches and shoots that has to be manipulated in the training of trees of the Morello Cherry, the wires should not be farther apart than 6 inches; but 9 inches would do for Pears, Plums, and Sweet Cherries. Fixed as indicated above the wires will be about three-quarters of an inch from the face of the wall. We advise that galvanised wires attached to walls having south, east, and west aspects should be painted white or stone colour, in case the action of the sun on the galvanised wire might prove injurious to the shoots of the trees attached thereto; but in your case, if the wall has a north aspect, it is immaterial whether you paint the wires or not. We should not expect trees of any kind to succeed well trained immediately upon or over galvanised iron roofs and fences.

FERN FRONDS.

ALTHOUGH Ferns must necessarily relinquish the foremost place as decorative plants in favour of flowering plants, owing to their general lack of brilliant colouring and their non-possession of any visible flowers at all, yet among foliage plants they cannot be surpassed. Their diversity of form and cutting is extraordinary, even in the specific forms, while when varieties come into question it seems infinite. Normally they vary in type from tiny, simple, undivided fronds, such as we see in our native Adder's-tongue or in Asplenium septentrionale, up to huge and much-divided ones, as in the majestic Tree-Ferns. Between these two extremes lie all grades of division on very similar lines, *i.e.*, we have a central stalk or stipes, from each side of which spring others, and from these still smaller ones up to the fourth or even fifth stage, while from all these spring a network of veins, between which lie the cellular tissues which complete the frond and render it a complicated, leafy expanse of smaller or greater area. This type of frond is the commonest, but there are numerous species in which the fronds are not divided at all, such as our common Hart's-tongue, the Bird's-nest Fern (Asplenium nidus avis), and numerous members of the Polypodium genus. In these the central rib has two more or less broad wings, one on each side, forming together a plain-edged frond of ribbon, spatulate or other form, and between the divided and undivided types there are various grades of partial division, coupled with a varietal tendency on the part of the undivided types to form projections at the edges, indicating an approach to the commoner type. Outside these, again, though only to a certain extent, since the ground-plan of ribs and sub-ribs is similar, we have the Ferns of the Maidenhair type, in which the minor divisions are quite distinctly stalked and independent of each other, and are also peculiarly shaped, usually wedge-fashion, imparting to the whole frond a widely different and lighter aspect than that of the rest of the divided section. Fern fronds, as a rule, differ from the foliage of flowering plants in springing individually and directly from the growing centre, and not, as in the latter, from already developed branches. This growing centre or caudex varies, however, greatly in type. In a very large number of species, we may point to our common Male Fern as the type; a circlet of fronds springs up around the centre on the principle of a shuttlecock, a fresh batch arising each season, when those of the previous season drop down and decay, leaving a small portion of their base as a contribution to the root-stock or caudex. It is in this way that a Tree-Fern forms its trunk, while many Ferns similarly planned work their way horizontally instead.

Another and a large section we may typify by the well-known Hare's-foot or Squirrel's-foot Ferns (Davallias). In these the horizontal root-stock lengthens much faster, with the result that the fronds rise one after the other and stand separately. Nevertheless, despite this difference they originate from the growing points on the same spiral plan as in Ferns generally, but assuming immediately an upright position at right angles to the root-stock. Our common Polypody forms a familiar type of this kind, as well as the Davallias, and these two above-described classes embrace the bulk of the Fern family.

Nature, however, is fertile in variants. Thus for instance, in the Ostrich-feather Fern (Struthiopteris) and in the Nephrolepis, we have Ferns of the true shuttlecock type, which develop underground runners of the creeping root-stock kind, which, after penetrating the soil for some distance, form a shuttlecock set of fronds from a terminal bud. In this particular connection it is worthy of remark that probably all the fronds of shuttlecock-forming Ferns have incipient buds near their bases, which are the rudiments of such runners, and in case of damage to the centre of growth, or even a check, they frequently assert themselves and form young plants, but closely adjacent and not at a distance. In this way an old plant is usually of a bush like form, except in those which form trunks like the Tree-Ferns, in which this tendency appears to be suppressed. In the common Bracken we have a very marked example of a rapidly extending root-stock, with fronds at long distances. In this case the root-stock plunges deeply into the soil, even many feet, the fronds pushing their way to the surface all the same. The result is that the Fern spreads very quickly, and is very difficult to eradicate when once established. We have said that the frond differs from ordinary foliage in not originating from branch buds; but here, as usual, Nature makes exceptions to her general rules in the shape of bulbil-bearing fronds. There are many examples of this kind both specific and varietal. In these young plants are generated either from the plain surface of the fronds, as in Asplenium bulbiferum and Woodwardia orientalis, by buds in the axils of the subdivisions as in many varieties of Polystichum, in a berry-like form in Cystopteris bulbifera, by bulbils at the backs of the fronds in connection with the spore-heaps as specifically in Lastrea prolifera, and varietally in several Athyria, and by terminal buds at the end of lengthened fronds as in Adiantum lunulatum, Camptosorus rhizophyllus and others. In none of these cases, however, does the presence of bulbils enable the Fern to form an ascending bushy plant as in the case of trees; they all depend for permanent existence on some chance bringing them in contact with the soil or an equivalent. Finally, the great and main characteristic of the Fern-frond is its spore-bearing character, which is evidenced in many ways. These may appear in dot or line-like heaps arranged in various ways on the backs of the fronds, at the edges or elsewhere, in distinct masses at the frond tips as in Osmunda regalis, on separate divisions of the fronds as in Anemia and Adder's-tongue, or in undefined sheets as in the Platyceriums or Stag-horn Ferns. They may also be borne in little cups on the frond edges as in Davallia and Trichomanes. The microscopic spores are as a rule contained in tiny globular-stalked vessels called "sporangia," which burst open when ripe with considerable force, discharging the contained spores to a good distance; but in a few species they are contained in little cases of a different shape, "synangia," escaping through openings in the top The mode in which these spores are borne is one of the most constant features even under great variation of specific and varietal form, and hence has been chosen by botanists to form the distinguishing marks between various genera. *Chas. T. Druery, F.L.S., V.M.H.*

NEW OR NOTEWORTHY PLANTS.

SCAPHYGLOTTIS COGNIAUXIANA, De Wildeman, nov. sp.*

This small species bloomed for the first time in the Brussels Botanic Garden at the beginning of December. It was received from M. Alf. Cogniaux, the well-known writer of the monograph of Brazilian Orchids in the *Flora*

* *Scaphyglottis Cogniauxiana*, De Wild., nov. sp.—Caules uumerosi, plus minusve arcuati, ad nodos geniculati, flexuosi et interdum radicantes, virides vel fuscescentes, articulis inferne vaginatis, fusiformibus, 1,8—4 cm. longis et 3—5 mm. diam., apice mono vel diphyllis. Folia suberecta, lincaria, basi breviter vaginantia, rigidiuscula, uuinervia, ad apicem obtusissima et suboblique emarginata, 6—11·5 cm. longa et 2—3 mm. lata, nervo mediano supra canaliculato subtus non vel vix prominente. Flores 1—3, subsessiles, squamis longiusculis arcte vaginati, plus minusve patuli, viridiflavi, squamis 4—6 mm. longis. Ovarium liucare, rectum vel paulo arcuatum, 11 mm. circ. longum. Sepala tenuiter membranacea, leviter concava, triuervia, circ. 4 mm. louga, acuta, dorsale, 2 mm. latum, lateralia, 1·7 mm. lata; petala erecta, liucari-subspatulata, subacuta, uuinervia, vix obliqua, 4 mm. longa et circ. 1 mm. lata. Labellum subtiliter 3—5-nervium, concavum 3—5 mm. long et 2·2 mm. latum, inferne augustatum, apice rotundatum, emarginatum, ad margines iutegerrimum. Columna erecta, recta vel vix incurva, apice dcutata, 2 mm. circ. longa, et 1·8 circ. crassa. Brazil (*Import. Delaet*, 1901).

Brasiliensis, who himself received the plant from the Maison Delaet. We have pleasure in naming it after Professor Cogniaux, by the aid of whose monograph we were enabled to identify the plant. It should be classed, as our description will show, closely with S. prolifer (R. Br.), Cogniaux (cf., *Fl. Bras. Orchid.*, v., pp. 10—17), which, like S. Cogniauxiana, has the chin of the flowers but slightly marked, a characteristic which at once caused me to assign the plant to this genus. The difference between the two species is easily seen; in S. prolifer the leaves are about $\frac{3}{4}$ to $1\frac{1}{2}$ inch long, and from 2·5 to 5 mm. (about $\frac{1}{10}$ to $\frac{1}{5}$ inch) wide, while in our plant they measure $2\frac{1}{2}$ to $4\frac{1}{4}$ inches long by 2 to 3 mm. ($\frac{1}{12}$ to $\frac{1}{8}$ inch) wide; the latter therefore are narrower and longer. In S. prolifer the sepals are pointed, the petals subspatulate, obtuse, the lip emarginated; in S. Cogniauxiana the sepals are pointed, the petals sub-acute, the lip bordered to the top. What still further differentiates the two plants is the length of the ovary, which in the older species, figured in 1824 by Lindley in the *Botanical Register* (t. 825), is very short, about 4 mm. (or $\frac{1}{6}$ inch) long, and with bracts surrounding it to the top; in the newer species the ovary is much longer than the bracts sheathing it, and may be $\frac{3}{5}$ inch (11 mm.) in length. *E. D. W.*

KEW NOTES.

LISTROSTACHYS HAMATA, *Rolfe*.—This is certainly one of the prettiest of the genus and is now flowering in the warm Orchid-house. It was sent to Kew in 1899 by Mrs. W. T. Martin, of Brixton, amongst a small miscellaneous collection of Orchids, which were gathered near Lagos, West Tropical Africa, and first flowered in December, 1900, proving to be a new species. It has flowered each year since that date.

The plant grows erect, having flat, leathery leaves 7 inches in length by $1\frac{1}{4}$ inch broad, deeply lobed at the apex. The plant now in flower has eight pairs of leaves and is carrying two racemes of flowers 4 inches in length, and each having seven large, white, vanilla-scented flowers. There is no distinct shaped lip, as is generally the case in this genus; the form of the flower is somewhat similar to that of a Hyacinth, with slender segments. The sepals are rather larger than the petals; they are $1\frac{1}{2}$ inch long, linear-acuminate, and curved backwards for half their length. The spur is nearly 2 inches long, light-green in colour, and has the remarkable character of being distinctly hooked at the tip; the ovary is triangular in shape and $1\frac{1}{2}$ inch long. At the base of each flower is a large, dark-brown, foliaceous bract. L. hamata succeeds well under such conditions as are generally afforded Aërides, Angræcums, &c.

ONCIDIUM PORRIGENS, *Rchb.*

This is an old species that was introduced by Messrs. Low & Co. from North Grenada, and was described by Reichenbach in the *Gardeners Chronicle* in 1868, p. 125, but it is very seldom seen in cultivation. The following is Reichenbach's description:—"This is a species of no other than botanical merit; both sepals and petals are horse-chestnut-brown, with honey-coloured ends; the lip is cinnamon [coloured], bearing an orange-coloured callosity, with some deeper spots." Notwithstanding this description, it is a species that is worth growing in a collection of Orchids. The Kew plant was obtained under the name of O. trulla, with which it is closely related. It is a large-growing species, with deep-green flask-shaped pseudo-bulbs 5 inches in length, each growth having usually about eight large arching leaves, the longest of which is 2 feet, and 2 inches in width. The plant now in flower has two branched spikes, each 5 feet in length, and consisting of about twelve spikelets having numerous flowers, the diameter of which is rather less than 1 inch. *W. H.*

SOME NEW FACTS CONCERNING THE ECONOMY OF THE CRANE FLY (TIPULA OLERACEA) AND ITS NATURAL ENEMIES.

SINCE the days when John Curtis published his *Farm Insects* in 1860 much has been written on the depredations of the Tipulæ or crane flies, but comparatively little that is new has since been added to the interesting account which "Rusticola" has given to us of these destructive pests. Four years ago there was an alarming plague of the larvæ on the golf-links in the marshes of the Dee, Cheshire. It was

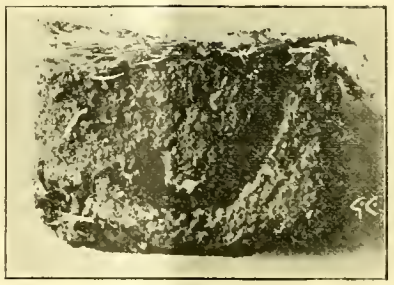

FIG. 16.—HORIZONTAL SECTION OF THE SUBTERRANEAN DWELLING OR BURROW OF THE LARVÆ ("LEATHER-JACKET") OF TIPULA OLERACEA. (*Actual size.*)

on this occasion that the writer had exceptional opportunities of observing the habits of these insects, and some facts then gleaned may at least prove of interest if not instructive. It should be clearly understood, however, that there are at least three species of crane flies which are destructive to crops and plants of various kinds, and also that the larvæ of all of them are popularly known as "leather-jackets." The following facts, however, concerns only one

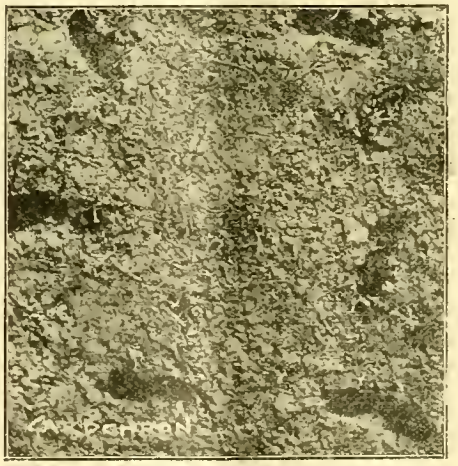

FIG. 17.—TRANSVERSE SECTION OF SIX BURROWS OF THE LARVÆ OF TIPULA OLERACEA ACROSS THE CURVED PORTION. (*Actual size.*)

species, Tipula oleracea, one of the largest and most familiar of the family:—

The infected area under observation extended over several hundred acres, covering practically the whole of the grass land of the marshes, a great portion of which is perpetually grazed by sheep, the remainder being reserved for the use of the golf club. It was on the ground of the latter that the observations were chiefly made. The unmown grass on the links is generally short, and amongst it grows patches of White Clover, with here and there tufts of the Sea Pink (Armeria maritima), and other less common plants. Almost every square yard of grass was injured, and more especially in the shallow depressions and deeper hollows. In these the grass was so completely destroyed that there was not a green blade left, and the dead brown patches extended in every direction over the whole of the land. So effectually had the "leather-jackets" severed the crowns of the plants that one could with little difficulty roll back the turf into large masses, leaving the ground smooth and bare,

FIG. 18.—THREE BURROWS OF THE LARVÆ OF TIPULA OLERACEA EXCAVATED BY ROOKS. (*Actual size.*)

exposing the surface-tracks of the larvæ. Strange to say, the White Clover and the Thrift were left intact and uninjured, and large patches and isolated plants of the former were growing amidst and through the dead grass, the larvæ at the same time were swarming on all sides with nothing apparently to eat but the dead grass which they had severed from its roots. On exposing the bare ground one also succeeded in occasionally disinterring a "leather-jacket," but

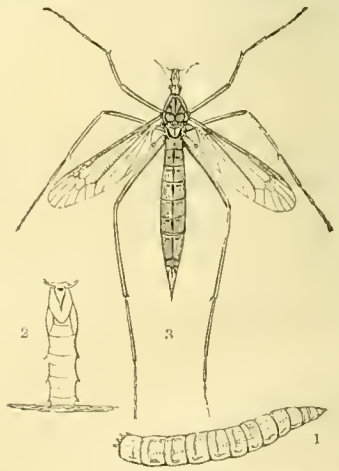

FIG. 19.—THE CRANE FLY OR DADDY-LONG-LEGS. 1, Grub; 2, the Pupa; 3, Mature Insect.

such instances were rare. By carefully skimming off a thin layer of soil one immediately exposed to view innumerable burrows large enough to admit an ordinary-sized slate-pencil. In these the larvæ were discovered, and by making a vertical section of the burrows one also found that each larva had excavated for itself a separate J-shaped dwelling (fig. 16), into which it had retreated for the day, and where, for greater safety, it had gone as far as it could into the upturned portion, carefully blocking the entrance with *débris* and soil so as effectually to conceal it. From this subterranean retreat the larvæ were with diffi-

difficulty extracted except by digging them out, and many suffered themselves, as do worms, to be extracted piecemeal with a pair of small forceps rather than relinquish their hold. Indeed the resistance they offered when occupying the upturned portion of the burrow was extraordinary. As to their numbers, there was an average of ten larvæ to the square foot, or ninety to the square yard; in the badly infected spots there would be quite double that number. The larvæ which were kept under observation were found to leave their burrows at night, returning again to them during the day. Pupation took place throughout the month of August, the first two flies appearing in the breeding-cage on the 11th of the same month, and others continued to hatch until the end of September. In the infected area the crane flies were more abundant in the early part of September, when they occurred in myriads; and on one occasion, during a prevailing north-west wind, millions of them were swept together into the sheltered corners of the golf pavilion.

Fig. 20.—Blackhead gull (Larus ridibundus), a natural enemy of the crane fly.
From a specimen in the Grosvenor Museum, Chester, mounted by the Author.

Natural Enemies.

During the month of June, when the "leather-jackets" or larvæ were devastating the grass, the rooks flocked to the infected area, and devoured the grubs in great numbers. Their feeding time was during the early hours of the morning, and again during the evening, after the golfers had gone away. Small parties were also to be seen at intervals throughout the day. The method adopted by the rooks for extracting the larvæ was simple, and at the same time extremely interesting. As already stated, each larva retreated during the daytime into the upturned portion of its burrow (fig. 17), where it was perfectly concealed and apparently safe, there being but one exit, and that invariably blocked at the entrance; then over all was the additional mat-like surface of grass. Apart from the dead grass there was therefore no external evidence of the existence of the larvæ. The rook has first of all to find out the larval retreat, and this it apparently does by probing with its beak and pulling away tufts of grass. Having located a burrow, the bird then ascertains the direction in which it is curved, finally excavating the overlying soil (fig. 18) exactly in the right place, thereby exposing the curved end of the burrow and its helpless tenant. It would be impossible to give anything like an approximate estimate of the number of grubs that were thus taken by the rooks; but it is quite safe to compute the number at 25 per cent.—a very high percentage considering the extent of the infected area. But the rooks were attracted to this rich feeding-ground in enormous numbers, and by their unremitting search for the grubs did more to reduce the devastating army than could any human agency. It was during the months of June and July that the rooks made their attack, and when the larvæ had pupated, and the flies began to appear, these birds left the district for other fields. Then, when the crane-flies appeared, they in turn were attacked by flocks of black-headed gulls (Larus ridibundus) (fig. 20), and to such an extent did they wage war against the insects that their "pellets" or "castings" (fig. 21) were left scattered over the land in hundreds, looking like little bundles of tightly-packed dead grass. On soaking one of the "pellets" in water it was found to contain the remains of about 400 crane flies and 1,600 of their eggs; the latter had evidently been taken while yet in the body of the parent. Each pellet probably represented a single meal, and there can be but little doubt that each bird would make at least two meals daily of these insects. If this were so a single gull would be accountable for the enormous number of 4,000 crane flies and their eggs per day, making an aggregate of 28,000 per week. As the gulls flocked together in hundreds, the number of insects which they devoured may better be imagined than described. Fortunately the birds were and are still strictly protected.

So far the evidence relating to the nature of the natural enemies of the crane flies and their larvæ has been gleaned from a comparatively small area, and that under very unusual circumstances. From other localities the writer has also found numbers of leather-jackets in the stomachs of both the curlew and the green plover or lapwing, and he has also seen late broods of the young of the yellow-hammer and the common wren fed extensively on the parent flies (Tipula sp.) (fig. 19). Thus we see that the Tipulæ form an important item in the dietary of several species of birds (one could add others from various authorities), and that these birds contribute in no small degree to check the increase and the ravages of these pests of the farm and garden. *R. N.*

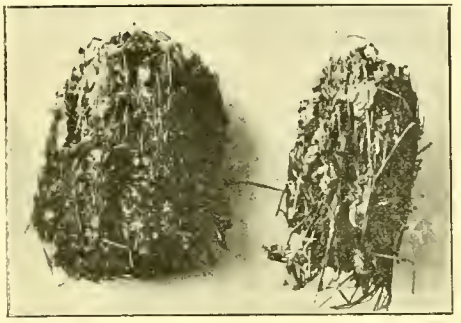

Fig. 21.—Two "pellets" or castings of the black headed gull, composed entirely of the remains of crane flies (Tipula oleracea). (*Actual size.*)

ALPINE GARDEN.

ARABIS FERDINANDI-COBURGI.

There are several members of the genus Arabis which have quite a distinct character from the well-known A. alpina and A. albida, which are so generally met with in gardens. Some are of the closest and densest habit, and form ideal plants, so far as regards their habit, for the collection of choice rock plants. Unfortunately, most of them are disappointing as regards their flowers, which compare very unfavourably with those of the more popular Arabises. One of these is the new Arabis Ferdinandi-Coburgi, introduced last spring. It is a beautiful little plant, with small rosettes of greyish leaves, green, however, in winter. It is only some quarter of an inch above the soil, and is almost moss-like in its appearance. As a flowering plant it is, however, rather disappointing, seeing that its blooms are not only small, but are of a yellowish-white—one of those nondescript hues which are disappointing. Yet the appearance of this Arabis when out of bloom will make it welcome to many lovers of alpine plants. *S. Arnott, Carsethorn-by-Dumfries, N.B.*

SOME NOTES ON FORCING VEGETABLES.

ASPARAGUS claims the first place, and may be obtained daily from now until April, though the return is not so good as that from Seakale. But it is only fair to add that a great improvement has taken place in the culture of roots expressly for forcing purposes, and when the length of time necessary to grow these roots is taken into account the cost is not excessive, and they make the work of forcing less difficult than it was formerly. The value of permanent beds, however, for furnishing a supply from February till April is very great. We find these beds a splendid addition, and they last for many years, whereas lifted roots once forced are valueless, and the work of years of preparation is lost in a single season. I did not intend to describe the best methods of forcing, for I have done so many times in the *Gardeners' Chronicle*, but will merely add that we use fresh leaves and manures largely. By using hot-water-pipes and sunk brick pits, as well as the manure and leaves, forcing is done with ease, and splendid results are secured. I am surprised that this system is not more practised in large gardens.

In the case of plants which are forced in permanent beds, encouragement must be given them after forcing to grow strongly and make good crowns for forcing the next season. Asparagus is not like many other crops, for if it be given occasional supplies of food and moisture excellent returns will follow for many years. For supplies earlier in the season than February I do not advise forcing plants in permanent beds, as the roots then more readily start into growth, whilst the lifting that others may be subjected to would cause a check to their growth. When space is plentiful and seeds of Asparagus are sown every year, forcing is attended with little difficulty, but my experience goes to show that in many gardens space and labour to grow the plants are none too abundant, and for forcing after January permanent beds are a great advantage. In our own case we force lifted roots from early December to the end of January, then rely upon the permanent beds till the end of April, and beds in the open for the latest period, which often lasts for four months, as we find that even in July there is a brisk demand for this vegetable. It will thus be seen that Asparagus may be had during eight months of the year.

SEAKALE

is a popular vegetable at this season, and during the last quarter of a century great progress has been made in the culture of this vegetable, not only by the trade but in private gardens, as very large quantities are now grown, and supplies may be had from November until April. I am not sure that Seakale from roots lifted and forced in Mushroom-houses or any dark warm place can compare as regards flavour with the produce from roots forced under pots in their growing quarters. The large market grower, however, who forces largely and in a different way, gets excellent produce; and the forcing is done upon the old system, except that the roots are placed together in bulk. Seakale-roots made suitable by special preparation for forcing may be purchased at such a reasonable price that there should be no difficulty in obtaining a plentiful supply at this season. Attention may also be called to the value of this plant, when merely given protection, for the obtaining of a late supply. If the plants be covered over now with a good body of soil, they will yield splendid produce in March and April, when good vegetables are scarce. It is surprising how much better in quality all vegetables are when they have not been forced severely. Even in forcing it is necessary to make the treatment as natural as possible, and the employment of too much heat results in poor flavour. It is not really necessary to remove Seakale-roots indoors, for if a certain number of roots, according to the requirement of the house, is placed in trenches and covered with warm litter, which can be added to as required, a full supply may be obtained, and the produce will be superior to that grown in a heated house. In any case a regular supply should be maintained by commencing to force fresh roots every three weeks, either in the Mushroom-house, in frames covered with litter, or in their permanent positions in the beds. *G. Wythes, Syon House Gardens, Brentford.*

(To be continued.)

FRUIT REGISTER.

PEAR-SHAPED CURRANTS.

IN the *Pomologische Monatshefte*, No. 10, 1904, Mr. Maurer, of Jena, gives a description with illustrations of various pear-shaped Currants, both red and white. Up to the present time but four varieties are known of Currants that produce berries of this shape. One of the white and one of the red-fruited Currants were raised by Mr. Goegginger, a nurseryman of Riga, and the two remaining sorts came from Switzerland. Mr. Maurer has subjected these to a series of carefully made experiments, with the result that Mr. Goegginger's pear-shaped Red Currant is found to be well worthy of note as a dessert fruit and for preserving. It is extremely decorative for table use, and either as a bush or a standard it is suitable for planting in the pleasure-garden, but it is not of sufficiently vigorous growth to render it suitable for market purposes. The remaining three Currants having pear-shaped fruits are of pomological interest only.

As a result of experiments extending over several years, bearing upon the number of seeds in each berry, and the weight of seed contained in each berry, Mr. Maurer states that in those seasons in which the crop was most abundant, each berry contained more seeds than in years in which the crop was poorer in quality. Also that in those crops that were better in quality, each individual seed attained also a greater weight than in years when the fruit was less abundant.

NOVELTIES OF 1904.

(Concluded from p. 30.)

THE following new and rare plants and fruits, &c., of special interest have been illustrated in the *Gardeners' Chronicle* in 1904:—

Aloe natalensis, November 19, p. 347.
Aloe striata, December 17, p. 423.
Aloe supralævis, December 31, p. 458.
Aloe Baumii, April 9, p. 226.
Apple "Rev. W. Wilks," October 8, p. 253.
Apple (six best cooking), Oct. 29, pp. 299—303.
Apple (six best dessert), Nov. 5, pp. 314—319.
Apple (Crab) Veitch's Scarlet, October 8, p. 252.
Apple (Crab) Frettingham's Victoria, October 8, p. 252.
Amaryllis Snowdon (Hippeastrum), April 30, p. 283.
Amaryllis (Mr. Chamberlain's), Dec. 3, p. 391.
Asparagus medeoloides myrtifolia, November 5, p. 323.
Astilbe (rose-coloured), August 27, p. 143.
Bambusa palmata, Supp., April 30.
Begonia Avalanche, June 18, p. 396.
Bougainvillea Maud Chettleburgh, Supp., November 12.
Bougainvillea spectabilis Cannell's variety, December 3, p. 383.
Bowkeria triphylla, Supp., December 10.
Begonia Margaret Gwillim, August 6, p. 90.
Begonia (Webb's Double), September 3, p. 167.
Calceolaria (Webb's Wordsley), June 11, p. 379.
Carnation Lady Carrington, August 6, p. 94.
Carnation Glow-worm, August 6, p. 95.
Carnation King Solomon, July 30, p. 78.
Carnation Lady Linlithgow, July 30, p. 79.
Caralluma crenulata, January 9, p. 19.
Caralluma Munbyana, February 6, p. 84.
Chrysanthemum marginatum, January 23, p. 51.
Chrysanthemum (Jap.) Lady Cranston, Supp., January 23.
Cheiranthus × kewensis, February 20, p. 123.
Castanopsis chrysophylla, August 27, p. 145.
Citrus "Plata Orange," February 6, p. 93.
Clerodendron myrmecophilum, April 9, p. 229.
Clematis × Mantua hybrid, June 25, p. 403.
Corydalis angustifolia, May 14, p. 307.
Corydalis nobilis, May 14, p. 308.
Corydalis thalictrifolia, May 14, p. 309.
Corydalis Wilsoni, May 14, p. 306.
Cotoneaster angustifolia, December 24, p. 441.

AGAVE AMERICANA.

FEW plants have a more stately appearance than the so-called American Aloe. Our illustration (fig. 22) exemplifies this statement. It was taken from a photograph kindly sent us by Mrs. C. W. Lea, Parkfield, Hallow, near Worcester. In the early part of November the flower-buds were generally expanded, showing globular masses of yellow stamens. The flower-spike was nearly 20 feet in height, and was produced between the end of June and the end of October. The plant is more than fifty years old. Of course the species is not an Aloe, and the statement that a plant only blooms when it has attained an age of 100 years is a perversion of the truth. The Agaves are mostly natives of Mexico and dry countries, but they have been largely introduced along the Riviera, where their majestic appearance adds greatly to the picturesqueness of the scenery.

VEGETABLES.

ROTATION OF KITCHEN GARDEN CROPS.

THIS is a subject of considerable importance in vegetable cultivation, but one which I am afraid does not in practice receive the attention which its importance deserves. It is from lessons learned in the school of long experience and of practical work that the following suggestions as to the rotation of crops are based.

The subject of rotation is rather difficult of approach. It may be likened to an endless chain, or a circle that is for ever revolving; there is really no end or beginning to the work, for which one must be always either preparing or planting. It will be convenient to take as the first of our crops Peas, early, mid-season and late.

It goes without saying that for the first early crop of Peas the position selected must be a warm one, such as a south border protected by a wall, hedge, or some other shelter. Presuming that the land has been well prepared and the varieties grown are the earliest to bear, this crop should be over early in June. The next crop to occupy the ground should be Cos Lettuce, planted in rows 12 inches apart and at the same distance between the plants in the rows. A light dressing of well-decayed manure should be applied to the land previous to planting this crop. The Lettuce should be over towards the end of July or early in August, when the land should be dug, without manuring, and Early Horn Carrots sown in rows 10 inches apart. This crop will occupy the ground during the whole of the winter months, giving a supply of excellent Carrots until others are produced the following spring.

SUCCESSIONAL CROPS OF PEAS.

It is a principle with all good gardeners to manure heavily and trench deeply annually some portion of their garden, so that after a few years the whole of the soil is subjected to the beneficial influence of this treatment. The portion of the garden receiving this culture during the current year cannot be devoted to a better purpose than the growing of successional crops of Peas, the last of which will be out of the ground late in October or early in November. The earliest of the midseason Peas will be harvested early in autumn, and the best crop I know of to follow the Peas is autumn and winter Lettuce. For this crop it is an advantage to divide the land into "breaks" 7 feet in width, with an 18-inch alley between them. The soil of the alley should be added to the surface of the bed, in order to slightly raise it above the surrounding level; by this means the soil will be kept much drier during the wet weather of autumn and winter. Cauliflowers in successional batches should succeed the Lettuce the following spring, the land in the meantime having received a moderate dressing of manure.

FIG. 22.—FLOWERING OF AGAVE AMERICANA AT PARKFIELD, WORCESTERSHIRE.

EARLY POTATOS.

One of the most important early crops the kitchen gardener is responsible for is that of early

Potatos, and, provided the land has been well prepared beforehand by liberal manuring and cultivation, no crop yields a more satisfactory return than this. The position allotted to the Potatos should be as favourable as that recommended for early Peas. The best crop I have found to follow early Potatos is that of the London Colewort. These, if planted in August, will make beautiful, compact heads before winter, and be as much appreciated as any crop at that season. They should be planted 10 inches apart each way, and the ground should receive a light dressing of manure before they are planted. For successional crops of Potatos the land that was under Cauliflowers the previous season should be utilised; if possible, it should be trenched and heavily manured during the winter. *O. Thomas.*

(To be continued.)

FLORISTS' FLOWERS.

THE AURICULA.

WITH the advent of the new year Auricula fanciers begin to get interested in their favourites if the weather is favourable. If frosts set in the plants may be well covered up with double mats hanging over the back and front of the frames. If the plants are frozen they require no air nor attention of any kind; they are at rest, let them rest; they are as safe in the frames as under a thick mantle of snow in their native Alps. We do not always have frost in January in this uncertain climate, and if the weather is mild surface dressing may be seen to, but after the plants have been surface-dressed, I do not care to allow them to be frozen hard. I place them in the Auricula-house, where the temperature is not allowed to fall more than 2° or 3° below the freezing-point. As soon as they are surfaced-dressed and frost is practically excluded growth commences, and the centre gradually unfolds, the heavily mealed varieties, pure white; the green-leaved varieties of richest emerald colour, with many shades of grey between the green and densest white. One remark I may make, and that is, that the green-edged Auriculas always have green foliage.

TOP-DRESSING.

This operation is performed for the purpose of renewing the soil, but to do this we need not dig half-way down the sides of the flower-pots, smashing and bruising the best roots. The Auricula plants are on the bench ready to be attended to, and even without turning the plants out of the pots, the practised eye of the florist can tell if the drainage is free. In many instances it is choked up, sometimes owing to worms or inefficient crocking. In that case the plant should be turned out and all the old drainage material cleared away. Clean, well-drained pots should be made ready, with some fibrous loam over the drainage. Clear a little of the soil from the base of the ball of roots and some from the top; this can be done without bruising any of the roots. The plants should then be returned to the clean pot, the base of the ball resting on the fibrous loam. Space enough should be left at the surface to allow of the top-dressing, which should be of good loam and decayed stable-manure in equal portions. Press the soil down firmly. This treatment in January is far better than the usual practice of top-dressing. During this operation in January and February all offsets having any roots attached to them should be removed and planted in small flower-pots, using sandy soil.

Any nice sturdy plants in small flower-pots, that show by the appearance of the crowns that they may produce good flower-trusses, should be repotted. There is considerable difference of opinion as to the best material to use for potting Auriculas. The best amateur grower in the South, Mr. T. E. Henwood, has come to the conclusion that good fibrous loam with nothing added is the best. The Rev. Francis D. Horner, the best of the Northern growers, recommended "one-part unctuous loam, one-part leaf-mould, and two-parts decayed sheep or cow manure mellowed under shelter." At the time this was written, Mr. Horner was growing Auriculas which excited the wonder of the best fanciers. I believe he does not now use quite such a rich compost. For my own part I have been most successful when I have used the following:—Three parts good fibrous decayed loam, one part leaf-mould, and one part decayed stable manure.

At the time of repotting or surface-dressing, see that all examples of the Auricula-aphis (Trama Auriculæ) are removed from the roots, and especially any that may be clustering around the necks of the plants. This pest favours any open parts where there is fibre, and especially over the drainage; and dryness suits our very troublesome insect better than wet. It is very quiet in winter, but increases at an alarming rate in hot weather. The fanciers were dreadfully frightened when it first made its appearance. I know one at least who thought his plants were ruined. My good friend, Mr. Ben Simonite, first sent it to me, and not knowing it was on the plants, it made a good start before I found it out. After thirty years' experience we now find that if it is cleared away from the roots at the annual repotting it does no harm to the Auricula. The ordinary fumigations of tobacco-paper do not trouble it much, although they may be strong enough to kill green-fly; but if any of it is above the surface of the ground Richards' XL-All vaporiser will kill it after two or three fumigations. It is certainly very tenacious of life, protected as it is to a great extent by its fluffy white covering which throws off water and doubtless helps to protect it from strong fumigations that kill green-fly instantly.

We may have a fine display of Auriculas from early in April until the end of May by a little attention to placing those that flower early in the warmest part of the Auricula-house, and the later-flowering varieties in frames on the north side of a dwelling-house. There is a saying amongst the Northern growers "that the Auricula in May has had its day." Probably the third week in April is the time to see the bloom at its highest point of perfection. The exhibition of the Southern section of the National Auricula Society will be held on April 25 next in the new Hall of the Royal Horticultural Society in Vincent Square, and this will be followed by another Auricula show a few days later at Birmingham, and another later still in Manchester. Many gardeners look down upon the Auricula as a flower not worth their attention. We need not travel far to find a reason for this. Gardeners require plants that will produce flowers to cut for room decoration, and Auriculas are not well adapted for this purpose; moreover, they require attention.

It was well said by the late Dean Hole that he who would grow Roses well must have Roses in his heart; but this remark applies even more to the Auricula. Rose shows are a modern invention, whereas Auricula shows have been held without a break for more than a hundred years—how much longer I am unable to say. The present-day amateurs are still continuing the work handed down to them by the florists of long ago, and under more favourable conditions. In these days the exhibitions are held under the auspices of the Royal Horticultural Society of England. In the old days the amateurs carried their flowers to a room set apart in some convenient public-house, and the merits of the flowers were discussed and the prizes awarded, while the members smoked their long clay pipes and drank the home-brewed ale. It was not a good setting for the lovely flower, and we are thankful that it can now be admired in better surroundings, and in the presence of a different, if not a more appreciative, company. In the *Florists', Fruitists', and Garden Miscellany* for 1851 there is a wood-cut of one of these meetings, entitled, "Meeting of Florists in the Olden Time." The design is worthy of George Cruickshank. The florists are all elderly men dressed in the costume of the seventeenth century. There is the old fireplace, and the massive table set out with Auriculas. The President and three other members, smoking their long clay pipes, are still discussing the points of the flowers; but the waiter is bringing in a large bowl of steaming punch, and the decision cannot be long delayed. It is a picture of old times well worth study. "Old times are changed, old manners gone"; but the Auricula is yet with us, and we hope to make a great show in the new Hall on April 25, 1905. *Jas. Douglas.*

The Week's Work.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Winter-flowering Carnations.—If strong cuttings of the varieties America and Mrs. S. J. Brooks are procurable, a batch propagated now will make strong plants for flowering in autumn and winter. I do not advocate the general propagation of Carnations until somewhat later for two reasons. First, because the stock plants at this time of the year are usually very drawn and weakly, and secondly, many of the varieties do not flower freely or satisfactorily until well into the new year. Of several varieties grown here the two named above are always good and reliable, the distinct shades of colour adding greatly to their usefulness as companions to each other. Let the cuttings be inserted in thumb-pots only, which should be well drained previously, and filled firmly with finely-sifted old potting soil, covering this with a layer of silver sand. Insert three cuttings in each pot, care being taken that the heel of the cutting rests firmly at the bottom of the hole made by a small dibber. The cuttings or slips should be carefully detached from the stock plants by the thumb and finger, and should require no trimming with a knife. If the cuttings are placed in a stove propagating case, a large percentage generally damp off. I have been very successful with a temporary arrangement as follows:—Place hand-frames on the water-pipes in a closed vinery or Peach-house where a minimum temperature of 55° is maintained. Put in this frame, to the depth of 3 inches, some Cocoanut-fibre or finely-sifted ashes, and into this material plunge the pots containing the cuttings. One watering should be sufficient until the cuttings are rooted. Cover the frame with a sheet of glass, and remove the glass each morning for a little while, to allow the moisture to escape. The heat from the pipes necessary to maintain the temperature of the house will afford the required bottom-heat and a suitable temperature above.

Propagating.—If cocoa-nut fibre is used for propagating purposes it is advisable to replace the old fibre each year with fresh material before the season's work commences. Where, from motives of economy or otherwise, this cannot be done, the old fibre should be heated in an old pail or some other vessel over a fire in order to thoroughly sterilise it and destroy any insects that may be present. Thoroughly cleanse the propagating-frames with a mixture of paraffin and soapsuds, afterwards allowing them to remain in the open for a few days.

Cyclamen. — Seedlings from seed sown last August that are not already potted off should be shifted without delay into well-cleansed and well-drained thumb-pots. A suitable soil will be loam and leaf-mould in equal parts, with a liberal proportion of silver sand, the whole broken small and passed through a fine sieve. Stand the pots on a shelf in a warm, moist atmosphere, as near to the light as possible. An occasional syringing with clear water will be beneficial to the plants.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Melons.—Melon fruits are often more appreciated at the end of April or beginning of May than later, because other soft fruits are less plentiful. Sow seeds of some strong-growing and quick-maturing variety, remembering that varieties having scarlet flesh generally ripen earliest. Instead of sowing the seeds and plunging the pots in a bottom-heat of 80°, I prefer to sow them direct into 12-inch pots, or on the bed. These two latter methods I have found produce the strongest plants. The beds should be made close to the glass, and be composed of good loam of medium texture, wood-ashes, and lime-rubble, which should be made firm. As Melon seeds are plentiful, two or three seeds may be sown in each pot, and the weakest plants removed afterwards. A steady bottom-heat of about 80°, and a temperature at night of 65° to 68°, with a moist atmosphere during day, will be suitable.

Winter Cucumbers.—A good supply of fruit is easily secured throughout December, but much skill and attention will be required to maintain a constant supply of these fruits during the first three months of the year. Plants that have been in bearing for some time should be top-dressed, whenever the roots appear on the surface, with a compost of rich, light loam, to which a small quantity of Thomson's Vine Manure has been added. Occasional waterings should also be given of clear, weak liquid-manure, at the same temperature as the soil in which the plants are growing. The plants should be trained thinly, cropped lightly, and encouraged to make free growth. In order to maintain a succession of fruits, seeds should be sown immediately in 3-inch pots; these should be plunged in a bottom-heat of 80°, and when the seedlings are well through the soil place them near to the glass in a temperature of 68°. Prepare for the reception of these plants by thoroughly cleansing the structure intended for them, and by the preparation of fresh beds intended for their planting. These beds should be as near to the glass as possible, and should be constructed of a mixture of two parts leaves to one of stable-litter on which is placed a moderate quantity of rich soil at intervals of about 4 feet. If young plants are not in readiness for planting, sow a couple of seeds in each mound. These will germinate quickly and grow strongly. Maintain a bottom heat of 80° with a night temperature of 68°. A generally humid atmosphere should be maintained by frequently damping the paths and beds.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage,

Hot Beds.—Where plenty of leaves and stable litter is obtainable, six parts of the former to one of the latter will be found suitable and sufficient to hold the leaves together. The material should be well mixed together and afterwards made firm. The bed should be from 4 to 5 feet in depth, which will be sufficient to produce abundance of heat for a long period. It is much the best plan to sink the beds by excavating the soil to a suitable depth and filling in with the heating material, because if the beds are exposed to cold winds through being raised much of the heat is wasted. When the portable frames are in position it will depend upon the nature of the crops what soil medium should be used; for such plants as Asparagus and Seakale just sufficient leaf-soil for plunging will be all that is necessary. Old potting soil, well screened, will be found admirable for carrots of the stump-rooted varieties, such as Sutton's Inimitable or Persian Horn; while for Potatos a compost of half loam and half leaf-soil, previously prepared, and fairly rough in texture, will be excellent for growing such varieties as Early Improved Ashleaf (unsurpassed for quality) and Sharpe's Victor. Strict attention must be paid to protecting the frames by suitable coverings, according to the state of the weather and degree of tenderness of crop. Trays of seed Potatos intended for successional crops should be placed in newly-started Peach-houses or vineries, where they will commence to sprout.

Broad Beans.—Little difficulty should be experienced in obtaining an early supply of these vegetables if such varieties as Veitch's Improved Long Pod, Green Windsor, or Beck's Dwarf Green Gem, be given the same treatment as previously advised for early Peas. For forcing these vegetables under glass place four or five seeds in a 7-inch pot, while for early crops in the open sow in small pots or boxes, and place in cold frames for planting-out in March. We have just finished planting a breadth of the first-named variety on a south border in the open, the rows being 2 feet apart, and the seeds placed in a zig-zag manner 3 or 4 inches distant, and about 3 inches below the soil.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant, Oxon.

Cordon-trained Wall Trees of Apples, Pears, Plums, and Cherries, when they receive proper cultural treatment, give excellent returns, both in regard to the quality and quantity of their fruit, and many of the finest exhibition specimens of these fruits are grown on cordon trees, which are equally adapted for growing in large or small gardens. If the work of pinching the shoots in summer was duly carried out in accordance with instructions given at the time, all that will be necessary now is to shorten the strongest shoots back to within three buds. In cases where the fruiting-spurs are too abundant these should be thinned, but it must be remembered that too severe practice in shortening these spurs, especially in the case of Plums, will often cause the spur to die completely. If it is desired to extend the leading shoot, it should be shortened to within 18 inches. Some varieties of Pears produce their fruit-buds on the ends of the shoots; the longest of these growths may be removed without fear of losing the crop. Where a considerable length of wall is available for planting, an oblique system of training will be found best, and the lower the wall the more obliquely should the tree be trained. In most cases an angle of 45° will be found suitable. The sap is much more equally distributed when the tree is thus trained, and a lot of useless growth at the extremity of the tree is avoided. Cordon trees may also be grown on wall buttresses.

Cordon Gooseberry and Currant-trees trained on north walls are valuable for producing late crops of these fruits, and for continuing the supply very late in the year. These should now be "spurred" back, but do not leave on the Gooseberry plants too many spurs. Such varieties as Bobby, London, Shiner, Leveller, Ringer, Surprise, Blucher, &c., will produce excellent fruits grown on this plan.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossums.—Plants of O. crispum now in various stages of development should be given generous treatment until the flower-spikes are well advanced, when slightly drier conditions at the roots should be observed. Weak plants, especially of the choicer varieties, should not be allowed to flower, while small newly-imported plants should only be allowed to develop two flower-buds, these being left in order to ascertain the variety. Plants that have finished flowering should be thoroughly rested by keeping them well on the dry side until new growth commences. Any plants that were not potted in the autumn, and which are now growing, may be re-surfaced or repotted as their needs demand. When preparing these plants for potting, remove most of the leafless pseudo-bulbs, so that large pots will not be required. Any pieces of valuable varieties thus removed should be placed on damp moss, with the object of propagating them, and thus obtaining duplicates of the varieties. For general purposes of propagation this method is not to be commended, the surest and quickest plan being to sever the rhizome between the two last pseudo-bulbs developed. This should be performed soon after the plant has flowered, when probably new growths will develop from both these pseudo-bulbs, and when the growths are an inch or two in length the division should be completed, and the pieces potted separately. This is the only reliable means of duplicating plants of varieties of Odontoglossums. O. Pescatorei needs much light and rather less water at the roots when the plants are nearing the flowering stage, otherwise the plants are liable to commence growing without producing their flower-spikes. O. Hallii, O. luteo-purpureum, O. sceptrum, and others of this section, should be staged at the warmer end of the cool-house, placing such members as O. triumphans, O. tripudians, O. Harryanum, O. polyxanthum, and the forms of O. crispum, in an intermediate position; while to plants of the Mexican section, such as O. Rossii, O. Cervantesii, O. nebulosum, O. maculatum, and O. cordatum, should be allotted the cooler end of the structure. The natural hybrids, such as O. excellens, O. Adrianæ, O. loochristiense, O. Wilckeanum, &c., together with the home-raised hybrids, O. Harryano-crispum, O. Rolfeæ, O. ardentissimum, O. bellatulum, &c., should be placed in a favourable position at the warmer end of the house, as their requirements coincide with those of O. crispum. O. cirrhosum and O. elegans need rather more heat than the cool-house usually affords. When these plants are approaching the flowering stage the application of water must be somewhat restricted, or growth will ensue instead of the production of flowering-spikes. O. hastilabium is another species that needs more favourable conditions with regard to heat and light. This species suffers from prolonged flowering, and should signs of weakening appear, remove the flower-spikes at once, and keep the plants dry for a period. The application of air to the cool-house at every available opportunity cannot be too strongly urged, both roof and wall ventilators should be used in mild weather, but when cold winds prevail restrict the ventilation to the lower openings. Whenever the outside thermometer does not indicate a temperature below 38°, a little bottom air should be permitted at night-time.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Creepers on Walls.—If it is intended to plant these, fix the necessary wires and prepare the borders for their reception. Established creepers that require pruning and tying should be seen to, taking care to make the cuts at an obtuse angle, and to place the tie neatly. Train the growth so that the wall can be discerned, as it adds to the effect if the creepers give a "traceried" appearance. Tender plants on walls, such as Ceanothus Gloire de Versailles, Ceres, and Indigo; Smilax asperrima, Magnolia grandiflora, Abelia rupestris, &c., must be protected from frost. In addition to well-known varieties of creepers, the following kinds are also good: Vitis Coignetiæ, this requires plenty of room, such as a sheltered gable—the colouring of its foliage is most brilliant in autumn; Buddleia variabilis Veitchiana—this is a marked improvement on the type; Indigofera Gerardiana—this plant flowers profusely; Elæagnus aureo-pictus, Schizophragma hydrangeoides, Jasminum revolutum, Garrya elliptica, and Lardizabala biternata. The following plants, being strong growers, are suitable for covering rough places or trees:—Polygonum Baldschuanicum, Lycium sinense, and Periploca græca. Clematis of the Jackmanni type should be cut back, leaving a few feet of last season's growth.

Preparation for Seed-sowing.—As seed-time is approaching have pans, boxes, and suitable soil put in readiness in order that sowing can be done without delay. The compost should be got ready and placed under cover, and should consist of sifted friable loam, leaf-mould and sand thoroughly mixed together and passed through a ½-inch sieve. Place suitable material for drainage in the pans, covering the drainage with some of the rougher soil. Make the soil in the seed-pans moderately firm, filling them to within 1 inch of the top. Sift a small layer of the compost through a ¼-inch sieve into the seed-pan, make the surface level, and then sow the seed. Label the pans carefully, and next cover the seed with some soil, using the ¼-inch sieve again. Make the surface firm, using a piece of board for the purpose. Water with a fine rose, or if the seed is very fine dip the pans for a few minutes in the tank. Shade till germination takes place. Fine, small seeds should be sown on the surface of the soil and not covered.

EDITORIAL NOTICES.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JAN. 24 { Roy. Hort. Soc. Coms. Meet. / Nat. Rose Soc. Com. Meet.

FRIDAY, JAN. 27—Roy. Bot. Soc. Meet.

SALES FOR THE WEEK.

MONDAY, JANUARY 23—
Greenhouse Plants, Gladioli, Border Plants, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY, JANUARY 24—
Important Unreserved sale of Nursery Stock, at The Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris, at 11. (Three days).

WEDNESDAY, JANUARY 25—
Azaleas and Palms from Belgium; Roses, Begonias, &c., at Protheroe & Morris's rooms, at 12.—Enormous consignment of 2,292 cases of Japanese Liliums, 1,800 Pæonies, Tuberoses, Lily of the Valley, &c., at 3 o'clock, by Protheroe & Morris.—Palms, Azaleas, Roses, Lilies, &c., at Stevens' Rooms, 38, King Street, Covent Garden, at 12.30

FRIDAY, JANUARY 27—
Flowering Shrubs, Spiræas, Roses, &c., at Protheroe & Morris's Rooms, at 12.—Imported and Established Orchids, at Protheroe & Morris's Rooms, at 12.30.

(*For further particulars see our Advertisement columns*)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —38·4°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 18 (6 P.M.): Max. 42°; Min. 34°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 19 (10 A.M.): Bar., 30·3; Temp., 37°. Weather—foggy.
PROVINCES.—*Wednesday, Jan.* 18 (6 P.M.): Max. 43°, Cornwall; Min. 24°, N.E. of Scotland.

Mites. A GROUP of insects which includes such pests as the itch-mite, the sheep-scab, the Currant-bud-mite, the red-spider, the bulb-mite, and others, has a painful interest for many, and a special interest for gardeners. Many of the insects justify their name by their extreme minuteness, and they escape observation not only from this cause, but from the fact that having done all the mischief of which they are capable, they migrate elsewhere, so that when the microscopist turns his lens on the galls or other excrescences which result from their puncture, no mites are to be seen. So difficult is the study of these creatures, and so generally unattractive are they, unless to professed specialists, that comparatively few entomologists have devoted their attention to them. Among the most indefatigable and most acute investigators of the Acarina is our valued correspondent, Mr. ALBERT MICHAEL, to whom we are under great obligations for information on these creatures, and whose works, published by the Ray Society in 1883, 1887, 1901, and 1903, are standard works on the subject on which they treat. A summary of Mr. MICHAEL's observations, together with those of other investigators, is contained in a pamphlet which is published separately, having originally been issued in the *Proceedings of the United States National Museum*, vol. xxviii. (1904). This is entitled a monograph of the Acarina or mites, and is prepared by Mr. NATHAN BANKS. It is full of anatomical details, which appeal mainly to entomologists, but many of the creatures concern gardeners, as anyone who has to deal with red spider knows. Mr. BANKS tells us that flowers of-sulphur, applied either as a dry powder or as a spray, is the best remedy. Campbell's fumigator, we may add, is well spoken of in this connection. Bisulphide of lime and tobacco water may also be used advantageously.

Ticks are not only directly injurious to the animals on which they feed, but many of them are subject to parasites which when conveyed into the blood cause fevers and other diseases. For ticks which affect poultry, the author recommends that the hen-house be washed out with kerosene, benzine, or gasoline, or the house be white-washed with carbolated lime; a mixture of kerosene and sulphur plastered upon the roosts is also very useful.

The bulb-mite, Rhizoglyphus hyacinthi, is responsible for an enormous amount of damage. It burrows into healthy tissue, thereby giving entrance to destructive fungi and bacteria. The best way, says our author, is to burn the affected bulbs as soon as the mite is discovered; but on this side of the Atlantic less drastic measures are sometimes successful. Some growers, Mr. BANKS tells us, secure good results by the following treatment:—"The soil of infested plants is allowed to become dry, then the bulbs are taken out and washed in tobacco-water and soft-soap, with a small amount of washing soda. Then they are sprinkled with freshly-slaked lime and left for two days. Then they are washed with the same solution as before, to which a little petroleum has been added. They are then repotted, and often do well."

The itch-mite, Sarcoptes, is another of this family whose presence is not regarded with complacency. Cleanliness and the application of sulphur ointment are the well-tried remedies. Sheep-scab is another most unwelcome visitor—he may be ousted by tobacco-water and sulphur used warm. Another group too well known to the gardener—at least so far as the mischief done by the species is concerned—is the Eriophyidæ, better known as Phytoptidæ. The creatures are readily overlooked, so minute are they, and hence some of the hairy or scaly excrescences on the leaves caused by these mites were once considered to be fungi, and named Erineum. When the hairs attract notice the mites have disappeared, another reason why the botanists have been misled. The Pear-leaf blister is very common in this country, and is due to the puncture of a mite, Eriophyes (Phytoptus) pyri. The insects pass the winter in the buds, and begin to feed before the leaves are unrolled. They form red blister-like spots nearly a fourth of an inch across. These spots become green by June and then turn brown, and the tissue becomes hard and corky. The spots often coalesce and form large blotches. Professor SLINGERLAND has shown that they can be practically exterminated by spraying the trees in winter with kerosene emulsion diluted with from five to seven parts of water. The Black Currant Gall-mite, Eriophyes ribis, penetrates the buds, causing them to swell, and badly infested buds die before opening. The mites breed throughout the year. They migrate in the spring when the buds are opening, and may be destroyed at this time by a wash of soft-soap and sulphur. It has been observed that this species can stand upright and even jump into the air and be carried some distance by the wind. In this country attempts to destroy the mite have not been attempted with much success. Mr. BANKS is to be congratulated on his work, and the thanks of the community are due to the authorities of the Smithsonian Institute and of the United States National Museum.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue represents a view in the conservatory at Upton Grove, Tetbury, the residence of C. HARDING, Esq. A conservatory is very pleasing at this dull season of the year, when well furnished with flowering subjects such as those depicted in our illustration, including Cinerarias, Primulas, Richardias, Begonia Gloire de Lorraine, &c. How trying the effects of such fogs as we have recently experienced are to those having the charge of plants under glass is only too painfully evident when one passes through such structures as these after a dense fog. To see one's plants, which have entailed months of skilful culture, ruined by the sudden descent of such climatic conditions is discouraging. A gardener's life, however, with all its disappointments, has its compensating joys.

THE GARDENERS' ORPHAN FUND.—Subscribers to this Fund will be glad to hear that Mr. GEORGE SMITH, who was one of the first to enjoy the benefits of this Society, has successfully passed the examination of the Sanitary Institute, a circumstance which leads us to hope that, thanks to the aid afforded in his earlier years, the foundations of his future success are securely laid.

THE CONGRESS OF THE FRENCH SOCIETY OF "CHRYSANTHEMISTS" will be held in Paris in the autumn of 1905, at Caen in 1906, and at Toulouse in 1907.

FLOWERS IN SEASON.—From Messrs. JAMES SMITH & SONS, Darley Dale, we have received excellently flowered examples of a new variety of the Mediterranean Heath, a plant well known to travellers in districts bordering the Mediterranean. Messrs. SMITH state: "We are sending you sample blooms of Erica mediterranea hybrida, which was raised in these nurseries some years ago. It is quite distinct from E. herbacea carnea, as each shoot is tipped with white during the summer. The plants have been in flower since the beginning of December, growing at an altitude of 600 feet above the sea-level. They succeed best in dry, brown, loamy soil. It is a valuable acquisition to the variety of hardy Heaths."

BULB SOCIETY OF HAARLEM.—The quinquennial exhibition of the Royal Bulb Growers' Society of Holland will, as we have already announced, be held at Haarlem from March 17 to 21 next. The exhibition it is expected will be large and interesting, and though mainly national in its objects, English and other foreign judges will be asked to adjudicate upon the exhibits, and will meet with a cordial reception.

EDINBURGH EXHIBITION.—At the Grand International Show to be held at Edinburgh on September 13, 14 and 15, 1905, Messrs. WILLIAM BULL & SONS are offering, through the Royal Caledonian Horticultural Society, special prizes, including a Silver Cup value ten guineas and £5 in cash, for new plants sent out by the firm of WILLIAM BULL & SONS.

BRITISH GARDENERS' ASSOCIATION.—Nearly one hundred gardeners of Reigate, Redhill and district assembled at Redhill on Tuesday, the 10th inst., to hear an address delivered by Mr. WATSON, of Kew, on behalf of the British Gardeners' Association. The meeting was enthusiastically in favour of the project, only one gardener present offering any opposition, whilst a resolution to form a branch of the Association in that district was adopted almost unanimously. Mr. SEAMAN, head gardener at Margery Hall, Reigate, was elected local Secretary of the Society.

—— On Friday the 13th inst., a meeting was held in the Free Library at Swansea to hear addresses by Mr. W. W. PETTIGREW, of Cardiff, and Mr. R. HOOPER PEARSON, London. An ex-Mayor of Swansea presided, and, in spite of the inclement weather, there were upwards of fifty gardeners and nurserymen present. It was unanimously decided to establish a local branch of the British Gardeners' Association. Mr. D. BLISS, Superintendent of the Public Parks at Swansea, was appointed to be the local Secretary, and he at once started with a list of twenty or more candidates.

A TRIP TO PARIS.—On Saturday last a party of gardeners from Evesham and the district started for Paris, where they intend to study the methods of French gardeners, with particular reference to the forcing of Lettuce and other outdoor vegetables. For years it has been a matter of surprise that glass is not more utilised in the Vale of Evesham, and it is hoped that this practical demonstration of what can be done by a comparatively small outlay will have the effect of inducing local growers to adopt this system of culture. About thirty prominent growers were included in the party.

—— One of the French gardening papers—we will not mention its name—begs its readers to receive the English visitors with every courtesy "at the gate," but not to tell their "hereditary enemies" anything beyond what all the world knows. This looks very much as if our contemporary is not anxious that the visitors should proceed beyond the gate. Happily for us, our own experience shows that French gardeners as a rule are most desirous to be of assistance to their visitors, and do not treat them as enemies.

MANURES FOR CHRYSANTHEMUMS. — M. GEORGE TRUFFAUT's researches show that while there are differences in constitution as regards varieties, yet as a whole it may be said that if it is desired to grow dwarf, robust plants with firm, regularly-distributed foliage and brightly-coloured flowers, the following facts must be borne in mind:—Phosphoric acid assists in the formation of woody tissue and chlorophyll, hastens the production of flowers, and specially heightens the brilliancy of their colours. Without potash the leaves are flaccid, the stems hollow, the flowers of bad shape, and their development retarded. Excess of nitrogenous manure is singularly injurious to the Chrysanthemum. Details of M. TRUFFAUT's investigations are given in the *Chrysanthème*.

THE RAINFALL IN 1904.—In last week's issue detailed information was given respecting the amount of rainfall at Rothamsted during the past year. The particulars from Rothamsted are specially interesting, because the gauge there is much larger, and offers better facilities for accurate observations than those possessed in most gardens. Our valued correspondent, Mr. MAWLEY, has also kept our readers fully informed concerning the rainfall and state of weather generally in West Hertfordshire, and these have been supplemented by the returns from the Royal Horticultural Society's gardens at Wisley, in Surrey. Several correspondents have also kindly furnished us with information of the amount of rainfall registered in private gardens, and though our space will not permit of these being given in detail, we have pleasure in appending the totals. Mr. H. PARR, Trent Park Gardens, New Barnet, registered 23¼ inches; Mr. A. H. HALL, Bostock Hall Gardens, Middlewich, Cheshire, 24·79 inches; Mr. FRANK J. CLARK, Wistow Hall Gardens, Leicestershire, 19·81 inches, being 4 inches below the average for the past sixty-two years; Mr. J. B. LOWE, D'Abernon Chase Gardens, Leatherhead, Surrey, 24·68 inches, as against 42·47 inches in 1903; and Mr. NEIL SINCLAIR, Hampton Manor, Warwickshire, 22·57 inches, being 10·50 inches less than that for 1903. The highest temperature during the year at Hampton Manor was 86° (shade), on August 3, and the lowest 7° on November 23. The greatest degree of sun-heat was 132°, on August 3. Mr. W. W. PETTIGREW, Roath Public Park, Cardiff, 42·28 rain in 1904, as compared with 56·37 in 1903.

HYBRIDISATION OF PINEAPPLES.—The following extract on this subject is taken from the Annual Report on the Public Gardens and Plantations, Jamaica, for the year ended March 31, 1904:—"With a view of raising a variety of Pine that would combine the fine appearance and shipping qualities of the Smooth Cayenne with the delicious flavour of the Ripley, experiments in hybridisation were instituted in the year 1901. As a result of the initial experiment, sixty-four plants were raised and planted out. The Ripley flowers were cross-fertilised between April 25 and May 20, 1901, and the fruits ripened in the middle of July; the seeds were sown in clean sand the first week in August, the seedlings potted into Bamboo pots early in September, 1901, and planted out at a distance of 2 feet apart in August, 1902. Several of the plants very quickly took the lead and grew vigorously, whilst a number of them exhibit a very feeble constitution: all differ from each other in appearance—some are spineless like the male parent, and some are spiny like the Ripley. The first fruit was cut on November 18, 1903, and was fairly good; the second one was stolen—it resembled very closely the 'Red Spanish.' The third to ripen was a curiosity, a rather poor 'Cayenne,' devoid of top. Others are now developing fruits. During 1901 preparations were made for extending this important work, and in the following year, 1902, Cayenne, Ripley, and Queen were brought into flower at the same time to permit of crossing and intercrossing, resulting in the following being raised:—

Ripley × Cayenne	900	seedlings.
Cayenne × Ripley	800	,,
Queen × Cayenne	100	,,
Queen × Ripley	25	,,
Ripley × Queen	120	,,
Fertilised by natural means ...	250	,,
Total	2,195	,,

These have been planted out at a distance of 9 inches apart in nursery beds, to be grown on to the sucker size and treated as such when large enough, e.g., dug up, trimmed, and planted out in 'field' beds. The third batch, numbering 500, raised in 1903, is now being nursed in 3-inch pots in the glass-house."

SKIN IRRITATION.—The inflammation of the skin caused by incautious handling of Rhus Toxicodendron is well known. A similar effect is produced by Primula obconica. The record of these facts has induced Mr. MAIDEN to search for other cases of a similar kind. Omitting such plants as the Nettles, Mr. MAIDEN enumerates Phlebatium argenteum (Rutaceæ), Dysoxylon Richii and D. Muelleri (Meliaceæ), Rhus radicans, diversiloba, and vernix (Anacardiaceæ); Castanospermum australe (Leguminosæ), Eucalyptus maculata, E. hemiphloia (Myrtaceæ), Cassinia aculeata, Pyrethrum Parthenium (Compositæ), Primula obconica, P. sinensis (Primulaceæ), Excæcaria Agallocha, E. parviflora (Euphorbiaceæ) Thuya Douglasi, Carrière [We are not able to identify this name. Carrière does not mention it, and we are left in doubt as to whether the plant intended be Thuya plicata = gigantea, which seems the more probable, or Pseudotsuga Douglasi]; Hyacinthus orientalis, Richardia æthiopica. No doubt the list could be widely extended; but it would be desirable to distinguish between those that act merely as mechanical irritants, like the hairs of Mucuna or the raphides of bulbs, and those that introduce some actually poisonous matter into the blood.

NATIONAL FRUIT-GROWERS' FEDERATION.—The meeting of the Council took place on Monday, January 16, in the new Hall of the Royal Horticultural Society in Vincent Square, Westminster. Mr. F. S. W. CORNWALLIS presided, supported by Col. C. W. LONG, M.P., President-Elect. Mr. WAGHORN, barrister-at-law, kindly attended, and had a long conference with the growers present on the subject of Preferential Railway Rates, and treatment of home-grown fruit in transit compared with that imported from abroad. The discussion was of a most important and interesting character, and when concluded the Council of the Federation appointed Mr. MISKIN to represent them officially as a witness before the Departmental Committee now sitting to enquire into the above question. The new Railway Services Committee, consisting of seven members, was then definitely appointed. The Finance Committee presented their Report, which showed a considerable improvement in the position of the Federation during the past year. After the rising of the Council the new Railway Committee held a preliminary meeting.

REDOUTÉ'S WORKS.—In the current number of the *Journal of Botany* is an important note relating to the date of publication of the several parts of Redouté's *Liliaceæ*, and of the same author's *Les Roses*, and *Choix des plus belles Fleurs*. Like the similar bibliographical note relating to the *Pinetum Britannicum*, published in our columns, this note is the work of Mr. B. B. WOODWARD, to whom the thanks of students are specially due.

THE CYPRESS-PINES OF NEW SOUTH WALES.—Mr. MAIDEN, in the *Forest Flora of New South Wales*, vol. ii., part 2, has an interesting chapter on the Australian species of Callitris. They vary greatly, so that field-knowledge is indispensable to a proper understanding of the genus. The trees are beautiful and very fragrant, yielding useful timber of showy appearance. The resin called sandarac is obtained from these trees, but at present little use is made of it in Australia. "There is nothing," says Mr. MAIDEN, "more delightful than the approach on a winter evening to a township where Cypress-Pine is used as a fuel. Its delicious perfume is borne on the air for miles, and is often the first intimation that the weary traveller experiences that he is approaching a human habitation, and that his long journey is drawing to a close." Eight species, natives of New South Wales, are described and figured by Mr. MAIDEN, viz., columellaris, Macleayana, verrucosa, robusta, Muelleri, propinqua, calcarata, and cupressiformis. There are thirteen species in all, for the Algerian plant, to our thinking, is no Callitris, but a Tetraclinis; though, according to Dr. T. A. HENRY, the resin is identical in composition to that of the Australian species. The African Widdringtonias are also nearly allied to but distinct from the true Callitris. With the usual perversity of popular names, these trees are not Cypresses, and are still more widely separate from Pines.

FLORAS OF INDIA.—The recent announcement of the undertaking of a Flora of the Punjab by Mr. DRUMMOND of the Indian Civil Service is another step towards completion of the botanical survey of the country. Of existing works on the botany of India the most important, of course, is Sir JOSEPH HOOKER's *Flora of British*

India. For Western India there is a Flora under preparation at Kew by Dr. THEODORE COOKE, late Principal of the College of Science at Poona. In Bengal we have Major PRAIN's *Bengal Plants* in addition to that valuable publication the Annals of the Royal Botanic Garden and the Records of the Botanical Survey of India. For Upper India there is Mr. DUTHIE's *Flora of the Upper Gangetic Plain*, the first volume of which has been lately published. The author is now busy with the subsequent volumes at Kew. In Southern India much valuable botanical work is being accomplished by Mr. C. A. BARBER, the Government Botanist there, and our knowledge of the resources of that part of the country in this respect is steadily expanding. Thanks to a complete organisation presided over by Major Prain as Director of the Botanical Survey of India, the general progress in Botany is as satisfactory as that in Agriculture, and further advancement is undoubtedly "the order of the day." *Indian Planting and Gardening*.

DONATIONS TO GARDENING CHARITIES.—The Altrincham and District Gardeners' Improvement Society has been enabled, by means of concerts promoted by it during 1904, to forward sums of £31 10*s*. to the Gardeners' Royal Benevolent Institution, and of £15 to the Royal Gardeners' Orphan Fund. This is worthy of imitation by similar gardening societies. Two pounds in addition were granted to purposes of local charity.

"THE RATEPAYER'S GUIDE."—We can best describe the scope of this pamphlet by quoting from its sub-title, which states that it contains: "Notes upon the assessment of property to and appeals against the poor rate. Machinery, hypothetical tenant, unoccupied property, caretakers, new houses, residences, public-houses, brickfields, mines, advertising stations, tithe rent-charge, woods, sporting rights, agricultural land, small tenements and compounding forms, and remarks as to appeals, reports of cases," are all passed in review. As the author, Mr. GODDARD, states that he has had thirty years' experience as an estate agent, surveyor and valuer, his opinions should be of value to those who need his assistance. It will be of interest to our readers if we quote the paragraph relating to the rating of woods:—"The Rating Act, 1874, defines land used for the growth of timber for a plantation or a wood, and not subject to any right of common, as rateable according to its value in its natural and unimproved state, *i.e.*, as uncultivated land without any timber upon it." The following paragraph defines the law respecting agricultural land:—"By the Agricultural Rates Act, 1896, the occupier of agricultural land is liable to pay one half only of the rate in the pound, payable in respect of building and other hereditaments. 'Agricultural land' is defined as 'any land used as arable, meadow, or pasture ground only, cottage gardens exceeding one quarter of an acre, market gardens, nursery grounds, orchards, or allotments, but does not include land occupied together with a house, as a park, gardens, other than as aforesaid, pleasure grounds, or any land kept or preserved mainly or exclusively for the purposes of sport or recreation, or land used as a racecourse.' Glasshouses in or on a market garden must be rated as buildings, and not as agricultural land." The book is published by the author at St. Stephen's Chambers, Wolverhampton.

TOUGHENED GLASS FOR GARDEN STRUCTURE.—A short time since a Bordeaux newspaper, *La Gironde*, drew attention to a new material for garden and other structures, which it termed "Verre armé"—glass-armoured iron meshwork. These remarks have been translated by Mr. MACDONALD, H.B.M. Consul at Bordeaux, and are now in the archives of the Foreign Office. A meshwork of wire of any pattern or measurement—square, oblong, octagonal, &c.,—is embedded in liquid glass, so as to form, when cooled and trimmed or polished, slabs, shelves, &c., suitable for carrying pots, &c., or for use in the ornamentation of conservatories and other structures. Severe tests give excellent results in favour of the new invention, and we think it will readily be seen that it may be made subservient to decorative purposes, based on the wirework. Nowadays the wireworker produces very artistic designs in iron, brass, nickel, copper, &c.; these, armoured or coated with glass to regulated depths, might be made to serve the double purpose of weight-carrying and ornamentation. Doubtless those concerned in horticultural architecture will see to all this.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.—The number published in December last contains coloured figures of—1, Cattleya velutina, Rchb. f.: 2, Cyripedium Orion, Sander; 3, C. Villebois Mareil, Cappe; 4, C. Manto, Rolfe; 5, Epidendrum prismatocarpum, Rchb. f.; 6, E. raniferum, Lindl.; 7, Eria clavicaulis, Wall; 8, Eulophidium Ledieni, De Wild; 9, Lycaste Skinneri var. hellemmensis, Cogniaux.; 10, Odontoglossum crispum var. Karthausi, Hort.; 11, O. armainvillierseuse var. ardentissima, Rolfe; 12, Oncidium Warcewiczii, Rchb. f.; 13, Schomburgkia undulata, Lindl. This useful little publication is edited and published by M. GOOSSENS, Avenue Walkiers, Auderghem, Brussels.

SNOWDROPS.—To see Snowdrops in flower in the open-air near London on January 15, in the midst of such weather as we have had, is sufficiently noteworthy, but when we say that the locality was the garden on the Thames Embankment the fact is more remarkable.

"AMERICAN GARDENING."—The Fruit-Grower Co., St. Joseph, Mo., announces that every subscriber whose name appeared on the books of *American Gardening*, the weekly horticultural paper formerly published at New York, will receive this month a copy of the *Fruit-Grower*, instead of the former publication. *American Gardening* will cease to be published, and arrangements have been made whereby this Company will fulfil all unexpired subscriptions to *American Gardening*. The *Fruit-Grower* is a large-sized "live" paper, which would be more attractive were the obtrusive announcements relegated to their legitimate place in the advertisement columns.

THE COLD WEATHER ON THE RIVIERA.—The Côte d'Azur is not invariably warm and sunny. A recent cold "snap" has done much damage to the flowers, and has affected prices in Covent Garden. The weather was the worst ever known on the Riviera, and the damage done to flowers is enormous. The total losses sustained by the destruction of the flowers is placed at £1°0,000 or more. Market gardeners and others declare they are crippled for the season. The scent trade will certainly suffer heavy losses, while the Orange-trees have been severely frost-bitten. The tropical garden at Monte Carlo has suffered terribly.

"THALACKER'S ADRESSBUCH UND KALENDER."—This is a very convenient little book for those who have dealings with German nurserymen, as it contains a list of the commercial firms in all the kingdoms and provinces of the Empire, together with a diary and various notes useful to gardeners. It would be improved by the addition of an alphabetical list of the names of persons as well as of places. We had some difficulty, for instance, in finding the names of Mr. SPÄTH and of Messrs. SEIDEL, of Dresden and Beyroydt. The railway map is too small to be of much service, and, owing probably to the want of space to put it on the right bank of the Elbe, Altona appears on the left side of that river. The following remarks taken from the preface will be read with interest:—"During the year 1904 [German] business transactions with foreign countries have remained about the same. That which has been gained on the one hand by a brisk export trade to England and America, and by the fostering of intercourse with Austria and other neighbouring countries, has, on the other hand, scarcely compensated for the injury to the horticultural trade caused by the Russo-Japanese war. It is undeniable that the insecure political position of Russia will have still further a disastrous influence upon our transactions, and as the ultimate results of the war cannot as yet be foreseen, it is not possible to realise how severely and permanently injured trade interests will be." The "Adressbuch" is published by BERNHARD THALACKER, Leipzig-Gohlis, and may be had from Messrs. WILLIAMS & NORGATE.

THE FRUIT INDUSTRY.—The Departmental Committee appointed by Lord ONSLOW to inquire into and report upon the fruit industry of Great Britain held sittings on the 17th and 18th inst. Evidence was taken from the following witnesses:—Col. Sir HERBERT JEKYLL, K.C.M.G., Assistant Secretary of the Board of Trade; Mr. BROOKE-HUNT, Superintending Inspector of the Board of Agriculture and Fisheries; Mr. W. CHAMBERS, and Sir THOMAS PINK.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—On Thursday last, as these pages were passing through the press, the supporters of this Institution met at Covent Garden Hotel to transact the business pertaining to the annual meeting, and to elect a number of pensioners to the Fund. In the evening the Committee and friends met at the annual friendly supper. Owing to our having to print a much larger number of copies than formerly, by reason of our increased circulation, these pages have to be sent to press earlier; but a report will be given next week.

LAWNS.—Messrs. JAMES CARTER & Co. publish a little pamphlet on the formation and management of lawns, cricket fields, putting greens, and other grassy grounds. The directions given are clear and practical.

"LE JARDIN" AND "THE GARDEN."—It is becoming customary, following in this respect the long-established practice of the *Botanical Magazine*, to dedicate the annual volumes of the gardening periodicals to certain distinguished gardeners. The last volume of *The Garden* was thus dedicated to Mr. BURBIDGE, of whom an excellent likeness was given, and its French namesake dedicates its eighteenth yearly volume to M. ALBERT TRUFFAUT, of Versailles, a gentleman held in high estimation on this side of the Channel as well as in France.

THE ROSARY.

ROSA GIGANTEA.

I SHOULD be greatly obliged to anyone who has grown this Rose for some years if he will state whether or not his plants were raised from seeds and are growing on their own roots, or whether they are worked on the Briar or some other stocks?

Mr. W. B. Hemsley, of Kew, states in the *Botanical Magazine* for September last that Mr Cant, of Colchester, was successful in flowering this beautiful Rose; the Editor of the *Gardeners' Chronicle*, in a note on p. 211, also says, Mr. Cant found it no good, and does not grow it any longer. I presume that from the description given by Mr. Cant, all who have seen the true R. gigantea will come to the conclusion that what Mr. Cant grew for Rosa gigantea was nothing of the kind. Some years before I got the true R. gigantea I bought two plants; one died, but the other flowered the second year, but it was not R. gigantea, it was a single Rose of a pinkish-white colour;

and the foliage was more like that of Rosa simplex, and much smaller than that of R. gigantea. The very fine figure of this splendid Rose, given in the *Gardeners' Chronicle* on July 6, 1889, p. 13, filled me with enthusiasm to try to flower this gem. Grow it I could, but to flower it in this country is not so easy a matter, although I believe ere long it will become one of the favourites in our Rose-gardens. I have had many conversations with travelled men, and ladies too, and they tell me we can have no conception what a grand sight this Rose presents when in flower in India and China; but, like many other plants of note that are not much grown, there are spurious ones sold. As a great traveller told me, unless this Rose is more grown there will remain a difficulty in obtaining it true, as he himself had seen several forms sold as R. gigantea.

Two years ago a nurseryman wrote me a very kind letter from Naples, asking me how to flower this Rose, as he had failed; but being ill at the time, I was unable to answer him, the letter being lost; but as he was evidently a regular reader of the *Gardeners' Chronicle*, I trust he may see now why he received no reply. Although I think this Rose would grow and flower well in and around Naples, I am given to understand Rosa sinica and its form lævigata is by many grown as R. gigantea in parts of Southern Europe; yet the two are quite distinct. *W. C. Leach, Albury Gardens, Guildford.* [At Kew this Rose has, we believe, not flowered, though it grows vigorously. The conditions in this country appear not to be favourable, though at Cannes, in Lord Brougham's garden, it has produced its splendid blooms. ED.]

KINGS WALDEN BURY PARK.

BY stopping at Hitchin station on the Great Northern Railway and proceeding about 6 miles, the visitor will arrive at the lovely residence of T. F. Harrison, Esq.

The mansion has been restored by Mr. Harrison, who has made wonderful changes everywhere and in everything. New gardens have been made, new bothies and new cottages have been built, and a splendid parish-room added and furnished, the reading-room is provided with all kinds of indoor games, from dominos to billiards. In the summer the young men have the use of a fine cricket ground provided with dressing-rooms, &c., and the whole overlooks the splendid grounds and lawns of the owner, who also joins in the games.

New walls have been built around the gardens and the choicest fruit-trees are planted against them. The glass department consists of about thirty houses, which are all modern. One lot was built by Messrs. Gray, of Chelsea, and forms a block of twelve divisions. In the greenhouses such flowering plants as Carnations, Lilies, Spiræas, Amaryllis, Primulas, and Cinerarias make a fine show early in the year.

In the stove, that beautiful Begonia, Gloire de Sceaux, is cultivated very successfully. Palms, Ferns, and Codiæums are well grown, and Asparagus Sprengeri throws sprays 10 to 12 feet long from a basket suspended from the roof. Many plants are grown for supplying flowers for cutting, such as Eucharis and Gardenias. Regal and zonal Pelargoniums are a feature. The Orchids include such useful species as Dendrobiums, Cattleyas, Oncidiums, and Cypripediums, besides others. Several houses are devoted to the forcing of Strawberries, French Beans, Tomatos, and Cucumbers.

The vineries are planted with the varieties Muscat of Alexandria, Black Hamburgh, Madresfield Court, Appley Towers, Lady Downes', and others. In the Peach-houses are well-trained trees of the best varieties of this fruit and of Nectarines. Some good ranges of pits have been erected.

A noticeable feature at these gardens is the recently-built fruit-room, which is the best that I have seen. It has two floors, an upper one for Pears, and the other for Apples; the size of each room is 30 feet by 20 feet. The structure is built on sloping ground, so that both rooms are reached from the ground-level. The walls are hollow, and double doors are provided, the inner one being of glass. A stage is erected in the centre with side stages all around. The roof is thatched with a rare thickness of reed, and is a marvel of good workmanship.

In the kitchen-garden, which has been made, hundreds of cartloads of soil have been brought from the park, as the natural soil is on gravel. A grass path runs down the centre, and on either side of this path are choice herbaceous plants and Roses. On the south wall is a good collection of Peaches and Nectarines.

Leaving the kitchen-garden the visitor crosses the road and enters the lawn, the entrance to which has been covered by an oak pergola some 70 yards long, which has been planted with

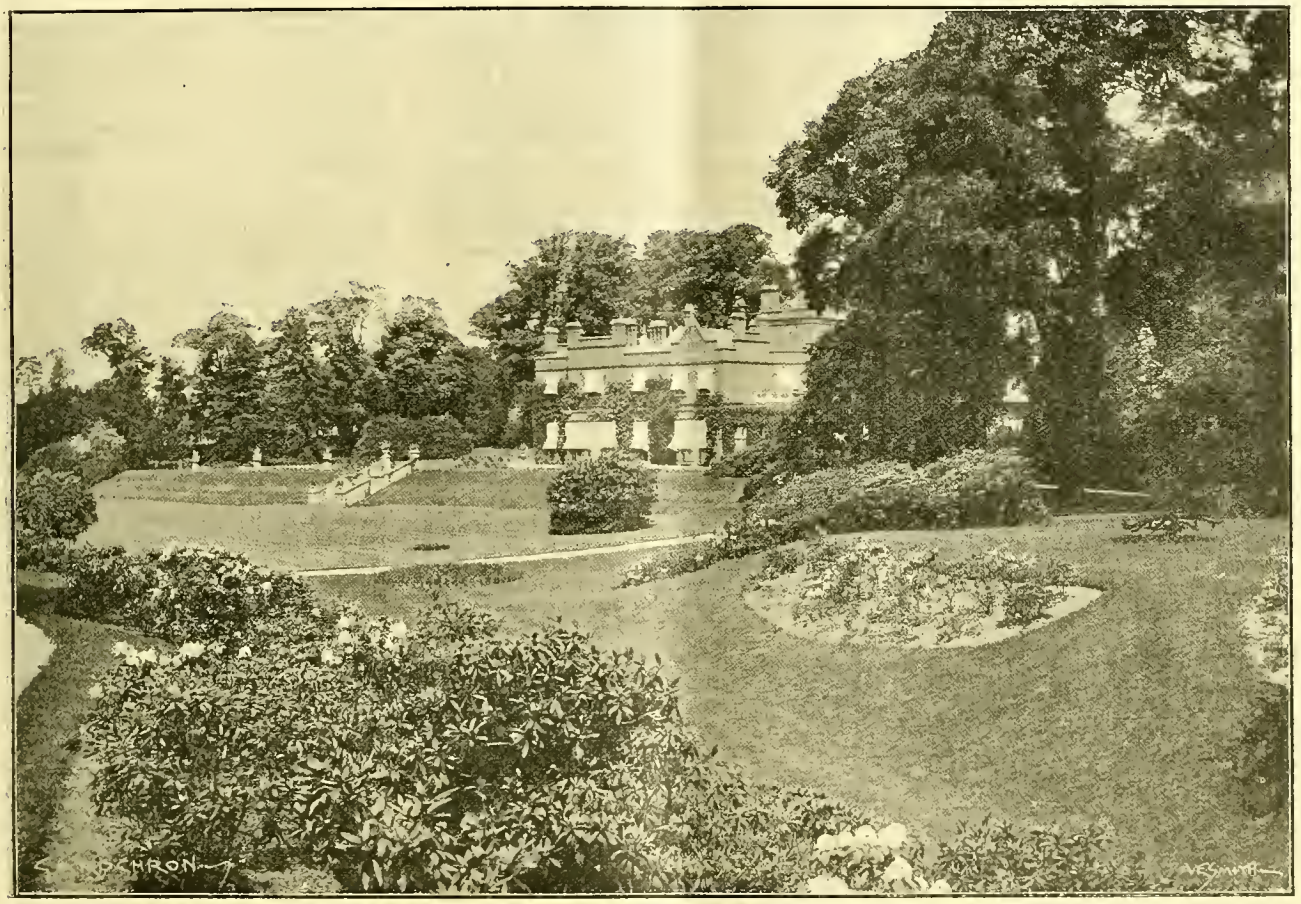

FIG. 23.—KING'S WALDEN BURY, HERTFORDSHIRE, THE RESIDENCE OF T. F. HARRISON, ESQ.

Roses, Vines, and other choice climbing plants. The Rose-garden is composed of large beds and arches for climbing and pillar Roses, and some extraordinary results have been obtained here, the plants making growths of from 10 to 15 feet in a season. All the beds were freshly soiled before Roses were planted, and all varieties make very healthy and vigorous growth. Quite recently many additions have again been made to the rosary; eight large beds have been planted, and trees, pillars, &c., covered. Some fine clumps of choice shrubs have been planted each year for ten years past.

Amongst the many trees and shrubs that succeed well are Garrya elliptica, 6 feet by 7 feet, and in perfect health; Betula Youngii, Choisya ternata, 8 feet high; Prunus in variety, Cupressus Lawsoniana lutea, Pinus excelsa, Sciadopitys verticillata (Umbrella Pine), Thuja dolabrata, Cupressus Lawsoniana var. Alumi, Abies concolor, A. nobilis glauca, Weeping Elm, and Beech. Willows are very effective by the lake, which has been made at the end of the lawn.

A wired-in fruit garden has been made near the stables. It is divided up by grass paths, and at each corner and in the centre are huge wire arches, over which are trailing Clematis. In this fruit garden are several hundred fruit-trees, including collections of Pears, Cherries, Plums, Apples, Raspberries, Strawberries, and Currants, each having a plot to itself.

Close by is the village church, a fine old structure, and here the Squire personally assists in the services, and some time ago provided a new organ at a cost of about £1,000.

In the park are some very fine Oaks of great age, but most of them are long since past their prime; there were plenty measuring 20 feet in circumference. A new avenue has been planted by a drive leading to the house, and the trees have made a good start. Mr. Hartless, the gardener, has had much uphill work to accomplish, but he has done it successfully, having a good and generous master. This makes hard work a pleasure to him. *W. A. Cook.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

APPLE LANE'S PRINCE ALBERT.—I was much interested in the remarks by Mr. Gerrish on p. 419 in your issue for December 17, 1904, on that excellent Apple Lane's Prince Albert, but I cannot quite agree with him when he says it is a better cropper than Newton Wonder. I have growing in one of my gardens under the same state of cultivation the varieties Bismarck, Newton Wonder, Lane's Prince Albert, Alfriston, and Bramley's Seedling. These trees all receive the same amount of feeding, whether it is stable or artificial manure, and certainly for the last five years both Alfriston and Newton Wonder have beaten Lane's Prince Albert in cropping qualities, although the last-named variety has yielded better crops than Bramley's Seedling and Bismarck. I am not writing to depreciate Lane's Prince Albert, but I give the result of my experience with these varieties. In the matter of keeping, Newton Wonder is with me an easy first. I have never been able to keep fruits of Lane's Prince Albert till March; with me they never keep longer than January. I hope this letter may be the means of other growers giving their views on this Apple, its cropping capabilities, &c. I am sorry to say that Mr. William Taylor, the raiser of Newton Wonder, is very seriously ill, and has not left his bed for several months. *Thomas Salsbury, King's Newton, near Derby.*

CEDRUS DEODARA VAR. ALBA SPICA.—This variety of the Indian Cedar promises to prove an excellent tree for planting in groups, or as specimen trees for effect. During the spring and early summer months the growing shoots, for 6 or 9 inches of their length, are of a milky-white colour. In most Conifers variegation is a sign of weakness, but in this case it does not seem to obtain, for our trees are making splendid growth each year. Should the variety prove constant, the effect of trees when they attain a height of 40 or 50 feet will be very effective. *C. Page, Dropmore.*

CRYPTOMERIA JAPONICA.—I have to-day measured a specimen tree of this species which was growing in the Pinetum here, and which had to be removed in order to allow more space to the fine Abies Brunoniana, well known to many of your readers. The dimensions were: height, 68 feet 6 inches; girth (at 5 feet), 5 feet 9 inches; at the ground line, 7 feet 3 inches. This tree was planted in 1847, three years after its introduction by Fortune, and must therefore be one of the oldest specimens in the country. It would be very interesting to know the measurements of other living specimens planted about the same date. The tree was in perfect health with branches to the ground-line. It is a great pity that many fine Conifers have been planted in gardens without thought being given to their future development. Philip Frost, I believe, always advocated plenty of room, but did not always succeed in obtaining it for his favourites. *C. Page, Dropmore Gardens, Bucks.*

THE TRAINING OF YOUNG GARDENERS.—On p. 14 "J. G. W." thinks I might have pointed out somewhat more clearly in my previous note the remarks in his on p. 411 to which I took exception. I plainly stated that with which I did not agree, and also gave my reasons for so doing. "J. G. W." in his remarks misrepresented the value of the different departments in the garden, and also the standard of young English gardeners. The theory which he puts forward of bedding with perennials, and thus saving much labour and room in the glass department, has nothing new about it, but in most gardens is quite impracticable, if not altogether undesirable. Few gardeners nowadays enjoy the privilege of bedding with material that comes easiest to hand. Although employers usually appreciate perennials about the pleasure-grounds, in the borders, &c., I question if many of them would like to see the parterre, the terrace, or the flower-garden adjoining the mansion filled with them; and would it not create too much of a sameness in the garden? Again, most perennials, from their habit of growth and the short time they remain at their best, are altogether unsuitable for summer bedding. Evidently "J. G. W." has no alternative that would save us from utilising glass for the forcing of many choice vegetables and salads during winter and spring, as he has said not a word on this subject. *W. C. R.*

FALL IN POTATO PRICES. — How clearly is it shown that sanity is once more beginning to govern the prices asked for new varieties of Potatos, when we see Northern Star offered in the columns of the *Gardeners' Chronicle* at 10s. per cwt., or but a fraction over 1*d.* per lb. How indeed have the mighty fallen! That offer may well merit the attention of others who ask prices varying from 6*d.* to 3*s.* 6*d.* per lb. for this greatly over-praised variety. A Hampshire grower offered me the variety at 5*s.* per bushel, and he would be very glad to sell at that price. Should not this fact do much to help to kill that gross inflation of prices which so astonished sane people during the past year? Certainly no variety of Potato ever raised was worthy the prices said to have been paid during the past year. All this booming and fooling of purchasers does no good in the end, but much harm, as only disappointment can follow when wonderful swans are after all found to be very common ducks. *A. Dean.*

FACTS AND FANCIES IN FORESTRY.—The other day, a forestry lecturer told a Carlisle audience, presided over by Sir Wilfrid Lawson, that "from 18 inches to 3 feet was the minimum depth at which they could plant forest trees." It is Brown, of course, who dwelt on the importance of "great depth," drawing erroneous conclusions from farm and garden crops. The above "minimum depth" at once rubs out most of the millions of acres of waste land proposed to be planted, for it may be safely asserted that a very small portion of our poor waste lands have more than 6 or 9 inches depth of soil, and the above "minimum" would appropriate all the deepest and best agricultural land. A few weeks earlier, Mr. Augustine Henry, lecturing on forestry also, at Castle Douglas, N.B., told his audience "that soil determined the species of trees to be grown, and that was about all. Forests grew where there was scarcely any soil. They knew of paying forests where there was nothing but bare, solid rock." Both extracts are from a Northern contemporary, and are characteristic of the old and new schools. I do not feel sure about the "bare rock" idea, but Dr. Henry is much nearer the mark, and apparently better informed than the Carlisle lecturer. It is simply astonishing where big trees of all kinds are found growing on solid rock with the scantiest sod over it—whinstone and granite rock, too—as in Cumberland, Kirkcudbright, and Aberdeen. Where I live, in the South Yorkshire uplands, over large tracts it is difficult to get a spade down deeper than 9 inches owing to the presence of solid rock, and the depth of soil is less than that in many places; yet all over this district once stood the finest Oak forests in Britain, described by Evelyn as probably "not excelled in Christendom," so straight and big were the trees. Other and later estate records testify the same thing, and plenty of fine trees show that the deep-soil theory is a pure fiction. *J. S.*

THE APPLE SELECTION.—To all your readers, native or foreign, this must have been of great interest. But to give a complete answer to the question, "What Apples shall we plant?" we must first know the merits and demerits of the particular varieties we intend to plant. I do not know any book on Apples that treats this matter fully. That excellent book, Hogg's *Fruit Manual*, is not a guide in this way. If you, Mr. Editor, would spare some space every week to the necessary complement of the census of Apples, written by your best pomologists or growers, I believe this would be of interest and great benefit to all fruit-growers. For instance, if Beauty of Bath is in many ways preferable to Irish Peach, which belongs to the best six dessert Apples, or Keswick Codlin to Ecklinville Seedling, because the last-named is too soft and very liable to spot, a comment is highly necessary. I should like to see the varieties judged in the following way:—1, fruitfulness; 2, growth, liability to canker and spot or otherwise; 3, quality, size, colour; 4, suitability for market or not; 5, kind of soil and position wanted. *B. G. van Heyst, Wyk-by-Duurstede, Holland.* [Our columns are open to the discussion of this and other practical matters, subject only to the limitations imposed by circumstances. ED.]

CHRYSANTHEMUM MRS. SWINBURNE AND ITS SPORT [see p. 28].—Although white-flowered Japanese Chrysanthemums are numerous Mrs. Swinburne is so distinct from all others that it is certain to become a popular variety, especially for late flowering. The florets are distinctly ribbed or fluted. They are semi-drooping, and build up a full solid flower that is at once attractive. The pearly-white colour is quite distinct from any other variety known to me. The yellow sport, Mrs. Beech, is an exact counterpart of its parent, except in colour. *E. Molyneux.*

HOLLYHOCKS.—I find the easiest way to procure an annual display of Hollyhocks is to plant at the end of March robust seedlings raised from seed sown in the previous May. Such plants can be bought quite cheaply in either single or double varieties, and if these are planted in deeply-dug and heavily-manured soil in an open position, and encouraged to grow vigorously, spikes of flowers 12 feet in length are easily obtained. After the flowering period is passed I dig up the plants and throw them away, as I find the second year they are quite useless, being smothered with fungi, and weakly in growth. As this system is so simple I do not trouble about the fungus, for during the first season of planting it does not affect them so far as their flowering is concerned, although a few of the lower leaves may be disfigured. Hollyhocks prefer an open position where they can have an abundance of air; overcrowding they abhor. Abundance of moisture at the roots during dry weather is a gain to growth, which cannot be too vigorous. I gave

the singled-flowered varieties a good trial, but think them very poor and not nearly so effective as a Mallow in the border. I now grow none but doubled-flowered varieties. *E. M.*

MYROBALAN PLUM.—As a substitute for Quickthorn I also largely planted this Plum in Scotland, on the west coast—in fact, the west coast of the outer Hebrides—where the soil is of the poorest nature, peaty and wet, and the situation of terrible bleakness, being just on the seashore, and open to all the terrible north-west gales that sweep across the Atlantic. My experience is exactly the opposite to that of Mr. Duncan, mentioned on p. 29. Although planted in such an exposed situation, the Myrobalan often made shoots from 7 to 8 feet in length in one season. I have not tried the plant in England, but if I desired a quick-growing hedge I would without hesitation plant the Myrobalan Plum. It is ornamental as well as useful, and retains its leaves much longer than Thorn—at least it did so in the outer islands of Scotland, where the thermometer very seldom registered more than 3° or 4° of frost during the winter, but might not do so in places more inland. *Grigor Roy.*

—— I cannot agree with Mr. Ward that this Plum is superior to Quickthorn for hedging purposes, and my experience leads me to say that it is not nearly so good for hedges as a well-managed "Quick," though to see a well-cultivated hedge of the latter is indeed a rarity. This arises from two common mistakes, viz., the planting of double rows of plants 10 inches apart, and neglecting hard pruning at the start. The result is, under such conditions, a "thin" fence at the bottom, and one that occupies too much space. A single row gives much the best result. Plant three Quicks to every foot of ground, and prune them down to within 4 inches of their base when planted, and do not wait twelve months, as advised by Mr. Ward. I look upon this delay as a waste of time. The Myrobalan Plum will grow much more rapidly than "Quicks," but I have never seen a thick base to any hedge made with this subject. There are many persons who plant Quickthorn in a slipshod fashion, and then expect a quick growth; whereas if the site had been trenched and manured freely at the time of planting, the difference in the growth would have been perceptible. Too often the base of the hedge is allowed to become choked with weeds and grass, which not only prevent growth, but rob the roots of nutriment and moisture to an astonishing extent. *E. M.*

—— A few years ago I had charge of a place where an impenetrable fence was wanted to enclose part of the grounds. We trenched the ground 2 feet deep and about 18 inches wide, working in a quantity of good manure. In the autumn we planted the Myrobalan Plum about 6 inches apart zigzag in the rows, and the following autumn we cut the plants down to about 18 inches from the ground, in order to obtain a good foundation in the hedge. We trimmed the hedge annually, and also cleansed and mulched the plants with good manure every autumn; at the end of five years we had a thick impenetrable hedge 5 feet 6 inches in height. To prevent rabbits from attacking the plants, we used wire staked all round the outside of the hedge. I may state that cattle as well as rabbits and hares are fond of the plant. *A. R. Pearce, Kenilworth.*

—— My experience with the Myrobalan Plum differs somewhat from that related by correspondents on p. 29. Having to resuscitate several old fences here, I planted this Plum rather freely three or four years ago, and while it is distinctly useful for filling gaps and growing in an old hedge-bottom where Quicks will not grow, I should not think of substituting it for Quick in a new fence, or in portions of a hedge that can be cleaned out and trenched, in which case in my experience Quick or Quick and Holly have no equal. At the same time the Myrobalan is a useful plant in many places where the Thorn will not grow well, and associated with Privet will fill many an unsightly gap under trees and in wet, boggy land. I cannot say even with judicious cutting back that I have found it so impenetrable as it is described by Mr. Ward. *H. Jenkins, Acaster Malbis, York.*

APPLE WYKEN PIPPIN.—John Rogers, in his *Fruit Cultivator* (1834), mentions, as Mr. W. Miller does, the place of origin of this nice but now little grown dessert Apple as being near Coventry. Rogers states that he saw the original tree forty years previously, and that it was then in a state of decay. That would of course be long prior to Lindley's view of the tree in 1827, when it was merely an old trunk. Dr. Hogg writes of the flavour of Wyken Pippin in rather glowing terms, as delicious and first-rate. Rogers was content to say of it, "juice not abundant, but very agreeable;" but much would depend on the culture under which the respective fruits were grown. I had an old tree of the variety under my charge forty years ago, and it was then a splendid cropper, the fruits were of a suitable size for dessert, clean and handsome. We then thought it to be one of the very best-flavoured Apples. It is worthy of remark that when well matured the fruits keep well into the new year. It is a good Apple almost forgotten. *A. D.*

—— Mr. Miller may lament the preference for Worcester Pearmain over Wyken Pippin, but the fact remains that as a market Apple the latter is almost useless, while the former will realise probably more money than any other variety of Apple. Of course there are two ways of looking at Apples—for home consumption and for profit. For the latter purpose it is the showy varieties that are required, dull-looking fruit, no matter how good in point of flavour, is quite useless for sale in shops. Highly-coloured although poorly flavoured examples are freely purchased by the British public. *E. M.*

ORCHID NOTES AND GLEANINGS.

PLATYCLINIS (DENDROCHILUM) UNCATA.

A FINE, healthy plant of this rare and pretty species is now in flower at Burford. When seen with only two or three spikes of flowers, there is little to recommend it; but the plant under notice, with about forty spikes of its graceful pendulous racemes, is one of the prettiest Orchids for use as a specimen for the table or drawing-room. The flowering racemes are about 10 inches in length; the individual flowers are small and numerous, and of a greenish-yellow shade. Coming from the Philippine Islands, one would naturally suppose that the plant would require the highest temperature available in Orchid-houses, but after repeated trials it has been found to thrive better if suspended in a cool, shady part of what is familiarly called the intermediate-house. In this house the foliage is not so liable to attacks of red-spider as it is when grown in a warmer temperature.

CIRROPETALUM MEDUSÆ.

In the *Gardeners' Chronicle* for January 9, 1897, p. 25, a fine illustration was given of the Malayan Cirropetalum Medusæ, with eleven spikes of flowers. The plant is now again in flower at Burford, having fifteen equally good spikes. It is a curious and interesting species. The scapes are nearly erect, and bear upon their apex a large, dense, globose cluster of flowers, which are cream-coloured, freckled with pink, the two lateral sepals of each flower being so lengthened out as to give the spike the appearance of a head with very long, dishevelled hair. This species was introduced from Singapore by Messrs. Loddiges in 1841. The plant now in bloom has been in Sir Trevor Lawrence's collection since 1878.

ANORÆCUM DISTICHUM.

A large, healthy specimen of this rare species is also in flower. The flowers are produced singly and in pairs from the axils of the imbricated leaves; they are small, but of snowy whiteness, and are very sweetly scented, especially at night. Altogether there are about a thousand flowers open on the plant, which forms a charming and attractive object in the warm-house. It is a native of the west coast of Africa. *W. H. W., Burford Gardens, Dorking, January 6.*

BOOK NOTICE.

THE CULTURE OF FRUIT TREES IN POTS. By [illegible] J. Brace. (John Murray.) Price 5s.

THIS book, written as it is by a thoroughly practical fruit-grower, and one who has devoted the best years of his life to this particular branch of fruit-culture in the nurseries of Messrs. Rivers, contains within its 110 pages the very essence of pot fruit-tree cultivation, which is now, after a lapse of more than fifty years from its inception, becoming more and more appreciated by amateurs and by practical gardeners. The writer of this notice started this system of culture nearly ten years back with a prejudice against its practical utility for the actual supply of choice dessert fruits of various kinds, more especially for early forcing and for late supplies. He was soon convinced of his error in more ways than one, and is now a strong advocate of the system.

The author treats the subject in a plain and practical fashion and in such a way that it becomes not only interesting but most instructive. With the ease gained by experience he deals with the varied phases which fruit-trees in pots must pass through to ensure success. The opening chapter treats upon the houses and their construction, position, soils, &c., as well as with the cost of erection, which is essential. This is followed by the method of furnishing of the houses with trees. Here the caution against overcrowding should be particularly noted, and a word from the writer may not be out of place upon this subject, viz.—it is a fallacy to suppose that pot trees can be successfully grown from start to finish under the shade of other trees—started they may be, but a speedy provision must be made for light and air as soon as leaf-growth commences. The advice as to separate compartments and the advantages thus afforded is sound, and such compartments should wherever possible be provided.

The third chapter of the book should be read and re-read by everyone who contemplates this method of cultivation. It gives the best possible advice, which may be safely followed not only by those who are commencing, but by those who have already done something in this way. To the latter will be made plain the rocks upon which their expectations have been wrecked. The remarks upon the longevity of the trees should be specially noted. This is a point that the writer has frequently had to explain to enquirers who have erroneously supposed that the trees are short-lived, and he has pointed out trees, both of Peaches, Nectarines, and Plums, that have been forced continuously for ten years, and of Cherries for a somewhat shorter period. The chapter upon varieties might fairly have been extended, so as to have included those grand Nectarines Cardinal and Early Rivers, which are invaluable for early forcing, so also might that of Plums, especially of late kinds. Beginners and others should note the advice upon such a simple matter as "gathering the fruits"—it is sound.

The question of insects and their extermination is fully discussed in a clear manner. This is a matter which if once grasped will save infinite trouble and annoyance.

The calendar of operations for each month in the year for the unheated house is replete with sound advice, which the author in a future edition might well supplement with his practical knowledge of forcing. The plans given of suggested erections are explicit in detail, whilst the examples both of shoots as regards pruning, and of trees in respect to training are admirable. The author may be congratulated upon his work in general, and more especially upon the cultural details that he has so clearly laid down. The numerous illustrations add materially to the value of the work.

PLANT NOTES.

LOBELIA TENUIOR.

Now that the time for ordering seeds has arrived, I would say to those that may not have had the opportunity of seeing this charming species of Lobelia in flower, that it is exceedingly useful for conservatory decoration during the spring and summer months, and also for the draping of vases in the open garden.

The habit of the plant is slender and graceful, and it has lovely blue flowers with white centre, the individual blooms measuring 1½ inch in diameter. The plants grow 2 feet in height, and the profusion and duration of the flowers is remarkable. They close at night and open again in the morning, to all appearance with renewed brightness. *W. Fyfe.* [See illustration in our issue for January 19, 1901, p. 46. ED.]

REHMANNIA ANGULATA.

This new half-hardy herbaceous perennial plant grows well under the most simple culture, and is still in flower here. The flower-spikes measure upwards of 3 feet in length, and the plants continue to flower for months. *W. Fyfe, Lockinge Gardens, Wantage.* [See Supplement in our issue for May 9, 1903. ED.]

CARPOLYZA SPIRALIS.

THIS pretty little South African bulbous plant is seldom seen except in botanic gardens. It does not make a great show, but is interesting on account of the spiral twisting of the lower part of the thread-like flower-scape, the spiral probably being produced for the purpose of giving rigidity to the slender scape, which otherwise would hardly be able to hold itself erect. The bulb is oval, about ¾ of an inch long, and produces about eight dark-green filiform leaves from 4 to 6 inches long.

The scape is filiform, from 4 to 6 inches high, the lower half being spirally twisted, and of reddish colour; the upper half of the scape is quite straight, bearing an umbel of from three to six flowers on pedicels 1 to 2 inches long. The flowers are white, tinged with red on the outside, and are nearly ⅜ of an inch in diameter. In the Cambridge Botanic Garden they are afforded the same treatment as Ixias and Freesias, seven or eight bulbs being planted in a 5-inch pot. They are now flowering, and prove interesting subjects for the cool greenhouse, where they last in good condition for several weeks. The plant is figured in the *Botanical Magazine*, t. 1383. It is also known under the genus Ilessea. *E. J. Allard, Botanic Gardens, Cambridge.*

TACSONIA VOLXEMI.

In the Tacsonia Volxemi, first described and figured in these columns, we have one of the most beautiful conservatory climbers in cultivation. Its brilliant crimson flowers on long thread-like footstalks depending loosely from the roof trellis are everything that can be desired in a conservatory climber. It is easily raised from seed sown on any light sandy soil, covered to the thickness of about a quarter of an inch (the seedling being large) with some of the same kind of mould, placed in heat and watered. If the seed is good the young plants will appear within a fortnight or three weeks from the time of sowing. They should as soon as large enough to handle be placed singly in 3-inch pots in a mixture of four parts fibrous loam and one of leaf-mould, with a sprinkling of sharp sand added, returned to heat, and watered. Shift the plants into 6-inch pots before the roots become matted, and grow them on until about 3 or 4 feet high, when they should be planted out in a narrow, well-drained border or a 12-inch pot, training the growths loosely to the roof of a greenhouse or conservatory. The best compost is formed of three parts fibrous loam and one of peat with a good sprinkling of sand. When well established thin the shoots, but do not stop them. The plant may also be increased by cuttings put in in the ordinary way. *H. W. Ward.*

TRACHELIUM CŒRULEUM (BLUE THROATWORT).

This attractive perennial from the Mediterranean region belongs to the Campanula family. It is not only a very attractive border plant, but is also one that deserves to be grown in pots. It is a sub-shrubby branching plant from 20 to 30 inches high, producing in summer large clusters of pale blue flowers. Grown in pots, Trachelium cœruleum will compare favourably with Statice profusa, which plant it resembles in habit of growth, form, and colour of flower, either set up in a miscellaneous collection of plants in the exhibition-tent, or for the decoration of the greenhouse and conservatory. It is also a suitable plant for vases. It is easily propagated by seed, cuttings, or division of the roots. The latter is the best and certainly the quickest way of working up a stock, potting up the divisions in spring in suitable-sized and properly-drained pots, in three parts light loam and one of leaf-soil, with sufficient sharp sand added to render the whole somewhat porous. The plants should be afterwards grown on in a cold pit or frame like Spiræas and such-like plants, transferring them to the greenhouse in due time. *H. W. W.*

CULTURAL MEMORANDA.

LOBELIA QUEEN VICTORIA.

In order to obtain a large stock of these plants for flowering well the first season, it is advisable to sow the seed earlier than is usually recommended, in order to allow the seedlings ample time to develop into strong plants before planting them in the open. When a good stock has been obtained, no difficulty will be experienced in keeping up the required quantity by division of the old plants. Sow the seed moderately thin in clean, well-drained pans, filled to within half an inch of the rim with good, fresh sandy loam, pressed moderately firm. Do not bury the seed too deeply, but cover the seed-pans with a square of glass. During the period when the seeds are germinating the soil must not be kept too moist. Place the pans in a moderate temperature near the glass until the seedlings appear, after which time the glass covers should be gradually removed. Prick-out the seedlings when large enough into other pans, and finally pot them singly in small pots to be grown-on and gradually hardened off prior to planting them in the open. Although with suitable convenience these plants may be raised later, I have always found it the better plan with perennials to sow early, and have the plants nicely forward before the sun-heat is too powerful. June and July are suitable months for raising these plants from seed sown in cold frames. *H. Markham, Wrotham Park, Barnet.*

LAW NOTE.

WITHDRAWAL OF AN APPEAL UNDER SECTION 17 OF THE PHARMACY ACT, 1868.

NOTICE has been given of the discontinuance of an appeal from the decision of the Lord Mayor on August 8 last upon the three summonses taken out by the Pharmaceutical Society of Great Britain under Section 17 of the Act of 1868. The Lord Mayor then imposed three fines of £5, 1s., and 1s.; with five guineas costs to the Society, for selling XL-All Insecticide, containing nicotine, without the bottle being distinctly labelled "Poison." The other summonses were for selling to a person unknown, and for not making proper entry of the particulars of sale as required by Section 17.

COLONIAL NOTES.

TRANSVAAL PLANTS.

IT has occurred to me that some of your readers may be interested in the ornamental flowers of the Transvaal veldt, many of which, though apparently unknown in English gardens, are fully as showy and worthy of attention as many of the Californian species which are such old favourites at home. There is one important difference between the ornamental species of the two countries which may have something to do with the widespread cultivation of the one and the general neglect, if such it be, of the other. Those of California are largely annuals—Gilias, Phacelias, Collomias, Godetias, Eschscholtzias, and the like: those of the Transvaal are mainly perennials—often deep-rooted, and transplanted and grown less easily — Ipomœas, Vignas, Tephrosias, Lasiosiphons, Gomphocarpi, Eulophias, Gazanias, Dimorphothecas, Gerberas, and the like. Perhaps, as seems to be the case with those species of the genus Dimorphotheca already in cultivation, they need protection in an English winter; but I scarcely think that many of them would need greenhouse treatment, unless possibly to protect them from excessive moisture during the dormant season. On their native veldt, many of these plants have to stand winter-night temperatures of 22° Fahr. (10° of frost), and in some places as low as 7° Fahr. (25° of frost) is recorded. The high veldt is mainly treeless, and exposed to the full sweep of bitterly cold winter winds; but at this period of the year the plants are naturally dormant, and their roots are deeply buried in the soil. Another condition which would be difficult to reproduce in England, and which might be necessary to successful cultivation, is the dryness of the long winter season, during which the plants remain dormant; during the past season over much of the Transvaal we had no rain heavy enough to wet the soil below 2 inches for over six months (April to October inclusive). When the November showers came, the tardy spring flowers appeared with a rush; many deep-rooted species did not wait for the rains however, but were able to flower early, probably owing to special structural arrangements and deep-rooting habits.

I hope to describe a few of our more showy perennials in subsequent letters. *Jos. Burtt-Davy, Government Agrostologist and Botanist.*

PLANT PORTRAIT.

ROSE MADAME NORBERT LEVAVASSEUR.—Stated to have originated as a cross between Crimson Rambler and Gloire des Polyantha, both forms of R. polyantha. The flowers are rich crimson-red. *Gartenflora*, January.

SOCIETIES.

ROYAL CALEDONIAN HORTICULTURAL.

The Annual General Meeting of the above Society was held in Edinburgh on Wednesday, 11th inst. The Council's report showed a very large increase in the number of entries both at the spring and autumn shows, that arrangements had been almost completed for the international show, and that the schedule which will be issued shortly will contain a number of new features not included in any show formerly held by the Society. In framing the schedule it had been the aim of the Council to endeavour to stimulate all branches of horticulture, whether cultural or in the domain of scientific investigation and experiment. The Council also reported that they intended shortly to revive the publication of papers dealing with horticultural subjects, which had been started in the early days of the Society, but shortly thereafter discontinued. The financial statement showed a successful state of affairs, the excess of income over expenditure for the year to November 30 last being £123. The Chairman, Mr. W. H. Massie, appealed to the members to endeavour to secure new members and to do all that was possible to strengthen the Society in view of the international show to be held in September. *P. M. T.*

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.

JANUARY 14.—The annual banquet of this Society, started sixteen years ago, with the object of bringing together and encouraging the young French-speaking gardeners who come to England to improve their knowledge of horticulture, was held at the Café Royal, Regent Street, on the above date, and was in every respect a decided success. M. Philippe de Vilmorin, who had come specially from Paris to preside, won the sympathy of all the persons who assembled to do honour to the Chairman, and to show their appreciation of the work done by the Society. After the loyal toasts, "The President of the French Republic" and "The King," the Chairman, in a vigorous and very concise speech, after reviewing the progress of the Institution, urged the young members to work with a will, and by their good conduct to strive to deserve the good feeling which, he said, is shown to them by the British nation in general and by their various employers in particular. He laid great stress on the benefit which they derive from their belonging to the Society, which is presided over by Mr. G. Schneider, whose time and experience are so generously placed at their disposal.

Mr. Schneider in reply to the Chairman's toast said that not only the Society placed young French gardeners here, but also made a special feature of placing young English gardeners abroad, and had been very successful in that respect. They had placed in France many of the young Englishmen who were present on this occasion. The Society is in a very flourishing condition, and this is largely due to the good fellowship existing between English employers and *employés*. He then read letters from Messrs. Léon Geoffray, Ministre de France, Dr. M. T. Masters, Harry J. Veitch, Cuthush, Geo. Nicholson, and Wm. Robinson, expressing their regret at being unable to be present on this occasion.

There were present a goodly number of members of the National Chrysanthemum Society, to whom young French gardeners are indebted for the present good position of their Society. Mr. C. Harman-Payne paid a just tribute to the illustrious family of De Vilmorin, a member of which was in relation with the Royal Horticultural Society at the time of the foundation of that Society in 1804; this was M. Pierre Philippe de Vilmorin, the Chairman's great-grandfather.

M. Edouard Sève, Belgian Consul-General, also addressed the company, thanking the Association for the great advantages which his young countrymen derived from their connection with it during their stay in this country. M. Alfred P. Huguenet, Directeur-Redacteur of the only French weekly paper published in London, *La Chronique*, also addressed the meeting. To that journal we are indebted for the opportunity of publishing the portrait of M. de Vilmorin.

One of the young French members, M. Serra, in the name of all his colleagues, thanked the Chairman for his devotion to their cause, and the English nurserymen and the English horticultural Press for their valuable help.

Mr. Geo. Gordon responded to this last toast. Among the company, which numbered seventy-nine, we noticed, besides the speakers, Messrs. Ed. Sherwood, T. Bevan, Percy Waterer, W. Howe, Brian Wynne, Hawes, Hiehle, E. Such, D. Ingamells, Collingridge, Withy, Tyler, Drost, R. C. Tucker, J. Gaskill.

Mr. G. Schneider announced the adhesion of many life members, also of honorary, titular, and correspondent members, and in appropriate terms cordially thanked his young friends for the handsome present which they made him on this occasion, and which he greatly appreciated.

M. PHILIPPE DE VILMORIN.

GARDENERS' DEBATING SOCIETIES.

BATH GARDENERS' SELF-HELP AND DEBATING.—The first smoking concert of the Bath Gardeners' Self-help and Debating Society was held on Monday, January 9, at the Foresters' Hall, Bath. Dr. Paton, one of the vice-presidents, occupied the chair, the meeting being well attended. During the interval a presentation was made to the chairman of the Society, Mr. Parrott, by Dr. Paton, who expressed his pleasure at the progress the Society was making. He felt that such meetings for social intercourse must in the end tend to benefit everyone who attended them. Mr. Parrott in response thanked the gathering heartily for the present and acknowledged the work of Mr. McLaren and Mr. Butt in the formation of the Society and the great help rendered by the Committee. Although only three months old the Society had a membership of 118, which he thought was excellent, but they hoped to double or treble that number by next year. Dr. Paton left at this stage, and Mr. Parrott presided during the rest of the proceedings. *O. G. McL.*

BATH AND DISTRICT GARDENERS' IMPROVEMENT.—The monthly meeting of the members of this Association was held on January 12, when Mr. W. F. Cooling presided over a satisfactory attendance. Excellent exhibits of fruits and vegetables were staged, while prominently placed on the table was a beautiful bunch of Iris stylosa from the open-air, a remarkable fact, considering the time of the year. In the usual competition held, prizes were awarded to Mrs. Tollemache for a collection of vegetables, and to Mr. R. B. Cater for Primulas. Mr. Curtis gave an address, the subject of which was "Stove Plants."

CARDIFF GARDENERS.'—The opening meeting of this Society for the new year took place at the Sandringham Hotel on Tuesday, January 10, Mr. Tom Clarke presiding. A large gathering attended to hear a lecture entitled "The Twelve Best Vegetables to Grow for Exhibition," written by Mr. E. H. Battram. Unfortunately this gentleman was too unwell to attend, and in his absence Mr. John Julian was asked to deliver a lecture entitled "Some Hints upon the Selection and Staging of Fruits and Vegetables for Exhibition," which he had previously delivered to the members of the newly-formed Bassaleg Cottagers' Association. Mr. Julian gave many valuable hints on exhibiting, and gave reasons why exhibits were ofttimes either successes or failures. Mr. H. R. Farmer opened a discussion, which was well taken up by the members. *J. P.*

BRISTOL AND DISTRICT GARDENERS'.—The fortnightly meeting of the above Association was held on Thursday, January 12. Col. Cary Batten, the President, opened the proceedings, addressing a few words to the members and congratulating them on the progress the Association was making, and hoped it would be maintained. It was always a pleasure to Mrs. Cary Batten and himself to pay the Society a visit. Mrs. Cary Batten then presented the prizes which were awarded the successful competitors for three plants in bloom. On Col. Cary Batten leaving, Mr. W. A. Garaway was invited to take the chair for the remainder of the evening, and he then called upon Mr. Binfield to read a paper on "Decorative Plants," which dealt with the method of the cultivation of Palms, Crotons, and Poinsettias, the formation of suitable composts, the method of potting, the most suitable temperature, and the general treatment to observe in their cultivation. A discussion followed. The next meeting of the Society will take place on January 26, when Mr. Woodward, member of the Newport Association, will lecture on "The Rotation of Kitchen Garden Crops."

CHELMSFORD AND DISTRICT GARDENERS'.—At the weekly meeting of the above Society, held on Friday, January 13, Mr. Alger Petts presiding, Mr. W. Seabrook gave a paper on "Apples." He referred to the enormous sums paid yearly to the foreigner for fruit that might well be produced at home. He advocated the dwarf system of growing Apple-trees, especially the bush and cordon methods, the pyramid plan of training being somewhat adversely criticised. An ideal Apple soil was in his opinion a sandy-clay. He advised planting trees on a hillock rather than deeply, as deep planting was often the cause of failure, and loss of trees. Mulching in May in preference to winter mulching was advised. Among all the 1,000 or so varieties of Apples Mr. Seabrook thought ten varieties of good table, and ten good culinary Apples were all that were required. In buying and selecting trees for planting the speaker warned his hearers against purchasing cheap trees from afar. He advised buying the best that were procurable in the district from reliable growers. *S. M. C.*

SOCIAL EVENING AT KEW.—The Kew Gardeners' Social was held on Friday, January 13, in the Boat House, Kew. About 150 guests assembled and spent a very pleasant time. Mr. H. J. BAKER was Master of Ceremonies, and to Mr. G. H. PRING, the Secretary, the thanks of the meeting were also due.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending January 14, 1905.

1905. JANUARY 8 TO JANUARY 14.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	Wet Bulb.	DAY. Highest.	NIGHT. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	40	39	47	37	28	41	43	44	Tot 0·13	3 31

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Jan. 14, is furnished from the Meteorological Office:—

"The *weather* during this week was mostly fair in the south and east of England, and unsettled elsewhere. Heavy rain and a little snow were experienced in the north of Scotland, and a considerable amount of rain in Ireland and the north of Scotland. During the 11th a thunderstorm, accompanied by hail, occurred at Leith.

"The *temperature* was above the mean, the excess ranging from 1° in Scotland, N., and England, S.W., to 2° or 3° in the other parts of the kingdom. The highest

of the maxima were recorded at the beginning of the week, and the lowest of the minima at its close. The former ranged from 51° in Ireland and the Channel Islands, to 51° in Scotland, W., and the latter from 21° in England, S., and the Midland Counties, to 30° in Ireland, and to 32° in the Channel Islands.

"The *rainfall* was much more than the mean in Scotland, N., and a little more in Ireland, but elsewhere there was a deficit. In the Channel Islands, and in England, S.E. and N.E., the fall was very slight.

"The *bright sunshine* was very abundant in England, the Channel Islands, and the East of Scotland, but only just equalled the normal in Scotland, N., and was below it in Scotland, W., and over Ireland. The percentage of the possible duration ranged from 50 in England, E., 35 in England, S., 33 in the Channel Islands, and 32 in England, N.E., to 12 in Scotland, N., and to 8 in Ireland, N."

THE WEATHER IN WEST HERTS.

A Bitterly Cold Wind.—The recent spell of very mild weather lasted eleven days, when a change to lower temperatures took place. On the coldest day, the 16th, the highest reading in the thermometer-screen was 29°—making it the coldest day as yet of the present winter. During the previous night the exposed thermometer showed 15° of frost. The last few days and nights of cold weather have already affected the ground temperatures, which are now about 1° colder at 2 feet deep, and about 3° colder at 1 foot deep, than is seasonable. The only fall of rain or snow worth mentioning was that of the 16th. On the evening of that day the ground was covered with snow to the mean depth of half an inch. This coating was, however, mostly melted by the rain and sleet which were afterwards deposited during the night. The measurement of rain and melted snow on the following morning amounted to nearly half an inch. One effect of the rain falling upon the frozen ground was to bring about what is termed a "glazed frost," or "silver thaw," which caused the roads and pathways to become very slippery early on the following day. On all but one day, when the soil was frozen, some water passed through both percolation gauges during the week. The sun shone on an average for nearly three hours a day, or for more than twice the seasonable duration. On three consecutive days the mean daily record was nearly 5½ hours; but two other days were altogether sunless. On two days in the early part of the week the wind rose in the windiest hour to 17 miles—direction west. The most noteworthy feature was, however, the biting easterly winds of the 15th and 16th, which from 10 A.M. on the 15th until 9 P.M. on the 16th blew with a velocity of from 7 to 15 miles an hour. It was not, however, so much the strength of the wind as its low temperature and extreme dryness which caused it to feel so excessively cold. The mean amount of moisture in the air at 3 o'clock in the afternoon was as much as 13 per cent. less than the average quantity for midwinter at that hour. *E. M., Berkhamsted, January* 17, 1904.

ANSWERS TO CORRESPONDENTS.

AUCUBA JAPONICA: *Cabbage.* You are right in supposing the flowering growth to be that of A. japonica. It is a green-leaved variety of this species, and the flowers on the growth received are female flowers. This shrub, as its name denotes, is a native of Japan.

BONE-MANURE: *T. T. T.* Crush the bones as finely as you can, and apply in that state. Although the manurial properties of the bones are not so soluble as when treated with sulphuric acid and converted into superphosphate, their effect is felt for a much longer period in soil.

BOOKS: *Hortus.* We know of no suitable up-to-date work on the subject of table decorations. Old books on table decoration deal with old-fashioned methods, and are next to useless.—*W. F. Elementary Botany* by Percy Groom, M.A., price 3s. 10*d.*; and *Chemistry of the Garden*, by H. H. Cousins, M.A., price 1s. 1½*d.*, post free, from our Publishing Department.—*J. W. M.* Mendel's *Principles of Heredity*, by W. Bateson (Cambridge University Press); *Journal of the Royal Horticultural Society* (1900), vol. xxv., parts 1 and 2; also a paper by C. C. Hurst, to be had from Thornley & Waddington, of Leicester.

CALANTHE BULB SPOTTED: *F. L.* The brown markings on the pseudo-bulbs sent are superficial, and do not extend to the tissues. It is probable that condensed moisture on some occasions when the temperature of the house has fallen rather low may have caused the damage. When grown from the same stock for a number of years the plants are liable to degenerate, and show similar disfigurement to that on your specimens. During the resting period keep them in a structure where ventilation is employed. Repot the pseudo-bulbs when they have commenced to make growth. If the stock does not improve get fresh pseudo-bulbs.

CHRYSANTHEMUM: *Nurseryman.* We see no fungus on your cuttings at present, but there are indications which seem to point to the future development of the fungus. Watch them carefully, and apply liver-of-sulphur ½ oz. to 2 gallons of water, in the form of spray. This will do no harm, and if fungus be really present it will do good.

CUCUMBER PLANTS DISEASED: *Reader.* A thorough investigation has failed to reveal the presence of any fungus or insect pest, and the plants are from this standpoint perfectly healthy. No mention is made of the plants having been sprayed or exposed to vapour of a fungicide, but the bleached edges of the leaves and the colour of the green parts point very strongly to injury from vapour or spraying, which has killed the more susceptible plants.

CYCLAMENS: *Beginner.* It is not uncommon for very old corms to cause trouble at the flowering season. You should raise a few plants from seeds each year, and it would then be unnecessary to keep the plants after they are two or three years old. With a view of encouraging the flowers to develop properly this season take care to keep the atmospheric temperature of the house pretty regular, and see that the proper degree of moisture is obtained in the atmosphere and at the roots of the plants.

CYPRIPEDIUM INSIGNE. *T. B.* It is not usual for this plant to produce two flowers on a spike, though we have seen other specimens.

DENDROBIUMS FAILING: *J. D.* Judging by the pseudo-bulbs of Dendrobium Wardianum sent, which are decayed on the basal half, we think that the growths were not sufficiently matured in heat before they were put into the cold vinery to rest. The temperature of 45° you mention would affect prejudicially any but the most perfectly-finished pseudo-bulbs, and it is possible that the temperature of your house has fallen even below 45° on particular occasions.

MAIDENHAIR FERNS ON WALLS: *A. S.* The back wall appears to be the more favourable site for growing your Ferns; a situation beneath the front staging and close to the dry-heat radiating from the hot-water pipes would not appear to be at all favourable. But you are on the spot, and better able to judge in this respect. With regard to keeping the soil on the wall, a good plan is to obtain turves, and secure them in a position against the wall by stretching wire-netting over them. You can introduce pieces of peat, &c., beneath the netting and thus form an excellent nidus for the plants. The whole need not protrude more than an inch or so from the surface of the wall. You will need "battens" at intervals on which to fasten the wire-netting. This is a cheap and ready method, and one that can be performed by yourself. If your employer is willing to bear the expense, and wishes for more elaborate work, there are firms who will cover the wall with a kind of rock-work, with "pockets," &c., suitable for planting the Ferns. This system would produce a better effect.

NAMES OF FRUITS: *H. A. R.* 1, Cox's Orange Pippin; 2, Dumelow's Seedling (Wellington); 3, Ribston Pippin; 4, Lincoln Pippin.—*W. D.* Miller's Glory.—*J. H.* 1, Uvedale's St. Germains; 2, Tardive de Mons; 3, Striped Beefing.—*Derby.* 1, Queen Caroline; 2, Old Hawthornden; 3, London Pippin; 4, not recognised from the deformed fruit received; 5, Castle Major; 6, Warner's King; 7, Greenup's Pippin; 8, Tower of Glamis.

NAMES OF PLANTS: *C. J., Sussex.* Epidendrum atropurpureum, commonly called Epidendrum macrochilum album in gardens.—*A. R.* 1, Oncidium tigrinum; 2, O. varicosum; 3, Phalænopsis speciosa; 4, Stanhopea insignis; 5, Zygopetalum maxillare.—*Formosa.* 1, Pteris cretica; 2, Adiantum gracillimum; 3, Pellæa rotundifolia; 4, Selaginella cæsia.—*H. N.* 1, Probably Cedrus Deodara; 2, Cryptomeria japonica; 3, Cupressus thyoides; 4, Abies Nordmanniana; 5, Sequoia gigantea (Wellingtonia); 6, Thuya orientalis variety.

NOTICE TO LEAVE: *Ignorance.* It might only be necessary to give a week's notice in your case; but as you are paid fortnightly you would be better advised to give a fortnight's notice.—*Clifford* and *J. R. R. G.* It is usual to give and receive a month's notice, but as no agreement exists and you have been paid weekly, a week's notice is all you can claim. In the case of a head gardener the requirements would be different, and longer notice would be required.

ONION DISEASE: *G. T.* The diseased Onions with the crowns blackened and rotten are in a condition that is far too common. The disease attacks almost any kind of bulb, especially those of Hyacinths and Onions. In your case small lumps or "sclerotia" are being formed in the rotting parts. In the following season they would produce a small Peziza, called Sclerotinia bulborum (see *Gardeners' Chronicle*, vol. xvi., 1894, p. 160). There is no cure when the disease is established. All that can be done is to burn all diseased bulbs which can be found, in order to prevent the disease from spreading, as the sclerotia will hibernate, and be capable of germination after resting for two or three years. *M. C. C.*

SEEDLING ORANGES: *Constant Reader.* There are two ways in which these fruit-trees can be propagated, viz., by budding and by grafting. Budding is the most simple plan, but should not be done until the first week in July. The process is identical with that of budding fruit-trees and Roses. After the trees are budded they should be placed in a somewhat shady position and watered whenever necessary in order to cause the sap to flow freely. Grafting should be done during the first or second week in March. The best kind of grafting for Oranges is "side grafting." Cut down the trees to the required height, and select a scion about half the size of the stock. The scion should be securely tied to the stock with worsted, or if the tree forming the stock is extra large some untwisted soft string may be used to advantage. Bast or raffia should on no account be used. Grafting wax sufficient to cover the top of the stock and scion should be applied to the graft in order to keep out water. The grafted trees should be kept in a close place, preferably a pit, and shaded whenever there is sunshine. The temperature of the pit may range from 40° to 45°, but must not be allowed to exceed 50°. After the grafts have formed a good callus the trees may be gradually brought to the light and the shading discontinued. The grafts need not be untied until the autumn, unless the tying material is found to be cutting into the stock. If you intend to use your seedling trees as stocks it will be necessary to obtain scions of good varieties from a nurseryman. Probably Messrs. Rivers & Son, Sawbridgeworth, would be able to supply you. *J. B.*

STANDS FOR GRAPES: *G. W. W.* The recognized size for Grape stands is as follows:—12 inches at back, 1 inch at front, and 12 inches at base from back to front. The width of the board is generally left to be determined by the exhibitor, according to the size of the bunch or bunches.

TREE CARNATIONS: *A Beginner.* See the note on this subject in the weekly Calendar "Plants under Glass," on p. 38.

VEGETABLE TRAYS: *G. W. W.* The usual size of the trays for exhibiting vegetables are as follows:—For six kinds, 4 feet by 4 feet; for nine kinds, 5 feet by 4½ feet; and for twelve kinds, 6 feet by 4½ feet.

CONIFERS AS RECLAIMERS OF WASTE LANDS.

PERHAPS there is nowhere a more desolate and uninviting piece of land for planting than the many hundreds of acres now lying waste in the mining division of Cornwall. Between Truro, Hayle, the Bristol Channel, and Mount's Bay, and eastward from it, extending in a zigzag line almost to Falmouth, there lie indications of mining operations which have been carried on from time immemorial. The more modern workings appear the more desolate. The ancient, either by Nature's own hand or by human agencies, have become covered by vegetation. The newer workings are at present unmistakable. Some of the valleys have proved capital dumping places for the *débris* hauled up from the adjacent mines. In others this waste has been conveyed some distance from the shaft's mouth and thrown into great heaps known locally as "burrows." This *débris* consists chiefly of varieties of granite of several different shades and textures. "Elvan" and slaty formations are also met with and excavated from these vast subterranean mines. In addition to these broken rocks there are huge burrows of ashes, cinders, and other foreign material. These all go to account for the colour in the landscape, so that on a clear day there may be seen a feature which is not altogether sombre. In this parish (Gwennap) there is at least a square mile where there is not a single plant growing! In other places there may be seen solitary specimens of Calluna vulgaris, species of Ericas, and Gorse; and these appear first where the ashes from the engine-boilers were thrown, then on the elvans and on soft clayey material which is washed out of the granite.

In 1864 E. Beauchamp-Beauchamp, Esq., came into possession of Trevince, which was at that time in the centre of a copper and tin mining industry. He at once fenced in about one hundred acres of wretched stone-bestrewed and in many instances, so far as plant-life goes, poisonous mine-land, and planted Scotch Fir, Larch, Pinus austriaca and P. insignis. Spruce were not planted with the above-named species, as is usually done. Now it must be remembered that disintegration and decomposition go on at various rates, that rain falling washes away iron and copper in solution (by the way, the average rainfall here for seventeen years is 42 inches), and that frost does its part in breaking down these materials to form soil. The plants were planted when about one foot high. Curiously enough, those taken from the seed-bed started to grow sooner, and a smaller percentage of them died than of those that had been previously transplanted. The ground was not dug or any preparation made for planting beyond driving a pick into the ground three times to make a triangular loosening; after this the plants were put in behind the spade. Those planted forty years ago have now reached heights varying from 40 to 55 feet. It must have taken some courage to plant what was literally a "howling wilderness." To-day there is a fine game covert and a splendid shelter. Thinning has been carried out sparingly around the sides, but more thoroughly in the centre. Pontic Rhododendrons have been planted as an undergrowth by the hundred, and in May and June an acre of these plants in bloom is a sight not soon forgotten. Various shades of colour are found among them. Seedlings are to be found in thousands growing in the sides of cuttings which used to be watercourses, and a smaller number on flat ground. These are taken up and planted in the nursery and grown on until they are about 2 feet high. The Pine leaves, the leaves of the Rhododendrons, and the decaying parts of the other plants (Ivy, Heaths, &c.) have assisted the atmospheric agencies to such an extent that what was once a wilderness has indeed become a garden.

There is no doubt whatever that this land, when this crop of wood is taken off (with, of course, the necessary levelling of the smaller burrows), will become good agricultural land in a much shorter period than if this *débris* were left to atmospheric agencies alone. When such a transformation takes place, one is led to question the causes which have contributed to it. The soil—if soil it can be called—is about the last that a planter would choose. Where rocks are mechanically broken up, there will always be bits which are extremely angular, and the question is: Do these edges—some of them sharp, and hard enough to cut glass—induce roots to increase in number? If this is so, this, with increased facilities to take up food dissolved out of the granite, will account for the success attending these plantations.

Narrow belts of trees are not advised, because of the prevalence of strong winds; it is better to plant a considerable area if possible. The last piece planted here is triangular, and measures 21 acres. Larch from about thirty years old and upwards are usually decayed in the middle; when felled, you may pull out handfuls of spongy, fibrous material from the centre of the trunk. Whether this is due to the soil, or a disease of the plant itself, is a question for older planters than the writer. The younger trees make excellent poles for fencing, &c. None of the other species show any signs of disease; they all produce good timber. *H. W., Trevince.*

NEW OR NOTEWORTHY PLANTS.

STAPELIA DIVERGENS, N. E. BROWN (*n. sp.*).*

THIS is a very distinct species, belonging to the same group as S. variegata, and is very similar to it in the general appearance of the stems, although the flowers are quite different, the unspotted rim of the annulus and the widely divergent tips of the outer coronal-lobes being very characteristic marks of the species. It seems to be a rare plant, as I have only seen it twice—the first time about fifteen years ago, and this autumn it has flowered in the garden of Sir Thomas Hanbury at La Mortola, from which latter plant the description in footnote is made.

* *Stapelia divergens.*—Stems 1½—3 inches high, often decumbent at the base, 4-angled, ¼—½ inch square, glabrous, green or purplish; angles rounded, with conical, spreading teeth, 1½—1½ line long, usually with a minute denticle on each side of the acute withering tips. Flowers 1—4 in a fascicle, successively developed near the base of the young stems. Pedicels 1—1½ inch long, glabrous. Sepals 2½ lines long, 1 line broad, ovate-lanceolate, acute, glabrous. Corolla, when in bud, shortly conical, acute, from a broad, flattened 5-angled base; when expanded about 2 inches in diameter, nearly flat, with a raised central annulus, very minutely ciliate with simple hairs all along the lobes, otherwise glabrous on both sides, slightly rugulose on the inner surface; lobes about 9 lines long and 7 lines broad, deltoid-ovate, very acute or acuminate, light yellow, labyrinthically marked on the lower two-thirds (as well as on the disc of the corolla) with thick, irregularly-ramified brownish-crimson lines, the markings on the apical part becoming broken up into spots; annulus about 1⅓ line high, nearly circular, with a horizontally spreading (scarcely recurved) rim, bright canary-yellow, marked in the basin-shaped rugulose depression with rather crowded small round brownish-crimson spots, which are absent from the smoother rim, underneath the margin of which is a crenated band of connected brownish-crimson spots. Outer coronal-lobes ascending-spreading, 2 lines long, 1 line broad at the base, 2—2½ lines broad across the tips of the two subulate, straight, widely divergent points into which they are divided for two-thirds of their length, pale yellowish, dusted with dark crimson-brown on the points, with a triangular spot at the base of the notch and a square spot of crimson-brown at the base. Inner coronal-lobes 2-armed, pale yellowish, dusted with dark crimson-brown; outer arms 1⅓ line long, erectly spreading, compressed-filiform, very slightly thickened (not distinctly clavate), and very minutely tuberculate at the apex; inner arms 2 lines long, filiform, clavate, and minutely tuberculate at the apex, connivent at the base, then erect with recurving tips. Origin unknown; probably a native of South Africa. *N. E. Brown.*

KYLEMORE CASTLE.

THIS edifice, one of the seats of his Grace the Duke of Manchester, is situated in the heart of Connemara, Co. Galway. It is about 175 miles from Dublin, whence the visitor must proceed by the main line of the Midland and Great Western Railway of Ireland as far as Galway, and thence by the Company's branch line to Clifden, the capital of Connemara. The Castle is situated in a beautifully chosen position at the foot of the Doughruagh Mountain, and stands on a wide terrace at the north-west corner of Lough Pollacapul, the site commanding a remarkably grand prospect of Kylemore Pass, being bounded by a majestic amphitheatre of mountains, the acclivities of whose sides slope to the water's edge of the loughs beneath.

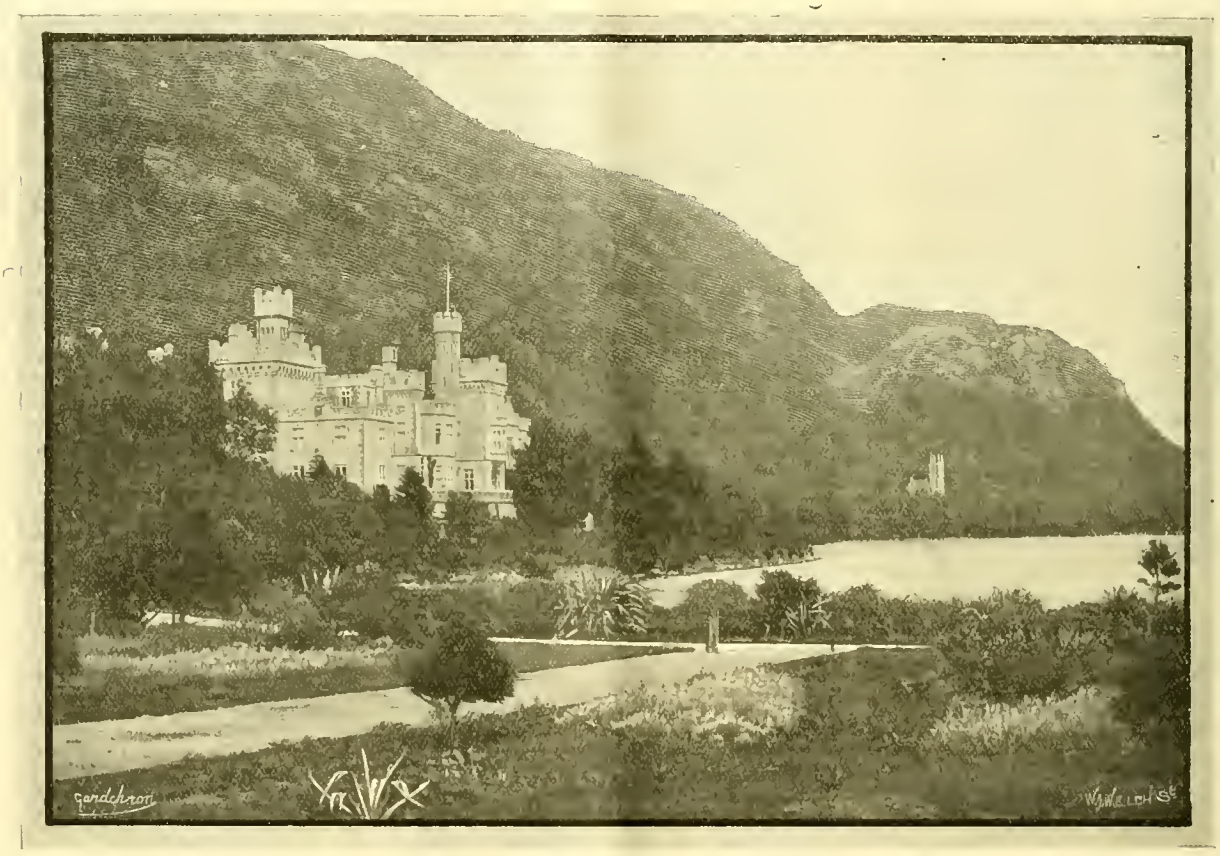

FIG. 25.—KYLEMORE CASTLE, CO. GALWAY.

The Castle is in the Scottish barouial style, and has its principal façades faced with cut Kingstown granite. The policies are intersected by a winding carriage-drive about 2 miles in length, traversing in its course the lower portion of a beautiful hanging wood rising and falling in succession by easy gradients, and skirting in its course Loughs Pollacapul and Maladrolaun, and bordered for the entire distance by a great variety of Rhododendrons and other ornamental shrubs, interspersed with clumps of Pampas Grass and New Zealand Flax. The two last-named plants grow most luxuriantly, the deep, free, bog soil, combined with a mild temperature and humid atmosphere, suiting them admirably, as it also does other comparatively scarce ornamental plants. We measured one clump of Phormium tenax, grown from a single plant, and found it measured 21 feet in diameter and 10 feet 4 inches in height, while on one plant of Pampas Grass we counted fifty-five plumes or panicles. There are two distinct varieties of the Pampas Grass at Kylemore, the well-known Gynerium argenteum, and a seedling variety that flowers a month or six weeks earlier than the ordinary form.

Amongst the shrubs we noted the following: Berberis stenophylla, one specimen of which measured over 11 feet in height and 20 feet in diameter; Escallonia macrantha in great profusion, and a variety said to be E. coccinea, a specimen of which measured over 12 feet in height and over 15 feet in diameter. There are also good specimens of that attractive evergreen shrub, the shore-loving Griselinia, G. littoralis, the specimen we measured being over 15 feet in height. Euonymus latifolius, Olearia Haastii, Arbutus Unedo, Acacia dealbata, Leycesteria formosa, Hydrangea Hortensia, H. H. stellata prolifera, &c., are all growing in profusion and in good form.

Immediately to the east of the Castle, on a lawn in front of a large orchard-house, we noticed a fine specimen of Cordyline australis, 22 feet high; there is also a good example of Eucalyptus robusta, 50 feet high. The Blue Gum (Eucalyptus Globulus) was not planted here till 1896, but specimens about 3 feet in height planted at that time have already attained a height of 15 feet. On this lawn we also noticed a fine specimen of Phormium tenax variety, turned out of a pot only three years since.

Skirting the main avenue, and a little to the west of the Castle, is the pinetum, planted on a piece of reclaimed bog land; and here a great variety of Conifers is in excellent condition. The different varieties of Cupressus Lawsoniana have been planted freely, and are of heights varying from 15 to 30 feet. We found a specimen of Cupressus gracilis pendula measuring 20 feet; a fine, healthy plant of Abies polita measured over 21 feet, whilst a specimen of A. ajanensis was found to be 18 feet in height. Cryptomeria elegans, Retinospora plumosa, and R. p. aurea are also represented by specimens 10 to 18 feet high, and furnished with branches to the ground. A striking feature at one end of the pinetum is a clump of hybrid Rhododendrons, 72 yards in circumference and 20 feet 3 inches in height at the centre.

Among the varieties of the taller coniferous trees planted alongside the avenues and throughout the grounds, Pinus insignis, P. austriaca, and Cupressus macrocarpa form the leading features. None of these have been planted more than thirty years, but some of them are fine specimens considering their age. One tree of Pinus insignis which we measured was found to be 8 feet 9 inches in girth at 3 feet from the ground, and numerous specimens of Cupressus macrocarpa are from 40 to 50 feet high, many of which are laden with cones.

The gardens are situated about a mile westward from the Castle, and are intersected by a broad walk or carriage drive. The flower-garden consists of two gentle grass slopes on either side of the central walk, and these are laid out with flower-beds in several geometrical designs, and interspersed with specimens of Pampas-Grass, Gunnera manicata, tall permanent plants of Cordyline australis 15 to 30 feet in height, Aralia chinensis, A. Sieboldii, Hydrangea Hortensia, and H. H. stellata prolifera. Space forbids going into detail, but we noted some of the leading features. At the date of our visit in the second week in September several small circular beds of Sedum spectabile at once arrested

the eye, they were one mass of rosy-pink colour, and the symmetry of the beds was perfect. A large oblong bed of Fuchsia Rose of Castile was also very pretty. These plants had not been moved for several years, and as a consequence were fine specimens, and were smothered with flowers. Several beds of Fuchsia Monarch (a dark self), growing under similar conditions, were also very effective. Two isolated beds of Veronica Andersoni var., permanently planted, were pretty, they had been smothered with their pale blue flowers, but their rich, creamy, variegated foliage was sufficiently telling of itself. Four large L-shaped beds, planted alternately with Anemone japonica and A. j. alba, were full of flower. A bold effect was produced by a large crescent-shaped bed filled as follows—the back with Hydrangea Hortensia, the centre with Dahlia Glare of the Garden, and the whole edged with Chrysanthemum Golden Shah, Lobelia cardinalis, Begonias, Pelargoniums, Gladioli, &c., were all planted with good effect. Florists' flowers included collections of Roses, Carnations, Pentstemons, &c.

The glasshouses, which number over twenty, are spacious and well furnished. In the Palm-house we noticed healthy specimens of Kentia Belmoreana and K. Fosteriana, Phœnix rupicola and P. reclinata, Latania borbonica, Euterpe edulis, &c., whilst the side stages were well furnished with such subjects as Hippeastrums, Dracænas, small Palms, large, well-flowered specimens of Cypripedium insigne, &c.

In a lofty conservatory were fine specimens of Sabal umbraculifera, Dicksonia antarctica, Strelitzia Reginæ, Camellias, &c., the rafters being furnished with climbing Roses, Plumbago capensis, Pleroma macranthum, Bougainvillea speciosa, &c. In this house we also noticed a batch of Streptocarpus of fine strain.

The Banana-house, which measures 72 feet by 26 feet, is well stocked with healthy plants of the ordinary variety Musa Cavendishii, these being planted in a bed along the centre of the house. The plants were fruiting freely. The rafters were furnished with such subjects as Clerodendron Balfourianum, Cissus discolor, Begonia President Carnot, several varieties of single and double Hibiscus, Allamandas, &c., whilst the side stages contained a miscellaneous collection of stove plants.

A lofty span-roofed plant-house had the central stages entirely filled with plants of a good strain of carefully-selected single and double Begonias, whilst the side stages were entirely occupied with Malmaison Carnations, which looked the picture of health.

FIG. 26.—THE WATERFALL IN THE GROUNDS AT KYLEMORE CASTLE.

The corridors connecting the various houses were well furnished with climbers and other plants; the former embraced Acacia Baileyana, Clianthus puniceus, Begonia grandiflora, Swainsonia galegifolia, Pleromas, Tacsonias, Roses, &c.

Two lofty cool ferneries had their back walls covered with Ferns and Mosses, the body of the house being treated with real rockwork, forming arches and other designs and planted with a variety of Ferns, foliage Begonias, &c., interspersed with specimen Palms and Tree Ferns. A span-roofed stove contained a good collection of Codiæums, Caladiums, winter flowering Begonias, Pandanus Veitchii, &c.

Of fruit-houses there are a considerable number. One vinery was chiefly filled with Muscat of Alexandria Grapes, the canes bearing a good crop and the fruit well finished considering the external atmospheric conditions. Another vinery, 90 feet in length, contained the varieties Mrs. Pince's Muscat, Royal Muscadine, Royal Vineyard, Madresfield Court and Gros Maroc. A lofty house had a very good crop of Black Hamburgh, and a companion house was filled with young healthy plants of Bowood Muscats.

Peaches and Nectarines are grown in quantity, many houses being devoted to these fruits. The crop was partly gathered at the time of our visit, but the samples we saw were of excellent quality. The varieties of Peaches grown are Prince of Wales, Princess of Wales, Noblesse and Royal George, and of Nectarines, Milton, Downton Improved, Stanwick, Elruge, Byron, Violette Hative and Pine-apple.

In the Melon-house a good second crop was being gathered, and in the centre of this house we noticed good specimens of Begonia Gloire de Lorraine and B. Turnford Hall, also a collection of Codiæums, Caladiums, &c.

A large Tomato-house was furnishing an excellent crop. The variety Stirling Castle is chiefly grown for ordinary purposes, but the Peach Tomato is largely used for dessert.

There are extensive and well-stocked kitchen-gardens, and an orchard; also a long herbaceous border in the kitchen-garden containing an up-to-date collection of this deservedly popular class of flower. There are also fine hedges of Escallonia macrantha, and of a variety of Fuchsia; the latter is said to be F. exoniensis. We did not recognise it, but it is certainly distinct from F. Riccartoni, although of the same type. Both in the grounds and alongside the neighbouring highway there are miles of this Fuchsia, forming a source of much pleasure.

FIG. 27.—PHORMIUM TENAX IN THE GARDENS AT KYLEMORE CASTLE.

Mr. Wm. Comfort, the head gardener at Kylemore Castle, is naturally an enthusiastic horticulturist, as he is descended from a race of gardeners; and his four brothers, like himself, all followed their forefathers' calling. *C.*

SOME NOTES ON FORCING VEGETABLES.

(*Concluded from p.* 36.)

FRENCH BEANS are more costly to force than Asparagus, and from December until the end of January the returns that can be obtained from them are not worth the space they would occupy. This at least is so in this part of the country, but near the coast better results may be possible. The plants require much sun-heat in addition to artificial warmth, and sun-heat is very scarce in January. I have frequently had more pots in January than pods, and yet every care was taken to secure a crop. With the lengthening days there will be a better chance, and the plants will give a really good return. The present is a good time to sow seeds in pots or heated pits for furnishing supplies in early spring. Choose a quick-growing variety and one that produces pods of good size. In

many gardens pots are used largely, and they are convenient, but where a pit with bottom-heat can be spared for the purpose the plants crop grandly. It may not be necessary to sow the seeds in their growing quarters, as if sown in small pots and planted out afterwards they succeed well. We sow seeds every week from now until the end of April or even later.

PEAS.

All gardeners cannot spare space for the cultivation of Peas in frames or pots, and the return is not equal to that yielded by Beans, at the same time if a good variety for forcing is chosen the crop is an appreciable one. For years, when I had a limited quantity of glass only at my command, I grew this crop at the front of a Peach-house, and got a good return, the variety being American Wonder. Now there are much better varieties, such as Chelsea Gem, Sutton's Ideal, and May Queen. We also find Carter's Daisy a most valuable forcing variety, though a little later than those named. It is a splendid cropper. There is a great gain by growing a dwarf Pea in frames, as grown thus the plants are near to the glass. Peas will not stand severe forcing, for if too much heat be employed the haulm becomes weakened at the base and doubles over. For culture in frames or pits seeds sown now will give a good return a month earlier than the first crop in the open garden.

CHICORY.

On the Continent forced Chicory is a favourite winter vegetable, but in this country it is mostly grown for use as a salad. The new growths when about 4 inches long, before the leaves expand or open out, are the portions used. Chicory needs but little forcing. If put in a dark place where there is an atmospheric temperature of 50°, this will be ample; and I have seen excellent samples that have been cultivated in cellars. The roots used for forcing are grown in the previous season and stored in a cool place till required for forcing. In the southern part of the kingdom they require but little protection; the Witloof or Brussels Chicory gives a much finer growth than the common or Barbe de Capucin.

ROOTS.

Under this heading forced Carrots and Turnips are important spring crops, the former requiring a longer time to mature, but both are much appreciated when grown quickly. We get our earliest supplies from heated frames, but these are not of the best quality; the best are grown in hot-beds largely composed of leaves, as these retain their warmth a longer time, and on the beds we place frames. The latter part of January is a good time to make up beds. Avoid using too much bottom heat; far better place the heating materials in bulk for a time, and, by frequent turnings over, allow the rank steam to escape. Sutton's Inimitable Forcing Carrot is the earliest I have grown; it is a small, globe-shaped root, and of most delicate flavour. Early Nantes and Early Gem are both good forcers, but any kind grown under glass should be sown thinly and in good soil.

Turnips mature quickly and need but little warmth. If given very much heat top growth becomes too rapid, and the roots suffer in consequence. In France these roots are largely forced for supplying the Paris markets; the long roots, not unlike a large Radish, find most favour for early supplies. We grow Carter's Early Forcing and Sutton's White Gem; these are much earlier than the globe-shaped roots, and though not so good for keeping, they are valuable for cultivation in frames and warm borders.

Potato culture under glass should now be given attention, and in many gardens the tubers are grown in pots. *G. Wythes, Syon House Gardens, Brentford.*

BOOK NOTICE.

A GARDENER'S YEAR: By H. Rider Haggard. Illustrated. (Longman, Green & Co.) 8vo, pp. 404, 12*s.* 6*d.*

As week by week the substance of this book was issued in the pages of the *Queen*, we could but be struck with its superiority to the ordinary productions of a similar class. Indeed since the publication in our columns of Mr. Bright's "Year in a Lancashire Garden," the parent of so many other like works, we have not come across a book which, judged from a gardening point of view, is so satisfactory. It does not profess to be a text-book, but it is a clear and thoughtful record of the author's doings during the year 1903.

It starts with an introductory chapter descriptive of the garden, its adjuncts and of the author's co-workers. We use this expression because it is evident that the writer not only writes of his garden but works in it. Where employer and employed work in this way together the result is generally good.

"It is not in the grandest places," says the author, "where most money is spent, that the best gardeners are always found, but rather, I believe, in those where the employer takes a lively personal interest in what goes on from day to day, and is in constant consultation with his servant or servants, how to attain the greatest measure of success of which his means and circumstances admit. Thus sympathy and co-operation are established which are often lacking when the bond is one of money alone. . . . In this matter they become friends, the link between them being the welfare of the plants and flowers in which they take an equal pride, and the result of that friendship is on the part of the master kindness and consideration, and on the part of the man, service, not of the lip or eye, but of the heart. Would that it were thus in every business!"

Although the general principles of cultivation in the case of Orchids are the same as those which, with the requisite modifications according to circumstances and special requirements, should regulate the growth of plants in general, yet we find Mr. Haggard saying that he would rather hire a man who had never seen an Orchid than a "new head who 'understands Orchids'! Better far take a novice who is willing to learn and train him." This savours of sarcasm, but it illustrates our statement that the author is a worker as well as a writer.

After this exordium we begin with the first of January and we are conducted day by day to the end of December. Each day's operations are recorded, with occasional comments and thoughtful remarks, which betoken not only the garden-lover but the accurate observer. The year 1903 was, it will be remembered, one of the most dismal on record, and for fruit absolutely the worst, and yet the author found his garden "as delightful as ever to work and wander in, and even to describe." With such a spirit it is no wonder that the gardener found his garden in better order than it was at the beginning of the year, and that good progress was made. We should like to make several extracts from this delightful book, but space, or the want of it, compels us to refrain. We must, however, indicate the passages relating to Kew, to the Temple Show, to Messrs. Protheroe & Morris's auction room, as specially interesting to readers at a distance.

Like most people, Mr. Haggard girds at the names given to plants, whether in scientific jargon or in misleading vernacular. Indeed, the book shows that in this one particular the proofs have not been revised, or we should not read of "Eremuri Robustus," "Aralia Chinensis Pyramidilis" (whatever that may be), "Vandas Teres," "Angræcums Eburneums," and other similar distortions.

We have little doubt but that a new edition will be called for, and that will afford the opportunity for correcting these minor flaws. The plant described on p. 242 as belonging probably to Sarraceniaceæ seems rather to have been a Drosera or Sundew, such as often makes its appearance in the sphagnum. The book is prettily illustrated, has a good index, and may be commended to the garden-lover as a most serviceable and suggestive guide.

MARKET GARDENING.

EVESHAM GARDENERS' VISIT TO PARIS.

THE visit of a party of Evesham market gardeners to Paris last week cannot but have a beneficial effect upon this industry, not only in the Vale of Evesham, but throughout the country. The idea was started in a letter from Mr. C. D. McKay, of the firm of Watkins & Simpson, which appeared in the *Evesham Journal* a few weeks ago. The result of the letter was a public meeting, at which a committee to organise the trip was appointed, with Mr. John Idiens, of the firm of John Idiens & Sons, Ltd., Evesham, as hon. secretary. The visit took place last week in bitterly cold weather, and it is certain that, at this time of the year at any rate, the French gardeners have no advantage over the Evesham men in point of weather. The gardens of Vitry-sur-Seine were first visited, and it struck me that there was considerably less protection here against the wind than at Evesham, where the hills and woods form a natural wind-break. Most of the Vitry gardens, which are small, are enclosed by stone walls, and it is odd that these walls are not utilised, as they would be in Evesham, for fruit-trees. As a matter of fact, we saw no fruit trees at all. Our object in visiting these gardens was to get an insight into the way the Frenchmen grow Lettuce and other vegetables under glass, to supply the Parisian and London markets. In this we were successful, thanks to the trouble Mr. McKay had taken to ensure that we should go to the right districts and have efficient guides. We found the French gardeners most willing to give us all the information in their power, and thus we learnt a great deal. The growing of these Lettuce does not seem to be a very complicated matter, and depends, after all, upon the preparation of the seed-bed, at which work the Frenchman is a past-master.

The natural soil of Vitry is not so rich as that of Evesham, but it has gone through such a prolonged period of preparation that it is next to impossible to find any natural soil. The system adopted is as follows: all the top soil is removed from the spot where it is intended to form the bed, and then a thick coating of stable manure is placed therein. Upon this again is placed a coating of the prepared soil, and then the Lettuce are planted. As soon as the crop has been cleared, the whole of the manure and soil is taken away, made into mounds and allowed to thoroughly rot for a year or more and is then used again as the prepared soil. From this it will be understood that the work of providing suitable soil is continually going on.

The frames in which the plants are grown are about 13 feet long and 4 feet 6 inches wide, standing 9 inches at the top and 7 inches at the bottom. There are three lights, and we were told that the cost of the whole is about 13*s.* They can be secured for less money in England, and indeed any man with a knowledge of rough carpentry could easily make the frames during the winter months. The frames are filled with the Cabbage or flat Lettuce, and those we saw last week were in various stages, so that when one batch is cleared another lot will be coming on. Radishes and Carrots are also grown in the frames, and these will be ready in rotation after

the Lettuce. There is no artificial heating of the frames except that which is provided by the manure, and the lights are covered with straw mats, which are made by elderly men and boys in the gardens. These mats are composed of Rye straw, and are exceedingly well made. Similar ones might with advantage be introduced into Evesham for the purpose of covering Radish-beds and frames, thus replacing the loose straw and the dirty bags which are so untidy and wasteful. Cos Lettuce are grown under cloches or bell-glasses, of which we saw a very large quantity. They are transplanted three times. In the first place, six or ten are placed under a cloche, and then when they have made sufficient growth half that number is taken away, and at the last move one only is placed under the bell-glass, but so that no space shall be wasted each is surrounded with four of the flat variety. Water is essential, and this is supplied by means of a large tank in each garden, whence it is distributed to all parts of the garden. The expense of sinking a well and laying down a pumping apparatus would not be necessary in Evesham and many of the villages round, as the public supply would be available at a small yearly outlay. Ventilation, too, is very necessary, and early Lettuces can only be procured by the exercise of constant care and attention.

One of the gardeners told us that his outgoings on a garden of not more than 2½ acres was £600 a year, and few of our local gardeners have such a heavy outlay. Despite this, and of the fact that the freight from Paris to London is about 80*s.* a ton, as compared with about 25*s.* from Evesham, they are able to supply the London market at a profit. The Frenchmen have no advantage over us in point of soil or, if last week be taken as a criterion, in climate. They may score off us in that they have stable-manure nearer to them; but they have to fetch it from Paris, 8 miles, and Evesham could easily obtain it from Birmingham and London. What a pity it is that our waterways have become derelict! for the canals and rivers would be most useful for the carriage of this stuff and for lowering of railway rates.

In one of the gardens we saw an Asparagus-bed where the roots were all exposed to the weather—a very different system to that usually carried out in the Evesham neighbourhood, where the plants have been bedded-up for some time. The French beds will soon be covered up, but before this is done the roots will be covered with a coating of stable-manure, and then the soil will be replaced a little at a time. The crowns we saw certainly looked very strong, and were of great size. The system in vogue is to plant the beds when the plants are two years old, and not when a year old as here; to let them lie idle for a year, and to start cutting when they are four years old, and not three as at Evesham. The practice of exposing the roots and manuring them has been carried out with great success by a few gardeners round Evesham, but it is by no means general.

One great point which impressed itself upon all who paid the visit was that it is no use producing a crop unless it is sent to market in an attractive form. The markets at Paris and Covent Garden were visited, and the Evesham men there saw how their foreign and English competitors heat them in the packing and grading of their produce. This has long been one of the failings of the Evesham grower. No one can get better crops from the land, but in consequence of careless and untidy packing the produce very often fails to realise anything approaching its value.

It is hoped to organise further trips to the fruit districts of France, Germany, Belgium, and Holland, and arrangements are in progress for the first visit, which will be to the Black Currant district of France about the middle of May. These Currants are one of the most remunerative fruit crops if a good yield be obtained, but the bushes bear so seldom that comparatively few are grown round Evesham. We are told that under the system employed in France failure is the exception; so let us by all means find out how it is done. *One of the Party.*

CHRYSANTHEMUMS.

I AM sending you a photograph (fig. 28) showing our Chrysanthemums here. The stage is about 2 feet 6 inches from the ground, and there are hot-water pipes under it, therefore the only way we can manage to display our Chrysanthemum-plants is to tie them down to form a bank. Some of the plants were 7 feet high, and all over 5 feet this season. We have to bend them down to cover the pots, then slope them up to the glass at the back, which would be about 2 feet 6 inches from the stage. It is a delicate task to tie them down, as the growths are apt to snap; but anyone having a stage like ours may profitably tie the plants similarly when they are in flower. There are 100 pots. We generally put two plants in a pot, or three in 12-size pots, in case one plant should break in the bending; and it is easy then to lay a plant each way, so that the colours may be mixed. *W. C. Smith, Ecton Hall Gardens, Northampton.*

FIG. 28.—TRAINED CHRYSANTHEMUMS.

ORCHID NOTES AND GLEANINGS.

CATTLEYA LABIATA SPLENDENS.

A VERY large and richly coloured flower of Cattleya labiata is sent by F. W. Moore, Esq., Royal Botanic Gardens, Glasnevin, Dublin, who remarks that it is by far the best of its class which he has seen. The sepals are broad and flat, and the crimped-edge petals rather over 2½ inches in width. Both sepals and petals are of a bright rosy-mauve colour, with a small silver-white base to each segment. The side lobes of the lip are of the same colour as the petals, the broad front being ruby-purple. There are fine yellow lines on the reddish base of the lip on the inside. It is a very excellent form, and few flowers can compare with it for bright colouring at this season.

"THE ORCHID REVIEW"

for January gives a general summary of the events of the past year, so far as they concern Orchidists. Mr. Wrigley denounces the fog fiend from Bury, so that it is evident that growers in the neighbourhood of London are not alone in their grief. Mr. Francis Wellesley and Mr. Rolfe contribute jointly a very interesting paper on Cypripedium (§Paphiopedilum) Fairrieanum, its history and the hybrids derived from it. We await the continuation of this note with interest.

WINTER FLOWERS IN THE SOUTH-WEST.

FLOWERS in the open-air are few in the dull days of winter, and such blossoms as greet us in dark December are welcomed with a delight that would doubtless be much modified, if not altogether absent, did they attain perfection amid a host of floral beauties in sunny June. A few, however, are lovely enough to hold their own against strong competition, and dwellers in the favoured south-west are often enabled to admire, in the depth of winter, the beauty of the blossoms of tender shrubs and plants that in colder districts would perish in the open-air.

Christmas Roses, with their extended period of bloom, have provided flowers uninterruptedly for many weeks, commencing with Helleborus altifolius or maximus towards the end of October, and continuing with their various forms, such as the Bath, the Riverston, and the Brockhurst varieties, then the two forms of H. angustifolius, or St. Brigid's Christmas Rose, Apple Blossom, and Madame Fourçade, some of which will blossom well into February, when the Lenten Roses will commence their display. From November onward the Winter Jasmine (J.nudiflorum) has graced rock, trellis, and arbour with a golden maze of slender, flower-laden shoots. The Winter-Sweet (Chimonanthus fragrans) was in flower at Christmas. When trained against a wall, as is generally the case, it has no decorative value, and is only useful for providing its sweetly-scented flowers for the house; but in the south-west, where it is often grown in bush-form in the open, it is attractive. One specimen, growing on a lawn and backed by a spreading Yew, is 8 feet in height and as much through, and is a pretty sight when in full flower, the pale yellow blossoms, borne in profusion, showing up well against their dark setting. In the same garden is another example that is fully 15 feet in height, and has formed a small tree with a spreading top.

In the first week of January the Glastonbury Thorn, of legendary lore, opened its first flowers; but this is sometimes in bloom as early as November. Some of the shrubby Veronicas, especially a handsome variety bearing rich rose-crimson flowers, have been in bloom through the entire winter, and in January a few scattered blossoms, white and red, still remained on Lapagerias growing against north walls. Every morning as I look out of my window I see the yellow flower-spikes of Cytisus racemosus, though some twenty miles distant large bushes have been completely killed by 18° of frost. Three days before Christmas I picked the first flowers of Clianthus puniceus from the open wall, but the earliest blossom of the white variety, growing hard-by, will evidently not expand for another month. The white variety of Daphne indica is in flower, and in another week Prunus Davidiana alba will expand its first blossom. The quaint Hamamelis arborea, to my mind the most decorative of the Witch Hazel family, has perfected its curious flowers, the narrow petals of which before they expand look like rolls of ribbon, and when open have the appearance of twisted strips of gold-leaf. With even the smallest shoots thickly set with these singular flowers, a bush is a very attractive sight.

Lonicera fragrantissima, a bush Honeysuckle, has every shoot crowded with small, ivory-white, sweetly-perfumed flowers. This will grow to a height of 6 feet, and with the Prunus and Hamamelis, is perfectly hardy. Coronilla glauca, in full flower in November, retained many of its blossoms until after the New Year, but the last flower-head of Eupatorium micranthum, better known as E. Weinmannianum, faded in the second week in December, and the flower-panicles on the great bushes are now covered with fluffy grey down. Garden banks are bright with colonies of Cyclamen Coum and its varieties, deep rose, pale pink, and white.

In the first week of January the Winter Aconites showed their flowers, on a dull day globes of gold set in Elizabethan ruffs of foliage, but in a sunny hour widely expanded. The lovely Algerian Iris stylosa or unguicularis is perhaps our most valuable winter blossom, for, from the end of October until the close of March, scarcely a day passes when buds on the point of expanding may not be cut for indoor decoration. These flowers are as welcome for their fragrance as for their beauty, and it is difficult to know which to admire most, the lavender type, the white variety, or the purple speciosa. The plants are most abundant bloomers, a clump a foot across producing fully 200 blossoms in a season. Crocus Imperati opened its first flowers a week before Christmas; it is as great a gem as the autumn-flowering C. speciosus, and is doubly valued for producing its blooms in mid-winter. The tender colouring of the flowers, lavender-mauve within and buff striped with deep purple on the outside, is very pleasing. The charming little Ionopsidium acaule is never out of bloom with me. Self-sown seedlings spring up in the borders, paths and walls, and are never interfered with, except to introduce a fresh occupant to the beds. The Winter Heliotrope (Tussilago fragrans), grown in an out-of-the-way corner, where it interferes with nothing, has provided its scented flowers for the house for many weeks. The first of the Snowdrops has appeared, and Clematis balearica or calycina, clambering over a tree, has displayed the first of its greenish-white flowers spotted with purple in the interior. Small bushes of Agathæa cœlestis still hold some dozens of flowers, and a stray blossom or two are to be found on great plants of Arctotis aspera arborescens, Mesembryanthemum aurantiacum, and the Cape Pond-weed (Aponogeton distachyon). Next month, to all appearance, Acacia dealbata and Erica lusitanica or codonodes will be in flower.
S. W. Fitzherbert.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Chysis bractescens.—These plants having rested in a cool part of the Cattleya-house since the last pseudo-bulbs were developed, now that growth is again apparent should be afforded treatment accordingly. As soon as the new roots are being emitted, any repotting that is needed should be performed. They should be put in pans having about an inch of drainage, using a root medium of two parts peat to one of semi-decayed Oak-leaves and sphagnum-moss, to which should be added some silver-sand and small crocks to keep the whole porous. The above compost should occupy about a third of the pan's capacity, finishing the surface with peat and sphagnum-moss in the ordinary way, so that none of the leaf mixture is exposed. Suspend the pan in a light part of the warm-house for a couple of months, returning the plants after that period to the Cattleya-house, in order to complete their growth. Give water very sparingly for some considerable time after there has been root disturbance, and do not wet the young foliage. C. aurea, with other species and hybrids, need similar treatment to C. bractescens.

Cypripediums.—Though most Cypripediums are of easy cultivation, some species, such as those of the C. concolor section, with C. Drueryi, C. Stonei, C. Sanderianum, and hybrids related to them, offer considerable difficulty. C. concolor, C. niveum, C. Godefroyæ, and the variety leucochilum, should be given a position in the warm-house where it will not be possible for drip or water from any source to lodge in their leaves. The compost around the roots should be kept moderately dry, and when water is needed the receptacle should be immersed nearly to the rim only, taking great care to keep it from the leaves. C. bellatulum will thrive best suspended in the temperature of the intermediate-house. C. Drueryi and the others mentioned need the warmth and moisture of the East Indian-house, and must not be allowed to remain dry for more than a day or two at a time. Many kinds are now in a suitable condition for being potted or top-dressed, and this work may be taken in hand before the needs of other species cause a certain amount of pressure. If the plants are to be repotted, pick out as much of the old material as is possible without disturbing the roots and drainage, and substitute fresh compost. Use moderately large pots, and make them one-half full with drainage material, or even more than half-full in the case of large receptacles. Work the potting materials amongst the roots, distributing the roots towards the sides and surface as much as possible. Make all moderately firm, and finish off the surface neatly, just below the rim. It is not possible to name all the species that need attention, but any plant that flowered during the autumn may now be overhauled. The rooting medium may be composed of peat and sphagnum-moss in equal parts, selecting lumpy peat from which little of the fine particles has been shaken. Loam fibre may be added for some kinds, such as C. insigne, C. villosum, and C. Rothschildianum, and their varieties; but in or near large towns its use is more harmful than otherwise. Nor is leaf-soil recommended for many sorts, though such as C. Curtisii, C. superbiens, C. callosum, C. Mastersianum, and hybrids of like affinity make good progress in a compost which includes a small quantity of leaves. An intermediate temperature and moist sweet atmosphere suit most of the sorts, and it is important that the plants be protected from draughts. Having no pseudo-bulbs, the plants need a certain amount of moisture at the roots at all times; but following the disturbance of repotting and during the winter months the application of water should be carried out with extreme care. Spray the plants overhead in the morning on all favourable occasions.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Jerusalem Artichokes.—If these tubers are not already lifted this work should now be done, and as the soil is at present in good working condition, the seed-tubers for next year's crop may now be planted in ground that has been well prepared. If these vegetables are given a favourable position they will be of much better quality than when grown with strong manure in some out-of-the-way corner. Plant in rows 2 feet 6 inches apart and at a distance of 18 inches apart in the rows. The white variety is much superior in quality to the old purple one.

Cauliflowers.—We are now potting the seedlings raised from the seed sown early in November, using 3-inch pots for the purpose. The young plants must be kept near to the glass, and for the present allowed a temperature of about 45° to 50°. The varieties are Early London, Walcheren, and Autumn Giant. Seeds may also be sown of Extra Early Forcing Cauliflower, of Superb Cos Lettuce, and of Leeks. The last-named should be sown as advised for Onions, with the exception that the pots for the Leeks should only be half filled with soil, in order to add more soil as growth advances. The variety Lyon is of superior quality and of large size. We have only recently finished cutting Cauliflowers after a long and constant supply. Varieties valuable for their compact form and delicate white heads are Early London, Walcheren, and Sutton's Christmas White. Snow's Winter Broccoli has also proved exceptionally serviceable, and is now available for cutting.

Improving the Soil.—Readers may understand better the practice adopted here if I convey an idea of the nature and composition of the soil in the kitchen-garden at Lockinge. When it was brought under cultivation for that purpose some thirty-four years ago, it was of a poor, white chalky, pasty nature, some 6 inches in depth, with 9 inches more of solid white chalk, resting upon a chalk-rock foundation. Deep cultivation therefore as generally understood was impossible until additions had been made of similar soil

from the neighbourhood, and of manure and burned garden refuse, leaves, &c. The average depth of the soil at the present time does not exceed 2 feet, but by adding leaves during the last ten years in much larger quantities, and by applying less strong manures, the appearance and character of the soil has been changed from a light to a much darker shade of colour. Being more porous, the soil permits a freer access of air, and is therefore a better medium for the roots of plants.

Change of Manure.—It being of the utmost importance that manures of different types be applied alternately, we find that the use of air-slacked lime in considerable quantities upon our cold, freely-manured soil becomes not only an important fertiliser of the soil, but it tends to destroy insects.

Digging is an almost daily operation, of great importance, and should be done well; but we do not find it necessary to trench the ground oftener than once in six years. Not until the third year after trenching do we attempt to grow such crops as Carrots, Parsnips, and Beetroot, because of the numbers of fanged roots that would be produced. When the soil becomes more settled the roots go fairly straight down to the decayed and decaying substances at the bottom of the trench, and are much more regular in shape and finer in quality.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant, Oxon.

Cherry-trees trained as Cordons must not be grown too vigorously, otherwise the fruit will be liable to drop. Varieties of Cherries best suited to this mode of culture are May Duke, Archduke, Royal Duke, Guigne d'Annonay, Reine Hortense, Empress Eugénie, Guigne de Winckler, and Morello. These should always be "worked" on the Mahaleb stock, as they are much more fruitful on this than on the Cherry stock, and form more compact and fertile trees if kept well pinched. The Mahaleb stock exerts a similar influence on the Cherry scion as the Paradise stock does on the Apple. The Mahaleb ungrafted forms a very ornamental tree, and is very effective when planted as a single specimen on the lawn, its peculiar habit of growth and the perfume given off by the small white flowers in the spring being very attractive.

Morello Cherry-trees, if not already trained, should be given early attention. The pruning and tying of these trees, growing as they do on the north side of the wall, being extremely cold work, should always be performed in the autumn, as the work can then be done in much more comfort, and with more thoroughness. The Morello Cherry produces its fruit on the wood made during the previous summer. The leading branches of the tree should radiate from the main stem, and all intervening space on the wall should be filled with the strongest fruit-bearing wood. The trees should be carefully pruned, cutting out all the weak shoots, and those in an unsuitable position for tying in. Shorten the strong-growing shoots on young trees where more wall-space has to be covered. In tying the trees the operator should aim at furnishing the tree with young fruit-bearing shoots from the base to the summit, allowing a space between the shoots of at least 3 inches. Branches of old trees which extend throughout the tree with only fruit-bearing shoots at the ends should be shortened, and wherever possible removed altogether. Varieties of Cherries succeeding well on north walls are May Duke, Empress Eugénie, and Archduke. The fruits of these will be found valuable for culinary purposes, and they ripen earlier than the Morello. The north wall may also be used with advantage for prolonging the season of Plums, for which purpose the varieties Coe's Golden Drop, Victoria, The Czar, and Prince Englebert are suitable varieties. The variety Coe's Golden Drop will often in a dry autumn hang till the leaves fall and until the fruits are quite shrivelled. In districts where bullfinches and blue-tits abound Plum and Cherry trees should be protected with nets, using forked sticks to keep the nets from the trees. Much damage is done to the trees when shooting small birds; the shots often induce the formation of canker. Only in exceptionally cold weather are the buds of Morello Cherry-trees attacked by birds; these usually need no protection.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Herbaceous Calceolarias.—Plants raised from seeds sown last July will be making steady progress. If potting is necessary, a slight shift should be given. Good turfy loam and spent Mushroom-manure in equal parts, with a small proportion of lime-rubble and silver-sand, will be suitable for this purpose. It is advisable to either fumigate the plants or to dip them, before being potted, in a solution of "Quassia extract" in order to destroy and check green-fly. Water should be afforded very sparingly at first, but light and air should be admitted freely.

Mignonette.—A sowing may be made in small pots in a mixture of old Chrysanthemum soil and broken lime-rubble. The soil should be pressed firmly and watered before the seeds are sown. Sow thinly, cover the seeds lightly with soil and place the pots in a cool frame kept rather close. As the seedlings appear thin them out to about two or three plants in a pot. Place the plants as near to the light as possible, and when nicely rooted shift them into larger-sized pots. Allow a circulation of air to pass between the plants, in order to keep them robust.

Begonia Gloire de Lorraine.—Where large specimen plants are required some of the strongest of the stock plants that flowered early and have since been rested, may be plunged in leaves or fibre, in a warm house, and started into growth, in order to produce early cuttings. In a week or two's time sufficient cuttings for a first batch will be ready.

Allamandas and Bougainvilleas.—Specimen plants in pots that have been allowed sufficient period of rest, may be pruned to within two or three buds of the old wood, at the same time retaining sufficient of last season's growth necessary to make an evenly-balanced plant. If Bamboo canes are used for stakes, replace the old with new well-sharpened ones, which must be driven firmly into the ball of the plant. If these plants are placed in a warm, moist house, and are kept freely syringed, they will soon start into growth. When the roots have become active the plants should be turned out of their pots, the old balls reduced by means of a sharp pointed stick, and then repotted in a compost consisting of turfy loam and peat in equal parts, some broken charcoal and silver sand, and a small quantity only of plant-manure.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Bedding Roses.—The hybrid Teas are most effective for flower-garden bedding, as they are of moderate growth, and hardier than true Teas, and they flower almost perpetually. A very slight protection from frost, such as afforded by bracken or Fir branches, is necessary. For affording brilliant colour in late autumn I recommend Gruss an Teplitz. It is a vigorous grower, but keeps within bounds in a bed of average size. Other good crimson-flowered varieties are Marquise de Salisbury and Liberty. I do not know of a white counterpart to Gruss an Teplitz, but Souvenir du President Carnot is quite first-rate, bearing very large upright flowers in fine clusters. Madame Pernet Ducher, Augustine Guinoisseau and Viscountess Folkestone are good varieties. Camoens is a beautiful China rose, and Papa Gontier is excellent. The China Roses are of smaller growth, but very floriferous, being the truest perpetuals. Nothing can surpass these Roses for garden adornment. They are suitable for beds by themselves or as margins to other Roses. The common Blush China is hard to beat, and Madame Eugène Resal, Madame L. Messimy, Red and White Pet, and Cramoisie Supérieure, are splendid. Good drainage is essential for Roses, and they need light rich soil at least 2 feet deep.

The Wild Garden is the most fitting place for Roses that will not succeed when "cribbed, cabined and confined" in geometrical beds, or tortured on iron bars and chains. Choose a piece of ground of a diversified character, where every group can have a suitable position allotted to it. Imagine "fountains" of Polyantha grandiflora, villosa nivea, Crimson Rambler, and "waterfalls" of Wichuriana, hillsides planted with rugosa, Madame Georges Bruant, Conrad F. Meyer, Madame C. F. Worth in masses, with specimens of Aimée Vibert, Alister Stella Grey, and standard Wichurianas occupying prominent positions. Many of the robust growers have only transient floral beauty, but they afford splendid effects. R. Wichuriana and its hybrids flower in July and August; R. humilis and R. rugosa are nearly always in bloom; Pissardi has produced semi-double white flowers in autumn; lucida and rubrifolia have charming foliage, and, last but not least, Zéphyrine Drouhin, a lovely shade of rosy-cerise colour, is very charming in autumn.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Strawberries.—The end of January is generally sufficiently early to commence forcing, although those growers who require very early fruits commence in December. Strawberries started now should be allowed a temperature of 45°, with a slight increase during the day. As soon as the flower-trusses appear and the young leaves are pushing freely, liquid-manure may be unsparingly given. Remove all superfluous flowers from the trusses, and allow the plants the lightest situation in the house. Fertilise the flowers during the brightest part of the day, and allow plenty of warm, fresh air to circulate among them. As soon as the fruits are set they should be thinned to about six or nine berries, and the plants allowed a higher temperature. They must at this stage be freely syringed and liberally fed with manure-water until the fruits change colour, when they should be placed in a cooler and dryer atmosphere and the feeding should be discontinued. Fresh batches of plants may be introduced as required. Keep a strict watch for aphides, &c., and use remedial measures before they reach the flowering stage. Avoid fumigating the plants when they are in flower.

Peaches and Nectarines in Pots are especially adaptable for early forcing, especially such varieties as Alexandria and Hale's Early among Peaches, and Cardinal and Early Rivers among Nectarines. The trees should be healthy, the wood well ripened, and the house light and well ventilated. During the early stages of forcing the temperatures must not be allowed to exceed from 45° to 50° at night. During the time the trees are in flower a temperature of 50° should be maintained with a free circulation of air on all favourable occasions. Pollinate the flowers daily about noon with a small camel's-hair brush, and maintain a moderately moist atmosphere by damping the paths and borders of the house. If green-fly makes its appearance on the trees, mild fumigations must be employed before the flowers open. Syringe the trees in the morning if the weather is bright and favourable, and again in afternoon, except when they are in flower. Pay special attention to the watering of the trees.

Cherries.—To obtain ripe fruits early in May, much patience must be exercised during the early stages of forcing. At a later period, when the days lengthen and the sun-heat increases in power, the trees may be encouraged to develop more rapidly, and a little heat may be employed in the water-pipes, which should however be shut off at night-time, excepting in severe weather and when the temperature falls below 40°. Maintain a moderately moist atmosphere by syringing the trees morning and afternoon in good weather. Some artificial heat should always be used during the time the trees are in flower, with free ventilation both day and night when the weather is favourable.

Plum-trees, similar to Cherries, produce excellent crops when grown in pots, and they require the same low temperature during the early stages of forcing. Indeed their treatment should be almost identical until after the fruits are set and commence swelling, but they require a longer time to ripen their fruit.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR FEBRUARY.

THURSDAY,	FEB. 2	Linnean Society Meet.
SATURDAY,	FEB. 4	Société Française d'Horticulture de Londres Meet.
WEDNESDAY,	FEB. 7	British Gardeners' Association, Meeting at Croydon.
FRIDAY,	FEB. 10	Royal Gardeners' Orphan Fund' Annual Meeting and Election of Candidates.
MONDAY,	FEB. 13	United Horticultural Benevolent and Provident Society's Committee Meet. British Gardeners' Association, Meeting at Birmingham.
TUESDAY,	FEB. 14	Royal Horticultural Society's Committees Meet, also Annual Meeting of Fellows.
THURSDAY,	FEB. 16	Linnean Society Meet.
FRIDAY,	FEB. 24	Royal Botanic Society Meet.
MONDAY,	FEB. 27	Birmingham and Midland Counties Mutual Improvement Society Meet.
TUESDAY,	FEB. 28	Royal Horticultural Society's Committees Meet. National Rose Society's Committee Meet.

SALES FOR THE WEEK.

MONDAY AND FRIDAY NEXT—
Border Plants, Perennials, Roses, Azaleas, Fruit Trees, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12 o'clock.

WEDNESDAY NEXT—
Palms, Plants, Azaleas, Roses, Fruit Trees, Herbaceous Plants, Lilies, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12 o'clock. — Roses, Azaleas, Palms, Shrubs, Lilies, &c., at Stevens' Rooms, at 12.30.

FIRDAY NEXT—
Importation of Burmese Dendrobes, 450 Odontoglossum crispum &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(*For further particulars see our Advertisement columns.*)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·0°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January 25* (6 P.M.): Max. 47°; Min. 41°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan. 26* (10 A.M.): Bar., 30·6: Temp., 38°. Weather—bright, with little sunshine.
PROVINCES.—*Wednesday, Jan. 25* (6 P.M.): Max. 45°, W. of England; Min. 35°, E. of Scotland.

The National Potato Society.

SPECIAL societies are under a special obligation to justify their existence. If they fail to do so, their utility is not apparent, and they divert energy and funds which would be more profitably expended in supporting societies with broader aims and less selfish objects.

The Potato is such a very important factor in feeding the people that a special society to care for its improvement and the extension of its culture was called for. If anyone doubts this he has but to look at the Report of the first year's working to have his doubts removed. There is always a fear that these minor societies may become too exclusively commercial, and be influenced too much by persons mainly interested in the financial side of the question. Of course self-interest is a most potent factor, but it should not be made the be-all and end-all of societies established not for the benefit of individuals, but for the advancement of the cause and the general welfare of the community. The acquisition of knowledge is the first requirement, and then its application to practical purposes. Exhibitions got up for the mere purpose of awarding prizes to enterprising men of business are not likely to excite general sympathy. Men of business have their appropriate rewards in other ways. The case is altered when the acquisition of new facts and the wider diffusion of knowledge relating to them are concerned. From this point of view the independent trials carried out in various parts of the country by the Potato Society are valuable, and will be increasingly so as each year adds its quota to what is already known. A glance at the Report before alluded to will illustrate our meaning better than any elaborate disquisition on our part, and will, as we have said, show that the National Potato Society has already justified its existence, and bids fair to do great good by regularising and systematising our knowledge, whether of scientific or of commercial matters relating to the Potato. Some extracts from the Report are given in another column.

The Gardeners' Royal Benevolent Institution.

THE annual meeting of the "Gardeners' Benevolent," to give the Society its colloquial designation, always gives rise to mixed feelings. On the one hand, there is the feeling of satisfaction at the self-denying labours of a businesslike Committee and the consequent good work done. On the other hand, there is the disappointment that at least half the applicants for relief must be passed over for want of the requisite funds. True that approved candidates, if they have been subscribers or are the widows of subscribers, are eventually sure to be elected. But waiting under such circumstances is such wearisome work that every effort should be made to lessen its duration. Such efforts are indeed made, and it is hardly possible to exaggerate the benefits which accrue from the two subsidiary funds, the Victorian Era Fund, which furnishes some amount of relief to approved candidates during their period of expectancy; and the Samaritan Fund, instituted for the purpose of supplying timely aid to those more or less directly connected with the gardening industry without any other condition than that of need. The permanent income of the Society and the regular annual subscriptions should suffice to defray the cost of the pensions, and would do so if the annual subscriptions were increased in proportion to the necessities of the case; but the two subsidiary funds need constant replenishment to enable them to afford prompt relief to cases as they arise. The pension fund may be looked on as an insurance in case of need, and as a particularly good investment. This being so, self-interest should suffice to ensure a sufficient income for this department of the Society. The subsidiary funds may be regarded as purely benevolent agencies, and as such should command the sympathies of everyone. We are unfortunately obliged to use the conditional words "should" and "may," when it would be so much more satisfactory to be able to employ more direct phraseology.

Possibly the percentage of annual subscribers amongst gardeners might be increased by the more extended adoption of the instalment method of payment. It is not always convenient to pay the whole amount at one time, but if the payments were spread out over the whole year, no inconvenience would be felt. No doubt if such a plan were carried out the work at the head office would be largely increased, and the results might not justify the extra cost of collection. But this difficulty might be got over by extending the powers of the local secretaries and of the auxiliary branches. Already much is done by these local agencies, but we do not believe that the limits of the usefulness of those that are in existence have by any means been reached, whilst the number of such branches is only a fraction of what it might be. Some gardeners do their duty in this matter, and some employers act up to their responsibilities, but it is quite clear that while all do not, many more would do so were the claims of the Institution more directly brought under their notice. It is a pitiful thing to see gardeners ignoring their duty of supporting the Institution according to their ability, and it is a lamentable thing to see employers who have the means suffering their old servants to become pensioners without contributing to the Institution which helps to lessen their responsibilities.

It is to the local secretaries and auxiliary branches that we look for aid in this matter. Circulars sent through the post and appeals made in the Press are feeble in comparison with personal intervention. We are all so plagued with circulars that a very large proportion of them find their way straight to the waste-paper basket with no more than a glance. The word in season spoken by man to man is much more effectual. A suggestion from the gardener to his employer that for one day in the year he should throw his grounds open at a small charge for the benefit of the Institution has proved effectual already, and would be much more so if more generally acted on.

A small poll-tax from all casual visitors to flower-shows throughout the whole country would bring in a large amount in the aggregate, and if the amount were paid for with the ticket of admission, the extra outlay would not be felt.

Gardeners' Debating Societies are rapidly increasing, and these might individually do a good deal, whilst if they were properly organised so as to be able to act collectively they would be able to accomplish much more. From this point of view we have great hopes from the newly-founded British Gardeners' Association, instituted for the benefit of employers and employed. Isolated units can accomplish little; associations for reciprocal effort can do much.

The Annual General Meeting of the Gardeners' Benevolent was held at the Covent Garden Hotel on Friday, January 20, at 3 P.M.

Mr. HARRY J. VEITCH, in proposing the adoption of the Report and Balance-sheet, which we reproduce on p. 62, said that it was of greater length than any previously presented by the Committee; but the work of the Institution is greater year by year, and its responsibilities have increased. Not only did the Committee commence last year with a larger number of

pensioners on the books than ever before, but they were going to elect that day six more pensioners than they did then. They knew from the correspondence that the Institution was more popular in the provinces now than it had ever been, and the Committee believed this to be due in a large measure to the successful efforts of the "auxiliaries." The Reading Auxiliary had collected during the past year a sum of about £129, and at Worcester and other centres good work had been done. After an appreciative reference to the amount of work discharged by the Secretary, Mr. G. J. INGRAM, Mr. VEITCH said the Committee proposed that instead of electing eighteen pensioners, as suggested in the Report, they should that day elect twenty. He made reference to the usefulness of the Victorian Era and Samaritan Funds.

Mr. ALDERSON seconded the adoption of the Report, and it was carried unanimously.

On the proposition of Mr. ARTHUR W. SUTTON, seconded by Mr. GEO. MONRO, Mr. HARRY J. VEITCH was re-elected Treasurer. Whilst seconding the resolution, Mr. SUTTON announced his intention to provide a year's pension for one of the unsuccessful candidates on that occasion, for which he would present to the Committee the sum of £20.

Mr. G. J. INGRAM was then re-elected Secretary on the proposition of Dr. M. T. MASTERS, F.R.S., seconded by Mr. SEGAR.

The retiring members of the Committee were re-elected, and Mr. GEORGE WOODWARD was elected a member of that body in place of Mr. OSBORN, deceased; and Mr. EDWARD SHERWOOD in place of his father, Mr. N. N. SHERWOOD, who retired.

The Auditors and Arbitrators were re-elected, Mr. GEO. MONRO reminding the meeting that although the Institution was obliged by statute to appoint Arbitrators, they had fortunately never been in such a position that the Arbitrators had been called upon to act.

Several gentlemen were then appointed scrutineers of the ballot, and the meeting was adjourned until 5.45 P.M., when the successful candidates were announced as follows:—

	Votes.
WILLIAMS, EDWIN	4,566
BENBOW, ELLEN	3,976
PAGET, LOUISA S....	3,624
JOHNSTON, JOHN...	3,562
THORNTON, HENRY J....	3,528
SMITH, ANNA M	3,509
ALLWARD, ELIZA...	3,285
BROWN, DUNCAN...	3,056
PAGE, ANNE	3,047
DIXON, PETER	2,894
HEYWOOD, GEORGE	2,881
HARRIS, CHARLES	2,860
CANN, GEORGE	2,856
HUDDY, JOHN	2,765
ODLIN, WILLIAM	2,734
PELLETT, WILLIAM	2,586
GARLAND, SAMUEL	2,544
WYNNE, THOMAS	2,449
LEE, FREDERICK E.	2,396
HAWKINS, BENJAMIN	2,279

Additional pensioners were afterwards elected as follows:—

	Votes.
PLUMMER, MARY A.	2,165
PORT, JAMES	1,622
BROOKS, SAMUEL	2,104
BRADBERRY, JOHN	851

The first-mentioned candidate was elected by the munificence of Mr. N. N. SHERWOOD, the second by that of Mr. ARTHUR SUTTON, and the two remaining candidates were placed on the Fund by the Committee in exercise of their right under one of the bye-laws. The Committee selected a subscriber and a non-subscriber. The votes given above are the numbers the candidates obtained in the general poll, when they failed to get in the first twenty.

The scrutineers reported that there were twenty-four spoiled votes, and in one instance a subscriber who should have given 5 votes endeavoured by inadvertence to give 85!

The Annual Friendly Supper took place at the same Hotel (Covent Garden) at 6 P.M., Mr. EDWARD SHERWOOD presiding. The Chairman referred to the valuable services of Mr. HARRY J. VEITCH to this Institution, and the fact that owing to the general respect in which Mr. VEITCH is held by all horticulturists, the last annual festival was so great a success that £1000 had been added therefrom to the Victorian Era Fund.

Mr. SHERWOOD pleaded for more auxiliaries, and suggested that concerts and bazaars might be arranged in order to benefit the Fund. A musical society with which Mr. SHERWOOD is connected has raised a sum of £50 by means of a concert. Mr. SHERWOOD read an interesting letter from his father, stating that he presided at one of the Friendly Suppers held thirty-six years ago, and expressing unabated interest in the objects of the Institution. Mr. ARTHUR A. SUTTON responded, and expressed regret that Mr. H. J. VEITCH was not able to remain with the company and respond to the toast as in former years. Mr. SUTTON gave many interesting items relating to the work and responsibilities of the Institution, and incidentally remarked that of the pensioners on the Fund there are two over ninety years of age, forty-six over eighty years of age, and seventy-three over seventy years of age.

Mr. H. J. HICKS proposed "The Committee, Honorary Officers, and Country Friends," which was responded to by Mr. GEO. MONRO and Mr. W. ATKINSON, Sheffield.

BATH BRANCH.

The twelfth annual general meeting of the Bath branch was held at West's Dining Rooms on Thursday evening, January 19. The chair was taken by R. B. CATER, Esq. Mr. J. MILBURN (Hon. Secretary) read the Report for the year. The financial statement was very satisfactory, last year's total being £33 18s. 5½*d.*, and for this year, £44 17s. 1¾*d.* The sale of flowers and collection at the Bath Rose show realised £13 10s., against £15 1s. 1½*d.* last year. The Bristol and Bath Auxiliary has this year transmitted to the parent Society the sum of £78 15s. Five life members have been elected to the Institution—two from Bristol and three from Bath.

The Institution was founded in 1839, and at the present time there are on the permanent funds for their lives 204 persons, 116 men and 83 widows, who are receiving £20 and £16 a year. There are eleven pensioners in this neighbourhood—three in Bath and six in Bristol and Clifton. They receive from the parent Society £204 a year in pensions.

R. B. CATER, Esq., was unanimously elected President in place of the Rev. E. HANDLEY. The Committee of Management was re-elected, as was the Secretary.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mrs. MARY PLUMMER and Mr. JOHN JOHNSTON tender their heartfelt thanks to all subscribers who so kindly assisted in placing them on the list of pensioners.

CAMELLIA HOUSE AT LEYSWOOD. — The Supplementary Illustration to our present issue affords a view in the Camellia-house at Leyswood, Groombridge, Kent, the residence of Mrs. TEMPLE. Though Camellias have ceased to be cultivated as large specimen bushes to the extent they were formerly, when hard-wooded greenhouse plants were exceedingly popular, there are, happily, some gardens in which a collection has been retained, notwithstanding the caprice of fashion. Leyswood is such a garden, and our readers will easily see that the plants have not only been "spared," but they are cultivated with conspicuous success. The plants are full of luxuriant growth, healthy foliage, and bear abundant flowers, which, after all, are of considerable service when they have been cut with part of the shoot attached or pulled and wired. Mr. ERNEST BRISTOW, the gardener, informs us that the house is 80 feet long, 32 feet wide, and 17 feet high. "The plants are grown in a compost of loam, peat, leaf-mould, and sand, in which they grow vigorously, making young growths often exceeding a foot in length. Many of the plants are from 10 to 12 feet high. They are pruned fairly hard immediately after flowering. No artificial heat is used except to keep out frost, and abundance of air is admitted whenever possible. About sixty varieties are planted in the house. A few of the best are Albino Botti, Isabella, Regina Margherita, Caterina Loing, Superbe, alba plena, Bertha Ravene, Bonomiana, Marie Teresa, Isabella Galletti, imbricata tricolor, Michel Angelo, incarnata, Angela Cocchii, Etrusca, imbricata, centifolia carnea, Solfatara, Donckelaarii. On the roof of the house Roses, Clematis, Lapagerias, &c., succeed, and are effective in their season."

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS (SCHOOL TEACHERS).—The Royal Horticultural Society will hold an examination in Cottage and Allotment Gardening on Wednesday, April 5, 1905. This examination is intended for and will be confined to elementary and technical school teachers. It has been undertaken in view of the increasing demand, especially in country districts, that school teachers shall be competent to teach the elements of cottage and allotment gardening, and in consequence of the absence of any test whatever of such capacity. The general conduct of the examination will be on the same now well-known lines as that of the more general examination, save in obvious points to which they would not apply. Intending candidates are requested to send in their names early in March. A Silver-gilt Flora Medal will be awarded to the candidate gaining the highest number of marks, and each candidate will receive a Certificate of the Class in which he has passed.

—— GENERAL EXAMINATION. — The Society's Annual Examination in the Principles and Practice of Horticulture will be held on Wednesday, April 12, 1905. The Society is willing to hold an examination wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations will consent to supervise one on the Society's behalf, and in accordance with the rules laid down for its conduct. A copy of the Syllabus covering both examinations will be sent to any person on receipt of a stamped and directed envelope. Questions set at the Royal Horticultural Society's Examinations 1893-1904 may also be obtained at the Society's Offices, Vincent Square, Westminster, price 1s. 6*d.*

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, February 2, 1905, at 8 P.M., when the following papers will be read:—"New Chinese Plants from the Neighbourhood of Hong Kong," with lantern slides, by W. J. TUTCHER, F.L.S.; and "European Marine Species of Cirolaninæ (Isopoda)," by Dr. H. J. HANSEN, F.M.L.S.

APPLE FENN'S WONDER,—Mr. THOS. SIMPSON, Henham Gardens, Wangford, writes to say that this Apple, which was illustrated in our pages on January 14, is in future to be called Lord Stradbroke. The variety is a chance seedling which appeared in Henham Gardens some years ago.

FLORAS OF INDIA.—In addition to the works on this subject which we mentioned on p. 41, reference should also be made to the late Col. Sir HENRY COLLETT'S *Flora Simlensis*, a small book especially useful to amateurs on account of the excellent illustrations.

THE MASSACHUSETTS HORTICULTURAL SOCIETY.—In the *Transactions* for 1904 mention is made of the famous library of the Society, probably the best of its kind in the world. An account is also given of the Arnold Arboretum, to which we have frequently referred. The city of Boston maintains the roads and paths, whilst the management and scientific direction are under the supervision of Harvard University. Professor SARGENT, the author of the *Silva of North America*, and other works, is the Director, and his library of about 10,000 volumes has been made over by him to the Arboretum. Nature-study and the protection of native plants are treated of in this number, as well as the culture of the Gladiolus and of the Pæony. The part is well illustrated.

M. VIGER.—The President of the National Horticultural Society of France has been named as Chevalier of the Legion of Honour, the distinction having been conferred by the President of the Republic in person.

THE FROST ON THE RIVIERA.—The *Revue Horticole* gives a deplorable account of the destruction caused by the recent severe weather not only on the north side of the Mediterranean, but also in Tunis and Algeria. The crop of Roses is mostly destroyed, also Violets, Anemones, Reseda, Ranunculus, and other flowers, have been almost entirely ruined, and in the market gardens there are no more Artichokes, Lettuces, Radish, Carrots, Turnips, or Cauliflowers. What the effect will be on the Palms it is too soon to judge. It is a curious fact that our own growers have lately been supplying the Paris markets with forced Tulips and other flowers.

SIR HENRY GILBERT'S LIBRARY. — The library of the late Sir HENRY GILBERT, which is extensive and very rich in works relating to chemistry and the theory and practice of agriculture, is offered for disposal. But for the fact that the Rothamsted Trust has already the library of the late Sir JOHN LAWES, we should have supposed that Sir HENRY GILBERT's collection would naturally have been retained at Rothamsted, and not be separated from the scene of his lifelong labours. As it is, the library would be a most valuable acquisition to some of the now numerous agricultural colleges, and we trust it may soon find a home in one of these institutions.

"MY GARDEN DIARY."—Messrs. SUTTON & SONS, of Reading, have prepared a useful book of notes for the present year, entitled *My Garden Diary for* 1905. The pamphlet includes useful gardening hints for every month in the year, besides special directions for managing bulbs, seeds, &c. Blank pages are left on which suitable records can be made, and with various illustrations and a pretty coloured cover the whole publication is very attractive. Needless to say, the directions therein given may be implicitly followed.

RAMSEY HORTICULTURAL SOCIETY.— Lord DE RAMSEY has been re-elected President of the Society, and the annual show is to be held on the August Bank Holiday.

THE SCILLY ISLES.—The winter at Scilly has been the best on record. The thermometer at Tresco Abbey has only on one night fallen below 40° Fah. There has been little wind. The flowering of the Pelargonium is the best ever experienced in winter in the island.

THE HAMPTON COURT VINE.—Visitors to Hampton Court Palace just now, if wishing to see the famous old Vine, will find themselves debarred that pleasure for a brief period, as the vinery itself is undergoing a complete change. The old house which had for so many years sheltered the Vine is entirely removed, and its place taken by a new one of the same area, but of a semi-span form, giving a much steeper roof—a great need for a vinery. The rods of the Vine, all now bundled and covered up to keep the buds from harm, will in the future be tied to wires fixed to light iron spandrils, and will be 2½ feet from the glass. That will seem to many persons to be of considerable distance; but it may be taken for granted, as the arrangement is being carried out under Mr. A. MACKELLAR's instructions, that so eminent a gardener knows well what he is advising. A great gain to both Vine and its Grapes will be found in the exclusion of visitors from the inner area of the vinery, as under the old arrangement and with a flagged floor the dust raised coated both foliage and Grapes with dirt. A small room has been cut out from the residence of Mr. JACKS, the veteran custodian of the Vine, which adjoins the vinery, and that will presently form a glassfronted lobby having an entrance and an exit. Visitors will be permitted into this lobby only. It will not well contain more than a dozen persons at a time; and on certain days the regulation of the thousands who flock to see the Vine will doubtless be a matter of some difficulty. A glass corridor running along the back of the vinery would have been better. Hot-water-pipes will replace the old brick flues, and as the whole of the flagging is removed, the floor will be converted into a border, into which it is hoped new surface roots may be freely formed, and in time new rods also.

SWERTIA TASHIROI is the name of a species figured and described (in English) in the *Journal de la Société d'Horticulture du Japon*, November 30, 1904. Its large white pendulous flowers make their appearance in November. The plant is a native of the south of Kioushiou and of the Island of Yayéyama. M. MAKINO recommends this plant for cultivation.

PRICES OF KEW "HAND-LISTS."—A correspondent writes contrasting the cheapness with which the excellent leaflets of the Board of Agriculture are distributed in comparison with the Kew *Hand-Lists*. We submitted the letter of our correspondent to headquarters at Kew, and learn that—

"1. The Director is most anxious that the Kew publications, in the sale of which he has no pecuniary interest, should have as wide a circulation as possible.
2. The principle upon which the present prices are fixed is not intelligible to him, and is to a large extent undoubtedly prohibitive.
3. The Director has, however, no control over the prices, which are fixed by the Controller of H.M. Stationery Office.
4. If the Stationery Office cannot meet the legitimate demands of the horticultural world, why not give private enterprise a chance?"

MR. CHAMBERLAIN AND THE BRITISH GARDENERS' ASSOCIATION.—Mr. W. WATSON, the Secretary of the British Gardeners' Association, having forwarded copies of the "Plea" prospectus, &c., to the Right Hon. JOSEPH CHAMBERLAIN, M.P., has received the following letter:—

"Highbury, Moor Green, Birmingham,
January 23.

I am desired by Mr. Chamberlain to acknowledge the receipt of your letter of January 20, and to say that he cordially approves of the proposal to establish the British Gardeners' Association and cordially wishes it success.

J. WILSON."

To W. WATSON.

THE BRITISH GARDENERS' ASSOCIATION.—"The Aims and Objects of the British Gardeners' Association" was the subject under discussion at a meeting held under the auspices of the Loughborough and District Gardeners' Association, at the Town Hall, Loughborough, on the 17th inst., Mr. J. T. SMITH presiding over a large and representative attendance of local gardeners. In the course of his address Mr. W. H. DIVERS, head gardener at Belvoir Castle and a member of the Committee of Selection of the "B. G. A.," after giving a most interesting account of the early history of gardening and the great advancement that has been made in all branches of gardening within recent times, said that most unfortunately there had not been a corresponding advance in the wages paid to gardeners. He then proceeded to explain the objects and programme of the Association, pleading that hearty support should be given to it by both employer and employed. After some discussion, upon the motion of Mr. D. ROBERTS, of Prestwold Gardens, Loughborough, it was unanimously resolved that "All those present pledge themselves to give their support and co-operation to the British Gardeners' Association." Mr. W. BEGBIE having been elected Local Secretary, the usual hearty votes of thanks were accorded to the lecturer and Chairman.

—— A representative meeting of the gardeners and nurserymen of Cardiff and Newport districts was held at the town hall on January 16, to consider the advisability of organising a local branch of the British Gardeners' Association. Mr. STEPHEN TRESEDER, F.R.H.S., presided. Mr. R. HOOPER PEARSON (London) and Mr. W. W. PETTIGREW (Superintendant of Parks, Cardiff), were the principal speakers. Mr. Pettigrew, in opening the proceedings, urged the need for co-operation among gardeners. Mr. R. HOOPER PEARSON explained that the aims of the Association were to better the conditions of labour and the wages of gardeners, and at the same time to raise the standard of the gardener and gardening, so that the employer will be benefited as much as the *employé*. Mr. HUGH A. PETTIGREW proposed that a branch of the British Gardeners' Association should be formed to embrace the Cardiff and Newport districts. A number of gardeners in the district had already, he said, joined the Association. By forming a branch however the members would have more weight and influence in helping forward the aims of the Association. Mr. FRED TRESEDER (nurseryman) seconded the resolution, which was carried unanimously. Mr. HUGH A. PETTIGREW was elected local Hon. Sec.

THE FIRE DANGER IN COUNTRY HOUSES.—The *Estate Magazine* calls attention to the fact that in 1904 there were no fewer than thirteen destructive fires in country mansions, involving in many cases the loss of historical documents, pictures, libraries, and other property that money cannot replace. The causes were mainly due to defective flues and imperfect electric-light installations.

THE HUGE CHRISTMAS-TREE which was the delight of so many children visiting the Crystal Palace during the Christmas holidays was, as usual, supplied by Mr. JEREMIAH COLEMAN, of Gatton Park.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE APPLE CENSUS.—If it has done nothing else, the Apple census has helped to accentuate the fact that it is too much to expect that the growers of, or those commercially interested in, our fruit should also be critical judges as to their excellence in flavour, otherwise we should not see so second-rate an Apple as the King of the Pippins in the high position in which it is placed. Half a century ago it was considered to be bright and useful, for King Pippin cider was well known and duly appreciated in Kent. When planting an orchard, I wrote to Mr. Scott, of Merriott, Somersetshire, for some trees, whereupon he strongly advised me to put in some Golden Winter Pearmain, which he said was a larger, better grower, and of upright character, and far uperior in flavour to the King Pippin. I did so, and was well pleased with the change. Again, though handsome, is the Worcester Pearmain first-rate? I consider Blenheim Pippin the best all-round fruit that I ever grew, both for beauty of colour, form, size, and flavour; and some years ago I was awarded a Cultural Cer-

tificate at the Royal Horticultural Society for its quality of growth. I never found Cox's Orange Pippin so good [as Blenheim Pippin], nor equal to the Ribston Pippin, though it was better in colour. Irish Peach being placed where it is is another and a greater surprise. Warner's King is with me a grand Apple and a wonderful bearer. One tree that I have has been loaded for three successive seasons with large and fine fruit. My trees of the King of Tompkins County, though the variety is not a great bearer, have proved highly satisfactory, the Apples being large and fine. Bramley's Seedling deservedly has many admirers. Why Dumelow's Seedling comes in where it does I am at a loss to know; but to my thinking the selection of Lord Suffield is the greatest mistake of all. With the exception of its earliness, I think in comparison with some others it has nothing to recommend it. I quite agree with Mr. George Bunyard in this respect. He says he has seen it "much grown about Worthing." So have I, and the trees were most prolific; but no one would buy the fruit, and when the ground was strewn with Apples, though they were offered to be given to anyone who would fetch them away, no one would do so, and this not without reason, for I have a dish heaped with peeled, cut, and cored Lord Suffield, and after the cooking (?) the bottom was scarcely covered with the semi-acid pulp. For my own part, I generally divide Apples into three varieties—that is, coloured, yellow or green, and russets, the last having amongst them some of the very finest-flavoured Apples that I have ever tasted, being totally different from others, and yet these are never mentioned, nor, indeed, are others of the very highest quality. Truly taste is a gift, and not acquired, nor is a critic on this likely in any way to be biassed. I will return to this subject again. *Harrison Weir, F.R.H.S., Poplar Hall, Appledore, Kent.*

STATICE FRUTICANS.—In reference to the note on Statices which appeared on p. 419 of your issue for December 17 last, what I meant to say is that I had a solitary plant of the species Statice fruticans in my garden, growing in the vicinity of other Canary Statices (S. macrophylla, S. brassicæfolia, S. macroptera, S. imbricata), and that for two or three years I did not succeed in reproducing S. fruticans, the seed invariably giving rise to hybrids with the other neighbouring Statices. The seed was plentiful. If grown quite isolated from other species, and only a single plant, S. fruticans will hardly produce seed at all. The same is the case with other Canary Statices. I simply state the fact observed by me, and do not venture to give any explanation. *P.*

RAINFALL IN CO. KILKENNY.—Our record of rainfall for the past year was 37·62 inches, and though considerably under last year's total of 50·66 inches we are only just under the average, which for the past eight years is 39·50 inches. *J. G. W., Bessborough.*

RIPENING WOOD-GROWTH ON NORTH WALLS. —In reference to "A. D's" remarks at p. 13 regarding the ripening of the Victoria Plum on a north wall in Hampshire, I may say that not only the Victoria but also trees of Prince Englebert, Mitchelsons, Old Orleans, and Coe's Golden Drop ripened good crops of fruit on a wall having a due north aspect in Longford Castle Gardens every year during the years I had charge of the gardens there. The fruit of Coe's Golden Drop gathered from the trees growing against the north wall extended the supply of that delicious Plum, previously obtained from trees growing against walls having west and east aspects. Some seasons, it is true, the fruit on the north-wall trees had to be artificially ripened by placing them one deep in cotton-wool-lined trays, covering them with tissue-paper, and then putting them on a shelf in a Melon-house or vinery in which a somewhat dry, airy, and warm atmosphere was maintained for the ripening off of the fruits in those houses. These conditions tended to put plenty of flavour into the Golden Drop Plums, which were highly appreciated in the dining-room so late in the season, and elicited favourable comments from host and guests. Indeed, I am justified in going farther by saying that the trees on the north wall bore good crops when trees occupying east and west walls were but scantily cropped, inasmuch as the trees on the north wall were much later in coming into flower, and so escaped injury from frost. I may say that the brick walls in Longford Castle Gardens are 14 inches wide and from 9 to 12 feet high, and in the aggregate afford a total length of 1,700 yards *H. W. Ward.*

CRYPTOMERIA JAPONICA.—The list of largest specimens in the United Kingdom given at the end of the "Report of the Conifer Conference" mentions a specimen of this tree growing at Coollattin, Wicklow, 67 feet high, with a girth of 5 feet at 5 feet up, as the finest tree out of twenty-eight returns sent to the late Malcolm Dunn. As the Conifer Conference was held so long ago as October, 1891, this tree, if still growing and undamaged, should be much finer than that mentioned by Mr. Page, of Dropmore Gardens (see p. 44). The finest Cryptomeria japonica in the Pencarrow collection is one planted by Sir Wm. Molesworth in 1849, and is now 62 feet 6 inches high, with a girth of 8 feet at 5 feet from the ground. This tree is well clothed and of perfect shape, tapering to a point. I well remember the beautiful Abies (Tsuga) Brunoniana mentioned by Mr. Page. It was, I think, about the time of the Conifer Conference that, while I was foreman at Dropmore, the late Prof. Carl Hansen came to that place. Mr. Herrin was engaged with Lady Louisa Fortescue, and his loss was my gain, for I had the good fortune of piloting the famous Danish arboriculturist around the pinetum. I shall never forget the Professor's expressions of admiration when we came to this Tsuga. After assuring himself of its identity—for although politeness itself, Mr. Hansen would take neither my nomenclature nor that of the labels, but wisely examined each tree we came to—he was at first literally dumb with admiration; then, after a few remarks in Danish, he turned to me with "Ah, my young friend, I am overjoyed! You, who live with these wonderful trees growing like this in the open-air, cannot realise what they are to me, who hitherto have only seen this tree growing in a pot wintered in the conservatory. I really must take home some of these beautiful strobiles." So we gathered up the fallen cones by the dozen. *A. C. Bartlett, Pencarrow Gardens.*

—— Mr. Page's remarks on this tree (see p. 44) are of great interest, and I should be much obliged if he could give particulars of the amount of growth that was made during the first thirty years of the tree's life, as compared with that of the last thirty years, as shown by breadth and leading shoot. Also could he give the cubic contents of the tree as ascertained by quarter girth measurement? As the Japanese "fever" is now very prevalent, facts of this kind are of value, and may possibly indicate what we may expect to take place in the case of other species. *A. C. Forbes.*

CEDRUS DEODARA VAR. ALBA SPICA. — I quite concur with all Mr. Page wrote on p. 44 respecting this excellent variety. We have two trees in the pleasure-grounds that have been planted eleven years. At the present time they are only 13 feet high, but 56 feet in circumference. The peculiarity of this variety here is that it grows in the form of a bush. Mr. Page does not state if the tree at Dropmore grows in bush form. Our trees are admired by everyone who has seen them. *Thos. Harris, Lower Grayswood Gardens, Haslemere.*

THE LAST OF THE FAMOUS ARAUCARIA AT DROPMORE.—For the past three years this fine old tree has stood in the grounds here a withered mass of leaves and branches. Gardeners and other visitors have from time to time called in to see it, or asked the question—"Is the Araucaria still standing?" Last week it was taken down. I found nearly all the main roots near the surface were quite decayed, but, strange to say, those at the base were pliant, and seemed to have some life in them. This appears to indicate that the decay commenced at the surface roots first and gradually spread downwards. *C. Page, Dropmore Gardens, Bucks.*

THE TRAINING OF YOUNG GARDENERS.—As "W. C. R." appears to wander further from the above subject with each letter, I do not think any good purpose will be attained by prolonging this discussion, but should like to add that I had no idea of advancing new theories when advocating the use of suitable perennials instead of the usual class of tender summer bedding plants, but rather that of economising time and labour in cases of necessity. "W. C. R." doubts if many employers would like it; but I would remind "W. C. R." that employers are not cast in a mould, neither are gardeners. *J. G. W., Bessborough.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

JANUARY 24.—A meeting of the Committees took place on Tuesday last in the Royal Horticultural Hall, Vincent Square, Westminster. Notwithstanding the cold weather then obtaining, there were many more exhibits staged than on the previous occasion, Orchids constituting the predominating feature.

The ORCHID COMMITTEE recommended Awards including two First-class Certificates and seven Awards of Merit. On this occasion Mr. HARRY J. VEITCH retired from the Chairmanship of this Committee, and he is succeeded by Mr. J. GURNEY FOWLER, the Society's Treasurer; Mr. VEITCH will remain as a Vice-Chairman. The Committee awarded a Gold Medal to a collection of Orchids shown by G. F. MOORE, Esq.

The FLORAL COMMITTEE recommended Awards of Merit to Cotoneaster pannosa and Erica mediterranea hybrida. There were groups of Cyclamen, Primulas, Carnations, forced shrubs, Ferns, alpine plants, &c. The FLORAL COMMITTEE met on this occasion in a room on the first floor, which, it is presumed, will be the future home of this Committee.

The FRUIT AND VEGETABLE COMMITTEE recommended no awards to novelties, and had few fruits to inspect, but there was a large collection of Potatos from Mr. H. J. JONES.

In the afternoon seventy-one new Fellows were elected, and a paper on the German methods of fruit preserving was read by the Assistant Secretary.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. H. B. May, Jas. Hudson, Jno. Green, G. Reuthe, Chas. Blick, John Jennings, W. Howe, J. F. McLeod, C. R. Fielder, R. Wilson Ker, Geo. Nicholson, H. J. Jones, R. W. Wallace, H. J. Cutbush, C. E. Shea, C. E. Pearson, W. Cuthbertson, Chas. Jeffries, E. H. Jenkins, C. J. Salter, W. P. Thomson, M. J. James, C. T. Druery, R. Hooper Pearson, and J. A. Nix.

Messrs. H. CANNELL & SONS, Swanley, Kent, filled the entire side of one of the centre tables with pot-plants of their strain of Primula sinensis. The group was attractive and bright, the colours and form of the flowers well developed, and the plants well cultivated. They were exhibited in batches in their respective colours, such as Cannell's Blush, Cannell's White, Cannell's Red, &c. One batch exhibited as Swanley Giant Improved was of a very fine type, the flowers being large and of an excellent colour of rose shading to crimson. Messrs. Cannell also set up a pleasing batch of that useful winter-flowering plant, Coleus thyrsoideus (Silver Flora Medal).

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, set up a number of flowering plants of Coleus thyrsoideus, Eupatorium vernale and Cheiranthus kewensis. The whole were interspersed and relieved with suitable foliage plants. Messrs. VEITCH also presented specimens of Hamamelis arborea and H. mollis, the latter having brighter and broader petals than the former, although the crenated appearance of the flowers is absent in the newer species. Plants of Cotoneaster pannosa were well furnished with its pleasing red berries or pomes (see Awards).

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, set up a collection of Ferns, many of the

choicer and newer species were represented. A number of Selaginellas were included—S. grandis, S. mertensia variegata, S. stolonifera and the dwarf-growing S. apus [apoda]. The same firm displayed a number of plants of Eranthemum pulchellum in flower (Silver Banksian Medal).

A group of Cyclamen staged by Mr. W. SEWARD, Nurseryman, Hanwell, was an object-lesson in good culture. The strain is evidently a very fine one, and the colours have been selected with rare judgment. The individual plants were well grown and profusely flowered, the flowers being large and of excellent substance, colour, &c. (Silver-gilt Banksian Medal).

Messrs. AMBROSE & SON, Cheshunt, Herts, filled a large space with greenhouse plants, cut flowers, stands of Grapes, &c. Eucharis grandiflora was shown well, as were also Carnations, Lily of the Valley, Roses, &c. (Silver Banksian Medal).

From the gardens of Sir W. PLOWDEN, at Aston Rowant House, Oxfordshire (gr., Mr. W. H. Clarke), came a collection of sprays of coniferous trees, including Thujopsis borealis lutea, Pinus excelsa, Picea Pinsapo glauca, Juniperus sabina alho-spica, J. drupacea, J. hibernica, Cupressus funebris, and many forms of C. Lawsoniana, Picea Engelmanii, Thuja Lobbii, &c.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, staged hardy ornamental foliage and berried plants, Ivies, Euonymus radicans, E. latifolia alba, Aucuba vera (excellently berried), &c. A basket of Hamamelis arborea was noticed.

Mr. W. HAYWARD, florist, Fife Road, Kingston-on-Thames, set up examples of the florists' art—baskets, bouquets, and vases of flowers, &c. The Chrysanthemum Winter Cheer was utilised to good effect in a large artistic basket, proving its value as a late variety. Bouquets of Lily of the Valley and of Narcissus made a pleasing display (Silver Banksian Medal).

Mr. H. J. JONES, Lewisham, brought two vases of Chrysanthemum Market Gold, proving the value of this variety for producing flowers late in the season.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., arranged several boxes of alpine plants in a natural manner, filled with some of the earlier-flowering species, utilising pieces of rockwork towards the background, among which was arranged dwarf Conifers, Pernettyas, Skimmia japonica, &c. Among the alpine plants in flower we noticed Adonis davurica, Iris Danfordii, Cyclamen Coum, Sternbergia Fischeriana &c. Irises were a feature in this collection (Silver Banksian Medal).

Messrs. CUTBUSH & SONS, Highgate, also staged a group of Magnolias useful for conservatory and general decoration as well as for planting in the open. The members exhibited were carrying numerous flowers, and the species and varieties represented were M. amabilis, M. conspicua (pure white), M. Soulangeana, M. Halleana (double-flowered, white), &c. M. Soulangeana was by far the handsomest variety shown, the large flowers with claret-colour on the exterior of the petals being pure white in the interior. Palms interspersed among the group and an edging of Aralia Sieboldi gave a suitable finish to this handsome exhibit (Silver-gilt Banksian Medal).

Messrs. T. S. WARE, Ltd., Feltham, Middlesex, staged numerous pans of Alpine plants, few of which were in flower. Saxifrages were represented in numerous species in both the sections, and most of the other species of plants suitable for rockeries and alpine gardens found a place in the collection. Such a collection would make a fine display later in the season when they are in flower. Lithospermum rosmarinifolium and Adonis amurensis were shown in flower (Bronze Flora Medal).

A few hardy bulbous plants were exhibited by Messrs. BARR & SONS, 11, 12, and 13, King Street, Covent Garden, including excellent pans of Galanthus Elwesii, the flowers of which were larger and of superior form to the ordinary G. nivalis.

The Misses HOPKINS, Mere, Knutford, Cheshire, had a small exhibit of coloured Primroses, Polyanthus, &c., and a large basket containing well-flowered plants of the altifolius variety of the Christmas Rose.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, set up ornamental baskets filled with plants of Cyclamen in named varieties. The variety Low's Salmon is of a pleasing shade of the colour indicated. Good types of "whites," "reds," &c., were also represented, as well as some of the "crested" section.

Begonia cheveneyensis, exhibited by Mrs. ALEXANDER, Cheveney, Maidstone (gr., Mr. Chas. Crane), is a large-flowering variety of the type represented by Begonia Gloire de Lorraine. It appears to be very like with plants shown on previous occasions under the name of Marie.

Carnation King's Walden Lady exhibited by S. F. HARRISON, Esq., King's Walden Bury, Hitchin (gr., T. J. Heartless), is a perfectly-habited Tree Carnation, with flowers of moderate size, in colour pale yellow and rich pink.

Chrysanthemum Lady Belper, a white-flowered Japanese or decorative variety, shown at the meeting on January 3, was again exhibited by Lady BELPER, Kingston Hall Gardens, Derby (gr., Mr. Cooke).

Hæmanthus natalensis was exhibited in flower by LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr., Mr. J. Hudson). As some doubt was expressed in respect to the identity of the plant, it was agreed to refer it to Kew. The flower-spike was rather more than 2 feet long, and Mr. Hudson stated that the species required a less degree of warmth than most other Hæmanthus, open-air treatment in summer being advantageous.

Awards.

Cotoneaster pannosa.—This is a gracefully-habited species from China, with ovate or oblong leaves about 1 inch long, and small red berries produced in clusters at the end of short axillary, growths. The lateral branches from the main stems droop prettily in an arching manner, and would be very useful when cut for decorative purposes. Shown by Messrs. JAMES VEITCH & SONS, Ltd. (Award of Merit).

Erica mediterranea hybrida.—This is a hybrid obtained from a cross between E. carnea and E. mediterranea hybrida, said to have been raised by Mr. SMITH, Darley Dale Nurseries. In the present instance plants were shown by Messrs. ROBT. VEITCH & SON, The Nurseries, Exeter. The plants were in flower before the middle of December, and are flowering very profusely at the present time. The highest of the flowering growths were a little more than 1 foot from the ground, and the numerous flowers were of rosy-lilac colour (Award of Merit).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Secretary), De B. Crawshay, W. A. Bilney, N. C. Cookson, W. Boxall, W. H. Young, H. A. Tracy, A. A. McBean, W. H. White, G. F. Moore, H. Ballantine, R. G. Thwaites, J. Douglas, E. Ashworth, W. Cobb, H. Little, W. Bolton, R. Brooman-White, and Francis Wellesley.

G. F. MOORE, Esq., Bourton-on-the-Water (gr., Mr. W. H. Page), was awarded the Gold Medal for a magnificent group of Cypripediums, Lælia anceps varieties, Calanthes, Sophronitis, &c. The Cypripediums were represented by many fine and rare specimens, all well bloomed and finely grown, and bearing in the aggregate about 350 flowers. The Lælia anceps were plants of the white varieties, bearing together 40 spikes. Among the Cypripediums noted were C. × Mrs. Wm. Mostyn, Chardwar variety, different in habit to Mr. Wellesley's form, which had previously secured a First-class Certificate, but evidently of the same parentage; a fine C. × aureum virginale, C. × nitens Ball's variety, C. × Fascinator, C. × Thompsoni, C. × Troilus, C. × Evenor, varieties of C. × Leeanum and C. insigne, C. × Amy Moore, a very fine hybrid.

Messrs. SANDER & SONS, St. Albans, received a Silver Flora Medal for a neat group in which the central plant was the noble Cypripedium × Leeanum J. Gurney Fowler, which secured a First-class Certificate (see Awards). At one end was a pan of the new and singular Cypripedium Gratrixianum recently discovered by Messrs. Sander's collector Micholitz. The broad leaves of some of the plants somewhat resemble C. Haynaldianum, the flowers being between those of C. exul and C. × nitens. Others noted were the fine C. × Rolfii stupendum, C. × Phœbe exquisitum, C. × Lady Wimborne, C. × nitens splendidum, C. × Helen II., Dendrobium × Schneiderianum, two fine specimens of D. nobile nobilius, and the pretty and singular Epi-Lælia × Fletcheriana (E. atropurpureum × L. harpophylla). The spikes bore one to three pretty orange-coloured flowers with white labellums tinted with rose.

Mr. J. CYPHER, Cheltenham, secured a Silver Flora Medal for a very bright group of good things staged in his customary effective manner. In the centre were a number of good Lælia anceps Sanderiana, many bearing five flowers on a spike, and with them the variety giganteum with the purple middle lobe of the lip much expanded. A fine Cypripedium × Morganiæ bore three spikes; the pretty and distinct C. × Leeanum Cypher's variety, twenty flowers, and others were equally well flowered; C. × nitens Arle Court variety was a good and well-marked form; C. × Lathamianum had twelve blooms, and C. × Madame Jules Hye, C. × Charlesianum giganteum, good varieties of C. × Sallieri and C. × Lilian Greenwood were also noted. Other fine features in Mr. CYPHER'S group were a very handsome Odontoglossum × crispo-Harryanum, with a grand spike of large white flowers finely barred with purple; and good Lycaste Skinner alba.

Messrs. CHARLESWORTH & Co., Bradford, received a Silver Flora Medal for a very fine group of hybrid Orchids, in which a good show of the fine orange-and-crimson Lælio-Cattleya × Charlesworthii as usual in the winter groups were the principal feature. Other good hybrids were the new pale yellow L.-C. × Andromeda, L.-C. × Digbyano-Warscewiczii, and other hybrids of L. Digbyana and some Odontoglossums.

M. CHAS. VUYLSTEKE, Loochristy, Ghent, was awarded a Silver Banksian Medal for a small collection of hybrid Odontoglossums, including two good O. × Vuylstekei, one being a magnificent dark variety; two good O. × Wilckeanum, O. × crispo-Harryanum, O. × loochristyense, and a pretty hybrid between O. × crispo-Harryanum and O. crispum.

Messrs. JAS. VEITCH & SONS, Chelsea, staged a compact group in which the best things were Cypripedium × Æson giganteum, a bold flower of fine substance; C. × Baron Schroeder, finely blotched with purple; C. × Evadne, C. × Creon, C. × Actæus albida, C. insigne Sanderæ Veitch's variety, a good form raised from seeds; Selenipedium × Pallene (leucorrhodum × Boissierianum), a delicate white flower tinted with pink; and C. × Leucas (Niobe × insigne Sanderæ), which resembles a pale form of C. × Priam.

The Right Hon. Lord ROTHSCHILD, Tring Park (gr., Mr. Arthur Dye), sent a large photograph of a magnificent plant of Phalænopsis Schilleriana, natural size. The plant was purchased at the Burton Constable sale, 1881, and it has flowered freely in its season ever since. The specimen, which was photographed at Tring Park, January 9, 1905, bore a flower-spike having seven main branches and eleven secondary branches, with eighty-eight expanded flowers and eleven buds. The two longest leaves were 15½ inches in length by 5½ in width, and the specimen probably the best ever seen under cultivation. The flowers were between 3 and 4 inches across.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), showed the rare Maxillaria Lindeæ, with fine white fragrant flowers, with pink lines on the petals and yellow-and-brown lip.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr., Mr. Balmforth), showed the pretty Cypripedium × Venus, C. × Maudiæ magnificum, varieties of C. × aureum, and two other Cypripediums, which secured Awards. Also a specimen of Lælia anceps Sanderiana with several spikes, the best having six flowers.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), showed the beautiful Cypripedium × Mrs. Wm. Mostyn, which previously obtained a First-class Certificate; the new Cypripedium × Mrs. Francis Wellesley (Sanderianum × Gowerianum); the very handsome C. × Hera Westfield variety; C. × Dicksonianum (villosum × memoria Moensii), a showy flower having a rose-purple upper sepal with white tip and yellow petals, and lip tinged with red-brown; C. × Cassandra Westfield variety; and Lælia × Clio (glauca × cinnabarina), with yellow flower.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. Davis), showed Cypripedium × Mrs. E. V. Low (insigne × niveum), and the richly-coloured C. × Mrs. Wm. Mostyn, Chardwar variety.

Messrs. HUGH LOW & Co., Enfield, staged a small collection, in which was a well-flowered plant of Cypripedium × Minos, Low's variety, with several flowers; C. × aureum virginale, and other Cypripediums; also a good plant of Lycaste Skinneri alba.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. Chapman), showed Calanthe × Magpie (Wm. Murray × seedling), a good dark rose-coloured flower mottled with white; C. × Phœbe (Veitchii × Turnerii), of an uniform light rose colour, and three others which secured Awards.

J. FORSTER ALCOCK, Esq., Northchurch, Herts (gr., Mr. Foster), sent Cypripedium insigne Northchurch variety.

Messrs. DUCHESNE LANTHOINE & Co., Watermael, Belgium, showed a form of Cypripedium insigne

with a clear greenish-yellow flower with white upper half to the dorsal sepal.

Awards.

FIRST-CLASS CERTIFICATE.

Cypripedium × *Lecanum* "*J. Gurney Fowler*," from Messrs. SANDER & SONS.—The most massive form of C. × Lecanum, and with the thick substance of C. × aureum. Dorsal sepal broader than high, pure white with a small green base and median purple line petals and lip broad, cream-white tinged and marked with purple, the petals having a distinct sulphur-white margin.

Calanthe × *Chapmanii* (× burfordiense × Oakwood Ruby).—The perfection of the clever work on Calanthes at Oakwood. Flowers deep crimson, with a small, lighter eye. A finely-shaped flower and of large size. Quite the most gorgeously coloured Calanthe.

AWARDS OF MERIT.

Cypripedium × *San-Actæus* (insigne Sanderæ × Actæus), from NORMAN C. COOKSON, Esq. — An attractive hybrid, with greenish flowers, excepting the greater part of the dorsal sepal, which is pure white.

Odontoglossum × *mirificum* (luteo - purpureum sceptrum × crispum), from NORMAN C. COOKSON, Esq.—A well-formed flower, cream-white, profusely marked with chestnut-brown colour.

Lælio - Cattleya × *Charlesworthii magnifica*, from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins).—A great improvement on the original form. Flowers reddish-orange, with claret-red labellum, veined with gold.

Cypripedium × *G. F. Moore* (Mrs. Wm. Mostyn Chardward variety × Sallieri aureum), from G. F. MOORE, Esq. (gr. Mr. Page).—A magnificent hybrid, which will still further improve. The flowers partake of the character of C. Sallieri, but the large dorsal sepal is cream-white, with a few purplish markings. The texture of the flower is wax-like and its surface glossy.

Cypripedium × *aureum* ("The Shrubbery variety"), from F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth).—A very large and finely-formed flower; greenish-white tinged with purple, the greater part of the upper sepal pure white.

Cypripedium × *Lawrebel* ("The Shrubbery variety"), from F. MENTEITH OGILVIE, Esq. — Flower almost wholly purplish-crimson, changing to rose towards the white margin of the dorsal sepal.

Cattleya × *Octave Doin* (Mendeli × Dowiana aurea), from Messrs. CHARLESWORTH & Co., Bradford. A pretty flower with blush-white sepals and petals, and ruby-crimson lip veined in the throat with yellow.

CULTURAL COMMENDATION

to Mr. H. Alexander, Orchid grower to Captain G. L. HOLFORD, C.I.E., Westonbirt, for a grand plant of Odontoglossum × Adrianæ var. Countess of Morley, with many flower-spikes.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq., in the Chair; and Messrs. Jas. H. Veitch, F. Q. Lane, Geo. Kelf, Alex. Dean, S. Mortimer, W. Bates, J. Cheal, H. Parr, W. Fyfe, Ed. Beckett, J. Willard, O. Thomas, J. Jaques, Geo. Norman, and Jas. Gibson.

As usual there were several dishes of Apples presented for Awards, one variety Round Winter Nonsuch being found to have received an Award several years ago, while none of the other varieties presented was up to the standard required by the Committee.

W. H. LONG, Esq., M.P., Trowbridge, Wilts (gr., Mr. W. Strugnell), staged thirty dishes of Apples, the examples generally being well developed and of excellent colour (Silver Banksian Medal).

A collection of local and but little known Apples was sent by R. C. APPLETON, Esq., Bar House, Beverley, Yorks. Many of the varieties had but little to commend them judging from their appearance, and no doubt the majority of the names could be traced as synonyms of well-known varieties, which is usually the case with Apples having local names. Those that especially appealed to us were the varieties labelled Boston Russet, Newland Sack, Forester (a pleasing culinary variety), and Honey.

Sir W. D. PEARSON, Bart., M.P., Paddockhurst, Sussex (gr., Mr. Wadds), presented a box of Sutton's Winter Beauty Tomato. The fruits were well finished, and the grower was given a Cultural Commendation.

Mr. H. J. JONES, nurseryman, Lewisham, set up an extensive exhibit of Potatos, staging 130 varieties. As fancy baskets and a white table-ground were used for their display, they made an imposing exhibit and attracted much attention. Most of the newer varieties that have been so much in evidence recently were included, also the latest novelty from America, Noroton Beauty, which has acquired a considerable reputation in the United States.

Lecture on Fruit Preserving.

In the afternoon the Assistant Secretary (Mr. THOS. E. SEDGWICK) delivered a lecture on "The German Methods of Fruit Preserving." Mr. J. L. WOOD occupied the Chair.

After pointing out that by the term "preservation of fruit" are understood various means for carrying over the overplus of one season or one year for use in another, when the fruits or vegetables in question cannot be obtained in a fresh state and in sufficient quantities, the lecturer pointed out that while there was a great number of books devoted to the subject in German, and a few in French, there was no handbook or compendium on fruit-preserving in the English language.

The German Government's efforts to encourage and aid both fruit-growing and the disposal of the crop to the best advantage were mentioned. These included State Loans, Acts of Parliament, and large expenditure on Government Fruit Schools, the principal of which was the Royal School of Garden, Fruit, and Vine-culture at Geisenheim, on the Rhine.

The thoroughness and attention to details evinced by Germans in all their undertakings was next exemplified by the care with which they gathered, stored, packed and despatched their fruit crop, and treated the overplus of fresh fruit for preserving.

A series of German labour-saving machines was exhibited; some removed a fine shaving of peel from Apples or Pears, some also cored and ringed them at the same operation, some were designed to cut Beans and other vegetables in uniform slices, but the machine which attracted the most attention was a small domestic "Gnom" evaporator, which could be placed over an ordinary kitchen range, and thus be applied to dry the fruit or vegetables by means of the waste heat of the range. The form of this machine was extremely simple; an iron frame was filled with wooden trays, each of which had a wire bottom, thus allowing the hot air to pass through all the trays and to remove the moisture from the tissue of the fruit laid thereon. This water could be restored by soaking the dried material in water, but care should then be taken to cook it in the water in which it had been soaked. The larger factory machines were also mentioned.

The various systems of bottling and tinning at present practised in Germany were described, and a series of vacuum and screw-stoppered glass bottles and solderless tins was shown and the methods and advantages of their respective use described.

Considerable stress was laid on the care that the Germans always take in placing foods on the English market to ensure their being uniformly graded, of recognised good quality and flavour, and carefully packed in their bottles without too much juice or sugar solution either above or below the body of the fruit.

The absence in Germany of jam or marmalade as understood by us was replaced by three methods of preparation, named marmalade, must (pulp), and mark (marrow), all of which were treated in a similar manner, but with varying quantities of added sugar and different extent of boiling. The fruit is boiled, and when soft is forced through a sieve, and the pulp thus derived is again boiled and then potted for use. In Germany the skins, cores, and oddments of fruit are often treated together so as to avoid waste, and the product sold for household purposes. The Germans were, however, already studying the English systems of jam-making, doubtless with an ultimate eye upon our own markets.

The experiments and reports which had already been made as to various methods of fruit preserving in this country were summarised, and it was noted that absence of large fruit and vegetable-drying factories in our own country compelled the English Government to spend millions of pounds in Germany during the late South African war.

The formation of the National Fruit Growers' Federation and of the National Fruit and Cider Institute, and the appointment by the Board of Agriculture of a Departmental Committee on Fruit, all tended to show that our fruit industry was waking up to the great possibilities of the future: and the exhibition of jams and bottled fruits in the Royal Horticultural Hall in December, 1904, had shown that the English are still able to preserve fruit in a manner which will compare favourably with that of our Continental rivals, who on that occasion failed to send a single exhibit, and thus we should look forward with confidence to the time when all our dried and bottled fruit and jams are home-grown and home-preserved, and all fresh fruit required for our markets in the colder seasons will be provided by the Colonies of our Empire.

NATIONAL POTATO.

WE extract the following particulars from the Report of the Society's Proceedings in 1904:—

AN ELECTION OF POTATOS.

In view of the number of applications received for advice as to the choice of Potatos for various purposes, it was decided to institute an election among members of the Society, with a view of ascertaining what the majority of the experts thought about the matter.

A form was issued, the result of which is tabulated herewith.

The varieties are shown in order, according to the number of votes they received. Where certain varieties are bracketed they received an equal number of votes.

A few comments on the returns may be of interest.

(1) The presence of Royal Kidney, Factor, Sir John Llewelyn, and Northern Star, in section after section, proves the sterling all-round merit of these sorts.

(2) Mr. Findlay's varieties loom largely throughout.

(3) The appearance of Evergood at the head of three sections proves that in spite of the disappointing results of which some growers have complained, it is a variety to be reckoned with, especially for damp, heavy land. On strong clay in the Secretary's garden it has thriven splendidly.

(4) King Edward VII. is the most popular coloured Potato.

(5) The prominence of Langworthy in the best-for-flavour section will draw merited attention in England to a variety long esteemed in Scotland for its cooking qualities.

(6) Up-to-Date is declining in general favour.

(7) Discovery, as a very late-growing disease-resister, earns the praise of many shrewd growers.

(8) The total number of varieties which received votes was as follows:—Section 1, 82; Section 2, 91; Section 3, 61; Section 4, 62; Section 5, 42; Section 6, 44; Section 7, 24; Section 8, 23; Section 9, 43; Section 10, 48; Section 11, 53; Section 12, 60. It had been hoped to publish the names, but the number is too great.

(9) Owners of meritorious novelties will doubtless be of opinion that their specialities deserve precedence over certain of the varieties herein honoured. Probably this is so, deserving novelties will come to the front in due course. This election does not in any way prejudice them; it serves the purpose of giving the large number of Potato growers who cannot afford to buy expensive novelties a useful guide to the best standard sorts. From this point of view it admirably serves its purpose.

THE BEST DISEASE-RESISTING POTATOS.

1 Evergood (Findlay)
2 Discovery (Sutton)
2 Royal Kidney (Findlay)
4 Northern Star (Findlay)
5 Sir John Llewelyn (Harris)
6 King Edward VII (Butler)
7 Eldorado (Findlay)
8 Factor (Dobbie)

THE BEST POTATOS FOR FLAVOUR.

1 Langworthy (Niven)
1 Sir John Llewelyn
1 Factor
4 Royal Kidney
5 Evergood
6 Duchess of Cornwall (Kerr)
6 Snowdrop

THE BEST POTATOS FOR HEAVY LAND.

1 Evergood
2 Royal Kidney
3 Northern Star
4 Factor
4 Up-to-Date (Findlay)
6 Duchess of Cornwall
7 Langworthy
7 Windsor Castle (Sutton)
7 Sir John Llewelyn

THE BEST POTATOS FOR LIGHT SOIL.

1 Sir John Llewelyn
2 Northern Star
3 Evergood
4 Factor
4 Royal Kidney
4 King Edward VII.
5 British Queen (Findlay)
5 Duke of York (Daniels)

THE BEST WHITE ROUNDS FOR EXHIBITION.

1 Windsor Castle
2 Northern Star
3 Cigarette (Kerr)
3 Snowball (Carter)

THE BEST WHITE KIDNEYS FOR EXHIBITION.

1 Sir John Llewelyn
2 Royal Kidney
2 Satisfaction (Sutton)
2 Snowdrop
2 Duke of York
2 Factor

THE BEST COLOURED ROUNDS FOR EXHIBITION.

1 Reading Russet (Sutton)
2 Vicar of Laleham
2 Dean
2 Herd Laddie

THE BEST COLOURED KIDNEYS FOR EXHIBITION.

1 Mr. Bresee
2 King Edward VII.
3 Edgecote Purple

THE BEST FIRST EARLY POTATOS.

1 Sir John Llewelyn
2 Duke of York
3 Sharpe's Victor

THE BEST SECOND EARLY POTATOS.

1 British Queen
2 Royal Kidney
3 Sir John Llewelyn

THE BEST MAINCROP POTATOS.

1 Evergood
2 Factor
3 Royal Kidney
4 Duchess of Cornwal
4 Northern Star

THE BEST LATE POTATOS.

1 Northern Star
2 Discovery
2 Up to-Date
4 Factor
4 Goodfellow (Findlay).

TRIALS IN 1904.

In the spring of 1904 it was decided to select ten representative varieties and plant them in different districts, s that they could be tested on

various soils simultaneously. The results of those trials are given in three tables.

GENERAL REMARKS SUMMARISED FROM THE RETURNS.

Yield.—The two varieties which came out at the top are Factor and Up-to-Date, Factor being first at seven centres, Up-to-Date at six. The returns would indicate that these two varieties are equal in cropping power; but two unaccountable failures are recorded against Up-to-date at Edmonton and at Cresswell, Stoke-on-Trent, which reduce its position considerably in the average returns per acre. Many of the growers report that these two varieties appear to be identical in growth and habit. Doubtless the dry season has much to do with the excellent results yielded by the old Up-to-Date, which has always been a dry-season Potato.

Royal Kidney and British Queen come next in order, each being the heaviest cropper on two occasion. Both varieties cropped well, but the evidence points to these being distinctly inferior in this respect to Factor and Up-to-Date.

Immediately behind them came Evergood and Cramond Blossom, which are almost exactly equal. The season did not seem to suit Evergood, whereas Cramond Blossom grew vigorously, but was rather disappointing when lifted, having suffered much from growing out.

King Edward VII. gave about the same average crop, and on one occasion came out first among all the varieties by a few marks.

Empress Queen did badly, but the fault in many cases lay with the seed, which was not satisfactory of either this variety or King Edward VII.

The last two varieties, Sir John Llewelyn and Ninety-fold, ought not properly to be considered alongside the others; they are early varieties, and should be treated on different lines from the other maincrop varieties. The seed of these two varieties was not very good.

Indeed the whole value of the trials is somewhat affected by the indifferent character of the seed available in 1904, complaints were general of blanks, and some varieties suffered much more than others.

If the trials are repeated in 1905 with the seed derived from the 1904 trials better results will accrue.

Incidence of Disease.—The disease of 1904 came late, but was pretty general. Details were not always furnished of the amount of diseased Potatos, but the following list shows the totals obtained by adding the records together from all of the centres which gave particulars:—

	lb.		lb.
Cramond Blossom ...	230	Royal Kidney ...	32
British Queen	153	Evergood	30
Up-to-Date	145	King Edward VII. ...	20
Factor	116	Empress Queen ...	13

Thus Royal Kidney gives comparatively the best result.

Flavour.—The reports are so conflicting that no general conclusions can be drawn.

Northern Star.—Of the varieties tried on a small scale Northern Star was generally reported disappointing, yielding a large number of small tubers and with rhizomes that travelled extensively.

Discovery, of which 1 lb. was kindly furnished to each centre by Messrs. Sutton & Sons, was slow to start and never completed its growth, remaining green and vigorous when the haulm of all other varieties had died down. The yield proved disappointing, but each centre has now material for a further test in 1905.

Eldorado.—The plants of Eldorado kindly supplied to a few centres by Mr. W. J. Malden never quite recovered from the shock of transplanting, an operation which was followed by some rather trying weather. Not being specially nursed, in most cases the yield was not heavy, but each centre has now some home-grown seed for a proper trial in 1905.

TRIAL FORMS.

In addition to the centres tabulated, trials were conducted in Shropshire. Copies of blank trial forms may be had free from the Secretary by anyone wishing to conduct trials in 1905.

MEETING OF THE GHENT CHAMBRE SYNDICALE.

JANUARY 8.—At the meeting of the Chambre Syndicale des Horticulteurs Belges, at Ghent, on the above date, the following Awards were made:—to M. M. Janssens & Putzeys of Merxem-Anvers (*par rappel*), for Cypripedium aureum var. virginalis; for C. confetti (C. Spicerianum superbum × C. insigne Walacci); for C. Admiral Togo (C. Sallieri × magnificum × C. Boxalli atratum) (*à l'unanimité*); for C. Janssensi (C. Spicerianum × C. villosum aureum, and for Lælia albida (*à l'unanimité*); to M. F. Lambeau, of Brussels, for Cypripedium Albertiano-nitens var. F. Lambeau; for C. aureum Etoocle; for C. Albertiano-nitens var. superbum (*à l'unanimité*); for C. de Langheanum (*par rappel*); C. auriferum, C. Madeleine, C. Spiceriano-nitens, C. Albertiano-nitens, C. Albertiano (C. Chantini × C. Sallieri Hyeanum) (*avec félicitations du Jury*); for C. Acheron, Cattleya Trianæ var. (*à l'unanimité*), and for C. Trianæ. M. C. Vincke-Dujardin of Bruges, obtained similar Awards for each of the following Orchids: Cattleya Trianæ Mlle. Suzanne Vincke (*avec félicitations du Jury*); for C. Trianæ (three separate specimens). Lælio-Cattleya Cinno-Warneri (L. cinnabarina × C. Warneri) was staged by M. F. de Bièvre, head gardener at Laeken Palace; Cypripedium Elmireanum superbum, by M. Pynaert van Geert; Cattleya Trianæ, by M. Praet; Lælia Finckenniana (L. albida × anceps Sanderiana), hyb. nat., by the Marquis de Wavrin, and Lælia anceps Amesiæ, by the same exhibitor (*à l'unanimité*).

Certificates for superior cultivation and flowering were allotted for Lælio-Cattleya Bièvreanum (L. crispo × C. Rex), from M. F. de Bièvre; Cypripedium nitens var. Houtteana, from M. de Schryver-Block, and for Cattleya Trianæ from M. Vincke-Dujardin.

The following Honourable Mentions were given: for Cypripedium Damyre (C. Sallieri × C. insigne Chantini), from MM. Janssens & Putzeys; for C. aureum Ibis and C. aureum Cyrus, both from M. F. Lambeau; and for C. Trianæ from G. Vincke-Dujardin; and C. Trianæ, from M. E. Praet.

In the Second Section of the Exhibition M. Th. de Martelaere obtained a Certificate of Merit for Carnation Mme. Th. de Martelaere; M. Pynaert van Geert, a Certificate for cultivation and flowering of Cyrtoceras reflexum, and M. L. de Smet Duirirer, Cultural Certificates for Ficus pandurata and for F. neriifolia.

GARDENERS' ROYAL BENEVOLENT INSTITUTION. (See also p. 56.)

Report of the Committee for the Year ending 1904.

JANUARY 19.

"IT is with much pleasure the Committee present their Annual Statement, with accounts (as audited) for the year 1904. They desire to express their gratification and thankfulness at being able to report the continued success of the work which has for its object the permanent and also the temporary assistance of a class who, before being overtaken by misfortune, declining years, or other causes, do so much for the necessities and pleasures of others.

At the commencement of the year 207 pensioners—being three more than at the beginning of the previous year, 121 men and 86 widows—were each receiving, for life, £20 and £16 a year respectively, involving an annual liability of £3,796. During the year 17 of that number have died—11 men and 6 widows—whilst one man has relinquished the pension in consequence of a change in his circumstances, and one widow has been removed to an asylum, owing to her mental condition, thus creating 19 vacancies. Of this number two were filled in by the Committee in accordance with Rule III., 13 being widows whose distressing circumstances rendered them eligible for the allowance of £16 a year. The number of pensioners, therefore, at the end of the year was 190, and the Committee recommend the increase to-day of that number by the election of 18 from a list of 56 approved applicants, as set forth in the voting papers, making a total of 208 pensioners, the largest number of beneficiaries on the funds in receipt of annuities for life at any period in the history of the Institution.

The Committee are keenly sensible of the pressing needs of the many applicants appealing for aid, and heartily wish they were justified in extending the benefits of the Institution to a much larger number.

The anniversary festival dinner, held in June last, was a very great success, a large sum being raised on behalf of the funds. This result was mainly due to the well-deserved popularity of the Treasurer (Harry J. Veitch, Esq.), who occupied the chair on the occasion, and whose convincing and able advocacy of the claims of the Institution, his untiring zeal and devotion to its cause, met with so ready and gratifying a response from all parts of the United Kingdom; in consequence of which a much-needed further sum of £1,000 has been added to the 'Victorian Era Fund.' The Committee tender to Mr. Veitch their most grateful thanks for his services and liberality on this as on all other occasions in connection with the cause. They further desire to place on record their deep sense of indebtedness to Mr. Veitch for his kindness and generosity in compiling and issuing, at his own expense, a 'History of the Institution,' which has already proved of much benefit in creating and sustaining interest in the work.

The Committee have also to express their sincere thanks to those gentlemen who acted as stewards and collectors in connection with the Festival: to the donors of fruit and flowers; to Mr. James Hudson for superintending the decoration of the tables; to the Horticultural Press for its valued gratuitous services and to other helpers in all parts of the country, whose kind and practical aid is sincerely appreciated.

The Committee have to report the receipt, with grateful thanks, of a legacy of £100 from the late Mr. Herbst, of Richmond, who for many years was a warm supporter of the Institution.

The several auxiliaries have again proved of much value as adjuncts to the work, and the Committee most gratefully thank the honorary treasurers and secretaries whose names are hereby mentioned, to whose exertions the success attained is mainly due:—

BRISTOL AND BATH.

Presidents.	*Hon. Treasurers.*	*Hon. Secretaries.*
J. H. Lockley, Esq.	W. A. Garaway, Esq.	Mr. Geo. Harris.

WORCESTER.

Rt. Hon. Earl Beauchamp, K.C.M.G.	J. Hill White, Esq.	Mr. Percy G. White.

DEVON AND EXETER.

C. R. Collins, Esq.	Mr. W. Mackay.	Mr. W. Mackay.

WOLVERHAMPTON.

C. T. Mander, Esq., J.P.	Mr. Bradley.	Mr. R. Lowe.

BERKSHIRE, READING AND DISTRICT.

Robert Grey, Esq.	Arthur W. Sutton, Esq., J.P., V.M.H.	Mr. H. G. Cox.

LIVERPOOL AUXILIARY.

Col. the Rt. Hon. the Earl of Derby, K.G., G.C.B.	A. J. Crippin, Esq.	Mr R. G. Waterman.

Acknowledgment is also made, and sincere thanks tendered, to the "Hurst & Son" Musical Society (Edward Sherwood, Esq., President) for their kindness in allocating the proceeds of a dramatic performance given on behalf of the funds: to Mr. A. J. Brown, of Chertsey; and to the Gardeners' Mutual Improvement Society at Altrincham, for organising successful concerts in the same cause.

The Committee would also refer to the kindness of Arthur W. Sutton, Esq., in contributing the sum of £20 to pay a year's pension to W. Smith, the highest unsuccessful candidate at the last election, whose case was of a most necessitous character. This candidate has recently died, but the help afforded by Mr. Sutton's timely generosity was a source of much comfort to him.

Efficient aid in making the claims of the Institution more widely known was rendered by Leonard Sutton, Esq., who gave a handsome donation expressly for that purpose with very gratifying results. The Committee offer these gentlemen their most cordial thanks.

The "Victorian Era Fund" and the "Good Samaritan Fund" still continue to be the means of providing much needed benefits. The Committee have been able during the past year to distribute from the first-named Fund the sum of £159 2s. to the unsuccessful candidates at the last election who had formerly been subscribers in amounts proportionate to the length of time they had subscribed, and £90 has been given from the latter Fund to numerous applicants, whether subscribers or not, who were found to be in urgent want of temporary assistance.

The Committee cannot emphasise too strongly the value and usefulness of these two Funds; from the one they are enabled to help the "waiting" candidate, who, but for its aid, would receive no assistance until elected on the permanent funds, and from the other they are able to bestow gratuities in cases of emergency and need. It is a matter for thankfulness, as already mentioned, that the Committee have been able to add £1,000 to the capital of the "Victorian Era Fund," thus increasing its annual income and providing a larger sum for yearly distribution.

The Committee, with very great pleasure, draw attention to the munificent gift of £500 from N. N. Sherwood, Esq. (trustee), for the purpose of founding a pension to be called the "May Sherwood Campbell" Widow's Pension. The Committee most gratefully thank Mr. Sherwood for his benefaction and for this further proof of his continued practical sympathy in the work by specially providing for a widow's declining years.

As in the previous reports the Committee have again to deplore the loss, through death, of many staunch friends and supporters in the past year.

Foremost amongst them may be mentioned the Very Rev. the Dean of Rochester, and Mr. S. Osborn.

Dean Hole had been associated with the Institution for many years. He presided at the Anniversary Festival in 1872, and had often been present at subsequent Festivals, making eloquent and touching appeals on its behalf. In season and out of season he was ever ready to evince his sympathies with the work. His loss will be keenly felt, and his kind and valued services will ever be gratefully remembered.

Mr. Osborn had been a member of the Committee of Management since 1886, and was a regular attendant at its meetings; a practical gardener himself, and one who had for so long taken an active part in the affairs of the Institution, his experience and opinions were much valued by his colleagues, by whom he will be greatly missed.

The Committee are glad to be able to announce that the Duke of Westminster has kindly consented to preside at the sixty-seventh Anniversary Festival Dinner, to take place on June 16 next, at the Whitehall Rooms, Hôtel Métropole. They trust His Grace will receive a large measure of support on the occasion, and that the Festival will prove as successful on behalf of the Institution as those hitherto held.

In conclusion, the Committee earnestly solicit increased support to their work. At the close of to-day's election there will be thirty-five applicants left on the list who are appealing for permanent aid, some of whom are blind. To assist them an additional income is required, and whilst not lacking in thankfulness for the means placed at their disposal in the past, the Committee again plead for renewed effort, so that with a larger income they may feel warranted in extending the benevolence of this National Horticultural Charity to a greater number of those who "justly lay claim to its help."

SOCIETY FOR HORTICULTURAL SCIENCE.

THE Society for Horticultural Science met at Philadelphia, Pa., during the annual meeting of the American Association for the advancement of science, on December 27 last, and had a very successful gathering. There was a good proportion of the members present, and several important papers were presented, of which abstracts are given below. One of the sessions took the form of a union meeting with the Society for Promoting Agricultural Science, and the addresses of the two Presidents were listened to by the combined audiences.

WHAT IS HORTICULTURE?

Dr. L. H. BAILEY, Dean of the College of Agriculture at Cornell, in his address discussed the problem "What is Horticulture?" He took up the question of the growth of horticulture as a specialized subject. It had originally begun as an offshoot from botany. It was a growing interest and would in the future become more and more sub-divided. Horticulture joins hands with the plant biologists on the one hand, and with business on the other. Horticulture is contributing greatly to our national wealth; it supplies important foods. He felt that the work in the future would be not to develop so much something we can name so much as something we can measure — to make better plants and to enable cultivators to improve the plants they now grow. Then there was the art side of the subject, covering the whole ground of rural improvement and home adornment. The day must come when each home would have its plant room, not necessarily indoors, just as it now had its library. In the teaching of horticulture in the colleges there must be greater segmentation, and the subject would break up differently in different parts of the country, according to the condition of affairs. There were many commercial sides, each of which needed a specialist. Botany has declined to extend its sphere to subjects that come too near to real human affairs, and has left a larger part of its domain uncultivated. Horticulture has seized this territory: it should hold it.

ORCHARD CULTURE.

Professor JOHN CRAIG discussed the value of an orchard survey, the purpose being to ascertain the causes underlying failure or success, aside from the personal question involved. In other words, to ascertain the underlying fundamental principles of orchard management by an actual analysis of practical conditions. The conclusions often arrived at by the investigator did not carry the weight they deserved, very often because the volume of facts dealt with was too small to make an impression on the practical grower. He felt that if these facts could be gathered from the field and orchard on a larger scale—take an entire county, for instance, and map its orchards—they would have a much better reception from the practical man.

THE HORSE BEAN.

Professor W. T. MACOUN, of Ottawa, Can., reported on the value of the Horse Bean as a cover crop in rows.

POTATOS.

H. J. EUSTACE, of the New York station, reported some successful results in the breeding of Potatos for increased yield. He showed the possibility of enormously increasing the Potato crop of the country by breeding stock for seed. In a field of one variety the yield per hill varied enormously—from 16 to 53 ounces. From 100 hills the 25 heaviest and 25 lightest were selected. The process was continued till 125 hills of each were had. These were duly planted and given good ordinary care and attention. The crops gathered were uniformly in accord with the ancestry. The average yield from the 10 rows heavy seed hills was 362 bushels 15 lb. per acre; that from the light seed hills (5 rows), 339 bushels 10 lb. per acre—a gain of 23 bushels 5 lb. per acre of marketable tubers.

HORTICULTURAL WORK.

Professor JOHN CRAIG, of Cornell, drew attention to a great number of questions that were still unsolved in horticulture and suggested that the Society could with advantage evolve some plan of co-operation of its members, looking to the simultaneous work on a problem in different parts of the country. He endorsed research work along the lines laid down in the paper of Professor Hedrick; also the influence of stock on scion and the reverse; again, how does the stock influence the fruit? How can we secure definite variation? True, these cannot be answered in the lifetime of the individual, but the individual must begin in order that the institution shall continue.

THE ELECTRIC LIGHT.

Professor C. P. CLOSE detailed recent experiments in the growing of plants in the new Cooper-Hewett mercury-vapour electric light, which had been made at the Delaware station. The 4-H pattern lamps were used. The rays have no red in them and looked at through a red glass no light can be seen. The candle-power of each lamp is about 650, and the expense per candle is about one-eighth that of the candle-power of the incandescent light and about three-fourths that of the arc light. Grand Rapids and Boston Market Lettuces were used in the experiment; seeds sown December 14. These were put into a chamber from which daylight was excluded, after they had made four to six leaves, all of which were removed. Plants from a sowing on January 25 were also put in at the same time. These had four small leaves and they were left on. The cultural conditions were not of the best, as regards ventilation and heat during the growing or lighted part of the twenty-four hours; it was at night that the light was on. Of the first setting all were lost by disease except a dozen immediately beneath the light. Radishes were also grown. From a commercial view the experiment was not a success. Chlorophyll was formed, but the plants made a very spindly growth. The object in view was the utilisation of basement barns, and under more favourable circumstances the results must be better.

In the course of a discussion it was the feeling that the light might be used as a supplement to natural daylight in forcing salad plants during the "dark days" of midwinter.

DEFINITION OF VARIETIES.

The importance of co-ordinated variety tests, a subject that received the serious attention of the Society at the St. Louis meeting, was again brought up in the two papers of Professor L. C. CORBETT and Professor W. W. TRACY, both of the Department of Agriculture. The first-named described a system of variety record blanks, which had been devised and had been in use for two years, and the further use of which he felt would tend to properly classify garden varieties in vegetables, and make the introduction of spurious novelties less likely to occur. The great need at present was to arrive at a definite understanding of what really constituted a horticultural variety, as the general trade descriptions, in many cases, dealt with generalities and, in some cases, could actually be reversed. The descriptions of two Tomatos, Stone and Success, were cited. It is evident that neither seed-growers nor the producers of exhibition plants have any fixed notion regarding varieties. This shows the necessity of carefully executed descriptive records. It was stated that the stocks used for these co-ordinated variety tests should have a common origin and be grown under the same environment long enough to have been properly fixed.

Professor TRACY, in his paper, emphasised the necessity of having a distinct varietal type to adhere to in seed-growing. He told of many confusing cases as one in which there were two types of Melon in the introduction of a new variety; one grower had selected his stock to the green type, another to the white rind type. The importance of minute distinctions from the practical standpoint was great, as in Lettuce, where a difference in texture of leaf meant a better forcing variety, but grown outside there was no difference discernible. There were three distinct types of Refugee Wax Bean in the American seed trade to-day. The same thing was true in other vegetables. This instability of type has led to substitution being looked upon lightly in the seed trade. Horticulturists should demand from the introducer of a new variety a distinct and accurate description of what he considers the type to which it should be grown, and this should be rigidly adhered to in the growing of seed to be sold under that name.

A Commitee of the Society was appointed to make an investigation of this whole subject, to report at the next meeting of the Society, the two presentors of the papers being named with power to add to their number.

CARNATION.

Mr. JESSE B. NORTON, of the Department of Agriculture, told of some recent experiments that are being carried on there in the breeding of Carnations, and exhibited a number of seedling flowers to illustrate his deductions on the application of Mendel's law to the breeding of such. He classified the seedling flowers into three groups, as single, semi-double, and double What he calls semi-double are the typical florists flowers; the doubles embracing the split calyx, and monster flowers, which an investigation showed have all the stamens transformed into petals. In the semi-doubles they are not so modified, hence do not burst the calyx. In the seedlings of one capsule all these types are represented in a seemingly regular proportion. Thus the following figures were given as actual records:—

double 6		double 74	
semi-double 15	total 28	semi-double 147	total 273
single 7		single 52	

Other characters also coincided with these figures as, for instance, the matter of odour. According to the law we should expect to have the progeny of a hybrid separate into the dominant and recessive types in the proportions of 1, 2, 1. This, we find, very nearly approximated by the figures given above. As a suggestion to the practical florist he asks, "Would it not be well to cross the single and the extreme double types, rather than always selecting both parents from

the standard types, as by that method there should be a greater proportion of true florists' type produced—that is, if Mendel's law holds?" The work has only just commenced at Washington, and these suggestions were but the inferences drawn from an examination of the results so far obtained.

PLANT ASSOCIATIONS.

In an interesting paper on the relationships of plants in the orchard, Professor U. P. HEDRICK, of Michigan, opened a very important topic. He urged the necessity of studying the growing relationships of plants as cultivated for economic purposes, especially in regard to the orchard. It had been demonstrated long ago that certain species of grasses did best when grown together. Mr. Spencer Pickering, in England, had conducted recent experiments on the effect of grasses grown about Apple-trees. Thistles are said to poison Oats; and the Peach and Potato do not do well together. May not plants affect the soil organisms? A knowledge of the societies of cultivated plants should help us in the study of climate and soils in fruit growing. In botany we give definite names to plant societies; we speak of this or that flora and all understand; horticultural floras are just as real. We need to have them named and classified. Plants are not passive to the attacks of parasites; they make every effort to resist, and by a better understanding of the relationship of host and visitor we can help the plants of the farm and garden to throw off their foes. A study of weeds would be beneficial; weed floras would act as a guide to the adaptability of the soil for certain crops. And an understanding of the relationships would be helpful. Chickweed, which grows after the trees have made their growth, acts as a first-class late cover crop for an orchard. An orchard at Brigham City, Utah, an orchard under irrigation, had Peach trees in which catch crops were grown, and the speaker could tell, almost from the appearance of the foliage, what catch crop had been grown there. The effects of the intermingling were very pronounced. In pot experiments at the Michigan station now under way, Peach-trees were grown in pots, and various other plants with them. Elberta was the variety of Peach. Thirty trees were selected. Fertilisers were added and good drainage provided. The pots were sunk to the brims in coarse cinders. The plants were set 6 feet apart each way, watered as necessary, and not pruned. Three pots were in each test. Potatos, Tomatos, Oats, Rye, Rape, Mustard, crimson Clover, Peas and Beans were the catch crops planted in the pots. Leaves on the trees with Oats and Rye were the smallest and fewest in number. These trees were the earliest to mature. The effects were most noticeable with the Oats. The Potato pots and the Tomato pots suffered next in order, as named in the foregoing respects. The yellowing of the foliage was not nearly so noticeable with the Solanums as with the grains. Next in degree came Mustard, then Rape, followed by the check trees, and most vigorous of all was the crimson Clover pots. The Peas did not make a growth.

SULPHUR WASHES.

Sulphur washes for orchard treatment were discussed by P. J. PARROTT, of the New York Station. In view of the excellent results that have been reported from the use of the sulphur washes in one or two States, it was thought that there was a possibility of introducing a more systematic method of spraying which should include the sulphur wash as a regular part of the orchard practice. At present there is only the Bordeaux spray so used, or rather the Bordeaux-arsenical sprays. These, however, do not repel the sucking insects such as scale and lice. Investigations show that the newer treatment has a good effect in controlling San José scale, Peach-leaf curl, and Peach-scab. By giving one application of the sulphur wash during the dormant season and supplementing with the two latter usual Bordeaux-arsenical sprays, the best results were had in the general control of all the troubles that affect the orchard.

BREEDING HARDY FRUITS.

"Methods in Breeding Hardy Fruits," were discussed by Professor N. E. HANSEN, of the South Dakota Station. He explained that it was found necessary to secure a more favourable condition at blooming time, and the work was therefore done under glass after raising the trees, &c., in tubs for a year or two before blooming. They are wintered in a special cellar with windows to give some light. During late winter and early spring they are brought into the greenhouse and the crossing done there. Dwarfing stocks are necessary, such as Paradise for the Apple, Quince for the Pear, and Western-sand Cherry for the stone fruits. Much success has been had in hastening the fruiting season of cross-bred seedlings; and Strawberries from the cross of the wild with the tame have been brought to the fruiting size in the same year outdoors and fruited under glass in the winter. This saves much time in selecting varieties for propagation. Apple graft hybridisation has been carried on extensively, and the fruiting of hundreds of trees is awaited. Grafted on the Western-sand Cherry the Peach has been found to fruit as a very small tree. This stock would appear to promise advantages for use in private gardens and orchard houses and for dwarf plantations on dry, sandy soils. In growing a quarter of a million fruit seedlings, the many seedling variations appearing give evidence to support the mutation theory of De Vries. Plant breeding in its modern aspect, he says, is plant inventing, rather than the observing of an ever-changing panorama.

Election of officers resulted as follows: President, L. H. Bailey; secretary-treasurer, V. A. Clark; assistant secretary, U. P. Hedrick; W. R. Lazenby is made chairman of the executive committee. *L. Barron.*

(For "Gardeners' Debating Societies," see p. xiii.)

ENQUIRY.

EARLY AND LATE PEACHES.—I should like to know the names of the best early variety and of best late variety of Peach for growing in a cold house to be trained upon a trellis 16 inches from the glass roof? By best, I mean with reference to quality of fruits, prolific bearers, and with vigorous constitutions, not liable to mildew. *L., Isle of Wight.*

TRADE NOTE.

MR. W. NAPPER.—In consequence of the retirement from business of Mr. Wimsett, Mr. Napper is open to an engagement. Previous to coming to Chelsea Mr. Napper was connected with the once famous nursery of Lucombe Pince & Co., of Exeter.

ANSWERS TO CORRESPONDENTS.

ALMANAC: *T. Norman A.* You have omitted to supply us with your address.

"CACTUS" PELARGONIUMS: *W. & J. B.* We think your flowers are very good examples of the type, which may be useful for certain forms of decoration, although in our opinion they are not so effective as the ordinary form of the zonal Pelargonium.

CARNATIONS: *Montis. The American Carnation and How to Grow It.* by Chas. Willis Ward (New York: A. T. De la Mare Printing and Publishing Co.). You will find an exhaustive article on the subject of your other question in our issue for August 6, 1904, p. 88, where special soils and manures for Carnations are discussed.

CARNATIONS DISEASED: *A. & F. F.* They are affected with Puccinia dianthi. You will find an account of it in the books you mention.

CYPRIPEDIUM AND PAPHIOPEDILUM: *T. B.* There are differences between these two groups, and some think the differences to be so important as to necessitate the breaking up of the old genus Cypripedium into other groups of equal value. This is a matter of opinion, but among growers the prevailing tendency is to retain the old genus in its entirety, and we think for garden purposes this is the most convenient plan, as the proposed new genera can be treated as sub-genera or sections, and thus the necessity of adopting new names is avoided. The following is a key to the genera. In the first two the ovary is three-celled, with axile placentas; sepals valvate. Selenipedium has plicate leaves, persistent perianth, subglobose seeds. Phragmipedilum has conduplicate leaves, deciduous perianth, fusiform seeds. In the following two genera the ovary is one-celled, with parietal placentas and fusiform seeds. Cypripedium has plicate leaves, persistent perianth, and valvate sepals. Paphiopedilum has conduplicate leaves, deciduous perianth, and imbricate sepals.

EUCHARIS GRANDIFLORA (AMAZONICA): *R. J. B.* We have repeatedly illustrated very fine specimens of this exceedingly useful flowering plant, but it is quite impossible for us to say where the largest specimen in the country may be found, especially as Eucharis are plants which are sometimes subjected to division at the time of repotting.

"FLORA CAPENSIS": *G. P.* Lovell Reeve & Co., Henrietta Street, Covent Garden.

GARDENERS' NOTICE TO LEAVE: *Constant Reader.* The custom is to give or receive a month's notice. In order to claim this in a court of law, it would however be necessary to afford proof that you are a "menial" servant in the meaning of the Act relating to domestic servants.

GAS-LIME: *Ajax.* You do not state how much gas-lime was applied, or when. If a heavy dressing was given the land may have to be left idle for a year.

GRAVEL: *T. D. F.* You had better obtain offers from the Gravel Company, and from several contractors.

GRUBS: *J. R. E.* They are the larvæ of one of the common weevil, and are as destructive in this form as in the beetle stage. You can do nothing better than trap them with pieces of Potato, Carrot, &c. A small flower-stake should be stuck in the Potatos, &c.; this will indicate the position of the trap, and be useful for withdrawing it.

HYACINTH AND TULIP BULBS: *G. A. M.* There appears to be nothing deficient in the quality of the bulbs, which are a very fair sample. It is likely that something has been introduced in the ashes from your gas-house which has poisoned the roots and killed them. Sulphur compounds would act injuriously in this way.

NAMES OF FRUITS: *R. W. R.* The Pear is over ripe. Send again earlier next season.—*S. P.* 1, Wyken Pippin; 2, Claygate Pearmain.—*L. E. W.* Wyken Pippin.—*A. B. S.* 1, Beauty of Kent; 2, Red Winter Queen; 3, Cellini Pippin; 4, Winter Red Sweet; 5, Sturmer Pippin; 6, Manx's Codlin.—*W. H., Devon.* Leon Leclerc de Laval.—*Sale.* Rather small fruits of Glout Morceau.

NAMES OF PLANTS: *H., Dulwich.* Hippeastrum vittatum, generally called Amaryllis vittata; it grows well as an ordinary warm greenhouse plant, a dry rest being given the bulbs after the foliage dies off.—*E. L., Oxford.* Probably the Bracken (Pteris aquilina) come up from spores under glass. The specimens are small, drawn, and very imperfect barren fronds. Send fertile fronds when available.—*J. H. B., Falmouth.* Olearia Forsteri.—*Correspondent.* The Red Wood, Sequoia sempervirens.

LILY OF THE VALLEY: *J. V.* Please write in French or German, or even in Dutch.

PINES: *J. C.* The foliage is attacked with a fungus closely allied to if not the same as that which attacks the Scotch Fir, and called Peridermium pini. The same fungus also grows on the common Groundsel, but then assumes a totally different appearance. By inoculating the Pine with the fungus on the Groundsel the Peridermium is produced.

RIGHT OR LEFT-HANDED DIGGING: *W. D.* Some regard one way as left-handed and some the other, but we believe that the general opinion is that the man who has his right hand at the top of the spade is right-handed in his work, although he uses his left foot for forcing the spade into the ground.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS: *W. J. D.* Your letter has been forwarded to the Secretary of the Royal Horticultural Society, and we have no doubt he will reply to you.

SOPS-IN-WINE: *C. S. & Co.* In *A Dictionary of English Plant Names*, by Jas. Britten, F.L.S., Dianthus plumarius, the origin of the garden Pink, is stated to be known as Sops-in-Wine. Another author, R. C. A. Prior, attaches the name to D. caryophyllus.

VIOLETS DISEASED: *G. S. H.* Your plants are attacked by a fungus, "Ascochyta violæ." Spray the plants with potassium sulphide, 1 oz. to 3 gallons of water, every fortnight. Select another situation and fresh soil for a future plantation, getting a new stock from a distance.

VINES ON WALLS.

AMONGST other old books on gardening I happen to possess two, both of which give considerable prominence to the culture of Vines on walls. Of course, the means for growing fruit of any kind under glass two hundred years ago would be possessed only by rich people, and if those of limited means were desirous of cultivating Grape-vines, it would become a question of utilising walls for the purpose or going without Grapes. Even now, as one rambles through the villages of Surrey and some other counties in the south of England, wherever a gable end of a house is exposed to the south a white Sweetwater Grape-vine has been planted, probably not in quite recent years, as many of them may be considered to have been planted half a century or more ago. In most cases they bear very poor Grapes, nor anything like a fair crop, not because the Vines are too old, but because sufficient attention is not given to them. The numerous main branches have been fixed to the walls years ago, and the laterals have been spurred back year after year, until they are now so weakly that few or no bunches form upon them. The County Council lecturers might instruct the villagers how gradually to cut out the old gnarled stems and replace them by young wood trained up from the base of the Vine, as only in this way can fruitful spurs be obtained.

Vines grown out-of-doors are liable to mildew; this troublesome pest invariably settles upon the bunches, and I do not know any better way to free the berries and leaves from it than syringing with soft soapy water in which some flowers-of-sulphur has been well mixed. The sulphur can be syringed off with clear water subsequently. "Shanking," which is the terror of gardeners who grow Vines under glass, is unknown upon out-of-doors Vines. With proper cultivation I get bunches of Grapes weighing 2 lb. on the south end of my house, but they seldom ripen well. The rods are trained in the same way as that in which gardeners train them in vineries.

A good treatise on fruit-culture was written by a clergyman, the Rev. John Lawrence, A.M., Rector of Yelverton, Northamptonshire, and published by Bernard Lintot, between the Temple Gates in Fleet Street, in 1716. The worthy clergyman was a good gardener, and had to work with limited means. He tried various methods to ripen his Grapes, such as training the Vines on the sloping roofs, and also by putting the bunches into flasks (glass flasks probably, but he does not say so). In the flasks they ripened sooner, "but they were apt to be mouldy for the want of free air, and had an insipid taste; and the slopes, though they admitted more of the sun's rays, yet they subjected the fruit more to the rains, dews, and cold nights." This Rector, evidently self-taught, had some failures, but he gives the sum of his successful culture of Vines and fruit-trees in this the fourth edition. He found that walls were best, and the climate was much the same as our own, although Old Sol, according to the astronomers, must have decreased twenty miles or so in diameter by combustion during the intervening years.

The varieties cultivated were the White Muscadine and the Black Cluster—these two were most to be depended upon, and the White Raisin Grape was admirable for tarts. Doubtless if the same care were exercised in cultivating Grape-vines now, and the right sorts were grown, the same measure of success would be attained. Our author writes—"Vine of all others needs pruning most, and though it is easiest performed yet it is least understood. Our climate is not so favourable, or the sun over bountiful of his ripening heats, but there is need of all the care and the greatest art to help nature forward in bringing Grapes to any degree of perfection in England;" but he adds, "With a little diligence and timely care there has seldom been a year but I have had good Grapes, and most years great plenty."

Mr. Lawrence deals with all manner of fruit-trees, and gives excellent advice as to planting, pruning, and subsequent summer and autumn treatment.

As some evidence of the interest taken in fruit-tree culture another book on the same subject was published in the following year, 1717, with the title of *Paradise Retrieved;* or a "Method of Managing and Improving Fruit-trees against Walls or in Hedges, contrary to Mr. Lawrence and others upon Gardening," by Samuel Collins, Esq. Printed for John Collins, Seedsman, over against the Maypole in the Strand.

Mr. Collins seems to have rushed into print principally to show the mistakes in practice and errors of judgment made by the aforesaid worthy Rector. I did not intend to follow the discussion, but rather to allude to the importance each author attached to Vines and Vine culture on walls. Mr. Collins advises two ways of growing them; the more practical of the two was to train the growths in single rods to the wall, although the distances apart, 14 inches, would be too close to each other. Once in eight or nine years each rod was to be cut down near to the ground, and young rods were to take their place, the cultivator of course being careful only to cut down intermediate shoots, so that the wall would always be furnished with fruiting canes while the young canes were in process of development. His second method was to train three canes from one root up to the top of a wall furnished with fan-trained Peaches and Nectarines. "These Vines fill the wall to the top at what height soever, and as the roots do not prejudice the stone fruit so neither does the dropping of the leaves damage the fruits, but in wet summers very much conduce to the keeping of it sound."

In the first decade of the nineteenth century (1803) an important treatise on fruit-trees was written by Mr. Wm. Forsyth, gardener to His Majesty at Kensington and St. James's, and it is rather curious that he should deal with the treatment of Vines on walls which had been planted between Peach and Nectarine trees trained exactly as recommended by Mr. Collins nearly a hundred years previously. The Vines had been sadly neglected at the time they passed into the care of Mr. Forsyth. The fruit produced was small, hard and unfit to be sent to the table." He cut them down and trained up two canes from each plant, allowing them to grow their full length. Two of these canes produced 120 fine bunches of Grapes, weighing from one pound to a pound and a quarter each. The following year (1791) he trained five Vines in the same way with considerable success, and in the third year, when all the Vines on the wall had been furnished with young wood (1793), he sent "for the use of His Majesty and the royal family, 378 baskets of Grapes, each weighing about 3 lb."

Mr. Forsyth does not state whether the garden was at Kensington Palace or St. James's, nor does he state the variety from which he obtained such good results. For the results were good, as he adds, "Every one who saw them said that the large bunches were as fine as forced Grapes." The varieties recommended by Mr. Forsyth for open walls were the July Grape, and specially Morillon Noire Hâtive, the white or common Muscadine or Chasselas, the white Frontignan or Muscat Blanc, the small black Cluster; the Auverna or true Burgundy Grape the best for making wine.

There are hundreds of gable ends of houses and walls furnished with Grape-vines, which bear none or worthless fruit owing to no care being bestowed upon them; the old branches have, as has been stated, had the laterals spurred back in some instances for half a century, until the Vine is utterly exhausted. I know plenty such walls that are of no value whatsoever, positions that

would grow splendid Marie Louise Pears, if Grapes are not cared for.

One thing I may be allowed to state here, and that is that our youths, although they have more spare time than we used to have, do not give so much of it to their gardens. They are either playing cricket or attending cricket matches, or reading about them and discussing them in summer, or football in winter. To me it seems a sad waste of time, especially when ten times more pleasure could be obtained from cultivating even a small garden plot. At a recent annual dinner of the Royal Gardeners' Orphan Fund, Sir John Llewelyn said he would like to see every cottager in a position to grow good Potatos, and his wife able to cook them. It seems in these days that the wife will have to grow the Potatos as well as cook them. It is an old saying "that all work and no play makes Jack a dull boy"; but if it is all play and no work it will make Jack a useless man. *J. Douglas.*

CORDYLINES AT ABBOTSBURY.

The illustration (fig. 29) shows a row of plants of Cordyline indivisa growing in the gardens here, some of which were in flower at the time the photograph was obtained. The plants are about 16 feet high, and on the left of them are Bamboos, chiefly Arundinaria Simoni and Phyllostachys viridi-glaucescens, P. mitis and P. aurea. With the exception of P. aurea they are above the height of the Cordylines

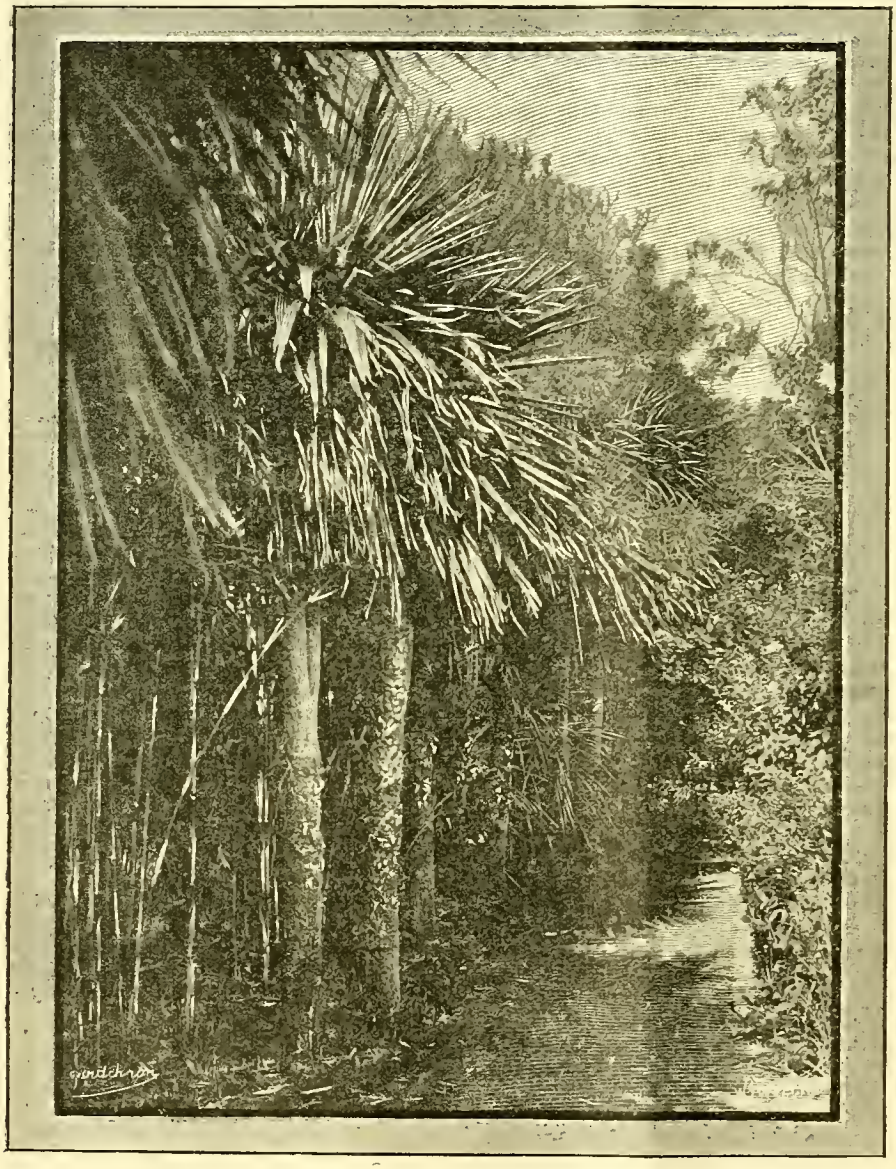

Fig. 29.—Specimens of Cordyline indivisa in Lord Ilchester's garden at Abbotsbury, Dorsetshire.

On the right-hand side of the picture is a feathery-like tree, also higher than the Cordylines, which is Eucalyptus coccifera, raised in Abbotsbury from own saved seed, the original plant being of great age. At the extreme end of the picture is a very large plant of Acacia dealbata, which will be covered with flowers in the spring. This Acacia is about 25 feet high. All the Cordylines at Abbotsbury flowered most profusely in 1904, and in November, when they were ripening their seeds, they appeared, as seen at a distance, to be again in full flower, owing to the effect of the little white fruits. Unfortunately they are very tender, and even those shown in the illustration were cut down by frost, and the present ones are the second or third that have been thrown up. We find the best protection is hay-bands wrapped around them from bottom to top, taking the bands off early in the spring. *H. Kempshall, Abbotsbury Castle Gardens, Dorsetshire.*

THE SPECIES OF EREMURUS.

The genus Eremurus consists of noble Liliaceous plants, closely allied to the Asphodels, inhabiting the drier regions of Asia Minor, &c. There are about thirty species known to botany, but only nine of these are in general cultivation, and but six of them are worth attention as effective garden plants. Their introduction to gardens is of comparatively recent date; E. spectabilis, one of the undesirables, and the plant upon which Bieberstein founded the genus, has been known for centuries. E. Bungei appears to have been next in order of arrival, but it was not until E. himalaicus and E. robustus reached us that the Eremuri gained the favour they now enjoy. Hybridists have taken them in hand, and quite a dozen hybrids known to me await increase of stock before being furnished with names, whilst six are already available for the best garden use in some quantity.

There has always been a difficulty in thoroughly acclimatising bulbous and tuberous plants from the East, the climatal conditions differing so markedly from our own, and Eremuri have shared with the rest of such plants a good deal of neglect on account of cultural difficulties. Happily, rapid propagation by means of seeds and less rapid root increase have rendered it quite unnecessary to import plants, and wide distribution of the home-raised article has rendered a coddling treatment equally unnecessary; one can grow Eremurus of some kind or other in every British garden, and grow them well.

Cultivation.

Eremuri are noble subjects for the flower garden, requiring only that a warm position and light soil be selected for them. E. Bungei, E. Warei, and E. Olgæ and their forms grow best in soils of limestone formation, and lime in some form or other is almost necessary for them. The site should be well drained and a quantity of builder's rubble introduced into the soil, and it is better to raise the bed or border above the general level, so that the crowns may rest in a dry state. The broad-leaved species of Eremurus delight in a free-feeding soil of deep tilth. It does not matter if it is light or heavy, provided it does not hold moisture in suspension 18 inches from the surface. Protection of the crowns just as the flower-spikes are showing is very necessary, for water collected during the night and passed down the leaf channels forms a pool in the morning, and this, freezing solid and thawing suddenly, injures the flower-spikes. A few Fir or Spruce branches laid over the crowns when frosts are expected in late spring will be all the protection needed. It is not necessary to protect the crowns in winter; they are capable of withstanding any frosts they are likely to endure without harm, and protection during winter will only encourage them to grow at unseasonable times. In cold or wet districts E. Bungei and its group would be safer lifted during winter. The loss of a few roots is not a matter of importance to this species and its allies, for I have found the root stocks when shorn of roots grow and flower just as well without them as with them. It is better to leave established clumps alone if in a light, dry soil. All the species must be planted in autumn save E. Bungei, which may be planted in December.

Propagation.

Propagation, other than natural increase of root-stocks, which one cannot influence appre-

ciably, can only be effected by seed raising, and the process is not easy with such species as Bungei, Olgæ, and their forms, which are extremely difficult to nurse through the seedling stages. Where the soil is naturally heavy, frames filled with sandy loam are useful as seed-beds.

Seeds that are freshly gathered and well ripened germinate freely enough if sown immediately in warm borders or frames. The first season's growth is but little more than an inch of pallid leaf, with a thickened base, and growth lasts from six to ten weeks, when the seedlings rest for a year. One can, however, extend the first season's growth by carefully watering the site and shading it from the strongest sunshine just before midsummer, thus preventing the seedlings from resting till they have added the maximum amount of material to the store root, a light being placed over them to keep them dry when they have grown all they will for that season. Next spring growth will appear early, and a light covering of litter is generally necessary to protect the young shoots as they pierce the soil. Again, just before midsummer water and carefully shade the site, so that the root-stocks be encouraged to develop fully. The third year's cultivation is merely a repetition of the first and second, and by this time they will have made the familiar thonged root-stock, when it be better to lift and replant them—the glaucous and narrow-leaved kinds in soil charged with lime-rubble, the broad-leaved kinds in ordinary light soil, rendered friable by adding leaf-soil in limited quantity. *G. B. Mallett.*

(To be continued.)

HORTICULTURE AT KIMBERLEY.

If the question be asked, "Do tree destruction and tree planting affect the climate, decrease or increase the rainfall, increase or lessen the long periodic droughts, increase or lessen the deadly hail-storms of the high veldt," the answer is "that they do so to an enormous extent," and no better evidence can be cited in confirmation of the effects on the climate of tree-destruction around Kimberley, even when those trees were nothing more than a forest of Mimosa scrub, growing as they do in a dwarf form on the wind-swept diamond-fields and lying over 4000 feet above sea-level.

But let us pass over the unfortunate tree destruction of the early days of the Kimberley mines (it was done partly in ignorance, but chiefly because the transport of fuel in those days by ox-waggon, some 700 or 800 miles from the coast, was slow and very expensive) and confine ourselves to the telling of what has been done during these past fifteen years in trying to make a desert literally to blossom as the rose in the way of tree-planting for shade, fruit, flowers, and vegetables, and to increase and make more regular the annual rainfall of the high veldt.

Favoured with a good soil and a supply of water pumped from the mines, Kenilworth, a suburb of Kimberley, the property of the De Beers Consolidated Mines, Ltd., was taken hold of by the late Mr. Cecil Rhodes, and he, with that wonderful gift he possessed of selecting the right men, got hold also of the right person in Mr. F. Fenner, F.R.H.S., as his Superintendent of Forestry for the immense tract of lands held by his Company. Mr. Fenner was at that time (about 1889) at Cape Town in a nursery. His previous experience in England had been extensive. Ten years had been spent at the Bagshot Nurseries; and for six years, before coming to South Africa, he had been the manager of one of the oldest and largest nurseries in Liverpool. But his knowledge of South African horticulture, with its range of climates, its different trees and plants, had been limited. His grip of difficult new work was what one would expect from such a man, and he overcame great difficulties by sheer force of intelligence combined with industry. It is commonly related of him that when he was sent by Mr. Rhodes to spy out the land he was to plant, he wept when he beheld the desolate wilderness which lay stretched out before him. I must state, however, that Mr. Fenner denies this fable. He felt, he said, downhearted; but he was determined that the work Mr. Rhodes desired him to do should be well done. A wholesome faith, that! Here, then, at Kenilworth, the ugly and apparently God-forsaken township of mine-tailing heaps and drainage *débris*, Mr. Fenner set to work to make of it—as now surely it is—Kenilworth the Beautiful; and after fifteen years of intelligent if hard labour, encouraged by liberal masters, a good soil and climate, what do we find?

Twelve miles of tree avenues, six lines deep, giving shade, tranquillity, a peaceful rest as you emerge from the glaring diamond floors and come upon this sylvan spot. These deeply-formed avenues are now, after twelve or fifteen years' growth, about 50 to 70 feet high, and consist of Casuarina (the Beefwood-tree), having a very graceful pendent foliage, and a tree well adapted for droughty climates; Grevillea robusta, also a graceful tree and a drought resister when established; Pinus insignis, P. Pinea, and Cupressus macrocarpa, and many species (I do not know how many) of Eucalyptus, but some of the species I cite—viz., E. citriodora, E. robusta,

Fig. 30.—ZEBRAS IN THE ENCLOSURE FOR WILD ANIMALS IN THE GARDENS AT KIMBERLEY.

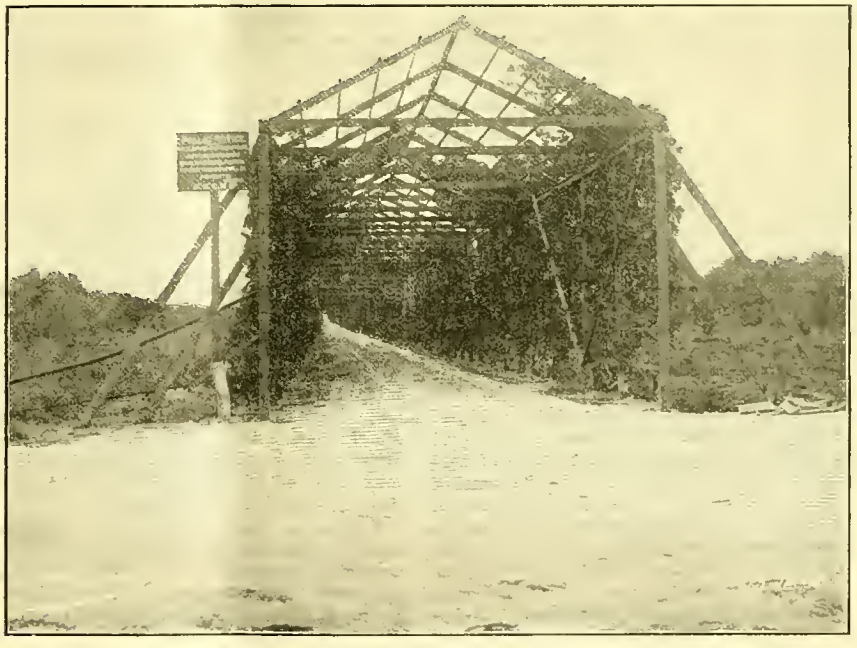

Fig. 31.—HORTICULTURE AT KIMBERLEY: GRAPE-VINE AVENUE, ONE MILE IN LENGTH. (SEE P. 68.)

E. resinifera, E. maculata, E. botryoides, and E. globulus.

But of all the trees at Kenilworth and Kimberley, the finest, the shadiest, and the best drought resister when well established, revelling as it then does in the long dry winter drought of six months' duration on the high veldt, is the Pepper-tree, Schinus Molle. It is, of course, not to be confounded with the pepper of commerce, but its seeds, the prolific nature of which is astounding when the male and female trees are near together, when placed in the mouth, have the flavour of black pepper; hence, I presume, its common name. This tree, I believe, is South American in origin, but it got to South Africa, we believe, from Australia, for Mr. Fenner informed me that he found a lone specimen of it growing, when he first came along, at the waterworks, the position outside Kimberley held so tenaciously by the Boers in the late siege time. This was a solitary male specimen, which bore no seed, but it was good to look upon and to sit under, and full of vigour and shade. Mr. Fenner at once rightly came to the conclusion that it had been brought from Australia by an early digger, and to Australia he therefore sent for seed. The first supply was a failure; but a second lot of seed he obtained turned out to be properly ripened and harvested (sound seed of this tree seems to require to be specially harvested), and hence the whole supply of the Kimberley district at least has come from this clever instinct of discovery, the possession of which is so necessary to success in the Colonies. How grand a tree it is let those who knew Kimberley twenty-five years ago and who know it now as a pleasant health resort, full of shade, brightness, and cleanliness, and of monuments, squares, avenues, and good roads made and planted during and since the ever-memorable siege of 1899—1900.

I had at first thought that Mr. Fenner was entitled to the honour of having introduced this marvellous tree into South Africa (barring our friend the digger), but I have since come to learn that Mr. G. Baikie, F.R.H.S., Horticulturist to the Central South African Railways, had himself, quite by accident, so he tells me, sent to Europe for the seed of Schinus Molle, amongst many other seeds he was then trying as being the most suitable for growing on the high veldt. This was on the Transvaal higher veldt, some fifteen years before Mr. Fenner procured the seed from Australia; and Mr. Tidmarsh, of the Grahamstown Botanical Gardens, verifies Mr. Baikie's statement of its introduction into Africa on a commercial basis some thirty years ago.

It is quite evident that Schinus Molle should not be pruned, or if necessary it must be cut as sparingly as possible, for it bleeds profusely when cut, giving forth a juicy, glutinous substance (it surely cannot be a useful substance like that expelled from the rubber-tree!) It has a way of feathering out at the bottom, covering its own roots with its foliage, Nature's method of conserving its own moisture, which, like the camel of the desert, makes and keeps it independent of water supply. The foliage covering the roots in very fact prevents radiation and loss of moisture in the burning sunshine. This lower foliage or root-covering material, if measured, will be found coincident with the lateral root-growth.

At Mafeking I found that the beautiful siege avenue of Pepper-trees, abutting on the town lands eastward of the town, where no shade or shelter previously was, and which had been planted as a memorial immediately after the siege had ended about four years ago, and now had developed a shady, healthy growth, a streak of evergreen in a dry and thirsty land, had quite recently been ruthlessly pruned; and I noticed all the trees bleeding, dying probably, weeping tears of shame at the ignorance shown of its unique habit, not evidently yet understood of the people who had with such good sense planted this tree. I am quite sure that all South African gardeners will agree with me that the man who had committed such folly deserved to have . . . . for he had done not less than £1,000 worth of damage in a few days with a half-crown knife (which should at once be taken away from him, lest he commit further great sins) in sheer ignorance of the habit of this wonderful drought-resisting, evergreen shade tree.

But to return to Kenilworth. The great belt of these lofty and leafy trees goes around the township, six lines deep, forming a grand shelter, and the 12 miles of avenues radiate from a central circus. Here, within this belt of trees are constructed alongside, well-made roads with turfy side walks, kept green in winter droughts by the shade of the trees, the pretty detached houses of the De Beers' *employés*, managers, clerks, and foremen, and near by, within a specially planted belt of trees for shelter, is the 50-acre orchard of fruit-trees now in grand bearing condition, consisting of all the best kinds of Apples, Pears, Plums (Japanese as well as European), Peaches, Nectarines, Apricots, Figs, Mulberries, Cherries, and the Citrus fruits of all kinds, which latter do well and yield large crops, by reason of the wise and necessary shelter provided. Mr. Fenner has devised an excellent cyanide fumigating movable cabin, by which means he is able at the proper season to thoroughly cleanse and keep healthy all his fruit-trees. He has also devised and erected a large, cool and commodious fruit-room, well shelved, thatched, and covered with straw.

Here, again, are the nurseries, which are the feeding grounds of the continual planting which is being done in and around Kimberley by the De Beers Company, which includes Beaconsfield township as well as Kenilworth, and a new suburb some miles distant towards the hill country and the Modder River, where an electric railway is being built by the Company, and the immense tract of farm lands held by De Beers north of Kimberley towards the Vaal river. The Vine avenue, planted by Mr. Fenner, now much more umbrageous than that shown in the illustration (fig. 31, p. 67), yields an average of 40 tons of Grapes per annum, is over 1 mile long, and a carriage and pair can be driven through it. Mr. Fenner is about to plant an avenue of Mulberry-trees: this fruit, so luscious even in Europe, is ten times more so when grown under the African sun.

All the fruit, flowers, and vegetables grown at Kenilworth are supplied free to the hospitals, sanatorium, the officials of the company, their white workmen, and to the native compounds, where thousands of the black labourers for the mines have most comfortable quarters, kept clean and sweet by a perfect system of sanitation. Herein lies, I think, the chief reason why De Beers have no native labour difficulties, for they look after and take an interest in all their work-people, both white and black.

I have no doubt whatever that the planting policy inaugurated by the late Mr. Cecil Rhodes, and still supported by De Beers' jointstock enterprise, and ably carried out by one of the foremost of South African horticulturists, does even now in the present well repay the proprietors, and future generations yet unborn will bless them.

I must not omit to mention the existence of a splendidly equipped meteorological observatory at Kenilworth, which lies not obscurely within this green oasis, doing good and most useful observational work for Kimberley and district. Belonging to De Beers, it is under the charge of one of their officials, Mr. Sutton, an able meteorologist and a Fellow of the Royal Meteorological Society. Here are to be found instruments of the newest patterns—photographic barometers and thermometers, anemometers and sunshine recorders. In meeting Mr. Sutton I found we had like tastes in practical meteorology. I mentioned to him a new method of sunshine recording I had but imperfectly tested by the "wiping-out" effects of the solar rays of a red ink line streak, which I think might have some advantages over the present photographic and burning sunshine recorders. Mr. Sutton was good enough to promise me that he would make further experiment of the plan, and I hope he will succeed. *Alfred Chandler, F.R.Met.Soc., F.R.Hort.Soc.*

EXPERIMENTAL CULTIVATION.

(*Continued from p. 21.*)

MANURES FOR SPECIAL CROPS—GOOSEBERRIES.—Well-devised courses of manurial experiments with Gooseberries are greatly needed, but they should be carried out on the same plan, at the same time, in as many different districts as possible. The crop is an important one, and worth both time and money to endeavour to secure some definite conclusions. At present the work which has been done in a systematic manner has given, in several cases, contradictory results. It is almost impossible to determine how far these differences are due to the variations of soil, to the effects of local or climatic conditions, to methods of cultivation, to the system of recording the crops produced, or to the manures used.

GREEN OR RIPE FRUITS.

There is a point, too, which must be remembered in this connection, namely, whether the crop is to be gathered green or ripe. In either case the grower requires large fruits and heavy crops; but with regard to the first, earliness is the great consideration, and, apart from varietal tendencies, any manure which assists this will be of distinct value. These objects have not been always separated, as they should have been in experimental work; and I would advise a course of treatment in which production of early large fruits, to be gathered green, should form the first series, to be followed by a second series in which the fruits are to ripen before the records are taken.

STABLE-MANURE v. ARTIFICIALS—POTASH.

The chief consideration is to test how far the value of stable-manure can be increased or decreased with profit by the addition of chemical manures; the form suggested for Strawberries would therefore be suitable—*i.e.*, 30, 20, and 10 tons of stable-manure with and without the chemical equivalents of a complete manure, and including a plot or plots not receiving the dung but only the artificial manure.

It has been stated on good authority that potash salts have a material effect upon Gooseberries, and further experiments are desirable to test how far this may be general. Upon heavy and good medium soils I have not observed any more marked effect with Gooseberries than with Strawberries, especially as regards the fruit gathered when green. A bulky manure which will exert some mechanical influence on the soil, and an ample supply of phosphates with nitrogen, are the chief requisites which my experience and trials have proved most profitable in Gooseberry culture. It is possible to supply these plants with all the essentials of their requirements in the form of chemical compounds, which it might be assumed must support them, and yet they will be seen to starve out of existence in a few years. Instances are well known where the efforts of chemical manures alone on heavy soils, as regards Gooseberries, have been evident to the most casual observer, and required neither

weighing nor measuring records to prove the point conclusively as far as these special cases were concerned.

APPLES.

No fruit known to me has given such conflicting and puzzling results in experiments with manures than the Apple, and it therefore affords abundant scope for extended work of a carefully organised character.

The principal questions which require answering are the effects of manures in combination or singly upon, 1st, the growth of the tree; 2nd, early and continued fertility; 3rd, the size and development; 4th, the colour; 5th, the flavour; and 6th, the keeping properties of the fruit. To investigate all these matters thoroughly would be a great task and a lifelong work; haphazard or ill-devised attemps are worse than useless—they are absolutely misleading. It is far better to restrict efforts to one or two points and deal with these as exhaustively as possible; it is at least the surest way to secure some return for the labour. This one of the lessons we learn from experience; there is so much demanding attention, and the beginner who examines the matter is so eager to be first in the field with the commencement of his work, that in a few years he is overwhelmed, and a large proportion of otherwise good work is lost because it cannot be carried to completion.

Two great difficulties beset experiments with Apples; one is that, as with all grafted or budded trees, it is not easy to obtain a number on identically the same stock, and this renders the comparison of the work by different observers in some measure uncertain. The other is that a considerable period must elapse before reliable results can be secured. After the trees arrive into bearing, the variation of seasons will often affect the amount and quality of the crops to a far greater extent than any system of manuring can do. It is only therefore by having a long series of years to draw conclusions from that a trustworthy average can be ensured.

There are two periods however which come well within the range of the cultivator; one is the growth of the young tree from the time of budding or grafting until fruit-bearing commences, the other is when the trees are fully developed and either have had no special treatment or all have been treated alike, and probably show signs of diminished size of fruits or lessened fertility. In both these cases it is possible within a few years to produce some results by experimental manurial tests that may be of service, and upon which conclusions of general value may be founded.

The whole life of an Apple-tree would thus be divided into three parts: 1st, the period from the bud to fruit bearing; 2nd, from fruit bearing to maturity; and 3rd, from maturity to decline. Dealing with Apples on a dwarfing stock, the first may cover three to five years; the second is of uncertain and variable duration, perhaps from ten to twenty years, and presents the chief difficulties to the experimenter. The duration of the third depends upon many circumstances, amongst which the natural habit of the variety, and the health of the tree from its youth onwards, will have their respective effects.

For many reasons it is desirable to define clearly to which period observations are directed, and while it is eminently desirable to have continuous experiments, it would also be useful to have some confined to the first and third periods, for these come within the power of a far greater number of persons. Investigation might therefore deal with a study of the following:—

1. Effects of animal manures, with and without complete artificials, in different quantities.
2. Effects of phosphates.
3. Effects of potash.
4. Effects of nitrogen.
5. Effects of various substances, such as lime, iron, sulphur, magnesia, and others.

In the special series of experiments 2 to 5, a standard or normal experiment in 1 should be selected for comparison, together with a plot that is unmanured.

For declining trees a comparative trial should be made of manures in a solid state and in solution, as there is frequently a material difference both in the absolute effects and in the time requisite to display them.

Two important matters demand attention in experiments with young Apple trees, namely to have as many individual trees as possible subjected to one course of treatment, and the other is to select them with the utmost care in order that both in root and branch growth there will be a close approach to equality of vigour. The natural variations in strength and other qualities which cannot be detected are so great that averages drawn from a few individuals may be rendered most deceptive by one exceptionally good or one very bad tree.

As regards conclusions, too, a remark of Pfeffer is worth due consideration, viz., "The function of an essential element is by no means directly indicated by the results which its absence produces (see *Physiology of Plants*, vol. i, p. 424). *R. Lewis Castle.*

(To be continued.)

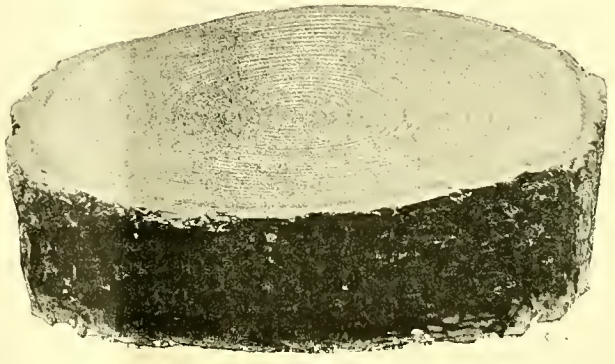

FIG. 32.—SECTION OF DOUGLAS FIR FROM STEM 50 FEET HIGH AND 18 INCHES IN DIAMETER. (*One-sixth natural size.*)

THE DOUGLAS FIR.

THE reader, on inspecting our illustration (fig. 32), must please remember that it shows a section of the trunk about 18 inches across, and being reproduced one-sixth only of the natural size, does not, on first inspection, give an adequate idea of the real size. The photograph was sent us by the courtesy of Mr. John Booth, and represents a section of a tree planted by him near Berlin on light loamy soil some thirty years since. The stem measured 1½ foot through, and was 50 feet in height. About two-thirds of the wood is reddish, like Larch, and resembles it in quality.

FRUIT REGISTER.

APPLE TOWER OF GLAMIS.

I AM sending samples of this excellent culinary Apple for your inspection, in support of my contention that it is one of the best varieties of cooking Apples extant. Our soil here is a very heavy loam resting on a clay subsoil, while the climate is unusually cold and damp, and by no means favourable for the production of Apples. In spite of these conditions the above variety does splendidly, the trees showing no sign of canker, and are quite a contrast to several other varieties here, which fall an easy prey to this disease. Another good point in its favour is that it is an excellent cropper, and even in 1903, one of the worst years for Apples on record, our trees of Tower of Glamis bore average crops of fruits. The tree is such a vigorous grower that its proper place is in the orchard, where it should be given plenty of head room, and allowed to grow unpruned, save in the centre, for the first year or two after planting. The branches will year after year become studded with fruit-buds, invariably followed by good crops of fruit, which, if properly harvested and stored, keep well into the new year. I have been using Tower of Glamis for culinary purposes during the past two months, and still have them in good condition. *W. H. Yates, Rotherfield Park Gardens, Alton, Hants.* [Certainly a most desirable variety for use late in the season; the specimens sent were of excellent quality. ED.]

ALPINE STRAWBERRIES.

The *Revue Horticole* has a coloured illustration of a Quatre Saisons Strawberry named Millet. The fruits are borne in raceme-like clusters. Each fruit is about 1½ inch long, ¾ inch wide in the middle, and tapering to either end; bright red with projecting "seeds"; flesh milky-white, sweet, perfumed, and of such consistence as to travel well.

PEAR VICE-PRESIDENT COPPIERS.

A chance seedling raised by M. Coppiers. The fruits are of moderate size, with delicate flesh of a slight almond flavour. The Pear is of medium size, regularly pear-shaped, with a moderately long stalk and a slightly depressed eye. The skin is dull brown, assuming an orange tint at maturity. Season September, October. *Bulletin d'Arboriculture*, January.

GRAPE PRINCE OF WALES.

This is pronounced in some catalogues to be a sport from the variety Mrs. Pince; but it seems doubtful, as the foliage is quite unlike that of the latter variety. It is, however, of first-class quality, and probably the best Grape of recent introduction. I planted two fruiting-canes, purchased from Messrs. James Veitch & Sons last March, and allowed each red to carry a bunch of Grapes. At the time of writing the berries are of a jet black colour, solid, and of an excellent Muscat flavour. I am of opinion that as a late Muscat-flavoured Grape there is nothing to equal this variety. I wish I could allow the bunches to hang till March, but they are required for use now. It is a vigorous grower, and produces long, tapering bunches, with large, oval berries that develop a beautiful bloom. Those growers who desire a good late black Grape should not fail to plant this variety. I have tasted Diamond Jubilee at different places this season, and am not impressed with it. I cannot speak too highly of the

qualities of the variety Prince of Wales, and those who plant a cane of it will, I am sure, not regret having done so. *C. J. Ellis, Warren House Gardens, Stanmore.*

TREE FERNS.

WITH few exceptions the cultivated species, being natives of New Zealand, require only a moderate temperature during autumn, winter and early spring, such as that afforded by an intermediate-house in this country, say 45° as the highest by night and 55° by day when sunny, or 5° less in dull weather. This regimen will suit Dicksonia antarctica, D. cicutaria, D. squarrosa and D. Youngi.

The Cyatheas dealbata and medullaris, as well as the Cybotiums princeps, Schiedii and spectabilis, are best grown, at least throughout the colder months, at which periods growth is or should be in abeyance in this country, in a house having a temperature by night of 50° to 55°, and 60° by day.

An important point is aërial moisture, for if this be not afforded constantly, in large amount in the season of growth, and lessened quantity at other seasons, fine fronds will not reward the cultivator, and thrips and scale will greatly increase, to the detriment of the plants and the loss of their beauty. These plants, from whatever country they come, are found only in moisture-laden localities, and near or beneath the shade of tall trees, so that any lengthened exposure to direct sunlight or arid conditions of the air is sure to be injurious to them.

In the summer, when there is much drying sun-heat, the stems should be damped with water through a fine rose syringe twice a day, or still more often, if, owing to the use of the conservatory by the inmates of the mansion, it is impossible to keep the paths constantly damp. In a state of nature the stems are kept moist by the dead fronds that hang around them; but no gardener having an eye to tidiness would permit such a state of things to exist in a trim conservatory; and as a substitute for the brown and withered fronds of previous years, the stems are sometimes covered with Selaginella denticulata, S. cæsia, and others, Ficus repens (stipulata), which afford the required hindrance to the undue evaporation of moisture.

In the spring, when renewal of growth takes place, there are often intervals of strong sunshine, and moisture may then be applied to the stems once a day, with a slight sprinkling of the crowns in the early morning and at closing time. Owing to the aërial or stem roots taking up large quantities of moisture, and the true roots keeping close at home, large pots or tubs are uncalled for, except in the case of aged specimens of great size, and such are best planted in a properly prepared station in a border, although such plants are less useful in decorative work, for being once planted they cannot be moved about. As a soil in which to grow any of the species, a sound turfy loam, one year in stack, mixed with one-eighth of sharp coarse sand, sandstone broken to the size of Horse Beans, together with a small quantity of leaf-mould, and one-fourth of the whole to consist of hard peat, should be used. Let this be prepared, if possible, a month previous to using it. Pot firmly, using a blunt rammer, not forgetting to afford ample space for the application of water.

If manure be applied in the root-waterings, it should be of the mildest description, these plants being extremely "clean-living," decaying tree-leaves and spent Mushroom-bed material, at the rate of 1 bushel of either in 40 gallons of water, being the strongest that it is desirable to use, and then only in the season of growth. The drainage should be sufficient but not excessive; and, as root-distnrbance causes a check to the plants, the material placed immediately over the crocks should be of an enduring nature.

When Tree-Ferns reach this country they usually present the appearance of crownless and rootless boles. For convenience sake these may be put into pots or tubs just large enough to accommodate the bulbous end, stood in an intermediate-house, and syringed twice a day, no attempt at forcing them to vegetate being made. The bulbous end may be bound round with sphagnum or ordinary moss. When roots appear generally at the root end and along the stems, potting in a proper fashion may be forthwith carried out.

If a sheltered spot can be found in the pleasure-grounds or flower-garden, preferably on the north side of tall trees, the Dicksonias, if portable, may be risked outside during July, August, and the early half of September, guying them securely to stout stakes driven deeply into the soil, a full-sized slate or tile being placed under each pot. Keep the soil around them moist, and attend to their requirements as if under glass. *F. M.*

KEW NOTES.

EPIDENDRUM ENDRESII, *Rchb.*—Although named and described in the *Gardeners' Chronicle* by Reichenbach so far back as April 7, 1883, this lovely species is still very scarce. This is no doubt accounted for by the fact that it is difficult to import in good condition, and it is also very slow to increase under cultivation. A very healthy little specimen is now in flower in the Cattleya-house. Its time of flowering is therefore almost the same as that of the original plant, which was found by Endres in Costa Rica in flower in December. The plant has three flowering stems, the tallest of which is about 8 inches, and having an aggregate of twenty-eight flowers; the sepals and petals are white, the large lip being blotched with violet. At Kew this delicate species is grown well at the cool end of a Cattleya pit, in a compost of fibrous peat and sphagnum-moss in equal parts. (See *Gardeners' Chronicle*, April 18, 1885, p. 504.

PLATYCLINIS LATIFOLIA, *Hemsley.*

A specimen with twenty spikes is now flowering in the warm Orchid-house. It is a robust-growing species with tapering pseudo-bulbs about 1½ inch long, and broad somewhat leathery leaves about a foot in length. The flower-spikes are borne on slender peduncles, gracefully arched, and 2 or 3 inches longer than the leaves; the flowers are creamy-white, rather large, and arranged in two distinct rows on the rachis; at the base of each flower is a reddish bract about half the length of the sepals. P. latifolia is very fragrant, as also are several other species. P. cucumerina and P. glumacea are also flowering.

HIPPEASTRUMS.

The most attractive feature of the greenhouse (No. 4) at the present time are two handsome groups of Hippeastrum crosses, arranged with Ferns. They are among a very early batch of a large stock of bulbs, from which a series of displays will be produced for some considerable time. These bright and beautiful groups have now become quite an annual feature at Kew, special attention having been given to the careful selection and judicious crossing of this popular class of plant during the past ten years, resulting in the production of a very high-class strain. The plants have large, well-formed, bold-looking flowers, with broad and almost uniform segments. The colours are very rich and varied, the deep red forms being perhaps the most pleasing, of which Sir William is typical. The lighter forms are also well represented, though they are not so extensively grown at Kew as the darker ones. *W. H., January 26.*

The Week's Work.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Fruit-trees. — The pruning and training of pyramid and bush trees should be undertaken with great care. Young pyramid trees require to have their branches trained as nearly equi-distant as possible. Trees that are making suitable growth should have their leading branches shortened to within 12 to 18 inches. The main central shoot of a pyramid tree should be perfectly straight. In bush trees all the continuation branches may be shortened as in the pyramid, allowing sufficient growth to remain on each to preserve a well-balanced tree, but the side growths on the leading branches should be shortened to three buds. Older trees that are in a fruit-bearing condition require similar treatment to those described above, but in a modified form, and any cross branches and misplaced shoots must be removed entirely. Trees that are growing too freely and that are unfruitful should be noted that they may be subjected to root-pruning in the autumn. The spurs may be treated in the same way as advised in a former Calendar. Much discretion is necessary when manuring fruit-trees. They should not all be given it indiscriminately, for by so doing a vigorous-growing tree that is manured will become still more vigorous and unfruitful.

Training.—After pruning is completed the shape of pyramid trees may be considerably enhanced by training the branches at a suitable distance apart, and in the case of those varieties, such as Annie Elizabeth Apple and Le Lectier Pear, whose growth develops perpendicularly, this is essential in order to admit a free circulation of air and light. The lower branches should be pulled down to the required position by strong tar-twine and fastened to neat pegs driven securely into the ground or tied to an iron or wooden hoop encircling the tree. Each consecutive branch may be tied to the branch below until the whole tree has been trained. In the case of young trees these ties may be removed after one season, but should remain longer in older trees, which take more time to "set" their branches. The heads of young standard trees may be treated as advised for pruning pyramids. Trees planted late last spring and left unpruned may now be cut back to a growth-bud, always selecting one growing in an outward direction. The side-growths should be shortened to a growth-bud.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Lobelias.—Plants of Lobelia fulgens that were lifted in the autumn and wintered in a heated frame will now be in suitable condition for dividing into small clumps for potting. The pieces should be potted into 4-inch pots, using a compost of leaf-mould, manure from an old Mushroom-bed, and loam. Encourage the plants to develop suitable growth by placing them in a pit with a temperature of about 60°. When they are well established they should be shifted into cold frames to become hardy. The variety Queen Victoria has crimson foliage; this, with Firefly, Ibis, and Lord Ardilaun, are all excellent varieties. Lobelia cardinalis and L. syphilitica are North American species, and can be treated in a similar manner. L. Milleri is a fine rich-purple hybrid.

Dwarf Evergreens.—The following shrubs are all suitable for growing under trees and in shady places:—Andromeda (Leucothoe) axillaris and A. Catesbæi; these are excellent subjects for planting on banks or borders, never becoming too large, and always attracting attention with their slender arching stems. They are peat-loving plants, but will also thrive in sandy or gravelly soil. In open situations they often develop bronze-coloured foliage. The plants are propagated from seed, from layers, and by division, and are somewhat slow in growth until well established. Gaultheria Shallon is seen at its best when spreading over steep banks or on rough, rocky places. Skimmia japonica will grow in shady situations, but will never develop its beautiful berries under

such conditions. Hypericums are splendid subjects for planting under the shade of trees, where they form a "carpet" of growth. Ivies, Periwinkles, Berberis, and Veronica Traversii are also suitable for this purpose. Where space is unlimited Rhododendrons are unsurpassable for this kind of planting, while Aucuba, Holly, Yew, and Box may all be used.

Berry-bearing Shrubs. — Some of the more suitable for planting are Pernettya mucronata (which is always effective), Cotoneaster horizontalis, C. microphylla, C. Simonsii (one of the best species), C. frigida, Crataegus Pyracantha var. Lelandi, Hippophae rhamnoides, and Leycesteria formosa.

Hollyhocks are indispensable for hardy borders, and in places where the fungus is a scourge, it is best to treat them as annuals. Sow the seed now, and when the seedlings are up encourage them to make strong plants by May. Too much fire-heat will be prejudicial to robust growth.

Carnations, Verbenas, and *Centaurea candidissima* may also be sown now.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Main Crop Peas.—Our general practice with regard to sowing this crop is to do so on the first opportunity that presents itself in the new year. The ground selected for the purpose is that in which Celery has been grown, and with this object in view the trenches for the Celery are made 6 feet apart. When the Celery is dug the soil is allowed to remain in the form of trenches, with the result that a much larger surface is exposed to the influence of the weather. Previous to sowing the Peas the ground is first levelled, and then shallow trenches are made about the width of a spade and at a depth of from 2 to 3 inches on the site occupied by the Celery trenches, which allows ample space for taller-growing varieties, to which we give the preference. The variety which is largely grown here for the main crop is Criterion; this grows to a height of 6 feet. According to my experience this variety has had many rivals but no superiors during the past twenty-four years of my practice. For later crops the variety Autocrat is unsurpassed, being of robust growth and of a free-fruiting character, yielding Peas well through November or until cut down by frost. The Gladstone, also a late-cropping variety, is probably unsurpassed for the size of its pods. The varieties Alderman, Gradus, and Prizewinner are also amongst the most desirable varieties to grow.

Brussels-Sprouts. — For early crops seeds of this highly-esteemed vegetable should now be sown as advised for Cabbages, and the general treatment required is the same. A soil too loose in texture and over-rich has a tendency to produce plants whose sprouts are but sparingly produced and of a large, loose character. The sprouts should be round, compact, of medium size, and closely developed upon the stem. For the main crop sow seeds on a warm border early in March. The drills should be sufficiently far apart to allow the hoe being used freely between them. Suitable varieties to grow are Sutton's Exhibition and Dwarf Gem.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cypripedium insigne and Varieties. — These plants may soon be put in order for the season, renewing first the surface compost of those that do not need to be repotted. In repotting the plants do not disturb the roots very much, and if the roots are difficult to turn out of the pots, insert an old table-knife, and work it round next the inside of the pot to loosen them. Then place the plant in a fresh pot, and fill in around with more drainage material, and a compost consisting of two parts peat and one part each of sphagnum-moss and good yellow loam-fibre, adding a little sand or small crocks. This grand cool-growing Orchid needs a genial atmosphere, and a temperature ranging between 53° and 60° at this season, and a sufficient supply of water to just keep the rooting medium moist. With the above species may be grown such as C. Arthurianum, C. Niobe, C. nitens, C. villosum, C. Boxallii, C. purpuratum, &c., which in most respects may be treated as advised for C. insigne.

Cypripedium Spicerianum.—This species resents disturbance at the roots, and so long as the plant thrives with an annual renewal of the surface potting materials, it should not be disturbed. If it is found desirable to repot the plant, carefully divide it into convenient pieces, without causing more than necessary damage to the brittle roots. Place the plant in the new pot, and insert pieces of crocks amongst the roots, filling the pot in this manner to within 3 inches of the rim. Place moss over the crocks, and fill the pot almost to the rim with a compost consisting of two parts peat, and one each of fibrous loam and moss, adding a sprinkling of sand as the work proceeds. Make the whole firm, but not hard, and have the centre of the plant somewhat above the level of the receptacle. Give the plant a gentle watering immediately afterwards, using a rosed can for the purpose, and allow the roots to approach dryness before watering again. Afford shade in moderation, sufficient moisture in the atmosphere of the house and at the roots, and keep the house at a temperature of from 55° to 65°. Avoid growing the plants in a close atmosphere, at the same time avoid draughty ventilation. During the summer months deluge them with rainwater overhead. C. Spicerianum has probably been used for hybridising purposes more than any other species, and generally with good results, notably in the case of C. × Leeanum, one of the finest winter-flowering Cypripediums. This hybrid should be treated in the same way, and disturbance and division of the plants will be attended with little danger if carefully carried out. Other hybrids should be treated in a manner similar to that appropriate to the species whose characters are most predominant in the hybrid. For instance, C. × Buchanianum, in which C. Druryi occurs, should be grown in the warmest house, and be carefully watered during the winter months. In all hybrids bear in mind the peculiarities of the parent species, and treat the plants accordingly.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

THE season is approaching when the potting and topdressing of plants must be given attention. It will greatly facilitate matters if suitable material for this work is now prepared. If the loam can be cut from a well-built stack of soil little trouble will be found necessary in order to bring it to a suitable condition for use, but if the soil is in a wet and cold condition, considerable time must elapse before it can be properly prepared. When the soil is in this unworkable condition it is advisable to spread the turves thinly in a place where they can be protected from the weather and allowed to gradually ameliorate, in preference to the usual practice of placing them in baskets or in similar receptacles in the stoke-hole or on very hot water-pipes. Flower-pots of various sizes should be examined and cleansed, particularly the inside of the pots, before being stored ready for use. These matters, small in themselves, are of vital importance to success, apart from the pleasure that is gained from seeing the work proceed smoothly and without hindrance.

Richardia [*Calla*] *Elliottiana.*—Little difficulty is now experienced in flowering this beautiful golden-coloured Arum, thoroughly ripening and afterwards resting the plants for a suitable period being the principal requirements for success. For producing an early batch of these flowers some of the strongest rhizomes should be potted and placed in a warm-house. A suitable compost for these plants should consist of two-thirds loam, on of peat, and a liberal addition of silver-sand. The rhizomes should be potted deeply. When potting the plants use sufficient of the compost to cover the drainage, and then place a layer of silver-sand; plant the rhizomes on the sand, and then fill the pots to within an inch of the rims with the soil, which should be sufficiently moist to enable the grower to dispense with watering until root-action has started satisfactorily.

Chrysanthemum Plants that were propagated from cuttings taken in November should be removed to a shelf or staging near to the glass, and allowed to remain there for some days previous to being potted. Care must be taken to avoid draughts, which will otherwise check the plants. Where two or more cuttings are growing in a pot, these should be separated without loss of time, and potted singly in thumb-pots, as no advantage will be gained by giving them a larger shift at this season. Cuttings rooted singly in a pot may require a slight shift, but unless the pots are well filled with roots this operation is better deferred for a few days. The plants should be stood in a closed frame with a little fire-heat, and placed near to the glass. They should be syringed frequently, and under these conditions will make roots readily. A suitable covering of mats will be better than excessive artificial heating for protecting the plants from frost at night-time. Stock plants that are retained for supplying further cuttings should be examined, and those that show no signs of developing growth should be plunged to the rims of the pots without delay in a brisk bottom-heat of leaves, while the plants should be syringed occasionally to induce growth.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Permanent Vines.—Severe weather, with cold easterly winds, following mild weather, has made it necessary to bestow extra care and attention in the ventilation of early vineries; some air should, however, be admitted early in the day when the weather is favourable, in order to encourage strong, healthy growth, and to carry off excessive moisture. From the time the bunches are visible advantage should be taken to close the houses early on bright days, and thus encourage the Vines to grow freely; at the same time the temperature may be allowed to fall to 58° in the morning. Remove from free-setting varieties, such as Black Hamburgh, Foster's Seedling, and Madresfield Court, all weak shoots and any small bunches that are not required. This should be done before the Vines are in flower. It is not advisable to tie the shoots down too soon at this early period of growth, except those whose points press against the glass, and these should be brought down by degrees. Stop the shoots two or three leaves beyond the bunches according to the amount of space available, giving sufficient room for the principal leaves to have full exposure to light and air. The night temperature should be gradually increased to 65° by the time the Vines arrive at the flowering stage, increasing the day temperature correspondingly, but always allowing a fall of 5° in very cold weather. Pollinate the open flowers at midday, and at the same time keep the atmosphere of the house somewhat drier. Another watering may be given at this stage to those Vines which are confined in well-drained inside borders; this will generally be sufficient until the Grapes are set.

Early Muscats.—These require a temperature of about 5° higher than other varieties, especially at the period when the Vines are in flower. Remove all bunches except the most compact ones on each shoot, which will allow more than enough for a full crop. Keep the points of the bunches when in flower well to the light, and if possible pollinate them with Black Hamburgh pollen. All Muscat houses should now be closed, as Muscat Grapes require a longer season in order to finish than most other varieties.

Mid-season Houses which contain several varieties of Grapes should now be started, in order to supply ripe fruit during July and August. See that the inside border is sufficiently watered, and if necessary use tepid water for the purpose. Syringe the Vines two or three times daily, according to the conditions of the weather, always allowing the canes to become dry before night-time. A night temperature of 50°, rising to 65° with sun-heat, will be found suitable.

Young Vines.—Should home-grown Vines be required for planting in May, "eyes" should now be put in. Select buds from wood that is firm and well ripened. Remove some of the wood below the buds, and insert them in small pots filled with loam and sharp sand, and then plunge the pots in a bottom-heat of 75° to 80°.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, FEB. 4 { Société Française d'Horticulture de Londres Meet.
WEDNESDAY, FEB. 7 { British Gardeners' Association, Meeting at Croydon.
FRIDAY, FEB. 10 { Royal Gardeners' Orphan Fund, Annual Meeting and Election of Candidates.

SALES FOR THE WEEK.

MONDAY AND FRIDAY NEXT—
Hardy Border Plants and Perennials, Roses, Azaleas, Greenhouse Plants, Fruit Trees, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.
WEDNESDAY NEXT—
Azaleas, Rhododendrons, Palms, Border Plants, Roses, Fruit Trees, &c.; 1,484 cases of Japanese Liliums, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Lilies from Japan, also Palms, Roses, Shrubs, &c., at Stevens' Rooms, at 12 30.
FRIDAY NEXT—
2,000 Odontoglossum crispum, consignment of Cattleya Warneri, &c., and an importation of Cattleya Trianæ, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·3°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, February* 1 (6 P.M.): Max. 54°; Min. 39°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 2 (10 A.M.): Bar., 30·1; Temp., 44°. Weather—bright, with sunshine.
PROVINCES.—*Wednesday, Feb.* 1 (6 P.M.): Max. 48°, London; Min. 43°, N. of Ireland.

L'entente horticole. WE have inserted the following communication because, although some exception may be made to it on points of detail, and whilst exaggerated importance is, as we think, given to the proceedings of certain special Societies, yet the principle laid down is one to which general assent may be given. The Royal Horticultural Society to our own knowledge has been represented in former years, either directly or indirectly, at Amsterdam (twice), Brussels (repeatedly), Florence, St. Petersburg, Paris (frequently), Düsseldorff, and Haarlem, and in this very year a deputation from the Society will visit Paris, so that our correspondent's statements require some modification.

The interesting report in the *Gardeners' Chronicle* (see p. 47) of the annual dinner of the French Horticultural Society of London, held at the Café Royal on January 14, conveys to those who were not present only a faint idea of the remarkable degree of support that the officers and members of the National Chrysanthemum Society accorded to their French colleagues.

Both the Chairman, M. Philippe de Vilmorin, who came specially from Paris to preside at the dinner, and Mr. George Schneider, the President of the French Horticultural Society, must have been deeply impressed with the sympathy and manifest goodwill displayed by the members of the English special society, which was so largely represented. And this feeling is largely the outcome of a thoroughly international policy that has been pursued by the National Chrysanthemum Society for at least fifteen years or more. As a result it is probably better known on the Continent, but particularly in France, than any other special society in this country, and has many friends and sympathisers where it could not otherwise have expected to have them.

Having been the first and probably the only English horticultural society of any kind to lay the foundation stone that forms to-day the basis of the "Entente cordiale," as it exists in its present form amongst the gardening fraternity of the two nations—a work in which the heartiest co-operation of the French Horticultural Society has been unstintingly accorded—we may well enquire how it is that other societies are content to remain in a condition of insular and almost indifferent isolation. The main reason would appear to be that there are in England very few of our horticultural societies that have active working members with either a sufficient knowledge of the French people, the French language, or French horticulture generally.

In the case of the National Chrysanthemum Society it has long been different. The very flower to which its energies have been constantly devoted for more than half a century is essentially a French one. Many of the most important points in its history are closely associated with French workers, and many of the great improvements in the popular autumn flower have been and are still due to French cultivators. The National Chrysanthemum Society recognises these facts, and never fails to acknowledge them by participating as often as is possible and convenient in the great Chrysanthemum shows and conferences that are held abroad, and has sent deputations to the Continent for this purpose more frequently than all the other English horticultural societies put together have done for other purposes, whatever they may have been.

As a result, when great international gatherings are held, the National Chrysanthemum Society is not forgotten, and it is worthy of mention that it is the only English society that has ever exhibited the produce of its members abroad. On each occasion the result was most gratifying, and the jury made the highest award in its power to the exhibit. But this phase of the question is of minor importance; there is still the more important one of almost total abstention from anything like official recognition by leading English horticultural societies of great international horticultural gatherings abroad—possibly the sole exception being the Ghent Quinquennials [?]. Last May, when the Royal Horticultural Society of Piedmont held its jubilee show in Turin, almost every important horticultural society in Europe was represented by the personal attendance of some of its officials. During the festivities, which were under Royal patronage, we had frequent occasion to lament the absolute indifference (to use the mildest term we can) of English horticulturists in contributing to the success of that great gathering.

In 1900, when the Paris International Exhibition was open to the world at large, it was remarkable that no English exhibitor took part in any of the periodical flower shows that were held between May and October excepting the Chrysanthemum men. It is equally remarkable that not one horticultural or floricultural society in the United Kingdom paid anything like an official visit to the exhibition, except our own National Chrysanthemum Society—a fact that cannot have escaped the notice of our French *confrères*. For some years past there has been in existence a Société Française des Rosiéristes, which holds a yearly show and conference, in much the same way as the French Society of Chrysanthemum Growers does; yet we never heard that there has been anything like a friendly and official visit to one of these shows by the English Rose-growers, who are surely indebted in some measure to French growers for having played their part in the development of the Queen of flowers. In fact it is more than probable that many members of the National Rose Society are even unaware of the existence of a French sister society, and that it will hold on May 23 next in Paris an International Show and Conference, to which Rose-growers of all nations will undoubtedly be warmly welcomed.

I feel tempted to ask the question in these days of the "Entente cordiale," when so much depends upon mutual esteem and regard between every section of the two great nations who are neighbours, "Will this opportunity be allowed to slip by without English and French Rose-growers following the example already set them by the devotees of the not less popular flower?"

The National Horticultural Society of France is organising, as it does once in every ten years, an International Horticultural Congress and Show, which will be held from May 20 to 28 next. There is no doubt that individual visitors from this country will be present, for happily there has always been recognised by individual horticulturists of both nations a feeling of common interest and regard for each other on account of the love that each has for his calling. Amateur and professional alike, no matter in what branch of the gardening art they are interested, can always meet on the neutral ground of horticulture on the best of terms, and without regard to the rival claims of politics or nationality. These meetings can and do frequently take place informally; but what we should in this year of grace 1905 more rejoice in than anything else beside is to see some of our leading horticultural societies in the United Kingdom do their part towards further cementing the "Entente cordiale," as has already been done by several other organisations on both sides of the Channel. In a few years' time England and France will have been at peace for a hundred years; as the time draws near surely each and every one of us might well do our best to hasten, if possible, the time when the sword and the spear shall be turned into ploughshare and reaping-hook. Others, such as medical men, scientific men, parliamentarians, and commercial men, have in an organised way begun, and why should not representative horticultural societies follow? The opportunity is close at hand, let us hope that it will not be neglected, so that our friends on the other side may see that a large and important section of the community like the gardening fraternity of this country, as represented by some of its leading societies, regards the "Entente cordiale" not an expression of mere empty compliments, but as founded on an honest desire to promote the best interests of our two countries and a cordial determination to do everything to further the friendly intercourse between all those who are actively engaged either for profit or pleasure in the great and peaceful art of horticulture. *C. Harman Payne.*

NATIONAL CHRYSANTHEMUM SOCIETY.—The Annual General Meeting of the members of the above Society will take place at Carr's Restaurant, 265, Strand, W.C., on Monday next, February 6, at 7 P.M., CHARLES E. SHEA, Esq. President, in the chair. In addition to the usual business transacted at this meeting the members will be asked by the Committee to consider some proposed alterations to the rules.

—— The following notice is being issued to raisers, importers, and distributors of new varieties of Chrysanthemums:—"The Executive Committee has decided that after January 1, 1905, a department of plant registration shall be instituted by the Society. Raisers, importers, and distributors of new varieties (whether members of the Society or not) are requested to send to the Registrar appointed by the Society, on or before December 1 in every year, a list of all new varieties they intend to send out in the ensuing year; such list to contain the name and description of variety, the name of raiser and of the distributor, and the section to which the new variety belongs, forms for which purpose will be provided upon application to the Registrar. Growers are requested where possible to submit any such new varieties previously to the Floral Committee for classification. The information thus obtained will then be inserted in the *Annual Report and Schedules of Prizes* every year, and thus the Society's Official Catalogue will practically be kept up to date. The Registrar at present is Mr. C. HARMAN PAYNE, 141, Wellmeadow Road, Catford, S.E."

SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE.—This Society will hold, from May 20 to 28 next, a great international exhibition of horticultural products and of cognate industries. Foreign visitors are invited to take part in the proceedings, and a deputation from our Royal Horticultural Society will attend. The schedule and the programme of the Horticultural Congress, which will be held at the same time, will be sent on application to the Secretary of the Society, Rue de Grenelle, 84, Paris.

MINISTER AND GARDENER. — The death is announced of the Rev. DAVID LEWIS, in his sixty-eighth year. In addition to being pastor of Elim Baptist Church, Mr. LEWIS was head gardener to the late Lady LLANOVER at Abercarn Uchar which position he retained to the end.

THE BRITISH GARDENERS' ASSOCIATION.—Meetings for the purpose of organising branches of the British Gardeners' Association will be held in the following towns: Croydon, February 7; Waltham Cross, February 7; Norwich, February 8; Leeds, February 11; Birmingham, February 13. Also in Manchester, Liverpool, Bath, Crawley, Newport (Mon.), Exeter, Wylam-on-Tyne, and Altrincham. It is hoped that gardeners residing near any of these towns will make further enquiries concerning, and will make an effort to be present at, the meetings. Up to the present meetings have been held in the following towns: Oxford, Haslemere, Bournemouth, Caterham, Redhill, Sunderland, Ipswich, Swansea, Cardiff, Loughborough, Newport, Isle of Wight, and Newcastle. Secretaries of Gardeners' Societies are invited to communicate with the Secretary of the Association, with a view of making arrangements for meetings in their respective districts.

—— Gardeners who wish to become members of the Association, but who are in doubt as to any point, are invited to communicate with one or other of the following gardeners, if in or near their district, they being either secretaries of branches of the Association, or taking an active part in its promotion:—A. C. BARTLETT, Pencarrow Gardens, near Bodmin; W. G. BEGBIE, Stanford Hall Gardens, Loughborough; D. BLISS, Superintendent of Parks, Swansea; A. J. G. CHALICE, The Nurseries, Plympton; E. G. CREEK, Westerfield House Gardens, Ipswich; J. COUTTS, Killerton Gardens, Exeter; W. H. DIVERS, Belvoir Castle Gardens, near Grantham; A. GAUT, 61, Belle Vue Road, Leeds; C. G. GIRDHAM, Avondale, Cecil Road, Hale, Altrincham; W. HALL, Mowbray Park, Sunderland; S. HEATON, 36, Hill View Road, Oxford; J. D. JONES, 3, Acacia Road, Bournville, Birmingham; C. H. SNOOK, West Hill Gardens, Shanklin, I.W.; J. W. MALLINSON, Longwathby R.S.O., Cumberland; J. MILBURN, Victoria Park, Bath; H. A. PETTIGREW, St. Fagans Gardens, Cardiff; C. S. RITCHIE, Benellen Towers Gardens, Bournemouth; W. SEAMAN, Margery Hall Gardens, Reigate; J. UDALE, 2, Ombersley Road, Droitwich.

VENTNOR IN JANUARY.—The extreme mildness of the winter climate at Ventnor, Isle of Wight, was conspicuously noticeable on Sunday last, January 29. We had left London on the previous day, where everything out of doors was in the grip of hard frost, and skating was so common along the route of the L. & S.W. Railway that lakes two to three acres in extent were available and safe as far south as Guildford. On Sunday morning, during a walk along the sea front at Ventnor, however, the following plants were observed in flower on the undercliff, and in open-air gardens on the Esplanade—Veronica Traversii and other species; yellow and coloured Primroses, Snowdrops, Viburnum Tinus (in flower everywhere), Escallonia macrantha, Marigolds, Chrysanthemum frutescens, (Marguerites), 4 feet high and 5 feet across, specimens in front of Waveney Villa having scores of excellent flowers upon them; Aubrietia, Arabis alpina, Helleborus species, Vinca major, Pansies, Jasminum nudiflorum, several varieties of Roses, Ivy-leaved Pelargoniums, some of which being trained against the fronts of houses were nearly 10 feet high, and freely flowered; zonal-leaved Pelargoniums in the open and under verandahs, as at the Clarendon Boarding Establishment on the hill near to the railway station, where they are from 6 to 8 feet high; Iris stylosa, of which a plant on the "Cascade" facing the sea bore nearly a dozen perfectly fresh flowers of pale-blue colour; Mesembryanthemums in several varieties—these grow abundantly, and flower all through the year in many an island garden. Coronilla glauca, so commonly cultivated in pots in less favoured districts, was trained 6 to 8 feet high on the front of the Esplanade Boarding House, and presented a display of yellow flowers from every shoot. These plants could all be seen from the Esplanade, but on further search many more remarkable specimens were found to be in flower in a garden at St. Lawrence, and spring Cabbages were ready for cutting in a garden at Bonchurch, to both of which we hope to refer in a subsequent issue. Before leaving the sunny Esplanade (where ladies were making good use of their sunshades) the official meteorological instruments were inspected, and they read thus:—*Barometer:* 39·9° (abnormally high); *Thermometer:* 52° (in shade). At the same time the thermometer in Pier Street, which is not so much exposed to the sea-front, read 45° What a delightful winter resort Ventnor offers to Londoners, whose good spirits may have suffered from the effects of fog and the disappointments incidental to suburban gardening!

CHANGES IN THE LONDON PARKS.—The recent death of Mr. KEMPSALL, who was for many years Superintendent of Clissold Park, has involved several changes in the management of the London parks. The chief of these is the raising to a higher grade of the Victoria Embankment Gardens, of which Mr. F. W. WRIGHT, who kept the gardens so well three or four years back, has been requested to again take charge. Mr. J. H. BATES goes from the Embankment to Clissold Park, Mr. G. DODSON from Kennington Park to Springfield Park, Mr. T. WEATHERSTONE from Battersea Park to Kennington Park, and Mr. F. PHILP becomes Superintendent at Myatt's Fields. On January 31 Mr. WEATHERSTONE was the recipient of a handsome testimonial in the form of a timepiece, subscribed for by his colleagues at Battersea Park. Mr. ROGERS, the Superintendent, made the presentation.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mrs. E. ALLWARD and Mrs. ANNA M. SMITH desire to thank the subscribers to this Institution who elected them as pensioners on the Fund at the recent election.

IN MEMORY OF GORDON.—About a year ago, says the *Sussex Daily News*, Mr. ALBERT HILLMAN, of Ersham, near Hailsham, was fortunate enough to secure, through the Egyptian Government, a cutting from the Rose tree growing on General GORDON's grave at Khartoum. This cutting has produced five young trees, one of which has been graciously accepted by Queen ALEXANDRA. It occurred to him that it would help to keep green the memory of the great Christian soldier if one of the young trees were planted in Hailsham churchyard; and as the 26th ult. was the twentieth anniversary of General GORDON's death Mr. HILLMAN, with the consent of the Rev. F. CLYDE HARVEY, Vicar of Hailsham, planted the tree in a prominent position about 9 yards south-west of the Lady Chapel.

HORTICULTURAL CLUB.—The annual meeting will be held at the Hotel Windsor, Victoria Street, on February 14, at 5 P.M., and the annual dinner will be held at 6 P.M. at the same place.

MANCHESTER BOTANICAL GARDENS. — The Council in their Annual Report report a heavy loss as the result of the year' working. The accounts show that the total income was £1,734 8s. 10*d.*, while the expenditure was £3,443 3s. 6*d.*; the deficit on the year's working was thus £1,708 14s. 8*d.*, bringing the total deficit to £11,431 7s. 6*d.* The Council are aware that the serious annual losses incurred in connection with the Society's work cannot continue, and that something must be done immediately to save the Society. The Trustees and Council, working in conjunction, have agreed that in order to maintain the Gardens for the public they should be offered on very reasonable terms to the City of Manchester, the amount fixed upon being £20,000. If the negotiations with the City of Manchester are carried through, the Council of the Society will devote itself to horticultural work from an educational standpoint. Flower-shows will be held in the Gardens as formerly. Lectures on horticultural subjects will be given periodically, and when possible in conjunction with the shows. These lectures and reports of shows will be printed and issued in the form of an annual journal of the Society's proceedings, with illustrations of new and rare plants, &c., and sent to all members of the Society.

RETARDED LILY OF THE VALLEY. — On Jan. 27 we were shown some extraordinarily good specimens of Lily of the Valley obtained from retarded crowns in the nursery of Messrs. THOS. ROCHFORD & SONS, Broxbourne. They were 18 inches high, of unusual strength, and most of the spikes had thirteen, fourteen, and even fifteen "bells" upon each. Retarded crowns are most useful for forcing before Christmas, and these flowers at the end of January are therefore worthy of remark.

SARRACENIA CATESBÆI.—In a recent part of the Contributions from the botanical laboratory of the University of Pennsylvania is an article by Dr. MACFARLANE on this species, which has been confounded with S. flava. Plants were grown in the Edinburgh Botanical Garden under the name of S. flava picta, the pitchers of which in their microscopic structure resembled those of S. rubra No light was thrown on these plants till Dr. MACFARLANE received fresh specimens from Mobile, Alabama, and eventually was enabled to visit the plants in their native home. Specimens were collected and cultivated in the university garden at Philadelphia. The flowers produced were of a pale lemon colour and in some cases almost white. They were at once seen to be identical with those of the so-called S. flava picta of British botanic gardens. A full description is given, from which we learn, among other things, that whilst in S. flava the leaves appear in April and wither in October, in S. rubra they last till the end of November or early December; in S. Drummondi they persist till February or March of the succeeding year, and in S. Catesbæi they remain green till the end of April. Those of S. variolaris, psittacina and purpurea last still longer. Dr. MACFARLANE speaks of S. Catesbæi as the most successful fly-catcher of all the species, and it is the earliest species to flower, he having collected flowering specimens in Alabama as early as February. S. flava comes next in order, then S. variolaris, S. psittacina and S. purpurea, whilst S. rubra and S. Drummondi flower a month later than S. Catesbæi. [See a monograph, with numerous illustrations, of the garden forms of this genus, including a note on S. Catesbæi, in the *Gardeners' Chronicle*, June 25 and July 2, 1881. ED.]

ROYAL HORTICULTURAL SOCIETY.—As this sheet is passing through the press we have received a copy of the Annual Report of the Council. We are precluded therefore from doing more than call attention to some of its contents. As our readers know the year has been a specially memorable one, and the opening of the new Hall and of the garden at Wisley constitute, in the slang of the day, a "record." Some nine thousand pounds are urgently required to pay off the building debt, and the trustees of the Lindley Library, we may add parenthetically, are still "passing rich on £40 a year." Thanks to the munificence of Baron Schröder, however, the library is in course of installation in the new building, in a manner that it never was before. At Wisley, a range of glasshouses has been erected, together with residences for the officials. A research laboratory is promised in the future. We greatly regret to hear of the discontinuance of the Holland House Show, but the Council, we are told, is seeking some other locality wherein to hold its summer show. The usual financial statements are published. We must defer further comment till another issue.

ROSE SHOW AT THE CRYSTAL PALACE.—The Crystal Palace Rose Show has been definitely fixed for Saturday, July 8. Schedules can be obtained from Mr. G. CASELTON, Superintendant Gardener, Crystal Palace, S.E.

HARDY ORANGES.—In his annual report Secretary WILSON, of the Department of Agriculture (United States), states, regarding the production of new Citrus fruits: "The efforts that have been made by the Bureau of Plant Industry for a number of years in the matter of producing by budding new Citrus fruits, so as to build up varied industries in the South, have met with very gratifying results. The hardy Oranges, which have been secured as a result of the crossing of the sweet Orange with the hardy Japanese Oranges, are now ready to distribute, and the work of distribution will be inaugurated in the coming winter. There has been fruited this year for the first time a sweet Orange of the hardy type. This is an accomplishment which the Department hoped for when it first inaugurated the work. The other new Citrus fruit developed from the Bureau's investigations, such as the new Tangelo, which is a cross between the Tangerine and the Pomelo, a new velvet-skin Orange, and several other creations, will all prove exceedingly valuable in sections where the climatic conditions will permit the growing of these more tender sorts."

COBHAM PARK.

(*See figs.* 33, 34, *and Supplementary Illustration.*)

IF the visitor to Cobham, in Surrey, proceeds from the village along the road leading to Effingham, he will pass by the pretty old church, cross the bridge which spans the river, and in about five minutes come upon the estate of C. Combe, Esq. The estate, and even the gardens, will be found on either side of the road—on the left hand the dwelling-house, pleasure gardens, shrubbery, lake, &c.; and on the right hand the kitchen and fruit gardens, including the glasshouses. The view of the house shown in the Supplementary Illustration is one taken from the north front, at some distance away, and having the lake for the foreground. The house is a stone building, and was erected in the year 1872; it stands on a somewhat steep incline, the ground falling from the south to the north.

The lake is 3½ acres in extent, and, together with running streams, gives to the estate the appearance of being abundantly watered. The river affords facilities for boating, and the lake for fishing. On January 28, at the time of our visit, the lake being frozen over, a good area for skating was afforded.

There are plenty of timber trees in the grounds, and numerous Conifers have been planted during the past thirty years to impart a furnished appearance to the view in winter. The most prominent subjects, however, are several old Cedars that were probably as high twenty years ago as they are to-day. One of these, on the south front of the house, towers well up above the building, and may be seen in the illustration. It is a noble fellow, albeit the leading shoot was lost years ago, and the form of the tree thereby decreased in symmetry. Of the younger Conifers one of the most attractive is a specimen of Cedrus atlantica glauca rather more than 20 feet high, of perfect shape, and making rapid growth each season. On the north-east side of the house one of the paths passes under the Weeping Beech shown in fig. 33. This tree spreads over a considerable area, provides dense shade from sunshine, and is a popular feature of the grounds. A more remarkable tree is a decrepid specimen of the common Lime about 60 feet high. The trunk is quite hollow for several feet upwards from the base, and at a point 4 feet or so high decay has eaten across the sides towards the back of the trunk, almost as a saw might have cut it. Though the sides still exist therefore, the principal support for the tree is at the back, and when in leaf, under the influence of wind the trunk from above the point where decay has destroyed the sides may be seen to sway a little from side to side, but is yet firmly held erect by the good tissues still remaining at the back of the trunk.

There are several borders of herbaceous perennial plants around the shrubberies, and stretches of beautiful green lawn between the trees afford charming walks from the dwelling-house. Paths also extend into the wood or shrubbery over an area of nearly 10 acres, and in

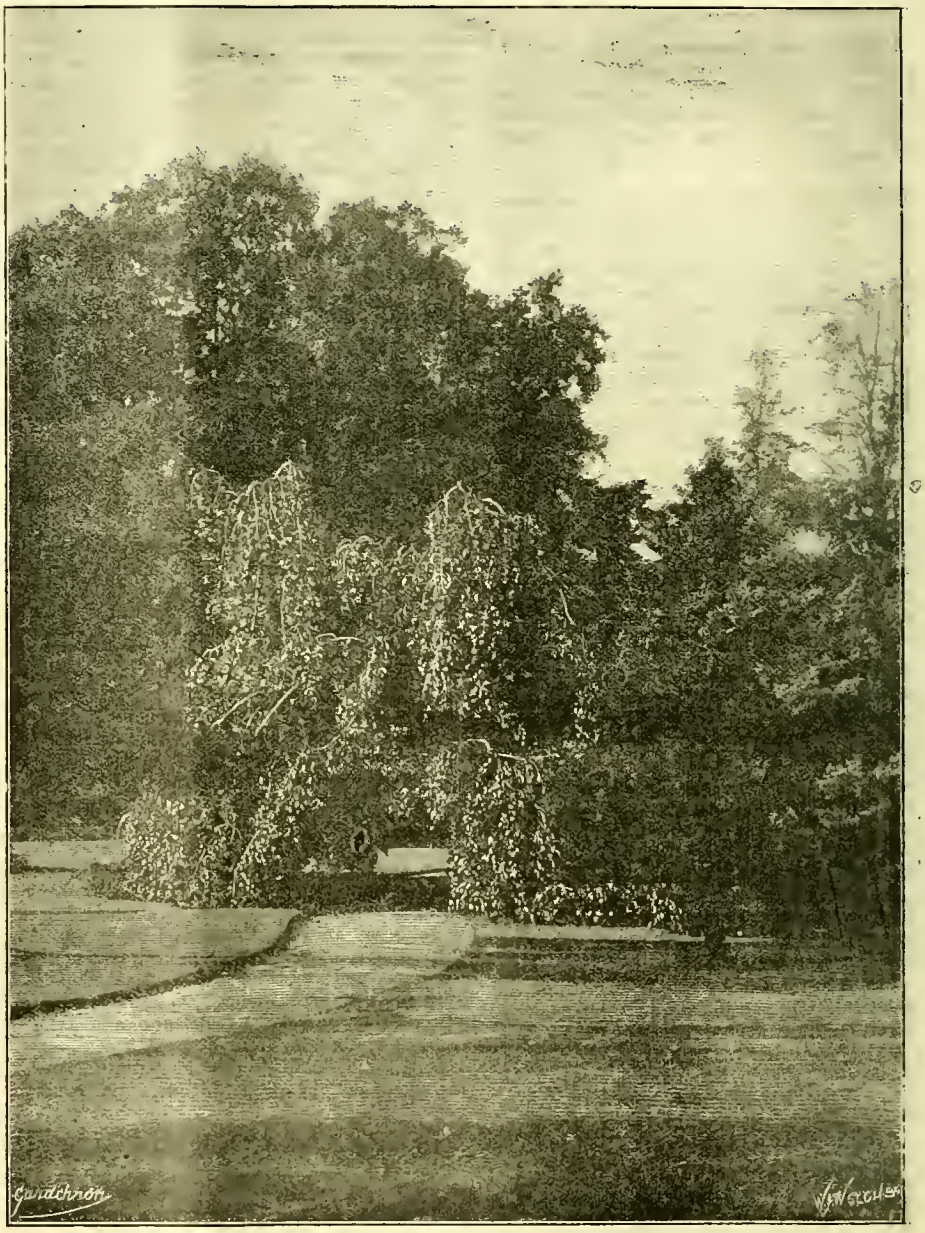

FIG. 33.—WEEPING BEECH IN THE GROUNDS AT COBHAM PARK, SURREY.

summer are very appreciable. On the south front the pleasure-ground has been extended recently, and the effect from this aspect might be further improved in the same direction and by the provision of a flower-garden with informal beds.

Kitchen and Fruit-garden.

On the other side of the road is the kitchen-garden, of about four acres extent, surrounded by walls which are put to excellent use in the cultivation of fruit-trees. Pears, Apricots, Peaches, Nectarines, Plums, &c., trained against these walls crop freely, and in seasons like that of 1904 need to be thinned severely.

Figs ripen well on the outside walls, but are not nearly so successful as they are at a residence at Bonchurch, Isle of Wight, belonging to Mr. Combe's son, where a magnificent wall-tree of the variety Negro Largo is the best in the neighbourhood, although standard Fig-trees in the open are common there. The kitchen garden plots at Cobham are for the most part surrounded by espalier fruit-trees, and though some of these are aged, such specimens are being gradually removed and young trees of the best varieties planted in their stead. There is an orchard on rather higher ground than that of the garden, so that altogether the garden and orchard supply ample crops of hardy fruits. Kitchen-garden produce, being of great importance, is given close study, and such crops of Onions, Asparagus, various Brassicas, &c., as were obtained last season were the result of an intelligent use of manures, in which animal and chemical manures were employed. Early forcing of vegetables is carried out here as thoroughly as in most places, for at Christmas there were supplies of new Potatos, French Beans, Seakale, Asparagus, Rhubarb, Mushrooms, &c. The Asparagus is forced in frames from plants raised in the same garden from seeds. Seakale is forced in the permanent beds. Peas (Sutton's Harbinger) are now 2 inches high in frames, and are already through the soil in the open garden, as also are Broad Beans. Spring Cabbages appear very promising, and Cauliflower plants under hand-lights are in a forward condition for transplanting when the season is a little further advanced.

There are numerous Peach-trees under glass, two houses with hip-shaped roofs having a length of nearly 200 feet. One house of 120 feet length is provided with means of heating, and the other is not. All the best varieties of Peaches and Nectarines are cultivated in these houses, and the trees are excellent specimens of good training; the crops observed upon them from time to time have been abundant. Notwithstanding this, very heavy crops of Tomatos are obtained from the same houses from plants put into the borders and trained as horizontal cordons. The earliest Peaches are in another lean-to house, which, being in two divisions, affords space for Fig-trees also. These Peach trees are now setting their flowers. There are four vineries, and the vines show the same skilful treatment that is applied to other departments of the gardens. At the present time there is a moderate supply of well-preserved Grapes in bottles, and the earliest canes are breaking nicely into growth. Melons and Cucumbers are cultivated in sunk pits having span-shaped roofs; young Melon-plants are now making growth, and large supplies of Melons, Cucumbers, and Tomatos are produced each season.

There are several plant-houses, the principal one being a structure of considerable size, having a span-roof. It is divided into two divisions, one of which contains a first-class collection of Codiæums (Crotons), Cordylines (Dracænas), and like foliage plants, whilst the other is furnished with Palms and other species that require a less degree of heat. Codiæums are grown with better success than is obtained in many gardens; the plants retain their foliage well, and develop extra good colour. They are propagated by "ringing," not by cuttings.

At the present time there are good displays of Cyclamens, Primulas, and other winter flowers Herbaceous Calceolarias, Souvenir de la Malmaison Carnations, Chrysanthemums, Poinsettias, Pelargoniums, Coleus thyrsoideus, Gloxinias, Begonias, &c., are grown in numbers proportionate with the means at hand.

The concluding paragraph in this note may well be one respecting the gardener's cottage, depicted in fig. 34. The photograph was obtained last spring, when the magnificent Wistaria sinensis was irresistible with its prodigal display of flowers and liberal perfume. What a delightful cottage the picture pourtrays! Its occupier is Mr. William Honess, who has been gardener at Cobham for the past four and a half years, having succeeded his father in the position. Mr. Honess's experience in good gardens at Keele, Hatfield, Welbeck, &c., is now of the greatest service to him. In August last his friends had the pleasure of congratulating him upon his selection of a fair young lady from the locality to share with him "Wistaria Cottage."

Fig. 34.—Gardener's cottage covered with wistaria at Cobham Park.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

Right or left-handed digging.—I have always looked upon the man as a right-handed digger who held the top of the spade with the left hand whilst the right hand moved along the helve of the spade, and the right foot drove the spade into the ground; the leverage is obtained by the left hand at the top of the spade, but the spadeful is lifted and turned over by a sympathetic motion between both hands. The reverse of these positions of both hands and feet are, in my way of looking at it, left-handed diggers. But the spade makes no complaint so long as it is cleverly and masterly handled either way. "*An Old Digger.*"

Myrobalan plum.—"E. M.," on p. 45, says he "cannot agree with Mr. Ward that this Plum is superior to Quickthorn for hedging purposes, and that his experience leads him to say that it is not nearly so good for hedges as a well-managed Quick;" adding, "though to see a well-cultivated hedge of the latter is indeed a rarity." Be this as it may, I have in my mind's eye miles of Quick hedges, some alongside the King's highway from Portarlington to Mount Mellick, at a point where it passes through the "Wilmott-Chetwoode" estate. These hedges are 4 feet through, 5 feet in height, and are rounded at the top, and as the result of close annual trimming from the first year of planting are a veritable network of short, close growth from the base to the summit. Other examples of Quick hedges of a different type may be seen in the Inverleith Row Nurseries, Edinburgh. These are (or were some years ago) from 18 inches to 2 feet through at the base, narrowing upwards on both sides to a point some 6 feet from the ground. These hedges were planted as wind-screens in various parts of the nurseries as protection for seedling trees, &c., and were pictures of good cultivation; but it must be borne in mind that they required years of growth before they attained this solid, uniform mass of thorny growth and handsome outline. I could also name estates in Wiltshire in which it is no rarity to see well-cultivated Quick hedges. However I may remind "E. M." that I recommended the Myrobalan Plum as being superior to the Quick "as regards quickness of growth, and impenetrableness of fence" for hedging purposes. "E. M." says that it is a waste of time to wait twelve months before cutting down the Myrobalan Plum after planting, and is of the opinion that the plants should be cut down to within 15 inches of the ground as soon as planted. This is not my opinion, as I prefer any kind of plants intended for permanent hedges to push their roots well into the ground, and make free top-growth the first year, cutting them down the following spring. "E. M." admits that the "Myrobalan Plum will grow much more rapidly than

Quick," adding "that he had never seen a thick base to any hedge made with this plant." This no doubt was owing to the fact that the plants were not pruned to within a foot or 15 inches of the ground the first year after planting, as recommended by me on p. 29. Or it may have been caused by the plants having been cut down as soon as planted, in order not to waste time. *H. W. Ward.*

THE EVESHAM GARDENERS' FRENCH TRIP: WILL IT BEAR FRUIT?—Some of the older of the Evesham gardeners have expressed themselves as very doubtful of the result of trying to force Lettuce after the French method in Evesham, and point out that as many as twenty years ago they tried to force Lettuce under the bell-glasses is done near Paris. But they forget that they did not try the right variety, and it is pretty certain that they did not prepare the seed-bed as the Frenchman does. Everything depends upon that work being properly performed. Then it is claimed that the atmosphere in the valley of the Avon is too humid, and that the plants will damp off. The remedy for that is care and attention in the ventilation of the frames and cloches. The difficulty of obtaining manure is probably more imaginary than real; it can be bought in Birmingham at a reasonable figure, and the railway companies are certain to grant special rates, for they already carry manure from London 108 miles into a fruit-growing district for 4s. 6d. a ton. They would be sure to do the same for Evesham if properly approached, and that would bring the cost of the manure up to about 6s. a ton. Would the Lettuce sell if grown? is also asked; and the answer to that is, that the Frenchman with expenses heavier than those of the Evesham grower can send to Covent Garden and pay a freight of 80s. as against the Evesham man's 25s., and still make a handsome profit. The experiment is to be made. In a week or so the retired gardener who conducted the Evesham men through the Vitry and Ivry gardens will be in Evesham for the purpose of giving demonstrations of how the Frenchman sets to work. It is hoped that he will be accompanied by another gardener, who is likely to remain in the district for at least two years, for a very large firm of growers are negotiating with a man to take an engagement for that period. We shall see what we shall see. Within the last few weeks a large number of glasshouses have been built close to Evesham, and from this it is evident that some of the younger generation of gardeners realise the importance of branching out in a fresh direction. It has always been a source of surprise that in this fertile valley so little use was made of glass, but this is now fast disappearing. Perhaps in no branch of their work do the Evesham men need instruction so much as in the packing and grading of their fruit and vegetables. Of recent years there has been a steady improvement in this direction, and less is heard of the pernicious and injurious habit of "topping," for which the district held an unenviable notoriety, but there is still need for great improvement. A case bearing on the necessity of grading fruit occupied Judge Ingham and a jury for some hours on Saturday last. A gardener and dealer, of Hampton, near Evesham, sued a firm of brokers of Covent Garden for £39 2s. 10d. for breach of contract in the purchase of 300 "pots" of Blenheim Apples at 5s. a pot, the damages representing the difference between the contract price and what plaintiff realised when defendants refused to accept delivery. The contract was not disputed, and in it defendants contracted to buy 300 pots of best Blenheims at 5s. a pot, all the small to be sorted out. Two consignments of Apples were sent, and both were refused on the ground that there were a large proportion of seconds included. The difficulty with regard to the first consignment was adjusted, but when the second lot arrived the defendants refused to accept any more, so plaintiff had to sell the Apples as best he could. It was suggested on behalf of plaintiff that defendants found that they had bought the Apples very dear, and wanted to get out of the deal. A sample of the second consignment was produced by defendants, and a lot of expert evidence called, the consensus of opinion on that side being that the sample contained a large proportion of seconds, and that the best were not very special. For the plaintiff evidence was called to the effect that the fruit was sorted, and that only best Blenheims were sent. After a very long hearing the Judge summed up in the following words: "The only question I shall ask the jury is: 'Were the Apples which were rejected best Apples from which all the small had been sorted out? You have heard the expert evidence and you have seen the Apples. It is for you to decide the question.'" The jury after some consultation answered the question in the negative, but intimated that they would like to make a remark. This, however, they were not allowed to do. Judgment was accordingly entered for defendants with costs. The defendants had entered a counter-claim, but withdrew it with the exception of one item, 8s. 6d. for three empties, which was admitted, and for which judgment for them was entered. *S.*

EARLY AND LATE PEACHES. — In reply to "L.," Isle of Wight, on page 64, in my opinion the best early varieties of Peaches are Alexander, Waterloo, Amsden June, and Hale's Early. These four varieties ripen in very close succession—so close indeed, that the second and third mentioned could well be dispensed with in gardens where space is limited. The best late varieties of Peaches are Crimson Galande, Princess of Wales, and Sea Eagle. If "L." has room only, for say six Peach trees, I should recommend the following varieties:—Alexander, Hale's Early, Early Grosse Mignonne, Violette Hâtive, Crimson Galande, and Sea Eagle, which are all excellent varieties in every respect, being good growers and free bearers of fine, handsome fruits which colour well and are of excellent flavour when well ripened. If space would permit of three more trees being planted in the cool-house referred to, Early Rivers, Lord Napier, and Pine-apple Nectarines would yield a fairly good succession of large, handsome fruits of good quality. *H. W. Ward.*

CHRYSANTHEMUMS TIED DOWN.—The illustration of "tied down" Chrysanthemums on p. 53 is perhaps, from a pictural point of view, rather taking, but I imagine few gardeners will attempt to copy Mr. W. C. Smith in his delicate and (to me) very painful task of destroying the natural beauty of habit that each variety possesses, besides rendering the flowers useless for cut purposes. It would be much better to select dwarf-growing kinds, of which there is an abundance of varieties, for the purpose. If cuttings be taken from the top growths at the end of May, and the plants grown on in 5 or 6-inch pots, they will make admirable subjects for placing on the front row of the stage, attaining a height of about 15 inches. Assuming that the Chrysanthemums are grown as bush plants, they should not be of the height mentioned, 5 to 7 feet being far too tall. Your correspondent does not state that his plants are grown as bush plants, but I infer this from the number of plants grown in each pot, and from the photograph of the distorted plants on the front stage. *A. Jefferies, Moor Hall Gardens, Essex.*

CEDRUS DEODARA ALBA SPICA (see p. 59).—Our trees of the above variety of Cedar are all of pyramidal shape, and each has a good leading shoot. I recently saw about fifty trees growing in a nursery, but did not notice one of spreading habit. Are Mr. Harris's trees much exposed to strong winds? *C. Page, Dropmore Gardens.*

APPLE LANE'S PRINCE ALBERT.—Here in Co. Kilkenny this Apple is very satisfactory; in fact, were I limited to one variety I should grow Lane's Prince Albert. With regard to its cropping capabilities, my experience is that young trees (on both the Crab and Paradise stocks) generally crop so heavily that if not severely thinned the fruits would eventually weaken the trees. Young trees never fail to carry a crop. The fruits develop an excellent colour for the variety, in proof of which I may say that at Dublin fruit show, held in October under the auspices of the Department of Agriculture, we were placed 1st in a class in which there were fifty-three competitors, and were 1st also at Belfast in November. The fruits do not keep well so late as March, but at present they are good and firm, and are very good eating even uncooked. The variety has been largely planted in this district during the last two years, under the direction of the Department of Agriculture, and I do not know any variety likely to give better returns. Bismarck is another variety that is proving satisfactory in these gardens, making healthy growth and cropping exceedingly well. I may say the soil here is of a warm, light nature. *J. G. W., Lessborough.* [Our correspondent sent excellent specimens of both varieties.—ED.]

—— I have found this Apple to be by far the most certain cropper, surpassing in this respect both Newton Wonder and Alfriston. The latter variety does not finish well here, and consequently shrivels with keeping. I find Newton Wonder keeps for the longest period, while Lane's Prince Albert keeps well to the end of February. I should certainly advise growers in this district to plant the variety, as it is a sure cropper. *Geo. Ellis, Nidd Hall Gardens, Ripley, Yorks.*

—— Mr. Thomas Salsbury in a recent issue asked for growers' opinions of that excellent Apple Lane's Prince Albert. We have no hesitation in saying that in our opinion it has no equal, its cropping capabilities are not comparable with those of any other culinary Apple, and with regard to its colour and appearance we saw several tons of this Apple almost as highly coloured as that grand dessert variety Worcester Pearmain. Bramley's Seedling runs it very close in cropping capabilities, but in weight we find Lane's Prince Albert far ahead. A small fruit of the latter variety will turn the scale at ¾ lb., and will keep in condition till the end of March, being now in as good condition as when picked. No doubt your correspondent picked his fruits before they were ready for gathering. *Mr. Nye, Manager, Walpole Orchard Co., Walpole, Wisbech.*

PUBLICATIONS RECEIVED.—*Almanack* for 1905, from Messrs. Kent & Brydon, Darlington.—A *Pocket-book*, from Messrs. Bakers, nurserymen, Wolverhampton and Codsall.—Nova Scotia: *Provincial Government Crop Report*, November, 1904. The whole season proved unfavourable to growth in many parts of the Province, but the failure is not serious enough to discourage the hopes of the farmers for the future.—*Cassell's Popular Gardening.—The Faraday House Journal*, January. Mosier; and Bulletin No. 95: *The More Important Insect Injuries to Indian Corn*, by S. A. Forbes.

NEW OR NOTEWORTHY PLANTS.

CYPRIPEDIUM GRATRIXIANUM (SECT. PAPHIOPEDILUM), HORT. SANDER.

UNDER this name Messrs. Sander & Son, of St. Albans, exhibited as a new species the plant here illustrated (fig. 35). The flowers have so much of the appearance of those of some forms of C. insigne or of C. exul, if that be considered as distinct, that its position as a separate species is a matter of opinion, but the habit is different, and we are told that the leaves are broader than in any form of C. exul. The plant is tufted, the leaves 20 cent. long, 4 cent. wide, coriaceous, glabrous, linear-oblong, channelled in the middle of the upper surface, midrib prominent beneath, tapering to the base, where they are sharply folded and purple-spotted. Apex rounded, minutely notched. The flowers measure 11—12 cent. across at their widest expansion, and are borne on a scape which is covered near the top with fine purplish hairs. Bract oblong lanceolate, purple-dotted, conduplicate, rather shorter than the three-sided, three-ridged ovary. Standard broadly obovate undulate, puberulous on the outer surface, contracted but not recurved at the base; greenish at the base and for two-thirds of its length; upper portion and margins porcelain-white, the whole studded with rather large, nearly

circular purple spots. Lower sepal about half the size of the upper one, shorter than or very slightly exceeding the length of the lip, oblong, greenish with a few purplish dots; lateral petals spreading, slightly incurved, oblong-spatulate, wavy at the margins, pale greenish-brown, and shining; lip of a similar but deeper colour, with a shell-like convolute prolongation on either side; column slightly hairy at the base; staminode roundish, flattened, yellowish, villosulous, with a shining projecting boss near the apex. The most striking differences between this plant and C. exul are to be found in the habit, foliage, and in the standard, which tapers to the base, and in the side-lobes of the lip, which are more prolonged. The plant is a native of Annam.

The drawing was made in the nursery of Messrs. Sander, and the description was drawn up from a specimen kindly furnished by those gentlemen. *M. T. M.*

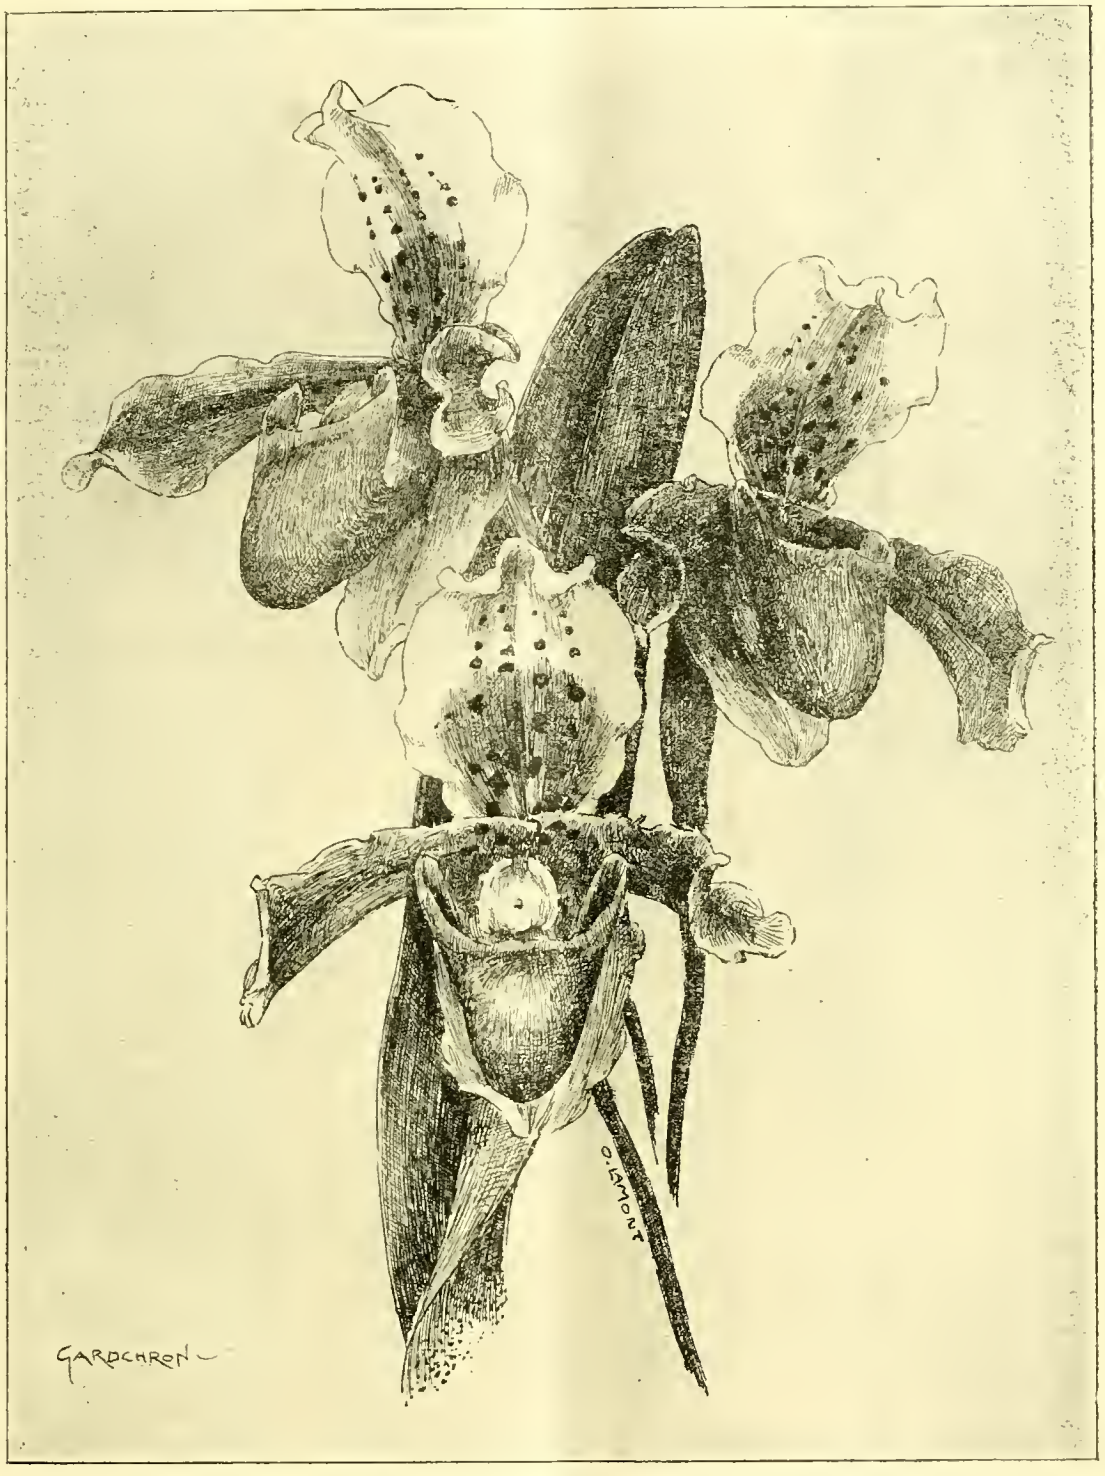

FIG. 35.—CYPRIPEDIUM (§ PAPHIOPEDILUM) GRATRIXIANUM (HORT. SANDER).
Flowers greenish-yellow, dorsal sepal porcelain-white above, purple-spotted

Obituary.

JOHN KITLEY.—We regret to have to announce the death of Mr. John Kitley, for the past few years manager to the Orchard Company, Ltd., Scotby, Carlisle. Mr. Kitley was well known as a practical horticulturist, and was well versed in Agriculture and Forestry. For many years he managed the extensive estates of Rothiemurchus, Inverness-shire, removing from there to

Warwick, from thence to Derby, and finally ending his useful career at Scotby, where his integrity won for him the esteem of all those who came in contact with him. He leaves a widow, four daughters and two sons to mourn his loss.

JAMES EDWARD RANSOME.—On January 30, in London, after a short illness, James Edward Ransome, of Holme Wood, Ipswich, aged 65 years.

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 24.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Drs. Cooke and Rendle; Messrs. Michael, Massee, Saunders, Bowles, Shea, Gordon, Odell, Hooper, Holmes, Chittenden (Hon. Sec.).

Henslow Testimonial.—Dr. MASTERS reported on this, and announced that the presentation would be made at a meeting of the Scientific Committee in March.

Big Bud in Hazel.—Mr. SAUNDERS reported upon this as follows:—"The Hazel buds are certainly attacked by mites, which very much resemble the Black Currant mite both in appearance and in their manner of life, but according to the great authority on these creatures (Dr. A. Nalepa) they are different species. If he is correct, the mites from the Nut bush would probably not attack the Currant bushes. The species attacking the Hazel is Eriophyes Avellanæ, the other is E. ribis. The study of this genus of mites is very difficult, as the mites are quite invisible to the naked eye; consequently the mounting of specimens for examination under the microscope is by no means an easy task. These mites attack plants in a great variety of ways, some attacking the buds, others the leaves, forming blisters on them, as in the case of the 'Pear-leaf blister mite,' or curling the edges of the leaves, like the species which attacks the Hawthorn, or forming the galls like little coral beads on the upper side of the leaves of the Maple, or the curious 'nail galls' on the leaves of the Lime. If the Nut-bushes are badly attacked, I should certainly root them up and burn them; otherwise cut out the infested shoots and burn them, keeping a good look-out for further infestation, which should be at once treated in the same manner." Mr. MICHAEL remarked that it was extremely unlikely that the same species of mite would attack plants so widely different as the Hazel and the Currant, although species are known that attack more than one plant. Mr. GORDON stated that he had seen Hazel growing near Black Currants attacked by the bud-mite, while that in other parts of the same garden was free; but this might have been because the conditions were favourable for both kinds of mite.

Spots on Phyllocactus.—Dr. COOKE reported as follows on this:—"The dark convex spots near the edge were hard and somewhat resembled "sclerotia," but no mycelium or spawn could be found, nor anything which could be construed into a fungoid structure. What the dark bodies are must still remain as a 'puzzle for the curious.'"

Branch of Ash Fasciated.—Mr. ODELL showed a specimen of this common growth, cut from the tree 10 feet above the ground.

Slime-fungus on Walnut.—Mr. DAVIDSON sent a Walnut having the fungus Phycomyces nitens growing upon it.

Mite on Bark of Apple.—Mr. GRIGGS sent a piece of Apple-bark infested with the mite Orobutta lapidaria. The mite is frequent upon the bark of Apple-trees, but causes no injury to them.

Disease of Beech-trees.—Dr. COOKE reported upon the specimens sent to the last meeting, on which the common fungus, Tubercularia vulgaris, was growing. The stumps growing near by had another fungus, Xylaria hypoxylon, upon them.

Pear, Diseased.—The decay in the Pear brought to the last meeting by Mr. SHEA, which appeared as brown spots in the flesh, nothing being visible on the outside, Dr. COOKE attributed to the fungus which caused the "brown rot" of fruit, and to which the black Apple recently exhibited also probably owed its peculiar appearance.

Gall on Eucalyptus occidentalis.—Mr. HOLMES showed specimens of this on bark, known commercially as Mallet-bark. A large quantity is being imported from Australia for tanning purposes. Mr. SAUNDERS took the specimen to examine further.

Spraying Apparatus.—Mr. HOLMES also showed a simple form of spraying apparatus which is shortly to be put upon the market.

Fungus on Peach-tree.—Mr. HOOPER brought a fungus found growing on a Peach-tree. Mr. MASSEE took the specimen to report upon at the next meeting.

Spirits of Tar for Wounds on Trees.—Mr. HOOPER asked whether this might be used, and both Mr. GORDON and Mr. SHEA spoke of excellent results arising from its use.

Cyclamen-leaves discoloured.—Dr. COOKE reported on Cyclamen-leaves received from Stevenage that the rusty spots showed no sign of fungus. It was suggested that the injury was probably caused by a mite similar to, if not identical with, the Begonia-mite.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

WORCESTER AUXILIARY.

JANUARY 16.—This branch held their annual meeting at Worcester on the above date. Owing to the unavoidable absence of Sir Frederick Godson, M.P., Mr. W. Crump was voted to the chair.

A most satisfactory balance sheet on the year's working was presented and adopted, the accounts showing a balance of over £100 to the good. Upwards of £16 net had been received by the Society from the opening of Madresfield Court Gardens during last May. Three sums of 5 guineas each from this collection were offered and accepted by three members of the Auxiliary, willing to contribute similar sums and thus constitute themselves life members, at the same time doubling the amount originally available for handing over to the parent Society.

There being no county candidate this year votes were given optionally to the most deserving candidates. The Chairman pointed out that before this auxiliary branch was formed more money was received from head-quarters by pensioners in this county than was subscribed by the whole of the gardeners and gentry in the same area.

Altogether some £775 had been forwarded to the parent Society. Still, it was felt by all the members that there were many gardeners in the county who ought to become guinea subscribers, and it was finally resolved that every member should try to introduce one fresh member during 1905. Also that more gardens could be opened to visitors and thus benefit the Society, as is done at Madresfield Court, if their employers' consent could be obtained by those in charge. Madresfield Court Gardens will be again opened on the first Thursday in May. *Corr.*

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 19.—At the meeting held on the above date Messrs. SANDER & SONS, St. Albans, staged a fine group of plants, amongst which were several good Cypripediums. Awards of Merit were given to Zygopetalum × Mackayo-crinitum, a handsome, intensely-coloured flower; Cypripedium × nitens var. splendida, C. × nitens var. "Mammoth," C. × Phœbe var. exquisita, and C. × Lady Wimborne. A First-class Certificate was awarded to C. × Rolfeæ var. stupenda (Silver Medal).

E. ASHWORTH, Esq., Wilmslow (gr., Mr. Holbrook), exhibited Cypripedium × vexillarium var. Rougierii and Cattleya chocoensis alba, the latter having previously been dealt with by the Committee.

PHILIP SMITH, Esq., Sale (gr., Mr. Kitchin), exhibited a good plant of Cypripedium × J. Howe.

A. WARBURTON, Esq., Haslingden, staged three fine Cypripedes, viz., C. × Euryades Sander's var., C. × aureum var. Hyeana (both of which received First-class Certificates), and a seedling from C. Leeanum var. Albertiana × C. insigne, which was given an Award of Merit.

M. VUYLSTEKE, Ghent, staged a small and interesting group of various hybrid Odontoglossums (Vote of Thanks).

Messrs. J. COWAN & Co., Ltd., Gateacre, had a good group of Odontoglossums, Cattleyas, Cypripedes, &c., for which a Silver Medal was awarded.

G. W. LAW-SCHOFIELD, Esq., Rawtenstall (gr., Mr. Shill), obtained a Silver Medal for a well-grown collection of distinct Cypripedes, principally hybrids, amongst which was a fine form of C. × Euryades.

Mr. D. MCLEOD, Chorlton-cum-Hardy, was given a Vote of Thanks for a small group of Cypripedes. *P. W.*

WOODBRIDGE HORTICULTURAL.

JANUARY 20.—The annual meeting of the Woodbridge Horticultural Society was held on the above date. The chair was taken by Mr. John Loder, J.P. There was a large attendance.

The Hon. Secretary (Mr. John Andrews) reported that the £25 Rose Challenge Cup had been won four times by Mr. Cant, of Colchester, and therefore became his property. It was resolved that a prize of £5 be given this year instead of a cup.

The Hon. Secretary announced that he must tender his resignation after this year's show. This decision was received with very great regret. Mr. Andrews said he should always take an interest in the Society, and would do all he could for it; but the time had come when he must ask to be relieved of the burden and responsibilities of the secretaryship. Eventually the question was referred to a sub-committee.

LONDON DAHLIA UNION.

JANUARY 24.—A meeting of the supporters of the Union was held at the Hotel Windsor, Victoria Street, on the above date. Mr. John Green, Chairman of the Union presided, and there was a good attendance; in addition a number of letters were received promising continued support. The Annual Report congratulated the members on the success of the exhibition held at Earl's Court in September last.

There was keen competition in most of the classes, especially in that for twelve bunches of Cactus Dahlias. Mr. Gledstanes has generously promised to continue his prizes in 1905 and in 1906.

Arrangements are being made for holding an annual exhibition in the Prince's Hall at Earl's Court during the third week in September in the present year. The balance sheet showed an income of £69 1*s.* 9*d.*, and an expenditure of just over £67, leaving a small balance to be carried forward. Mr. John Green was re-elected Chairman of the Union, and Mr. R. Dean, Secretary, and both were thanked for their past services. Much regret was expressed at the absence of the Secretary through illness.

CROYDON HORTICULTURAL MUTUAL IMPROVEMENT.

JANUARY 25.—The fifth annual dinner was held at the Greyhound Hotel on the above date, under the Presidency of Mr. J. J. Reid (President of the Society), the vice-chair being taken by Mr. R. Hooper Pearson, of the *Gardeners' Chronicle*. The tables were decorated with plants and flowers.

The attendance was large, the arrangements were perfect, and the gathering was a most successful and pleasant one, affording every encouragement for the holding of similar meetings in the future. When the Chairman had proposed the toast of "The King," the Vice-Chairman proposed that of "The Society," which he said had now 133 members. He hoped the Society would continue to progress, and that it would give attention to the science as well as to the practice of gardening, and thus help gardeners and employers to obtain the utmost pleasure and profit from their gardens.

Mr. Douglas Young supported the toast, and Mr. H. Boshier (Hon. Secretary) in reply gave a very encouraging account of the Society's circumstances.

Mr. M. E. Mills gave "Kindred Societies," and this was responded to by Dr. Jackson.

The Chairman presented the prizes awarded for essays, the prize-winners being as follows: "Pruning and Training of Hardy Fruit Trees," 1st, Mr. T. W. Briscoe; 2nd, Mr. W. A. Cook: "Birds of Our Gardens," 1st, Mr. J. Sugden; 2nd, Mr. H. Peckham.

Other toasts included that of "The Chairman," and "The Horticultural and Local Press."

The proceedings were enlivened by songs and instrumental music.

NATIONAL CHRYSANTHEMUM.

JANUARY 25.—A meeting of the Committee which carried out the Market Show at Essex Hall on December 14 last was held at Carr's Restaurant on the above date Mr. R. Ballantine, Chairman of the Committee, presiding. The secretary, Mr. R. Dean, presented a balance-sheet showing receipts from subscriptions of £26 10*s.* 6*d.*; medals given as prizes, £8 18*s.* 3*d.*; tickets sold and payments at the doors amounted to £2 10*s.* 6*d.*; showing a total of £37 19*s.* 3*d.* On the credit side medals were awarded to the value of £21 7*s.* 9*d.*; hire of hall, £5 5*s.*; printing and circulating the schedule, £1 15*s.*; show expenses, £8 3*s.* 1*d.*; leaving a small balance to be carried forward. Great satisfaction was expressed that the show receipts had covered all the expenses. A general opinion was expressed that the show should be repeated during the present year, and various suggestions were thrown out, all of which will be considered by the Committee at a meeting to be held shortly.

In the evening a large number of supporters of the show dined together at Carr's Restaurant, under the presidency of Mr. R. Ballantine, the tables being prettily decorated with Chrysanthemums supplied by Mr. Geo. Prickett. Mr. D. Ingamells acted as dinner-secretary, and everything passed off in the pleasantest manner possible. Great satisfaction was expressed at the first appearance of Mr. R. Dean after his severe illness.

ABERDEEN CHRYSANTHEMUM.

The annual meeting was held in the Round Room, Music Hall Buildings, Aberdeen, on Saturday evening, 28th ult. Mr. J. C. Minty presided in the absence of the usual chairman, Mr. Esslemont. The Committee's

statement showed that the Society was in a flourishing condition. The annual exhibition was held on the 18th and 19th November, and they had to congratulate themselves on its success. The total funds at the credit of the Society was now £195 9*s.* 11*d.* The total income for the year was £414 8*s.*, and they had increased their balance by £49. The Report was unanimously adopted. The meeting then proceeded to the election of office-bearers, when the following were elected:—Hon. President, Lord Provost Walker; President, Mr. James Esslemont; Vice-President, Mr. A. Kynoch. A committee of twenty was also elected. Mr. M. H. Sinclair was re-appointed Secretary and Treasurer. It was decided to hold this year's show on November 17 and 18.

GARDENERS' DEBATING SOCIETIES.

REDHILL, REIGATE AND DISTRICT GARDENERS'. — This Society held its fortnightly meeting on January 17, Mr. W. P. Bound in the chair, there being about ninety members present. The subject of the lecture was "The Influence of Manure on Plants," given by Mr. Howard, of Wye College, who has arranged to give a series of three lectures on this subject. Mr. Howard dealt in a very lucid and comprehensive manner with his subject, pointing out the best methods of storing and preserving stable or animal manure in order to maintain all the manurial properties until applied to the plant. He also went very minutely into the analysis of artificial manures. A very helpful and interesting discussion followed.

CARDIFF GARDENERS'.—At a meeting held at the Sandringham Hotel on Tuesday, January 24, Mr. T. Clarke presiding, Mr. H. R. Farmer, Cardiff Castle, gave a very interesting lecture, entitled "Plants and Floral Decorations Suitable for a Private Establishment," Many valuable hints were given upon the colouring of foliage and upon other details. The lecturer advised the use of very light and graceful flowers and foliage for dinner-table decoration, and the use of the most graceful plants for grouping about the interior of the mansion. Mr. Mayne opened the discussion, which was well taken up by the members. *J. J.*

CHELMSFORD AND DISTRICT GARDENERS'.—At the weekly meeting on Friday, January 27, Mr. Hammond, of Widford, gave a paper on "Orchids." He traced the history of their introduction into England, and referred to the 330 genera and 4,000 species now known. The speaker spoke of the difficulties collectors have to contend with. Often on reaching England a rare specimen is found to be dead. The speaker dealt fully with the method of culture, and showed the fallacy of the old idea that Orchids were too difficult for the average man to grow. In the discussion that followed, the use of leaf-mould in growing Orchids was deprecated, and it was the opinion of many members that the unattractive appearance of Orchids when not in flower was a hindrance to their ever becoming popular conservatory plants. *S. M. C.*

BATH GARDENERS' SELF-HELP AND DEBATING. —The fortnightly meeting of the above Society was held on Monday, January 23, Mr. T. Parrott occupying the Chair. There were several excellent exhibits on the tables, including Cyclamen and Cinerarias. The minutes of the Committee meeting contained proposals for forming a sick benefit club, and for holding a Chrysanthemum show in November. Eight new members were added to the roll of the Society. A presentation has been made to the Society of a number of books on gardening. The Chairman opened a discussion on Mushroom-culture, which formed the first of two subjects for debate during the evening. After this subject had been well discussed, Mr. Bickerstaff commenced a debate on Cyclamen. *G. G. McL.*

CHESTER PAXTON.—The second meeting of the above Society was held on Saturday, January 28, at the Grosvenor Museum, Chester, when Mr. R. Newstead, A.L.S., the Curator, delivered a lecture on "Some Common Birds of the Orchard and Garden." The lecturer said the fact is well known that certain birds inflict injuries upon fruit-trees and their products, and also upon some of our cultivated vegetables, but it is not equally well known that they are in many instances of great service in destroying the insect-pests of the garden. Mr. Newstead's remarks were based entirely upon the personal investigation of some 2,000 stomach contents of birds, supplemented by careful observations in the field. The lecture was fully illustrated. The vagaries of the bullfinch, the greenfinch, the titmice, and the starlings were much discussed at the close of the lecture.

KINGSTON GARDENERS'.—At the last meeting of the above Society Mr. Mills, of Coombe House Gardens, Croydon, gave a paper on "Chrysanthemums," chiefly from an exhibitor's point of view. The lecturer described in detail the methods of cultivation he had found suitable from practical experience, asserting that careful attention to small details is the secret of success in Chrysanthemum-growing. Valuable information was given on cultural points and on exhibiting the flowers. The dreaded "rust" disease was said to be overcome by the use of "Bentley's Mildew Specific," which should, however, be used at double strength on fully-developed foliage. Numerous diagrams were used to illustrate the remarks. *J. T. B.*

SCHEDULE RECEIVED.

KIDDERMINSTER AND DISTRICT HORTICULTURAL SOCIETY'S Daffodil Show on Saturday, April 15; Summer Show on Saturday, July 15; and Dahlia Show on Saturday, September 16.

COVENT GARDEN FLOWER MARKET.

THE amount of trade has not varied much during the past weeks, and most subjects remain at about the same prices. Indian Azaleas continue plentiful, and of these the white varieties and those of a pink or salmon shade of colour sell better than the "reds." Among Ericas there are now persoluta alba and fastigiata, both small-flowering white varieties; E. gracilis vernalis, hyemalis, and melanthera all continue plentiful. Boronia megastigma in well-flowered plants is now seen. Acacia ovata, and A. Drummondi are good. Plants of Cyclamen improve in quality and are consigned by several growers, prices being well maintained for best plants. Cinerarias are plentiful. The strain grown for market is remarkable for the dwarf habit of the plants and for the bright colours of the flowers, which are not of large size. Hyacioths and Tulips are good in quality, and in all shades of colour. Some pot plants of the latter are seen, but the majority are grown in boxes. Lily of the Valley continues to be plentiful both in pots and in boxes. Daffodils are more plentiful; on Tuesday morning prices were lower. Begonia Gloire de Lorraine and the white variety can be had in good plants. Primula sinensis is seen but the plants are of poor quality. Well-flowered plants of Primula obconica sell moderately well. Codiæums (Crotons) and Cordylines are seen in good plants. Other foliage plants are plentiful Palms, including Areca lutescens, Cocos Weddelliana, Phœnix reclinata, are very good, with the usual plentiful supply of Kentias, Latanias, &c. Prices for Palms generally are low. Of Feros there are now much larger supplies of the small sizes, and prices are low. Good plants in 48's, in all the usual market kinds, are plentiful; but in some varieties larger plants are not quite so numerous.

CUT FLOWERS.

Very little that is new among cut flowers is to be reported. Tulips are the most prominent, being seen on every side; some fine double varieties in crimson, pink, and yellow colours are seen; prices vary but little. Supplies of Daffodils were rather short this morning, and best flowers were making an advance of 1*s.* per dozen. The most prominent varieties seen are Sir Watkin, Henry Irving, Horsfieldi, Golden Spur, and princeps. Roses still continue very scarce; Niphetos is almost the only sort exposed for sale in any quantity; on Tuesday 15*s.* per dozen was being asked for best flowers; of Catherine Mermet. Supplies of Chrysanthemum flowers hold out, and some good blooms are seen.

Orchid-blooms continue plentiful, and among them there is now more variety. In Carnations I find that the variety Enchantress commands 7s. per dozen for best flowers. Good prices are maintained for other sorts that are of sufficiently good quality. French flowers are more plentiful, but considerably short of what is usual at this season of the year. Double white Stocks may be added to the list, but they are very poor in quality. The French flowers have not recovered from the recent severe frost. Roses appear to have suffered very severely, and although some are arriving they are very poor in quality. *A. H., Wednesday, Feb.* 1.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending January 28, 1905.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Jan. 28, is furnished from the Meteorological Office:—

"The *weather* during this week was dry and fine over the Kingdom generally, but slight rain was frequently experienced in the extreme North and North-West of Scotland.

"The *temperature* was below the mean in nearly all parts of England, as much as 4° in England, S.W., but in England, N.E. and Ireland, S., it just equalled it, and in Ireland, N. and over Scotland, was 1° or 2° above it. The highest of the maxima were in almost all cases recorded on Saturday, when they ranged from 54° in Scotland, E. and England, N.E., to 56° in England E. and S.W. The lowest of the minima occurred, as a rule, either on the 26th or 27th. In England, S.W. and England, S. (at Llangammarch Wells and Swarraton), the thermometer fell to 16° and 18° respectively, but elsewhere the minima ranged from 21° in the Midland Counties to 27° in Ireland, N., and to 31° in the Channel Islands.

"The *rainfall* was less than the mean in all districts. Over the East of Scotland and the greater part of England the fall was extremely slight; at several stations there was no measureable quantity.

"The *bright sunshine* was in excess of the mean over the major portion of the Kingdom, but deficient in Ireland, N., and also in Scotland, N. The percentage of the possible duration ranged from 46 in the Channel Islands, 33 in England, S.W., and 31 in England, S., to only 11 and 11 respectively in Ireland, N., and Scotland, N."

THE WEATHER IN WEST HERTS.

Barometer remarkably high.—This has been a week of changeable weather, but on the whole rather warm. On the warmest day the highest reading in the thermometer screen was 50°, and on the coldest night the exposed thermometer showed 15° of frost. The ground is at the present time at about an average temperature at 1 foot deep, but about 2° colder than is seasonable at 2 feet deep. On two mornings the grass on the lawn was coated with hoar-frost when the temperature of the air was from 5° to 8° above the freezing-point. This unusual phenomenon was no doubt due to the frozen condition of the ground keeping down the temperature of the grass when the air above it was comparatively warm. No rain worth mentioning has fallen for over a fortnight. Small amounts of rainwater came through both percolation gauges on each day during the week. The sun shone on an average for 3¾ hours a day, or for about 2 hours a day longer than is usual at this season. On the 29th ult. nearly 7 hours of clear sunshine was recorded—making it with one exception the most sunny day I have yet recorded here in January. The atmosphere was very calm at the beginning of the week, but on the last day the velocity rose early in the morning to 18 miles an hour—direction west. The mean amount of moisture in the air at 3 P.M. fell short of a seasonable quantity by as much as 9 per cent. For three days the barometer continued singularly high, and on the 28th at midnight it stood at 30·98 inches, which is the highest reading I have yet recorded here. *E. M., Berkhamsted, January* 31, 1905.

†*For actual temperature and condition of barometer at time of going to Press, see p.* 72.]

TRADE NOTE.

MR. F. J. CROOK, since relinquishing the charge of Hall Court Gardens, consequent on the death of Captain Murray Aynesley, has commenced business for himself at Brookside Nurseries, Curdridge, near Botley, Southampton.

ANSWERS TO CORRESPONDENTS.

APPLE: *G. F. T.* The shoots are badly cankered, the canker being probably due to a fungus, Nectria, and there is an abundance of insect eggs. Cut the trees hard back; or if you can plant them on a different site it will be well to do so.

BIRD: *Gardener.* The beautiful bird you send is the brambling (Fringilla montifringilla); it is also known in some parts of the country as the mountain finch. It visits us in autumn and winter, its presence and relative abundance depending in a great measure upon the severity of the weather on the Continent. Your specimen, on dissection, was found to contain Beech-masts (their favourite food) and a few seeds of the Knot-grass.

BOOKS: *Gardener.* The Handbook of the Farm Series, published at 2s. 6d. each, includes *The Live Stock of the Farm*, and *The Dairy of the Farm*, either of which would be suitable for your purpose if you can obtain them from a second-hand bookstall. If not, apply to Messrs. Vinton & Co., Ltd., 9, New Bridge Street, Ludgate Circus, E.C., who publish a number of similar works.

BULBS DISEASED: *J. S.* The roots of the bulbs are completely destroyed by the bulb-mite, Rhizoglyphus hyacinthi, which are present in immense numbers. For preventive measures see p. 40 of the issue for January 21, 1905.

CATTLEYA TRIANÆ: *M. L.* Your Cattleya Trianæ seems to have made premature growth, which failed to mature in consequence of the absence of the necessary degree of light, and probably air, to maintain it in health. Cut off this growth and place the plant near to the glass of the roof of the house in which it is growing, and keep the material about the roots moderately dry until new growths appear.

CAPE GOOSEBERRY: *A.* The cultivation of this plant is not at all difficult, and it will thrive in any common garden soil. It is best propagated from seeds and by division of the plants. You should keep them somewhat on the dry side in a cool greenhouse until the spring; they can then be started into growth and should readily produce their inflorescences followed by the inflated calyces enclosing the fruits, which are edible.

CHINESE PRIMULAS: *R. M.* Are all the flowers parti-coloured? The combination of crimson and blue, if not due to a bruise, is very curious.

EUCHARIS BULBS FAILING TO FLOWER: *A.* Although we find no specimens of the Eucharis-mite on the bulb you forwarded, there are indications that this pest is present in the stock. This, however, would not be sufficient to account for your bulbs not flowering. The reason appears to us to be due to their small size, the specimen sent being much too small to develop a strong flowering spike. Encourage the bulbs to develop by affording them a temperature of from 65° to 70°, rising to 80° in the summer, giving them plenty of water except for a few weeks in autumn. Many skilful gardeners experience much difficulty in successfully flowering these plants. On p. 412 of our issue for December 10, 1904, you will find a note from a correspondent who gives details of his plan of flowering these plants successfully.

FERN ROOTS: *W. B.* We find no insects on the roots of your Ferns. Probably what you have seen on the roots is the White Fly that is so common in houses where Tomatos are grown. Your plants showed signs of being pot-bound. Remove some of the old soil and repot the plants.

GARDENERS' NOTICE: *Gardener.* The foreman is only entitled to claim a week's notice.

NAMES OF FRUIT: *M. E. B.* 1, Ross Nonpareil; 2, Claygate Pearmain; 3, Norfolk Beefing.—*A. R.* Lord Lennox.—*B. Y.* 1, Forfar; 2, Chelmsford Wonder.

NAMES OF PLANTS: *A. H.* Retinospora squarrosa.—*Constant Reader, Leicester.* 1, Cypripedium barbatum; 2, Dendrobium primulinum, rather common in gardens; 3, Begonia hydrocotylifolia; 4, Fittonia argyroneura.—*C. H.* 1, Eranthemum pulchellum: 2, Polypodium glaucum; 3, Asplenium bulbiferum; 4, Selaginella viticulosa; 5, Davallia Mooreana; 6, Caustis flexuosa.—*A. B. W.* Dendrobium cariniferum, and a narrow-petalled form of Lælia autumnalis.—*Thurso.* 1, Dendrobium primulinum; 2, Phalænopsis Stuartiana; 3, Epidendrum polybulbon; 4, Hæmanthus puniceus.—*J. H., Severn.* One of the garden-raised forms of Begonia subpeltata.

ORCHID-GROWER: *W. P.* Advertise in the horticultural papers of those colonies you desire to settle in; or you might apply to the authorities at Kew Gardens, who fill many colonial appointments, although they generally have suitable men of their own staff who receive these appointments. Try the larger Orchid-growing firms, such as Messrs. Sander, St. Albans, who are often requested to furnish competent men.

PLANTING EARLY PEAS AND POTATOS: *T. L., Sandown.* In such a warm and sheltered position as you describe, first early Peas may be sown during the last week in January or during the first week in February, selecting a fine day for the purpose and when the soil is fairly dry. If the ground at the time of planting is at all heavy and wet, the drills should be drawn somewhat deeper, say, at a depth of 5 inches, and an inch and a half of drier and finer soil placed at the bottom of the trench, similar soil being placed over the Peas when sown. When the drills are filled in the soil should be heaped up so as to form a small ridge over the drill in order to throw off excessive rain. Mice are often very destructive to early-sown Peas, therefore a sharp look-out must be kept for these pests and set traps. The first or second week in March (according to the state of the weather) is early enough to plant first early Potatos out-of-doors. If planted before this time, and a spell of cold weather follows, the tubers often rot in the ground. In order to ensure early and satisfactory crops, it is advisable to look over seed Potatos without delay, arranging them in single layers in shallow boxes or on the floor of a light cool room from which frost is excluded. Here they will soon start naturally into growth, and when planting time arrives they will have formed sturdy "chits" or growths an inch or two in length. At the time of planting the Potatos must be handled with all possible care so as not to damage the young growths. The rows should be planted at a distance of 10 inches apart, and 2 feet should be allowed between the tubers.

POTATOS: *G. R.* We cannot undertake to name varieties of Potatos. Send them to a trade grower, who may be able to assist you by comparing your tubers with his named varieties.

TREE FERN: *Constant Reader.* You will incur no danger of losing your plant if it is severed, but you must be particular afterwards in syringing the stem frequently in order to keep the aërial roots moist. Maintain plenty of atmospheric moisture in the house. Reduce the leaf surface if possible by removing any leaves that can be spared. Place a layer of sand beneath the stem when replanting. See note respecting Tree Ferns on p. 70.

ILLUSTRATIONS.

A FLORIDA GARDEN.

ON April 5, 1904, after an absence of about nine months in Philadelphia, I returned home to my place among the hills of Orange County, Florida. In Savannah I saw gorgeous masses of Azalea indica in full bloom, the bushes being frequently 7 or 8 feet high and as much in diameter. The fragrance of Noisette, Tea, and Hybrid Perpetual Roses was noticeable everywhere. In Bonaventure Cemetery I noticed the fine effect of groups of large Camellias in combination with Magnolia grandiflora and Azaleas. Only a few lingering blossoms were seen among the huge Camellia-bushes, their principal flowering time being the months of February and March. In Jacksonville I found great clumps of Crinum asiaticum, and tangled masses of Bignonia Tweediana in full bloom, while the delightful fragrance of the Maréchal Niel Rose and other Tea Roses was perceptible everywhere.

I found my garden in the full splendour of its spring garment. The Amaryllis hybrids of my specially robust evergreen strain were in their full glory; their brilliant hues almost dazzled the eyes. The glowing red varieties appear as if sprinkled with gold-dust, while many of the light-coloured ones are delightfully fragrant. How noble they look, and how far superior they are to the true Lilies, particularly in regard of brilliant colouring and varied hues! Large beds of the orange-coloured Amaryllis (Hippeastrum equestre) were a sheet of glowing orange-red, which could be seen from quite a distance. Low bushes of Lantana Camara were a mass of orange and yellow, violet and primrose. They are in bloom here throughout the year, if not cut down by sharp frosts. Leonotis Leonurus, embellished with enormous quantities of orange-yellow-coloured flowers, arranged around the stems, is a feast to the eye when at its best. The air was impregnated with the delightful perfume of the Maréchal Niel and woodland Margaret Roses which grew vigorously along the verandah. Here we also find Clerodendron Balfouri and Allamanda Williamsi covered with blossoms, the first one pure white with red, and called here "bleeding heart"; the second with brilliant yellow flower tubes. The Bottle-brush shrubs are as conspicuous as they are beautiful, particularly the larger-growing crimson Metrosideros robusta, the scarlet M. lanceolata, Callistemon rigidus and C. speciosus, and a species with rosy-purplish dense flower-trusses. The bottle-brush-like flowers are very conspicuous, terminating each twig, and creating an almost magic effect among the Palms, Cycads, Cypresses, and Magnolias. They belong to the most valuable open-air shrubs we have in Florida. Magnolias—including about twenty different varieties of M. grandiflora—are, together with the Palms, the glory of my garden. They begin to open their flowers during the last days of March, and lingering blossoms may be detected as late as November. These grand, creamy flower-chalices are always deliciously sweet-scented.

The fragrance of the blossom of Magnolia glauca, Datura suaveolens, Hall's Honeysuckle, and Oleanders, is almost overpowering. While strolling around in the garden for the first time since I came home, I scarcely knew which way to turn, there were so many objects to be seen, and many of the plants had made such a tremendous growth that I scarcely recognised them again. Strobilanthes Dyerianus, Acalypha Godseffiana, Solanum azureum, and S. Wendlandii, Maranta arundinacea, Cuphea micropetala, Aphelandra aurantiaca, Cassia floribunda and others, had made a wonderful growth around the house and alongside the verandah. I planted them just before I left for Philadelphia in July of the previous year; they were all small pot-plants when I set them out. Cardinal redbirds fluttered through the tangled labyrinths of Elæagnus Simoni and E. reflexa and the dense specimens of Cupressus torulosa and C. Knightiana; mocking-birds, cat-birds, thrushes, and Carolina wrens chanted their sweetest melodies, crested flycatchers whistled, blue jays screamed, ground-doves cooed, quails uttered their call-notes, woodpeckers hammered, and the savage cries of a brood of young butcher-birds in the garden were heard. My colony of purple martins, consisting of sixteen pairs, were busily engaged with nest-building, and their happy and joyful life adds a great charm to the place. Every morning with sunrise, and often before, I stroll around in the garden, examining plants and observing birds. One morning I discovered a Surinam Cherry-bush (Eugenia Micheli) with ripe fruits of the size of a Plum. The colour is glossy red, the fragrance very aromatic, and the taste of the juicy fruit, though peculiar, is very delicious. Many of the different species and varieties of Cocos Palms were in full flower; others had almost ripe fruit.

The Australian Silk-Oak (Grevillea robusta).

The crowning glory of my discoveries, however, was a tall Grevillea robusta in full bloom. While looking up in the dense tree, covered with an abundance of deep green foliage, I saw in the interior of it a glowing mass of colour. This was caused by an enormous wealth of bloom in the central part of the tree; but there were no flower-trusses on the extremities of the branches. The colour of the very peculiar flower-racemes is a deep orange-scarlet suffused with yellow, which contrasts in a marvellous way with the foliage, which is deep glossy green on the upper side and silvery-white underneath. The flower-trusses, often three and four together in one bunch, are found close to the branches, and fifty to sixty are frequent scattered along one small twig. The discovery of this flowering tree was quite a sensation to me. I had never before beheld the blossoms, and their beauty and brilliancy far exceeded my expectations. Among the greatest pleasures of gardening are the surprises in store for us. The flowers lasted in full beauty for a month.

Grevillea robusta is quite a common tree here, being known by the very inappropriate name of "Silk-Oak" or "Fern-tree." The tree in itself is highly ornamental and always beautiful. The specimen which was in bloom with me is a particularly fine variety, different from all the other Grevilleas in my grounds. The flowers were very brilliant, and the display was a most charming one when seen from below. A few flower-racemes are very interesting, but when they appear in dense masses the effect is glorious. I had always been under the impression that the flowers were rather insignificant, and that the whole value of the tree was to be looked for in the beautiful foliage and symmetrical growth. Since I had the chance to see the beautiful combination of flowers and foliage I have a much higher opinion of Grevillea robusta.

The tree, which consists of three trunks, is about 30 feet high. It is a picture of health and beauty, being surrounded by several plants of Cocos campestris, a large red Oleander and several specimens of Phœnix canariensis. From above it is sheltered by the crown of a long-leaved Pine (Pinus palustris). The whole group is a very striking one. The tree is about ten years old. I planted it out in the fall of 1897, when it was about three years of age and 2 feet high. Previous to this it had served as an ornament in a lady friend's home at Milwaukee.

Grevillea robusta is the only member of the family Protaceæ which thrives to perfection in my Florida garden in high, dry Pine land. Even closely allied species, such as G. Hilliana, G. Preissii and G. Thelemaniana, did not grow with me. Although remaining healthy for several years they did not make any growth and finally pined away. The beautiful Silver tree (Leucadendron argenteum), from the

Table Mountain of South Africa, which is such a grand success in the gardens of Santa Barbara and elsewhere in Southern California, was an entire failure in my garden. But Grevillea robusta thrives like a native even on the poorest sand, though in rich soil it grows much faster, soon attaining a large size and a very healthy appearance. If manures are not applied to the plant the leaves often have a yellowish cast instead of the deep glossy-green hue. Most of my trees were killed to the ground during the big "freeze" in February, 1895, which made such a terrible havoc among the Orange groves of Florida. They soon sprouted again and formed fine specimens. None of them, however, has attained the size and beauty of the one referred to in the above. They all seem to be different from it in growth, and the foliage is not as dense and deep green. If well cared for, Grevillea robusta is one of the most beautiful and magnificent exotic ornamental trees we have in Florida—certainly the finest of all the Australian trees, which, as a rule, are very precarious with us.

All the species of Eucalyptus, with the exception of E. robusta, soon lose their beauty, and finally perish apparently without a cause. The very pretty Flame-tree (Brachychiton acerifolium) grew with me with great vigour for several years, but it suddenly died. The fine Acacias grow to an enormous size in the course of a few years, but they likewise die out suddenly. Only the rather tender Tristania conferta and the different species of Callistemon and Metrosideros grow well in my garden, but the Grevillea robusta excels them all. Indeed, I do not know of another exotic tree that is so successfully grown. It has all the good features of an ornamental shade-tree—rapid growth, fine form, beautiful foliage, and brilliant flowers. It is easily raised from seeds. Being of very easy culture, and thriving perfectly well in the dry atmosphere of a living-room, it is well adapted for the plant-lover. For this purpose it is largely grown by our florists for home decoration, and large numbers are annually sold under the name of "Fern-trees." Perhaps the many beautiful allied species, which are famed for their gorgeous flowers, would do well in Florida if grafted on Grevillea robusta. *H. Nehrling, Florida.*

NEW OR NOTEWORTHY PLANTS.

A REMARKABLE HYBRID NARCISSUS.

A long time ago, twelve years ago at least, and possibly fourteen or fifteen, I made an experiment which perhaps may be classed among what Mr. Darwin used to call "fools' experiments." I placed the pollen of a florists' variety of Narcissus Tazetta on the stigma of a flower of Corbularia monophylla previously deprived of its anthers. I have mislaid my notes, and in what I have to say I must trust to my memory only. The flower gave me ripe seeds (I forget how many), some of which germinated and produced bulbs. The foliage of the young bulbs—longer, broader, and stouter than that of the female parent—led me to suspect that the pollen had produced an effect; and this was confirmed by the experience that the bulbs, cultivated in a pot in a cool greenhouse, would not, even after several years, flower. Seedlings of C. monophylla flower well within four or five years.

I then planted-out the bulbs in a cold frame. Here they seemed to thrive; the foliage grew bigger and stouter, but still no flower appeared. I was encouraged to persevere by a remark made to me by Mr. Engelheart—that hybrids in which N. Tazetta took part were very slow in flowering.

After the bulbs had remained in the cold frame for some years (four or five, I think), I took them up and repotted them. I found some of them much larger than, at least twice as large as, any bulb of Corbularia monophylla which had passed through my hands.

Last year one bulb flowered in a cold greenhouse, and this year some five or six have followed suit, the several flowers differing somewhat in size, but being otherwise much alike. They may be described as follows: The bulb bears from three to five stout, erect, dark green channelled leaves, each about 35 cm. long or less, and 3 mm. broad. A stout round scape 25 cm. (both leaves and scapes are probably somewhat "drawn up" by greenhouse cultivation) or less in height, bears one or two flowers, pure white save for the orange of the

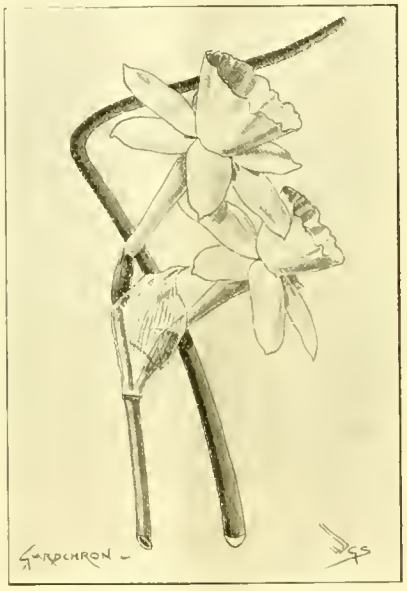

FIG. 38.—A HYBRID NARCISSUS:—CORBULARIA MONOPHYLLA × NARCISSUS TAZETTA. FLOWERS WHITE.

fairly abundant pollen, very like those of N. triandrus, except that the stamens are of equal length, and the cup is large and somewhat bell-shaped, as in my hybrid N. triandrus, crossed with Corbularia monophylla. In one flower the cup is most distinctly lobed; and possibly subsequent flowers may show other differences. Some flowers have a diameter, from the apex of one segment to that of the opposite, of 2·5 cm., the cup having a diameter of 1·5 cm.; other flowers are smaller. There is only a trace of fragrance.

Trusting to my memory alone I should say that the ripe bulbs resemble very fine bulbs of N. triandrus. I have now a score of bulbs; but some of these are off-sets, and I quite forget how many bulbs the seed originally gave me.

The plant is of little value on the ground of beauty, but is perhaps interesting as showing the nature of the product of two forms so distant as its two parents. Although I have had to trust to memory I do not think that any error has crept in during the long course of the cultivation of the plants. I do not know the origin of the florists' forms of N. Tazetta; but I imagine that they are "sports" or the products of selection rather than the results of any hybridisation, so that in dealing with them we are really dealing with N. Tazetta.

According to the system of nomenclature which I have suggested, I should call this hybrid Narcissus Montaz ×; but I am free to confess that my system, though intellectually very useful, rather strains what seems due to the ear. *M. Foster, Shelford, Cambs., January* 30, 1905.

VANDA WATSONI, *Rolfe. n. sp.**

A striking new Vanda has been introduced from the interior of Annam by Messrs. Sander & Sons, St. Albans, through their collector, W. Micholitz. It is closely allied to V. Kimballiana, Rchb. f., which it closely resembles in habit, and when out of bloom the two are difficult to distinguish, but the flowers are very different in structure and colour. The flowers of V. Kimballiana have a stoutish spur 7 or 8 lines long; but in V. Watsoni this is replaced by a shallow sac scarcely 2 lines deep, while the front lobe of the latter is concave, fimbriate, and white, not flat, entire, and purple, as in the older species. Our novelty has the flowers entirely white, with the exception of the crest and interior of the sac, these being deep yellow dotted with red-brown. Other details of structure are given in the technical description. Good dried specimens have been sent to Kew by Messrs. Sander & Sons, and living ones by Mr. F. W. Moore, of the Royal Botanic Garden, Glasnevin, where the species has just flowered. It is dedicated, at Messrs. Sander's request, to Mr. W. Watson, Curator of the Royal Botanic Gardens, Kew. It grows at about 5,000 feet altitude, and will probably require the same treatment as V. Kimballiana and V. Amesiana, which three species form a very natural section of the genus. *R. A. Rolfe.*

* *Vanda Watsoni*, n. sp.—Plant almost identical in habit with Vanda Kimballiana, Rchb. f. Leaves subterete, channelled on the upper surface, up to 14 inches long by 2 lines broad, narrowed upwards and subacute, with membranaceous sheaths at the base, dull dark green. Scapes slender, a foot or more long, about 12-flowered. Bracts ovate-oblong, obtuse, 2 lines long. Flowers white, with some red-brown spots on the crest and interior of the sac of the lip. Dorsal sepal obovate-spatulate, obtuse, 9 lines long; lateral pair similar, but oblique at the base, 10 lines long. Petals 9 lines long, obovate-spatulate, obtuse, deflexed, twisted at the base so as to bring the back surface to the front. Lip 8 lines long by nearly 6 lines broad; front lobe cordate-elliptical, obtuse, fimbriate, concave, inflexed at the base till the margins meet, side lobes incurved, fleshy, truncate, with two acute angles, about a line long; base saccate; sac obtuse, nearly 2 lines deep, 1½ line broad from side to side, but only half as broad from front to back, deep yellow inside, dotted with red-brown, with an erect 3-lobed yellow callus filling the front of the sac. Column 3 lines long, white, its foot bearing a truncate or obscurely 3-lobed callus opposite to the one in the sac. Native of Annam. *R. A. Rolfe.*

FORESTRY.

GROWTH OF DURMAST OAKS.

I have ventured on a former occasion in your columns to recommend the durmast or sessile-flowered Oak to North-country planters as preferable to the pedunculate species or sub-species. Unhappily the durmast Oak is no longer in the British market; those who wish to plant it must either collect their own acorns or buy them abroad; and the durmast does not bear acorns so frequently as the pedunculate Oak.

Nearly eight years ago, in the spring of 1897, we planted about two acres of ground where the great storm of December, 1894, had made a clean sweep of some Beeches about 100 years old. Wishing to make an Oak grove of the ground, we set it with three-year-old seedlings from acorns carefully collected from the fine durmast Oaks in Mr. Bagot's deer park at Levens, Westmoreland. These were planted widely, about 15 feet apart, and the intervals were filled with Larch, Corsican and Scots Pine.

The result has been as remarkable as it was

unexpected. The Oaks have kept pace with the Larch, and have far outrun the Scots. Many of them are 12 feet high, an extraordinary growth in eight years from planting, and far beyond anything that a pedunculate Oak could do here. The soil is good and well drained, but not deep—about 14 or 16 inches of gravelly loam upon boulder clay; ground inclining gently to the east, but swept by sea winds from west and north-west.

I have drawn attention formerly to the comparative freedom of the durmast from galls. Examining this plantation to-day, I could find only two durmast Oaks with "apples" on them. One of these has received a severe twist in early youth, and carried about a dozen apples; the other, about 10 feet high, has four apples on it. But the growth from an old stool of pedunculate Oak in the middle of the wood was thickly set with apple-galls.

Recent authorities (Mr. A. C. Forbes is the latest) recommend the sessile-flowered Oak for dry and sandy soils. The prevailing character of our soil in the west of Scotland is moist, even where the drainage is perfect, owing to the humid atmosphere and the retentive subsoil. Yet the superiority of the durmast Oak over the pedunculate is very well marked, and it is a pity that nurserymen cannot be induced to supply it true. *Herbert Maxwell, Monreith.*

BOOK NOTICE.

THE COUNTRY DAY BY DAY. By E. Kay Robinson. (London: William Heinemann, Bedford Street, W.C.)

A BOOK such as is this, dealing with country scenes and illustrated with photographs, is always welcome. We have here a daily record of what Mr. Robinson sees of the bird and beast—especially the bird—and plant life around him, beginning with the frozen-out birds and withered leaves of January, and ending with the drooping flower-leaves of the Hellebore at the end of the year. The book makes no pretence to being a record of scientific observation, but is in fact just an account of everyday events in the country, such as most see though perhaps only the few observe or chronicle. In the paragraphs devoted to the winter days there is naturally a scarcity of incidents, and a tendency to fill up with general remarks; on the summer days there is plenty to be said.

By quoting part of the entry for May 25, we can show a very fair example of the author's style:—"The soft green fronds of the bracken are spreading wide in the glades, and the second act of the annual drama of the woodland opens. First came the dainty flowers of spring, blue Violets and pale Primroses, starring the soft earth, which was then all velvet-green with the budding points of later flowers; and these have carried on spring's scheme of colour music to a high crescendo of vivid pink and white, deep hazy-blue and pure golden-yellow. . . . The third act will come when the sunset hues of autumn begin to glow in the dying bracken-fronds in every shade of copper, gold, and bronze; and the fourth will follow when the brown and broken litter of dead Fern rustles to the stealthy tread of the pheasant listening to the beaters."

Mr. Robinson's "scrappy story," as he calls it, is not confined to one district of England only, but is intended to apply to the country generally, with due allowances made for variations in climate and seasons. We hope the facts he relates may teach many readers to observe and appreciate for themselves, if not to add their own share to the many modern books on nature-study.

POTATOS.

THE COOKING TEST.—Being much interested in Potato-culture, and having grown most of the new varieties during the last twenty-five years, I have been much impressed in reading the reports, &c., that have lately appeared in the *Gardeners' Chronicle* on that wonderful cooking test, "where," as you say, "the judges were called on to taste and deliver judgment on no fewer than sixty-seven varieties." Well may you ask, "How did they do it?" It has long been a belief with me that a Potato when cooked only retains its flavour for a certain time, a few minutes making a difference, so that in my opinion the cooking of sixty-seven varieties and the tasting of such a number must have been a most trying ordeal for the judges, and I should think that only a small portion of each variety could have been tested by any one of the judges selected.

In cooking Potatos more depends on the way the cooking is carried out than many think. Unless Potatos are cooked in their skins one never gets the real flavour, and it is seldom indeed that two varieties can be found that cook exactly alike—some sorts taking longer than others. As Mr. Mayne ably points out, p. 2, *Gardeners' Chronicle*, January 7, "soil is the most determining factor in flavour." When living in North Ayrshire, N.B., many years ago, we always broke up a portion of land that had been pastured for some years previously (termed old lea there). In the autumn this land was ploughed deeply, then well broken up and manured in spring previous to planting the Potatos. Under this method of cultivation it seemed to me that all varieties, or nearly all, were alike good, so dry and mealy that it was difficult to cook them, as they were very apt to break up in the cooking. Under this method of cultivation the yield per acre was less, yet the quality was all that could be desired. Here I have grown immense crops of beautiful, clean large tubers on land that has been under a Wheat crop the previous year, yet the cooking quality was deficient. In garden culture, of all the manures, &c., that I have tried nothing equals fresh lime freely used.

We generally trench down a brake of Strawberry plants each autumn, giving the land a fairly good dressing of farmyard manure at the time of trenching. In spring we spread a good coating of fresh lime over the surface of the ground and work it into the soil as the Potatos are planted, using five-pronged steel forks for the work. Last spring we had several of the newer varieties, including Sutton's Discovery, Northern Star, Sir John Llewelyn, &c. In planting these we used a good quantity of old hotbed materials—leaves and stable-manure—making an opening 7 or 8 inches deep, and half filled the opening with this material, to which were added some wood-ashes. The result was simply amazing as regards weight of crop and sound tubers, there being no signs of disease. In fact, I have never before seen such crops, yet the result is that the Potatos are wanting in quality, being soft and waxy when cooked. The variety Sir John Llewelyn is an enormous cropper, beautiful to look at, yet (with us at least) sadly wanting in quality when cooked.

I am surprised to hear that Potatos grown in Essex were better and more esteemed than those grown in Scotland. We are at the present time using a sample of "Langworthy" grown near Dunbar last season, and if any of those varieties from Essex are as good, then they are good indeed. I have frequently during the twenty years I have been in England, had Potatos quite as good in every way when cooked as any grown in Scotland in my experience, but then only when the seasons were favourable and when the seed came direct from Scotland. If it turns out that Potatos of better quality can be grown in Essex than in Scotland it will be the greatest event in Potato culture that has taken place. I fancy the farmers in East and Mid Lothians must be feeling very uncomfortable at present, especially some I know who cultivate for the London markets from 300 to 500 acres of Potatos annually. I have always been under the impression that it was the quality of those Potatos that created the sale for them in the London market; yet I must have been mistaken, as many others no doubt have been. I fancy there will need to be another "cooking" and "testing" match again before many are convinced of the folly of growing Potatos in Scotland for the London markets that are only second-rate as compared with Potatos grown so near to London as Essex is. *David Kemp, Stoke Park Gardens, Slough.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT WESTFIELD, WOKING.

A VERY remarkable collection of Cypripediums, Lælias, Cattleyas, and Lælio-Cattleyas has been got together by Francis Wellesley, Esq. (gr., Mr. Hopkins), and the plants thrive in a very satisfactory manner in the well-arranged houses provided for them.

One of the chief items of interest in the collection is the complete set of hybrids of the now nearly lost C. Fairrieanum. Of primary crosses of that coveted species Mr. Wellesley has C. × Princess, C. × Edward, C. × H. Ballantine, and the fine Westfield variety of it, C. × Mrs. F. L. Ames, C. × Juno, C. × Baron Schröder, seven very distinct forms of C. × Niobe, C. × Gaskellianum, C. × vexillarium and its varieties superbum, "Rex," and Rongieri; and four forms of C. × Arthurianum. Of secondary crosses of C. Fairrieanum, C. × vexill-Io, C. × bella, C. × Statterianum, C. × Norma magnificum, C. × Abraham Lincoln (Niobe × orphanum), C. × Minos, and the fine varieties Youngii, Westfield variety, magnificum and superbum, C. × Laura, C. × Imogene, C. × Little Gem, C. × Thalia, Westfield variety, C. × Arthurianum × insigne Sanderæ, C. × Niobe × Leeanum, C. × Niobe × Haynaldianum, C. × Niobe × philippiniense, and C. × vexillarium × Argus.

It will be seen that the pretty little C. Fairrieanum, although now at the vanishing point in collections, has played a very important part in the hands of the hybridist, and the field of its usefulness is being further developed at Westfield.

It has been advanced by hybridists that by inter-crossing the hybrids of C. Fairrieanum, and especially those nearest like it, that a seedling practically identical with the species may be obtained. But Mr. Wellesley has worked hard in this direction and with but little result, for the seed vessels obtained seem to have little or no good seeds in them. Out of 120 crosses between Fairrieanum hybrids made and sown at Westfield, but one small plant has resulted, although other hybrids are coming up in great profusion, some of them being the result of very wide crosses.

The hunt for C. Fairrieanum in the hills of Assam and other parts of India has been long continued, but hitherto fruitlessly. If, however, it is determined to have it in gardens again it will be obtained from its native habitat if the search is continued, before it will be raised by the means prescribed, if Mr. Wellesley's tests are final.

Cypripedium × Mrs. Francis Wellesley (Sanderianum × Gowerianum magnificum) is a most beautiful hybrid, flowering for the first time. Unlike some hybrids of C. Sanderianum, this is a robust grower, its handsome ivory-white foliage, barred and veined with dark green, being finely developed. The stout purple stem bears large

flowers, the ovate-acuminate dorsal sepal white with heavily-blotched raised lines of chocolate-purple, the basal part tinged with pale green. The long, extended petals yellowish-white tinged with rose, and with an obscure green veining and many large warted blotches of chocolate-purple, those on the upper edge being furnished with long blackish hairs. The lip is large, and very suggestive of C. Sanderianum; cream-white tinged with rose on the face; staminode rose colour. It is a very beautiful and distinct hybrid.

Cypripedium × Mrs. Wm. Mostyn, figured in the *Gardeners' Chronicle*, February 1, 1902, p. 75, from the plant when it was awarded a First-class Certificate, is one of the handsomest hybrids ever raised, its fine dorsal sepal being bright purplish-rose of different shades with a broad white margin, and the yellowish lip and petals finely marked with red-brown.

The fine collection of species and hybrids of the C. niveum and C. bellatulum class are suspended near to the glass of the roof and sparingly watered until spring comes. One fine tuft of C. bellatulum album is pushing many growths and the remarkable yellow, purple-spotted C. × Wellesleyanum is now forming a fine specimen. Most of the hybrids of this class are in the collection, and all are found to be impatient of water on the foliage during cold dull weather.

Many pretty hybrids are in flower, and good batches of different forms of C. × Hera, C. × Sallieri, varieties of C. insigne. Especially fine are the specimens of the best forms of Cypripedium Lawrenceanum, of which even the reputedly slow-growing albino, C. Lawrenceanum Hyeanum, has made a sturdy specimen.

In the Cattleya and Lælia-house the occupants are in fine condition, and some of the best varieties are now represented by several specimens. By judicious dividing the plants are found to grow more vigorously and produce better flowers than when left in close masses. A batch of albino Cattleyas of the C. Mossiæ class are in grand health and showing well for bloom. Lælio - Cattleya × Eunomia Westfield variety has a model flower nearly equal in size to that of a good Cattleya Trianæ, and of a clear dark rose colour with purplish-crimson front to the lip. Lælio-Cattleya × Charlesworthii magnifica is like L.-C. × Cappei in size and in the rich coppery-orange tint of its flowers, the labellums of which are light reddish-claret.

Other showy Orchids were in flower, and many of the plants bore nearly mature seed capsules; but, thanks to the good cultivation accorded them, are still plump and vigorous. Among plants not in flower two instances were noted pointing to the difficulty of identifying imported plants by the appearance of their growths. In one instance was a plant of Cattleya × Hardyana imported with C. aurea, and exactly like C. aurea in growth. Another plant of it imported with C. Warscewiczii was totally different in growth, and with the rounder greener pseudo-bulbs and leaves of C. Warscewiczii. The second instance was of Lælio-Cattleya × Gottoiana. One imported with Lælia tenebrosa had the slender hard growths of that species, while the other got with C. Warneri was Cattleya-like in growth. In both cases there is but little difference in the flowers.

Stenoglottis fimbriata.

This rare and pretty South African terrestrial Orchid is in flower on several specimens in the gardens of Mrs. Brightwen, The Grove, Stanmore. The plants bear handsome crowns of bright green leaves, heavily barred and blotched with dark purple, arranged rosette-like close above the surface of the soil in the pots in which they are growing. The inflorescences arise from the centre of the growth, the scapes bearing leafy bracts spotted like the leaves, and terminal spikes of blush-white and pale lilac flowers. A number of strong plants of the more robust-growing Stenoglottis longifolia are in the same house, and some singular Satyriums, Disas, &c., Disa sagittalis being in flower, which, in common with many other rare and curious plants, Mr. J. W. Odell, the gardener at The Grove, cultivates very successfully. The Stenoglottis, Disas, &c., are grown in a warm greenhouse in winter and in a cool frame in summer. *J.*

TRELOYHAN.

The Cornish residence of E. Hain, Esq., M.P., is situated on the cliffs overlooking St. Ives Bay, on both sides of which the coast is practically treeless. To the right, just across the bay, are the sand-dunes of Hayle, amongst which are scattered the huts and works of the National Explosives Company. Westwards the scenery and vegetation are typical of the wild North Cornwall coast—steep, rugged cliffs, and poor, shallow soil growing coarse grass, with patches of gale-stunted Heather and Gorse. These are the surroundings amid which Mr. Hain built his home, made his garden, and laid out his grounds. Trees, one would have thought, were wholly out of the question; but it is the trees at Treloyhan which strike one most upon approaching St. Ives. As will be seen in the illustration [see fig. 38], there is a healthy and vigorous plantation of mixed trees almost on the very edge of the cliffs. This plantation is composed chiefly of Sycamore, Ash, Beech, and the Cornish Elm.

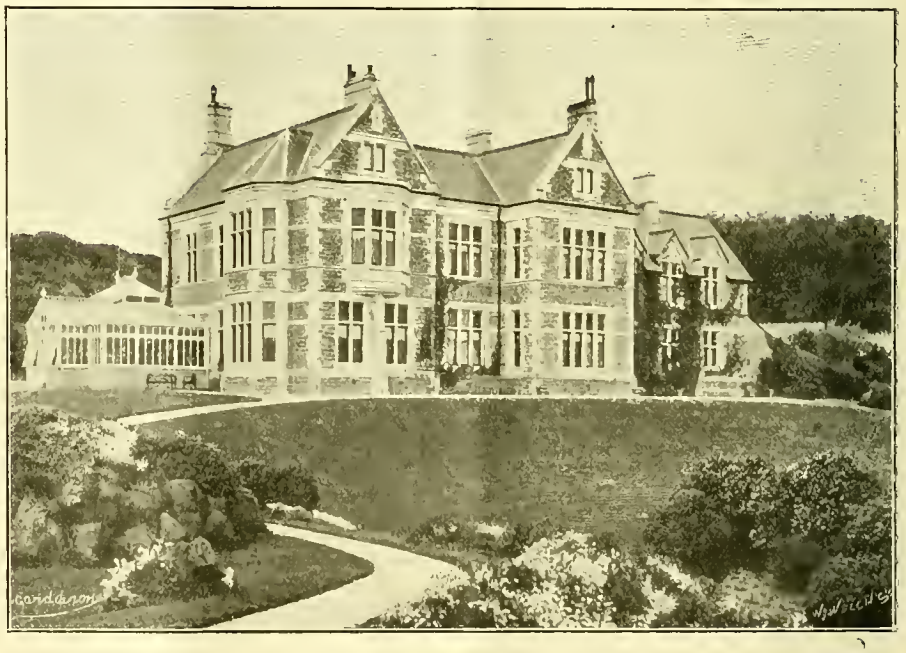

Fig. 37.—Treloyhan House, Cornwall, the residence of E. Hain, Esq., M.P.

The gardens were designed and laid out by Messrs. Robert Veitch & Son, of Exeter, whose well-known landscape gardener, Mr. Meyer, most skilfully took advantage of the slight natural undulations. Where possible, such depressions were increased, and in the shelter thus provided he planted tender shrubs. A disused mine-burrow which had been partially filled up provided an ideal site for a rockery, which in the short space of seven years has become well furnished. A dripping-well suitably planted is one of the features of this rockery.

Close by the rockery a fine variegated Phormium tenax has thrown up a vigorous flower-spike much stronger and more erect than the spikes of Phormium Cookianum, a species which flowers and seeds so freely in all parts of Cornwall. Many kinds of Iris are thriving here, and there is a small collection of hardy Ferns; while in the full sunshine a patch of Eschscholtzia was a blaze of colour last season. Next comes the nucleus of a collection of hardy Cacti, the most promisin of which is Opuntia camanchica.

The shrubberies are already a feature of Treloyhan; for the most part they encircle the lawns, which are irregular in outline, and form a series of bold curves. At the outset large numbers of the commoner shrubs, Laurels of both kinds, Rhododendron ponticum, &c., were wisely planted to form screens and nurse-plants. These are being gradually removed, leaving the choicer kinds, which now appear well able to look after themselves. Most conspicuous among the many and varied shrubs are Griselinia littoralis, which seems to have an especial predilection for the Cornish air, and quickly forms large bushes; Veronicas in variety, Berberis asiatica, Geum, Cistus, Althæa frutex (Hibiscus syriacus), and, of course, many Escallonias, E. exoniensis ×, bearing masses of creamy-white flowers, was very good; the white E. floribunda also had a profusion of flowers, and the common E. macrantha, planted thickly along the top of a stone ledge, has quickly transformed an eyesore into an object of beauty.

Conifers.

An experimental planting of Conifers has been made. It is too soon to say which will succeed, but up to the present many are thriving. The tallest are upwards of 20 feet in height, and of them the most promising are Araucaria imbricata, Abies Nordmanniana, Cryptomeria japonica, Larix leptolepis, Picea excelsa, P. nigra, Pinus austriaca, and P. insignis; the latter tree does exceedingly well in Cornwall, and will withstand a considerable amount of wind. The deciduous trees which have grown the best are the common Ash, Sycamore, Turkey Oak, Cornish Elm, Service Tree, and the Purple Filbert.

As a whole Cornwall is not a Rose country; where they are grown with success the plants have to be frequently renewed. Out of a large collection planted nearly a decade ago only

Merveille de Lyon, Baroness Rothschild, Alfred Colomb, Marie Baumann, and Boule de Neige remain. These are healthy, and flower freely; so probably it is an instance of "the survival of the fittest."

The kitchen-garden is well stocked with the crops usually grown in a private establishment. The soil is light and sandy, but with deep digging and the frequent use of the hoe satisfactory crops of vegetables are produced. Potatos are grown in plots almost on the seashore, the standard varieties being Myatt's Prolific, Ashleaf, and Main Crop. Mr. Madge told me that the dreaded Potato disease is practically unknown! Can this immunity be due to the salt-spraying given by the gales?

Apples canker early; those which produce the best crops are Cox's Orange Pippin, Blenheim Pippin, Lane's Prince Albert, Rymer, Bismarck, Golden Noble, and Stirling Castle. Of Pears, Mr. Madge would name but three as being uniformly satisfactory—Bon Chrétien, Marie Louise, and Beurré d'Amanlis.

The Glasshouses.

The small conservatory attached to the mansion is well furnished with Palms, Begonias, Fuchsias, Ferns, Agapanthus—a pot of the variegated form in flower looked very neat. In the centre of the house, which is left clear for tea-tables, &c., stands a large cage containing Java sparrows and canaries, which strike a note of tropical colour.

In the vineries good Grapes are obtained; Golden Amber (well coloured and of good size), Foster's Seedling, and Madresfield Court Muscat were the best at the time these notes were taken.

The well-filled stove contains many useful and interesting plants, the most striking of which are Anthuriums in variety, several large pots of Pancratium, Allamanda Schottii, and the brighter-coloured A. nobilis, and, what I was surprised to see in a private garden, a fine plant of the "Bowstring Hemp," Sanseviera guineensis. *A. C. Bartlett.*

CHRYSANTHEMUMS.

French National Chrysanthemum Society.—From *Le Chrysanthème* we learn that the Society now numbers 721 members, inclusive of forty-seven affiliated societies—not a bad list for a ten-year-old society. The awards to seedling-raisers, made as a result of the certificates granted by the Floral Committee, were—1, a Gold Medal to M. Ernest Calvat; 2, a Silver-gilt Medal to M. Rozain Boucharlat; 3, a Silver Medal to M. Alfred Chantrier.

M. Viger, President of the National Horticultural Society of France, is also Honorary President of the French National Chrysanthemum Society, and has very ably conducted the proceedings at eight of the annual Conferences of the Society. This gentleman has recently been appointed Knight of the Legion of Honour.

Although a late Minister of Agriculture, M. Viger has acquired the reputation of being almost a Minister of Horticulture, and this his latest honour has been much appreciated by the gardening fraternity in his country, as it has by those English gardeners who know what he has done for the craft.

The colour-chart in course of progress, which will be issued under the auspices of the Society, will shortly be ready for publication. Each colour is represented in four distinct shades, and there will be approximately about 400 colours in all. Although published in French, it has been considered necessary to make it useful for florists in other countries, so that uniformity of colour description may be observed. It will therefore be in five languages. The French part, and the entire charge of the whole publication, is in the hands of M. Dauthenay, the German part is being done by Mr. Max Leichtlin, the Italian by Mr. N. Severi, the Spanish by Mr. Miguel Cortes y Coll, and the English by Mr. Harman Payne.

Following the example of the American and English sister societies, the French National Chrysanthemum Society is about to issue an official catalogue of Chrysanthemums. It will be published in instalments. *C. H. P.*

Chrysanthemums Tied Down.

In reply to Mr. Jefferies I may say that the plants illustrated were all bush plants. We do not "stop" them at all, but pick out all the latest plants in the autumn to tie them down, so as to produce a good effect at Christmas time. The photograph was taken about a week before Christmas. The flowers, as Mr. Jefferies stated on p. 76, are not much use after being cut and if long stalks are required; but we grow many bush

Fig. 38.—Treloyhan House: showing belt of trees overlooking St. Ives Bay, Cornwall.

plants and do not have to cut those that are tied down. We also grow some dwarf plants by rooting extra cuttings now, putting several in a 60-sized pot. They are planted out later on, and the tops of them are layered in July, as one would Carnations. I think these make better plants than those obtained from cuttings rooted in May. Plants under 3 feet high however are not much use for our purpose as they cannot be bent sharp down to cover the pots without breaking them. I presume anything trained in any shape or form would be in Mr. Jefferies' view objectionable; but tastes differ. The object we seek to obtain is a bank of flowers, and the illustration showed that this is secured. Chrysanthemums have been trained in this way here for several years past, and have been appreciated by all who have seen them. *W. C. Smith, The Gardens, Ecton.*

CHRYSANTHEMUM ALLMAN'S YELLOW.

This proves to be the most useful late-flowering decorative variety that I have yet met with; the flowers are 2 to 3 inches across, when grown naturally and not disbudded. The florets are slightly reflexed, and of deep yellow colour, very much the same shade as that of Duchess of Sutherland, when the latter has been disbudded and grown well. The only variety comparable to Allman's Yellow for late flowering here is Princess Victoria, but for many purposes a yellow flower is more useful than a white one. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

MARKET CHRYSANTHEMUM WINTER CHEER.

We learn that since Mr. W. Hayward, of Kingston-on-Thames, exhibited flowers of this fine late pink-coloured Chrysanthemum at a meeting of the Royal Horticultural Society last month, he has been inundated with applications for stock. Mr. Hayward exhibited the flowers as purchased by him in the market, and presented it not for any award as a new variety, but to show its fine decorative uses so late in the winter. The stock is held by some market-growers, and it is understood they have no present intention to put plants into commerce, being content to find a good market for the flowers. Novelties however come thick and fast, by seed and by sports, hence even a superior variety may soon be on offer.

APPLIANCE TO PREVENT "DRIP."

THE Orchids here having suffered considerable injury from water dripping from the roof, I have recently had beading fixed to the rafters, as shown in the accompanying illustrations (see fig. 39, A, B, C), and this has proved very successful in preventing the causes of the mischief. The use of the beading will save the expense and inconvenience that would be caused by reglazing the roof. The cost of the beading is about 7*s.* 6*d.* for a length of 500 feet. Before fixing the beading put a thick coat of white-lead slightly thinned with linseed-oil on the under surface. Use inch brads, about 6 inches apart. Two coats of paint at least should be given the beading. *F. G. Brewer, The Grange Gardens, Brentwood, Essex.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cattleya Schilleriana.—This grand Brazilian species commences to grow very early in the year, and under proper conditions produces its flowers in April or May. Newly imported plants should first be fixed in pans of suitable size which have been furnished with a large quantity of drainage material, and over this a thin layer of peat and sphagnum moss should be placed. There may be some plants which, owing to their habit of growth, cannot be fixed in pans, and these may be tied to Teak-wood rafts with a little peat and sphagnum moss intervening. Growth being now in progress, suspend the plants near to the roof-glass in a light, warm spot in the Cattleya-house, affording very limited supplies of water until there is root action. Just previous to the making of new roots fresh surface material may be given. Hybrids from C. Schilleriana should be given more exposure to light than most of their kindred require, and when their pseudo-bulbs are nearing maturity a long period of rest is needed. C. Whitei, C. Vulcan, C. F. W. Wigan, C. Prince Edward, &c., all thrive best suspended near to the roof glass, where light, heat, and air are most abundant.

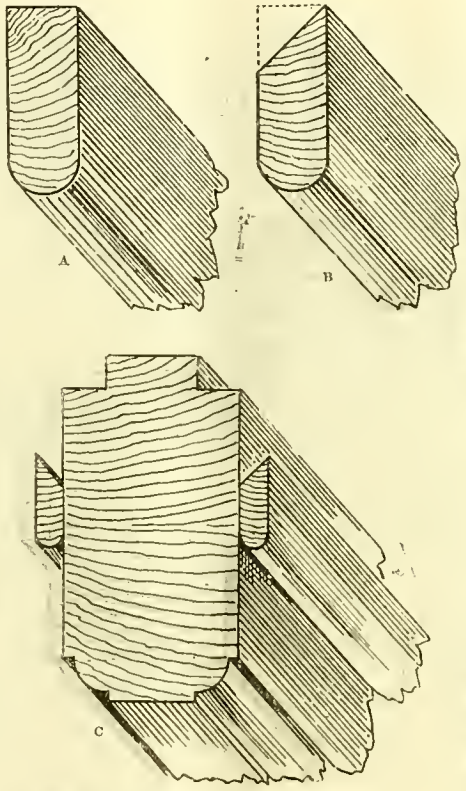

FIG. 39.—APPLIANCE TO PREVENT "DRIP."

A—Three-eighth Beading (*actual size*).
B—Beading bevelled on one side.
C—Rafter showing Beading fixed (*reduced*).

Cattleya Warneri, being another species that makes early growth, should be given a favourable position. On no account should growth be hastened by applying an extra degree of heat, or the plants will not flower well, and further disaster may occur. A central position in the house suits them best, and very little water must be given before new roots appear. Let the plants have perforated pans or baskets and ample drainage material, with a moderate quantity of peat and sphagnum-moss to root into. Repotting or surfacing should be done just when new roots are about to appear.

Odontoglossum citrosmum should be suspended or staged near to the roof-glass in a house having an intermediate temperature, and to ensure a plentiful supply of flowers in season water must be withheld until the youngest pseudo-bulbs show signs of excessive shrivelling. Continue this practice until the flower-spikes appear in the young growths, when freer applications of water may follow. Potting operations should be deferred until after the flowering period, for it is then root-action recommences. A small proportion of semi-decayed Oak-leaves mixed with the peat and sphagnum-moss has proved to be beneficial to this plant, employing pans when such a mixture is used.

Miscellaneous Orchids.—Plants of Platyclinis glumacea have commenced to grow again after a long rest, and should be placed in a light, warm position to induce good growth. Little water is needed until the slender scapes are well advanced in growth, increasing the supply as the leaves develop. Renew the surface materials of those plants not needing a shift. When new roots appear repot those that require it into well-drained pots or pans, using a mixture of equal parts of peat, fibrous loam, and sphagnum moss, with sufficient sand and small crocks to ensure free drainage. Use water in moderation until the plants are re-established, and when fully developed return them to the Cattleya-house in order to mature. Bletia hyacinthina should be placed where it can obtain the maximum amount of light in a cool, airy house, and be gradually watered as the growths elongate. Stenoglottis longifolia is also commencing to grow, and should be placed near the glass in a cool-house. Give the plants little water until the growths are well advanced. When needed divide the stools, and pot the stronger pieces in well-drained pots, using a mixture of soil for potting similar to that advised for the Platyclinis.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Gardenia plants that are well furnished with flower-buds will be benefited by a teaspoonful of Clay's Fertiliser to a gallon of water applied two or three times a week.

Jacobinia chrysostephana.—After a period extending over many weeks in full flower this plant has now ceased to be effective. The seed-vessels should be removed as in the case of those of a Rhododendron to encourage growth. Whether the plants are to be grown on or to be increased by propagation, they should first be given a thorough cleansing with "Quassia-extract," afterwards removing them to a light warm-house, and freely syringing them with clear water. Exercise great care not to allow the plants to become sodden at the roots, or failure will be certain. The wealth of flower and richness of colour produced by this plant during the dull dark days of December and January will amply reward anyone for the trouble taken to bring it to a state of perfection. Cuttings may be taken when young growths have been made, detaching a good heel from the old wood with each cutting. The plants require a warm, moist atmosphere, and the soil should consist of loam and peat in equal parts, with a little charcoal and silver-sand added. Let the rooting space be more or less restricted, afford water with great care, and immerse the plants in "Quassia-extract" regularly not less than once a week.

Justicia coccinea is somewhat different in its habit of growth to Jacobinia chrysostephana, but its requirements are identical with those of that plant. Its rich scarlet flowers have very great effect when grouped amongst other plants.

Achimenes and Tydæas will now be showing signs of active life, and before being allowed to make growth should be shaken out of their old soil and repotted in a good compost of peat and loam in equal parts with a liberal supply of silver-sand added. The pots should be well drained and filled to within 2 inches of the top with the compost, together with a layer of silver-sand, placing the corms evenly but not too thickly over the surface. More of the compost should then be added and pressed lightly with the fingers. They should be placed near to the glass in the plant stove and syringed lightly.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Cornet, Impney Hall Gardens, Droitwich.

Fruiting Pines.—Plants of the Queen variety which were selected and placed in the fruiting-stove at the commencement of last month for special treatment, as advised in a previous Calendar, will, in the majority of cases, give indications of fruiting during this month. At this stage the temperature at night should be increased to 70°, at the same time weak guano-water at a temperature of 85° should be applied in order to feed and stimulate the plants. Keep the atmosphere somewhat drier during the period the plants are in flower; the presence of too much moisture often causes deformed fruits. When the plants have passed the flowering stage maintain plenty of atmospheric moisture in the house, which can be obtained by damping the paths and beds several times daily, at the same time avoid syringing the plants overhead at this early season. See that the evaporating pans are kept filled with water; and put a handful of guano in these occasionally. In cold weather, when much fire-heat is necessary, the beds which are supplied with bottom-heat must be carefully watched to see that the temperature does not exceed 90°.

Figs.—Pot-trees that have been subjected to a steady bottom-heat of 75° to 80° will in many cases have fully developed their foliage, and their embryo fruits should be swelling freely. Syringe the trees plentifully on bright days, but on cold dull days unfavourable to ventilation, damping the paths and other available spaces will be sufficient. Remove all superfluous fruits before their flowers open, as by this means the dropping of fruits is reduced to a minimum. It is a great mistake to allow more fruits to remain on the trees than they can properly mature. The growths of pot trees should be pinched at the fifth leaf to guard against overcrowding. Trees that are planted in the borders should as far as possible be grown on the extension system and the superfluous wood removed in the winter. Very little growth will take place while the trees are in flower. As soon as the fruits commence to swell, the night temperature should be increased to 65° or 68°, allowing a day temperature of 85° or more with sun-heat, with plenty of atmospheric moisture. Liberal supplies of liquid and of artificial manures should be given to trees growing in pots and shallow borders Houses for later crops should be closed as required. Trees growing in cold-houses should be pruned and cleaned, and the borders top-dressed with good loam, bone-meal, and wood-ashes or lime-rubble.

Grape-room.—The bunches must be examined weekly to remove decayed berries. Refill any bottles with soft water if the water has decreased, for during the first fortnight much water is taken up by the wood. Keep the room darkened, and at a temperature of 40° or 45°. The floor should be kept dry, and sufficient air allowed to ensure the atmosphere being dry and sweet.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Damsons and Bullaces succeed well as pyramids, and will grow in a much poorer soil than most fruit-trees. They require little pruning, it being only necessary to shorten the leading shoots and to remove all useless wood. Trees of this description will often succeed in a cold and damp part of the garden; they may also be successfully used as wind breaks.

Old Orchard-trees in a neglected state may be induced with care and attention to carry satisfactory crops. Old, dead, and decaying wood must be removed, and the branches judiciously thinned. Where much of this work has to be performed, it may be executed from the ground, where the operator has a much better idea of what is necessary. The Standard and Giant Tree Pruners are admirably adapted for this purpose; an aërial saw attached to the former is easily workable. A long handled pruning chisel is also useful; this is driven upwards with a mallet, and the cuts made by it do not require trimming, as do those made by a saw.

The Destruction of Insect Pests.—Immediately the pruning of fruit-trees has been completed, all the prunings should be carefully raked up and removed with the loose surface soil to the fire heap. The trees should be cleansed with a solution containing caustic soda and crude potash, prepared as follows:—Dissolve 1 lb. of potash and 1 lb. of soda by warm rain-water in separate wooden or earthenware vessels; on no account should metal vessels be used. When each substance has become thoroughly dissolved mix them together, adding water up to 10 gallons, when the wash will be ready for use. All the trees here have been sprayed once, and many will be done again. The work can be carried out expeditiously by using a Vermorel's Knapsack Sprayer, applying the wash at a temperature of 150° Fahr. Choose a day for applying the liquid when there is no wind, and do not let the mixture touch the clothes. A few of the earlier varieties of Pears and Apricots may, if not already done, be left until the autumn. A non-poisonous concentrated alkali preparation can be purchased which is very effectual. The Mussel-scale is a persistent pest, and will attack the fruit later if not destroyed. Two applications are necessary thoroughly to cleanse these from the bark.

Mosses and Lichen.—Where trees are infested by these growths, in which many destructive insects hibernate, scrape off the moss or lichen from the bark and burn them, spraying the trees afterwards with the caustic preparation. Poorness of soil and stagnant water, as well as a moisture-laden atmosphere favour the growth of these plants. Dig a hole 3 feet deep near to or between the trees, and if this should fill or partially fill with water, means must be taken to drain the land. If no water appears, afford the trees a dressing of manure, or remove the soil down to and from around the roots, and replace it by other soils rich in organic matter.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Seed Sowing.—The following seeds may now be sown in moderate heat: Centaurea candidissima, East Lothian Stocks, Cobœa scandens, Michaelmas Daisies, Cannas, and Verbena venosa. Seeds of the two latter species should be soaked for twenty-four hours in water before sowing. Delphiniums usually flower early in the summer, but if treated as annuals by sowing seeds early and pricking the seedlings out into cold frames, subsequently planting, they will make a good show in late summer. If seeds of Eucalyptus Globulus and Grevillea robusta are sown now, and the plants potted on, they will be of a useful size by the month of June.

Plants in Frames.—When mild weather prevails ventilate freely all frames containing Violas, Calceolarias, herbaceous plants, &c. Remove decayed leaves, and stir the surface soil. If it is desired to increase the stock of Calceolarias, the tops can now be taken off, and if they are inserted in sandy soil they will make roots.

Auriculas, Daisies, Carnations, and other plants that were planted last autumn may have been loosened by the frosts, and will require to be made firm again.

Wild Garden.—Hydrangea paniculata grandiflora succeeds well here on a steep bank with south-west aspect in well-cultivated loam. The plants should be pruned now by cutting out all weak growths and by shortening last year's shoots to 2 or 3 buds, which will cause the inflorescences to be of large size. Carefully top-dress the plants with animal manure and soil. Chemical manure can be applied later.

Purple-leaved Shrubs.—The Japanese Maple, Acer palmatum atropurpureum, is the most effective of purple-leaved shrubs. It requires liberal treatment in a sunny sheltered position. There are many more good varieties. Amygdalus purpurea requires to be given a good position, but Berberis vulgaris atropurpurea is less particular. Prunus Pissardi thrives in most positions and soils, and can be pruned to keep it within bounds, or for providing branches for indoor decoration. Quercus pedunculata purpurea is good, and for open spaces Fagus sylvatica purpurea, Acer platanoides Schwedleri and the purple Sycamore are excellent.

Trees and Shrubs with Silvery or Grey Foliage.—Amongst deciduous sorts, the Silver Birch, Salix regalis, Populus argentea, Acer Negundo var., make conspicuous objects in the distance; and for a foreground, Cerasus Mahaleb var., Cornus sanguinea var., Weigela var., are all good. Amongst evergreens, Retinospora squarrosa and R. pisifera sulphurea are beautiful; and the dwarf-growing Euonymus radicans var., Rhamnus alaternus var., Vincas, Eleagnus macrophylla, Osmanthus ilicifolius var., Veronica Andersoni var. (tender), are interesting. The sub-evergreen Atriplex halimus is suitable for sandy places.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Cabbage.—To keep up a supply of this vegetable during the summer months seeds should now be sown in a warm pit or frame, and as soon as the seedlings are large enough to handle they should be pricked-off in some light soil and placed in a similar structure near to the glass, and allowed plenty of light and air, in order to keep the plants sturdy. They will be suitable for succeeding the plants sown in August for spring and early summer use. Two good varieties of Cabbage for present sowing are Ellam's Early and Carter's Model.

Carrots for the General Crop.—Beautiful in shape, colour, and quality are Veitch's Scarlet Model of the stump-rooted type, and Sutton's Red Intermediate. Last season, Carter's Blood Red, quite a new colour, produced long, handsome roots of fine quality.

Beetroot.—Sutton's Blood Red and Carter's Perfection are of perfect table quality; Carter's Crimson Ball is valuable for early use.

Shallots and Garlic.—Embrace the first opportunity of planting these bulbs on ground prepared as for Onions. They should be planted in drills drawn from 9 to 12 inches apart, allowing from 4 to 6 inches between the plants in the rows. Plant the bulb just below the surface. The variety Large Jersey Shallot will be found the best for general purposes.

Parsnips—In the event of mild weather these roots would soon show signs of growth if left in the ground. They should therefore be lifted with care and stored behind a north wall, putting sufficient fine soil between each layer of roots to exclude light. Sutton's Tender-and-True may be relied upon for good appearance and quality.

Turnips.—To maintain a supply of young and tender roots sow seeds thinly on gentle hot-beds, selecting the variety Carter's Early Long Forcing. If the seeds are sown in drills some seeds of the French Breakfast Radish may be sown between the rows. The Turnips will be fit for use in from ten to twelve weeks from the time of sowing. The variety used here for the general supply is Snowball. From seeds of this variety which were sown in the first week in September we have been pulling and will continue for some time to use roots in quantity and of excellent quality.

Stachys tuberifera (Chinese Artichoke).—This tuber naturally makes early growth of a very brittle nature. It is therefore necessary to plant early, because of the difficulty when allowed to start first of handling the tubers without breaking the growths. Plant the tubers at a depth of 4 or 5 inches, allowing 15 inches between the sets, and 20 inches between the rows.

Mint.—The demand for Mint will now increase. Place sufficient roots in a temperature of 55° to 60°. Make new beds also on well-prepared ground, and if the soil is of a light and porous nature the plants will succeed best.

Thyme.—Where the supply is limited, plants lifted and placed in the temperature as advised for Mint will produce growths, which, if inserted as cuttings, will soon make roots. When the plants have been hardened off, plant them in beds.

Sweet Basil.—Make successional sowings in a temperature of 55° to 60°, according to the demand, in well-drained boxes, covering the seeds lightly.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER 41, Wellington Street, Covent Garden, W.C

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEB. 13—British Gardeners' Association, Meeting at Birmingham.

TUESDAY, FEB. 14—Royal Horticultural Society's Committees Meet, also Annual Meeting of Fellows.

THURSDAY, FEB. 16—Linnean Society Meeting.

SALES FOR THE WEEK.

MONDAY, FEBRUARY 13—
Roses, Greenhouse Plants, Gladioli, Spiræas, &c., at Protheroe & Morris' Rooms, 67 and 68, Cheapside, E.C., at 12.

WEDNESDAY, FEBRUARY 15—
Azaleas, Gloxinias, Fruit Trees, Japanese Lilies, &c., at Protheroe & Morris' Rooms, at 12.

FRIDAY, FEBRUARY 17—
Hardy Border Plants, Shrubs, Roses, Gladioli, &c., at Protheroe & Morris' Rooms, at 12.—Imported and Established Orchids, at Protheroe & Morris' Rooms, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·1°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, February* 8 (6 P.M.): Max. 48°; Min. 42°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 9 (10 A.M.): Bar., 30·4; Temp., 48°. Weather—dull.

PROVINCES.—*Wednesday, Feb.* 8 (6 P.M.): Max. 50°, S.W. Coast of Ireland; Min. 45°, E. Coast of Ireland.

The Thames Embankment Gardens.

WE have often had occasion to remark that these gardens undergo small transformations in the matter of flower-beds, edgings, the arrangements as regards isolated trees and shrubs, and of the foregrounds of shrubberries.

It will be conceded by any person capable of forming a just opinion on such matters that these alterations have rarely been satisfactory. The original design was itself feeble and inappropriate, and the outlines of the shrubberies meaningless, while the arrangement of the beds round the bandstand near Charing Cross, where people most do congregate, affords an excellent example of how not to do it. The none too spacious grass plots have quite lately been made smaller by the introduction of numbers of small beds of puerile forms, and by the planting of isolated trees, destructive of all dignity and breadth of treatment, and making "spotty" effects which are very unsatisfactory.

What seems to be required is the masking of the actual size and form of the ground by a large central mass of choice, deciduous and evergreen shrubs and trees of low stature, the shrubs consisting of specimens of from 4 to 10 feet in height when planted, and not of small nursery stock as we have seen planted at conspicuous angles of the shrubbery lines this winter, which must take many years ere they form handsome objects. Many such fine shrubs as also trees might be grown in the extensive parks of Battersea and Victoria, or in special reserves elsewhere, thus lessening the cost to the ratepayer.

The treatment of the flowering shrubs as regards their pruning also leaves much to be desired, it being an exceedingly rare thing to find any that are furnished with bloom, although even in the murky climate of London it is not impossible to secure the ripening of the wood and the formation of flower-buds. Why should we not have groups of Cerasus pseudo-Cerasus Watereri, which bears a profusion of delicately white flowers, and C. p.-C. James H. Veitch, which is equally floriferous, and the type form; Hydrangea paniculata and H. p. grandiflora; Deutzias in variety, the finer varieties of Lilac, also the Persian variety, a capital bloomer not growing over-tall; Philadelphus in variety, including the beautiful coronarius, P. Lemoinei Boule d'Argent, and P. Avalanche?

Besides these we may mention the following among many desirable plants that are worth a trial, though doubtless all would not succeed:—Mahonia, Buddleia globosa, B. Lindleyana and B. variabilis, Calycanthus, Ceanothus, Choisya ternata, Cratægus, Cydonia (many varieties), Forsythias, Fuchsia Riccartoni, Magnolia Soulangeana, M. Lenné, M. stellata, Photinias, Rubus, Viburnum Opulus, V. plicatum (these are obtainable at cheap prices, and soon grow into good dimensions, and most of them succeed in ordinary soil), the Honeysuckles, both climbing and shrubby, the Clematis of the coccinea hybrid strains, and C. Jackmani, and other garden hybrids, herbaceous and tree Pæonies. Indeed the number of species ready to the hand of the planter is so great that we could not find space in an article of this kind to give the reader a tithe of them, and some at least would survive the smoky atmosphere and other untoward conditions.

The Bamboos of a hardy nature might be employed to give diversity to the aspect of the gardens; and the best of these for the purpose are Arundinaria japonica (Metake of gardens), already in use, A. nitida, A. Simoni (one of the tallest), A. S. var. stricta, Phyllostachys aurea with stems 12 feet in height (a very graceful species), P. Boryana, P. nigra (a species of striking appearance), and a few others.

The present shrubberies are so arranged and planted as to admit of a foreground of flowering plants, a method that seems to be overdone, leaves much of the soil bare during the winter, and is costly, as it means the purchase of great numbers of Dutch bulbs and the providing of summer bedding plants. Much of this labour and outlay might be avoided, and a clothing of the soil afforded at all seasons by the employment of small shrubs in lieu of summer-flowering plants. Such permanent occupants might consist of Berberis Darwini, B. Thunbergi, B. stenophylla, Cotoneaster microphylla, and C. Simonsii; Cydonia japonica, Gaultheria Shallon, G. procumbens, Pernettya mucronata in variety, Skimmia japonica, Hypericum in dwarf varieties, double-flowered Furze, Vinca major and V. minor in variegated varieties, and Euonymus radicans. If peat could be obtained, many American plants could be grown to give additional interest to the garden. It may be said that these plants could not adapt themselves to the distressful conditions, and this, indeed, may be true of some, but not of all.

The designer of the garden could never have intended to plant Poplar-trees round the boundaries, to remain till they died of disease or old age, but simply to give it a somewhat furnished appearance till such time as better things attained a good height. Now these trees overtop the rest, and have become anything but ornamental, besides shading the garden unduly on the embankment side, and when in leaf robbing the soil of moisture and nutriment. Their place in every case should be occupied by choicer trees, say Pavias, Maples in variety, Ailanthus glandulosus, Amelanchier canadensis, the common Birch and several varieties, Carpinus in variety, Catalpa bignonioides, Gleditschia sinensis and G. triacanthos, Juglans nigra (American Walnut—a handsome, quick-growing species, suitable if planted on the north and west sides), Pyrus Aucuparia (Mountain Ash), P. Sorbus, and P. torminalis, Ginkgo biloba (a good town tree), and Alnus cordata. Forest trees ought to find no place in the garden owing to the lack of space and the injury they would cause to the adjacent shrubs.

The westernmost garden does not admit of much improvement excepting in the choice of the plants with which it is furnished in the spring and summer seasons. Flowering deciduous shrubs and quite low-growing trees might give it distinction where now it has none, and a fountain and water-basin with Water-Lilies would be better than the exaggerated sarcophagus-like bed now occupying the central position.

When we think of the beauties of the Park Monçeau, the Luxembourg, and even of the Tuileries garden in the centre of Paris, it makes us blush for the shortcomings of the gardens of the metropolis, and wish for something much better and more satisfying. The latest horror at Charing Cross consists of a number of scrolls (we were about to write scrawls) cut in the not-too-abundant turf, and planted with Ivy pegged down to the soil.

CYPRIPEDIUM × LEEANUM "J. GURNEY FOWLER" (see Supplementary Illustration).—The surprises which await the patient hybridist even when flowering a fresh batch of a hybrid previously well known, gives zest to the pursuit, and go far to account for the enthusiasm with which it is followed by all who have seriously taken it up. Cypripedium × Leeanum was one of the earliest of the showy hybrid Orchids, and the original batch of seedlings displayed great variation, the range of which has been much extended by more recently raised batches, in which the best forms of Cypripedium insigne and C. Spicerianum have been used. At the Royal Horticultural Society's meeting on January 24, Messrs. SANDER & SONS, St. Albans, exhibited Cypripedium × Leeanum "J. Gurney Fowler," for which a First-class Certificate was awarded, the variety being considered by far the best of its class yet shown. Our Supplementary Illustration was prepared from the plant then exhibited. The flower, which is of a very thick substance, has the dorsal sepal pure white with a small greenish base, from which ascends a dotted line of purple up the middle, with shorter purple lines on each side. The ground colour of the petals and lip is yellowish-white, suffused over the greater part of the surface with purple, the petals having a sulphur-white margin.

MIDLAND CARNATION AND PICOTEE SOCIETY.—At the recent Annual Meeting of this Society, Mr. THOS. HUMPHREYS, Curator of the Edgbaston Botanical Gardens, Birmingham, was elected Hon. Secretary and Treasurer.

ROYAL HORTICULTURAL SOCIETY. — The next meeting will be held on Tuesday, Feb. 14, and the one hundred and first annual meeting of the Fellows of the Society will be held during the afternoon of the same day. The Report of the Council for 1904 will be presented, and the President, the Vice-President, the Treasurer, and the Secretary will be elected for the ensuing year, together with three members of the Council.

—— Exhibitors are reminded that the shows in the Royal Horticultural Hall will close at 5 P.M. in future during the months of January, February, November and December, and at 6 P.M. in the rest of the year. This regulation, which is recorded in the new Arrangements for 1905 just issued, will come into force at the next show, February 14. The Council have just arranged to hold a summer Show in the grounds of Chelsea Hospital on July 11, 12 and 13, 1905. The Schedule for this Show and for the autumn Rose, Fruit and Vegetable Shows will be issued in about six weeks' time.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, February 13, when the discussion will be resumed on the papers by Mr. A. R. STENNING (Fellow) and Mr. WILLIAM MENZIES (Fellow), read at the meeting of January 16, entitled respectively "Urban and Rural By-Laws and suggested Amendments," and "Building By-Laws in Rural Districts."

LINNEAN SOCIETY OF LONDON. — At the meeting on Thursday, February 16, 1905, at 8 P.M., the following papers will be read:—1. "A Revised Classification of Roses," by Mr. J. G. BAKER, F.R.S., F.L.S. 2. "The Botany of the Anglo-German Uganda Boundary Commission," by Messrs. E. G. BAKER, SPENCER MOORE, and Dr. A. B. RENDLE.

LIÈGE.—In connection with the great exhibition in Liège this year there will be held three special horticultural shows. The first is to be devoted to flowers, from May 7 to 10; the second to Roses, from June 25 to 27; and the third to market gardening and fruit culture, from October 20 to 23.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. HARRY J. VEITCH, the Treasurer of the Gardeners' Royal Benevolent Institution, desires us to acknowledge, on his behalf, with thanks the receipt of an anonymous donation of £1 from Leeds in aid of the funds.

"THE SWEET PEA ANNUAL."—This is the official publication of the National Sweet Pea Society, and is edited by Messrs. HORACE WRIGHT and C. H. CURTIS. A society with more than a quarter of a hundred vice-presidents and as many members of the Executive Committee ought to possess a considerable dynamic force. The pages before us do indeed give evidence of much industry. The tables show which varieties are most favoured by exhibitors; thus, out of 107 varieties and out of 1,561 bunches shown in 1904, "Miss Willmott" was exhibited on sixty-five occasions, Black Knight and Dorothy Eckford almost as frequently, and so on through a gradually diminishing series till we come to the last twenty, which comprise varieties only shown once. A similar list gives statistical details relating to the number of times a "1st prize" was awarded. In this list Dorothy Eckford is placed first, followed by Black Knight, Jeanie Gordon, Lady Grizel Hamilton, and Miss Willmott. A very useful enumeration of the varieties according to colour is given. It must be remembered that these figures refer exclusively to the results as seen at exhibitions. Even more desirable would be an audit compiled from gardens in various localities and showing what are the best varieties to be grown for general rather than exhibition purposes, and giving wherever possible the reasons for such selection. It is noteworthy that all our variations of Sweet Peas are derived from one annual species, a native of Sicily, for the record of the Ceylon habitat no doubt originated in error. The range of variation is therefore the more interesting in that it has not been up to the present affected by hybridisation, and thus shows what an amount of diversity may be obtained from a pure species. It is noteworthy also that while "seed-sports" are common, true sports or bud-variations have not, so far as we know, been produced. True sports indeed appear never to be produced on annual plants, *e.g.*, the China Aster. In the present annual Mr. PERCY WATERER gives some interesting details as to his method of crossing and the results he has obtained. Such investigations are of great value in reference to the Mendelian theory of inheritance, and will, we hope, be strenuously pursued as being of greater intrinsic value than mere exhibiting or prize-winning. There are a number of cultural articles, and others devoted to the decorative uses of the Sweet Pea, so that the devotees of this attractive flower are well provided for. We venture to think they will be better pleased if in another "Annual" the advertisements be confined to their legitimate place, and not be suffered to intrude in the text. As the Society depends for its income on the annual subscriptions rather than on advertisements there is the less excuse for this "out-of-place" arrangement.

FROST IN TUNIS.—According to the *Revue Horticole*, the frost on the south side of the Mediterranean from January 1 to 4 was as destructive as on the north side. Caladiums, Hibiscus, Tecomas suffered severely; Araucaria excelsa, Ficus elastica, and others were destroyed. The Aleppo Pine, the Date Palm, and some other Palms have not suffered. At Nice, where 9° to 10° below zero of Centigrade were experienced, the Carnations were ruined. Roses from Marseilles to Genoa are completely destroyed; so are the Marguerites. Indeed, many of the small cultivators are completely ruined. So unusual are such conditions that the growers had neglected the precautions which, if adopted, would have very materially prevented the disasters.

FRUTICETUM VILMORINIANUM.—Under this title M. MAURICE DE VILMORIN has, with the co-operation of M. BOIS, prepared a catalogue of the shrubby and arborescent plants in the Arboretum formed at Les Barres by the first-named botanist. The list is a very full one as it comprises the names of certain species not yet in cultivation at Les Barres. It is enriched with notes and illustrations, which will be greatly appreciated by students. The collection is very rich in Chinese species, for the elaboration of which M. DE VILMORIN had the assistance of the late M. FRANCHET. The plants are arranged according to their natural orders, but in addition a very full alphabetical index is supplied. The value of such a catalogue becomes more and more apparent with use, but the care with which it has been compiled is obvious at a first glance.

POST OFFICE VAGARIES.—In these days of perplexity and conflicting statements as to the condition and future prospects of the commerce of the country, and as to the desirability of securing preferential treatment from our colonies, it is interesting to see the views taken by our Australian colonies as represented by their postal authorities. The following extract is taken from the Post Office daily list for Monday, January 23, published by authority of His Majesty's Postmaster-General:—"'AUSTRALIA.'—Exceptional treatment of printed matter, catalogues, price-lists, and other advertising matter are subject to Customs Duty at the rate of 3*d.* per lb. Single copies are chargeable." To commercial men this regulation must be extremely objectionable; but if some such tax could be levied here on the hosts of circulars which reach us, unasked for and undesired, we think the Chancellor of the Exchequer might benefit, whilst certainly the annoyance to individuals would be abated.

EUGENIA UGNI.—Messrs. VEITCH favour us with fruits of Eugenia Ugni gathered from plants in the open-air against a wall in their Combe Wood nursery. The plant fruits commonly in a greenhouse temperature, and fifty years ago it was the subject of much attention. Messrs. VEITCH in 1854 obtained a Silver Banksian Medal for it, and in 1857 the late Sir WENTWORTH DILKE offered a prize for it at the great horticultural show held in that year. The fruit is pleasantly aromatic in flavour but it has never won a permanent place in public estimation.

"BOTANICAL MAGAZINE." — The February number contains coloured illustrations of the following plants:—

Yucca guatemalensis, Baker, t. 7997.—An old inhabitant of the Royal Gardens, Kew, and one of the handsomest of the genus, but it is not quite hardy. It is distinguishable in the section to which it belongs by the leaves, which are minutely denticulate, not filiferous. Its identity is not yet fully established, for it has no fewer than six synonyms. In any case it is a noble plant when in bloom, and when out of bloom its appearance is striking. The description is from the pen of Mr. Hemsley.

Tulipa linifolia, Regel, t. 7998.—A species from Turkestan, flowering at Kew in May. The dwarf habit and brilliant crimson flowers render this plant attractive for cultural purposes. It is allied to T. montana, from which it differs, according to Mr. C. H. Wright, who furnishes the description, in the segments of the perianth being equal, and not narrowed at the apex.

Angelonia integerrima, Sprengel, t. 7999.—An under-shrub, described by Mr. F. A. Skan as having sessile, lanceolate, glabrous leaves and lavender-coloured corollas, like those of a Pentstemon, and thickly spotted with purplish dots. It is a native of Brazil and Paraguay. It requires greenhouse treatment.

Bulbophyllum crenulatum, Rolfe, sp. nov., t. 8000. A species distinguished by its club-shaped inflorescence, crenulate lateral sepals, and ovary with six crenulate wings. The four-sided, two-leaved pseudo-bulbs are produced at intervals on a creeping scaly root-stock. The scaly flower-stalk proceeds from the base of a pseudo-bulb, and is terminated by a recurved, densely many-flowered spike of minute purplish flowers. It is a native of Madagascar, and flowered at Glasnevin.

Gnidia polystachya, Bergius, t. 8001.—A pretty greenhouse shrub from S. Africa. The foliage is minute, densely crowded, leaves linear; flowers small, yellow, in dense heads at the tips of the branches. It belongs to the Daphne family (Thymelaceæ). Described by Mr. N. E. Brown from a specimen derived from the Cambridge Botanic Garden.

HOOKER'S "ICONES PLANTARUM." — This publication, which is edited for the Bentham Trustees by Sir WILLIAM T. THISELTON-DYER, is chiefly devoted to the description and illustration of new and rare plants selected from the Kew Herbarium. The last issued part (January) contains twenty-five uncoloured illustrations mostly of plants of botanical interest, among them notes on a valuable set of plants collected in Western Australia by Mr. G. H. THISELTON-DYER, the son of the Director of Kew. A good figure of the Chinese Tulip Tree is given (see HEMSLEY, in *Gardeners' Chronicle*, November 28, 1903, p. 370), and several of the plants figured appear worthy the attention of plant-importers.

AFFORESTATION. — Mr. JOHN F. MAHLER, owner of Penissa, Bronygarth, North Wales, has presented to the Denbighshire County Council 50 acres of land for the purpose of demonstrating sound principles of timber planting, and the excellent financial results obtainable therefrom. It is Mr. MAHLER's desire that the Council should without delay give practical effect to one of the most important recommendations of the Forestry Committee of the Board of Agriculture. He does not wish to fetter the Council by attaching conditions to the gift, beyond stipulating that the land shall be for ever devoted to the illustration of practical forestry. *Daily Graphic.*

JASMINUM NUDIFLORUM.— A correspondent of *Nature* enquires how it is that the flowers of this winter-flowering shrub get fertilised. From the construction of the flower it would appear to need the assistance of insects; but at the time of flowering there are no insects about. We are tempted to ask whether in this country fertilisation, apart from mere pollination, does take place. Has anyone seen in this country ripe fruits of this species? For ourselves, we cannot recall having seen the fruits more than once or twice.

"ONE-AND-ALL GARDENING." — This cheap and popular publication issues with the present year its tenth annual volume. It contains articles by the Editor (Mr. E. O. GREENING), by the late D. T. FISH and Mr. D. S. FISH, and various other gardening authorities. Its contents are useful and practical, but not unmixed with lighter reading, as, for instance, in the paper by Mr. JAMES SCOTT on "Scenes from Fairyland," where a popular account, with pictures, is given of scenes in the life of an aut, a red-spider, and other minute creatures, studied by the aid of a microscope. The other pages are also illustrated. The Annual may be had from the Agricultural and Horticultural Association, Ltd., 92, Long Acre, W.C.

THE DÜSSELDORF EXHIBITION.—A Silver-gilt medal and diploma have been received from the Committee in recognition of the excellence of the illustrations of Orchids published in the *Gardeners' Chronicle.*

APPLES.—The *Journal of the Board of Agriculture* for January contains an article on Apple-culture by Mr. GOARING, which is worthy the attention of those who possess orchards. The article deals with the site and soil of the orchard, the preparation of the soil, the protection from wind, the selection of the trees, their nature, bush or standard, the methods of planting, pruning, manuring, washing, packing and grading the fruit, and storing. A list of suitable kinds is given, but as it does not state for what special locality the varieties are selected, the list is to that extent incomplete.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

SOME EFFECTS OF THE EARLIER FROSTS AND FOGS.—The earlier frosts seem to have been more than usually severe, accompanied, as some of them were, with densely thick fogs. With me the following plants have suffered injury:—Golden Privet has been divested of all its leaves; Escallonias, whether on walls or open borders, have been killed to the ground; Cotoneaster microphylla, which formed a lovely fringe round the walls of my house, has suffered severely, and will have to be cut hard back; C. Simonsii has lost its leaves, but otherwise is all right; large plants of Berberis Darwini and B. dulcis have been killed to the ground; varieties of Euonymus have also been crippled severely. In the Midland Counties I am afraid we are rather inclined to be prematurely boastful as to the hardiness of some of our exotic introductions, and an occasional lesson in this respect may do us no harm. Once I lived in a little house, the walls of which I had luxuriantly covered over with varieties of the beautiful blue-flowering Ceanothus, but this was far too good to last; there came a frost which killed the whole to the ground. The house was afterwards covered with Wistaria, Pyracantha, and varieties of Ampelopsis. That fogs accompanied by frosts whilst the plants were still full of sap may have had something to do with the destruction of outdoor plants seems to be strengthened by the account given in the *Gardeners' Chronicle* by Mr. Watson (see p. 12) of the mischief wrought amongst the indoor plants at Kew by the thick sulphurous fogs which sometimes hang like a funeral pall over London and its suburban districts. I never happened to be in a London fog, but I am quite willing to believe that it is very much thicker than anything of the kind we have down here. Beyond the difference of the place of origin, there is really no distinction to be drawn between a fog and a cloud; a fog is simply a cloud resting upon the earth; a cloud is a fog floating high in the air. The upper cloud, however, I think we are safe to admit, may be much freer from town contamination than the lower one. In reference to fogs and the dangers and mischiefs resulting therefrom, I am pleased to note that Sir Oliver Lodge, Principal of the University of Birmingham, is now making a study of those disagreeable and hurtful town fogs, and, thinking the subject may be interesting to some of your readers, I herewith quote an extract from the *Birmingham Weekly Post*:—"Fog Dispellers: Quite a host of representative people have, I am told, attended at the Birmingham University in order to see at work the fog dispeller designed by Sir Oliver Lodge. It is not unlikely that in some places the apparatus will be installed for practical public work. I hear that the capital outlay to provide a number of dispellers at various places in Birmingham, sufficient to effectively remove fog, would cost something like £2,000. After that the outlay would, I am assured, be quite nominal." I have taken the liberty and responsibility, on the strength of the above quotation, to send a copy of Mr. Watson's "Effects of Recent Fogs on Plants at Kew" (see *Gardeners' Chronicle*, p. 12) to Sir Oliver Lodge, with the hope that whilst he is meritoriously at work upon a scheme with a view to free towns of smoke and fog, that he may also give consideration as to whether an installation of his "dispellers" might advantageously be fixed at Kew and other similar valuable botanical establishments, and so prevent any further recurrence of the disaster so amply explained by Mr. Watson. *W. Miller, Berkswell.*

ELECTRICITY, PLANTS, AND FOG. — The following letter from Sir Oliver Lodge has been sent to us by Mr. W. Miller, of Berkswell, for publication:—

January 25, 1905.

The question of the effect on plants of a discharge of electricity into the air would be a very interesting subject for investigation, and it would be quite possible to arrange for it, if, as I suppose, the ordinary electric mains are available at Kew; but that the effect would be beneficial to the plants I cannot guarantee—it might be the reverse. It would probably act directly upon the plants as well as upon the fog, and in so far as it acted upon the fog it would have a tendency to deposit it upon the plants, which would certainly be injurious. Irrespective of that, however, the effect of electrified air in a greenhouse or other enclosure ought to be studied, and perhaps someone will have leisure to take it up at some future time.

OLIVER LODGE.

University, Birmingham.

HOW TO TRANSPLANT A MEDIUM-SIZED TREE OR SHRUB.—Assuming that a site has been chosen, a suitable compost prepared (principally leaf-mould), that the soil is in proper workable condition, and a hole has been made that is undoubtedly large enough for the shrub or tree, then put a conspicuous mark on the "best side" of the specimen to be moved, and tie up the branches carefully with soft rope; mark a circle—say 3 feet from bole—and outside this dig a trench, using the spade so that the blade is in a line with diameter of ball. When the trench is a little deeper than the lowest roots; carefully use a fork or pointed stick amongst the roots to reduce the ball to reasonable dimensions. Use a planting handbarrow to carry the specimen to the new site, trim broken roots if necessary, judge the right depth, put in a layer of compost, place the tree in right position, spread out by hand the lowest layer of roots, cover with fine soil, then another layer of roots, make firm by treading, and so on till the operation is finished. If done successfully the tree will appear better than it did before. *W. A. Miller.*

APPLE LANE'S PRINCE ALBERT.—My experience in our heavy soil is that this variety of Apple crops remarkably well, developing fruits of a good size, which keep well till March. Grown as a bush or especially as a half-standard tree, I consider it one of the best kitchen Apples we have. A large fruit-grower for market near here has acres of it planted as half-standards, and he speaks well of it. In consequence of the trees cropping so freely they should be frequently surface-fed with suitable manures. Some years since I experimented with several trees of this variety with regard to manures, and found that those trees receiving an annual dressing of Thomson's Vine-manure lightly forked-in near the surface succeeded infinitely better than any other, both in the amount of crop, in quality of fruit, and in growth. *E. M., Swanmore Park, Hants.*

—— The notes on page 44 from your correspondents supporting Apple Lane's Prince Albert on the one hand and Newton Wonder on the other, are both interesting. I find myself that it is difficult to discriminate between their qualities, as both are excellent croppers; but during the seasons 1902 and 1903, when Apples were scarce, Lane's Prince Albert proved the more reliable variety. Although I feel sure that the variety Newton Wonder will be very largely planted in gardens during the next few years, it is more suitable for growing as standard trees. No votes from Scotland or Wales were given to this Apple at the recent selection, but I have no doubt it will receive more votes at the next election. Lane's Prince Albert always keeps well with me to the end of February or for an even longer period, while Newton Wonder will keep to the end of April or the beginning of May. We have a large standard tree of Newton Wonder at least thirty years old; it would be interesting to know the origin of this variety. *F. J., Droitwich.*

RIGHT OR LEFT HAND DIGGING.—In all my experience in relation to the use of the spade in digging, it has been held that the question of right or left hand was determined by the side of the worker on which the spade was held. If on the right side it was right-handed; if on the left side it was left-handed. It is worthy of note, such at least is my experience again, that 90 per cent. of diggers use the tool on their right-hand side. All the same those who habitually work it on the left hand-side do equally good work. It is all a question of use. It is of far greater importance in digging that the spade be a long one, that its blade be kept as erect as possible, and that the soil be deeply worked. If it be so then is good work done. *D.*

SEED PACKING.—The experience of Kew in the distribution of seeds to all parts of the world may be termed exceptionally successful, and it is often achieved without much trouble. Indeed it is too often the case that seeds received at Kew are rendered worthless by the special methods of preparation and packing adopted by the senders. There are, however, certain kinds of seeds which soon lose their vitality if kept dry, and amongst these are all kinds of Oak-acorns. For the last twenty-five years, at least, consignments of acorns have been sent annually from Kew to South Africa. They used to be packed in beer casks, the acorns being put in through the bung-hole, and the casks filled up with water; but an experiment made about fifteen years ago proved that this method was less successful than that of packing the acorns in a wooden case in layers with moist cocoa-nut fibre between each layer. The report was—"Acorns sent in water a failure, those sent in cocoa-nut fibre have germinated on the way, and we have now 1,200 strong seedlings from them." Last October we had an application for a quantity of acorns of Quercus pedunculata, Q. sessiliflora, and Q. Cerris, for St. Vincent. They were packed in damp cocoa-nut fibre in wooden boxes, beginning with a layer of fibre at the bottom, then a layer of acorns, and so on till the boxes were filled. They were labelled "To be placed in a cool place in the hold." The report just

received states that "The acorns of Quercus pedunculata have germinated well; Q. sessiliflora are not quite so forward; and Q. Cerris still less so." I can strongly recommend damp cocoa-nut fibre and wooden boxes for all seeds that perish easily, and that can be conveniently packed in them; for instance, seeds of Para rubber, Ceara rubber, and Brazil nuts. For seeds generally I know of nothing better than paper packets and calico bags, and the more moisture there is in the seeds themselves when thus packed the better. Hermetically sealed tins or bottles should never be used. *W. Watson, Kew.*

EARLY PEACHES. — In the "Fruits under Glass" Calendar, on p. 55, Mr. F. Jordan states that Early Alexander and Hale's Early are especially adaptable for forcing in pots. It would be interesting to know what results Mr. Jordan gets from these varieties. I have found these two varieties utterly unsuitable for early forcing. When they did not drop their buds (and the American varieties are notorious offenders in this respect), they would not swell. The only Peaches I have found that will force are Duchess of Cornwall and Duke of York. This year I have discarded Alexander and Hale's Early; they are useless. Cardinal and Early Rivers Nectarines are admirable for early forcing. They seldom fail to give the best results. I should very much like to see fruit of Alexander and Hale's Early ripe by the beginning of May. *Thos. Tomlinson, Tower House Gardens, Streatham.*

—— In reply to the letter printed above I may state that I have found Alexander the best early Peach we have tried for very early forcing in pots, and have gathered excellent Peaches from this variety at the end of April and beginning of May. Hale's Early is good in all respects, but is ten or twelve days later than Alexander, although similar to that variety in appearance. All the American varieties are liable to cast their buds, but both the varieties mentioned are good growers, which compensates to some extent for this failure. They require a low temperature during the early stages of forcing, and above all they should never be allowed to become dry at the roots at any season of the year. This is often an unsuspected cause of bud-dropping and other failures. I have never found any difficulty in getting the fruits to swell to an average size upon healthy trees. Duke of York and Duchess of Cornwall are, I believe, excellent varieties for very early forcing, and are no doubt all Messrs. Rivers represent them to be, but I have not tried them sufficiently yet to recommend them with any confidence. *F. Jordan, Impney Hall Gardens, Droitwich.*

CORDYLINE INDIVISA.—On page 66 there appeared an illustration purporting to be "Specimens of Cordyline indivisa in Lord Ilchester's garden at Abbotsbury, Dorsetshire." It is very evident that these are not Cordyline indivisa but C. australis, a species very commonly met with along the south-western coast. This is more generally known as Dracæna australis, and a representation of what is probably one of the finest specimens in England, growing at Penjerrick, Cornwall, appeared as a supplementary illustration on May 18, 1901. Cordyline indivisa is very distinct from C. australis, having pale glaucous-green leaves fully 6 inches wide and about 4 feet 6 inches in length, with orange-red midribs. It is a rare plant, but specimens exist at Enys, Trewidden, Menabilly and Trelissick, and also in some Irish gardens. I believe this species to have flowered but once in the British Isles, this having occurred at Tresco Abbey Gardens, Isles of Scilly, in April 1896, when I had the pleasure of seeing and photographing it. It is a very striking foliage plant and is more tender than C. australis, which is quite hardy in the south-west. On January 19, 1901, the supplementary illustration showed a specimen of C. Banksii, growing in Dr. Hamilton Ramsay's garden at Torquay, under the name of Cordyline indivisa. I pointed out at the time that C. indivisa was a very different plant, and I have reason to believe that Dr. Ramsay was eventually satisfied that his plant was C. Banksii. These two instances, however, show how little is generally known of Cordyline indivisa vera. *S. W. Fitzherbert.*

THE APIARY.

FEEDING.—If beekeepers are to be successful they must attend to feeding. The months of February, March, and April prove the most disastrous to bees. It is useless to commence stimulative feeding, for a short spell of hard frost would almost mean ruin to bees so fed. Further, the period of comparative rest is with us, and good candy made of honey into which pure cane sugar has been kneaded proves the best of all foods save except honey. Take some good honey and heat it; then work in sufficient sugar to make it of the same consistency as clay is when ready for moulding. Slip this under the quilt and cause as little disturbance as possible.

COVERS AND QUILTS.—Look to the roofs and see that they are not leaky, for damp causes death to bees. One of the best covers is one of tin: but if calico be nailed on the top and then well painted this proves very effective. If the quilts have got damp remove them, or dysentery will result from neglect. Replace with dry quilts, taking care to make them fit at the corner so that no heat can escape from the brood-chamber. A very good quilt may be made of a small bag loosely filled with sawdust or cork-dust, which can often be obtained of any grocer who sells foreign Grapes. *Chloris.*

A VIEW IN THE WINTER GARDEN IN THE STATE BOTANIC GARDEN IN BRUSSELS.

THE Botanic Garden at Brussels possesses the most beautiful winter garden in Belgium. It contains some of the rarest and oldest Tree Ferns known on the Continent. Amongst these we may mention:—Cyathea Schauschin, hort., with a trunk 6 m. 80 high; Alsophila phaleolata [?], hort., 5 m. 50; two plants of Cyathea insignis, Eaton, 5 m. 25; C. medullaris, Swarz., 6 m. 70; Dicksonia regalis, Baker, 2 metres high, having twelve fronds, and 1 metre in circumference of the trunk; and D. Schiedei, Baker, 0 m. 80 high, fifteen leaves, and 0 m. 90 in circumference. The House was built in 1878. In its higher part the roof is 60 feet from the ground.

FIG. 40.—VIEW OF A CORNER IN THE WINTER GARDEN OF THE STATE BOTANIC GARDEN, BRUSSELS.

In 1903 the collections were enriched by the valuable gift of Count de Kerchove, of Denterghem, when he distributed the well-known plants he had cultivated in the famous Court winter garden at Ghent. The largest specimen of Angiopteris known is also in the Brussels Botanic Garden. The species is A. evecta var. Teysmanniana. It has eighteen fronds, and some of them are 12 feet long. The spread of fronds is 21 feet across, and the stem 32 inches in diameter. Our illustration (fig 40) shows a bed of various species of Cypripedium in flower planted together at the base of the great mass of Monstera deliciosa, 15 feet high, and measuring 12 feet in diameter.

A TOMATO DISEASE NEW TO ENGLAND.

FROM a basket of Tomatos for sale were selected several fruits which showed on them a matlike, velvety growth of irregular size and greenish-brown colour. At first sight the injury appeared as if caused by the well-known parasitic fungus, Cladosporium fulvum, Cooke, and the correct fungus would have undoubtedly escaped detection if a broad, whitish, delicate margin surrounding the dark spots on the fruits (see fig. 41) had not raised my suspicion, as I had never observed this appearance in connection with the Cladosporium disease.

The selected fruits showed various stages of the attack—some were apparently healthy, others showed one or more diseased patches. Some of the fruits were brought to the laboratory and placed under a glass cover, whilst one badly attacked I selected for investigation. The microscopic examination showed that the whitish portions, which caused my suspicion, were formed by the vegetative, hyaline hyphæ or threads of a fungus, which had reached its mature stage in the centre of the spots, where the numerous ripe conidia or spores of the fungus produced the dark colouration of the spots.

The fungus resembled closely a disease of Potatos known in America as "Early blight," which is caused by Macrosporium Solani. The history of this fungus is as yet insufficiently known, as it is said to undergo various changes in its development, representing at times a fungus described as Alternaria Solani by Prof. Sorauer (*Zeitschrift der Pflanzenkrankheiten*, 1896, vol. iii., p. 1). Prof. Sorauer obtained specimens of the "Early blight disease" from America in 1896, conducted a series of interesting experiments, and succeeded in infecting portions of Tomato leaves with it. From the illustration and description given, the fungus now under consideration appears to be the same as that investigated by this distinguished fungologist. However, one difference should be pointed out. The conidiophores of Alternaria are said to be of the same colour (darkish-brown) as the spores of the fungus; in this case the hyphæ and conidiophores were hyaline. That peculiarity would bring the position of the fungus nearer the genus Polydesmus. The spores of the fungus are of various shapes and sizes—long, narrow clubs varying to shorter, broad-based clubs. They are muriform and have distinct thick-walled divisions of varying number (see fig. 42). They are borne in chains on the ends of the colourless conidiophores, but were also found springing from the sides of them (see fig. 42, B). The presence of the longitudinal sections in the spores distinguishes the fungus from Polydesmus, which is said to differ from Alternaria only in the spores having no longitudinal sections, a character which I have never found to exist, and I am consequently of the opinion that the separation of Polydesmus from Alternaria is not justified, and that the two genera are the same, Alternaria being the fungus first described. The difference in the colour of the conidiophores of the fungus here dealt with, and of Alternaria described elsewhere, is not sufficient to induce me to think that it is distinct from the fungus of Professor Sorauer, Alternaria Solani, as they agree in every other respect.

It was interesting to observe the rapid spread of the fungus on the fruits kept under cover in ordinary room-temperature. Within twenty-four hours every fruit was more or less covered with the whitish mycelium, showing that the spores were actively germinating and reproducing the disease. After thirty-six hours the growth had become more dense and its colour had changed to a greenish hue. At this stage the conidiophores bore many, though still immature spores, whilst full maturity was attained forty-eight hours after placing the fruits under cover.

From this observation it will be seen what a pest this fungus may prove to Tomato growers. They must combat the fungus wherever it is noticed, getting in the first instance rid of all infected plants and spraying the remaining ones and the soil with Bordeaux-mixture, which if repeated should effectually prevent the spread of an attack by this fungus into an epidemic.

BACTERIAL DISEASE.

In conclusion I may refer to a bacterial disease which I have observed frequently on Tomato fruits.

FIG. 41.—DISEASED TOMATO. (*Two-thirds natural size.*)

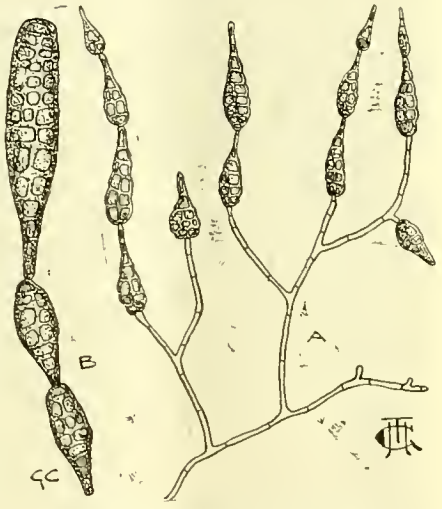

FIG. 42.—ALTERNARIA SOLANI.
A—Fungus magnified 225 ×, showing colourless hyphæ and dark spores borne in chains.
B—Chain of spores enlarged 500 ×, showing the irregular cell divisions.

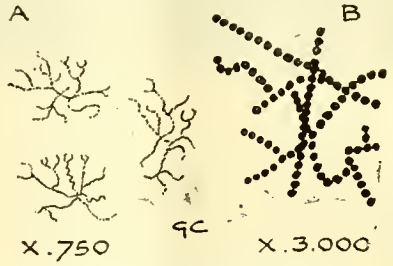

FIG. 43.—BACTERIOSIS OF TOMATO.
A—Groups of Bacteria, enlarged 750 ×.
B—Portion of a group, enlarged 3000 ×.

Bacterial diseases of plants, as for instance gummosis of Cherry-trees and of Cucumbers, &c., are by no means of rare occurrence, but I have not been able to discover any description of a similar attack on Tomatos. I may here remark that at the beginning of this bacterial disease no mycelial fungus growth whatever was present, and I am convinced that in this case the bacteria were the primary cause of the injury. The ripe fruits became attacked, showing roundish patches somewhat paler in colour than the rest of the fruit and slightly depressed. In this stage an attack is difficult to detect, but soon the spots become vitreous, and on touch feel softish and pulpy. At a later stage the epidermis is slightly raised as if an air bubble had developed underneath it, which in my opinion is undoubtedly due to the development of certain gases accompanying the putrefaction of vegetable (and animal) tissues destroyed by bacteria. Soon now the epidermis bursts and a slimy pulp oozes out containing myriads of bacteria, which form small groups of very fine thread-like chains (see fig. 43). Thus the disease appears like gummosis of Cucumbers, and I propose to call it "Bacteriosis of Tomatos" in future.

In this stage mycelial fungi of semi-parasitic nature, like Botrytis, &c., soon make their appearance. As a bacterial disease of this description is, I presume, only visible to a keen observer, and in most cases altogether escapes notice, the true parasitic nature of such secondary mycelial fungi must be doubted or remain at least to be proved by successful inoculation experiments. Nothing has yet been determined as to how best to deal with this malady, but all fruits so attacked must be got rid of. Whether changing the conditions of culture or temperature would have the desired effect must be proved by further experiments.—*Hans Th. Güssow, Upper Norwood.*

LAW NOTE.

PURCHASE OF ORCHIDS FROM ILLUSTRATIONS.

THE Belgian Tribunal of Commerce is at present sitting in judgment on a case which interests Orchid-lovers, and particularly English Orchid-growers, who anxiously await the final decision. An English amateur bought from a firm near Brussels five small plants for 30,000 francs (about £1,200), which were alleged to be rare varieties of Odontoglossum crispum. The plants were not in flower at the time of purchase, and, according to general custom, the contract was made on the strength of certain water-colour drawings purporting to be correct reproductions of the five plants when in flower. In due course the plaintiff found that the flowers of the Orchids he had bought had none of the superior qualities represented by the water-colour drawings, which formed the basis of this contract.

The English amateur, through his counsel (M. Maurice Frison), asked the Tribunal to decree the cancellation of the contract, alleging the non-existence of the rare qualities and the superior points which were asserted to exist by the seller at the time of the purchase. He (the amateur) considers that the Orchids sold to him were not worth a tenth part of the price paid, and alleges that the water-colour drawings which were submitted to him were not truthful reproductions, but merely fancy pictures.

M. Wauwermans, for the defendant, pleaded that the Orchids might have been changed, if not by the plaintiff, at least by one of his staff; and that, under the circumstances, it is impossible to admit a cancellation of a sale regularly entered into by both parties.

We shall publish the judgment in due course.—*Extract from "L'Etoile Belge," January 24, 1905.*

Obituary.

DR. WILHELM SCHWACKE.—The death of this gentleman on December 11, 1904, is announced. He was Professor of Botany at Ouro Preto (Minaes Geraes). He had explored the provinces of Rio Janeiro, St. Catherine, Minaes Geraes, and the valley of the Amazon, and enriched European herbaria with specimens from those regions.

SOCIETIES.

LINNEAN—General Meeting.

JANUARY 19.—Prof W. A. HERDMAN, F.R.S., President, in the Chair.

Mrs. Catherine Crisp, Mrs. Constance Percy Sladen, Miss Ellen Ann Willmott, Miss Emma Louisa Turner, Mrs. Mary Anne Stebbing, Miss Sarah Marianne Silver, Mrs. Lilian Jane Veley, Miss Margaret Benson, Miss Annie Lorrain Smith, Miss Gulielma Lister, and Miss Ethel Sargant were admitted Fellows. Mr. Thomas Vere Hodgson, and Miss Viola Annette Latham, M.D., were proposed as Fellows. Mr. Eardley Wilmot Blomfield Holt and Miss Emilia Frances Noel were elected Fellows. The Rev. T. R. R. Stebbing exhibited and explained specimens of Crustacea, in various ways remarkable for structure, habits, habitat, or colouring, collected by various naturalists.

Dr. Augustine Henry, F.L.S., gave a discourse on Botanical Collecting. The actual methods were briefly alluded to, stress being laid on truthful labelling of the specimens at the moment of collection, instead of months afterwards, when identical numbers were often given to plants of different *provenance*. With the aid of nearly fifty lantern-slides, he gave illustrations of his travels in China, demonstrating that the popular idea of that country as one vast rice-field was fallacious, as it mainly consisted of mountain ranges cut up by deep valleys. In some of the slides the home of the wild forms of the Chrysanthemum, Primula sinensis, &c., were shown; and the lecturer alluded to the early history of horticulture in China, stating that the first botanical garden there was made 111 B.C. in Shensi, plants from subtropical regions, as the Banana, Areca Palm, and Orange, being introduced. Other slides showed typical forms of subtropical deciduous and evergreen trees; and the occurrence of epiphytes and lianes in vast numbers was mentioned. Referring to the statements in the text-books Dr. Henry said that the assertion that epiphytes of higher types than Ferns do not occur in Europe is too sweeping, as in the moist warm climate of Ireland, in Wicklow Cotyledon Umbilicus covers the trunk and branches of the Alder, while Rhododendrons in two cases were seen by him growing on the bark of Pinus sylvestris; and Pyrus Aucuparia seems to be a true epiphyte in various parts of Scotland and Wales. Dr. Henry alluded to "mimicry" in plants, in the case of two species of Lysimachia (a protomorphic genus in China), one of which mimicked Paris quadrifolia, with four leaves, while the other recalled another species of Paris with ten to twelve leaves. He referred also to the extraordinary richness of species on calcareous soils as compared with other soils, a fact constantly seen in China, and well marked also in France, and asked for some explanation. In China, as elsewhere, pure woods were rare, being only formed by a few Conifers, like Abies Fargesii at high altitudes in Hupeh, Cupressus funebris in the same province at lower levels (the home of the Reeves's Pheasant), Pinus Massoniana (almost everywhere in the central and southern provinces), other species of Pinus more local; also certain species of Oak widely distributed, and Alnus nepalensis in Yunnan. The explanation of the occurrence of pure forests was also a subject not completely understood—e.g., in this country Ash seeded freely, and in some places for a time looked as if it would grow into a pure wood; but apparently pure forests of Ash only occurred on extremely rich soil in some districts in Russia.

With regard to botanical collecting, three stages had occurred. At an early period plants were collected to be merely named and classified; in fact, they were treated like postage stamps. The second period began with Sir Joseph Hooker, who did much to promote and develop the study of the geographical distribution of plants. The third period, that of the present day, was a step forward, in that attention should be paid to the plants themselves as social organisms, living in harmony and yet in competition together; and Dr. Henry urged that the time had come when the hunt for new species should cease to be the sole aim of the collector, and the study of the known species be taken in hand in their living conditions. He advocated map-making of small areas, census-taking, measurements, records of natural seedlings, soil, shade, &c.; and, to illustrate this plan, showed a series of slides taken in France, the idea of which was to explain how the commoner species of trees behaved at different altitudes and on different soils. These slides included Beech, Spruce, Pinus Cembra, Pinus montana (which, according to Dr. Henry, often attains 80 feet in height, and thrives on peat-mosses and on rocky soil so thick with boulders that practically no vegetation existed except this hardy Pine), Larch, Quercus sessiliflora and pedunculata. He pointed out that the two last-mentioned species differed as to soil and situation, and complained that their areas had never been mapped out in England. The causes favouring the existence of the two very different forms of the common Birch were unknown, yet in Scotland this problem could easily be attacked.

The systematic botanists had only asked from collectors specimens with leaves, flowers, and fruit, material to be named and classified; yet in trees and shrubs the winter and the seedling stages were also of extreme interest. Elm seedlings and seedlings showing the difference between the two common Oaks were not to be found in the national herbaria, and are not described in books.

Dr. Henry also referred to the small amount of work that had been done in regard to peat-mosses, and the great importance of studying the ancient forests, of which these mosses were, to put it broadly, the ruins. He mentioned extraordinary growth of trees in deep peat-mosses of the present day, as Alder averaging 95 feet; even the Oak also occurred.

Owing to the small amount of attention that had been paid to scientific forestry in this country, trees had met with scanty recognition from the authors of local floras; and in some cases species (as the Arbutus) were put down as shrubs, though there was plain evidence that they attained the size and fulfilled the functions of forest trees.

FEBRUARY 2.—Prof. W. A. Herdman, F.R.S., President, in the chair.

Mr. Eardley Wilmot Blomfield Holt, Miss Emilia Frances Noel, Miss Alice Laura Embleton, Mr. William James Tutcher, and Mr. Stafford Edwin Chandler were admitted Fellows. Miss Emily Mary Berridge, B.Sc. (Lond.), Mr. Frederick Hugh Capron, B.A. (Oxon.), Miss Helen Charlotte Isabella Fraser, B.Sc. (Lond.), and Miss Dorothea Frances Matilda Pertz were proposed as Fellows. Miss Lilian Suzette Gibbs, Mrs. Henderina Victoria Scott, Mr. Charles Blades Coverdale Storey, and Mr. Richard Henry Yapp, M.A. (Cantab.), were severally balloted for and elected Fellows.

The President having announced that the Council had approached Her Majesty the Queen with the view of obtaining Her Majesty's consent to become an honorary member under the provisions of the Supplemental Charter and new Bye-laws, read the following letter from the Queen's Private Secretary:—

Buckingham Palace, January 27, 1905.

SIR,—I have had the honour of submitting your letter and Reports to the Queen. I am commanded to inform you that Her Majesty will be pleased to comply with your request to become an Honorary Member of the Linnean Society.

(Signed) SIDNEY GREVILLE.

B. DAYDON JACKSON, Esq., Gen. Secretary.

The President then read the letter which he proposed to send in consequence of the foregoing:—

To the Queen's Most Excellent Majesty.

MADAM,—I have the honour to state that the gracious expression of Your Majesty's wish to become an Honorary Member of this Society was duly communicated to the General Meeting of the Linnean Society of London held yesterday at Burlington House, and was received with acclamation, the Fellows all upstanding in their places.

The Roll of the Society will be submitted for signature at Your Majesty's pleasure.

I remain, Madam, with the deepest respect,
Your Majesty's most dutiful and most obedient Servant,
(Signed) WILLIAM A. HERDMAN,
President, Linnean Society of London.

The first paper was by Mr. W. J. TUTCHER, F.L.S., entitled "Descriptions of some new Species and Notes on other Chinese Plants." The species in question had been found on the island of Hongkong, with one from Kowloon, and one from Wei-hai-wei. He pointed out that the island lies just within the tropics, about 22° N. and 114° E. from Greenwich; it consists of irregular granite mountain-ridges, the highest peak being Mount Victoria, 1,800 feet. The average rainfall is 85 inches, most of which falls during the S.W. monsoon. The hills are broken up by ravines in which the vegetation is richest, but most of the vegetation which strikes the eye is due to the Afforestation Department, which has planted Pinus Massoniana in large numbers. Bentham's *Flora Hongkongensis* in 1861 enumerated 1,053 species from the island, 159 of which had not at that time been found elsewhese, but at the present time only about 50 of these remain peculiar to the island. The flora as now known amounts to about 1,400 species, of which 100 are regarded as endemic, though probably many will be found natives of the mainland. Botanising is difficult, as the collector has to hack his way through Bamboo and shrubs amongst the boulders. Ferns amount to 100, grasses about as many; Leguminosæ nearly as many; between 70 and 80 Cyperaceæ; Compositæ over 60, and Orchids 60. Quercus Eyrei, first found by Captain Champion, has not been collected by any recent collector till the author refound it in quantity. The luxuriance usually associated with tropical vegetation is here wanting, due to the poverty of the soil, which is almost exclusively disintegrated granite.

The new territory leased to Great Britain in 1898 has an area of about 300 square miles, that is, ten times the area of Hongkong. Lantao is an island resembling Hongkong, but its highest peak is 3,050 feet, with many well-wooded ravines, and when explored will doubtless prove rich in plants.

BRITISH GARDENERS' ASSOCIATION.

ON January 28, Dr. Groves, J.P., presided at a meeting of the Isle of Wight Horticultural Association at Warburton's Hotel, Newport, at which Mr. R. HOOPER PEARSON explained the aims and objects of the Association, with the view to the formation of a branch in the Island.

Mr. PEARSON referred to the difficulties which had in former years prevented co-operation among gardeners, and said those difficulties had now largely been removed. Though there had been immense progress in gardening there had been no progress in the direction of the amelioration of the material circumstances of the gardener's life. The Association would help every gardener to take a greater interest in his calling, as it existed for improving the status of horticulture and the gardener. Every member of the Association must be a man who had his profession at heart, prepared to give all the attention possible to make himself efficient, and the executive of the Association, with the confidence of the gardeners of the country, would then be able to exert sufficient moral force and influence to ensure that the status and remuneration of the gardener generally should be improved. The Association would be able to assist in the transfer of young gardeners from one place to another and to help in obtaining employment for gardeners; and the guarantee of efficiency implied by membership of the Association would be beneficial to employers. The Association would impress upon head gardeners the great importance of taking a greater interest in the training of their apprentices, so as to ensure a worthy generation of gardeners to follow them. He pointed to the fact that gardening authorities and large employers of gardeners, including Lord Windsor, nurserymen, and others, were hearty and liberal supporters of the Association, which had also the good wishes of Mr. Chamberlain and the President of the Board of Agriculture, Lord Onslow.

Mr. C. H. SNOOK, West Hill Gardens, Shanklin, proposed that a branch of the British Gardeners' Association be formed in the Island. This was carried unanimously.

On the proposition of Mr. A. KIME, seconded by Dr. GROVES, Mr. SNOOK was elected secretary of the branch. *Isle of Wight County Press, February* 4, 1905.

—— A meeting in connection with the above Society was held at Wylam-on-Tyne on February 2, members from several local gardeners' societies attending. The meeting was addressed by Mr. W. Hall, Superintendent of Parks, &c., Sunderland, and by some other Sunderland members of the Association, their exposition of the benefits to be derived from co-operation meeting with a very cordial reception.

NATIONAL CHRYSANTHEMUM.

ANNUAL MEETING.

FEBRUARY 6.—The annual General Meeting of the members of this Society was held at Carr's Restaurant, Strand, on the above date, when a moderately large number of supporters assembled. Much satisfaction was evidenced by the company in seeing the Secretary, Mr. R. Dean, present again among them. Although still indisposed, he was sufficiently recovered to take his accustomed place at the proceedings. Much regret was however felt that the President, Mr. Shea, was unable to be present owing to a severe attack of influenza. Mr. T. Bevan was thereupon unanimously voted to the chair. The Annual Report was submitted to the Fellows, from which we extract the following paragraphs:—

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

"Three exhibitions were held at the Crystal Palace in 1904. At the October show the classes for early Chrysanthemums did not fill so well as could be desired. The November show was a very great improvement upon that of 1903, both in respect to the site of the exhibition and the number of entries. The December show suffered somewhat from the damp foggy weather which prevailed at the time; still the exhibition was a commendable one for so late in the season, and distinctly better than that of the previous December.

Arrangements have been made with the Crystal Palace Company for three exhibitions to take place at Sydenham in the present year. The dates are October 4 and 5, November 1, 2, and 3, and December 6 and 7.

The experiment of holding an exhibition of market Chrysanthemums at Essex Hall, on December 14, proved a distinct and gratifying success, and excellent collections were staged, while the novelty of the exhibition attracted a good deal of public interest. The growers of market varieties for Covent Garden and the salesmen gave their warm and valuable support to the show. A satisfactory sum was raised

by special subscriptions for the prizes, and the cost to the Society has been repaid. The advisability of holding a show of incket Chrysanthemums is under consideration.

During the year six meetings of the Floral Committee were held, three at Essex Hall and three at the Crystal Palace, and twenty-five First-class Certificates were awarded. The usual number of meetings will also be held in the present year.

The annual outing in July last took the form of a visit to the princely domain of Waddesdon Manor, by the kind permisson of Miss Alice de Rothschild.

The annual dinner, presided over by the President, took place at the Holborn Restaurant on November 27. Over a hundred attended.

The financial position of the Society is satisfactory, notwithstanding that upwards of £50 additional was given in prizes at the November show as compared with 1903. The reserve fund amounts to £117 16s. 9d., £115 of which is on deposit.

Arrangements have been made for holding a conference meeting on early Chrysanthemums in connection with the October show at the Crystal Palace.

In May last the Royal Horticultural Society of Piedmont celebrated the fiftieth year of its existence by holding a great International Show in Turin. A deputation consisting of Mr. T. Bevan and Mr. Harman Payne attended on behalf of the National Chrysanthemum Society and were most cordially entertained, it being particularly emphasized that this was the first time an English horticultural society had ever been represented at such a show in Italy." [?]

The Secretary pointed out the very serious decline that is taking place in the matter of receipts from members' subscriptions, and urged all to support him to alleviate this by prompt payment, and where possible by the introduction of new members to fill the ranks of those who have fallen out. Since the year 1897 there has been a steady drop in this direction, while as many as 104 members were in arrears as recently as December 31.

The Report and Balance-sheet, on the proposition of Mr. Witty, was carried unanimously, a vote of thanks being awarded the Auditors.

ELECTION OF OFFICERS.

Mr. Witty proposed the election of Mr. Chas. E. Shea to the Presidency for the coming year, and that he be accorded a hearty vote of thanks for presenting his special prize of £5 5s. and for presiding at the Annual Dinner, with an expression of regret at the circumstances which compelled his absence that evening.

Mr. Taylor was elected Treasurer, and Mr. Foster Chairman of Committees, with Mr. J. H. Witty Vice-Chairman.

Mr. C. Harman Payne was re-elected Hon. Foreign Corresponding Secretary, a post which he has held since 1888.

Mr. Such proposed Mr. R. Dean as Secretary for the coming year, the proposition being received with great cordiality. Mr. Dean, in thanking the members for their appreciation of his past services, assured them that although now past his seventy-fifth birthday he would still continue to devote his best services to the interests of the Society.

One-third of the members constituting the Committee retire annually, and these, with the resignation of Messrs. H. J. Jones and J. W. Wilkinson and another, caused thirteen vacancies, which were filled by the election of the whole of the outgoing members, with the addition of Messrs. C. J. Ellis, W. Harrison, and J. Green.

The resolution to present the honorary fellowship of the Society to Mr. Ballantyne caused some discussion as to the advisability of conferring a diploma upon those admitted to this honour; this was understood to be already within the province of the Committee under the new additions to the rules.

An amendment was made to Rule XIV., the result of which will be that the Floral Committee will also be the Classification and Catalogue Committee. Rule XVI., relating to the Classification Committee was deleted, and the following words added to Rule VI.: "Honorary Fellows shall be admitted to such of the privileges of the Society *on such terms as the Executive Committee may from time to time determine.*"

Six new members were elected, and two Societies affiliated to the Society.

Mr. C. Harman Payne drew attention to the coming horticultural exhibition in Paris, and spoke of the advisability of the Society being represented. The proposition was favourably received, and Mr. Payne was deputed to receive names of those who would form part of the deputation, and who would be willing to pay their own expenses.

SCHEDULES RECEIVED.

TORQUAY DISTRICT GARDENERS' ASSOCIATION'S Spring Flower Show, to be held at the Bath Saloons, on Thursday, March 30, 1905; and Chrysanthemum Show, to be held on Thursday, November 2, 1905.

BOROUGH OF REIGATE COTTAGE GARDEN AND HORTICULTURAL SOCIETY'S SHOW at Stone House, Reigate, on Wednesday, July 12, 1905.

GARDENERS' DEBATING SOCIETIES.

CRAWLEY GARDENERS' MUTUAL IMPROVEMENT.—At the meeting of the members of this Association on January 17, Mr. R. H. Holton presiding, an interesting paper was read by Mr. J. Martin, gr. to Mr. P. Saillard, Buchan Hill, on "Malmaison Carnations." Mr. Martin said a span-roofed house with plenty of side and top ventilation was best suited to the growth of the Malmaison. He gave his methods of treating the plant from the time of "layering" to the time of blooming, mentioned the kind of compost which he had found most suitable, and the proper times for syringing and applying water. He advised that the layers should not be pegged too closely together, or, when rooted, they would become drawn and, as a consequence, be weak and partly spoiled. He also advocated that loam and leaf-mould intended for the culture of the Malmaison should be well burnt, so as to destroy wire-worm and other troublesome pests. When potted for blooming plenty of air is necessary for the plants to keep them free from diseases commonly known as "rust" and "spot." The shading of the blossoms, staking and feeding, and other essential work for the welfare of the plants were dealt with by Mr. Martin, and names of the best varieties were given, as well as the various recipes for the prevention and extermination of diseases and insect pests.

CHELMSFORD AND DISTRICT GARDENERS'.—At the weekly meeting on Friday, February 3, under the presidency of Mr. Rixon, Mr. C. Simpson, St. John's Nurseries, Chelmsford, gave a paper on "Grapes." A brief historical sketch of the Grape was given by way of introduction. The lecturer referred to the life-period of the Grape, and its capability of fruiting when 400 years of age. The speaker treated of most cultural points in detail, and in speaking of "shanking" thought this was due to defective borders or over-cropping, while "scalding" was caused from insufficient ventilation. A discussion followed. *S. M. C.*

DORCHESTER AND DISTRICT GARDENERS'.—The annual meeting of this Society was held on Monday, January 30. The chair was taken by Mr. E. A. C. Dare, who was supported by the Hon. Secretary (Mr. E. Nuttieg). The Annual Report showed that the meetings had been well attended. The Balance-sheet showed a net balance to the Society's credit of £9 4s. 9d. The election of officers for the ensuing year then took place. Captain Dymond was re-elected President. The Vice-Presidents were re-elected in a body, and the names of the Mayor (Mr. J. W. Fudge) and Captain E. A. Pope were added to the list. The Committee were also elected, Messrs. Biggs, Dare, and Sparrow filling the vacancies caused by three retiring members. Mr. Nutting was elected to the dual offices of Hon. Secretary and Treasurer.

REDHILL, REIGATE, AND DISTRICT GARDENERS'.—This Society held its usual fortnightly meeting on January 31, under the presidency of Mr. W. P. Bound. Mr. Plyman, of Wye College, lectured on "Manures and their Effects on Plants." This was the second of the series, and dealt chiefly with nitrates, phosphates, and nitrogen, all of which are very essential in the development of plants.

LIVERPOOL HORTICULTURAL.—The third meeting of the above Society was held on Saturday, February 4, Mr. Foster in the chair. Mr. Robert Newstead delivered a most interesting paper on "The Currant-bud Mite, its History, and the various suggested Remedies." The pest first originated in North Britain some years ago, and has since travelled almost all over the kingdom. In order to realise how minute this pest is, the number of them found on investigation in a single bud has been estimated at from 2,748 to 3,000. Seen under the microscope, they are of a glassy-white appearance. They multiply very rapidly from March till August. The lecturer spoke of experiments he has tried in order to combat them, but up to the present nothing has proved successful. *J. P.*

READING AND DISTRICT GARDENERS'. — The Annual Report of this flourishing Society records continued prosperity, a fact for which the members must be congratulated. The membership has now increased to 263, including an addition of thirteen during the past year. The meetings have been well attended, the average attendance being one hundred. The summer outings proved a great success, and were events of considerable interest. The Balance-sheet records a satisfactory financial state, there being a credit balance on the year's working of £28 8s. 1d. The first meeting held in the new year took place at the Abbey Café on January 30, Mr. W. J. Townsend presiding over a large attendance of members. The subject for the evening was "Winter Vegetables and Salads," given by Mr. J. Gibson, the well known vegetable exhibitor. The subject was treated in a most practical manner, and useful advice was given as to the keeping and storing of the various vegetables touched upon, including Brussels-Sprouts, Savoys, Broccoli, Kale, Cabbage, Rosette Colewort, Kohl Rabi, Artichokes, Stachys tuberifera, Salsafy, Scorzonera, Celery, Celeriac, Leeks, Spinach, Parsley, Turnips, Swedes, Beans, Rhubarb, Seakale, Mushrooms, Tomatos, Potatos, Lettuce, Endive, Chicory, Radishes, &c. A discussion followed. There were several excellent exhibits, including a basket of salads comprising Lettuce, Endive, Chicory, and Dandelion. Thirteen new members were elected.

NORTH FERRIBY GARDENERS'.—The fortnightly meeting of the above Society was held on Wednesday, February 1st, under the presidency of Mr. Burton. Mr. E. Wright, The Gardens, Thwaite House, Cottingham, read a paper on "Cyclamens." The essayist, who dealt with his subject in a practical manner, recommended raising the plants each year from seed. Plants raised from seed sown in October should flower the following year at about Christmas. The essay was much appreciated by the members, and evoked a good discussion.

EGHAM AND DISTRICT GARDENERS'.—A meeting of the above Society was held on the 1st inst. The evening was devoted to discussions on gardening subjects generally. Amongst other questions discussed was that of the best varieties of Peas, Potatos, &c., suitable for growing in the district, of the cause and remedies for the scab on Potatos, and of the advisability of removing the pseudo-bulbs from some varieties of Dendrobiums in order to enhance the flowers for cut flower decoration. An unanimous vote was passed in favour of the amalgamation of Gardeners' Mutual Improvement Associations for the exchange of lecturers, &c.

CHESTER PAXTON.—A meeting of the above Society was held at the Grosvenor Museum on Saturday, February 4, when Mr. N. F. Barnes, Eaton Gardens, read a paper on "Garden Design," the essay being illustrated by a series of lantern-slides. The history of garden design and garden architecture was traced from early times, the styles of many of the different periods being well illustrated by the pictures shown on the screen. It was shown that these styles varied very much in character, and some at least had evidently been influenced by the particular style of house architecture in vogue at the same time. Not the least interesting of the pictures were those of the new Dutch garden at Eaton, which was planned by and laid out under the supervision of Mr. Barnes. An interesting discussion followed.

KINGSTON GARDENERS'.—At the meeting of this Society, held on February 3, the Vice-President, F. G. Shipway, Esq., gave a very instructive paper on "Apple Culture," chiefly from an an amateur's point of view, with detailed advice for the cultivation of Apples in small gardens, including the most suitable stocks for grafting purposes, the best forms of trees to plant, the most suitable varieties, suitable soils and manures, and the diseases and pests attacking the Apple, with the best remedies for the same. The lecturer gave the following selection of twelve dessert and of twelve culinary Apples as being suitable varieties to grow:—Dessert: Beauty of Bath, Irish Peach, Devonshire Quarrenden, Duchess of Oldenburgh, Lady Sudeley, Worcester Pearmain, Cox's Orange Pippin, King of the Pippins, Alfriston, Braddick's Nonpareil, Court Pendu Plat, and Sturmer Pippin. Culinary: Early Victoria, Ecklinville Seedling, Lord Derby, Newton Wonder, Lane's Prince Albert, Warner's King, Wellington, New Hawthornden, Golden Noble, Beauty of Kent, Sturmer Pippin, and Bramley's Seedling. A collection of twenty-four dishes of fine and well-preserved Apples came from Mr. Alderman, Morden Hall Gardens. *J. T. B.*

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending February 4, 1905.

1905. JANUARY 29 TO FEBRUARY 4.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	Wet Bulb.	Day. Highest.	Night. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr. min.
MEANS	40	38	48	36	28	38	39	41	Tot 0·01	4 24

THE WEATHER IN WEST HERTS.

Three Very Warm Nights.—The present warm period has now lasted eleven days, during which there has not occurred a single unseasonably cold day or night. On the warmest day the temperature in the shade rose to 55°, and on three nights the exposed thermometer did not fall lower than 40°—which is 14° in excess of the average for a February night. The ground temperatures are rising, and at the present time the reading at 2 feet deep is about 2° warmer, and at 1 foot deep about 4 warmer than is seasonable. There occurred a little rain on two nights during the week, but virtually there has been no rain worth mentioning for three weeks The drainage through both percolation gauges has been gradually decreasing, and the daily measurements are now very small. The sun shone on an average for three hours a day during the week, or for an hour a day longer than is usual at this season. The winds have been, as a rule, high, but in no hour did the mean velocity exceed 18 miles—direction W.N.W. The average amount of moisture in the air at 3 o'clock in the afternoon was 6 per cent. less than is seasonable. The double Snowdrop was first in flower in my garden on the 6th—which is two days earlier than its average date of flowering in the same spot during the last eighteen years.

JANUARY.

A Remarkably Sunny January. — The temperature during the month varied a good deal from week to

week, but taken as a whole it was slightly warmer than the average. Although rather warm, there has been during the last eight years only one other January in which the mean temperature has been as low. On the warmest day the temperature rose to 53°, and on the coldest night the exposed thermometer registered 15° of frost—both high extremes for the month. Rain or snow fell on only nine days, seven of these being in the first half of the month, and to the total depth of less than 1½ inch, or about half the January average. On two days the ground was covered for a short time with snow to the depth of half an inch. The sun shone on an average for two and a half hours a day, or for an hour a day longer than usual, making this the sunniest January of which I have here any record. The wind was on the whole about seasonable in strength, and at no time exceeded 21 miles an hour; direction W.N.W. The air remained singularly dry, in fact drier than in any previous January, the mean amount of moisture in it falling short of the average by as much as 8 per cent.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October every month has been more or less dry. The total deficiency in rainfall for those four months is 4¾ inches, equivalent to a loss on each acre in this district of 107,200 gallons. Last year at the same time the amount of rain was to nearly the same extent in excess of the average. *E. M., Berkhampstead, February 7, 1905.*

[For actual temperature and condition of barometer at time of going to Press, see p. 88.]

MARKETS.

COVENT GARDEN, February 8.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

POTATOS.

Dunbars, 90*s.* to 100*s.*; Teneriffe, 12*s.* to 14*s.* per cwt.; Algerian, per lb., 4*d.*; Jersey, per lb., 6*d.*; various, home-grown, 60*s.* to 70*s.* per ton. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

FRUITS AND VEGETABLES.

GLASGOW, *February 8.*—The following are the averages of the prices during the past week:—Apples, American, 9*s.* to 18*s.* per barrel; do., Canadian, 12*s.* to 25*s.* do.; Oranges, ordinary 420's, 6*s.* to 7*s.* per case; do., large, 8*s.* to 10*s.* do.; do., extra large, 10*s.* to 14*s.* do.: do., large 714's, 8*s.* to 10*s.* do.; Lemons 8*s.* to 15*s.* per case; Grapes, home, 9*d.* to 1*s.* per lb.; Colmars, 10*d.* to 1*s.* 6*d.* do.; Alicantes, 8*d.* to 1*s.* 2*d.*; Bananas, 6*s.* to 12*s.* per bunch; Tomatos, 3*s.* 6*d.* to 4*s.* 6*d.* per box; Onions, 4's, 12*s.* to 13*s.* per case; 5's, 15*s.* to 16*s.* do.; Mushrooms, 1*s.* to 1*s.* 6*d.* per lb.

LIVERPOOL, *February 8.—Wholesale Vegetable Market (North Hay).*—The following are the averages of the current prices during the past week—prices varying according to supply:—Vegetables: Potatos, per cwt.: Bruce, 2*s.* 2*d.* to 2*s.* 6*d.*; Main Crop, 2*s.* 9*d.* to 3*s.* 9*d.*; Up-to-Date, 2*s.* to 2*s.* 4*d.*; Turnips, 6*d.* to 8*d.* per dozen bunches; Swedes, 1*s.* to 1*s.* 2*d.* per cwt.; Carrots, 3*s.* to 3*s.* 3*d.* do.; Onions, foreign, 14*s.* to 14*s.* 6*d.* per bag; Parsley, 6*d.* to 8*d.* per dozen bunches; Cauliflowers, 1*s.* 9*d.* to 2*s.* 6*d.* per dozen; Cabbages, 6*d.* to 10*d.* do.; Celery, 8*d.* to 1*s.* 4*d.* do.—Fruit: Apples, Americau, 7*s.* 6*d.* to 12*s.* 6*d.* per barrel; Canadian, 8*s.* to 16*s.* do.; Oranges, Valencia, 6*s.* 6*d.* to 8*s.* 6*d.* per case; large do., 7*s.* 6*d.* to 12*s.* 6*d.* do.; Jaffa, 3*s.* 6*d.* to 9*s.* 6*d.* per box; Bitters, 4*s.* 6*d.* to 8*s.* 6*d* per package; Lemons, Palermo and Messina, 5*s.* to 7*s.* per case; Naples, 3*s.* 6*d.* to 7*s.* 6*d.* per box. *St. John's.*—Potatos, 10*d.* to 1*s.* per peck: Cucumbers, 6*d.* to 8*d.* each; Grapes, English, 1*s.* 6*d.* to 2*s.* 6*d.* per lb.; do., foreign, 6*d.* to 8*d* do.; Pine-apples, 3*s.* to 5*s.* each; Mushrooms, 1*s.* to 1*s* 3*d.* per lb. *Birkenhead.*—Potatos, 8*d.* per peck; Cucumbers, 1*s.* each; Filberts, 1*s.* to 1*s.* 2*d.* per lb.; Celery, 1½*d.* to 3*d.* per stick; Apples, 1½*d.* to 3*d.* per lb.; Pears, 2*d.* do.; Grapes, English, 1*s.* 6*d.* to 3*s.* 6*d.* do.; do., foreign, 6*d.* to 8*d.* do.; Tomatos, English, 4*d.* to 6*d.* do.; Mushrooms, 1*s.* to 1*s.* 4*d.* do.

COVENT GARDEN FLOWER MARKET.

THE recent mild weather has caused flowering plants to develop rapidly, especially bulbous plants. Daffodils are over-plentiful and are considerably lower in prices, while Tulips and Hyacinths are also very plentiful. Richardia (Calla) æthiopica is good but is not much in demand. Genistas are now arriving from several growers. Marguerites continue abundant. Cinerarias are good; these are now sent by several growers. Azalea indica in various sizes are well-flowered, but the supply is somewhat over plentiful. There are also a few good specimens of A. Fielderi and of A. mollis. Of Erica hyemalis there are still some fairly good plants obtainable, as there are also of E. persoluta alba, E. fastigiata, and E. melauthera. There is not a large demand for hard-wooded plants; these now include Acacias armata, ovata, and Drummondi, Boronia megastigma, and Diosma gracilis. Plants of Begonia Gloire de Lorraine of good quality are still to be had. A few good Lilium longiflorum in pots are seen. Cyclamen are now very good, while Solanums are still to be had. Ferns in all sizes are plentiful, and since the mild weather has prevailed they have sold more readily. Palms are also plentiful; growers of these plants complain of diminished trade compared with that of a few years ago. Aspidistras in both green and variegated varieties are plentiful; prices for these do not vary much. Ficus elastica sells slowly; Ficus repens is not selling well just now. Hardy perennials and herbaceous plants are now to be had, also several varieties of spriug bedding plants. Hardy trees, shrubs, and climbers in variety are all procurable.

CUT FLOWERS.

The mild weather has made a considerable difference to supplies, especially among Roses, of which there is a regularly increasing supply. The variety General Jacqueminot is arriving from several growers; the flowers are not large, but they are bright in colour. La France and Caroline Testout are very good. also Kaiserin Augusta Victoria. Niphetos is now plentiful. Sofrano (English-grown) are of a good colour, but small in size. Catherine Mermet is not well coloured. Daffodils are coming from many sources, and are now the chief feature among cut flowers. It will be difficult to give even approximate prices. Some of the best varieties maintain good prices, but already the prices for ordinary samples have gone down considerably. Narcissus poeticus was as low in price on Tuesday as 4*s.* per dozen bunches. The varieties Paper-white and Soleil d'Or are also very plentiful. There are still fairly good Chrysanthemum flowers seen. The supply of Orchid-bloom is more than equal to all demands. In Carnations the variety Mrs. T. W. Lawson is now conspicuous. It is remarkable that there are very few really good flowers of the English varieties seen. The variety Madame Thérèse Franco (Mrs. Leopold de Rothschild) has been marketed in good condition. Liliums continue plentiful and there is little variation in the prices for these. Zonal Pelargonium "Raspail" is now more abundant and is lower in price. Violets are more plentiful, Snowdrops, Wallflowers, and other spring flowers are making their appearance.

Supplies of French flowers, with the exception of Roses, are coming in better again. Ranunculus, Anemones, and Double Stocks are all good. There are several different varieties of Acacias (Mimosa), some are past their best in quality. There are good supplies of all kinds of foliage. *A. H., Wednesday, February 8.*

ENQUIRIES.

LADY GARDENER.—I am anxious to know if there is any way for a girl to get training in gardening (of such a character as to fit her for obtaining a post as lady gardener) less expensive than the Horticultural College at Swanley or Lady Warwick's Hostel? Do any botanical gardens or large nursery establishments employ women gardeners? *E. C. C. D'O.*

PINUS INSIGNIS.—I would like to ask those who have planted this tree in quantity if it is usual or advisable to plant Pinus insignis in sacking? I know where there has been recently planted about 100 of these trees. They were received from the nursery, each plant with a nice ball of soil around the roots tied up in sacking, and with the advice that the plants were to be planted as received, without taking away the sacking. *W. J. P.*

MOSS.—Can any reader tell me where I can find some information respecting that curious Moss, Dicranum glaucum, which is found in the Pine-woods near Weybridge in rounded, unattached tufts of various sizes? I have never met with any explanation of the mode in which these tufts become entirely detached from the soil and self-supporting. *J. E. H.*

ACETYLENE GAS.—Is the spent carbide good for the kitchen-garden? What time would be best to apply it? Our soil here is of a rather stiff nature, resting on chalk. *G. A. H.*

ANSWERS TO CORRESPONDENTS.

A GARDENER'S TESTIMONIALS: *J. R.* The employer should certainly return the testimonials to you at once under the circumstances you have described, and especially after the trouble you have been caused. It would be well to consult a solicitor; and in future to avoid such needless worry by holding the originals and submitting copies only.

APPLE: *J. H. A.* The brown sunken patches are caused by a fungus called Gloeosporium fructigenum (see fig. in *Gardeners' Chronicle*, Oct. 8, 1904, p. 249). Spray with a solution of potassium sulphide—half an ounce to a gallon of water, and add one ounce of soft-soap. Commence first when the Apples are just set, and repeat at intervals of ten days until no trace of disease is to be seen. Cold storage prevents the spread of the disease when the fruit is ripe.

BOOKS: *W. J. S.* We know of no book in the English language treating exclusively upon Palms, but there are chapters on the subject in most of the books upon stove and greenhouse plants, or in the gardening encyclopædias, as *Thompson's Gardeners' Assistant*, new edition, edited by Mr. W. Watson, Curator at Kew.

CARNATIONS: *E. S.* Varieties of the type of Souvenir de la Malmaison should at no time be syringed, and even the damping of stages, paths, and other surfaces should only be done in bright weather; especially is this essential during winter. The tree or perpetual-flowering sorts, being less liable to the attacks of fungus, may be judiciously sprayed during all the growing season and in bright weather in winter. The foliage of these plants being of a softer character, aphides are sometimes troublesome, and a dry, arid temperature would encourage them; recourse must therefore be had to the syringe to minimise the risk and at the same time stimulate growth.

COBHAM PARK: *G.* Most of the glasshouses at Cobham Park, of which details were published last week, were, we are informed, built by Mr. James Gray, Chelsea.

COMPENSATION FOR TREES AND SHRUBS: *J. R. G.* We should suppose that the purchaser of the estate purchased the movable trees and shrubs also.

CORRECTION. In the paragraph on Ventnor in January, on p. 73, instead of Barometer 39·9 read 30·9. (See also under "Potatos.")

CROCUSES: *R. W. W.* The sepals and petals are more or less laciniate, and approach a semi-double condition.

CYPRIPEDIUM LEAVES: *F. H.* The injury is due to the presence of moisture on the leaves when the temperature was falling. Admit more air to the house, and spray the plants only when the temperature is rising and the weather bright.

DENDROBIUM: *Magenta.* A very good variety of D. nobile, being similar to the form known as D. nobile nobilius.

FIG-TREES DROPPING THEIR FRUITS: *G. S.* This may arise from several causes, and which it may be in your case we are unable to say. The atmosphere of the house should be kept moist, and the trees syringed overhead twice each day in bright weather, damping the floors and other surfaces instead when the weather is dull. Figs require heat, much moisture, a little ventilation at all times, varying in degree according to the condition of the weather, a restricted root-run, abundance of moisture at the roots, and applications of liquid manure when the flowering stage has passed and the fruits are swelling. The trees should not be permitted to carry excessive crops. See note in the "Fruits under Glass" Calendar on p. 87.

FUMIGATING TENDER PLANTS: *H. M.* Instead of seeking to obtain a moist atmosphere at such a time you should refrain from spraying the plants and damping the surfaces in the house for some hours, or all day, before the process of fumigating the plants is commenced. None of the plants should have moisture upon their leaves at such a time. Choose an evening when there is little wind, make the house as air-tight as possible, and remember that it is better to repeat the operation on the following evening than to make the application too severe on the first occasion.

HORTICULTURAL INSTRUCTOR: *W. F. Stanmore.* Among other qualifications it is essential to possess a good practical acquaintance with plain gardening, with a knowledge of how to do a thing and of the reason why, more especially in fruit and vegetable culture. The following requirements may also be mentioned:—An intimate acquaintance with the more common garden pests, both fungi and insects, and the methods to be adopted for their extirpation. Power of exposition by word with the use of black-board or of magic-lantern, and in simple language "understandable of the people." Competence to act as judge at shows and in garden competitions. Ability to show novices how to handle and work in the most efficient manner with any kind of tool or simple machine, and to demonstrate the various methods of grafting, inarching, budding, root-pruning, and making cuttings. To be able to show how properly to plant various kinds of hedges, and to train the same when planted; also how to "set in" trees for felling. To point out how best to grow window-plants; how to pack fruit and vegetables for market, including sorting and grading. Indeed it is not easy to tell you what subjects you should not be acquainted with, so multifarious are the matters coming within the purview of a horticultural lecturer.

LADY GARDENER: *J. W. H.* We do not know the lady's address. Write to the college authorities at Swanley, they may perhaps be able to supply it.

NAMES OF FRUITS: *W. B. S.* Pear Glout Morceau, and Apple Blenheim Pippin. (Thanks for Postal Order for 1s., which shall be given to the Gardeners' Orphan Fund).—*M. Bros.* Pear Belmont.—*A. H.* 1, Blenheim Pippin; 2, Emperor Alexander; 3, Dean's Codlin; 4, Hormead's Pearmain; 5, Newton Wonder; 6, Tower of Glamis.—*Y. E. H.* Not recognised. The fruit much resembles that of Annie Elizabeth, but upon comparison for flavour is much superior to that variety.

NAMES OF PLANTS: *J. W.* Cytisus monspessulanus.—*A. C.* 1, Dracæna intermedia; 2, Bilbergia iridifolia; 3, Dracæna concinna; 4, Hibiscus Cooperi; 5, Anthericum lineare variegatum; 6, Cyperus alternifolius; 7, Dracæna fragrans, probably, specimen bad; 8, Dracæna versicolor; 9, Yucca aloifolia mediovariegata; 10, Maranta Makoyana.—*F. G. G.* Petasites fragrans.—*W. T., Gloucester.* Odontoglossum × Adrianæ of ordinary quality, not worth sending for exhibition.—*J. P., Constant Reader.* Helxine Soleirolii, often grown like moss in Orchid-houses, and sometimes used in carpet-bedding out-of-doors.—*A. R. A.* 1, Epidendrum; 2, Cypripedium × Lathamianum; 3, Oncidium spilopterum.—*M. H. S. A.* Polygala chamæbuxus.—*Cilurum.* Jasminum Sambac and Chlorophytum elatum variegatum.—*F. P.* Eucalyptus Globulus in adult or fruiting stage.—*L. McC. (Shelton).* It is almost impossible for us to name plants from leaves only. 1, next week; 2, cannot tell without flowers; 3, Daphniphyllum macropodum; 4, Cupressus sempervirens; 5, Philesia buxifolia; 6, Viburnum lantanoides probably.—*W. S., Darlington.* Cœlogyne lactea, of no special commercial value.

NEW ZEALAND: *J. W.* There are undoubtedly good markets in the large towns, but we cannot accept the responsibility of advising you as to the prospects there compared with those existing in this country. Write to the Agent-General for that Colony, 13, Victoria Street, Westminster, London.

POTATOS: *T. L., Sandown.*—In our reply last week the distances for planting were by some means reversed. It should have read 10 inches from set to set in the rows, and 2 feet between the rows.

POWELLISED TIMBER.—In reply to numerous correspondents from Germany, France, and India, we may say that the office of the Company is at Temple Bar House, 28, Fleet Street, London, where full information can be had.

RECORD BUNCHES OF GRAPES: *H. H.* The largest bunch of Grapes of which we have record was one of the variety Trebbiano, weighing 26 lb. 4 oz. It was shown by Mr. Curror, gr. to G. Douglas, Esq., Eskbank, Dalkeith, at the the Royal Caledonian Society's show, held on September 15, 16, 1875. This was a handsomely-formed bunch, the berries closely and solidly packed, so that the shoulders stood out firmly in all directions, and the bloom was perfect. Another bunch of Grapes shown at the same time, but of the variety White Nice, turned the scale at 25 lb. 15 oz. This bunch was shown by Mr. Dickson, gardener to John Jardine, Esq., of Arkleton, Langholme, Glasgow. It is no little credit to the gardeners of Scotland to have thus produced the two largest bunches of Grapes upon record. In more recent years a bunch of Gros Guillaume, grown by Mr. McKenna, gardener at Phœnix Park, turned the scale at 20 lb. (see *Gardeners' Chronicle*, February 6, 1886, p. 168), and in 1898 a bunch of Black Alicante was grown at Pitcullen Vineries which weighed 13 lb. 6 oz. (see fig. in *Gardeners' Chronicle* for January 29, 1898, p. 72). Our "record" book gives 8½ lb. as the largest bunch of Black Hamburgh, produced at Oakfield Gardens, East Barnet, Hertfordshire, in July 1858. An account of this bunch in our issue of that date states that the Oakhill Grapes were sold in Covent Garden market at 16s. per lb. The largest bunch of the variety Muscat of Alexandria recorded in our book weighed 2 lb. 11 oz. Three bunches of this variety shown by Mr. Roberts, Charleville, in 1878, totalled 15 lb. 6 oz. in weight.

SNAIL PLANT: *R. S. P.* We suspect this plant is Medicago scutellata, which is known as the Snail Clover or Snail Trifoly, owing to the peculiar shape of the pods. The species is widely distributed.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES: *J. S.* The President is Mr. Geo. Schneider, 17, Ifield Road, Fulham Road, London, S.W.

COMMUNICATIONS RECEIVED.—E. M.—Under Gardener (your communication is of too personal a nature. Address the Committee upon the subject).—R. A. R.—Sir H. M.—S. W. F.—H. M.—F. Mason Good.—F. J. THE ROYAL HORTICULTURAL SOCIETY.

THE second centenary of the Royal Horticultural Society opens auspiciously. The new Hall and offices are complete, and though they are not faultless they are sufficiently so to silence the grumblers and those critics who seem only able to look at one facet of a crystal.

Nobody can say the Hall was not wanted—no one can deny that the want has not been well supplied. We know to whose munificence we owe the possession of a home. We cannot be too grateful for the help that Sir Henry Schröder and Sir Thomas Hanbury have afforded, and we do not forget that it was the liberality of Messrs. Elwes, Sherwood and Sutton that gave the initial impulse to the fund raised for the erection of the Hall and offices. Specially also we must not forget that their good example needs to be followed by many more before the debt now owing can be abolished.

The proceedings at the annual meeting held on Tuesday last are fully reported in another page, and the Report of the Council is in the hands of the Fellows. Sir Trevor Lawrence had just cause to be jubilant. He has been at the helm all through the dark days; he never flinched or despaired; but not even he could have imagined that the centennial year could have been consummated by the erection of a spacious and commodious Hall, by the acquisition of a garden five times bigger than Chiswick, and destined to rival, if not to eclipse, the glories of the old garden. In these dismal days how could he have looked forward to the accomplishment of these great facts, to a roll of Fellows numbering more than eight thousand, and to a substantial surplus on the year's working? We may almost say, looking back, that the impossible has been accomplished! In the future we have every reason to anticipate that while the routine work of the Society will be carried on under much more favourable conditions than formerly, real progress and advancement will result eventually from the establishment of a research station at Wisley. Utilitarian objects and the love of the beautiful are self-supporting, and need comparatively little assistance—they appeal to everyone; but if we want to increase the powers of the horticulturist, to open up new fields for his energies, increase his resources, and put weapons in his hands to combat the ills to which he is subjected, we must look to scientific research—research which may not at once appeal to the ordinary gardener, professional or amateur—research which cannot be carried out by him, but must be delegated to the specialist, unhampered by commercial considerations and unaffected (if that be possible) by the fascinations of floral beauty or other sensuous perceptions. With such views, we were pleased to hear the President's remarks on the speedy realisation of our hopes for a properly equipped and competently officered research station at Wisley.

It is a matter for regret that the summer show cannot be held this year in the paddock at Holland House, but this feeling does but intensify our sense of gratitude to Lord Ilchester for the privilege that he has accorded on former occasions. We have yet to see whether the location at Chelsea will be equally attractive.

Sir Trevor Lawrence's reference to the Secretary (Rev. W. Wilks), and to the work done by him and his staff, were heartily endorsed by the meeting. Indeed, it is impossible to over-estimate the value of Mr. Wilks's services, impossible not to attribute to him a very large share in bringing about the present prosperous state of affairs.

The financial matters, as explained by Mr. Gurney Fowler, are such as to ensure confidence in the future. Two things remain to be accomplished—the extinction of the debt and the endowment of the Lindley Library. The income of the Trustees is so extremely small that the vote by their brother-trustees of the Veitch Memorial Fund of £50 comes as a substantial temporary relief, and will, we trust, enable the custodians to proceed more rapidly with the binding and with the purchase of desirable books. In this connection we must not fail once again to record our thankfulness to Baron Schröder, who has borne the cost of the instalment of the Library in its present quarters in a fashion far more in consonance with the importance of the collection than has ever been the case before. The Library now can fairly take its place among the great metropolitan libraries, and those responsible for its management are relieved from the sense of humiliation they experienced at its former condition.

The speeches of Mr. Arthur Sutton, Mr. Elwes and others were very much to the point, and never were the thanks of the Fellows to the Council more truly earned than on this occasion.

ALPINE GARDEN.

CAMPANULA GARGANICA HIRSUTA.

HARDLY any of the Alpine Campanulas can lay claim to being more valuable for the rock-garden than C. garganica hirsuta, the pilose form of C. garganica, a well-known plant in this country. It comes early into bloom, and it continues to flower in almost constant succession until late in the year. It was still charming in the fourth week of October, with its little pale blue and white flowers, although it had been in bloom since early in June. This variety of the Gargano Bellflower, or the Bellflower of St. Angelo, is mainly distinguished from the type by the light-coloured hairs which cover its stems and leaves, so as to give them quite a grey appearance. It is as easily cultivated as the typical C. garganica, but it is a much prettier and more refined plant on the whole. Of slightly trailing or prostrate habit it makes an excellent rock-plant, and when seen hanging over a low ledge of dark stone, looks very pretty indeed.

Recently there has been introduced a variety with almost pure-white flowers, but slightly less vigorous (I use the word "vigorous" only comparatively, for it is not a strong grower), and it seems a little more tender during winter; but this will probably pass off as the plant becomes propagated in a less tender method. Very beautiful, however, as is this white variety, it cannot surpass the pale blue and white form which is recognised as the typical C. garganica hirsuta.

Like the other forms of the species, C. g. hirsuta, which is frequently met with simply as C. hirsuta, likes a rather peaty soil, together with abundance of water in the flowering season. It shows a preference here for a fair amount of shade, and does nowhere so well as facing the east, and in a spot where it only gets the full sun when it reaches near its meridian in summer. C. g. hirsuta is propagated by division or cuttings. *S. A.*

OXALIS LOBATA.

As a late-flowering alpine plant this bright little Wood Sorrel is invaluable. It is quite a pleasure to see its bright golden blossoms opening in the faint sun of October and November, and we should be delighted could we persuade it to keep them expanded when there is no sunshine. It is however a true sun-lover, even if it does not bloom until late in the year. It was introduced to me by the late Mr. H. Selfe-Leonard a good many years ago, and I can well recollect the pleasure given by its flowers one early November day when I came across the plant in bloom for the first time. Its bright little yellow flowers were most welcome and cheering, and I can never forget the pleasure they yielded then, just after frost had practically ruined my other flowers for the year. O. lobata is a native of Chili, but is hardy in most places with us, though in the coldest localities it might be protected with a little loose litter about it after it has finished blooming. It only grows about 3 inches high, and the flowers are displayed on a carpet of small glaucous leaflets. *S. Arnott, Carsethorn-by Dumfries.*

NEW OR NOTEWORTHY PLANTS.

PRIMULA DEORUM, VELENOVSKY.*

WE lately received from Messrs. Stansfield Bros., of Kew, Southport, a coloured drawing of a Primrose from Bulgaria, which we have compared with specimens in the Kew Herbarium, and with the original description by Velenovsky in the *Flora of Bulgaria* as cited in the footnote. The plant is allied to P. glutinosa, and with its lanceolate entire leaves and clusters of reddish-purple flowers, is likely to be popular with growers of alpine plants. There are specimens gathered in Bulgaria at Pilo Dagh at altitudes between 4,000 to 7,000 feet by Mr. Elwes in June, 1899, and these specimens agree better with the description by Velenovsky than does the drawing sent us. The differences are however unimportant, except in so far that they show that the plant attains larger proportions than is shown in the sketch. *M. T. M.*

Messrs. Stansfield's note runs as follows:—

"Enclosed herewith we are sending you a coloured figure of a new Primula deorum (Velenovsky). This is quite a new plant of recent introduction and as soon as the plant is better known it is sure to become a popular plant among Alpine plant growers. There is no doubt as to its hardihood, coming as it does from the lofty Mount Rilo, in Bulgaria, where it is found growing at an elevation of 8000 feet.

In its native habitat it is found growing just below the snow-line. It is generally found in grassy Alpine pastures and near the numerous Alpine streams which are so common in all Alpine meadows. It must therefore have plenty of moisture, growing as it does with its roots always in water. The general appearance of the plant is somewhat like that of Primula Clusiana. The flower-stalks are thrown well up above the foliage, sometimes 8 to 9 inches in height, upon the top of which are borne a number of purplish-violet flowers of a most striking character; sometimes as many as twenty flowers are found to be produced at one time. On planting it should be given a north aspect at the base of the rock garden where the plant can get a double portion of the rains which fall upon the rock garden. *W. H. Stansfield, Southport.*"

Since the above note was written we have come across a note and figure from Mr. Hindmarsh, in *Flora and Sylva*, ii. (1904), p. 239. Mr. Hindmarsh obtained the plant in 1902, and planted it in sandy loam in the open rock-garden, facing north, and at the foot of a large flat-topped stone. It is quite hardy with Mr. Hindmarsh, as also with Mr. Max Leichtlin.

* *Primula deorum.* J. Velenovsky, *Flora Bulgarica* (1891), p. 479.—"Perennis, *omnino glabra ad scapum superne et pedicellos valde glutinifera;* rhizomate crasso carnoso obliquo; foliis *carnosulo coriaceis*, viridibus, rosulatis sessilibus, oblongis basi leviter vel vix attenuatis breviter acutis integris vel apice pauci-dentatis, scapo, 3—4 plo brevioribus: umbella 5—10 flora sæpius unilaterali; involucri phyllis oblongo-linearibus pedicellis longioribus paucis basi non saccatis et inæqualibus, pedicellis calycem subæquantibus, calycis ad medium fissi laciniis triangulari-acuminatis; corollæ purpureo-violaceæ omnino glabræ tubo calyce triplo longiore laciniis tubo corallino tertia parte brevioribus; capsula ovoidea calyce non accreto inclusa. Floret Augusto. Folia 3—4 cm. × 5—8 mm.; scapus 6—10 cm., calyx 3—4 mm. longus; corollæ tubus 10—12 mm., limbus 13—15 mm.—In graminosis humidis inter nives ad fontes rivuli Cerni Isker summo M. Rilo. Planta colore et magnitudine florum, foliis læte viridibus subcoriaceis elegantissima. Rhizoma digito haud tenuius et folia sicca odorem gratum abietinum spirant. Scapus superne viscidus pedicelli et calyces sunt nigri. Umbella semper valde unilateralis fere subnutans. Species cum nulla alia comparanda sed ad affinitatem P. glutinosæ Wulf. spectans."

KEW NOTES.

PLECTRANTHUS CRASSUS.—This genus contains but few plants of horticultural value, but a species has been discovered at last that may claim to be a useful garden plant. The seeds of P. crassus were sent to Kew in February, 1902, by Mr. J. McClounie from British Central Africa. The species flowered for the first time under cultivation in November, 1903. The plants now in flower in the Begonia-house (No. 8) were grown from cuttings rooted in March of last year. Their habit of growth is quite distinct from that of most Plectranthus, which are usually much branched and bushy, whereas this species rarely branches naturally. The stems are erect, stout, and slightly woody at the base, having a height of 1½ to 2½ feet. The leaves are ovate, with a crenate margin, 4 inches long by 2½ inches broad; pale green in colour, and rather pleasantly scented. The terminal spikes of labiate, lavender-blue-coloured flowers are from 6 to 8 inches in length, and 1½ inch in diameter. A succession of flowers is maintained on the densely crowded cymose-whorls, which form the inflorescence for fully two months. Propagation should be by cuttings rooted in moderate bottom-heat, afterwards being grown on under cool conditions. Owing to its unbranched habit, it is advisable to grow three or more plants in a pot. This is one of the few flowering plants that does not appear to have been affected by the severe fogs.

FIG. 41.—PRIMULA DEORUM: FLOWERS ROSY-PURPLE.

CYNORCHIS LOWIANA.

A fine pan of this exceedingly pretty terrestrial Orchid is now flowering in the warm Orchid-house; it has twelve inflorescences, each of which is carrying from three to six large flowers. C. Lowiana is a native of Madagascar, and therefore requires during the period of growth a stove temperature, but it should be rested in an intermediate-house.

The South African species, Cynorchis compacta, is also in flower in the cool Orchid-house. There are several pans, each with a profusion of elegant inflorescences, some 4 inches in height, with white, spotted flowers.

EPIDENDRUM ALLEMANI.

This delightful species is very little known in gardens. It is of the same section of Epidendrum as E. cochleatum, E. inversum. E. fragrans, &c., and is sometimes imported from Brazil under the name of E. lonopsis. The plant has deep-green flasked-shaped pseudo-bulbs about 3 inches long, surmounted by two leathery leaves 9 inches long by 1 inch in breadth. The spikes of flowers are produced very freely; they are about 6 inches high, and have usually four to six flowers which are most deliciously scented. The individual flowers are 1½ inch in diameter when first expanded; the sepals and petals are pure white, and remain so for about three weeks, afterwards turning cream-coloured. The lip is of pure white with a few rosy-red markings near to the column. *W. H., February 8.*

THE SPECIES OF EREMURUS.

(*Continued from p. 67.*)

SPECIES AND VARIETIES.—*E. Bungei* (*aurantiacus*).—An old-time species, but still scarce enough to be called rare, and a border plant of sterling value, showing the greatest refinement in its symmetrical spikes of canary-yellow flowers. It has a black-brown root-stock, covered with a thick mass of coir-like fibre; long, wiry, thong-like roots form the usual cycle around the crowns, and the leaves exceed a yard in length and are arranged in loose, sedge-like tufts of a glaucous hue. The flower-spikes are 6 to 9 feet long, the upper third (sometimes half) being covered with a bristling array of pretty flowers, the petals of which glisten and the silky stamens bear orange-red anthers that look charming in contrast to the yellow of the petals. The flowers are so closely arranged that the pedicels are quite hidden when the spike is in full bloom, and one sees nothing but a silvery yellow cylinder bristling with myriads of anthers. The flowers are an inch in diameter, and the petals are rounded and often slightly recurved. It hails from Persia and flowers with us in July. A light soil and warm and dry resting season during early winter are very necessary for it.

Var. *præcox* is a slender and early-flowering form from Baluchistan, having but few roots, but these travel 3 to 4 feet distant from the root-stock, and they are coal-black in colour. The flower-spike is equally tall, but more slender, and the flowers open with those of E. himalaicus in June. They are smaller than those of E. Bungoi, but similar in colour and less crowded in the spike.

E. himalaicus.—The common white Eremurus, now so widely planted, is a stately subject that one could use effectively in association with low shrubs, so that the tall brushes, often a yard or more long, may be seen just above the surround-

ing foliage. The roots are nearly black, and very numerous, having somewhat scarious cuticles, and the whole root system covers a square yard when well developed. The leaves are glabrous, deep green, 6 inches wide, and a yard long, and they form a rigid rosette till the spike flowers, when the upper third recurves. The spikes vary from 6 to 10 feet in height, and quite one-third of their length is covered with multitudes of pure white flowers, each an inch across, the bristling anthers interlacing freely, giving a sheen of silk to the inflorescence. They open in irregular circles, eight to ten ranks every day, and when the terminal foot of spike is reached the top keels over, so that a plantation of goodly quantity has a curiously tasselled appearance. The inflorescence is often more than 6 inches through, and various specimens differ in density of spike. It is quite an easy plant to grow, and there should be no difficulty in making it succeed where it would look best. A good friable soil that drains water freely will serve, and if specimens are annually top-dressed with leaf-soil and loam, six to eight spikes from each clump may be expected in a space of six years; for each strong spike is followed by two crowns, which in their turn, generally triennially, split into two again and again. *G. B. Mallett.*

(To be continued.)

VEGETABLES.

ROTATION OF KITCHEN GARDEN CROPS.

(Continued from p. 38.)

The last crops treated of were those of early and midseason Potatos (late Potatos, unless the garden is unsually large, should be relegated to the field). Towards the end of August or early in September, a large breadth of ground which has been under the above crops will be available, and without further cultivation or manuring, with the exception of clearing and forking the surface of the land, may be used for the reception of crops of Spinach for use in winter and the following spring, and of Turnips for autumn and winter supply. These crops should be sown as early as possible after the Potatos have been cleared, in order to allow them as long a period of summer weather as is possible in order to develop strong growth.

Celery.

The crop I recommend to follow the Spinach and Turnips in spring is Celery. This allows the Spinach to remain on the land late into spring, an advantage which will be appreciated by those who understand the value of this vegetable at that season of the year when other vegetables are frequently scarce. Whether the old system of growing Celery in single rows, or the more modern and economical one of growing the plants in wide beds containing six or more rows of plants in a bed, be followed, the preparations necessary, if the highest success is to be attained, involve the adoption of intensive culture in its truest sense, and are equivalent in every way to ordinary trenching and manuring. In the first place, the soil in the beds must be dug out to a depth of a foot, and the bottom of the beds turned up to the depth of the spade, to ensure the earth being moved to a depth of at least 2 feet. In the bottom of the trench, after the digging is completed, a layer of good rotten manure should be laid at least 6 or 7 inches thick. This process, together with that of disturbing the soil to a good depth in the spaces between the beds when earthing-up the Celery, and with the subsequent digging of the land the following spring after the crop is cleared, prepares the ground as no other crop can do for Onions. Before leaving the subject of Celery, I should like to say that I have always endeavoured to have the Celery-beds formed as early in the year as possible, even before the young plants are ready for planting, because the ridges formed by the soil dug out from the beds offer excellent ground for the growth of Lettuce, French Beans, or other such fleeting crops as occupy the land for a short time, and are cleared away before the Celery needs to be earthed. In gardens where space is limited this effects a useful economy; and as regards results, the best Lettuces I have ever grown were produced in this way. *Owen Thomas.*

(To be continued.)

COTTAGE-WALLS.

Our late friend Edward Pynaert was wont to lament the circumstance that the residents in the Belgian country districts did not more frequently avail themselves of the walls and gables of their residences, which he spoke of as *pignons perdus*. In this country we do not think the complaint would have the same amount of justification. It is common enough to see a well-trained Pear-tree covering the walls of the gardener's cottage, and how many country rectories have we not seen which, like that shown in our illustration (see fig. 45), are made supremely beautiful by the use not of rare or costly creepers, but of such as are at the disposal of anyone! What more lovely drapery can be afforded than that furnished by the Wistaria, as figured in our issue for February 4, glorifying an otherwise plain frontage. Even suburban villas are lifted out of the commonplace by a veil of Veitch's Ampelopsis or variegated Ivy, though careful housewives object to the dust and dirt which accumulates on Ivy-covered walls, and to the shelter afforded to sparrows, mice, and other creatures, whose habits are not conducive to cleanliness. We have not space now to do more than indicate the wealth of material that is available for the purpose of wall-decoration or for more utilitarian purposes, but we cannot avoid alluding to the use that is made in the chalky districts of East Kent of Clematis montana. We remember passing through one large village almost every house front in which was clothed from base to gable with this beautiful climber, which is not so common elsewhere.

In fig. 46 may be seen what a fine effect is obtained from Roses growing on the gardener's cottage at Linton Park, near Maidstone, in a garden which is famous for its fruit trees and for its magnificent trees and shrubs, many Conifers in this collection having been illustrated from time to time in these pages.

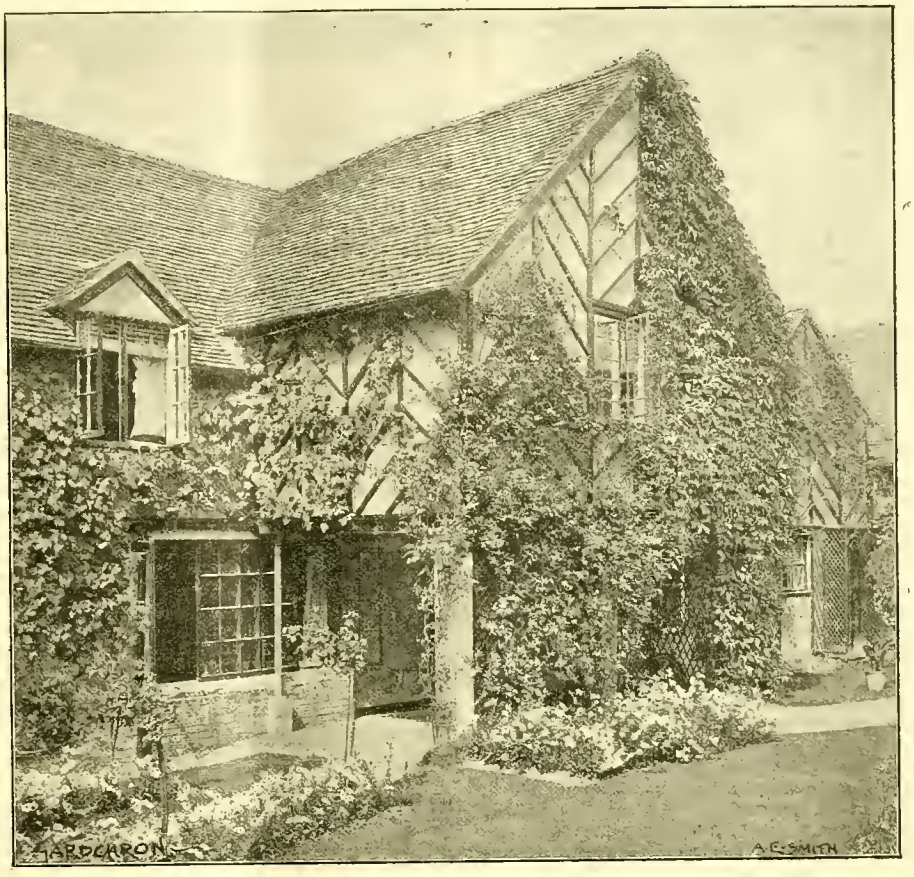

Fig. 45.—Odiham Vicarage, Hants, covered with vines, clematis, ampelopsis, &c.
(From a photograph by F. Mason Good.)

Fig. 46.—The gardener's cottage at Linton Park, near Maidstone.

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT GATTON PARK, REIGATE.

(*See Report of the R.H.S. Show*, p. 107.)

The showy Dendrobiums, which have been slighted for some time past in many collections, now form the principal feature in the well-grown collection of Jeremiah Colman, Esq., at Gatton Park (gr, Mr. W. P. Bound), and their beauty at the present time is very remarkable. The fine specimens which now beautify several of the houses were all grown in one span-roofed house with elevated central wood-work staging, and it is surprising how such a number of plants, now sufficient to adorn the whole of the warmer Orchid-houses, could be contained in the space. Another noteworthy fact is that the greater part of this vast collection of Dendrobes has been raised and perfected at Gatton during the few years which Mr. Bound has been gardener there.

There are several significant points about the management of the Gatton Park collection. In the first place the customary Orchid-pan, or half-pot with holes in the sides, has been abandoned, and plants intended for suspending are grown in pots of the ordinary flower-pot shape, but with the addition of three holes below the rim to take the wire-suspenders. The pots are crocked in the customary manner, and for Dendrobes a sprinkling of fine crocks is added to the compost. The crocks are broken by a machine with a handle to turn like a grind-stone, and in an hour or so as many can be prepared as would have taken a man a day to break in the old way.

For the general run of Orchids one-fifth of decayed leaves is added to the peat and sphagnum-moss, but no leaves are used for the Dendrobiums, which are potted into a compost of two-thirds fibrous peat and one-third sphagnum-moss, a sprinkling of fine crocks being added. Beyond this there is little to be said, except that the golden rule of Orchid-growing, to grow briskly in a warm healthy atmosphere and to rest the plants dry and cool, is observed.

At the present time it is estimated that there are over 10,000 Dendrobium flowers in the collection. There are most of the best varieties of D. nobile, including the clear white D. n. album, and the richly coloured D. n. nobilius, still the best of its class. D. n. Dormanianum has pretty well-rounded flowers, and the blush-white D. n. Colmani is better in shape than its ally D. n. Ballianum. Some other fine forms of D. nobile are also present, procured from cross-fertilised seeds, and which seem to have reverted. Many hybrids of the D. × rubens and D. × splendidissimum class exhibit great improvement on the old forms. The flowers of many of these measure from 4 to 4½ inches across, and exhibit fine tints of rose and purple, with deep claret-purple disc to the lip. The best noted were D. × rubens Gatton Park variety, D. × r. Miroir, D. × r. pulcherrimum, D. × r. grandiflorum, D. × Ainsworthii Colmanii, D. × A. Gatton Park variety, D. × Artemis in great variety, D. × Othello Gatton Park variety, D. × Apollo grandiflorum, D. × Juno, D. × Wiganiæ, and D. × Wiganianum, both represented by several fine and dissimilar varieties; D. × Cybele, D. × Owenianum, D. × Curtisii, D. crassinode album, D. × euosmum, D. × Socius, D. × Snowflake (Cassiope × nobile albiflorum), D. × Schneiderianum superbum, D. × melanophthalmum, and many others. The growths of the stronger-growing are 3 to 4 feet in length, and very stout and vigorous.

Some of the intermediate-houses had a good show of Calanthe × Bryan, and C. × Wm. Murray, in addition to the Dendrobes; and among other things noted were the fine yellow Phaio-Cymbidium × Chardwarense; several Spathoglottis aureo-Vieillardi, and the variety aurea, raised at Gatton Park; and Epidendrum × Boundii (radicans × Burtoni), groups of which in several houses prove it to be one of the finest orange-coloured winter-flowering Orchids.

The Cool Houses.

The largest Odontoglossum house was formerly the span-roofed Chrysanthemum house. It has been elaborately fitted for cool Orchids, a new house being built for the Chrysanthemums. The greater part of the plants in this house are large ones, some of them of gigantic proportions and all with surprisingly large pseudo-bulbs. Propagation is carried to the utmost extent possible with all classes of Orchids, and the general vigour and healthy character of the plants are largely attributed to this fact. Single bulbs often with young growths 2 or 3 inches long are unhesitatingly cut off to make separate plants if required, and nothing but success of the most gratifying kind has to be recorded of the process which the *Gardeners' Chronicle* took the lead in advocating some years ago. A large number of the specimens are producing very strong spikes. A few are in flower, including a pretty form of O. × Wilckeanum, very like a spotted O. crispum; also the beautiful Cymbidium grandiflorum punctatissimum, C. eburneum, Cochlioda Noezliana, some brilliant scarlet Sophronitis of the open-lipped militaris type; Masdevallia polysticta, M. triangularis, M. × Courtaldiana, and a few other Masdevallias; Odontoglossum Rossii majus, O. Cervantesii, &c. In one corner are about three hundred little seedling Odontoglossums. Although highly successful in raising most others, great difficulty was at first experienced with Odontoglossums, but success is now assured. One seedling Odontoglossum has a stout first bulb over an inch high, and others are following.

The Intermediate Houses

contain an excellent collection of hybrid Cattleyas, Lælio-Cattleyas, and a very valuable selection of fine varieties of species. All are alike vigorous, though many were in a bad state when acquired. Mr. Bound's first operation after indifferent plants are acclimatised is to free the front, active portion from the penalty of having to carry the unhealthy back bulbs, and that he considers the most important event in giving a good start to a plant. With a good show of Calanthes, a few good forms of Cattleya Trianæ, C. Loddigesii gigantea, Lælia anceps Schroderiana, Waddonensis, Dawsoni, Hilliana rosefieldiensis, Sanderiana and Stella, and others are in bloom; also Arachnanthe (Vanda) Cathcartii; and in the Cypripedium-house some of the best forms of C. × Leeanum, a remarkably fine C. Chamberlainianum, and others.

The Seedlings.

These are contained in a block of three span-roofed sunken houses, in one of which the seedling Orchids seem to be raised with the greatest ease, the space in the others being used for their growth in the earlier stages and until they pass into the general collection. Here are thousands of hybrid Dendrobiums, Cattleyas, Lælias, Lælio-Cattleyas, and many strange crosses, which were scarcely expected to be effectual. One of the most interesting is the result of crossing the white Diacrium (Epidendrum) with the widely different scarlet-and-yellow E. radicans. The habit of the plant is like a stout, close-growing E. radicans, and it has the same manner of producing air-roots up the stem. One is sending up a spike, so it will soon be tested. The collection of fine Nepenthes and the other things in this great and remarkable garden are also in excellent condition. *J.*

Vanda cœrulea.

A unique specimen of Vanda cœrulea was presented at the last meeting of the Société d'Horticulture de France by M. Marcoz. It resembles the ordinary type in all respects except the colour, which is of a charming rose-tint. There is only one other example extant, which is believed to be in the collection of Baron Schröder. The present example received a Certificate of Merit, and the name of "Souvenir de Mr. Bos." *D. M.*

POTATOS.

Warty Potato Disease and Lime. — Just prior to planting on mounds 4 feet apart a quantity of selected large tubers of some twenty-five new and old varieties of Potatos, I mixed with the soil of each mound a pint of fresh unslacked lime, broken fine. Out of thirty mounds, each having a single plant, one gave the whole of the tubers badly affected with what is called the warty disease. That was a tuber of Vermont Gold Coin. A second tuber of the variety from a different source gave clean produce. Obviously the first-named tuber must have been diseased before it was planted, though perhaps to a slight extent and unnoticed. It might be said that it was the lime application which kept the other twenty-nine plants and produce healthy. Were that so why not the thirtieth also? I fear lime is not in such case an infallible preventive. *A. D.*

Potato-raising.

Mr. Findlay, in a lecture on the development of new breeds of Potatos, recalls the fact that the production of fruit "plums" and seed in Potatos was at one time much more common than it is now, when Potatos are much more often grown for their tubers rather than for their flowers and fruits. Mr. Findlay does honour to the memory of Paterson, and goes so far as to say that he would not give a farthing for any Potato if he could not trace its descent from the Victoria, either on the male or the female side. Speaking of alleged crosses with Up-to-Date, Mr. Findlay doubts their existence, as its flowers when produced are sterile; indeed, he says "it is an utter impossibility for anyone to have got a natural seedling from it." The great Potato-raiser even goes so far as to say that he is "distinctly of opinion that natural cross fertilisation never took place in any part of the world at any period of the world's history." As to the raising of seedlings when obtained, Mr. Findlay describes his method as follows:—

"First, I get a shallow seed-pan, attend to the drainage, fill it up, or nearly, with well-decomposed leaf-mould, to which has been added a little fine sand. I take a flat piece of wood, and beat it down fairly firm and level, and sow the seeds thinly and evenly over the flat and firm surface. That done, I take and sift, after adding more sand, some more of this leaf-mould. The sifting will remove all grit and stones. Now sprinkle a small portion over the seeds, but see that you do it evenly and not over-thick—as near to an eighth of an inch as you can; give also a slight beat down. If the mould is fairly moist, you need not give any water for at least two days. Set your tray, to be out of the way of mishap, into the sunny corner of a cold frame. Put a piece of old newspaper or other paper over the tray, covering up with a piece of glass. Your great care now is to see that you do not allow the earth or mould to get dry; at the same time you must guard against making it too wet. In a week or ten days your seed should begin to braird. You must then give them more light and air. With average care, in a very short time you will have nice plants. When about an inch high, put them out in small pots singly. In another three weeks or so, if the weather is suitable and the season far enough advanced, plant them out in the open where you mean them to be permanently. After this, your

work is all in the ordinary course; only remember this, you must take care when you harvest them to keep the produce of every plant by itself—I mean those you intend to grow again. Fifty per cent. or more will be of no use to go further with; and this 50 per cent. left year by year you, if wise, will further reduce, until at the end of four years you have only one or two left as the sole representatives of your labour and care."

Continuing, Mr. Findlay remarked "that the raising of new varieties of Potatos possessing extra good productive powers was brought about by judicious selection of the parents, and not by promiscuously crossing one plant with another."

CHRYSANTHEMUMS.

NEW CONTINENTAL VARIETIES. — We are rapidly approaching that season of the year when the French raisers of new Chrysanthemums place upon the market their novelties of the previous autumn. The practice nowadays differs somewhat from that observed by the former generation of growers, for the new varieties are generally those that have been submitted to some competent tribunal for adjudication. Hence, allowing for differences of taste and peculiarities in the standard of excellence, the novelties come to us from France now with a kind of hall-mark that was never the case in the days when Simon Delaux, Louis Lacroix, De Reydellet, and other growers of twenty years ago were the providers.

How far this is an advantage the importer must judge for himself. In the olden time there was a great deal of weeding out required, and even now it is more than whispered that the process of selection is as necessary and as severe as it ever was. Tastes differ even in Chrysanthemums, and it is certain to my mind that in this respect the English and the Gallic taste will never be always in accord.

As for the flowers, it is evident that we owe to M. Ernest Calvat a debt of gratitude for a higher average quality, and up to the present he may justly be considered *facile princeps*. But no grower, either seedling raiser or cultivator for show, can hope to maintain for long an undisputed supremacy.

When last in Paris I was not therefore surprised to find that a new competitor had entered the lists, and with startling results. The Marquis de Pins exhibited a fine collection of big heavily-built novelties that were awarded the highest honours, and of these we certainly formed the highest possible opinion. That they would be introduced into this country we felt no manner of doubt, and during the past autumn we anxiously looked for them at our trade collections. For some unaccountable reason and in some mysterious manner the De Pin's seedlings failed to respond to our expectations, and yet we have it on good authority that at the last Paris Chrysanthemum show the novelties shown by this new raiser again took the highest number of first-class certificates and were awarded a medal of honour, these distinctions being conferred by two different bodies—the certificates by the Floral Committee of the National Horticultural Society of France, and the medal of honour by the jury on the day following.

Pressure on our space prevents any enumeration of these novelties. They will be found, with descriptions, in the *Journal* of the National Horticultural Society of France for November, 1904, and selections and appreciations of them from a French point of view in *Le Jardin* by M. Gaston Clément and M. A. Maumené.

Other raisers who have gained new seedlings worthy of commendation are Messrs. Aug. Nonin, De Reydellet, Héraud, Dolbois, Cavron, Rozain-Boucharlat.

A special note is necessary in the case of a new sport called Madame Guillaume Rival. This is a yellow counterpart of Madame Paolo Radaelli, from which it originated. *C. H. P.*

PELORIA IN ORCHIDS.

IT is not infrequently the case when matters become involved beyond hope of disentanglement that we have to extricate ourselves by going back to first principles. So the flower of an Orchid, as we generally see it, is a highly complicated structure, but every now and then we come across flowers which, if they are not actual reversions to an ancestral state of simplicity, are at least suggestive of such a condition. This is the case in a flower of Cœlogyne cristata obligingly sent us by Mr. George Paul. The reduction of the perianth to two whorls of two each, as shown in the illustration (fig. 47), is very common, so is the absence of the lip. Co-related with this condition we have a simpler form and a straighter direction of the column. This peloriate flower was one of several on the same spike that were normal.

FIG. 47.—CŒLOGYNE CRISTATA: REGULAR PELORIA OF FLOWER WITH DIMINISHED NUMBER OF SEGMENTS, &C.

THE ROSARY.

"THE BOOK OF THE ROSE."*

IT is not necessary to occupy much space with eulogy of a book in its third edition. The Rose public has confirmed our judgment when we said that the author was justified in calling his work THE *Book of the Rose*, and indeed, with the necessary limitations and qualifications, it remains so. What gives a special significance to the present edition is the lamentable fact that we shall have no further communications from the author's pen. The preface to this third edition is dated no longer ago than November, 1904, and very shortly afterwards the author died. His work here was finished—finished before his friends could have expected it to be. A better memorial to him could not be afforded than this one erected by himself and acclaimed by all rosarians.

FRAU PETER LAMBERT.

A hybrid Tea descended from crosses made between Kaiserin Augusta Victoria × Testout again crossed with Madame Abel Chatenay. The coloured plate in the *Rosen Zeitung* for December shows a Rose resembling La France or Mrs. W. J. Grant.

* By the Rev. A. Foster-Melliar. 3rd Edition. (Macmillan & Co.)

FORESTRY.

THE SESSILE-FLOWERED OAK.

SIR HERBERT MAXWELL'S note (see p. 82) on this tree refers to me as one of those recommending it for dry ground, apparently implying that its success under the opposite conditions as regards moisture contradicts my view of the sylvicultural value of the tree. All I have done, however, was to note the limited growth of this tree on dry ground, as compared with that of the pedunculate variety. The respective merits of these two varieties on wet ground, or rather ground usually associated with Oak, I do not profess to know much about. But wherever I have seen these two trees on dry sands or gravels, I have noticed the more vigorous growth of Quercus sessiliflora, and that it is much less liable to get stag-headed, or to throw out water-shoots than the other, which is evidently more exacting in the way of soil or climate. *A. C. Forbes.*

NOVELTIES.

"WOOD-MARKING PENCIL."

UNDER the name of "Holzmarkerstift," Messrs. Wolff, of Wevelinghofen, Germany, send us an anilin pencil intended for use on wooden tallies. The inscription made by an ordinary anilin pencil is very apt to "run" when it is used on the moistened surface of wood or paper, and the inscription is liable to be effaced by wet and the agency of the weather. These defects are largely overcome by the use of the pencil which Messrs. Wolff have sent us for trial. They enclosed an oak tally written by themselves of which we have tried to efface the inscription, but without success: and we have ourselves used the pencil on various woods, and find that, given the right sort of wood, the use of the pencil bears out the makers' recommendations. On a polished surface it is not so effectual as on a rougher tally.

THE CASTLES OF DEAL AND WALMER.

[See Supplementary Illustration.]

The historic buildings represented in our Supplementary Illustration are probably well known, at least by name, to most of our readers. Walmer Castle has for centuries past formed the residence of the Lord Warden of the Cinque Ports, the head of that historic assemblage of corporations to which was delegated the defence of that portion of the coast in which they were situated, the barons, as their freemen were called, receiving in exchange for service rendered concessions which have been gradually abolished, until but vestiges remain. The last of these privileges to be taken from them is the residence among them of their Lord Warden, for since the serious illness of Lady Curzon, and since the preparation of our illustration, the powers that be have declared the Castle to be unsuited to modern requirements, though why the defects cannot be remedied by suitable structural alterations we fail to see, for many another old building has had to meet the requirements of modern bye-laws and sanitary authorities.

Walmer Castle, together with its neighbour at Deal, and one which existed still further to the north-east, named Sandown Castle (now in ruins), were built by Henry VIII. for the protection of this part of the coast. They were all built on the same plan, and the view of Deal Castle seen at the top of our illustration serves as a good general view of all three.

The most important, from a garden point of view, is the one at Walmer, long the residence of the Duke of Wellington, and in one of the rooms in which he died. Of this Castle we subjoin a few interesting particulars. The Castle is fully exposed to the sea, and the guns which now repose so peacefully on the ramparts command a full sweep of the historic roadstead named the Downs, which are rendered a safe anchorage for ships by reason of the natural breakwater on their eastern side formed by the dreaded Goodwin Sands.

The lawn seen in the foreground of our picture is but a 100 yards or so in width, and separates the building from the beach and sea. The environment of Walmer Castle is especially striking, for in addition to the magnificent seascape, some good land scenery obtains in the immediate neighbourhood, a spot on the land side known as The Glen being charming, while the view seen from Hawk's Hill, an elevation adjoining the south end of the Castle grounds, is most picturesque. The policies of the Castle are extensive and well wooded, but the prevalence of cutting easterly winds, especially in the spring-time, has told injuriously on the vegetation, especially in the unsheltered parts of the grounds. The lawns are studded with trees of historical note, by reason of having been planted by historical men—among them a grand specimen of Lime, planted by William Pitt, while close by is a Tulip-tree (Liriodendron tulipifera) planted by his rival, Fox. Another is a Willow raised from a cutting which the great Duke obtained from Napoleon's grave at St. Helena. Higher in the grounds is a paddock, in which there are some fairly good groups of Conifers, including a good example of Cedrus Deodara and of Abies Pinsapo. The view from this part of the grounds is very fine, and lends itself to further development. The park is broken up very pleasingly by groups of evergreens, among which some clumps of Evergreen Oak are really excellent features. Arbutus Unedo also flourishes well in this part of the grounds.

The old moat has been laid out with shrubberies, and the walls with a south aspect have been planted with trained fruit-trees, principally Pears.

Our view of Deal Castle shows the trees whose growth has reached the highest limits of the ramparts from the moat. The large specimens of Fig-trees which luxuriate in the old moat and annually produce crops of excellent fruit should be noted. One of these trees at Walmer Castle, of the old Brunswick variety, and near to the main entrance, has rooted into the walls, evidently deriving its nourishment from the chalk with which the walls are encased, the lower portion of the tree being quite dead.

The kitchen and fruit gardens at Walmer Castle are extensive and are necessarily well protected by high walls and wind-breaks; there are also some excellent Yew hedges protecting the herbaceous borders. The walls on the sea side are covered with Irish Ivy, which is very well kept. Our illustrations are from photographs by Messrs. Franklin & Son, Deal.

The office of Lord Warden, as announced since our illustration was prepared, will in future be held by H.R.H. The Prince of Wales, whilst Walmer Castle itself will, subject to certain restrictions, be open to the public.

The Week's Work.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Early Peaches.—In houses where the fruits are beginning to swell freely the temperature may be raised to 55° or 58° at night, syringing the trees freely twice on bright days, but once only on dull or cold days. If a good crop of fruits has set, remove first all those that are on the underside of the shoots, leaving sufficient on the top and sides of the shoots to furnish a crop. Disbudding should be done by degrees at intervals of a few days, according to the amount of vigour possessed by the trees; the more vigorous the trees may be, the more freely may the young shoots be removed. Weak-growing trees should be encouraged to make growth by the exercise of more patience in carrying out the work of disbudding, in order not to cause a check to the tree. No more shoots should be allowed to remain permanently than are necessary to furnish the trees. Afford liberal supplies of tepid water to healthy trees as soon as the fruits have been thinned, as it is almost impossible to over-water Peach-trees growing in well-drained, inside borders. Where the trees are of considerable age, loosen the surface soil by means of a fork, and apply a mulch. In watering such trees apply diluted liquid-manure, and occasionally a sprinkling of Kirk's Vine Manure according to the directions issued with this manure, which I have found to be excellent for all fruit trees. Vigorous-growing young trees must be given no stimulants or the growth will become gross and unfruitful. If green-fly makes its appearance the trees may be fumigated lightly, care being taken to ensure that the foliage is quite dry before this operation is commenced.

Succession Peaches.—Houses that were closed at the beginning of the year should be kept well supplied with atmospheric moisture by syringing and damping the floors, &c., as often as the condition of the weather outside renders this necessary. The temperature at night should be 50° while the trees are in flower, and a free circulation of the air in the house is necessary, syringing being discontinued for a time. Peach-flowers generally set freely enough on healthy trees, but it is safest to pass a brush or rabbit's-tail over the flowers every day at noon.

Houses containing Later Trees may be ventilated night and day in order to retard the trees as long as may be necessary. Afford water freely to the roots if they are growing in inside borders. Keep the trees free from Aphis, and as soon as the flowers begin to expand employ a little warmth in the water-pipes.

Late Vines.—Vines which were cleared of fruit in December or early in January should by this time have been pruned, the houses in which they are growing should have been cleaned, and the borders top-dressed. These houses should be kept cool, and the Vines allowed complete rest. Such varieties as Gros Colmar and Lady Downes require a long season of growth, and should not be started later than the middle of February. The best time at which to apply artificial heat in these houses is the commencement of the season. This can be discontinued later if the summer proves hot and dry. The growing points of strong young Vines should be brought down to a horizontal position or even lower, in order to encourage the Vines to break evenly.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, S.W.

Thunias require potting annually, and as soon as the new growths develop from the old leafless stems this work should be accomplished without delay. Prepare a compost of two parts peat, one part each of fibrous loam and moss, a sprinkling of dry pulverised cow-dung, and some sand and small crocks to allow of proper aëration. Carefully remove the old potting material from the roots, also any of the roots that are dead, after which one or more of the pseudo-bulbous stems should be placed in position in their new pots, which should be rather more than half filled with drainage material. Tie the stems to a central stake, and fill in with the compost to near the rim, arranging the bases of the new growths just beneath the surface. Place the plants in a light part of the East Indian-house, withholding water at the roots until the new roots have entered well into the soil; they should, however, be sprayed overhead once or twice during the day on all favourable occasions, and the atmosphere should be kept moist by damping the surroundings. As growth advances increase the supply of water at the roots, and when the plants are approaching the flowering stage afford water in abundance, after which period they should be gradually inured to drier and cooler atmospherical conditions, but still be allowed plenty of water to the roots. When midsummer arrives the plants may be stood outside and allowed full exposure to sunlight. Propagation may be effected by removing half of each of the old stems and almost severing the removed portion between every other node, and then laying them on a damp surface in a warm house. When new growths are produced, insert the cuttings in small pots with a portion of the old stem attached, and grow them on in a brisk heat.

Ventilation.—The disparity between day and night temperatures at this season is often very great, frosty nights being followed by bright sunny days, with perhaps piercing cold winds. Under these conditions great care is needed in guarding against sudden fluctuations of temperatures inside the houses. The practice of damping should be general in the morning, and if the houses require it, the process may be repeated in the afternoon. Ventilation during windy weather should be confined solely to the wall ventilators on the sheltered side of the houses.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

The Rockery.—The arrangement of the stones should be on natural lines, and with the object of obtaining suitable positions for all classes of alpine plants. A soil containing a good proportion of humus will be the more suitable for general planting, but for special subjects special composts will be necessary. See that the soil is made firm, and do not allow any spaces to remain unfilled with soil. In some places retaining walls are necessary. These if built at a slight angle and with some prepared soil spread on each course of stone, can be made interesting by planting as the work proceds many desirable alpines, or small plants can be dibbled in the crevices after the wall is built. Plants suitable for this purpose, and that will thrive in sunny fissures of a wall-garden include Achillea argentea, Androsace lanuginosa, A. sarmentosa, Antirrhinum glutinosum, many Campanulas, Cistus in variety, Cyananthus lobatus, Dianthus, Saxifraga longifolia, Sedums, Sempervivums, &c.

Many annuals and spring-sown perennials are also suitable for wall-gardens, such as Anagallis Phillipsii (with flowers of gentian-blue colour), Saponaria ocymoides, Sedum cœruleum, Corydalis thalictrifolia, Alpine Poppies, Lychnis Haageana, &c.

Roses.—Should spring planting have been decided upon, prepare the beds for the purpose by incorporating into them some good loam obtained from the surface of an old pasture, and a good dressing of stable-manure. See that thorough drainage of the bed is provided. The work should be performed in dry weather, and when the soil is in a suitable condition. The habit and vigour of each variety should be taken into consideration when planting, and distances allowed between the plants accordingly. Measure and mark off the stations allotted for each plant. Prepare suitable holes for the reception of the roots, and place some fine soil among the fibrous portions, but on no account apply fresh manure. When planting dwarf-growing varieties, allow the point of union between stock and graft to be buried 1 or 2 inches below the surface of the soil.

Lawns that still require manuring should have the manure applied without delay. Remove moss, if present, with an iron rake, and top-dress with some fine rich soil containing lime. Level any inequalities of the surface, and use the roller on all favourable opportunities.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Propagating Stove Plants.—Steps should now be taken to proceed with the propagation of fine foliage and stove flowering plants in good earnest. Writing upon this subject, a remark with regard to a pest commonly known as "mite," described some time ago in the *Gardeners' Chronicle*, may not be out of place. This I believe to be responsible for many failures in the culture of tender plants. It does its work so effectually before the mischief is discovered that every opportunity should be taken to preserve the plants perfectly free from the pest. Immerse cuttings of plants of tender growth in a solution of "Quassia Extract," and allow them to remain for some time before inserting them in the cutting-pots. Growing plants can be dipped in the same liquid at regular intervals as was recently advised for Jacobinias. Batches of Clerodendron fallax, Allamanda neriifolia, and Dipladenia boliviensis, if propagated now, will make a bright and useful display towards the end of summer. Seeds also of Clerodendron fallax should be sown at this time singly in pots, and raised in heat. These will make much finer plants than those raised from cuttings, and will flower later.

Caladiums having remained dormant through the winter should be examined. Shake away the old soil from them, and repot them in a rich compost consisting of three-parts good fibrous loam, one-part peat and one-part of dried well-broken cow-manure, to which should be added sufficient broken charcoal and silver sand to keep the whole sweet and porous. The corms should be placed moderately deep in the pots on a layer of silver sand, and the soil pressed firmly round them with the fingers to within an inch of the surface of the pot. Do not use a potting-stick. They should be placed in a Cucumber-house or similar structure where plenty of heat and moisture are maintained. Afford very little water until the soil is well filled with roots. Very fine plants may be obtained by liberally feeding and potting-on the plants, but to obtain very large specimens the strongest corms should be selected.

Tuberous-rooted Begonias.—Shake the old soil away from the tubers, and lay them bottom upwards in boxes on a layer of sand or finely-sifted leaf-soil. Then place the boxes in a house having an intermediate temperature, and lightly syringe them. By this method no water can lay in the hollow of the crown of the tubers, but they should be examined frequently, and potted when growth and root-action have fairly commenced. Seeds of tuberous-rooted Begonias and Gloxinias should be sown without delay. Great care will be required in this operation. Finely-sifted old potting soil should be used, and well-drained pots or pans. If the soil is moderately moist at the time of sowing, water need not be applied for the present. Fill the receptacles with mould to the top, and firmly press the surface before sowing the seeds. After the seeds are sown the surface of the soil may be gently pressed by means of a smooth piece of wood. Glass should be placed over the pans to preserve the seeds from drip and insects. Place the pans in a warm-house for the seeds to germinate.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Seed Potatos.—Tubers selected for this purpose are usually those that are of insufficient size for culinary purposes. Every individual "set" should be furnished with a short, strong sprout, or even two sprouts, before being planted. This is of equal importance both for early and for main crop varieties. In order that these may develop, the tubers should be placed in boxes or in trays; a convenient size for these latter is 2 feet 6 inches in length, 18 inches in width, and 4 inches in depth; and they should be made so that they can be piled on top of one another, with spaces between each tray to allow the light to reach the tubers. The seed tubers should be stored in a cool, airy place from which frost can be excluded. The eyes will soon commence to sprout, of which all but two of the stronger on the upper end should be removed.

Soil for Potatos should always be in a state of good cultivation. The most suitable is that which has been well manured the previous season, and early in autumn was turned up and afforded partially-decayed leaves. At the time of planting our Potatos we apply lime freely, and soot is applied during the growing season. The selection of varieties should depend in a great measure upon locality; some varieties succeed well in one district and some in another. Here, last season, the varieties Improved Ashleaf, Duke of York, Early Puritan, Up-to-Date, and Northern Star produced abundant crops of good quality.

Storing Root-crops.—Onions stored for late use should be placed in an open shed, preferably behind a north wall. Turnips (if stored), Carrots, and Beet-root should all be examined—a work that can be performed in bad weather.

Tomatos.—Sutton's Winter Beauty is an excellent variety for fruiting in winter. Tomato plants are now benefiting from the effects of the lengthening days, and the flowers will soon be opening freely. In the morning, when the atmosphere is dry, tap the individual plants in order to pollinate the flowers, and maintain a moderately-dry atmosphere with a free circulation of air at a temperature of 60°. Keep the roots of the plants only moderately moist. Young plants raised from autumn-sown seeds should be given a position in a light, well-ventilated house. As growth proceeds repot the plants in 8 or 10-inch pots, using a light, porous compost, warmed to the temperature of the house.

Parsley.—Where hard daily pulling is the practice through the winter months, even where good provision was made at the proper time, the stock becomes almost exhausted in the new year. Upon clearing ground some weeks back of this herb the large roots were lifted, plunged in a mild hot-bed, and are now furnishing Parsley in considerable quantity. Seeds may now be sown on hot-beds or in boxes in warm fruit-houses. The seedlings will be useful for transplanting in sheltered open positions, when large enough to handle. A good variety of Parsley should be obtained by carefully selecting the seed from the best plants.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

American Blight or Woolly Aphis on Apple-trees.—The affected part should be scraped with a knife and all dead and decaying bark removed; next apply a few drops of coal-tar essence in hot water, well scrubbing the wound with it; this will destroy the insects. In order to prevent future attacks, work into every crevice or hole some warm colza oil, using a stiff painter's brush for the purpose.

Pear Maggot.—If trees were attacked with the Pear midge last season, remove the surface soil to the depth of 3 inches and burn it. If a large number of trees has to be done this operation would be a long one. The larvæ bury themselves in the ground and soon become cocoons. Many of these may be destroyed by frequently hoeing the ground under the trees, or a heavy dressing of kainit or sulphurated lime may be applied. This will furnish food to the trees as well as kill the insects. The same application may be employed with much success for trees planted on grass.

Codlin Moths may be discovered secreted below the bark of old trees; if not previously done this should be scraped off and the trees sprayed, limewashing the trunks with wash in which sulphur has been mixed. Small pieces of Linseed cake placed in 60-sized pots and just covered at the base of the tree will serve to capture many. The traps should be examined frequently, inserting the whole in a bucket of water so that none of the moths may escape.

Strawberries.—Commence preparation for making new plantations by trenching the ground, working in two layers of manure, one at the bottom of the trench and the other between the first and second spits. If the subsoil is of a poor description do not bring it to the surface, but if it is heavier than the staple soil, the shovellings from the bottom of each trench should be thrown up, for the finest Strawberries are produced upon soils of medium stiffness. Strawberries require firm soil, therefore the ground should be prepared a considerable time before the plants are put out that it may thoroughly settle. In gardens where late forced plants are usually planted out, the ground prepared as above recommended will become firm by the time this work will be commenced. Forced plants put out in summer are preferable to spring planting if the latter plants are allowed to fruit in the first season, when they should be building up strong crowns for the ensuing season. If space is very limited a crop of early Potatos may be raised on this ground, which, being so heavily manured, will not be impoverished by such a crop. The Potatos should be lifted by July, and the earliest Strawberry runners, which have been layered in small pots or turves, planted out immediately, choosing showery weather if possible for the purpose. Examine old plantations, and if the birds have scratched the manure over the crowns remove this and expose the crowns. On rich land a slight sprinkling of salt may be applied, repeating the operation when the fruits have set.

Protecting Fruit Blossoms.—Buds upon Apricot-trees have pushed considerably, therefore have protecting material in readiness, and if any tapes and rings require to be sewn let this work be done at once. A clumsy but effectual way of making a protector for fruit-blossoms upon an individual tree is to tie together a quantity of hay bands so as to form a net. In an old garden of note this system has been successfully practised for many years. Glass copings are better left down at present, as their use would tend to hasten the buds.

THE APIARY.

By CHLORIS.

Entrances, &c.—Keep the entrances so that only one bee may pass at a time, and keep them clear of dead bees. Should a very bright day come, and the bees are flying thickly, then the body-box may be lifted from the floor-board, and this latter be well cleared of *débris*.

Take Stock.—Most of us leave this too late, or forget our wants until the honey-flow is on. To avoid disappointment it will be well during this slack season to ascertain our needs, and order the materials at once of any of the respectable manufacturers. Having received the goods we may then fit up frames with whole sheets of foundation, and thus be ready for the swarms; also fit up the section-racks. How many of us can recall the times we have vowed to have everything in readiness for swarms! The result of neglect is often that foundation is not firmly fixed, and if the weather becomes hot it slips, and brood is destroyed.

APPOINTMENTS FOR THE ENSUING WEEK.

FRIDAY, FEB. 24—Royal Botanic Society Meet.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Hardy Border Plants, Azaleas, Roses, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Azaleas, Rhododendrons, Palms, Roses, Herbaceous Plants, Lilies, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 —1,354 cases Japanese Liliums, Davallias, Iris, Pæonies, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 3 o'clock.—At Stevens' Rooms at 12.30 P.M., Roses, Lilies, Azaleas, Rhododendrons, Palms, &c.

THURSDAY and FRIDAY NEXT—
Final Clearance Sale of Nursery Stock at Hassocks Nursery, Hassocks, Sussex, by Protheroe and Morris, at 12 o'clock.

FRIDAY NEXT—
Imported and Established Orchids at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.30 o'clock.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·8°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, February* 15 (6 P.M.): Max. 51°; Min. 46°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 16 (10 A.M.): Bar., 30·3; Temp., 50°. Weather—overcast and dull.
PROVINCES.—*Wednesday, Feb.* 15 (6 P.M.): Max. 48°, Guildford; Min. 45°, N. of Ireland.

The Gardeners' Orphan Fund.

IT is to be hoped that the warning note uttered by the Chairman, Mr. May, at the Annual Meeting held on the 10th inst. will be so earnestly heeded that at the next annual meeting less anxiety may prevail. Everyone admits that the objects of the charity are excellent, and at no time have we heard any complaint as to its administration, and yet the miserable tale has to be told that this year the Society could not, with due regard to its existing responsibilities, place one-half of the number of eligible candidates on the pension list. This circumstance is, perhaps, not surprising, however lamentable it may be, as a similar incapability occurs in most societies of the kind. What strikes us as more deplorable is the fact that the annual income from subscriptions does not increase, that the regular subscribers are falling off, and that their places are not filled, as they should be, in a higher proportion. It may be said that at the annual dinner the deficiency is made good. So it has been in the past, and so we hope it may again be; but a precarious and uncertain source of income is by no means so satisfactory as an assured revenue from regular subscribers. It is not spasmodic generosity that is wanted so much as the systematic performance of duty. It is humiliating to feel that we have to depend on the charity of the benevolent when we ought to be able by our own exertions to meet our obligations either to those who in their declining years need our assistance, or to those helpless ones who in the beginning of their lives have been deprived of their natural protectors.

Hitherto it has been the practice, at the discretion of the Committee, to allot to the guardians of the most necessitous of the unsuccessful candidates at each election a small sum (2*s.* 6*d.* weekly) as a gratuity until, by gradual accretion of votes, the orphan succeeds in securing election to the full benefit of the fund. We were told on Friday last that unless the annual subscriptions were augmented this practice might have to be curtailed or even discontinued; so that, instead of coping with the distress in our ranks, we should actually be doing less than our predecessors. That we must, and as we think ought to, look to our own community rather than to outsiders is shown by the fact that a special appeal made to a large number of ladies supposed to be interested in gardening, and whose sympathies, it might be presumed, would go out to the orphans, resulted in the receipt of a sum not much more than sufficient to pay the expenses connected with the issue of the circular. Surely it is only necessary to lay these facts before the gardening public to secure a largely-increased revenue for the Royal Gardeners' Orphan Fund!

THE VEITCH MEMORIAL TRUST.—At a meeting of the Trustees, held on the 9th inst., it was resolved that the sum of £50 be presented to the Trustees of the Lindley Library for the general purposes of the Trust. A Bronze Medal and £5 are also offered for competition at the Royal Caledonian Horticultural Society, on September 13 to 15 next, for six dishes of fruit, flavour and quality to be the primary consideration. A similar prize and medal are to be awarded for the three most distinct kinds in any one of the exhibits of vegetables, the object being to reward superior cultivation. Silver medals are also offered for improved methods of packing and transmitting garden and orchard produce, and for improved methods of affording shelter and protection to outdoor plants, as well as of heating, ventilating, and shading glass structures.

"FLORA AND SYLVA."—The second volume of this elegant publication has now been issued. The paper, type, illustrations, and binding are all alike excellent of their kind. The text is varied, and much of it of permanent value. Why Correas should be called "Australian Fuchsias" is not very obvious, for the resemblance is of the most superficial character, and in structure and lineage they have nothing to do with Fuchsias, while the name Correa is surely unobjectionable. "Cape Cowslips" as a substitute for Lachenalia may be objected to on the same grounds, but even more strongly. Vernacular names are most desirable when they are sanctioned by long usage, and not modern coinages, and especially when they are accurate, for in gardening as in other matters we should strive after truth as strenuously as after beauty. Printer's errors, like "filipenaulina" and "Aubretia" are, as we know by painful experience, never likely to be completely eliminated, but "Guelder Rose" for Gueldres Rose is something more than a typograpical slip. Here again the Viburnum has about as much or as little relation to a Rose as a Cabbage has to a Cucumber. Doctors differ in more important matters than etymology, as illustrated by an *obiter dictum* of Sir HENRY THOMPSON, who is here cited as having said that Strawberries of all foods known to mortals are those most conducive to the formation of lithic acid. This is a statement that should not be made without confirmatory testimony. We suspect it to be in conflict with general experience, and it certainly does not tally with the allegation made by LINNÆUS that he cured himself of the gout by eating Strawberries. So far as we know, LINNÆUS offered no more evidence on the subject than did Sir HENRY THOMPSON. Apart from its attractive appearance, the volume before us will be of substantial, permanent value by reason of the numerous monographs of plants of garden interest that it contains.

FOLIAGE BEGONIAS.—There is an interesting article on this subject, copiously illustrated, in the last number of MÖLLER'S *Deutsche Gärtner-Zeitung*. These handsome plants deserve more attention than they get.

"CUNARD CHRISTMAS AND NEW YEAR ATLANTIC SOUVENIR."—This publication for 1904—1905 contains an interesting account of the fine modern ships of to-day as contrasted with those of even a quarter of a century ago. Ocean travellers are now surrounded with not merely comforts but luxuries, and one of the additions during the season to certain of the Cunard liners is the fitment to them of the Marconi telegraphy apparatus by which they are enabled to receive constant messages from England and America, even when equi-distant from both continents. A vessel is now being built for this service to be propelled by turbine engines. The *Souvenir* includes some light literature for holiday reading. It is obtainable from the Company's offices, 8, Water Street, Liverpool.

KEW.—An "Appendix" to the Bulletin has recently been issued containing a list of members of the respective staffs of the botanical departments at home, in India, and in the Colonies.

MARKET MEASURES.—For purposes of conversion the Board of Agriculture, in their weekly return of market prices, have adopted the following rates:—

Apples, "bushel" = 42 lb.; "pot" = 63 lb.; "case" = 40 lb.; "barrel" = 140 lb.
Pears, "case" = 20 lb.
Beet, "pot" = 70 lb.
Brussels-Sprouts, "pot" = 40 lb.; "hamper" = 60 lb.
Onions, "Dutch bags" = 110 lb., taken as 1 cwt.: "Valencia case" = 120 lb.
Spinach, "bushel" = 24 lb.
Turnips, "pot" = 60 lb.
Potatos, "load" = 252 lb.; a "hag" of foreign Potatos = 1 cwt.

CASTILLOA RUBBER.—According to a note in the *Tropical Agriculturist* for January, the samples of rubber from Castilloa grown in Ceylon are the "finest yet seen." The rubber was procured by a simple method from quite young trees.

"GIFTS."—We have on more than one occasion pointed out that the remedy for illicit commissions rests with the nurserymen themselves, and if they would co-operate in the same way that they did several years ago in abolishing the more than questionable practices then prevalent in the seed-trade they would be equally successful now. One very great difficulty however remains to be overcome: How can the Dutch merchants be prevented from offering a discount to the gardener—a discount sometimes larger than what is given by our own firms? We have called attention to this matter before, and now we see that the *Agricultural Economist* is taking up the question. It is to be hoped that the newly-established Gardeners' Association will attend to this reform among others that are needed.

THE HANLEY (STAFFS.) HORTICULTURAL SHOW AND FETE.—Mr. JOSEPH KENT having retired from the office of Secretary, Mr. WM. POULSON, Town Hall, Hanley, has been appointed to the position.

ABERDEEN AND NORTH OF SCOTLAND AGRICULTURAL COLLEGE—LECTURES TO GARDENERS.—Under the auspices of this College several courses of lectures on various subjects have been given during the present session. The Governors of the College have just arranged for another course on "The Elementary Chemistry of Soils and Manures" for the benefit of horticulturists, professional and amateur. The lectures, which are to be delivered by Mr. JAMES HENDRICK, in the Agricultural Department of

Aberdeen University, on the evenings of February 21, 28, March 7, 14, 21, and 28 (Tuesdays), at 8 o'clock, are intended to assist gardeners and others in and around the city of Aberdeen to obtain scientific knowledge of the growth of plants, of what plants derive from the air, and of what they derive from the soil. The nature and composition of the soil itself in relation to air, water, fertility, &c., will be explained. Detailed information applicable to the special conditions required in the case of gardeners in regard to the use of manures, natural and artificial, will be supplied, while the results of the best methods for combating insects, fungus, and weed pests will be explained. Employers are recommended to make an effort to induce as many of their *employés* as possible to attend the course. No charge will be made for attendance on the lectures.

ENGLISH HOLLY IN AMERICA.—We learn that considerable quantities of berried Holly find their way to the American markets. We can hardly look on this fact with complacency, as we fear it will entail the mutilation and spoliation of one of our greatest ornaments. For once we should be glad if our cousins would put on a heavy import duty—but then we have no Holly to sell!

SOLANUM COMMERSONI AND EDIBLE POTATOS.—In a recent issue of the *Comptes Rendus* M. EDOUARD HECKEL speaks of Solanum Commersoni, Dunal, and its great variability under different conditions, and suggests its connection with the cultivated Potato, from which in some of its forms it can hardly be distinguished. Mr. HECKEL observes that:—"1st. S. Commersoni presents as many different forms as does the true S. tuberosum, therefore this species has certainly played an important part in the origin of our ordinary Potatos. 2nd. The striking parallelism existing between the same series of variations seems to disprove that close connection between the two original species which was so strongly urged by BAKER (who grouped all the forms of tuberous Solanums as simple varieties of one type—S. etuberosum). 3rd. The complete and permanent variations supervening upon alteration in the surrounding conditions, especially evident when COMMERSON'S species was grown in a moist situation such as it inhabits naturally, show how considerable is the range of variation in certain species, and how the phenomena of 'mutation' observed by DE VRIES may be so important that in two generations all the characteristics peculiar to a species may be lost. 4th. The violet variety of S. Commersoni seems actually, by its great productiveness (63·000 kilogrammes per hectare) and its preference for damp soils, to suggest its profitable culture in marshy soils, hitherto almost unproductive."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

CUCUMBER DISEASE OR "SPOT."—Until last year I have not had any personal experience of the dreaded "spot" in Cucumber-plants, and I had hoped that I should never again have a similar experience, but unfortunately the disease re-appeared in the plants in the month of July! As soon as I detected the small spots (about the size of the head of an ordinary pin at first), I dusted over the affected leaves with flowers-of-sulphur, with a view of destroying the fungus then on the leaves, as well as to render the latter less liable to further attacks. Finding that this did not have quite the desired effect, I cut the entire spots clean out of the leaves, or removed the leaves altogether where badly affected, but to no useful purpose, as the spots continued to spread not only in number but also in size—appearing on the young leaves as soon as unfolded! In each case I observed that the "spot" appeared on the plants near the door at the colder end of the house (150 feet from the heating apparatus). The disease generally appears after fire-heat has been dispensed with, say, some time in June, and sometimes before, when the quantity of fuel used in the furnace is not sufficient to warm the pipes at the top end of the house, with perhaps the same quantity of moisture distributed therein as when the water in the pipes was heated to the boiling point the entire length of same. I may say that I have never heard of the "spot" attacking Cucumber plants in private gardens, and I would at the same time remind the readers of the *Gardeners' Chronicle* that in private places Cucumbers are generally afforded artificial bottom and top-heat during the whole period of growth. Hence their immunity from "spot." Moreover, the plants in private gardens are cropped lightly, the young fruits being thinned out, the object being to obtain a regular supply of a few dozen fruits a week from a given number of plants for, say, a period of six months, whereas the object of the grower for market is to take all the saleable Cucumbers that the plants under skilful and generous treatment are capable of yielding in as short a time as possible; the plants too, being grown without bottom-heat of any kind whatever. Thus it will be seen that Cucumbers in private places and in market gardens are grown under very different conditions. As the result of my cogitations regarding the "spot" in Cucumber leaves during the last two seasons, I have arrived at the conclusion that a preventive, if not a remedy, is to be found in the vaporising of the Cucumber houses with sulphur once a fortnight from the end of April until the plants have done bearing. By the use of Campbell's Sulphur Vaporising Machine, every particle of leaf and stem growth will be finely and evenly covered with the sulphur deposit and with which the atmosphere is as a matter of course also impregnated to such an extent as to kill and further prevent the appearance of the fungus during the intervals indicated. No more moisture should be distributed in the Cucumber house, especially after the fires have been let out, than is absolutely necessary for the well-being of the plants. When the old ridges are removed from each house preparatory to starting a fresh batch of plants, sulphur should be burnt therein so as to kill any insect or germs of disease that may be in them, the wood and glass being then washed with water and the brickwork with hot lime, so as to make them clean and sweet before the new soil with which to form the ridges is wheeled in. I may say at once that, so far as my observations and conclusions based thereon count, the cause of "spot" appearing on Cucumber-leaves is not to be attributed to the composition and condition of the soil in which the plants are growing under expert management, but, on the contrary, to the fact of unfavourable external as well as internal atmospheric conditions occurring at a time when the vigour and energies of the first batch of plants have become nearly exhausted through the production of heavy and continuous crops of fruit during the previous ten or twelve weeks, the plants being consequently more likely while in that condition to experience a check from a sudden and unfavourable change taking place in the weather after fire-heat had been dispensed with, than a batch of young plants just coming into bearing would be. Neither, in my opinion, is the remedy for "spot" on Cucumber-leaves to be found in the application of liquid nostrums at the roots. Viewing, from a practical point, the "Practical Directions for Treatment" given by Mr. George Massee in his article published in a recent volume of the *Journal of the Royal Horticultural Society*, entitled "To Protect Cucumbers and Tomatos from Fungus," and quoted in Mr. Owen Thomas's interesting article (p. 439), I am unable to see what possible good could result from the carrying out of the directions given in the above-mentioned article; such, for instance, as the advice given as to the watering of Cucumber-plants, when a fortnight old, every third day for six weeks with a solution consisting of 1 oz. of sulphate of copper dissolved in 50 gallons of water, afterwards applying a stronger dose every fourth day. This advice should be carefully considered before being acted upon; even the application of rain-water only to young plants a fortnight old every third day may have a bad effect. *H. W. Ward.*

CEDRUS DEODARA VAR. ALBA SPICA.—In reference to this variety (see p. 76), the trees are growing in a position facing the west, and until three years ago they were much protected from north-east and east winds. The two trees growing here came from Messrs. John Waterer & Sons' nursery, Bagshot. If Mr. Page happens to be in the vicinity of Haslemere at any time, I shall be very pleased to show him our trees. *Thos. Harris Lower Grayswood Gardens, Haslemere.*

CRYPTOMERIA JAPONICA.—I have much pleasure in giving your correspondent, Mr. A. C. Forbes, the cubic contents of the above tree, quarter girth measurement, which is 64 by 8 feet, 28 ft. 5 ins. over bark. The timber, however, is not sound. The heart is decayed for some 16 ft. from the base of the tree. The cubic contents would be much more if the tree tapered less. Growth has been less rapid for the last fifteen years, the tree not making more than from 12 to 14 inches, instead of from 18 inches to 2 feet each year, as formerly. I thank Mr. Bartlett for his note on the Pencarrow tree. Mr. Elwes writes me that he measured one slightly larger at Killerton. It would be very interesting to know the growth made by the Coollattin tree since 1891. *C. Page, Dropmore Gardens, Bucks.*

—— Since reading the remarks by Mr. Page and other correspondents, I have measured a specimen of Cryptomeria japonica growing in the grounds here. Its height is 45 feet and its girth 8 feet at 5 feet up, and 11 feet girth at ground line. The diameter of the branches is 35 feet. There is no account of the time it was planted, but from inquiries I have made it appears to have been planted by the late Sir Richard Green Price, Bt., in 1862. *W. Palliser, Norton Manor Gardens, Norton R.S.O., Rads.*

JASMINUM NUDIFLORUM.—In answer to the enquiry on p. 90, I may mention that there are in these gardens two large plants growing in warm and favourable positions. As a rule both of them flower profusely each year. This season, owing to the absence of frost, the plants have presented a mass of well-developed and apparently perfect flowers for the past eight or ten weeks. In previous years I have never noticed fruits at any stage of growth, nor have I seen insects of any kind on the plants when in bloom. To-day I have examined several faded flowers, but did not discover one that showed any sign of fertilisation. Occasionally we find a bunch of berries on the large-flowering variety of J. officinale, but this is quite the exception. *H. Stark, Crag Head, Bournemouth.*

ST. JAMES'S HALL AND ITS HORTICULTURAL ASSOCIATIONS.—The closing of this well-known hall for public purposes serves as a reminder that the first National Rose Exhibition was held here on July 1, 1858; and on September 23 in the same year a National Dahlia Show. Subsequent annual national exhibitions were held, either at the Hanover Square Rooms, the Crystal Palace, &c., and, though the National Rose Society and the National Dahlia Society were not formed for a few years afterwards, there is no doubt that the idea of permanent societies took its inspiration from what was done at St. James's Hall. Of those who took part in these two exhibitions forty-six years ago, how very few indeed survive! *R. D.*

THE GARDENERS' ORPHAN FUND.—Coming fresh from the recent annual meeting of the subscribers to the Orphan Fund, I took the opportunity on the same evening, at a largely attended meeting of the members of the Kingston Gardeners' Society, to lay the claims of the Fund before them, and earnestly begged the Society to take some action in support of its objects. The promotion of a concert was not favoured, as here we are flooded with such entertainments. I suggested that a collection in small silver and coppers be made at each meeting of the members, and then at the expiration of the session the entire amount thus obtained should be sent to the Fund. That suggestion was so far favoured that the hat was at once passed round, and 8*s.* thus collected. That so good a result will follow at each meeting I do not anticipate, but if some 2*s.* or 3*s.* be collected the strain on the members' pockets, and no gardener is rich, will be

infinitesimal. Nevertheless a series of regular meetings might enable a goodly sum to be realised during each year. I told the members that when the annual election of orphans took place they could ballot for the privilege of representing the society as electors. If a society like ours could, for instance, raise, say £3, thus obtaining twelve votes, a good proportion of members would enjoy the privilege of being electors, and become keenly interested in the Orphan Fund and its operations. There are scores of these mutual improvement societies in the kingdom, as reports of proceedings in the papers from time to time show, but very few are subscribers to the Orphan Fund. Did all of them but make collections at their meetings from time to time, in the way we propose to do here, a very large sum might in that way be added to the Fund's income yearly. *A. Dean.*

EARLY PEACHES.—My experience with the variety Alexander quite agrees with that of Mr. Jordan. Some years ago, when taking charge of a garden in the Midlands, I found a young tree of "Alexander" growing in the large Peach-house among several others. As usual with young trees it had made a quantity of strong sappy growths; by judicious root-pruning and partial lifting it was brought into a bearing condition. When re-arranging the large house a year or two later, the tree was moved into the early house, and produced a moderate crop the first season, the fruits ripening during the month of May. In subsequent seasons the house was closed early in January, and as a rule we had fruits of good size and splendid colour ready in the first week of May. The bud dropping propensities were greatly mitigated by due attention to watering the border, frequent syringings overhead, and affording abundant ventilation during the summer, autumn, and early winter months. I should not have the slightest hesitation in planting "Alexander" Peach for early forcing. *H. S., Bournemouth.*

—— I should like to support Mr. Jordan respecting Alexander Peach. Here at Castle Hill is a tree that was one of the first sent out. I believe Messrs. James Veitch & Sons sent it here for trial when the variety was first introduced, about twenty-seven years ago. It is in the early-house, and bears each year a good crop of Peaches. The buds do not drop, because we afford plenty of water to the roots, and we commence to force the tree very gently in the way Mr. Jordan recommended. Some of the fruits ripen in the first week in May, and specimens have weighed from 6 to 8 oz. each. I can endorse all Mr. Jordan has said with regard to drought being the cause of all the mischief. In visiting gardens, I have observed the comparatively dry treatment of Peach-trees during the autumn and winter months, and have seen the same trees in the spring when the buds have dropped. *Jno. W. Barks, Castle Hill Gardens, Eletchingley, Surrey.*

—— We have had the varieties Hale's Early and Alexander for over eight years and they have not cast their flower buds. Neither variety shows such a profusion of flowers as do Royal George, Noblesse, Barrington, and other old English sorts, and, as Mr. Tomlinson states (see p. 91), some of the buds do not expand. They are trained on the front trellis of a curvilinear house, with trees of Royal George and Lord Napier Nectarine on the back wall. At one time we had a tree of Royal George also on the front, and we then used to close the house the first week in November, but it was as much as we could do to get a dish or two of ripe fruits the first week in May for a special function. Now we close on January 1, yet gather ripe Peaches as early as we did formerly, but they are from the variety Alexander. I think most Peaches and Nectarines cast their buds if planted in light, loose soil, and are not afforded abundance of water, especially after the fruit has been gathered and onwards. Out-door trees get more water at that stage than when in active growth. Our soil is stiff enough for anything. *W. P. R., Preston.*

THE GRAPE-VINE IN SOUTHERN ENGLAND.—As a subject that I have had in mind for many years, it gave me much pleasure to peruse Mr. Douglas's article in the *Gardeners' Chronicle,* February 4, on the cultivation of the Grape-vine on warm walls in our southern counties. That good Grapes can be obtained on out-of-doors Vines, if the culture is of the right kind and similar to that afforded by the old cultivators quoted by Mr. Douglas, is capable of proof. I have myself observed, as a boy, excellent Sweetwater, Parsley-leaved and plain-leaved varieties, Black Morocco, and Miller's Burgundy, produced on a south wall in the gardens at Stanley Grove, now St. Mark's College, Chelsea; at Eden Lodge, Kensington Gore, where my father was head gardener for several years; and on the roof of Vine Cottage, which stood where the Albert Hall was afterwards built. That which was possible then is equally so at the present date, although there may now be a greater amount of smoke emitted from house and factory chimneys. The gardeners of two or three generations back were good cultivators of out-of-doors fruits generally, taking great pains with the manuring, pruning, and training of the same, seeing that glass structures of any sort were less common, owing to the greater cost of construction, due to the heavy duty on imported glass and the consequent high price of that made in this country. Thomas Rivers, of Sawbridgeworth, advocated the employment of "gronnd" vineries, which were simply stretches of span-roofed frames of any length, according to space and requirements, with single rods of Vines slung along at the apex of the ridge, about 1½ feet from the ground-level, and the bearing shoots trained on either side at intervals of 1½ to 2 feet, in the same manner as house Vines on the short-spur system. The frames stood on a single or double line of bricks, as a means of preserving the woodwork from injury by damp. For affording extra space a trench similar to those thrown out for Celery was recommended. Rivers was a man of original and practical ideas, and to make the ground-vinery easily understood he constructed a number of them in his nursery as object-lessons for visitors. He also constructed "dug-out" vineries having lean-to and saddle roofs, with and without heating apparatus. The results were excellent in every way, although the means were of the roughest kind, no brick walls, and merely earth for the floors. He did not use the syringe much on his Vines, the moisture arising from the soil, more especially in the unheated vineries, being sufficient for the requirements of the Vines and keeping down red-spider, that plague in some gardens—in fact, the acarid could not live in the moist air of these structures. Of course the matter of ventilation received proper attention, and mildew was unknown. It seems a pity such inexpensive adjuncts to a garden have dropped out of use, for they served many useful purposes besides Grape-growing—such, for example, as the protection of saladings, early Broccoli and Cauliflowers in autumn and winter, and all kinds of early things in spring, as Peas, Cauliflowers, French Beans, Cabbage, Lettuces, Onions, &c. *F. Moore.*

HOLLYHOCKS.—It may interest your readers to hear that I make a specialty of growing the new type, which are annuals. The quick and luxuriant growth of the plants is not favourable to the establishment of the fungus. The seeds may be sown about the end of March, but if sown later of course they will not commence flowering so soon. Young plants transplanted about the beginning of May will commence to bloom about the end of July. They will remain in flower until late in the autumn. The branches that have borne flowers must be cut away, otherwise all the energy of growth will be devoted to the ripening the seeds. It is also worth while mentioning that the plants are just as hardy as those of the other types of Hollyhocks, therefore plants may stand another year, but I prefer to grow them year by year. I send to your address some packets of seeds of each strain by sample post and beg you to send these for trials to some of your correspondents interested in Hollyhocks in order that they may try these new strains. It is necessary to mention that the double strain is still not yet so perfectly double as those of the best varieties of Chater's Prize strains, but nevertheless the flowers are pretty nearly double, and ultimately I trust to have a strain that will compare with the best of any type of the biennial class. *Frederick Roemer, Quedlinburgh.* [The seeds in question have been forwarded for trial at the garden of the Royal Horticultural Society at Wisley. ED.]

SOCIETIES.

THE ROYAL HORTICULTURAL.

FEBRUARY 14.—It will be seen from the amount of space devoted in this issue to the doings of the Royal Horticultural Society, that Tuesday last was an unusually busy day. The attendance of Fellows is always greater on the day of the annual meeting than it is at ordinary meetings of the Society, and exhibitors seek to improve the occasion by bringing to the Hall as much as possible.

The report printed below will show what an important display was made of Orchids, and the ORCHID COMMITTEE recommended as many as one First-class Certificate, four Botanical Certificates, and two Awards of Merit to novelties.

The collection of Orchids from JEREMIAH COLMAN, Esq., was of great magnitude and excellence.

The FLORAL COMMITTEE recommended four Awards of Merit to novelties, but the FRUIT AND VEGETABLE COMMITTEE made no Award at all.

All the Committees sat in separate rooms on the first floor, but means should have been taken to see that sufficient room and seats were provided for the members. This will, we doubt not, be done on future occasions. The Society's officers have had an extraordinary amount of work to do during the past twelve months owing to the change of offices, and have done it remarkably well, but in the near future a normal condition of things may be expected to obtain.

Floral Committee.

Present: Geo. Paul, Esq. (in the chair), and Messrs. H. B. May, C. T. Druery, Jno. Green, F. Page-Roberts, (Rev.) C. E. Pearson, R. C. Notcutt, G. Reuthe, Chas. Blick, Jno. Jennings, C. J. Salter, Chas. Dixon, J. F. McLeod, W. Howe, W. Bain, Charles Jeffries, R. Hooper Pearson, Herbert J. Cutbush, E. T. Cook, James Hudson, W. Cuthbertson, George Gordon, W. P. Thomson, W. J. James, Harry Turner, and E. H. Jenkins.

Erica × Veitchi, a hybrid from E. codonodes (lusitanica), was shown by Messrs. ROBERT VEITCH & SON, Exeter. A plant nearly 4 feet high and as much in diameter was shown in flower from the open-air at Exeter. The flowers are white, and the habit of the plant is more like that of E. arborea than E. codonodes. The Committee recommended that the variety be tried out-of-doors at Wisley, it being very valuable if it will flower out-of-doors at this season.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, set up a large collection of ornamental foliage plants—Codiæums (Crotons), Dracænas, Ferns, Caladiums, Palms, Dieffenbachias, Begonia Rex, &c. A batch of Adiantum Farleyense occupied the centre of the group, and an excellent collection of Dracænas was staged to the right of these plants (Silver Flora Medal).

Messrs. WM. CUTBUSH & SON, Highgate, N., put up a handsome group of forced flowering plants—Magnolias, Lilac, Staphylea colchica, numerous species of Prunus and Pyrus, Spiræa prunifolia, Rhododendrons, &c. Magnolia Lenne was noticed with its claret-coloured petals, also a grand plant of M. Halleana (Silver-gilt Flora Medal).

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, displayed a group of choice specimen Ferns (Silver Banksian Medal).

Messrs. JAS. VEITCH & SONS, Ltd., King's Road, Chelsea, exhibited some excellently flowered plants of Primula × kewensis, Eupatorium vernale, Coleus thyrsoideus, Cheiranthus × kewensis, and a large group of pot plants of Loropetalum chinense.

Rev. H. BUCKSTON, Sutton Hall, Derby (gr. Mr. Shambrook), staged a number of pot plants of Cyclamen. The plants were of large size, perhaps not as compact as is desirable, but well and plentifully flowered (Silver Flora Medal).

Mr. K. DROST, Kew Nurseries, Richmond, showed a number of plants of Hippeastrums (Amaryllis). Colour, form and substance of the flowers were all alike superior in quality (Silver Banksian Medal).

Messrs. AMBROSE & SONS, Cheshunt, staged a miscellaneous collection of greenhouse plants, Cine-

varias, Carnations, Eucharis grandiflora, Tulips, &c. (Bronze Banksian Medal).

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, staged a small exhibit of greenhouse subjects, Acacias, Ferns, Boronia megastigma, Orange plants in fruit, &c.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, included in their exhibit a new Dracæna with narrow, vinous-coloured leaves, named The Queen; several pot plants of Loropetalum chinense, &c.

CHINESE PRIMULAS.

Several of the leading firms of seedsmen displayed large groups of Chinese Primulas, and these, with their bright colours gave a very pleasing appearance to the hall.

Messrs. JAMES CARTER & CO., Holborn, filled a side of one of the long tables with a collection of these flowers, exhibiting batches of plants in their respective colours. The plants represented a very desirable strain of this popular flower. A batch of plants of the "stellata" type occupied the centre of this group. The variety Princess of Wales was prominent (Silver Banksian Medal).

As growers of the Chinese Primula, Messrs. SUTTON & SONS, Reading, are difficult to excel. For excellence of habit and for brilliancy and variety of colours, the group displayed by this firm was most remarkable. Each plant was shapely, with foliage in due proportion to the inflorescence. They made a pleasing impression, and gave evidence of the great care and judgment displayed in their cross-breeding, selection, and cultivation. The collection entirely filled an extensive table, the groups on either side being marked off by a line of Cineraria plants running the whole length of the table. Among the few varieties our space permits us to mention are The Czar (a handsome type, with deep lavender or blue-coloured flowers), Crimson King (deep crimson), The Duchess hybrids of all shades of colour, The Pearl, and His Majesty (a handsome, semi-double white variety) (Silver-gilt Flora Medal).

Messrs. CANNELL & SONS, Swanley, also made an imposing display of these flowers. The strain is of a robust nature, with massive foliage and bold heads of flowers, a type which finds favour with many growers. The flowers are large and colours excellent, making admirable subjects for decorative effect. The stellata type was largely represented in this collection, among which was a new variety named Miss Ellen Willmott. Messrs. CANNELL'S strain of "Giant Mixed" is commendable (Silver-gilt Flora Medal).

Mr. W. PALMER, Andover Nurseries, Andover, Hants, staged a large batch of a double-flowered variety of Primula sinensis named Queen Alexandra. This is a tall, free-flowering variety, with soft, blush-coloured petals, the habit of plant being intermediate between that of the ordinary and of the stellata type. The remainder of the table was furnished with plants of another variety named Island Queen, carrying flowers of a pleasing soft pink colour (Silver Banksian Medal).

A fine spray of flowers of an interesting plant was exhibited by F. A. BEVAN, Esq., Trent Park, New Barnet (gr., Mr. H. Parr), in Bryophyllum calycinum. This plant freely produces bulbils from the edges of its leaves, and is one of the best examples of a plant that reproduces itself in that manner. An allied species, B. crenatum, was figured in these pages January 24, 1903, p. 59.

ALPINE PLANTS.

A large exhibit of Alpine plants was set up by Messrs. W. CUTBUSH & SON, Highgate, N., who arranged their exhibit in a natural manner, introducing pieces of rockwork in the group. Many choice plants were shown in flower. We noticed Tulip Kauffmanniana coccinea and T. K. aurantiaca; Iris persica, Danfordi, reticulata, Krelagei, and numerous other species; Narcissus minimus, &c.

Messrs. BARR & SONS, King Street, Covent Garden, contributed a good display of early-flowering species, such as Irises, Snowdrops, Anemones, Saxifrages, Scillas, &c. Among other species of Narcissus, we noticed the delicate N. Cyclamineus in flower.

The FOX HILL HARDY PLANT NURSERY, Keston, Kent, set up numerous pots and pans of such plants as Irises, Crocuses, Colchicums, Hepaticas, Saxifragas, Anemones, including many fine varieties and rare species. The collective exhibit presented quite a splash of colour. The charming Narcissus Clusii was noticed in flower (Silver Banksian Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, staged three boxes containing "Alpines," including a large number of plants of Cyclamen Coum, and of C. ibericum in varieties. Irises were well displayed, I. Danfordi, I. Heldreichi, &c. (Bronze Banksian Medal).

Messrs. THOS. WARE, Feltham, showed an excellent collection of Alpine and hardy plants in flower; Primula obconica and its varieties were prominent, Crocuses, Irises, Hepaticas, Saxifragas, and a host of similar plants, all presented in first-class condition, made a commendable exhibit. Plants of Sarracenia flava were shown in flower (Silver Banksian Medal).

Messrs. JOHN PEED & SON exhibited numerous pans of Saxifragas, most of the garden species being represented, also Sedums, Sempervivums, Hutchinsia alpina, &c. A box contained succulent plants such as Aloes, Echeverias, Opuntias, &c.

The Misses HOPKINS, Mere, Knutsford, Cheshire, staged a few Christmas Roses, Blue Primroses, &c.

Messrs. J. CHEAL & SONS, Crawley, arranged a small rockery in which were planted numerous Alpine and early-flowering hardy plants (Bronze Flora Medal).

The GUILDFORD HARDY PLANT NURSERY, Millmead, Guildford, contributed a small number of hardy plants and "Alpines" in flower, Galanthus Elwesii, Hepatica triloba, Bulbocodium vernum, &c.

Awards.

Carex Vilmorini.—A plant with extremely narrow green leaves was shown under this name by Messrs. H. CANNELL & SONS, Swanley, Kent. The numerous leaves droop arch-like in a most graceful manner, and the plant when cultivated in 3-inch or 4-inch pots would be very suitable for furnishing vases. The leaves appear only to get about 5 inches high before drooping, and 5-inch pots as shown are therefore rather too large to obtain the best effect from the plant (Award of Merit).

Crocus chrysanthus variety. — Miss WILLMOTT, V.M.H., exhibited a plant with white flowers, apparently near to the variety albidus. It had bluish-purple marks on the exterior of the three outer segments, and a yellow-coloured base in the interior of the flower. The flowers were exceedingly pretty, and the bright orange-red-coloured pistil very effective (Award of Merit).

Primula sinensis "His Majesty."—This is a double-flowering variety of the Chinese Primula, similar to those frequently exhibited by Messrs. SUTTON & SONS, but having larger, finer flowers of pure white. Shown by Messrs. SUTTON & SONS, Reading (Award of Merit).

Rose Prince de Bulgaric.—A very beautiful Tea Rose of warm pink colour, the outer petals becoming pure white, of good form and at present proving itself a first-class variety for forcing. Shown by Messrs. PAUL & SONS, The Old Nurseries, Cheshunt (Award of Merit).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, Francis Wellesley, J. W. Potter, R. Brooman-White, W. Boxall, W. H. Young, H. J. Chapman, J. W. Odell, H. G. Morris, A. A. McBean, H. T. Pitt, G. F. Moore, J. Douglas, W. Cobb, H. A. Tracey, J. Charlesworth, H. Ballantine, W. A. Bilney, F. W. Ashton, T. W. Bond, H. Little, W. Bolton, and Harry J. Veitch.

The great attraction was the very fine group of Orchids occupying the broad end staging and running the whole width of the Hall, staged by JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), and for which the Society's Gold Medal was awarded, and also the Lindley Medal, for excellence of culture. The group was made up of the greater part of the plants referred to in our report of the Gatton Park Orchids at p. 100, and the effective staging, with a backing of Palms and carpeting of Maidenhair Ferns and other foliage plants, was very cleverly carried out by Mr. Bound. In the centre was a group of Epidendrum × Boundii, fronted by a white Lælia anceps. On each side, high up at the back, were collections of hybrid Calanthes, the Dendrobiums forming the body of the group.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr., Mr. Ballantine), was awarded a Silver-gilt Flora Medal for a very fine group of rare Orchids. The Odontoglossums were well represented, the spotted crispums having for their best the perfectly-shaped, finely-marked O. c. Veitchianum, still one of the finest; O. × Adrianæ Victoria Regina, a great beauty; O. Hallii xanthodon, fine O. × Wilckeanum, O. nevadense, and others; two arrangements of the handsome Calanthe × Baron Schröder and C. Regnieri; Cypripedium × Baron Schroder, very finely marked with purple; C. × Lathamianum, C. × Calypso, C. insigne Sanderæ, and other Cypripediums, each with several flowers; varieties of Cattleya Trianæ, including the old and fine C. T. Russelliana; Dendrobium aureum album and some pretty hybrid Dendrobes; Masdevallias, Sophronitis grandiflora, &c.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, secured a Silver-gilt Flora Medal for a very excellent group in which the middle portion was made up of fifty fine and well-bloomed specimens of Phalænopsis Schilleriana, with one plant of the rare P. sumatrana. At the end of the group were selections of fine hybrid Orchids, including the showy and favourite Lælio-Cattleya × Charlesworthii, L.-C. × Sunray, L.-C. × luminosa, L.-C. × Andromeda, L.-C. × Myra, Cattleya × Octave Doin, Brasso-Cattleya × Digbyano-Warscewiczii, and other hybrids of Brassavola Digbyana. The Odontoglossums included some good O crispum, a very handsome and finely-shaped O. × ardentissimum heavily marked with rose-purple, Dendrobium atroviolaceum, Trichopilia suavis, &c.

Messrs. SANDER & SONS, St. Albans and Bruges, were awarded a Silver Flora Medal for a small group of very remarkable species and hybrids. The species included the superb new Cymbidium Sanderi and the new white Vanda Watsoni (for both see Awards), good Odontoglossum crispum including spotted varieties, Spathoglottis Amesiana, and several singular botanical Orchids. The finest of the hybrids were the noble Odontoglossum × Harryano-crispum Rex (Harryanum × crispum Rex), raised at Bruges, and which in its very fine colour shows the effect of the fine blotched O. crispum Rex. The flowers on the small plant measured 4½ inches diagonally; the sepals pale yellow nearly covered with large red-purple blotches; petals similarly coloured, but with smaller markings; lip white, with rose-purple spots in front of the yellow crest. Other pretty hybrids were O. × blando-nobile (blandum × nobile (Pescatorei), white, spotted with purple; O. × loochristyense Sander's variety, very rich in colour; good O. × Wilckeanum, Cypripedium × Helen H. pulchrum, &c.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), secured a Silver Flora Medal for an interesting group of Odontoglossums, Lælio-Cattleyas, &c. The Lælio-Cattleyas, most of which had the rare yellow L.-C. × Ernesti Princess Olga as one parent, were grown and flowered in three years from the seed. They were of pretty shades of yellow tinged with pink, and with ruby-crimson fronts to the labellum. The varieties shown were Lælio-Cattleya × Oakwood Alpha (Ernesti Princess Olga × L. Schroderæ), L.-C. × Oakwood Beta Lord Rothschild × callistoglossa (resembling L.-C. × callistoglossa in colour), L.-C. × Oakwood Gamma (L. Jongheana × L.-C. × Ernesti Princess Olga), and L.-C. × Oakwood Delta (C. Schröderæ × L.-C. × Ernesti Princess Olga). The group also contained the handsomely blotched Odontoglossum crispum (Lindeni, O. c. xanthotes Cooksoniæ, O. c. Cooksonianum, O. c. purpurascens, and the bright yellow, brown-blotched O. × Prince of Orange, and the fine purple-blotched O. × Wilckeanum Sibyl. Also Cypripedium × Orion bellum, cream-white with numerous purple spots.

Messrs. JAS. VEITCH & SONS, Chelsea, were awarded a Silver Banksian Medal for a neat group including Lælio-Cattleya × Pallas, L.-C. × Violetta, L-C. × warnhamensis, L.-C. × Haroldiana, Lælia × Mrs. Gratrix, the bright yellow Dendrobium × Ophir, two forms of Calanthe gigas, the variety excellens very fine in colour; and Cypripediums, Phalænopsis, &c.

Messrs. HUGH LOW & CO., staged a small group of very pretty forms of Cattleya Trianæ, Cypripediums, and the showy Lælio-Cattleya × Captain Percy Scott Bush Hill Park variety.

Mr. J. CYPHER, Cheltenham, had a very pretty group in which the varieties of Dendrobium nobile were very fine, including D. n. Cypheri, D. n. nobilius, D. n. Amesiæ, D. n. pulcherrimum, &c.; also Cattleya × calummata, Masdevallia gargantua, Cypripedium × aureum virginale, C. × Swinburnei, &c.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), showed Cattleya × chocoensis "Westfield variety," a charming white flower with distinct purple and yellow markings in the throat; C. Trianæ "Laura," white with lemon-yellow disc and slight pink tinge on the lip, &c.

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. W. H. White), showed Dendrobium × Euryalus purpurascens, as fine in colour as D. nobile nobilius; the pretty Cypripedium × Watsoni, and three others (see Awards).

W. M. APPLETON, Esq., Weston-super-Mare (gr., Mr. Brooks), sent Cypripedium × Leeanum Appletoniæ, and C. Daphne (exul × Charlesworthii).

Mr. JOHN ROBSON, Altrincham, sent Cypripedium × aureola, of the C. × aureum class.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, showed the fine yellow Mormodes badium luteum.

J. BRADSHAW, Esq., Southgate (gr., Mr. Whitelegge), showed Lycaste Skinneri "Glory," and Cattleya Trianæ "Fairy Queen."

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed Cypripedium Boxallii Rosslyn variety, and Lælia anceps Schroderiana Rosslyn variety.

Captain G. L. HOLFORD, C.I.E., Westonbirt (gr. Mr. Alexander), showed Sophronitis rosea.

H. S. GOODSON, Esq., Putney (gr. Mr. G. E. Day), sent Cypripedium × Katherine (insigne Sanderæ × superbiens).

De B. CRAWSHAY, Esq., Rosefield, Sevenoaks, showed the creamy-white, brown-spotted Odontoglossum × loochristyense "Theodora," a marvel of good culture, bearing a very strong spike of flowers and a large seed capsule on the last spike; also Lælia anceps Hollidayana rosefieldiensis, and Theodora.

C. J. LUCAS, Esq., Warnham Court (gr. Mr. Duncan), sent Lælio-Cattleya × bletchleyensis "Eric Lucas," of fine colour, and good specimens of Cypripedium × Lathamianum superbum, and C. Calypso, Warnham Court variety.

Awards.

FIRST-CLASS CERTIFICATE.

Cymbidium Sanderi. — A grand new species of totally distinct character, imported by Messrs. SANDER & SONS, St. Albans. The 2-feet-long scape rises erect and bore on the top in this case three large flowers in some degree resembling those of the best C. eburneum, but structurally different. The plant flowered on an imported spike, and four other flowers on the spike were not developed. Flowers 3½ inches across, sepals and petals white, slightly tinted with pink and with small purple spots at the base. The lip, which is the beautiful feature of the flower, is large, the side lobes curved to the column, the front lobe expanded, white with a most beautiful tracery of rose-purple dotted lines on both side and front lobes. From Messrs. SANDER & SONS.

BOTANICAL CERTIFICATES.

Vanda Watsoni, from Sir TREVOR LAWRENCE, Bart., and Messrs. SANDER & SONS. — See *Gardeners' Chronicle*, February 11, p. 82. Growth of V. Kimballiana. Flowers white.

Odontoglossum liliiflorum, from Baron SCHRÖDER.—An extremely rare Orchid of the form of O. ramosissimum. Flowers pink with a few purple spots.

Dendrobium cymbidioides, from F. MOORE, Esq., Glasnevin, Dublin.—This is the true plant, and very distinct from the one so named in gardens (*Gardeners' Chronicle*, January 7, p. 15). Sepals and petals yellowish; lip white marked with purple.

Dendrobium annulum, from Sir TREVOR LAWRENCE, Bart.—A graceful white Australian species.

AWARDS OF MERIT.

Cypripedium × *Leonie* (*Cravenie callosum* × *insigne Harefield Hall*), from J. F. CRAVEN, Esq., Beeches, Keighley, Yorks (gr., Mr. Corney).—A stately hybrid, much resembling C. insigne Harefield Hall, but broader and with more white in the dorsal sepal.

Cypripedium × *Honnoriæ* (*Drurii* × *Godefroyæ leucochilum*), from W. M. APPLETON, Esq.—Flower ivory-white dotted with purple, and bearing a purple line up the petals.

CULTURAL COMMENDATION.

To Mr. W. H. White, gr. to Sir TREVOR LAWRENCE, Bart., for a large pan of Sophronitis grandiflora with sixty flowers.

To Mr. Stables, gr. to DE B. CRAWSHAY, Esq., for Odontoglossum triumphans leopardinum with a branched spike of thirty-five flowers.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq., in the Chair, and Messrs. S. Mortimer, Thos. Arnold, Ed. Beckett, Alex. Dean, F. Q. Lane, W. Pope, Jas. Gibson, Geo. Kelf, G. Reynolds, H. Markham, W. H. Divers, G. Norman, J. Willard, Geo. Wythes, Owen Thomas, J. Lyne, W. Poupart, P. C. M. Veitch, H. Parr, and Chas. Foster.

A magnificent collection of Apples was staged by Messrs. G. BUNYARD & Co., Maidstone, Kent. The collection comprised most of the best-known varieties, exhibited in the best possible condition, and formed probably one of the finest displays of these fruits ever seen at such a late period in the season. The exceptional season no doubt accounted for the possibility of showing such meritorious fruit; but to this must be added the skill in cultivation and the perfection of means for keeping the fruits. The display was awarded a Gold Medal.

Although Apples were so excellently displayed from Kent, a collection from Herefordshire put up by the KING'S ACRE NURSERIES, Ltd., King's Acre, Hereford, was very meritorious, for the colour and finish of the individual fruits were extraordinary, such varieties as Blenheim Pippin being rosy-red all over, reminding one of such highly-coloured varieties as Worcester Pearmain (Silver-gilt Knightian Medal).

OSWALD P. SEROCOLD, Esq., Taplow Hill, Taplow (gr., Mr. R. Bullock), staged thirty-five dishes of Apples, principally of dessert varieties. The specimens were not over-large in size, but were of excellent finish, some fruits of Blenheim Pippin being especially noteworthy in appearance (Silver Banksian Medal).

ANNUAL MEETING.

The one-hundred-and-first Annual General Meeting of this Society was held on Tuesday afternoon last at the Society's Hall, Vincent Square, Westminster. Sir TREVOR LAWRENCE, Bart., K.C.V.O., V.M.H., the President, occupied the chair, and there was a large gathering of Fellows.

After the minutes of the last annual meeting had been confirmed, about a hundred new members were elected.

The Report of the Council was taken as read.

The PRESIDENT, in moving its adoption, said: It is now my duty to make a few remarks with regard to the Report that has been circulated amongst the members of the Society. In the first place I think that we, who have the good fortune to be Fellows of this Society, have every reason to congratulate ourselves upon what has taken place during the Centenary year. I have before me a letter from a very old Fellow of the Society, the Rev. Honywood D'Ombrain. He is not only an old member of the Society, but as he has arrived at an advanced age he is, unfortunately, unable to be among us. He says: "When I contrast the present flourishing condition of the Society with what it was in the dark days at South Kensington, I cannot but rejoice at the change which has taken place." There is nobody in this room who does not heartily reciprocate the feelings expressed by our friend; and when we consider the great interest taken in the art and craft of Horticulture throughout the country and throughout all ranks, I think it must be a subject of congratulation that the Society has arrived at its present position with every prospect of maintaining that position.

THE HALL.

With regard to the doings of the past year, of course the central occurrence was the opening of this Hall and this building by his Majesty the King and her Majesty the Queen. His Majesty has invariably shown a warm interest in the welfare of the Society. He subscribed to the funds for building this Hall, as did his Royal Highness the Prince of Wales. His Majesty was also present at the show in the Temple Gardens last year, accompanied by the Queen. Her Majesty was likewise present at the very beautiful show held in the grounds of Holland House.

We have now seen a little of the capacity and the utility of this Hall, and we know that, although it provides us with abundant accommodation, it does not provide us with any too much. We know that it is admirably lighted, and that it is well proportioned.

(Sir TREVOR LAWRENCE here read a paragraph from one of the leading papers testifying to the excellent acoustic properties of the Hall.)

It is impossible to pass from the subject of the Hall without saying a word of regret at the absence of Baron Schröder, to whom we owe so much. The Baron is in the Riviera, and I am sure we are all glad to learn from his gardener that his health is better than it has been. He unfortunately caught a severe cold when he was going out, and was confined to his bed We are proposing to put up a tablet to commemorate the connection of Baron Schröder with this Hall Not only has the Baron subscribed most liberally to our funds, but he has borne the expense of [transferring and] furnishing the Lindley Library—a costly operation—and he has used his influence with his friends to induce them to subscribe towards the building fund.

The Report of the Council enters so largely into all that is to be said with regard to the present position of the Society that it will not be necessary for me to detain you at any length.

WISLEY.

I may say a word with regard to one other matter of the greatest possible importance during the past year, and that is the acquisition of our new garden. The Society owes a great debt of gratitude to our friend Sir Thomas Hanbury for his generosity in this matter. In common, I dare say, with many here present, I had the pleasure of knowing the late Mr. Wilson for many years, and on many occasions I had the pleasure of going round his most interesting gardens. It is hardly possible to imagine that a more fortunate chance should have occurred than that which enabled Sir Thomas Hanbury to purchase this land and to present it to the Royal Horticultural Society. I can bear emphatic testimony to the excellence of the gardens. I went over the ground on two or three occasions during the spring, and on every occasion it was a perfect feast of interest and flowers; and I strongly recommend those who desire to see Primulas, Irises, and a vast variety of hardy plants, to go there during the proper seasons. Of course, it has been necessary for the Society to do a great deal at Wisley. The garden, as carried on by Mr. Wilson, was a hardy plant garden, and for the purposes of the Society it has been necessary to build ranges of hothouses and plant-houses and residences for the Superintendent and the fruit foreman. A good deal of money has been spent in that direction. Fortunately we have been able to obtain for the remainder of the Chiswick lease a sum of about £4,700, and that will go far to cover the outlay at Wisley. Then with regard to paragraph 7, which refers to the desire of the Council to establish a laboratory for scientific and experimental research in matters relating to plant life. Such a laboratory can hardly be said to exist at present in this country, unless you include Rothamsted, which for agricultural purposes has been of the greatest possible value. We wish to have a laboratory at Wisley to deal with more strictly garden interests and garden work. Already a very eminent gentleman has offered to institute some experiments there. It will cost us very little beyond a small honorarium. I am not at liberty to mention the details at present, but I can assure you it was an offer which would be received with the greatest possible acclamation by everybody in this room.

DEPUTATIONS.

The position of our Society in the world of horticulture is more and more being recognised by foreign nations. That is shown by the desire of foreign Societies, when they have meetings, anniversaries, jubilees, or whatever the occasion may be, that we should send deputations to take part in their celebrations. We have received an invitation from Paris to attend the great International Horticultural Exhibition which is to be held in May, 1905. That has been accepted, and, among other good things, it will help to accentuate, so far as horticulture is concerned, the *l'entente cordiale* which already exists between ourselves and our neighbours on the other side of the water. Similarly, we have received an invitation to take part in the Jubilee of the Royal Caledonian Society.

Then we all deeply regret the loss of some very eminent members. One of them, whose memory will always be green with us, and to whom we were greatly attached, was the Dean of Rochester, whose death is a very great loss to horticulture; and there are the Rev. C. Wolley-Dod, Mr. Hermann Herbst, and others.

THE STATE OF THE SOCIETY.

The Report speaks of the gradual increase of the Society. The numerical increase during last year was 914, and the total number of Fellows and affiliated societies is now 8360. There are no fewer than eight pages of affiliated societies, and more and more the country societies are endeavouring to associate themselves with this Society.

THE JOURNAL.

I do not think it would be possible to exaggerate one important branch of the Society's work, and that is the *Journal*. The *Journal*, as you know, is a model of what such a production should be. It is very different from what it was a few years ago when we first left South Kensington. Enormous strides have been made in its utility in every shape and way. The *Journal* contains not only a vast number of most interesting papers, lectures and reports, but it is also very admirably illustrated, and I venture to say the labours of our Secretary in editing the *Journal* and in furthering the interests of the Society, it would be impossible to exaggerate. I venture to say that if anyone were called upon to purchase an illustrated volume of such dimensions, he would probably have to pay a guinea for it. The Council are naturally very anxious to again thank the contributors to the *Journal*—the writers, the compilers of abstracts, and others; their work is of the greatest possible value, and that value is recognised by all kindred societies which exchange their publications with the Royal Horticultural Society.

THE LINDLEY LIBRARY.

There is one thing in connection with paragraph 17 I must not omit. Not only has the Library been liberally furnished by Baron Schröder, but we have received a donation from a source from which we could hardly have expected. I mean from the Trustees of the Veitch Memorial Medal—a donation of £50 towards the expenses of the Library

MEDALS.

As to the list of Awards and Medals, I must express the opinion (and I do so with all reserve and with

humility) that our Committees are a little too liberal with their Medals and Certificates. I think they total 1,169. The truth of the matter is that every new introduction, or some curious play of Nature, whether it be an interesting seedling or a hybrid, or whatever it may be, invariably makes its *début* at the meetings of this Society, and that naturally leads to the granting of a very large number of Certificates.

The Shows.

I think our show to-day is a type of what our Society is doing. It is hardly possible to exaggerate the interest which our shows are constantly creating. We are deeply indebted to Mr. Jeremiah Colman, who has been kind enough to rob his houses for the time to show what really can be done. Mr. Colman has given pleasure to a vast number of people, and I am quite sure you will agree with me that we owe him and others a deep debt of gratitude for furnishing our shows with such admirable exhibits.

Colonial Fruits.

One new departure in regard to the exhibits has already been made, and that is the exhibition of Colonial fruit. The exhibition we had during the winter was organised at very short notice, and we hope in future that we shall have a much more complete and more interesting exhibition than on that occasion. The next show of colonial fruits will take place on March 30 and 31, and we have every reason to believe that the Colonies will make a very considerable show, as they can do. Not only is the matters of interest to fruit-growers, but it is a very important element in the food supply of the people. Through our Colonies we can get, almost throughout the year, fruit and vegetables which conduce so much to the health of the people, without having to wait for the seasons to come round.

The Summer Show at Chelsea.

After some protracted negotiations we have made arrangements to hold our Summer Show in the grounds of the Royal Military Hospital at Chelsea, on July 11, 12 and 13. Although that place is not, perhaps, so central as the gardens of the Inner Temple, I believe it will be found that there is ample space, and that, after all, the efforts we have made to secure the place will be in the best interests of the Society.

Thanks to Lord Ilchester.

I do not think I ought to leave this subject without asking you, the Fellows of the Society here present, to give a very hearty vote of thanks to Lord and Lady Ilchester for their kindness in past years. We could hardly expect that Lord Ilchester would be able to let us have his grounds every year, and we are greatly indebted to him for what he has done in the past.

The Committees.

There is one duty that remains to me. I ask you to give your cordial thanks to our Committees. The Committees are composed, as probably most of you are aware, of the best experts in the kingdom in their various departments. They travel, many of them long distances, at their own expense, with no charge whatever to the Society. They give valuable time and valuable knowledge to the Society, and we owe them a very great debt of gratitude.

The Staff.

It is impossible to pass away from this subject without asking you also to give a hearty vote of thanks to the staff. We have got the best secretary that any horticultural society ever had, or I would venture to say ever could have. Not only does he work in a way which sometimes astonishes me, but I really should be at a loss to adequately explain to you the burden which has been thrown upon his shoulders during the past year or two. We are greatly indebted to him, not only for that, but for the kindness, courtesy, and consideration with which he does his work; and I am glad to say—and he knows a great deal more about this than I do—that the general staff are always willing to take any amount of trouble, and will work so long as there is work to be done without any questions as to hours. That thought never arises.

Finance.

I will conclude by saying that we have every reason to be thankful for the present position of the Society. We have now an income of £14,000 a year. We made a profit on our working last year of over £5,000, and the ordinary income from subscriptions is not quite £10,000, but it is £1,000 more than the ordinary expenses. I think if you take these facts into consideration there is every reason to be satisfied with the position of the Society; and so long as we continue to work simply and solely for the advancement of Horticulture, so long will the position of the Society be maintained.

Mr. Arthur Sutton seconded the adoption of the Report. He said on that occasion of meeting for the first time in their own Hall they could not be too thankful for the extremely happy issue as the result of past deliberations. He should like to propose a most hearty vote of thanks to the Council, who had carried them through this unique work. But for the Council the work would not have been carried through. They knew that at one time the Council did not seem to gauge the feelings of the Fellows, but since they saw what the Fellows wished, and heard some reasons in support of those wishes, the Council immediately took the matter up and carried it through successfully. One thing ought to be mentioned, if during the last two or three years any one had left the Council through not being quite able to fall in with all that was being done, they had at last rallied round the Council. Only one or two matters called for reference. He hoped if anyone present had not yet contributed towards the Building Fund, they would at once communicate with the treasurer.

Of course they were delighted to have Wisley Gardens. The lesson of to-day in matters horticultural was that nothing was impossible; what was needed was united action. They had heard that a substantial sum had been received on account of Chiswick which went a long way towards the expenses of reorganisation. One matter not alluded to by the President was the loss the Society had sustained by the death of Mr. Lloyd—a member of the Council. He was sure they would not like to separate without recording their deep gratitude for what Mr. Lloyd had done during the years he had been in office.

Among the new Vice-Presidents there was one name they were specially pleased to see, and that was the name of Sir John Llewelyn.

Amongst the new holders of the Victorian Medal of Honour, there was one whom they delighted to honour, although they might not agree with all that that gentleman said in the papers—he referred to Mr. Alexander Dean.

The Chairman had referred to invitations from foreign countries. It had often occurred to him and others that although they frequently received invitations, they seldom extended the same courtesy in return. He was looking forward with more hope than ever that this year or next the Council would see their way to inaugurate the largest international horticultural exhibition that had ever been held, and that they should return some of the hospitality to those who had been so kind to them in the past.

Statement by the Treasurer.

Mr. J. Gurney Fowler, the Treasurer, next made his statement. He pointed out that the Council could not, of course, bind themselves to the figures in the Report, because it might be found in furnishing the hall and offices that some small expenses would have to be incurred, or that some small structural alteration might be necessary.

Well, what was the position of the Society? Their funds, thanks to the generosity of the Fellows, had largely increased during the past two years. At the end of 1902 the funds, including life compositions, were £16,000. At the present time the funds amounted to £51,119, an increase of £35,120 in two years. This large figure was accounted for as follows:—Donations to Hall, £25,178 *8s. 8d.*; donations to garden, £31 *19s. 6d.*; life compositions and entrance fees, £1,040 *17s.*; surplus income, £8,866; total, £35,120 *5s. 2d.* As to the new Hall, the cost would be as nearly as possible £40,000, and that was the figure which they originally considered they would have to spend. He thought it was satisfactory to them that their estimate had not been to any material extent exceeded.

With regard to Wisley Gardens their cost of making, after setting off the amount they received for the Chiswick Gardens, would be about £690, a very small sum which could be easily met in that room. The increase in the funds during the two years having been £35,120, and the Hall having been erected and the Garden equipped, they were £5,145 worse off than they were in 1902. If these two large undertakings had not been carried out they would have been £9,906 *17s.* better off, so that adding these two figures together the sum of £15,052 *3s. 10d.* was required before they could say that the Hall and Gardens had been respectively built and equipped by the liberality of the Fellows and at no cost to the Society. The amount was divided into:—deficiency on new Hall account, £14,396 *6s. 10d.*; deficiency on equipment of Garden, £655 *17s.*; and he made once more the appeal which he made last year to Fellows to come and help. It was not the duty of a Treasurer to beg, and he did not like it any more than most Treasurers did, but he supposed that the duty of a Treasurer was to receive all that he could get, and to part with the same only with care and discrimination. They had entrusted him with the honour of being their Treasurer, and he should always feel that he had not fully carried out the duties entrusted to him until he could approach them in general meeting and say that the funds with which they entrusted him were in as good if not in a better position than they were when he took office. Now as to their income, for after all the capital could eventually look after itself if they were able to save a considerable sum annually. They would see from the Report that the surplus of revenue was £5,235 as compared with £3,641 in 1903, and £2,488 in 1902. In the hurry always incident to getting out the accounts and going to press, he regretted that he did not observe that the Revenue Account had not been credited with the Entrance Fees, £426 6s. There was no liability of the Society in respect to these, and they were just as much income as are the subscriptions. He had spoken to Mr. Harper, their Auditor, on the subject, and he had agreed to this being altered next year. The income for the year was therefore £5,661 *14s. 1d.* This is, he thought, a satisfactory showing. He pointed out, however, that only one number of the *Journal* had been published this year, and that three numbers might come in the next year. If this be the case, their accounts the next year would show about £1,600 additional expenditure under this head. He thought there was nothing else to say of any great importance on the Revenue Account except that it would be observed that the maintenance account of the new Hall since its opening has been £411, and only £10 has been received from lettings. Now as to the future, he had referred to the cost of the *Journal* and now he must call attention to the maintenance of the new Hall.

He thought the annual expenditure would not be much less than £1,800, viz., rent, £690; rates and taxes, £600; house staff, £150; fuel and lighting £150; miscellaneous, £210.

Then as to the Gardens at Wisley. They might cost more to keep up than the Chiswick Gardens, as they were nearly five times as large. They proposed to enlarge the Gardens gradually (not of course interfering with the wild garden at all) by bringing the various fields surrounding the wild garden into cultivation. How much this might cost or when the work would be done it was difficult to say, but there was no rent payable as at Chiswick, and therefore no money was wasted by not working the estate to the full.

The current year would be the worst from a financial point of view that they could see for some time to come. They had undertaken two new enterprises, neither of which could yet be said to have found its footing; but be looked for considerable increase in the letting of the Hall after this year. He hoped that the Garden would show some receipts from sales of fruit, &c., so soon as it is properly established. Bearing these points in mind, and for safety's sake taking credit for no additional subscriptions, he thought they would find that they could make both ends meet, and show a surplus of between £2,000 and £3,000, which should, he thought, be a satisfactory showing.

Speech by Mr. Elwes.

Mr. Elwes said he had belonged to the Society for a long number of years, but he had never heard anything like so full, so confidential, and so businesslike a statement from the Treasurer, and he felt quite sure that if they had known the quality and capacity of their Treasurer three years ago a great many of the things which had been said at those meetings would never have been uttered. A great item for consideration was the *Journal*. At present that cost about £1,400—a figure which might be doubled in consequence of three numbers of the *Journal* being issued instead of one. He had always steadily upheld the publication of the *Journal*, therefore no one could imagine that he would speak against it. He would, however, suggest that as the *Journal* was said to be worth the whole subscription, it should not be sent to people who did not want it.

The President: That is only my own opinion!

Mr. Elwes said if an extra guinea were charged the *Journal* would not find its way into the waste-paper basket, as was frequently the case at present, because people when they had paid something for a thing took care of it. There was another point. At the present time their Secretary had thrown upon him a great deal of work which was not expected from any other secretary. Other societies had their Publication Committees. The work of selection of matter for publication was attended to by specialists in the various branches of knowledge. If their Secretary said to a gentleman who had sent in a paper, "You must cut this down," that gentleman might think he had some personal grievance with the Secretary; but a Publication Committee could act without any fear of criticism, and the result would be to limit the quantity and very much improve the quality of the *Journal* which was what they wanted. No one man could read all the horticultural literature which was now published each week, and much of that published in the *Journal* might be eliminated with advantage.

As to Wisley, he did not know whether the Council had had sufficient experience of the soil and climate and other facilities to justify them in saying what could be done best at Wisley. As a private garden it was all right, but they wanted something more than a pretty place where to pass a pleasant day. They wanted a garden to do what Chiswick could not do, and private gardens could not do this because there were no facilities for experiments. Wisley might be made an Arboretum which would perhaps some day be equal to that at Kew. He thought this was a matter which should be settled, not perhaps entirely within the

Council, and that no considerable expenditure should be undertaken until the Fellows had had a chance, he would not say of criticising, but of expressing their opinion on the matter.

The PRESIDENT said the Council was grateful to Mr. Elwes for his support. As to the *Journal*, Mr. Elwes did not seem to make any allowance for country members who got very little more than the *Journal* for their money. If they curtailed the *Journal*, and so reduced expense, some of the country Fellows would be very much grieved, and he was afraid they would cease to belong to the Society. With regard to Wisley, the whole matter had been very seriously considered. The trustees of the Gardens had been placed upon the Gardens Committee by the Council, who thought it was the only suitable compliment that could be paid these gentlemen. As to the Gardens themselves, he thought the situation infinitely superior to that at Kew, and the soil not inferior. Nobody who knew Kew could think very much of the soil, and the Director there was always remarking: "What can you expect from such a deplorable soil?"

The Report and Accounts were then adopted.

The following were nominated as VICE-PRESIDENTS, viz.:—The Right Hon.. Joseph Chamberlain, M.P.; the Right Hon. The Earl of Ducie; the Right Hon. Lord Rothschild; Sir Frederick Wigan, Bart.; Sir John T. Dillwyn-Llewelyn, Bart.

The following were nominated as OFFICERS:—Sir Trevor Lawrence, Bart., K.C.V.O., V.M.H., *President*; Mr. J. Gurney Fowler, *Treasurer*; Rev. W. Wilks, M.A., *Secretary*; Mr. Alfred C. Harper, *Auditor*. No other names having been proposed there was consequently no need to ballot, and these gentlemen were duly elected.

Sir JOHN LLEWELYN, Bart., moved, and Mr. DRUERY seconded, a resolution of thanks from that the first annual meeting of Fellows in the new Hall, to Baron Schröder and everyone else who had worked to carry the scheme to a successful issue. The motion was carried with acclamation.

Captain HOLFORD, one of his Majesty's equerries, moved a hearty vote of thanks to the President.

Mr. W. A. BILNEY seconded, and the motion was carried with cheers.

The PRESIDENT, in reply, expressed his thanks.

BRITISH GARDENERS' ASSOCIATION.

In addition to those previously reported, meetings have been held at the following places:—

At Waltham Cross on February 7, Mr. J. Weathers, Horticultural Instructor for Middlesex, in the chair, Mr. W. Watson, Hon. Secretary of the Association, being the principal speaker, it was unanimously resolved to form a local branch of the Association, and gardeners resident in the district who are interested in the movement are requested to communicate with Mr. W. Isbell, 5, St. Mark's Road, Bush Hill Park, Enfield, who has agreed to undertake the duties of Hon. Secretary (pro. tem.)

At Croydon, also on February 7, there was a well-attended meeting of members of the Croydon and District Horticultural Mutual Improvement Society and others, to hear Mr. C. H. Curtis, who is a member of the Committee of Selection of the Association. The objects and programme of the Association, so clearly expounded by Mr. Curtis, met with the approval of the meeting, and it was agreed further to consider the formation of a local branch of the Association at the next meeting of the Society upon February 21.

At Norwich, on February 8, the February meeting of the East Anglian Horticultural Club was addressed by Mr. George Gordon, V.M.H., as a delegate from the Association.

At Leeds, upon February 11, a large gathering of the gardeners of the district assembled at a meeting held under the auspices of the Leeds Paxton Society, to hear Mr. George Gordon, V.M.H., speak upon the "British Gardeners' Association." As a result of the meeting the following resolution was carried unanimously: "That a branch of the British Gardeners' Association be formed in Yorkshire, with Leeds as a centre, and that this meeting pledges itself to give every possible support to the movement." A Committee was elected to actively carry on the work. Mr. George Carver, 75, Northbrook Street, Chapel Allerton, Leeds, was elected Hon. Secretary. As Secretary of the "Professional Gardeners' Friendly Benefit Society," Mr. Carver is well known and respected throughout Yorkshire, and all Yorkshire gardeners interested in the movement are asked to communicate with him.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 2.—S. GRATRIX, Esq., Whalley Range (gr., Mr. Cypher), exhibited some Cypripediums, the best of which was C. × Euryades "Gratrix's variety," a very handsome form. Dendrobium × Ainsworthii "Gratrix's variety" was shown from the same collection.

Mrs. S. GRATRIX exhibited Cattleya Trianæ var. Mrs. S. Gratrix, of good form, and of very pleasing character (Award of Merit); also Cypripedium × Briton, a hybrid between C. × Calypso × C insigne Harefield Hall variety (Award of Merit).

W. THOMPSON, Esq., Stone, Staffs. (gr., Mr. Stevens), sent a small but very good collection of Odontoglossums. O. × Vuylstekei Walton Grange variety being magnificent, was unanimously awarded a First-class Certificate. A fine plant of O. crispo × Harryanum with a spike over a yard long, with two branches, was awarded a Cultural Certificate. A Vote of Thanks was awarded for the group.

A. WARBURTON, Esq., Haslingden (gr., T. Raven), exhibited one of his own hybrid Odontoglossums, which was the product of crossing O. crispum var. Lindeni with a rose-coloured variety of O. crispum; the flower was small but well marked, and no doubt when the plant has grown strong it will be a valuable addition to the spotted forms (Vote of Thanks).

Messrs. SANDER & SONS, St. Albans, exhibited Cypripedium × Orion var. bella, a very pretty and distinct hybrid between C. concolor and C. insigne var. Sanderæ, showing the characters of both parents very plainly (Award of Merit).

Messrs. H. LOW & CO., Enfield, staged a few good plants, including Cypripedium × Mrs. Tautz (Award of Merit). Cypripedium × Minos Low's variety was shown also in a well-grown and well-flowered plant. A Vote of Thanks was awarded for group.

Father CROMBLEHOLME, Clayton-le-Moors, exhibited Cypripedium × Esperanda. *P. W.*

THE HORTICULTURAL CLUB.

ANNUAL MEETING AND DINNER.

FEBRUARY 14.—Much enthusiasm was shown by the members of the Horticultural Club on Tuesday last, the occasion being the annual meeting and dinner.

The annual meeting commenced at 5 P.M. in the Club room, Hotel Windsor, Westminster, when a satisfactory report was presented by the Committee. During the past year ten members have resigned, chiefly owing to the distance at which they reside from London, but nine new members were elected.

The papers read at the monthly meetings included the following: "The Use and Abuse of Botanising," by the Rev. Prof. HENSLOW, M.A., F.L.S.; "Back to the Land," by T. W. SANDERS, F.L.S.; "Himalayan Rhododendrons for English Gardens," by Sir JOHN LLEWELYN, Bart.; "Indian Primulas," by Sir GEORGE WATT, K.C.S.I.; "Gilbert White and the Selborne Society," by Prof. BOULGER, and "Syria and the Holy Land," by JOSEPH CHEAL. In July the members and friends visited East Burnham Park, the residence of Mr. and Mrs. Harry Veitch, and the annual outing there was much enjoyed. The party also inspected some fine trees at Langley Park.

The report was accepted with satisfaction.

All the officers were re-elected, excepting that Messrs. W. A. Bilney and Chas. E. Pearson were elected members of the Committee in place of the Rev. H. R. Burnside and Mr. Hudson, who have retired. A cordial vote of thanks was passed to the Hon. Secretary, Mr. E. T. Cook.

About eighty ladies and gentlemen sat down to dinner at 6 P.M., and Sir JNO. T. D. LLEWELYN, Bt., President of the Club, presided, supported, on the right hand by Mr. Harry J. Veitch, and on the left by Mrs. Veitch.

Owing to the kindness of Messrs. Jas. Veitch & Sons, the tables were plentifully and tastefully adorned with plants and flowers, and the event being also graced by the presence of a large number of ladies, the scene was a very pretty one.

After the Royal toasts had been honoured, Mr. GEO. PAUL proposed that of "The Royal Horticultural Society" in a capital speech, in which he referred to the events of that day, and to the flourishing condition of the Society. The Council and Fellows were now one body and one party; grumbling had ceased. And why should it not? They had now a Hall that was all they could wish it to be, and a garden that was likely to become all they could wish it to be. He anticipated the time when Wisley would become the centre of horticultural teaching in this country, when England, too small for farms, would be a vast garden.

Mr. W. A. BILNEY responded, and said that was the sixth occasion that day upon which he had had to do with horticulture, such was the work that befell members of the Royal Horticultural Society's Council. Mr. BILNEY went on to speak of individuals who had helped very materially in Royal Horticultural Society work recently, including Mr. H. J. Veitch and Mr. H. B. May. The speaker quite agreed with what Mr. Paul had said in regard to Wisley, and stated that the Council that day had decided to accept the offer of a famous gentleman to commence scientific research work there.

Sir JOHN LLEWELYN proposed "The Horticultural Club," and reviewing the work of the past year showed that much good work was being done. Referring to the former Secretary, Rev. H. H. D'Ombrain, Sir John said those present would be glad to know that he was in good health, and that the Committee had that day sent a telegram of congratulation to the reverend gentleman. Dr. Henry would shortly give a paper at the Club upon "Forests wild and cultivated," illustrated with lantern slides.

Mr. JEFFRIES responded, and gave some interesting particulars of the early history of the Club.

Mr. GEORGE MONRO, in proposing "The Visitors," referred to the frequent use of the Club-room by different societies, and said that it should be known as "The National Home for National Societies." The National Potato Society and almost every other national society used their room. Mrs. Monro had just suggested to him that the art of cooking Potatos was as important as that of cultivating them, and he therefore proposed that a National Potato Cooking Society be formed, and that Mrs. Harry J. Veitch become the first President.

Other toasts included "The Chairman," proposed by Mr. H. J. VEITCH, who said that the dinner was the seventh horticultural function he had attended during the day; "The Secretary," &c., and being interspersed with songs by "The Georgian Singers," and a humorous recitation by Mr. C. T. Druery, the proceedings were greatly enjoyed.

NATIONAL CHRYSANTHEMUM.

A MEETING of the Executive Committee was held at Carr's Restaurant on the 13th inst, Mr. Thomas Bevan presiding. The Secretary read a letter from Mr. C. E. Shea, President, regretting his inability to attend the Annual General Meeting on the 6th inst., thanking the members for re-electing him as President, and for their resolution of sympathy with him in his illness. A letter was read from the Secretary of the Crystal Palace Company confirming the dates of the three shows at Sydenham, namely, October 4 and 5, November 1, 2, and 3, and December 6 and 7. A financial statement was submitted showing a balance in hand of over £40. An election to seven vacancies on the Floral Committee was the next item on the agenda. A letter was read from Mr. C. Gibson, of Mitcham, an old member and exhibitor, who for many years had occupied a seat on the Executive and Floral Committees, withdrawing his name from the latter body. The Secretary was instructed to convey to Mr. Gibson the regret of the Floral Committee that circumstances had occasioned his withdrawal from that Committee, and to express to Mr. Gibson an appreciation of the excellent services he has rendered to the Society for many years. The following were re-elected on the Floral Committee:—Messrs. G. Prickett, W. Higgs, J. Lyne, and R. Kenyon; and Messrs. C. H. Curtis, G. Gover, and C. J. Ellis were elected to fill vacancies. Judges were appointed for the three exhibitions in the present year. It was resolved that a list of new varieties of the leading sections of Chrysanthemums be prepared for the Annual Report, Messrs. C. H. Payne, Crane, and Curtis undertaking to prepare the same.

The Market Show Committee made a report to the effect that a market show be held on December 13 next on the same lines as that of 1904; that the exhibits be confined to Chrysanthemums; that application be made for the use of the French Flower Market, Covent Garden, for the use of the show; that the last Committee be re-appointed with the addition of some leading market growers and salesmen. The report was unanimously passed.

The Schedule Revision Sub-committee made a report showing some alterations in the wording of several of the classes at the October show; while the conditions of the Affiliated Societies' Trophy Class in November was materially changed in the hope that the alteration would bring an increased competition in the future. The condition now reads, "A table of Chrysanthemums representative of not fewer than four sections, to fill a table space 18 by 3 feet, the flowers to be shown in vases.

It was resolved that the annual outing during the summer take the form of a water-trip from Staines to Windsor, application to be made to His Majesty the King for permission to visit Frogmore.

*** In our report of the annual meeting last week, we should have stated that Mr. Thos. Bevan was re-elected Chairman of the Executive Committee, on the proposition of Mr. Foster.

ROYAL GARDENERS' ORPHAN FUND.

FEBRUARY 10.—The annual meeting of the subscribers to the Royal Gardeners' Orphan Fund was held on Friday, the 10th inst., at "Simpsons'," Strand, London. There was a moderate attendance. Mr. H. B. May, Chairman of the Committee, presided over the proceedings.

REPORT OF THE EXECUTIVE COMMITTEE.

In presenting their Seventeenth Annual Report, the Executive Committee has again the pleasure of congratulating the supporters of the Fund upon a year's record of steady progress and enhanced usefulness. They could have heartily welcomed a larger measure of financial support, especially from the class whose children alone derive the benefits of the Fund; but in the face of the "hard times" it is a matter for

congratulation that the revenue (exclusive of legacies, &c.) shows an increase of some £35.

As will be seen from the accounts presented herewith, there has been a slight increase in annual subscriptions, which is unhappily considerably more than counterbalanced by the falling off under the general heading of donations. This the Committee greatly deplores, for the reason that the deficiency is attributable mainly to the smaller amounts obtained by means of collecting boxes, the sale of flowers, &c., at exhibitions, musical entertainments, and the opening of private gardens for the benefit of the Fund. On the other hand, the collection at (and in consequence of) the Annual Festival amounted to a larger sum than has resulted from any festival held since 1896.

The payments made on account of the children show an increase over the amount paid in the previous year of £74 10*s.*, largely owing to the increased number of candidates who required assistance while waiting for election. The Committee consider it extremely desirable that they should be placed in a position to meet the numerous pressing applications for assistance made under Rule 14, and again earnestly appeal to those most nearly interested in the matter for a larger measure of support to enable them to do so. It is the Committee's experience that in most of the cases that come before them the poor widows and children are left almost destitute, and most pitifully apply for help, that the Committee has been glad to grant assistance when possible, and to give promptly, thereby enhancing its value, but with so many claims coming upon them, it would seem that in the near future it may happen that this much-needed help will not be forthcoming without some increase in the annual subscriptions.

The number of orphans who have been elected to receive the benefits of the Fund during the past sixteen years is 189, and the total amount expended in allowances during the same period is £13,522 17*s.* 6*d.* At the commencement of the year the number of children receiving the full weekly allowance was eighty-eight, and ten were added to the list by election at the annual meeting. The number on the Fund on December 31 was ninety-three, while twenty-nine of the candidates waiting election were receiving temporary assistance.

The usefulness of the Fund has never been made more apparent than is evidenced by the greatly increased number of candidates seeking election at this meeting, and it is a source of keen regret to the Committee that the funds at their disposal do not justify them in recommending the election of more than fifteen—fourteen by election in the usual way, and one by resolution to receive the allowance from the "Emma Sherwood Memorial."

With a deep sense of gratitude the Committee once more acknowledge the munificent support accorded to the Fund by its Treasurer, Mr. Sherwood. In addition to a most generous annual subscription, Mr. Sherwood provided the means for placing a child on the Fund at the first election held in 1888, and has since maintained another child for ten years, by an annual payment, as an "Emma Sherwood Memorial." To these benefactions Mr. Sherwood has added a munificent gift of £500 to endow the "Emma Sherwood" Memorial in perpetuity; and the Committee feels assured that their heartfelt thanks to Mr. Sherwood will be shared in by every well-wisher of the Fund, and doubtless also by the poor orphan children for all time to come who will benefit under the trust.

The Annual Festival held on May 17, under the presidency of Sir Trevor Lawrence, Bart., K.C.V.O., again proved a most gratifying success. It seemed specially appropriate, in the Centenary year of the Royal Horticultural Society, that the President of that Society should occupy the chair and plead the cause of the poor orphan children of gardeners; and the Committee most gratefully acknowledge the great service which he rendered the Fund on that occasion, as his sympathetic appreciation of the good work done by the Fund and his warm-hearted appeal for aid in its support resulted in a subscription list amounting to £818 18*s.*, the largest amount collected at any Festival since 1896.

With very great pleasure the Committee make the announcement that the next Annual Festival will take place at the Hotel Cecil on Thursday, May 11, when, for the first time in the history of the Fund, the chair will be occupied by a Scottish nobleman—the Right Hon. the Earl of Mansfield having most kindly consented to preside on that occasion. The Committee feels assured that the well-known interest which Lord Mansfield takes in horticulture and arboriculture will ensure a record attendance, and that they will have the pleasure of welcoming many of their northern friends, and of receiving the cordial support of all interested in the welfare of the Fund on this occasion.

With very sincere regret the Committee records the death of one of the founders of the Fund, and for some years one of their most esteemed colleagues, in the person of Mr. Herman Herbst, of Richmond, whose genial presence in Committee and whole-hearted interest in the Fund at all times and seasons will remain a cherished memory with all who had the pleasure of being associated with him. A generous benefactor during life, Mr. Herbst did not forget the poor children in death, having left a legacy to the Fund of £100.

To the numerous local secretaries who continue to assist the Fund, often at the cost of much labour and inconvenience to themselves, and not infrequently under somewhat disheartening circumstances, the Committee again tender their warmest thanks; and especially do they desire to place on record their cordial acknowledgment of the great service rendered to the Fund by Mr. R. Scott, gardener, Moorfield, Manningham, who from the inception of the Fund has been Local Secretary for Bradford, and who on leaving the district has, much to his regret, been compelled to resign. Mr. Scott has ever been most energetic in pressing the claims of the Fund upon his neighbouring brother gardeners, especially at the meetings and exhibitions of the Bradford Chrysanthemum Society, and the Committee much regrets the loss of so enthusiastic a fellow-worker.

The members of the Committee who retire by rotation are Mr. W. R. Alderson, Mr. George H. Barr, Mr. George Cuthbert, Mr. William Howe, Mr. John Lyne, Mr. William Poupart, Mr. T. W. Sanders, and Mr. W. P. Thomson, and all being eligible, offer themselves for re-election.

To the Auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, the best thanks of the Committee are again tendered for their valued services in auditing the accounts. Mr. Barr is the retiring auditor, and is nominated for re-election.

P. RUDOLPH BARR } *Auditors.*
February 7, 1905. M. ROWAN }

The CHAIRMAN, in moving the adoption of the Report, congratulated the subscribers upon the fact that, although the times had been hard in the past year, the receipts to the Fund had been increased. At the same time the Committee was alarmed at the disproportion between their income from annual subscriptions and those from donations, annual festivals, and other more or less precarious sources. The responsibilities the Committee were called upon to undertake increased by leaps and bounds; they were that day only able to elect about one-half of the candidates, although all were deserving of relief. The powers vested in the Committee of helping candidates whilst waiting for election, by granting them 2*s.* 6*d.* per week, had been employed with beneficent results, but unless more financial support was forthcoming, it appeared likely that this could not be continued, at any rate in the degree that was now done. The Annual Festival might not always prove such a "humper" [source of income] as it had previously been, and then where would they be? He (the Chairman) pleaded for more annual subscriptions from gardeners and employers of gardeners. An income derived from such subscriptions would furnish a more satisfactory basis for the Fund to rest upon. Mr. May gratefully alluded to the good service rendered to the Fund by Sir Trevor Lawrence by the interest and sympathetic support he gave when presiding at the last annual festival dinner—an event that proved so successful. In connection with that dinner the Secretary (Mr. Wynne) wrote to the lady members of the Royal Horticultural Society, setting forth the claims of the Institution, and asking their help; but although there are about 502 such members, the amount received from them was hardly sufficient to pay for the cost of postage! We believe with Mr. May that if it could be brought home to these ladies what excellent work the Fund is doing they would not be found wanting in sympathy for the orphans it is the purpose of the Fund to assist.

The CHAIRMAN gave a few particulars of the career of one of these orphans, who by the grants from the Fund had been enabled to complete his schooling in a satisfactory manner, and had since obtained many certificates for proficiency in the theory and practice of plumbing (see p. 49).

Mr. W. MARSHALL (formerly Chairman of Committee) seconded the adoption of the Report and subsequently called attention to the great increase there is in the practice of nominating two children of one family at one election. He thought that when all could not be helped, it was better to assist two widows by giving them five shillings per week than one widow by giving her ten shillings per week. He had been a member of the Committee for ten years and was well aware of the pains that were taken to sift the cases that came before that body, and he only raised the question in order to draw the Committee's attention to it, being convinced they would do what may prove to be desirable in the matter. Mr. A. DEAN supported Mr. MARSHALL in ventilating this question, and said that on the list of candidates that day there were nine couples.

The Chairman referred to previous discussions on this question, and to a letter received from the Bournemouth Gardeners' Association in 1904 and again that day, in favour of preventing the election of two candidates from one family. Mr. MAY said that he would assure them that if in the interests of the Fund it became necessary for the Committee to have power to refuse two nominations from one family, he would ask the subscribers for that power.

Mr. LYNE struck another chord when he said that often more charity was exercised in relieving two children in one distressful home in which there might be six or seven children, than one in another home where perhaps there were only two.

Mr. H. J. VEITCH thought the best thing to do would be to decide to reject the second nomination until the child nominated first had been elected.

ELECTION OF OFFICERS.

Mr. H. J. VEITCH proposed that Mr. N. N. Sherwood be re-elected Treasurer, and that he be thanked for his past services and for his great liberality always. During the past year he had given £500 to endow the Emma Sherwood Memorial.

Mr. ALDERSON having seconded the motion, it was adopted with acclamation.

Mr. Rudolf Barr was re-elected to serve as Auditor, on the proposition of Mr. HOWE, seconded by Mr. WITTY.

The retiring members of the Committee were re-elected, on the proposition of Mr. A. DEAN, seconded by Mr. BATES.

In proposing the re-election of Mr. B. Wynne as Secretary, the CHAIRMAN paid a high and deserved tribute to the manner in which Mr. Wynne carried out his work. When the motion had been seconded by Mr. T. W. SANDERS, it was carried unanimously.

Scrutineers were then elected to examine the ballot-papers, and the meeting adjourned.

PENSIONERS ELECTED TO THE FUND.

When the meeting reassembled the Chairman declared the result of the poll as counted by the scrutineers. This was as follows:

1.	HOGAN, FRANCIS THOMAS	327
2.	KEMPSELL, WINIFRED ALICE ...	302
3.	MANN, DORIS MAY	302
4	MANN, MARGUERITE JANE	281
5.	RYDER, BEATRICE MARY	276
6.	COOMBES, FREDERICK	257
7.	DAY, ERIC CHARLTON	249
8.	PARKER, DOROTHY ELIZABETH ...	249
9.	BEST, ARTHUR VICTOR	230
10.	RYDER, CHARLES EDWARD ARTHUR	212
11.	HOGAN, WILLIAM BENEDICT	200
12.	GILLETT, ELIZABETH	178
13.	PECKITT, NORMAN ALEXANDER ...	172
14.	FOOTE, FRANK	167
	HARDES, BESSIE	158

The Chairman then declared the first fourteen names to have been duly elected, and announced that the Committee have selected Bessie Hardes to benefit under the Emma Sherwood Memorial Endowment. This child represented one of the most necessitous cases, and until a few minutes before the poll was closed, was among the fourteen successful candidates. The unsuccessful candidates, and the number of votes recorded for them, were as follows:—

Sparkes, Albert Richard, 145; Day, Arthur Leslie, 108; Page, Albert Edward, 104; Bundy, Olive Gertrude, 95; Stride, Doris Evelyn, 85; Hardes, Thomas Arthur, 69; Warwick, Percy E. S., 60; Reid, Arthur, 59; Tilbury, Ena Mary, 54; Warwick, Ivy Constance, 43; Boyce, Charles Alfred, 40; Mullens, Mary Eliza Marguerite, 32; Harrison, William Stanley, 25; Mullens, William Henry Norton, 26; Reid, Mary Janet, 20; Stride, John Edgar, 17.

THE FRIENDLY DINNER.

At 6 o'clock P.M. the Committee and a few friends met at the same Hotel and dined together. Mr. H. B. May, Chairman, presided, and the proceedings, which were enlivened by a few songs, were of the most cordial description.

GARDENERS' DEBATING SOCIETIES.

WORTHING AND DISTRICT HORTICULTURAL.—The first meeting of this newly-formed Society was held on February 2, under the Chairmanship of the President, Alderman E. T. Cooksey, J.P. Mr. C. Short, Broadwater Hall Gardens, gave an able and instructive paper on "The History and Cultivation of the Chrysanthemum." He described in detail the best time and the proper manner of taking the cuttings, also the methods of potting and watering these plants. The lecturer also gave information on the best methods for combating such pests as the rust disease, greenfly and mildew. *C. E.*

CHELMSFORD AND DISTRICT GARDENERS'.—At the weekly meeting on Friday, the 10th inst., under the presidency of Mr. Simpson, Mr. F. J. Chittenden gave a paper on "Gardening in Olden Times." Gardening was followed by the Egyptians, the Jews, and the Romans, the last-named of whom brought the art to England. Later the monks grew in their herb gardens plants for food and for medicine; but flowers for beauty were not grown till about the year 1500. In the fourteenth century manor and farm houses had a garden attached in which were grown Onions, Leeks, and strong-smelling herbs. Under Elizabeth flowers began to be cultivated for their beauty. The first record of gardening "accounts" dates from about the year 1340, and the first treatise on gardening was written by John Gardener in 1400. Robert Salle was an authority on grafting in the fifteenth century; while Parkinson wrote his work in 1629. A discussion followed. *S. M. C.*

GARDENING APPOINTMENTS.

MR. W. MORGAN, for several years Gardener at Sharston Hall, Northenden, Cheshire, as Gardener to Sir WM. EDEN, Bart., Windlestone Hall, Ferryhill.

Mr. W. R. COX, for the past seven years Foreman at Aldermaston Court, Reading, as Gardener to W. PARROTT, Esq., Barton Court, Kintbury, Newbury, Berks.

Mr. G. W. CUMMINS, formerly Head Gardener at Wallington, Surrey, and at Balmedie, Aberdeen, has been appointed Head Gardener to LEIGH GOLDIE-TAUBMAN, Esq., The Nunnery, Douglas, Isle of Man, the appointment dating from February 1, 1905.

Mr. W. H. KEARY, for eleven years Gardener at Carlton Hall, Saxmundham, as Gardener to Sir HUGH WYNDHAM, Royate Lodge, Petersfield, Hants.

Mr. WM. ROBERTS, for over two years Foreman at Delamere House Gardens, Northwich, as Gardener to ROSCOE BRUNNER, Esq., of Belmont Hall, Northwich, Cheshire. [Thanks for contribution of 2s. to the Gardeners' Orphan Fund. ED.]

Mr. F. SHERWELL, recently employed at Messrs. JOHN PEED & SON'S Streatham Nurseries, as Head Gardener at "St. Marys," Wokingham, Berks.

Mr. A. E. WALLACE as Gardener to J. GWYNNE, Esq., Kenton Grange, The Hyde, N.W.

Mr. G. PAGE, late Gardener at Silwood Park, Ascot, Berks., and previously of Rossett Holt, Harrogate, as Gardener to G. S. LYSAGHT, Esq., Nynehead Court, Wellington, Somerset.

Mr. G. J. DYMOTT, for the past year and ten months Gardener to G. D. NEWTON, Esq., Croxton Park, St. Neots, as Gardener to HENRY ADAMS, Esq., Cannon Hill, Bray, Maidenhead.

Mr. THOMAS MCMINN, Foreman in the Gardens, Bellacrum, Beauly, N.B., and previously Foreman for over three years in the Gardens, Oakmere Hall, Hartford, Cheshire, as Gardener to Captain HAWKES, Achnayairn House, Inverness-shire, N.B.

Mr. A. E. HORTON, late Gardener to H. H. PLATTEN, Esq., Harwood Hall, Upminster, as Gardener to T. L. BOYD, Esq., North Frith, Tonbridge.

Mr. G. PRESTON, late General Foreman, The Grove Gardens, Stanmore, as Gardener to Sir WILLIAM CRUMP, Glenthorne, Harrow Weald, Middlesex.

Mr. HENRY BURTOOT, late Foreman at Chevening Park Gardens, Sevenoaks, Kent, and recently employed in Messrs. JOHN PEED & SON'S Nurseries, as Gardener to The Lady WAECHTER, The Terrace House, Richmond, Surrey.

Mr. CLARKE, recently employed at The Streatham Nurseries of Messrs. JOHN PEED & SON, as Gardener to J. S. MANLEY, Esq., Rutland Lodge, Brixton, S.W.

Answers to Correspondents

APPLES: *D. F.* There are two well-known varieties of Apple to which the word "Duchess" might apply. One of these is Duchess's Favourite, an early dessert Apple of rich red colour, grown in considerable quantities in Kent for the supply of the London market. The other is Duchess of Oldenburg, also an early ripening Apple, used by some for cooking and by others for dessert. The skin of this Apple is greenish-yellow in colour, but streaked with irregular markings of red, very different to the unbroken colour of Duchess's Favourite. Which of these is meant by "Duchess" we cannot be sure, but should be inclined to think that it is Duchess's Favourite.

BOOKS: *J. V., Holland.* There is no book in the English language especially for the teaching of business correspondence for young gardeners.

CARNATION SEEDLING: *W. T.* The flower you send has no special merit, and is inferior in quality to others already in commerce.

CARNATIONS: *F. P.* We think the circumstances you mention are sufficient to account for the appearance, but we also see traces of red-spider and of thrips.—*A. G. F.* We find traces of eel-worm in the leaves. Turn them out and bake the soil.

CHARITY: *A. G.* The postal order for 1s. 6d. has been placed in our collecting-box for the Gardeners' Royal Benevolent Institution.

CURRANT SHOOTS: *W. & J. B.* The shoots you enclose are affected with the Currant-bud mite, See illustration in our issue for January 14, p. 31.

GARDENER'S NOTICE: *Mona.* If the gardener devoted his whole time to the service, and worked in the house occasionally, we think he would be entitled to one month's notice.

GLASSHOUSES IN NURSERY: *F. G.* We are not aware that the phrase "500 feet run of glass" has any other meaning than the obvious one. This is that if the houses were placed end to end they would extend for a length of 500 feet. By such a phrase no indication is afforded of the width of the houses or of the character of the roofs, which may be span-shaped in some and sloping from a wall in others. If the word "run" were omitted the sense and meaning might be the same, but its employment definitely indicates that square feet are not intended.

GRUBS IN MINT ROOTS: *T. W.* The grubs or larvæ are those of the garden swift moth, Hepialis lupulinus. Your better course will be to dig up the roots and transplant them on fresh ground, taking care at the same time to remove all the grubs you can find and destroy them. As a means of preventing the moths laying their eggs on the newly planted ground you might soak some old rags in paraffin and place them at intervals among the plants. This should be done early in May; or if practicable you might protect the plot with freshly tarred fish-netting. Apply to the infected ground a good dressing of lime and soot, and fork it over.

HYACINTH BULBS: *G. C.* The bulbs are swarming with bulb-mites. Destroy the bulbs by fire, and bake the soil before you use it again (see p. 40 of our present volume). The plant is Helxine Soleirolii.

LADY GARDENER: *E. C. C. D'O.* If you will apply to Mrs. T. Rothera, The Gardens, Burton Joyce, Notts, she will furnish the particulars you require; or write to Messrs. Ramsbotham & Co., Bletchley Nurseries, Bucks.

NAMES OF FRUIT: *Cultus.* Tower of Glamis.—*R. W.* 1, Hoary Morning; 2, Striped Beefing; 3, Gipsy King.—*Eiffel.* 1, Minchull Crab; 2, Annie Elizabeth.—*W. G. Canning.* Langton Nonsuch.—*C. L. B.* 1, Gascoyne's Scarlet Seedling; 2, Borsdörffer Seedling; 3, Ribston Pippin; 4, Cox's Orange Pippin; 5, Castle Major; 6, Tom Putt.

NAMES OF PLANT: *J. A.* Tulip Couleur ponceau.—*L. McC.* (from last week). Trachelospermum jasminoides var. variegata.—*Cultus.* Jacobinia chrysostephana.—*W. D.* 1, Begonia manicata; 2, Strobilanthes anisophylla; 3, Isoloma hirsutum; 4, Adiantum gracillimum.—*R. W.* Cordyline species, leaf only; Pteris serrulata cristata; Asplenium bulbiferum. The last-named is the Fern which bears young plants on the fronds. Why not number the specimens?—*F. C. P., York.* Cattleya Trianæ.—*W. H. H., Leeds.* Odontoglossum gloriosum of the best type.—*A. R.* 1, Odontoglossum Lindleyanum; 2, O. luteo-purpureum; 3, Masdevallia tridactylites.—*J. P.* A very fine variety of Cattleya Trianæ.—*C. P.* You should number the specimens. Pteris longifolia; Fuchsia procumbens, with fruits. Tetramicra (Leptotes) bicolor the Orchid; Acokanthera spectabilis, the white flower; Sedum carneum variegatum.—*C. J. P.* 1, Codiæum (Croton) trilobum Disraeli; 2, C. augustifolium major; 3, C. irregulare; 4, C. Weismanni; 5, C. pulcherrimum; 6, C. spirale.—*A. H. B.* Iris reticulata Krelagei.—*Constant Reader.* Varieties of Camellia japonica.—*J. H. P.* 1, Juniperus communis; 2, Taxsonia Van Volxemi; 3, Retinospora plumosa of gardens; 4, Thuya gigantea, the true plicata; 5, Cotoneaster microphylla; 6, Escallonia macrantha.—*W. R.* 1, Thuya occidentalis; 2, Thuya gigantea, the true plicata; 3, T. orientalis var.; 4 and 5, Cupressus Lawsoniana; 6, Juniperus excelsa.

POTTING CATTLEYAS: *T.* A safe time to repot the specimens of the large-flowered Cattleyas is when young roots are proceeding from the newly-formed growths. The plants should be kept rather dry until well advanced in growth. Over watering in any stage of growth is very detrimental to most Cattleyas.

POTATOS FOR NAMING: *Knighton.* We cannot undertake to name varieties of Potatos. Send them to a trade grower.

THE PROPAGATION OF CLEMATIS: *Desperandum.* Clematises are easily increased by grafting. First of all obtain good healthy roots upon which to work the scions. If you have any old specimens in the garden, or plants of the common species, C. flammula or C. vitalba, it will be an easy matter to dig up a supply of roots, the pieces of which should be from 4 to 6 inches in length, about the thickness of a quill, and if well furnished with fibres so much the better. The scions may be taken from old as well as from new wood, but the latter is preferred. Each scion should be limited to one joint or a pair of eyes, just below which a wedge-shaped cut or a simple straight cut rather less than 2 inches, long should be made, and the scion then immediately placed in position and securely tied with narrow matting in a damp condition. They will then be ready for potting-up, and in order to get the roots into small pots it will be necessary to wind them round, but in doing so be careful not to loosen or injure the scions. It will be advisable to plunge the pots in cocoa-nut fibre or tan in a light propagating case kept closed and having a temperature of about 65° to 70°. Sprinkle the pots overhead with a fine rose water-can occasionally. If water collects on the undersides of the glass it should be wiped off with tiffany every morning, or damping of the plants will result. As growth increases a small stake should be applied to each plant, air admitted by degrees, and later on the plants should be placed in a cold frame.

TULIPS DISEASED: *G. V. O.* The plants are attacked by a fungus allied to the one that causes the Snowdrop disease (Botrytis galanthina). All diseased bulbs should be destroyed, and the remaining ones dusted with flowers-of-sulphur. See *Gardeners' Chronicle* for March 2, 1889, p. 2.

THE PLEASURES OF GARDENING.

THE manifold enjoyments which horticulture can confer are not confined to any special season of the year, otherwise in all probability I should have chosen at this period a different theme. Doubtless the most memorable floral inspirations are chiefly experienced during the beautiful seasons of spring, summer, and autumn. In January and February we have the pendulous grace of the Snowdrop, flowering on the grave of winter like a living prophecy of the silently approaching spring. In March and April shine steadfastly upon our vision the golden glory of the Daffodil, with its fragrant companion, Narcissus ornatus, illuminating and transfiguring by their sun-like influence our gardens and lawns. Summer gives us the grandeur of the Oriental Lily and the loveliness of the luminous Rose; while autumn, whose colours are those of the sunset, has radiant Dahlia and Chrysanthemum beauties peculiarly her own. But not only do such exquisite seasons as these inspire the soul of the reverential horticulturist with "a sense of something far more deeply interfused, whose dwelling is the light of setting suns, and the round ocean and the living air, and the blue sky, and in the mind of man;" not only has he experienced, amid the summer twilight, in his own Garden of Eden, such ennobling moral emotions as these, he also must feel, as I did to-day, when he discovers a solitary sweet-scented Violet flowering amid the desolations of winter, that "Nature is but a name for an effect whose cause is God." The most magnificent Rose that adorns and makes odorous the garden in summer, with its glorious environment of deeply-glowing green, does not appeal more profoundly to the consciousness of the lover of Nature than does his first fair vision of the beautiful Anemone-like Christmas Rose. Its contemporary and successor is the equally brave Snowdrop, a flower universally admired and loved; though full of simplicity, its beauty is supreme. Fragrant plants that bring sweetness to the stern heart of winter are sufficiently rare, but there is one to which this unique attribute belongs; I allude to Tussilago fragrans, the Winter Heliotrope, whose odour much resembles that of the precious flower to which it has been instinctively compared. One of the brightest of the floral treasures of winter is Jasminum nudiflorum, the naked-flowering Jasmine, which amid every form of atmospheric adversity flowers with matchless beauty and wonderful luxuriance on our leafless garden walls.

But not only does Nature at this crucial season thus minister in rare and striking instances to our instinct for beauty, she also sustains, through her divine reliability, the inward atmosphere of gracious Faith. When we consign our fairest Roses to the ground we have the conviction that, surviving all the adverse and trying conditions to which by the elements they may be subjected, they will calmly put forth their lustrous leaves in April, form their embryonic buds in May, and subsequently at the touch of the great summer magician, more wonderful than Aladdin in the Oriental tale, glorify this green earth with the revelation of their flowers. No influence is more powerful than that of horticulture for generating the purest pleasures and fairest capabilities of our lives. Since man was driven from his primal, short-lived Paradise, many Edens have been created in every region of the world where cultivation is a possibility, through the combined powers of genius, assiduous perseverance, untiring patience, and intensest toil. We reap to-day that harvest of brightest beauty which our ancestors have sown. The horticultural present, with all its splendid results of culture and hybridisation, has been built upon the achievement of the past. But while the horticulturist is intensely conservative, always seeking the increased beauty rather than the destruction of the venerable types and forms of floral and vegetative life, he is at the same time essentially progressive. He forgets in his great earnestness the difficulties he has surmounted, the heights he has ascended, in the presence of those mountains of thought and aspiration that tower beyond his gaze.

"The heights by great men reached and kept
Were not attained by sudden flight;
But they, while their companions slept,
Were toiling upwards through the night."

David R. Williamson.

PLANT-COLLECTING IN CHINA.

WE learn from Messrs. Jas. Veitch & Sons that their traveller, Mr. E. H. Wilson, is about to return to this country, and in view of his remarkable success and of the importance of his introductions a slight sketch of his work may be read with interest.

The name of E. H. Wilson is now as familiar to all with any knowledge of plants as are those of Douglas, Hartweg, the brothers Lobb, John Gould Veitch, and others of the most successful collectors. He, like those named, had practically a virgin country to explore, and he made the most of the opportunity; but, unlike others, Wilson had great advantages: he had enjoyed a long special training, and the question of expense was not so serious as it was in the middle of the last century. Gifted with quite the right temperament, enthusiastic and resourceful, it is not surprising therefore that Wilson has been so successful.

Born in Birmingham, he received part of his early training in horticulture in the Botanic Gardens of that town under Mr. Latham, the ex-Curator. From Birmingham he went to the Royal Gardens, Kew, as a young gardener, and whilst there he obtained a national scholarship, which enabled him to take a course of lectures on botany at the Royal College of Science, South Kensington, under Professor Farmer. In the spring of the year 1899, Sir William T. Thiselton-Dyer, Director of the Royal Gardens, was asked to recommend to Messrs. Veitch a young man capable of undertaking a prolonged journey in China, and Wilson was suggested as a likely person.

The object in sending a collector to China was to obtain seeds and living plants of species almost certain to prove hardy in Great Britain, and more especially to obtain living specimens of some remarkable species known to exist in the upper part of the Yangtsze valley.

Wilson had been accustomed at Kew to the handling of seeds, and when in April, 1899, he sailed for China *viâ* America, he was given twelve months to learn what he could of the Chinese flora from Professor Sargent, of Boston, U.S.A., and from Dr. Henry, then in the service of the Chinese Customs.

An acknowledgment is due to Sir William Thiselton-Dyer for selecting Wilson, and an equal debt is due to Professor Sargent and Dr. Henry for the knowledge they helped Wilson to acquire.

Wilson arrived at Hong Kong in June, 1899, and after an adventurous trip to Sezemao, in Yunnan, undertaken to meet Dr. Henry—during which time he obtained Jasminum primulinum (see *Gard. Chron.*, March 28, 1903, p. 197)—he returned towards Shanghai to start on the main journey.

Fully equipped, and with definite written instructions, Wilson left for Ichang in February, 1900, a house-boat being his residence for all that summer. In the following April he found Davidia involucrata (see *Gardeners' Chronicle*, April 11, 1903, p. 235), the tree for which he was especially sent. The "Boxer" riots were disturbing, but Wilson displayed considerable courage and did not leave.

During 1901 the high mountain ranges north-west and south of Ichang on the Hupeh-Szechuan boundary were explored, and large quantities of seeds, bulbs, and dried specimens were obtained by Wilson

and sent home. Amongst those which up to the present have proved the more striking from a gardening standpoint, are Davidia involucrata, Astilbe Davidii, Clematis montana rubens, Senecio clivorum, S. tanguticus, Buddleia variabilis var. Veitchiana, Actinidia chinensis, Neillia sinensis, Aconitum Wilsoni, Artemisia lactiflora, Pinus Armandi, Spiræa Henryi, Viburnum rhitidophyllum, Brandisia racemosa, Deutzia discolor, Aconitum scaposum var. pyramidalis, Corydalis thalictrifolia, C. Wilsoni, numerous and various Vines, Maples, Spiræas, Rubuses, Magnolias, Limes, Birches, Pyruses, Roses, &c.

MR. E. H. WILSON.

From this journey Wilson returned in April, 1902, spending the summer and autumn at Messrs. Veitch's Coombe Wood nursery, and he started again for the extreme west of China, as far as the Tibetan frontier, in January, 1903, furnished as before with definite written instructions. Once more these instructions were carried out practically without a failure.

In six months, *i.e.* in June, 1903, he reached Kiating in view of the mountains of Tibet, the valley of the Min river, and the sacred mountain Omei.

At Tatien-lu, on the frontier of Tibet, he found the object of his journey, Meconopsis integrifolia (see Supplementary Illustration, *Gardeners' Chronicle*, October 1, 1904), and obtained quantities of seed, the results of which were distributed in September, 1904. Famine prevailed, labour was difficult to obtain, but Wilson evinced a dogged courage which ensured success.

Early in 1904 he again made a journey to Tatien-lu by a different route from Kiating, and in crossing some of the higher passes endured intense cold; his attendants were frost-bitten, and all suffered from snow-blindness.

Wilson describes the scenery of these regions as being of savage grandeur—the country like a sea of mountains, all the higher peaks being under perpetual snow. The Rhododendrons are gorgeous, and for miles and miles present in their season a mass of bloom. He returned to Kiating by the ordinary route, and reached it in safety on July 24, 1904.

In August Wilson again started northwards on an expedition to Sungpan, an undertaking which occupied fifty-two days. Of this trip he states: "Having cleared the low country, I got amongst some magnificent mountain ranges covered with a luxuriant flora, and in places well forested. The sides of these mountains are so steep that a flying-machine would be necessary to properly explore them. Species of Meconopsis occurred in plenty, and when collecting the seed we had to tramp about in snow nearly a foot deep."

In addition to the Meconopsis, a noteworthy find on this journey was a new species of Incarvillea.

The last excursion from Kiating was commenced in November, 1904, and occupied about sixteen days, the plant of which Wilson was primarily in quest being Dipelta floribunda (Caprifoliaceæ), a beautiful flowering shrub which inhabits almost inaccessible places on mountainous cliffs, and very seldom produces fertile seeds. Severe winter weather prevailed at the time, but Wilson accomplished the object of his mission, and returned again to his base at Kiating. This station he finally left on his homeward journey on December 5, reaching Ichang early in 1905, and subsequently left for England, where he is shortly expected.

We congratulate Messrs. Veitch on their enterprise, and on behalf of horticulturists and botanists we tender our cordial acknowledgments to their intrepid and highly successful collector.

THE VALUE OF STEWING PEARS.

For many months to come home-grown fruit will be scarce. Dessert varieties of Pears will be practically past, whilst almost the same may be said of Apples, whether of table or of cooking varieties. As a substitute for these, and to follow on for a considerable period, I know of no fruit more suitable than Pears of stewing varieties. They will keep good for many weeks, and when carefully stewed and served, few fruits can equal them as a sweet. Both in Worcestershire and Sussex I have been fortunate enough to have found some grand old specimen trees (standards) which yielded several bushels of fruit each, and very serviceable the fruit proved throughout the winter and spring months; indeed, these trees were considered as valuable as any in the garden or orchard.

In planting a new garden or orchard, or in renovating old ones, the merits of the stewing Pear are usually overlooked, though others of only second-rate quality, and which are only usable for a very brief period, are planted freely. It may be that many reject them thinking they may have to wait for a considerable time before the trees come into bearing, which is true to a great extent when standard trees are planted in the ordinary grass orchard; but fortunately there are other ways of growing and training them which may come under ordinary garden cultivation, such as bushes and espaliers, also as cordons on an east wall in inclement districts. Indeed, I am not sure that they might not profitably replace many inferior varieties now occupying valuable positions on a west wall or fence.

Unnecessary hedges, which yield no return, are sometimes used as divisions in kitchen gardens, proving in many cases cumberers of valuable ground, a haunt for birds, and receptacles for rubbish. How much better and more profitable would it prove were these grubbed and burnt, the site cultivated, replaced with a double row of strained wire trellis 5 or 6 feet high, and Pear-trees trained thereon, either as oblique cordons or espaliers, including some varieties whose fruits would be suitable for stewing! Several pyramids and open bushes might also be planted, while I would strongly advise landowners to plant a few tall standards in their grass orchards, or even in their pleasure grounds.

Of the different kinds we have under cultivation, Catillac is seen the most frequently in gardens, though the old standards referred to above were of the noted Black Worcester. In Dr. Hogg's *Fruit Manual* the following varieties are named under the heading of "Stewing":—Belmont, Besi d'Hery, Flemish Bon Chrétien, Gilogil, Verulam, Winter Franc Réal, and Uvedale's St. Germain. In some localities where the soil is not quite suited for good Pear culture, I

have found such kinds as General Todleben and Beurré de Rance hard and gritty, but they have proved very acceptable for stewing, though unsuitable for dessert. *Richard Parker, January.*

CYMBIDIUM SANDERI.

Our illustration (fig. 49) represents the fine new Cymbidium Sanderi, for which Messrs. Sander & Sons received a First-class Certificate at the meeting of the Orchid Committee of the Royal Horticultural Society, on February 14. It was discovered by Micholitz when exploring for Messrs. Sander in the highlands of Annam in 1904, at which time dried specimens of the flowers were received, and a very few plants came alive. It is a companion plant to the handsome white-and-purple C. Parishii Sanderæ, sent by the same collector, and is one of the finest introductions of recent date, a grand addition to the species, and destined to play a great part in the production of novelties in the hands of the hybridist. The plant has ovate, somewhat compressed pseudobulbs, which are furnished with gracefully-arching, narrow, bright-green leaves. The inflorescence rises erect, and by the evidence of the scars on the old flower-spikes, may have seven or eight flowers. The flowers are white delicately tinted with a faint shade of rose, the bases of the sepals and petals and the labellum being decorated with rose-purple. *J. O. B.*

FIG. 49.—CYMBIDIUM SANDERI (HORT. SANDER): FLOWERS WHITE, WITH ROSE AND PURPLE MARKINGS.
A new species. Awarded a First-Class Certificate at the Royal Horticultural Society's Meeting on February 14.

FRUIT REGISTER.

APPLE LADY HENNIKER.

During the month of February, when dessert Apples are scarce, Lady Henniker, although classed as a kitchen variety, is agreeable for dessert. As a standard tree or as a freely-grown bush one can usually make sure of a crop of the variety Lady Henniker when there are Apples of any kind. In some soils the fruits have a tendency to become spotted in the skin, and the spots are sometimes deeper than the skin, which is detrimental in every way, and interferes with their keeping qualities. As a late keeping dessert variety it is worth planting.

APPLE BLENHEIM PIPPIN.

After Cox's Orange Pippin, Blenheim Pippin is the most popular of Apples in the dessert section, and it would be more so but for the fact that too long a time is required to get the trees into bearing. When once this is done, however, it is remarkable how regularly this Apple will afford a crop of fruits. This is some compensation for the delay entailed. I have lately experimented with the variety, with a view of bringing it earlier into bearing, by grafting it on to ten-year-planted standard trees of Ecklinville Seedling, which is apparently an excellent variety for use as a stock. Half-a-dozen stout grafts were put on four years since, each one having three buds. The scions grew away rapidly, making in some cases from 2 to 3 feet

length of growth in the first season. Instead of cutting the shoots hard back to form a head, they were allowed to extend almost at will; I simply took out the points of the strongest shoots, and thinned out the shoots to avoid over-crowding. So successful has been this method that a nice crop of good fruit was produced last year, and there is a good prospect for the coming season. As the trees are standards, an opportunity is afforded of allowing a free extension of growth, thus enabling the branches to form fruit-spurs naturally, which is not so easy where the trees are restricted, as in the case of bush-trained or pyramidal examples. *E. M.*

Pear Virginie Baltet.

A fruit in perfection in December, of large size, club-shaped, oblique at the base where it joins the short stalk; skin yellow flushed with red, smooth; flesh melting, juicy, sugary, delicately perfumed. Raised and distributed by M. M. Baltet. *Revue Horticole*, February 16.

PELARGONIUM "MADAME CROUSSE."

The illustration at fig. 50 shows what a rich display of flowers may be obtained from Ivy-leaved Pelargoniums when trained as wall plants. The specimen figured is growing about 10 feet high against the front of the residence of Mr. R. H. Phillips, at Dudley Terrace, Ventnor, who being quite an amateur in horticultural matters is justly proud of the appearance the plant had in August last, when the photograph was taken. It must be pointed out, however, that the climate at Ventnor is so favourable that the plant thrives out-of-doors all the year round, and the roots therefore are not subjected to disturbance in autumn as would be necessary in districts where Pelargoniums have to be removed indoors. Even on Christmas Day last Mr. Phillips's plants bore forty-five "trusses" of flowers, some of which were fully expanded. An admirable testimony to the favourable character of the winter climate at Ventnor.

Fig. 50.—Ivy-leaved Pelargonium "Madame Crousse" on a house-front at Ventnor: colour of flowers rose-pink.

Pear Le Lectier.

An excellent late Pear. The form figured is Calebasse-shaped. *Bulletins d'Arboriculture*, February.

Kitchen Apples for Use in February & March.

For present use Striped Beefing is a good variety; the fruits are large in size and rich in colour. The tree grows strongly, and we have had to prune the roots every few years; but it is a variety which we should not like to be without. Another old but excellent keeping Apple is Rymer, one of our best kitchen Apples, and a most reliable cropper. Sandringham we still have in good condition, and this variety also bears well as a standard; as does Alfriston, another grand Apple for use during the next two months. The fruits are very large, and they cook well. Lane's Prince Albert and Newton Wonder are capital here, either as bush or standard trees: the former variety is especially fine as standards, and the trees appear to do well when grafted on healthy orchard stocks, thus showing that the Crab makes an excellent stock for the variety. *James Mayne, Bicton Gardens, Devonshire, February* 16.

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT BURFORD.

Sir Trevor Lawrence's famous gardens, sheltered by Box Hill, are exceptionally well situated for the perfection of the flowers of winter-blooming species, and often there is a fine show of flowers in the Orchid-houses there when there is a scarcity of bloom in collections less favourably situated. This winter, however, the fogs have reached Burford, and many of the showy flowers, and especially those of the Phalænopsis, were destroyed. In the Phalænopsis the display is only deferred, for the more backward buds have since developed.

Contrary to the usual experience in gardens, Phalænopsis amabilis (grandiflora) is one of the best to grow at Burford; one large specimen of it which has been in the gardens many years has eleven leaves and a very strong branched spike, and others of the same species are equally vigorous.

In the same house, with a good collection of rare Cypripediums, stands the strong plant of Cypripedium Stonei platytænium, now really two plants, though still in the same pot. Among the Cypripediums in flower recently was a fine specimen named C. × aureum Confetti, but which resembles a very handsome C. × Leeanum of the Albertianum class; several of the delicately-tinted Burford hybrid C. × hirsuto-Sallieri; a very large form of C. × Lathamianum, and other hybrids.

In the Cattleya and Lælia-houses the hybrids encroach steadily on the space formerly occupied by the species, which are now mainly represented by albinos and proved fine varieties. In this department the introduction of leaves into the compost for potting has proved highly beneficial, and the large number of rare plants of the Lælia, Cattleya and Lælio-Cattleya section never looked so well at Burford as at present. Mr. W. H. White, the Orchid grower at Burford, uses in most cases equal parts of leaves and peat, with a surfacing of sphagnum-moss, and so far he has had no reason to regret the use of leaves in the compost, though, like all cautious Orchid growers, he counsels great care in watering.

The hybrid Brasso-Cattleyas and Lælio-Cattleyas are well furnished with flower-sheaths, in some of which the flowers are showing.

In the intermediate-houses, which contain a very interesting collection of pretty botanical plants, as well as the best of the showy species, a good many species of Maxillaria are in flower, including the rare M. fractiflexa, M. arachnites, M. lepidota, M. pumila, M. leptosepala, &c. The very remarkable M. scurrilis, figured from Burford in the *Gardeners' Chronicle*, July 28, 1900, p. 65, is also thriving well, although refractory when first imported. The varieties of Miltonia vexillaria, M. × Bleuana, and the Brazilian species of Miltonia, are in fine condition, showing well for bloom; a rich purple form of M. × Binoti being in flower; and among other others noted in bloom or bud are Dendrobium Kingianum and its white variety; D. glomeratum with bunches of rose-purple flowers; the pretty white D. æmulum, and D. Fytcheanum with many spikes; the yellow-petalled D. × Melpomene, a companion to the fine yellow D. × Wiganiæ xanthochilum, raised at Burford, the fine white D. Ashworthiæ, and a few other Dendrobes. In the house in which the Sobralias and tall Epidendrums are grown, some of the Sobralias are in flower or bud, so also the brilliant scarlet form of Epidendrum × O'Brienianum, the rose-and-white E. × Ellisianum, E. purum, E. radicans, two varieties of E. polybulbon, and some of the smaller species. Also two good specimens of Spiranthes colorata with ornamental foliage spotted with white and upright spikes of red flowers; Odontoglossum Insleayi, Sophro-Cattleya × Chamberlainiana, one of the prettiest and most free-growing hybrids of Sophronitis grandiflora, with flowers and large seed capsules, Oncidium cheirophorum, &c.

In the warm-houses the principal show of Calanthes was past, and the plants of the later-flowering Regnieri section are in bloom. The Aërides, Angræcums, &c., promise a good supply of bloom, some of specimens being already advanced in spike. One grand specimen of Angræcum modestum Sanderianum, which has been in the collection twenty years, has fourteen large, fleshy leaves and four long spikes, and other rare species are about to bloom, including some very singular species of Angræcum. The new Vanda Watsoniana is in bud, and the unique V. × Marguerite Maron in robust condition.

The cool-houses have the Odontoglossums in fine health. Bright colour is given to the houses by a number of the brilliant scarlet Sophronitis grandiflora, among which is the original Burford specimen grown from a small plant obtained sixteen years ago and now finer than ever and bearing over sixty flowers and some buds. This plant has obtained two silver medals and has been

much admired when shown. Others in flower are several good forms of Oncidium varicosum, one having three spikes of bright-yellow flowers, with red-brown blotch on the lip; some pretty pans of Pleione humilis, with many white-and-rose flowers; the bushy evergreen Epidendrum montanum, with many heads of white flowers, and various other pretty species. Seedling Odontoglossums are being raised very satisfactorily. Formerly they were thought to be almost impossible to rear, but now it is known that they are not more difficult than other species if the proper place can be found for them.

The Masdevallia house has the specimens fresh and vigorous, as they always have been at Burford, but there are only a few in bloom yet. The rare M. trinema with beautiful silver-white flowers marked with purple; the very rare M. Burfordiensis with large, fleshy, claret-coloured flowers; the scarlet M. racemosa, and a few others were remarked in bloom, and the rare M. triglochin and M. deorsa, the latter having a singular pendant mode of growth. Of the same class Stelis micrantha, some pretty species of Pleurothallis, Octomeria, &c., are in bloom and bud.

In the remarkable collection of Bulbophyllums and Cirrhopetalums are many sending up flower-spikes, and the singular feather-lipped Bulbophyllum tremulum, the fragrant B. suavissimum, and some others, are already in bloom.

This famous collection contains a larger number of species than any other and these being native of very widely separated regions, it is a matter for congratulation that the collection maintains its reputation for good cultivation, and that some classes, as for example the Lælias and Cattleyas, have improved even on their former good quality.

COLONIAL NOTES.

NEW SOUTH WALES.

Christmas in New South Wales.—A correspondent, writing from Waverley (near Sydney, N.S.W.), sends us an interesting account of the weather recently experienced there. We read that "on Christmas Eve the temperature did not go below 90° until after 10 P.M. On the following Thursday 95°, on the Friday 91°, and on Saturday (New Year's Eve) 114° were registered. I think it was the record for December for forty years—moist, muggy, tiring heat, so that it was impossible to keep cool; all the crockery, furniture, and even one's clothes were hot to touch; but in the country towns, of course, the reading was much higher, and on New Year's Eve in some of the Sydney arcadea the temperature rose to 120°. New Year's Day turned out much cooler than the day preceding, and the heat-wave is gradually subsiding. To-day (Thursday, January 5) it is 86°, but rather thundery.

Bush Fires.—The poor country people are having a dreadful time, bush fires raging everywhere; stock, cattle, sheep, crops, and homesteads are being burnt out in scores, and it is sad to think what will happen if the rain does not soon come to put the fires out. In some districts there are as many as 20 to 30 square miles ablaze, and whole families, unable to get shelter from the fires, have sought refuge in every available creek and water-hole. These are infested with all kinds of animals and reptiles trying to escape the fury of the fire. A bush fire of good size once seen is never forgotten. The present outbreak is attributed to broken glass lying about, and the heat of the sun is quite sufficient to cause a light. I remember once, some years ago, in Goganjo (Queensland), seeing from a safe distance a fire raging on some hills. The flames seem to gallop along like some mad living thing, and shoot up the tall Gum-trees with frightful rapidity, and rush along the ground very often faster than a horse can gallop. In this present outbreak it is feared that there is much loss of life, and on all sides the tales of suffering from the country are heartrending. Five buildings and the Episcopal church at Bundanoon were reduced to ashes in a day; and one hears of similar catastrophes in every direction. One afternoon quite a panic broke out, and when the tram came in it was fairly rushed, the women carrying wet blankets and towels round their heads. The heat is something terrific, and smoke and cinders are flying everywhere; even the mail train had to return yesterday, and wait for a couple of hours before starting. A relief fund has been started in all the States for the aid of the sufferers."

PROLIFEROUS CYCLAMEN.

Mr. Denny, of Down House Gardens, Blandford, sends us a Cyclamen which differs in some respects from any that we have seen (see fig. 51). Florists would call it a semi-double variety; but it is something more than this, inasmuch as from the axils of the five normal sepals, between them and the five or six normal petals, emerge five or six separate florets, each consisting of from two to five separate petals without any calyx, but with one or two stamens. Within these adventitious florets was the usual corolla, tubular at the base, and with the stamens as usual opposite the petals. The case is therefore included under the head of axillary floral prolification. It is interesting to add that while the normal flower remained on our table for a week or more in a fresh condition, the five adventitious flowers withered quickly, and eventually formed a frill or ring of brown withered petals outside the still unfaded corolla.

Fig. 51.—Cyclamen flower from the back.

Showing the position of the adventitious flowers in the axils of the sepals between them and the normal petals which are shown in dotted outline. The plan shows the relative position of florets.

THE ROSARY.

GRAND DUCHESS (GROSSHERZOGIN) ALEXANDRA, H.T.

Flowers pale, primrose-yellow. *Garten Welt*, February 11, 1905, p. 234; coloured plate.

BOOK NOTICE.

Vegetables and their Culture. By T. W. Sanders.

Another book on vegetables has been published, and the author claims a place among the many, stating that others all fall short of necessary information. We do not go so far as this, but we do say that Mr. Sanders has in 463 pages touched upon most subjects that are worth the attention of vegetable growers. In the formation of the vegetable-garden the initial expense may deter those with villa gardens from adopting the advice given in the book, though it is excellent in its way. The plans are very helpful; but how often it happens that after the builder retires the garden that is to be is a mass of brickbats. One cannot adopt the advice given when only a quarter of an acre, or even less, is the space at command. Again, is it well to cut up the ground into so many paths or borders, and thus lose space?

Manures are dealt with largely; but we would advise beginners to depend more upon animal manures till they know how to use the chemical fertilisers so much advised. In a new garden the soil should be thoroughly tested before these are much employed. The author, as one would expect, owing to his previous experience as a gardener, wisely touches upon the value of salt; but it must also be remembered that few things are more injurious than salt employed at the wrong season; and this applies with equal force to numbers of other substances.

The cropping of the garden, which is an important item, is briefly touched upon. We would add that resting or purifying the soil is equally important, by clearing away the crops early and trenching or turning up the soil roughly.

The system of planting recommended entails a great deal of trouble, for each plant is covered over with an inverted flower-pot! It would be far better to draw drills and plant the seedlings in a smaller state. This point is overlooked by many. It saves much labour, there is no need to prick out the plants as advised, and a little filling up here and there is all that is needed. By having

drills also the moisture afforded the plants more readily reaches the roots.

The author touches upon seed-saving, but with respect to the Brassica family in a small garden this work is best left alone, as the plants degenerate so quickly.

The exhibition of vegetables is touched upon, but it is far better to get the best produce for home supplies than to centre one's attention upon a few things at the start. In the book is given the number of points allowed for each vegetable staged. Too much importance is given mere size, as some vegetables are almost worthless when grown too large.

Cultural notes follow, and these are mostly to the point. As regards Asparagus we do not agree with Mr. Sanders when he advises mulching new beds with short grass mown from the lawn. In planting we prefer a wide flat drill to ridges, spreading the roots out. It is advised that roots after forcing should be grown on for future use. This is loss of time; indeed in many gardens the roots in beds are left till they are so poor that they do not pay for the land occupied; better make new beds oftener.

There is no great gain in the southern part of the country in sowing Brussel-Sprouts in heat. By so doing large open sprouts result, and they are more attacked by caterpillars. Celery, for instance, is much better sown thinly, and for late supplies planted direct into the trenches. How often one sees large plants, upon which much time has been spent, collapse after planting, or they grow hollow and almost useless.

In regard to root-crops excellent advice is given upon "size" and cropping; but as regards Artichokes, it is stated that they may remain for years in the same position; we would, however, add, that much smoother roots, round, and of better quality, are obtained by good culture, treating them much the same as other roots. Parsnips are often sown much too early. The date here given, January or February, for home supplies would be better two months later, as a Parsnip large enough for any purpose can be grown in six months; for exhibition purposes, roots a yard long and very large are fashionable, but these lack the quality of smaller roots developed more quickly; and such roots do not keep so well.

Potatos are a leading feature. We regret to see some of the best kinds are omitted. Newer ones that have been much praised, although in only a few cases their merits have been tested, are now numerous. In giving a list of vegetables many good things are omitted; for instance, there are only four Cauliflowers enumerated, and this in a list of popular vegetables. Again, with early Turnips, the Long White, so much forced and grown for the Paris markets, is not named. The list, we admit, is a difficult part of the work, but it might well have been more general.

"BEEHIVES AND BEE-KEEPERS' APPLIANCES." Edited by Paul N. Hasluck. (Cassell & Co., Ltd., London, Paris, New York, and Melbourne).

Mr. Hasluck, the editor of *Work*, has collected information scattered over more than 20,000 columns of the above-named periodical, and now offers them in well-arranged and convenient form. Modern bee-keeping depends so much upon hives and appliances, upon the assistance of man rather than on the unaided work of the bees, that a handbook such as that before us is of great use. It contains mention of the newest improvements, and an abundance of illustrations dealing, as indicated by the title, with these rather than with the life and work of bees or with how to move and manage them.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Shading will be requisite for many of the more tender-leaved subjects, and if the permanent shading is not yet fixed for the season, sheets of tissue-paper should be spread over such plants as need protection from bright sunlight. Plants near the glass and exposed to the sun will naturally become dry on their surfaces; this should be guarded against, but excessive watering must also be carefully avoided, for seldom are two days alike. The permanent shading appliances should be prepared and fixed ready for use by the end of this month, and then only used when it is absolutely imperative to use them. Although many subjects are now showing signs of renewed activity, do not urge them forward by excessive heat and moisture, but rather maintain such conditions that the growth may be steady and solid.

Miltonia spectabilis and other species of Miltonia having creeping rhizomes should now be in a fit condition to be repotted or resurfaced, but they should be allowed to become moderately dry at the roots before disturbing them. Use pans filled with drainage material to within 2 inches of the rim, and fix the plants in position to form the specimen by using good fibrous peat and clean sphagnum-moss in equal parts, making this of slightly mounded shape. Pieces of rhizome having but few roots should be secured in position by means of short bent lengths of copper-wire, placing the growing points centrewards whenever possible. In top-dressing pick out as much of the old material as possible without disturbing the plants, and substitute fresh peat and sphagnum-moss. When the work has been done afford the plants a good watering, and place them on the stage in a shady part of a Cattleya or warm intermediate-house. Spray them overhead regularly, and afford water freely to the roots throughout the growing season. Miltonias of the Clowesii and Regnelli group being stronger-growing and deeper-rooting subjects, may be grown in pots containing drainage material to half their depth. Add a small proportion of Oak-leaves to the peat and sphagnum-moss, and surface with sphagnum-moss alone. These species need a less degree of heat, will bear more light, and having a greater depth of rooting medium, should not be watered so copiously as the others.

M. vexillaria, being now in a state of active development, must not be permitted to suffer from lack of moisture at the base, though where any leaf-mould is used and Fern-rhizomes are substituted for drainage, care must also be taken to avoid over-saturation. Spray the plants overhead once a week with some safe insecticide to keep them free from thrips. M. Roezlii should be afforded a warm, shaded position in the East Indian-house, and if the spot favours rapid evaporation, frequent overhead waterings will be necessary. Potting or top-dressing should be done when new growths appear. Use pans in preference to pots, so that width rather than depth be secured. Place an inch deep or so of Fern-rhizome at the bottom, fill in to near the rim with a compost consisting of one-third each of peat, sphagnum-moss, and Oak-leaves, and a sprinkling of fine sand, surfacing the whole with chopped sphagnum-moss. Afford water but sparingly for a considerable time afterwards, but keep the surroundings moist by daily spraying the plants and by damping between the receptacles. The hybrid between the above two species, M. Bleuana, thrives in a shaded part of the Cattleya-house, and flowers at various seasons of the year. After the plants have flowered, afford them a short rest by keeping them moderately dry. In other respects treat the plants in a similar manner as for M. vexillaria.

Cattleya Gaskelliana is now breaking into growth, and the necessary re-surfacing or potting should be done ere this get too forward. It likes a cooler position than most Cattleyas, hence the materials do not dry up very readily, and so if any leaves be employed infrequent waterings must follow, unless it be when the plants are rooting freely. Like C. labiata, this species should be shaded from all direct sunshine, or the leaves will acquire an unhealthy appearance; but if the shading be too dense it will detract from the quality of the flowers, or even prevent their production.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WITHES, Esq., Copped Hall, Epping, Essex.

Stove Plants.—Proceed with the repotting of any plants that require more root-room. Unless the potting shed is conveniently situated a temporary bench placed on the stage in the house containing the plants to be potted should be used. The necessary material for the work should be ready to hand, including clean pots of various sizes, well drained with broken crocks or charcoal. Avoid over-potting. Those plants that do not require a shift into larger pots should have their surface-soil removed and be afforded a top-dressing. Most stove plants succeed in a compost consisting of good turfy loam, leaf-soil, silver-sand, and broken charcoal, but exception should be made for such plants as Ixoras, Marantas, Dipladenias, &c. These require a liberal addition of peat soil to the compost mentioned. A little "plant-manure" added to the compost is very beneficial, but great care should be taken not to employ too much. A 6-inch potful of manure to a barrow-load of the compost is a good and safe proportion. Freshly potted plants will require careful watering for some time afterwards, but in the first instance they should be thoroughly watered with a rose water-pot to settle the soil. Creepers overhead planted in inside borders should be afforded a top dressing of good soil, but first the old soil should be removed and the roots examined. If they are in a healthy condition, a little dusting with bone-meal before the fresh soil is added will be of benefit to them, but should the roots be in a poor condition manure of any sort must be avoided and a little fresh soil only added until such time as the plants recover their vitality and are capable of making roots freely.

Ferns.—In order to obtain a supply of greenery for decorative purposes there is no better method of production than that of having plants growing on the wall of a house having a north aspect. Very little trouble is required in fixing a trellis or wire netting to hold the soil together, and if Ferns be planted now they will make considerable progress during their first season of growth. The appearance of a wall so treated always gives pleasure, and the growth of the plants is much finer than that of plants in pots. Ferns that require a warm, moist atmosphere should be repotted or top-dressed as may be needed. Equal parts of good turfy peat and loam, a little dried sheep droppings passed through a half-inch mesh sieve, together with broken charcoal and silver-sand in moderate proportions, will form a suitable compost.

Bouvardias, Fuchsias, Abutilons, Aloysias, &c., should now be pruned, placed in a warm-house, and syringed freely on warm, sunny days. A batch of Cannas may be introduced into heat for flowering early; if plunged in a bed of leaves they will soon start into growth, when potting-on or dividing, as may seem best, can be carried out.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Asparagus.—Few vegetables require less labour, are more appreciated, or can be more easily grown than Asparagus. In order to produce long bleached stalks, a considerable depth of soil is an advantage, but stalks about 6 inches in length and of proportionate thickness, one-half of which is fleshy and eatable, may be considered an ideal dish. Such can be produced in soil of very indifferent quality if it be worked well and manured to a depth of from 18 inches to 2 feet. The seeds should be sown thinly in drills 2 inches deep, and from 18 to 24 inches apart, in March, when the soil is in good working condition. Thin out the young plants when large enough to handle, leaving them 15 or 18 inches apart in the rows. Permanent plantations, whether in beds or on the level ground,

that were dressed in the autumn with farmyard manure, should now be lightly and carefully forked over, reducing the manure and soil to a fine condition, and removing any substance which would be likely to prevent the shoots from coming freely through the soil. Afford a dressing of nitrate of soda, applying about 2 lb. of soda over 50 square yards, or apply soot in much larger quantities. If the beds are very rich from annual applications of manure, apply a good dressing of air-slacked lime to them. Maintain the supply of forced Asparagus by forcing the plants in warm frames in which the Asparagus will be near to the glass.

Peas sown, as advised early in the year, in 4-inch pots have just been potted into 8-inch pots, placing them sufficiently low to allow of the stems being well moulded-up before leaving the soil 1 inch below the rim. Neat bnshy twigs were afforded to support the plants, and they are now in a position near to the glass in an atmospheric temperature of 45° to 50°, having a circulation of tresh air. Where suitable accommodation can be provided, boxes will be found to answer admirably for growing early Peas under glass.

Onions.—Seeds sown as advised early in the year under glass in a temperature of 55° to 60° have just been removed to portable frames on mild hot-beds, the pots being plunged in fine soil near to the glass. Close attention shonld be given to thinning that no deformed plants (which are visible early) be overlooked, for these would cause disappointment later on by the splitting of the bulbs.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Peaches and Nectarines.—It is well to defer the final pruning and tying of these as long as circumstances will permit; but although the branches have been released from the wires to defer the blooming period, the development of the buds has been so hastened by the warm weather that the work will have to be commenced forthwith. Failure in the cultivation of Peach and Nectarine trees out-of-doors is frequently due to the trees being overcrowded by old and useless wood. Growers are sometimes advised not to prune too much, and the process of disbudding being but little understood, the trees are soon allowed to reach the top of the walls, and the lower parts become quite bare. At this season, nevertheless, very little remains to be done, if all superfluous and old fruit-bearing shoots were removed last year after the fruits were gathered. Remove the ties and shreds, and if the trees were attacked with red-spider or have brown-scale upon them, thoroughly scrnb the old wood with a solution of Gishurst Compound, working it well into the crevices of the bark. The brush should be drawn in an upward direction when dressing the shoots, and unless the work be done very carefully, the buds may afterwards drop. White walls should be limewashed, and brick or stone walls be syringed with a solution of paraffin and soft-soap. If 2 oz. of soft-soap be mixed with the same quantity of flowers-of-sulphur and put into 1 gallon of water, it will make an excellent wash for trees and walls also. I use this when the trees have set their fruits, the sun-heat at that time and during the summer radiates from the wall, and carries with it fumes from the sulphur. When all has been made perfectly sweet, lay-in the main branches of the trees, securing them with soft tar-twine to the wires or nails, radiating them from the main stem at equal angles on each side the tree, afterwards filling up the intervening spaces with well-ripened fruit-bearing shoots of medium strength, allowing a space of 4 to 6 inches between each shoot. Well-ripened shoots, where space permits, should be tied-in their full length, but weak and immature shoots may be cut back to a triple or growth-bnd in the firm wood. Aim to have an evenly-balanced tree; let the shoots be clean, straight, and as equidistant as possible; shorten the lower branches more than the top ones, so as to secure more vigour in this the weakest part of the tree. New wires should be given two coats of linseed oil. In making the ties, allow the branches ample space to swell. Trees growing on light or gravelly soils should be examined, and if the roots are in the least degree dry, afford them a soaking with manure-water from the farmyard.

Stocks intended for grafting should be cut down to 18 inches of the ground, and old standard trees should be headed back. See that sufficient grafts (scions) are laid in for this purpose, covering them 8 to 12 inches in the ground.

Affix labels to all newly-planted trees, and to any others requiring new ones.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Tomatos.—The earliest plants are now making rapid progress, and require much care in the application of water to the roots until the first trusses of fruit have set, after which more liberal treatment may be afforded them. Pollinate the flowers, and pinch out the side-growths from the main shoot as they appear. Keep the atmosphere moderately dry where plants are fruiting, and a temperature of 55° to 60° at night, with free ventilation during favourable weather. Repot young plants for succession, always keeping plenty of plants in readiness for putting into permanent positions when they are required.

Melons.—If seeds have been sown as advised in a previous Calendar, and are growing in 12-inch pots, let fresh leaves be placed round the pots, if this be necessary to maintain the bottom-heat at 80° or 85°. Spray the plants with water twice on bright days, and keep the atmosphere moderately moist, applying a little ventilation early in the day in mild weather. The plants may be expected to grow more freely as the days become longer, and the house may be closed early on bright days, allowing the temperature to increase to 85°, afterwards falling to 70° at 10 P.M., or 5° lower in the morning in cold weather. Remove all surplus laterals as they appear, and stop the shoots when they have acquired sufficient length or are about 1 foot from the top of the house. Give careful attention to the pollination of the flowers to obtain as even a "set" as possible, two fruits being quite enough for the earliest plants to mature. More seeds should now be sown in 3-inch pots, and the pots plunged as advised in a previous Calendar. These will provide plants for planting in beds. Make preparations for these by thoroughly cleansing the house, and prepare the bed as previously recommended for Cucumbers. Place large turves of moderately strong loam, putting the grass side downwards, upon the bed to form a ridge, and fill up the centre with broken turf and a good sprinkling of wood-ashes. The plants may be put from the seed-pots into the bed as soon as they are large enough, planting them (not too deeply) at distances of 1 or 2 feet apart. It is essential that such plants never suffer a check from being pot-bound. Hero of Lockinge and Blenheim Orange are excellent varieties, but a few new varieties of repute may be planted also. British Queen is a white-fleshed Melon of medium size and excellent quality.

Strawberries.—As soon as the fruits change colour remove the plants to a cooler atmosphere, afford them more ventilation, and discontinue the use of liquid manures. When the fruit has been taken from the earliest plants, remove them to a cold frame to harden off before planting them out in the garden, where they will fruit again during September. Plants which are now swelling their fruits may have at night a temperature of 60° to 65°. Liquid-manure from the farmyard, also weak guano water and clear soot water, are useful at this stage. During the same period the plants are liable to attacks from red-spider, therefore syringe them well underneath and above the foliage, and do not allow them to suffer for want of water at the roots. Strawberry plants in flower should be afforded an atmospheric temperature of 55° and free ventilation. Pass the brush over the flowers at noon each day, and when they have "set," thin out the fruits to eight upon each plant. Introduce later plants to a house and place them near to the glass where the temperature will not exceed 50° at night. The present is a good time for those who have not the convenience for very early forcing, to introduce the first batch of plants, as they will soon commence to grow freely.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Herbaceous Border.—The following list of half-hardy annuals, &c., are all useful for adding variety to the herbaceous border. They should all be sown in the spring, the seedlings pricked off when ready, and be planted in the border in June:—Alonsoas, Arctotis grandis, Aster sinensis, Antirrhinums, Chamæpeuce, Diascia Barberæ, Dianthus, Francoa ramosa, Gaillardias, Gaura Lindheimeri, Hollyhocks, Hunnemannia fumariæfolia, Melianthus major, Nicotiana affinis, N. Sanderæ, N. sylvestris, Nemesia strumosa, Pentstemons, Phlox Drummondi, Salpiglossis, Scabious, Œnothera taraxacifolia, Polygonum orientale, and Zinnias. Lobelias comprise some of the finest of plants for beds, borders, and bog-gardens, and delight in a deep rich soil. Seed should be sown early in order to secure plants for planting in June. They may also be sown in July for flowering the next season.

Pentstemon Newbury Gem is a plant suitable for many positions in the flower garden. It is of dwarf habit and freely produces its scarlet-crimson coloured flowers. The stock can be increased from cuttings obtained by placing the old plants into heat, which can be performed now. The growths when removed root readily, and if potted-on develop into good plants for the borders.

Early-Flowering Chrysanthemums and Fuchsia Dunrobin Bedder can be similarly propagated.

Pelargoniums. — Prepare a mixture of sandy loam and leaf-mould for potting Pelargoniums that were rooted in boxes last autumn. Afford variegated and choice sorts the best positions in an atmospheric temperature of 60° to 65°. If desired, cuttings may now be inserted in small pots containing sandy soil, afterwards placing the cuttings on a gentle bottom-heat till rooted.

Repotting.—Plants of Humea elegans from seed sown last July and wintered in 4-inch pots should now be given a shift. Solanum jasminoides is a useful climber for flowering in summer, and if cuttings were rooted last autumn the plants should now be potted on.

Sub-tropical Plants.—Seeds of Ricinus may now be sown, putting one seed in each 3-inch pot. Place them in a temperature of 65° to 70°, and when the plants are ready move them into 5 or 6-inch pots. Encourage them to make good growth, then harden them off. Other sub-tropical plants, such as Melianthus major, Solanum Balbisii, S. Warscewiczii may be sown; also seeds of Antirrhinums and Pentstemons. See that the seedlings do not get "drawn," eaten by pests, or become dry or too wet. When watering, use sufficient water to wet the soil thoroughly, and let it be of the same temperature as that of the house.

The Propagation of Tender Bedding Plants can be commenced when they have made growths large enough to furnish cuttings.

THE APIARY.

By CHLORIS.

Feeding in March.—The critical season of the year is now almost with us, for it is from now until the middle of May that stocks die from starvation. Especially will this be the case this year in many parts of the country, for two reasons—(1) the honey harvest was almost a complete failure in some counties; (2) January and February have been very mild indeed, and early breeding has followed in consequence. About the end of the first week in March, when the weather is favourable, make an examination of the hives, ascertain their exact condition, taking note of the following points—(*a*) Has breeding commenced? (*b*) how much food is there stored and sealed? (*c*) and is the hive watertight? If breeding has started we know the stocks are headed by a fruitful queen; if there be no brood the sooner a queen is introduced, or the bees united to a weak stock headed by a queen, the better. Should stores be low syrup feeding should be commenced.

APPOINTMENTS.

TUESDAY, FEB. 28—Royal Horticultural Society's Committees Meet. National Rose Society's Committee Meeting.

MARCH.

THURSDAY, MAR. 2—Linnean Society's Meeting.

SATURDAY, MAR. 4—Société Française d'Horticulture de Londres Meeting.

MONDAY, MAR. 13—United Horticultural Benefit and Provident Society, Annual Meeting at Caledonian Hotel, London, 8 P.M. Birmingham Mutual Improvement Society's Meeting.

TUESDAY, MAR. 14—Royal Horticultural Society's Committees Meet. National Rose Society's Committee Meeting.

THURSDAY, MAR. 16—Linnean Society's Meeting.

WEDNESDAY, MAR. 22—Royal Botanical Society's Show at Regent's Park.

FRIDAY, MAR. 24—Royal Botanical Society's Meet.

MONDAY, MAR. 27—Birmingham Mutual Improvement Society's Meeting.

TUESDAY, MAR. 28—Royal Horticultural Society's Committees Meet.

WEDNESDAY, MAR. 29—Liverpool Horticultural Society's Spring Show (2 days).

THURSDAY, MAR. 30—Royal Horticultural Society's Exhibition of Colonial Fruits and Vegetables (2 days). Torquay Flower Show.

SALES FOR THE WEEK.

MONDAY NEXT—
Roses, Azaleas, Herbaceous and other Plants, Lilies, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Palms, Plants, Azaleas, Roses, Fruit Trees, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Roses, Lilies, Azaleas, &c., at Steveus' Rooms.

FRIDAY NEXT—
Border Plants, Roses, Perennials, &c., at 12, by Protheroe & Morris, at 67 and 68, Cheapside, E.C. —Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30 o'clock.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick = 40·5°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, February* 22 (6 P.M.): Max. 43°; Min. 35°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 23 (10 A.M.): Bar., 30·1; Temp., 39°. Weather—dull and overcast.
PROVINCES.—*Wednesday, Feb.* 22 (6 P.M.): Max. 38°, Plymouth; Min. 37°, N. of Ireland.

Cultural Science.

THERE is, or rather we should say, there was, a great need in this country of a journal wherein experts might speak to experts of their experiments and their speculations, discuss methods and results, until they are ripe enough to be laid before the general public. The *Journal of Agricultural Science*, of which the first part is now before us, is intended to supply that need. Papers of the description contemplated by the editors are as good as lost when published in the Transactions of learned societies, where they are necessarily overlain with the profusion of other matters; and they are not of a nature to be inserted at length in current periodicals of a less technical character, which must deal with established results rather than with lengthy discussions. The first paper in the copy before us deals with the much debated question of Mendelism. Evidence is gradually accumulating in support of this theory, but the subject is so complex and may be looked at from so many points of view, that records of detailed experiments are at the present stage specially valuable. Mr. BIFFEN, of the Agricultural Department of the University of Cambridge, leads off with the results of some experiments started with the object of obtaining some improvement in the quality of English-grown Wheat. Whilst in this country we grow an average of some 30 bushels to the acre, more than double the quantity grown on the same area in most other countries, yet the quality or "strength" of our Wheat as required by the miller and the baker is markedly inferior to that grown in Canada, Russia, and the United States. To remedy this state of things various experiments have been made in hybridising or cross-breeding, and these experiments till recently have been "a game of chance played between men and plants." MENDEL'S experiments go to show how definite results may be expected in future rather than haphazard chances. We need not here repeat the results of MENDEL'S experiments with Peas, as brought to light by Mr. BATESON; but, in order to show the practical value of such trials, Mr. BIFFEN says:

"If Wheats behaved in the same manner as MENDEL'S Peas, then the fixing of the chosen forms after the breaking of the type was going to be a simple matter, requiring merely the test of a single season, and not years of selection and inbreeding. If this were really the case, we had prospects of, so to speak, picking out the valuable characters from different varieties and building up an ideal type. There were possibilities ahead the breeder had hardly dared to hope for. Fresh experiments on the same lines as those of MENDEL were accordingly planned, with the object of obtaining definite knowledge as to the behaviour of all the possible characters of Wheat on hybridising."

We cannot here repeat the details as to the contrasting characters presented by the crossed Wheat plants, as shown in the very numerous trial plots supervised by Mr. BIFFEN. It must suffice to say that the results are in entire conformity with the results expected from a consideration of Mendel's Laws, according to which in the second generation of the cross-breds the "characters" presented are some "dominant," others "recessive," and that the proportion of one to the other is always three dominant to one recessive, or a very close approximation to that ratio—a ratio expressed by the formula 3 D: 1 R. There are exceptional cases, into the details of which we cannot enter. We conclude our reference with this important citation:—

"Any desired combination of the characters represented in any two varieties can be obtained 'fixed' in the first or at the most the second generation from the hybrids."

Mr. ALBERT HOWARD follows with an article on the influence of pollination on the development of the Hop. It is found that Hop-flowers which escape pollination from male plants, of which a few are found in most Hop gardens, are retarded in their development, and never make up the deficiency. They turned out at picking-time to be small, green, and unripe, and compared very unfavourably with the well-grown golden-yellow and ripe pollinated Hops. This is in accord with what was, we believe, stated in these columns sixty or more years ago, and which was also noticed in ROYLE'S *Materia Medica*, published about the same time.

Mr. HALL has an important paper on the indications afforded by the plant itself of the nature and proportions of the ingredients in the soil. To obtain results of value we require to know the average amount of certain constituents in a given plant, as well as in certain parts of that plant, on a given soil over a series of years, comprising extreme variations of seasonal climate, so that the problem is not so simple as it looks. One point, though of course previously known, comes out strongly; that is, in Mr. HALL'S words, "the fluctuations in the composition of the ash are reduced to a minimum in the case of organs of plants which, like the grain of cereals or the tubers of Potatos, are manufactured by the plant from material previously assimilated."

There are various other important contributions by Dr. BERNARD DYER, Mr. S. H. COLLINS, Prof. MIDDLETON, and others; but we have only space to allude to one other short note of Mr. HALL'S on a subject about which some of our correspondents have lately been enquiring; we allude to the use of calcium cyanamide and of calcium carbide as soil-fertilisers. Calcium cyanamide, says Mr. HALL, represents the first attempt on a commercial scale to avail ourselves of the nitrogen in the air as an artificially obtained manure. Calcium cyanamide is obtained by passing a current of nitrogen gas over calcium carbide at a high temperature. The result is a compound containing 20 per cent. of nitrogen. The trials made at Rothamsted with this substance in comparison with sulphate of ammonia, show that the cyanamide is an effective nitrogenous manure, but whether it is commercially more valuable remains to be seen. Whether the calcium carbide (a mixture of calcium and carbon) is of any value as a source of lime is not stated.

We have said enough to show that the *Journal of Agricultural Science* deals with subjects of as great importance to the gardener as to the farmer, and in the full assurance that progressive culture, whether in the garden or in the field, will depend on the application of scientific data to cultural practice, we heartily welcome the new publication.

ROYAL HORTICULTURAL SOCIETY. — The next meeting of the Committees of this Society will be held on Tuesday next, February 28, when a lecture will be delivered by the Hon. J. H. TURNER, the Agent-General for British Columbia, on Fruit-growing in that province, which will be illustrated by lantern-slides.

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, March 2, at 8 P.M., when the following papers will be read:—1, Zoological Nomenclature: International Rules and others (to be followed by a discussion), by Rev. T. R. R. STEBBING, M.A., F.R.S., Sec.L.S. 2, Biscayan Plankton, Part IV., The Thaliaceæ. By Dr. G. HERBERT FOWLER, M.A., F.L.S., &c.

ARBORETUM.—The number of the *Mitteilungen der Deutschen Dendrologischen Gesellschaft* for 1904, published at Bonn under the superintendence of M. L. BEISSNER, is full of interest to those lovers of trees to whom the German language offers no difficulties. Its contents are very varied, and refer particularly to the newer and most interesting introductions from Arizona, British Colombia, and elsewhere. There are also monographs of Ligustrum, Philadelphus, and Deutzia, the value of which would be greatly enhanced if the differential characters at least were given in Latin as well as in German. A full index is supplied, for which readers will be very grateful.

FLOWERS IN SEASON. — A box containing flowers of a number of named varieties of the florist's Primula has been submitted to us by Messrs. WILLIAM BULL & SONS, King's Road, Chelsea, S.W. There are good shades of colour among the varieties included, some of the flowers almost approaching a blue colour, notably one of a deep lavender shade which has received the name "Blue." There are also some of a semi-double type. Judging from the examples before us the strain is a desirable one.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the lecture hall of the Institution on Monday, February 27, when a paper will be read by Mr. HAROLD GEIFFIN (Fellow), entitled "Some Proposals for Improving the Law and Practice of Rating Property."

THE TOMATO TRADE. — Some interesting figures have reached us from the other side of the Atlantic which may be thus compressed: The Tomatos packed in Canada last year amounted to 297,750 cases, each of which contained two dozen tins, compared with 397,500 cases in the preceding year. Growers in the United States packed some 8,671,053 cases last year as compared with 10,282,309 in 1903.

SCAPHYGLOTTIS COGNIAUXIANA.—M. COGNIAUX informs us that the native country of Scaphyglottis Cogniauxiana, described in our columns by M. De WILDEMAN at p. 33 of our present volume, is not Brazil, as there stated, but Mexico. It was collected near Orizaba by Dr. PURPUS, who sent living plants to M. DE LAET, of Contich, and to M. SCHENCK, of Darmstadt.

POPULAR NAMES.—A well-known amateur horticulturist writes:—"How glad I am you have called attention to the absurd re-naming of Correas and Lachenalias! The proposed names are highly objectionable, and specially so to simple and ignorant people who are 'fond of flowers.' They help to confuse the very slight botanical knowledge they might possibly otherwise imbibe."

"COUNTRY LIFE IN AMERICA" is a magazine evidently suggested by our own periodical of a similar name. Paper, type, and illustrations are luxurious, and the subject-matter somewhat startling, as in the case of the article on "Tarpon-fishing."

THE AMERICAN CARNATION SOCIETY.—Our American exchanges are full of the doings of this Society, which held its annual meeting at Chicago on January 25. The reports enable us to obtain some notion of the enormous scale on which the Carnation is grown in the States. We note that the newly-elected President is Mr. PETER FISHER, the raiser of Mrs. Lawson Carnation. By the way we notice that Mr. FISHER is a native of Scotland, who migrated to Boston some quarter of a century ago. It is remarkable how many of the foremost gardeners in the States are of British origin. We do not wonder at their migration, but we are surprised that we hear so little of them after they have left the old country till some special circumstance brings them into note.

SEEDLESS APPLES.—Attention is directed by the *Country Gentleman* to the fact that the seedless Apple, like the stoneless Plum, has been known to pomologists for more than two centuries. Pliny and Theophrastus, at the beginning of the Christian era, are stated to have referred to seedless and bloomless Apples. ROBERT MANNING, of Boston, in 1869 wrote that he had seen this Apple under the name "No-core" at an exhibition of the Massachusetts Horticultural Society several years before. He said that he had also received a similar Apple from a French nurseryman. The greatest previous outbreak of the seedless Apple craze in this country occurred about 1890, or less than fifteen years ago. As to the merits of the variety Prof. BAILEY said, "It appears to possess no value aside from its curiosity." H. E. VAN DEMAN, then U.S. Pomologist, said of it: "My opinion is that the variety is practically worthless as a fruit, but it is quite interesting as a curiosity. Anyone who plants trees of this variety will be disappointed, except in having his curiosity satisfied." "*American Fruits.*" [Apart from malformations of this kind, which are common enough, botanical readers will know that among Rosaceæ unisexual flowers are by no means rare. ED.]

WELBECK.—Mr. JAMES GIBSON, late of Danesfield Gardens, Marlow, was appointed, on the 14th inst., to be head gardener to the DUKE of PORTLAND, Welbeck Abbey, Notts.

"THE GARDEN MAGAZINE." — Messrs. DOUBLEDAY, PAGE & Co., of 133, East Sixteenth Street, New York, the publishers of *Country Life in America*, have issued the first number of a new monthly gardening periodical under the above-mentioned title. It is destined to be, in the words of the promoters, a beautiful periodical, devoted to that most fascinating and refreshing of all subjects, the garden. Among the contributors we notice the names of Professor BAILEY and Professor WAUGH, and others, who afford a guarantee that the magazine will be all that it is intended to be. In an article on the best evergreen trees to be grown in the Northern United States the writer advocates the employment of native rather than of exotic species, a precept that might in this country at least easily be pushed too far. But the peculiarity of this article is that over the text is imprinted a figure of a life-sized spray of some Pinus—perhaps P. Strobus.

LIÈGE.—The Bulletin of the *Federation des Sociétés Horticoles de Belgique* for January 31 contains details concerning the congress to be held at Liège from May 8 to 10 inclusive in connection with the great flower-show to be held at the same time. The attendance of foreign guests is invited. The President is Baron M. VAN DER BRUGGEN, Minister of Agriculture, and the Chairman of Committee, M. CLOSON. Communications should be addressed to M. CH. GONTIER, 101, Rue de Statte, Huy, Belgium.

NEW PLANTS — Among newly-introduced plants mentioned in the Catalogue of Herr HEINRICH HENKEL, of Darmstadt, is Aponogeton monostachyum, the flowers of which are represented as on a simple spike, and described as creamy-yellow in colour. Many interesting aquatic plants newly introduced or not generally known are included in the list.

ROOKS. — As the result of an elaborate enquiry in Germany as to the utility or mischievousness of rooks, it is quoted in an article in the *Journal of the Board of Agriculture*, that crows and rooks are, on the whole, more useful than harmful, especially in the breeding season. He is however of opinion that it is requisite in some cases to diminish their numbers.

"THE GARDENING YEAR-BOOK AND GARDEN ORACLE."—This is a handy little book, prepared by the editor of the *Gardeners' Magazine*, for use in the garden office. It contains, in addition to an almanac and diary, articles on the events of the past year, new introductions, whether of flowers, fruit, or vegetables, a calendar of operations, notes on quarter days and taxes, so that the grave and gay are well mixed. The mean temperature of each day is given, but no locality is mentioned where the record was made, nor any indication as to the number of years from which the mean is taken. The anarchical condition of Russia might be illustrated by the statement that in the thermometer used in that country "the graduation begins at boiling-point, which is marked zero, and the freezing point is 150." This thermometer must surely be the one in use in the topsy-turvy house! We agree with the editor that this book is, as might be expected, literally packed with valuable information of an up-to-date character, and that a shilling spent in procuring a copy would be a profitable investment. It may be had from the office of the *Gardeners' Magazine*, 148, Aldersgate Street.

SPRAYING FRUIT-TREES.—It is satisfactory to read that the practice, of which we so frequently urged the adoption, is now carried out by many fruit farmers. We had imagined that our recommendations had been mostly ignored, but judging from an article in the *Journal of the Board of Agriculture*, the practice is spreading. To avoid risk of poison, no spraying should be done after the fruit has attained a fourth of its full size. The article should be read and acted on by all fruit-growers.

HARPER ADAMS COLLEGE.—The report of the experiments made under the direction of the Staffordshire County Council and of the authorities at the above-named college in Shropshire are chiefly interesting to agriculturalists. The following details concern Potato-growers in general. The trials of different varieties of Potatos at Orton and Cresswell are particularly interesting at the present time. The varieties to which the attention of farmers is particularly called are Sir John Llewelyn, Royal Kidney and The Factor. Each of these Potatos is an excellent cropper, a good resister of disease, and of full flavour when cooked. At Hilderstone the artificial manures appear to have had little effect upon the Potato-crop when used in conjunction with farmyard manure. The largest yield was produced by plot 3, which received 20 tons of farmyard manure per acre, the total weight being 17 tons 4 cwt. 2 qr. 21 lb., an increase over the unmanured plot of 7 tons 8 cwt. 1 qr. 1 lb. There were very few small Potatos, the crop was free from disease and of excellent quality. The good effects of a change of seed from the North are very plainly demonstrated from the results at this centre. The very high prices paid for the newer varieties of Potatos have resulted in the excessive propagation of many of them. This is thought by many authorities to be harmful to the variety, and that its vigour will be materially impaired. In order to obtain some reliable information on this point an experiment has been started on the following lines:—Three plots of ground were planted with—(1) whole sets; (2) cut sets, single eyes; (3) plants from cuttings. The variety selected was Northern Star. The whole sets and cut sets (plots 1 and 2) were planted May 6, and the cuttings were grown on in a cold frame, and planted out early in June. The rows were 3 feet apart, and the plants 18 inches apart in the rows. The ground was in very good order, and no manure was considered necessary. The plants grew rapidly, and from the appearance of the haulm it was impossible to see any difference in the plots. Disease was entirely absent. It will be seen from the table that the cuttings produced the heaviest weight of ware and smallest amount of seed size.

CARNATION FLAMINGO.—Mr. JNO. ROBSON, nurseryman, of Altrincham, informs us that he exhibited a basket containing "Flamingo" Carnation at the last meeting of the Royal Horticultural Society, and that the variety was awarded a Gold Medal in New York two years ago. We have repeatedly stated that it is impossible for us to undertake to notice every exhibit at these or any show. The matter has to be determined not only by the importance of the subject, but also by the time and space at our disposal.

OVER-SEA SUPPLIES FOR JANUARY.—Under this heading we give the monthly account abridged from the Trade and Navigation returns of the oversea trade of this country—only that connected with agriculture and horticulture being recorded here. It is hoped the reader may thus be able at a glance to see how this great division of industry stands in relation to the others—the figures on the one side being compared with the residue for the other. "Our" side will be divided into four classes, the first two affecting the "inner man," the third his immediate environment—from clothes to household goods; the fourth as connected with manufactures generally, as also seeds for sowing and for working up into other material. Figures connected with the animal kingdom have been carefully excluded. The Board of Trade Returns for the first month of the year give the total value of the imports as £47,766,460, which, compared with the figures for the same month last year, £46,132,520, shows an increase of £1,633,940. It matters not here whether the increased value is due to a rise in prices or to an increase in bulk. Our classification table will readily show the relationship of the products of the soil to the mass of imports:—

IMPORTS.

CLASS: DESCRIPTION OF PRODUCE.	1904.	1905.	Difference.
	£	£	£
Class I. — Cereals, and other field crops — Wheat, Barley, Oats, &c.	16,283,715	15,857,558	—429,157
Class II.—All other food cultures — Tea, Coffee, Fruit, &c.	3,851,771	4,429,088	+577,317
Class III.—Used in manufactures — clothing, household goods, &c....	9,404,030	8,425,533	—978,497
Class IV. — Miscellaneous — including seeds, flowers, &c.	3,011,774	2,858,552	—153,222
Values of Produce...	32,554,290	31,570,733	—983,557

It will be interesting to florists to note the figures with which they are concerned. The January imports of flowers amounted to £21,046 as compared with £23,395 in January, 1904—or a decrease of £2,349. The timber-merchant may note that there is a falling off amounting to some £301,164 (£737,851, compared with £1,039,015 in the first month of last year). It is of interest to note here that by arrangement between Archangel sawmill proprietors and the officials of the Crown Lands Department in that province, timber will in future be so supplied to the mills that a heavy reduction can be made in the prices paid by shippers. Turning now to the section of fruit and vegetables, we extract the following figures:—

IMPORTS—JANUARY.	1904.	1905.	Difference.
Fruits, raw—	£	£	£
Apples	190,121	199,673	+9,552
Apricots and Peaches	1,169	142	—1,027
Bananas	55,799	73,923	+18,124
Grapes	174	2,394	+2,216
Lemons...	38,785	30,590	—8,195
Nuts—Almonds ...	24,129	44,600	+20,471
Others used as fruit	28,773	27,973	—750
Oranges...	300,730	334,904	+34,174
Pears	685	1,341	+656
Plums	478	60	—418
Unenumerated ...	6,887	16,478	+9,591
Vegetables, raw—			
Onions ... ...bush.	67,287	85,249	+17,962
Potatos ... ... cwt.	180,422	24,694	—155,728
Tomatos ... ,,	32,081	32,001	—80
Unenumerated ,,	37,256	29,363	—7,893
Totals ...	965,728	903,383	—62,345

It is satisfactory to note here that since the issue of our last monthly table the Union Castle Company's ships have brought the following fruits from the Cape:—Apricots, 268 boxes; Peaches, 363 do.; Plums, 1,364 do.; Nectarines, 45; and Pears, 16—a total of 2,056 boxes. Coming now to—

EXPORTS,

we note in them an increase of £906,412—£24,989,777 for last month, compared with £24,083,365 for January in last year. These exports are entirely of British and Irish materials; but there is a separate "foreign and colonial" list, amounting to, for last month, £6,113,887 sent here to our "shop" for customers to purchase, and this section contains both agricultural and horticultural produce brought from oversea. We have but little of our own raising to spare for other folk.

GRAFTING AZALEAS.—There is an interesting article in the last number of the *Jardin* descriptive of the methods of cultivating the Indian Azalea at Dresden. In the nursery of M. SEIDEL the Azaleas are propagated either by cuttings or by grafting. Cunningham's White Rhododendron is commonly used as the stock. The Rhododendron itself is propagated by cuttings taken from plants grown in the shade. The young plants are potted in July, placed in a cool-house, and grafted in the following winter.

UNDERMOUNT, BONCHURCH, ISLE OF WIGHT.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE type of Primula sinensis shown in the Supplementary Illustration to the present issue has risen much in popular estimation during the past few years. Primula "stellata" is said to have originated in this country from seeds of the ordinary strain of P. sinensis, and in Messrs. Cannell's nursery at Swanley a variety was known under the name of "Lady." Whether Prof. de Vries would consider this as a new species produced by mutation is open to question. The original plants produced very numerous flowers, small in size, and having each petal marked with a wedge-shaped notch. They grew very tall, and the inflorescences were of lax habit, the leaves were long and narrow, and the petioles were dark in colour. Crosses were soon effected between "stellata" and the florist's type until the varieties obtained represented almost every degree of variation between the two types. Such a variety as that shown in the illustration is one combining some of the characteristics of both; it partakes of the habit of P. stellata, but the flowers are larger in size and possess greater substance.

Chinese Primulas are cultivated with much care and success in the gardens at Undermount, near Ventnor, the residence of Henry Michel, Esq., for besides the "stellata" varieties, similar to the plants illustrated, we were shown on January 30 a number of plants in flower representing an excellent strain of the florist's type; also some splendid plants of the old double-flowering varieties that have to be propagated by means of offsets. This type is little cultivated now, and there is no wonder, seeing that such good semi-double flowers as were seen at the last meeting of the Royal Horticultural Society can be raised true from seeds. At the same time such plants as we saw at Undermount growing in 7-inch pots, which were not a bit too large for them, were exceedingly attractive, and the variety grandiflora particularly had superior flowers to those obtainable from seeds.

In the glasshouses and particularly in the conservatory at Undermount, there are plenty of instances of good plant cultivation; but for us, even in January, the chief interest of the place was out-of-doors. Imagine, for instance, our being able to cut fully-opened white flowers of the fragrant Pittosporum Tobira growing 16 feet high on the exterior of the conservatory! Yet such was the case; and by its side were flowers of another fragrant plant, Cheimonanthus fragrans, fully open. In sheltered nooks and borders adjacent to but outside the warm-houses, Clivia miniata had flowers almost ready to expand; Adiantums and Pteris were growing in the crevices of the walls. Solanum jasminoides was trained against the same wall, Dimorphotheca Ecklonii and Cinerarias were growing, and also Hedychium Gardnerianum, which last season produced sixteen tall growths and an abundance of flowers. Flowers were appearing on plants of Acacia armata in the open borders; big bushes of Coronilla glauca were in flower, also Escallonia macrantha, and plants of Megasea crassifolia. On a bank, the face of which was covered with Ivy, there were groups of Gazanias, Wallflowers, and Mesembryanthemums, and open flowers on all these species. Other tender shrubs or plants we noticed included Abutilon vitifolium, Acacia floribunda, A. lophantha, and other species, Agathæa cœlestis, and Phlomis fruticosa (Jerusalem Sage). Further plants in flower were Vinca major, Kniphofias (Tritomas), which are said to flower during the whole year; double-flowered white Stocks, Petasites fragrans (winter-flowering Heliotrope), Roses, especially the variety Madame Berard; Erica Cavendishii; E. mediterranea was 4 feet high, and formed quite a bush, and the collection of Ericas generally is much prized. Lobelia Cavanillesii or L. laxiflora angustifolia is generally considered to be a greenhouse perennial, but in this garden it was growing nearly 3 feet high among the herbaceous plants, and bearing several of its yellow or reddish-yellow flowers. L. laxiflora has also been known as Siphocampylus bicolor.

But perhaps one of the most striking features in this garden was a group of Spring (!) Cabbages, perfectly ready to be cut. The plants were on a little bank facing the sea, and had quite solid, white-looking "hearts." Enquiry elicited the information that they were raised from seeds sown on July 28, and that they were planted out on September 2, 1904. The varieties were Flower of Spring, Ellam's Early, and Sutton's April. Ellam's Early appeared to have "turned in" as early as any of them.

The gardens at Undermount are in the care of Mr. George Cheal.

VEGETABLES.

ROTATION OF KITCHEN GARDEN CROPS.

(*Continued from p. 99.*)

Onions.—As already mentioned, the best vegetable to succeed Celery is the Onion. The deep disturbance of the soil, and the liberal manuring of the ground for the previous crop, provide conditions for the successful growth of Onions, with the assistance only of a light dressing of some approved artificial manure, such as nitrate of soda, which I have found excellent. The Onions should be sown during the first week in March. It sometimes happens that the Celery has not all been removed by that time; should this be the case, a good plan is to take up what plants remain, and plant them closely together in a shady and cool corner of the garden, where they can be preserved in a fresh condition for a much longer time than if left exposed to the drying winds of March in the open ground. This enables the grower to clear the ground in good time for sowing the Onions. Before these are sown the ground should be levelled, and afterwards trodden as hard as a heavy man can tread it. The drills should be drawn at distances 1 foot apart. If the crop is required for home consumption no thinning of the young plants is necessary, unless the seeds have been sown exceptionally thickly. The majority of the Onions thus produced without thinning will be quite large enough for kitchen purposes, and will keep longer in sound condition than those of a larger size, while the small ones are always in demand for pickling.

If larger specimens are required for exhibition or other purposes, higher culture and increased space must be given them.

Autumn Cabbage.

The crop to succeed the Onion is one of the most indispensable of the kitchen-garden, namely autumn-sown Cabbage, for spring and summer supply. These should be planted towards the end of September, using plants raised from seed sown about August 12, and as this crop occupies the land until the following September or October, a dressing of manure should be given when preparing for the crop. As soon as the Cabbages are removed in early autumn the land should be again heavily manured, and if time can be spared, bastard-trenched, and made ready for the reception of Strawberry plants.

Strawberries.

If these latter have been previously prepared by carefully layering, either in the ground or in pots, by the time the land has been prepared for them the plants will be strong, and have abundance of good roots, and should produce a moderate crop of fine fruit the following summer, and exceptionally heavy crops in the two succeeding seasons. At the expiration of this period (three years) the Strawberry plants in their turn must be cast away, making room for a crop of winter and spring Broccoli.

Broccoli.

These should be planted as soon as the Strawberry crop is over, which will be about the end of July. No preparation of the land is necessary for the reception of the Broccoli other than cleaning the surface of weeds. Plant the Broccoli in the solid earth without any digging, and use a crowbar instead of a "dibble" to plant with. Grown in this hard soil they make hardier and sturdier growth, and are in better condition for resisting injury from frosts during hard winters than when grown under more generous treatment. By planting succession crops of early summer and autumn Cauliflower and of winter and spring late Broccoli it is quite possible to produce a supply of those valuable vegetables for every week in the year. *O. Thomas.*

(*To be continued.*)

VANDA WATSONI.

Our illustration (fig. 52) represents a new species of Vanda in which the flowers, with the exception of the crest and interior of the sac, are pure white. The plant was introduced by Messrs. Sander and Sons, St. Albans, through their collector, W. Micholitz. When not in flower it so closely resembles V. Kimballiana that the plant might be easily mistaken for that species. The flowers, however, possess characteristics entirely distinct from V. Kimballiana, as will be seen on reference to a full description which appeared in our issue for February 11, 1905, p. 82. The species was recommended an Award of Merit by the Orchid Committee at the last meeting of the Royal Horticultural Society.

Fig. 52.—Vanda watsoni, a new species: flowers white.

MARKET GARDENING.

A REMEDY FOR GLUTTED MARKETS.

It has long been an axiom in the Vale of Evesham that half a crop of fruit is more remunerative to the grower than a full one; and many a time have Plums, especially the commoner sorts, been allowed to rot on the trees because the price they realised did not pay for picking. Growers who have sent their produce away to the distant markets on commission have often been brought into debt. How is this state of things to be altered? The Avon Orchard Co., whose headquarters are at Evesham, is determined to make an effort in this direction. It claims that cold storage has been found to answer excellently in

America, Canada, and other countries, and that it will be successful here; at any rate they are prepared to risk it, and have acquired extensive premises in the town, where the necessary machinery will be laid down at once. It is intended at first to provide accommodation for 100 tons of fruit, but this can easily be increased to 250 tons when required. If the system is found to answer, it will doubtless be adopted by others, with the consequent result that the markets will be controlled, better prices will be realised, and the season will be prolonged. In this connection it may be stated that cold storage has prolonged the American Apple season by four months. Imagine the result if the Evesham Plum season were lengthened by a third of that period!

Cold storage is not the only remedy for glut. Only a portion of their new premises will be taken up with this, the remainder being devoted to the canning of fruit, on much the same principle as is adopted in America and on the Continent. This it is claimed is more economical and quite as efficacious as bottling. This department will be under the superintendence of an expert either from America or the Bordeaux district of France.

THE TRIP TO PARIS AND ITS SEQUEL.

Already the recent trip to Paris of the Evesham gardeners is bearing fruit. A piece of old turf land has been broken up preparatory to its being laid out on the French plan. The small frames and cloches have been ordered, and the French gardener who is to take charge of it has arrived. Shortly we shall have practical demonstration of the possibility or otherwise of forcing Lettuce at Evesham. This experiment will also be watched with the keenest interest. A great deal more glass is being erected in the district, and the reproach that this fertile valley is very much behind the times in this important matter will soon be removed. *Hartley Smith.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

TREE-FERNS IN THE OPEN.—In his note upon Tree-Ferns, p. 70, "F. M." writes: "If a sheltered spot can be found in the garden, the Dicksonias may be risked outside during July, August and the early half of September." Happily there are localities in the British Isles where Tree-Ferns may not only be risked outside for two and a-half months of the year, but may be planted permanently in the open-air with practically no risk whatever. I can call to mind considerably over a dozen gardens in the south-west where Tree-Ferns are to be seen in the best of health, though absolutely unprotected through the winter. No plants can compare with these noble Ferns in the tropical character of their lace-like coronal of fronds, and visitors from colder districts can scarcely be brought to believe that they are as permanent features in the landscape as are the surrounding Oaks, Elms, and Firs that provide them with the needful shade and shelter. Such a picture as they present when growing in the open air is, naturally, only to be seen under the genial climatic conditions that prevail along the southern coasts of Devon and Cornwall, in the Isles of Scilly, and in certain spots in the South of Ireland. Shelter is a most important consideration for these Ferns when grown in the open, and is best provided by trees. Sometimes they may be met with growing on lawns or in spots obviously fashioned for their reception. In such cases, however beautiful they may be, they impress the mind with being exotic and not indigenous growths. On certain rare occasions, however, they may be seen amid such surroundings that they appear to have sprung from seed where they stand, and to harmonise with their environment as fitly as with that of their native tropics. Such an ideal home for Tree-Ferns has been found on Sir Arthur Pendarves Vivian's estate of Bosahan, on the southern bank of Helford River, a few miles distant from Falmouth. Here a deep and narrow tree-embowered coombe runs winding downward from the higher ground to the water's edge. On either side of the path stand the tall, brown stems, crowned with the green filigree of arching fronds, enjoying the absolute shelter from blustering winds provided by the thickly-growing trees that clothe the steep sides of the little valley. Even when the white horses course the neighbouring Channel scarce a leaf stirs in the recesses of this sequestered retreat, and the memorable blizzard of March, 1891, which created such havoc in the south-west, did the Ferns, the majority of which had then been planted one year, no material harm. In all there are about thirty Tree-Ferns in the dell, many of which are of large dimensions, one particularly stately specimen standing in a somewhat isolated position being 12 feet in height, and having a frond-circumference of over 50 feet, while its stem is more than a foot in diameter. A spot such as that described is admirably fitted for the culture of Tree-Ferns in the open, since it provides the requisite shelter, shade, and moisture; while the picture of these lovely denizens of the tropics, growing naturally amid surroundings devoid of any hint of man's handiwork, holds a charm that is absent where suggestion of human labour is apparent. Dicksonia antarctica is, I believe, the only Tree-Fern planted at Bosahan, and it is, indeed, the hardiest as well as the handsomest and best for planting in the open in this country. I have also met with D. squarrosa, as well as Cyathea dealbata and C. medullaris, planted-out, but all the finest specimens that I know are D. antarctica. *S. W. Fitzherbert.*

PRIMULA, WALLFLOWER, ETC.—I am sending you specimens of a type of Primula from which I am trying to save seed. Do you think it would have any commercial value when fixed? [We do not, judging from the specimens received. ED.] I have also sown seed from an almost white Wallflower. Would a white one be desirable? [Yes.] The vitality of seeds is marvellous. I sowed new Cucumber seed last year that had been inadvertently left on a shelf in a saucer in a cold shed; they were frozen and thawed repeatedly all through the winter, and at the time of sowing I had to rub the fungus-mould off them. Yet to my surprise every one grew much quicker and stronger than others that I had obtained from the seedsman, and made more satisfactory growth in every way than they did. The variety was Sutton's Epicure, a good, dark-skinned, "green-fleshed" Cucumber, with little core. This disproves the idea of our forefathers, who preferred old seed dried hard by carrying it for a long time in their waistcoat pocket, under the impression that it made the plants short-jointed and earlier fruiting. It must be remembered, however, that they grew their plants principally on beds of rank manure, and probably had not learned the value of potash when applied in the early stages of growth. I have left some of the same seed in the same position until now, and shall test them shortly. *An Old Subscriber and Constant Reader.*

TRANSPLANTING SHRUBS.—I read with interest Mr. Miller's note on p. 90 respecting the removal and replanting of medium-sized shrubs and trees. He stated that there should be a circular trench dug 3 ft. from the bole; but this would, after having taken a foot off all round as advised, leave 4 feet diameter of soil to be lifted bodily out of the hole. A more simple plan would be to dig a trench on one side of the circular trench, in such a manner that it will slope gradually to the bottom of the roots of the specimen, so as to allow the planting barrow or lorry to be pushed back, and by leaning the specimen to an angle, say of 45°, the planting-barrow may be easily got under the ball of soil, which will not be so liable to be broken as if it were lifted by several men. When the tree has been placed on the planting-barrow make it secure by using soft rope, putting some felt or other soft material around the place where the rope is to be fixed, so as not to damage the bark. The hole where the specimen is to be planted should be made exactly of the same shape as that from which it has been taken, and by pushing the lorry back into the spout-like trench the specimen will be very easily unloaded. Another little item I think ought to have been mentioned, and that is that the outside of the circular trench should be picked in, and not left like the sides of a pot, as this would give the roots a better chance, and they would not suffer so much in dry weather. *A. G.*

MARKET MEASURES.—I note your remarks as to what the Board of Agriculture has done in quoting the different market measures, but which I am afraid will not become universal. In Southampton fruiterers expect a bushel of Apples to weigh 50 lb.; some ask for 53 lb. All goods should be sold by weight instead of measure, as in the case of corn. Some sell Potatos by the sack, which may be any weight, according to the size of the sack. *E. M.*

THE ROYAL HORTICULTURAL HALL.—Referring to the note on p. 105 of the last issue alluding to St. James' Hall and its horticultural associations, "R. D." has missed two main points of his subject. Firstly, that the Royal Horticultural Society held shows there in 1858 and in 1859, during the gloomy period after the sale of 21, Regent Street, when the offices were hidden in St. Martin's Place, to blossom at South Kensington in 1860: Secondly, as St. James's Hall gave a suitable site for horticultural shows, the Royal Horticultural Hall now is doing its best to carry on both the horticultural and the musical traditions of its predecessor now to be demolished. *T. E. S.*

SEED PACKING.—We were much surprised to read the following remark contained in the note contributed by Mr. Watson on p. 91, where he says:—"For seeds generally I know of nothing better than paper packets or calico bags, and the more moisture there is in the seeds when thus packed the better. Hermetically sealed tins or bottles should never be used." How far such a remark is applicable to seeds sent through the tropics here we will not argue, but so far as it applies to the majority of English seeds for despatch abroad we feel we can speak with authority, it having been our privilege for over half a century to conduct an important business with the Empire of India and our Colonies in tropical and sub-tropical climates, and it has been over and over again proved that the ordinary vegetable and flower-seeds will rarely retain their vitality if sent away from here without some special treatment which eliminates a large percentage of the moisture contained in them, when harvested naturally in our temperate climate. To overcome this difficulty we have for many years not only subjected this class of seeds to a special drying process, but enclosed each packet in tinfoil, and this again is placed in a hermetically sealed covering from which the air is exhausted. We quite agree that roots such as Potatos, Artichokes, Dahlias, &c., which are principally composed of water, must on no account be put under tin, but cannot understand an authority from Kew applying the same restrictions to seeds generally. *James Carter & Co.* [The tin box as sent abroad had a double lid, but was by no means "hermetically sealed." ED.]

APPLES.—During a long life I have become fully aware that tastes differ widely. Some people prefer an acid or semi-acid Apple; others one that is less so, while a large number give preference to varieties that are sweet, and not a few like what is termed, a pine flavour. This therefore renders the task of coming to a right conclusion extremely difficult. In these times of almost universal smoking, I am apt to think that the palate loses the power of delicate discrimination. I have, I think, discovered that there is always a difference between the fruit of a yellow, green, red, or reddish-yellow Apple, and the most highly-flavoured Russet. Then I hear it said that some are brisk and piquant besides being crisp, while another tells me that he greatly prefers a soft-fleshed kind; another that he wishes for something with "a bite in it," beyond that of mere excellence. So it appears also that an orange-coloured flesh is not always that wished for, but the whiter the better. Then soil and locality have much to do with it, as witness an instance in the Alfriston, which grew well at Brenchley, while here it is almost destroyed by canker. After these remarks who can rightly say out of the vast number now grown which is "the" best? As I said

in my last letter I divide the sorts into three distinct series. Though I am sorry to say that with some anything that "is new" is said to be the best, whereas the old is at once neglected, though it is not surpassed. As for myself I confess to a leaning towards many Apples that I tasted and enjoyed long, long ago, for I have found that many appreciate, or think they do, by being led by the opinion of others, when they are told, "Ah, there is nothing now can be equal to this"; or "This is a long way the best ever grown." It is my idea, rightly or wrongly, that Nature only provides a certain amount of flavouring material to every tree, consequently apples of high excellence are produced in fewer numbers than those grown in greater quantity, and hence considered a good "market Apple." For my own part I think that no fruit is good, commercially good, if it is of a high order of merit; and market fruits should be graded, and thus the public, seeing what they are buying, would not afterwards find themselves deluded by having a lower stratum of inferior forms and sizes. If this were done I feel sure that the sale of our "home growths" would eventually prove to be far more profitable. There are in my opinion four divisions in Apples, of size, form, colour and flavour. I would observe among the yellows that I know of none superior in form or colour to the Golden Noble; when cooked it is excellent, rich, bright, and for Apple-sauce delicious, and of an orange-amber tint. Among the best of our judges of quality none surpasses the "chef," and the well-known Alexis Soyer, a cook of high repute, said that this variety as a culinary Apple was of the best, and that for sauce he always purchased it whenever he could do so. Some say that grand fruit, Warner's King, does not keep, but I have not found this so, and am now using it in fine condition. I like Bramley's Seedling much. Of green, none surpasses the Winter Greening, the French Crab, or the Gooseberry. The most beautiful in colour that I now have is Newton Wonder, and it is much liked. The Beauty of Kent has been very fine, and has had many admirers, though it does not hang on the tree so well as could be wished; but why is it that the most highly decorative fruit of all is now so discarded? I allude to the crimson "Sops in Wine." It is sixty years ago since I saw a tree growing beside a pond in Sussex, and the glowing charm is still fresh in my memory. And what an extraordinary Apple it is, with its skin, flesh, core, and even the seeds crimson! It was charming, and not only a curiosity, but, gathered when just ripe, most pleasant for the dessert. Everyone that tasted it, like Oliver Twist, "wanted more." And yet I cannot find it mentioned in any nurseryman's Apple catalogue, though for years I have searched for and wanted a couple of trees. Then for dessert, what surpasses the Russets for their peculiar flavour? The Rosemary Russet has not only a Pine-apple flavour, but is on the sunny side, bright in colour and in form elegant; and so are the Aromatic and Egremont Russet, not large in form, but delicious. Forty years ago the Boston Russet was much in request. Why not now? Then there are Brownlees Russet, and many more. But among so many of the highest class fruit that we have in Apples, who shall decide which is the best? He must be a bold man. Yet I will chance it! So I conclude by saying that for all purposes I prefer the Blenheim Pippin to any. *Harrison Weir, Appledore, Kent.*

"AN ONION FAMINE."—A paragraph has been going the rounds of the general Press stating that an Onion famine was a probable contingency. No reason has been given for this prospective famine. Seeing that we obtain so many Onions from France now, it is possible there may be a shortage of bulbs on the Continent. But it is always a matter for wonder that we should need to import Onions at all. We cannot grow many things that warm climates only will produce; but just as we can, if we will, grow the finest and best of Apples and Potatos, for instance, so can we grow the very best Onions. It is, indeed, a rare circumstance when we fail in getting good Onions. A very cold, wet summer is very unfavourable, but still these seasons occur seldom. Generally an Onion crop is one of the most reliable, and whether good or bad, is much more matters of variety and of culture than of season. What fine crops we see almost everywhere, in small gardens and on allotments of autumn-sown Onions, and what can be grown so well by cottagers or amateurs can be grown equally well and even better by professional growers on a large scale. But the mistake of sowing soft Tripolis and Reccas, instead of firm Spanish round and globe types, is continuous. Seedsmen perpetuate the error; writers of calendars and of advice to cottagers do the same, with the result that whilst huge crops relatively are produced the bulbs soon soften and decay. They have no keeping properties. Were it the rule to sow and grow in the same way only the hard brown Spanish varieties the bulbs would keep a long time after ripening. They would be equally fine, and, because firm and keeping, would be a better marketable commodity. But on deeply worked rich soil—for no crop so much needs "intensive" (that is the new term) culture as the Onion does or better repays it. Then when in the autumn the crop is removed, the ground, only needing light pointing over, is in splendid condition to receive Cabbage-plants for early spring cutting. One of our leading vegetable gardeners alternates plots of ground yearly for spring-sown Onions and Cabbages, getting in each case splendid crops; indeed his ordinarily sown Onion crop must when cleared run to fully 20 tons per acre; and what a paying crop that must be! A remarkable crop of Onions was seen last year at Highclere Castle, where Mr. Pope, having obtained some thirty-six samples of diversely named Onions, raised each one in pans or shallow boxes under glass in March, grew on the plants to become strong, then planted out in rows 14 inches apart, the plants being 6 inches apart in the rows. Not only was the general sample a fine one, though some varieties gave better bulbs than others, but these ripened very hard and clean. It represented per acre an immense produce, and on similar soil and culture a big crop should repay the original outlay some ten times over. *A. D.*

EARLY PEACHES (see pp. 55, 91, 106).—Dryness at the roots will cause any variety to drop its buds; but in the case of Alexander, Waterloo, Amsden June, and Hale's Early, all of which varieties are from America, there are other causes for bud-dropping. They are all far more liable to drop their buds than are our own English varieties. While at Ketton I had many opportunities of experimenting with these varieties, and I concluded that they ripen their wood earlier than the other kinds, and are also not able to withstand excitement in the dark days of winter so well as the others, as they are natives of a country where the sky is not liable to be overclouded for a week or ten days in winter without intermission as our sky is very often. On the other hand, I know some people succeed in growing them; possibly they do better under the old style of glazing, and where the trees are fully exposed in autumn by removing the lights. I was not able to test these two points, as I had Rendle's patent glazing, and for other varieties of Peaches and Nectarines I am convinced there is nothing equal to it; but the American varieties failed. I found nothing so good as Rivers' Early Louise. Started with fire-heat on December 1, it ripened its first fruits from April 30 to May 17, according to the season, and bore good crops of fruit, many of them 8 oz. and upwards in weight; it is of very good flavour when well grown, and the best variety I know for the earliest crop. One tree of Early Beatrice ran it very closely for first favourite, but this was the only tree of this variety that has proved worth growing so far as my experience goes; the fruits of all the others were very small, though undoubtedly the same variety. The good tree was grafted on an extra strong and vigorous stock, which had a rough, grey bark; its fruits often weighed 8 oz. each, and generally ripened about a fortnight earlier than Early Louise under the same conditions. Unless one could be sure of Early Beatrice being on the right stock, it is not worth growing, and even then only for ripening at the end of April and beginning of May. I have not yet had an opportunity of growing the newer varieties—Rivers' Duchess of Cornwall and Duke of York—but should certainly try them if I were planting an early Peach-house; they are nice-looking varieties of good flavour. All of the early-ripening varieties I have tried require extra care in handling and packing, owing to their skins being very tender, and abundance of air while ripening, in order to obtain a good flavour. Alexander and Waterloo, which are alike for all practical purposes, are excellent for growing on warm walls outside, as they ripen in the Midland Counties about July 12, and bear good crops of fair-sized fruits when grown in this way, without receiving any extra attention. Early Beatrice and Early Louise are very small, and practically of no value for growing outside. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

—— It is known to most gardeners that dryness at the root is one of the chief, if not the chief, cause of bud-dropping in Peaches; but I think that there must be some other cause that the varieties Alexander and Hale's Early should drop their buds in the manner they do. They are excellent on outside walls for fruiting when the indoor supply is failing, but they appear to me to be too impatient of early forcing, and this I think is the cause of the bud-dropping. I have grown these varieties side by side with other early Peaches, under exactly the same conditions, but have always found them drop a large number of their buds, while the other varieties growing with them have not suffered in the least. Alexander I have long discarded for forcing purposes, and Hale's Early will find no place under glass with me when our tree of Duchess of Cornwall has covered a little more wall space. Alexander and Hale's Early are only second-rate in flavour, and unless Peaches are preferred, we have two finer and more reliable fruits in Early Rivers and Cardinal Nectarines. Peach borders at no time should have any suspicion of dryness about them, whether the trees are in active growth or apparently at rest; while with all stone fruits the forcing should be commenced very slowly. I believe the Calendars of garden operations in the *Gardeners' Chronicle* attract the attention of practical gardeners more than formerly. *T. H. Slade, Poltimore Gardens, Exeter.*

HANLEY (STAFFS.) HORTICULTURAL FETE.—The announcement in your last issue would have been more correct had it been worded "resigned" instead of "retired" from the horticultural secretaryship of the above fete. May I take this opportunity of thanking all those gentlemen for their past kindness in helping me to build up the show so successfully? *J. Kent.*

POTATOS.

EFFECT OF MANURES ON FLAVOUR.—Practical experience has taught me to discard artificial manures in order to maintain the highest possible quality in Potatos. Of course, care in cooking is an important point, and all should understand that it is necessary to boil the tubers slowly until they are three parts cooked, then pour off the water, replace the lid, and stand the saucepan again on the hot plate until the tubers are quite cooked.

I enclose Potato tubers of the variety Up-to-Date, grown from divisions of one tuber, and produced from adjoining plots of ground, and from a stock where artificials have not been used for four years. During these four years the average crop has been 6¾ tons per acre. Farmyard manure only was used. No. 1 tuber was grown with farmyard manure at the rate of twenty loads per acre; No. 2 with farmyard manure at the rate of ten loads per acre, and 2 cwt. nitrate of soda; No. 3, with 4 cwt. of superphosphates, and 2 cwt. nitrate of soda per acre; No. 4 is from ground which had no manure for four years; during these four years the ground has been cropped with some of the Brassica family; previous to that it was meadow land, what is usually termed maiden ground.

Herewith is the result of a cooking test, viz., No. 4, 1st; No. 1, 2nd; No. 2, 3rd; No. 3, 4th. If we could only clear the matter by examination, then science would have rendered a real service to a great industry. *Geo. Kent, Norbury Gardens, Dorking.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 14.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Dr. M. C. Cooke, Messrs. Douglas, Bowles, Odell, Baker, Worsley, Gordon, Druery, Michael, Saunders, and Chittenden (Hon. Secretary).

Apples Rotting.—Mrs. LEE sent some Apples which appeared sound externally, but which on cutting were found to be rotten. Dr. COOKE reported upon these as follows: "There is every reason to believe that the Apples are affected with 'brown-rot,' caused by Monilia fructigena, which has been more common than usual during this winter. It is a fungous disease, although the fungus is not yet fully developed in the Apple sent. It is capable of passing on to healthy Apples in storage, hence all diseased fruits should be removed and destroyed as soon as the disease appears. The same disease attacks Apples, Pears, Cherries, Apricots, and almost all pulpy fruits, reducing them to a brown rot."

Worm-eating Slug.—Mr. SAUNDERS showed a specimen of the shell-bearing slug, Testacella haliotidea, which subsists on earth-worms, and consequently spends the greater part of its time in the ground.

A New Greenhouse Pest.—Mr. CHITTENDEN showed a number of specimens of a cockroach, Leucophæa surinamensis, in all stages of development. The species, which is widely distributed in the tropics, has been found only two or three times in England, and was not until now known to breed here. It was recently found in great numbers in tan at Broomfield Lodge, Chelmsford, and appears to be particularly injurious to Orchids.

"Navel" Oranges.—Mr. CHITTENDEN showed a specimen of this well-known form of Orange. All the larger fruits on some trees of the variety "Sustain," grown at Widford Lodge, Chelmsford, had sported in this peculiar way, while the smaller fruits were of the normal form.

Old Age in Plants.—A letter on this subject was received from C. B. LUFFMANN, Esq., of Victoria, Australia, the consideration of which was deferred till the next meeting.

Fungus on Tree Root.—Mr. SHARPE, of Westbury, sent a specimen of a fungus growing on the roots of a tree by a brook, which Dr. COOKE determined to be Peziza coccinea.

WEST INDIAN AGRICULTURAL CONFERENCE, 1905.

JANUARY 4 TO 13.—The fifth West Indian Agricultural Conference was held at Port-of-Spain, Trinidad, on the above dates. The representatives included the principal officers connected with the chemical, botanical, and educational services in the West Indies, and the scientific officers on the staff of the Imperial Department of Agriculture, as also delegates from the Agricultural Boards and the chief agricultural societies.

The Conference was formally opened on January 4 in the presence of a large gathering of the leading members of the official, commercial, and agricultural communities, when a hearty welcome was extended to the representatives by His Excellency the Governor (Sir Henry M. Jackson, K.C.M.G.). In his opening address the President of the Conference (Sir Daniel Morris, K.C.M.G., the Imperial Commissioner of Agriculture), reviewing the agricultural situation, expressed the opinion that marked progress had taken place in regard to the Sugar-cane, Cacao, Cotton, and other industries, and referred to the hearty manner in which the planters and the scientific men were working together for the welfare of the West Indies.

In the proceedings of the Conference a prominent position was assigned to the Sugar-cane industry. Papers that were presented to the Conference in connection with this industry included reviews of the principal insect and fungoid pests of the Sugar-cane, the field treatment of cane "tops" for planting, and the polarimetric determination of sucrose.

Trinidad being the foremost Cacao-producing colony in the West Indies, considerable interest attached to the discussion of important subjects relating to that industry. Mr. Hart read a short paper dealing with experiments that are being carried on with the view of improving the health and productiveness of Cacao trees. In Trinidad it was considered that shade trees were indispensable; in Grenada Cacao trees did not appear to require shade, while in other islands Cacao was grown both with and without shade. It was suggested by the President that a series of experiments might be carried out in Trinidad by the Agricultural Society with a view of obtaining definite information on the subject.

The attention of the Conference was next turned to the fruit industry. Mr. J. R Bovell (Barbados) read a short paper upon the efforts to establish a fruit industry in Barbados. Barbados enjoyed an advantage over the other islands in this matter, since Barbados was the last port of call. Experience had shown that fruit could be satisfactorily shipped from Barbados to England for eight months of the year in the ordinary holds of the vessel, without cool storage, provided the ships were adequately ventilated. Two of the ships of the Royal Mail Company had been fitted with cold storage appliances, and in the case of shipments by these vessels there had been no difficulty as to the condition of the fruit on arrival.

The subject of the recently-established Cotton industry was next brought forward. Brief statements were made by Mr. J. R. Bovell (Barbados), Dr. Watts (Leeward Islands), and Mr. W. N. Sands (St. Vincent).

Under the heading of "General subjects" a number of interesting papers were read by representatives. These included "Agricultural Banks," by the Hon. W. Fawcett (Jamaica); "Experiments in establishing Rubber Plantations," "Anthrax," and others. Attention was also devoted to matters connected with agricultural education.

Through the kindness of the Trinidad Agricultural Society, several interesting excursions were organised. These included a visit to the Usine St. Madeleine, a trip to the celebrated Pitch Lake, and visits to several Cacao and sugar estates. By means of these excursions the representatives were enabled to obtain a good idea of methods of cultivation adopted by Trinidad planters.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 13.—At the meeting of the Committee on the above date thirty-five new members were elected. The sick pay has been heavy during the past month, the amount paid out being £51 11s. Several members were allowed to transfer from the lower to the higher scale. The annual general meeting will be held on Monday, March 13.

ROYAL METEOROLOGICAL.

THE usual monthly meeting was held on Wednesday evening, the 15th inst., at the Society's rooms, 70, Victoria Street, Westminster, Mr. Richard Bentley, F.S.A., President, being in the chair. Mr. E. Mawley presented his report on the phenological observations for the year 1904. The weather of the phenological year ending with November, 1904, was chiefly remarkable for the persistent rains in January and February, the absence of keen frosts in May, the long continuance of hot and dry weather in July, and the small rainfall during the autumn. Throughout the year wild plants came into flower behind their usual dates, but at no period were the departures from the average exceptional. Such spring migrants as the swallow, cuckoo and nightingale made their appearance in this country at as nearly as possible their usual time. The yield of Wheat per acre was the smallest since 1895, while those of Barley, Beans, and Peas were also deficient. On the other hand, there were good crops of Oats, Potatos, and Mangels. The best farm crops of the year were those of Hay, Swedes, and Turnips. Both Corn and Hay were harvested in excellent condition. Apples were everywhere abundant, and all the small fruits yielded well, especially Strawberries, but there was only a moderate supply of Pears and Plums.

The other papers read were "Observations of Meteorological Elements made during a Balloon Ascent at Berlin on September 1, 1904," by Dr. H. Elias and Mr. J. H. Field; and "The Winds of East London, Cape Colony," by Mr. J. R. Sutton.

LINNEAN.

FEBRUARY 16.—Prof. S. H. VINES, F.R.S., in the Chair.

Miss E. WILLMOTT, F.L.S., exhibited thirty-water-colour drawings of Roses by Alfred Parsons, A.R.A., drawn at Great Warley, for her forthcoming volume on the genus Rosa, together with some admirable chromo-lithographs for the same volume.

The first paper was read by Mr. JOHN GILBERT BAKER, F.R.S., F.L.S., entitled "A Revised Classification of Roses." He dealt with the genus by dividing it into three groups. In the first group primary species were enumerated; in the second, sub-species and varieties; in the third, the principal hybrids. The primary species as estimated by the author are sixty-nine in number, and they are classified under eleven groups, which may be briefly diagnosed as follows:—I. *Simplicifoliæ*, with simple, exstipulate leaves. II. *Systylæ*, with styles protruded beyond the disc as a united column. III. *Banksianæ*, with free, deciduous, linear stipules. IV. *Bracteatæ*, with adnate stipules, having fruits and prickles in infra-stipular pairs. V. *Microphyllæ*, like the last, but the fruit is glabrous, with a thick green pericarp. VI. *Cinnamomeæ*, like the last, but the fruits red and glabrous, with a thin pericarp. VII. *Spinosissimæ*, prickles very unequal, never in stipular pairs. VIII. *Gallicanæ*, like the last, but with the prickles slightly unequal, and the leaflets coriaceous and rugose. IX. *Caninæ*, prickles equal, not in stipular pairs, leaves glabrous or slightly pubescent. X. *Villosæ*, like the last, but the leaves are very hairy. XI. *Rubiginosæ*, like the last, but the leaves are very glandular beneath.

The geographical distribution can be briefly stated as follows:—Five species are found south of the Tropic of Cancer in elevated situations, two in Abyssinia, one in the Neilgherries, and two in Mexico. There are six geographical regions in the North Temperate Zone, each with a considerable proportion of endemic species. 1. Europe, with 29 species. 2. Northern Asia, with China and Japan, 26 species. 3. Western Asia, with 18 species. 4. India, with 9 species. 5. Western North America, with the Rocky Mountains, with 10 species. 6. Eastern North America, 6 species.

The second paper was entitled "The Botany of the Anglo-German Uganda Boundary Commission," the authors being—Polypetalæ, Mr. Edmund G. Baker, F.L.S.; Gamopetalæ excl. Convolvulaceæ, Mr. S. Moore, F.L.S.; Convolvulaceæ, Apetalæ, and Monocotyledons, Dr. A. B. Rendle, F.L.S.

GARDENERS' DEBATING SOCIETIES.

CARDIFF GARDENERS' ASSOCIATION.—A meeting of the above Society was held at the Sandringham Hotel on Tuesday, February 7, Mr. Tom Clarke in the chair. Mr. Jones, a member of the Newport Gardeners' Association, delivered a lecture entitled "Annuals and how to Grow Them." Many of the most suitable subjects for this purpose were mentioned, especially those available for decorative purposes. The discussion brought out many interesting details on the subject.

KINGSTON GARDENERS'.—At the last meeting Mr. Jas. Gibson lectured on "Winter Vegetables," and gave details of cultivation and storage of all kinds of vegetables which mature naturally in winter, or which may be forced for use during winter and spring. Brussel-Sprouts, Savoys, Broccoli, Kales, Cabbage, Kohl Rabi, Carrots, Parsnips, Beet, Celery, Leeks, Spinach, Parsley, Turnips, Swedes, Asparagus, French Beans, and many others formed subjects for remark. The effects of the recent fogs were discussed, and even such a hardy variety of Broccoli as Late Queen was said to have been crippled in one garden. An appeal was made on behalf of the Royal Gardeners' Orphan Fund (see p. 105). *J. T. B.*

CRAWLEY AND DISTRICT GARDENERS'.—A paper on "Plants for Conservatory Decoration all the Year," was read by Mr. Goldsmith, Fircroft, Withdean, Brighton, on Wednesday, February 8, Mr. Brooker, Deerswood, presiding. Mr. Goldsmith dealt with his subject in a practical manner, giving his method of propagating and growing such plants as Poinsettia pulcherrima, Begonia Gloire de Lorraine, and Euphorbia jacquiniæflora, for making a display during the winter months. For succession during spring and summer, Cinerarias, Primulas, Amaryllis, Gloxinias, Begonias, Carnations, Fuchsias, &c., were recommended. Mr. Goldsmith described from his long experience the most suitable soil required for striking cuttings and for their subsequent growth.

[Numerous Reports are of necessity held over. Ed.]

LAW NOTE.

WE have received from the defendants in the case alluded to on p. 92 a statement giving their version of the occurrences, but as the matter is still before the Court it is desirable not to publish any further remarks till the verdict is given.

ENQUIRY.

CRANBERRIES FOR MARKET SUPPLY. — I am anxious to obtain some information and advice on the cultivation for market of Cranberries, Blackberries, Brambles, and Raspberries. I well remember some twenty years ago visiting in America a Cranberry-bog, where the crop yielded a very considerable profit, but I did not at the time take sufficient interest or note of the procedure beyond observing that irrigation played a most important part, not only in dry weather but also in winter, for the plants were flooded and totally submerged in frosty weather. I understand the fruit is not cultivated in England, and should be glad to know the reason. My intention is to lay down twenty to thirty acres with the fruits named, and I seek information as to the most suitable land and district, and details as to crops and cultivation. *Bramble.* [*Cranberry Culture*, by J. J. White, a book published by Orange, Judd & Co., 245, Broadway, New York, in 1870, affords very full information as to every phase of the cultivation of this crop in America, and illustrates the methods employed to flood the land. The Cranberry requires certain conditions in respect to position and soil, and unless a very suitable locality is selected the enterprise will be unsuccessful. Blackberries, such as Rubus laciniatus and the "Wilson Junior," may be cultivated successfully on similar supports to those afforded Raspberries. ED.]

MARKETS.

COVENT GARDEN, February 22.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

REMARKS.—Fruits are now arriving from the Argentine Republic, including Plums, Peaches and Pears, prices for which are:—Plums, 6*s.* to 8*s.* per case; Peaches, 5*s.* to 8*s.* ditto (fifteen to twenty fruits), and Pears, 6*s.* per case of thirty fruits. Cape Plums realise from 5*s.* to 10*s.* per case; Peaches per box of from fourteen to twenty-four fruits, from 4*s.* to 10*s.*; Nectarines per box of from eighteen to twenty-four fruits, 10*s.* to 15*s.*; Cherbourg Broccoli realised from 9*d.* to 1*s.* per dozen; St. Malo, 1*s.* to 2*s.* ditto, and Cornish crates of this vegetable from 6*s.* to 8*s.* per crate.

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 55*s.* to 75*s.* per ton. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

At the end of last week there was a revival of trade, and pot plants sold fairly well. The cold winds on Monday, however, caused a check to trade, and on Tuesday morning the market was again very quiet. A splendid consignment of Indian Azaleas was in the market on Tuesday, but at 8.30 A.M. many of these plants remained unsold. Trade conducted after this hour means reduced prices. Plants of Cinerarias were abundant and of good quality, but these sold very slowly. Genistas were also over plentiful. Marguerite plants are well flowered, but some are not well furnished with foliage. Plants of Cyclamen are good; the weather does not affect these much. Ericas also stand the cold well; E. persoluta alba continues good; E. Wilmoreana is well flowered. Plants of Spiræa japonica are now plentiful, and S. multiflora compacta is now obtainable. A few good Lilac plants are seen, and these make from 3*s.* 6*d.* to 5*s.* each. Azalea mollis is more abundant. Hyacinths and Tulips continue over plentiful, and for these prices vary considerably. Richardia (Calla) æthiopica has but little demand. Among the Acacias now seen A. cordata, A. verticillata elegans," and A. Drummondi are good, while large plants of A. armata are fairly well flowered. Begonia Gloire de Lorraine is still seen, but is not so plentiful. There is little variation in the supplies of Palms, Ferns, and other foliage plants. Several growers have already commenced marketing roots of hardy border plants, and on Saturday there was a good trade in these, but the recent cold weather has put a check on this. Well-flowered Pansies were in the market on Saturday. Supplies continue to be exceedingly abundant.

CUT FLOWERS.

Although the cold weather may have checked some subjects, Roses are now at their best, or almost so; the variety, Bridesmaid is of a good colour. Flowers of General Jacqueminot, though not large in size, are very bright in appearance, and are now fairly plentiful; "Caroline Testout" is the best pink variety seen. Daffodils are abundant; Golden Spur is the finest yellow, and best samples of these realise good prices. Princeps is good, but this being such a free-flowering variety, supplies are overdone; Telemonius plenus is also over-plentiful; Emperor sells fairly well. The small-flowered Narcissi Soleil d'Or and Paper-white, from the Scilly and Channel Islands, are good, but over-abundant. Carnations are now plentiful, and even choice specimen flowers remain on the stands at closing time. Flowers of Eucharis, Camellias, and white Azaleas are all over-plentiful. Supplies of Gardenias are short, those seen realise high prices; Lily of the Valley is not so abundant, and may advance in prices at any time. In Orchid blooms there is little variation, but prices are possibly lower. Supplies of Lilium longiflorum are likely to be short, those flowers which should be coming in now were ruined by the fogs in December. Callas are not so plentiful, and with a shortage of Liliums, prices for Callas may go up. Violets are abundant and of good quality, but if the present cold weather continues supplies will fall off.

Among imported foliage we now get the Galax leaves from America, both in green and dark-bronzy shade. *A. H., Covent Garden, Wednesday, Feb. 22.*

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending February 18, 1905.

1905. FEBRUARY 12 TO FEBRUARY 18.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	At 9 A.M. Wet Bulb.	DAY. Highest.	NIGHT. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.

THE WEATHER IN WEST HERTS.

A change to wintry weather.—The long and almost unbroken term of warm weather, which had lasted three weeks, came to an end on the 20th, since which time low temperatures have prevailed. During the recent warm period there occurred but one unseasonably cold day, and only one cold night. Since the change came the winds have been cold, but as yet the exposed thermometer has only registered 7° of frost. The ground still remains rather warm for the time of year, the temperature at 2 feet deep being about 2° warmer, and at 1 foot deep 1° warmer, than is seasonable. On two days there occurred frequent sharp showers of rain, hail, soft hail, snow, or sleet, but the total measurement only amounted to about a quarter of an inch, bringing up the aggregate rainfall for the last five weeks to only about half an inch altogether. The percolation through both the soil gauges, which had almost ceased, was re-started by the snow, &c., of the last two days. The sun shone on an average for two and a half hours a day, which is about a seasonable duration. The winds were, as a rule, light, and on two days in the windiest hour the mean record was 17 miles—direction west. There was again a seasonable amount of moisture in the air at 3 o'clock in the afternoon. A selected patch of yellow Crocuses first showed an open flower on the 21st, which is two days earlier than its average date of flowering in the previous eighteen years. *E. M., Berkhamsted, February 21, 1905.*

[*For actual temperature and condition of barometer at time of going to Press, see p. 129.*]

ANSWERS TO CORRESPONDENTS.

Address: *D. J.* George Massee, Esq., Gateacre, Sandycombe Road, Kew, Surrey.

Asters: *F. H.* The Chinese Aster is attacked sometimes by a worm (Enchytræus parvulus), and more commonly by a fungus disease. We do not think your plants fail owing to unsuitable cultivation, but to disease. When the plants again reach the stage you have described, kindly send us a specimen for examination.

Carnations: *Improver* The plants are attacked by a fungus, Helminthosporium. Burn the diseased plants and spray the healthy ones with weak Condy's fluid.—*H.* and *J. E.* Your Carnation is of very large size, of brilliant colour, and very fragrant, but it is not of the best florist's type in respect to form and petal.—*Carnation.* Assuming your stock was vigorous when the growths were put into the small pots used for layers, we would recommend the use of a little bone-meal and Thomson's Vine and Plant Manures and soot, in the proportion of three parts of the manures to one of the soot; add about a 6-inch potful of this mixture to a barrowload of soil. This should be repeated at all subsequent pottings, and you may increase the quantity of manure if the plants are really robust. Such a soil, if other conditions are suitable, will produce the necessary colour and vigour; but "Carnation" must bear in mind that no amount of feeding will produce the desired results if conditions conducive to successful cultivation are absent. We do not recommend sulphate of ammonia; its action is too stimulating to be of any permanent advantage, and we should not elect to propagate from stock that had been so treated. Water in which sheep droppings have been thoroughly soaked, if clarified, and a slight addition of soot made to it, will afford an excellent liquid manure; while Clay's Fertiliser, if afforded occasionally, will help in maintaining the green colour of the foliage which is so much admired. Clay's Fertiliser should be applied at the rate of, say, a teaspoonful to a 6-inch potful of soil. Or it may be used as a powder on the surface of the soil, or in water. If applied as a powder, the manure should be covered slightly with fine soil.

Cemetery Superintendent: *East Anglian.* If the Superintendent has personally to undertake the gardening department, then a qualified gardener is the proper person to receive the appointment. If the election has been made from political motives, as you suggest, then the action of the electors is most reprehensible. Efficiency and personal character are happily quite independent of political opinions, and should be kept so.

Ferns: *Pleris.* The brown marks are probably caused by cold draughts or drip. It is not fungus.

French Chrysanthemum-raisers: *W. M.* M. Ernest Calvat, 40, Rue Saint-Laurent, Grenoble; M. Aug. Nonin, 16, Route de Paris, à Châtillon-s us-Bagneaux, and others. The novelties raised by the Marquis de Pins may be obtained from M. M. Anatole Cordonnier et Fils, de Bailleul (Nord), France.

F R H.S.: *J. H. S., Liverpool.* The "honour" is not to be bought, nor is it to be had by examination. Get the recommendation of some Fellow, send your cheque to the Secretary, Vincent Square, Westminster, and if no Fellow present objects you will in all probability be elected at the next meeting.

Grafting Roses in Winter: *S. W.* (1) We suppose you mean the grafting of Roses to be grown on in heat for the supply of buds for use as soon as the outdoor stocks are ready for budding. The process generally adopted is that known as whip-grafting, and the scion used contains only one bud. (2) *The Book of the Rose*, by Rev. A. Foster-Melliar, M.A., to be obtained from our Publishing Department, price 6*s.* 4*d.*, post free. The work of grafting and other means of propagation are thoroughly explained in this book.

Grass Seeds: *Lawn Grass.* The mixture you name is a very good one, if modified to suit the particular soil for which it is to be used.

Hybridisation of Gladiolus: *J. E. E.* We have no knowledge of the paper you name, nor can we say where you could obtain a report of the Conference on Plant-breeding. You might apply to the Secretary of the Horticultural Society of New York.

Malformed Swedes: *J. C. G.* The development of adventitious buds on the roots of certain members of the Natural Order Cruciferæ, such as Turnips, and others of the Brassica genus, &c., is not at all uncommon, and instances can often be noticed when passing through fields in which crops of these plants are growing. The cause is generally attributed to some agency, such as that of insects or bacteria, setting up injury to or an irritation in the affected region, causing an excessive flow of sap to that particular part, such as is seen in the specimens you forward. As the Turnips are really swollen stems and not true roots, the production of adventitious buds is not surprising. You will find an excellent illustration of this kind of malformation in the *Gardeners' Chronicle* for January 3, 1877, p. 149.

Manure for Mushroom Beds: *Mushroom.* The material should be in an intermediate condition in regard to moisture, neither very dry nor wet. If some be squeezed in the hand and no moisture is emitted the manure is too dry, and should be damped. But it is much better not to allow the natural moisture to evaporate so much before making the bed so that it would be necessary to add water. After such an addition the temperature of the bed will not rise so high or continue so long as it would otherwise have done, and there arises considerable difficulty in making the bed firm. From your letter we think you require to use damper material more intermixed with straw. Insert the spawn when the heat of the bed is from 75° to 80° and is declining. Be careful to use fresh living spawn.

Names of Fruits: *J. C. W.* Hollandbury.—*C. R.* 1, Reinette du Canada.—*Mill Hill.* There were two Apples, not three. 1 is Rymer, and the other, 2, Norfolk Beefing.—*X. Y. Z.* 1, Beauty of Kent; 2, Dredge's Fame; 3, Broad Eye Pippin.—*Carlton.* 2, Calville St. Sauveur; 3, Hoary Morning; 4, Reinette Grauville; 5, Marie Guisse.—*H. H.* Pear Winter Nelis.

Names of Plants: *Knightons.* Tulip Murillo.—*W. H. E., Hants.* 1, Selaginella plumosa; 2, S. cæsia; 3, Salvia gesneræflora; 4, Dendrobium undulatum.—*G. M.* 1, Thuya gigantea (plicata) var. with yellow leaves; 2, Cupressus (next week); 3, Abies concolor; 4, A. grandis.—*J. E.* Alonsoa incisifolia.—*Carlton.* Cupressus sempervirens.—*F. P. D.* Pelargonium echinatum.—*T. H. T.* 1, Cyrtomium falcatum; 2, Asplenium bulbiferum; 3, Selaginella Wildenovi; 4, Sanchezia nobilis.—*J. O.* 1, Polygala Dalmaisiana; 2, Ruellia Portellæ; 3, Maranta argentea; 4, Odontoglossum pulchellum.—*F. E. G., Witney.* 1, not recognised—send in flower; 2, Daphne Mezereum, white variety; 3, Primula verticillata; 4, Begonia Gloire de Scéaux.—*Correspondent.* 1, Cypripedium × Charles Canham; 2, C. villosum, of very good form.—*W. H. W.* 1, Sisyrinchium grandiflorum; 2, probably a form of Adiantum cuneatum, but specimen very imperfect; 3, Asparagus decumbens; 4, Selaginella caulescens; 5, Asplenium bulbiferum.—*J. W.* We cannot undertake to name florists' varieties of flowers.

Oak Post that is Worm-eaten: *F. A. B.* We presume that it is only the sapwood of the Oak post that is worm-eaten. In that case, the soil should be cleared away from the bottom of the post until all the decayed portion has been exposed, and the worm-eaten wood chopped or scraped away. Allow the exposed wood to get thoroughly dry, and then apply hot coal-tar until all cracks and fissures are filled up. The soil can then be filled in round the base of the post. If the post is decayed aboveground, the same treatment would be suitable, but the tar could be applied at once, as the wood below will be dry enough already.

Seed Capsule: *C. S. & Co.* Probably Phormium tenax, the fruits of which are described as being exactly similar to that you have sent us.

Spiræas: *J. E. K.* The plants appear to have rotted off from excess of moisture.

Strawberries: *E. T. C.* The plants have been allowed to get sodden at the root, and when in this condition the leaves were frosted.—*Anxious.* Dip the plants in moderately strong tobacco-water, and syringe them thoroughly with clear water on the following day. Repeat the process if necessary.

Thermometer to Register Frost: *J. B.* Most of the thermometers in use in this country are made to register the Fahrenheit system. In this system water freezes at 32°; therefore if the mercury in your thermometer stands at 31°, there would actually be 1° of frost at the time, and if at 20, there would be 12° of frost. Zero is 32° below freezing-point, when the Fahrenheit thermometer is at 0.

Trapping Crickets: *G. W. B.* These are very elusive insects and difficult to destroy. Smear some phosphorus paste on to pieces of bread, and place these on the stages and round about the plants. Another good plan for trapping these and similar pests is to roll garden mats and place these on the hot-water pipes under the staging. Allow the mats to remain during the night, and in the morning open them, and numbers of the insects will be found hidden in the folds of the mats.

Trenching: *T. T. T.* In the process of trenching a trench is first dug one, two, or more spits in depth and a yard in width, the soil from this opening being taken to where the trenching operations will finish. The base of this empty trench should be loosened to a depth of 6 inches or more. Next the soil of another yard of land is dug, and the soil inverted into this first trench, the top spit being thrown into the bottom of the opening, the second following, and then the third, the soil being thus inverted as well as transposed. This operation is repeated until the whole of the ground is trenched. "Bastard" trenching differs from the foregoing, and may be briefly described as follows:—The first trench is opened one full spit in depth and 2½ feet or a yard in width. Dung is put in and forked into the bottom of the trench, the opening being then filled with the top spits of the second trench, and so on. The advantage of this plan of working is that the good soil is retained at the top—an important consideration on land where the subsoil is of poor quality. The bottom soil is enriched and loosened for the penetration and nourishment of the roots, which, descending deeper, are not so liable to suffer from drought during summer. Strong soil is rendered capable of absorbing more moisture, and yet remain drier at the surface by reason of readily passing to the subsoil. This method of tillage ensures a thorough shifting of the soil. We know of no book which treats exclusively upon trenching, but all the more important of the books on gardening contain articles on the subject.

Ventilating: *M. L.* The use of ventilators at the side of the house on a level with plants is a thing of the past in Orchid-houses. Such ventilators are bad and we advise you not to use them. The top ventilators, if managed in accordance with the condition of the weather outside, will answer your purpose unless there are small bottom ventilators in the sides near to the ground-line.

Wolff Pencil: *J. W. W. and Others.* We gave the name and address of the makers, and presume that the pencils can be had from any garden sundriesman. They should be advertised.

CULTURE FOR PROFIT.*

THIS is a book which appeals to those interested in the commercial side of horticulture as well as to agriculturists proper. They will certainly find it very interesting, and we believe they will derive much profit from studying its details and regulating their procedures accordingly. The keynote to the whole volume is struck in the assertion on p. 5, where it is stated to be "universally admitted that agriculture does not pay." Incidentally we may remark that however true this may be of agriculture and of fruit farming, it is not, making allowance for exceptions, equally correct in regard to horticulture. Assuming this to be true, as we believe we have every right to do, we think the author might well have given a little more attention to the methods of horticulture. We know of farmers who, failing to make their business pay, have devoted their attention to market-gardening, flower culture, bulb growing, Mushroom-growing, and fruit cultivation, especially under glass. These are men who have known how to adapt themselves to altered conditions and furnish an interesting illustration of the principle of natural selection. Moreover, they show the farmer the advantages of what is called intensive cultivation. The man of business, as we are told in the introduction to the present volume, endeavours to produce the best article he can, and [important qualification] the one most suited to his customers' requirements. At the same time he tries to make his incomings exceed his expenses by discovering means of cheapening his processes or of increasing his values. These are obvious truisms, but we incline to the belief that the horticulturist is more fully alive to their importance than is the farmer. Of course we are speaking of the rank and file, not of the leaders of the agricultural profession. But we do not wish to enter on any discussion on this subject. We desire simply to give our readers some notion of the subject-matter of this book and of the way in which it is treated.

Speaking in general terms, the author draws a distinction between the cultivator and the merchant. A man may be a careful and a skilled cultivator; but he may be, and often is, unable to dispose of his produce to advantage. He does not get an adequate return for his capital, his knowledge, his skill, his time, and his labour. It is a case of division of labour and of specialisation, and it is hardly to be expected that, under modern conditions, any one man or any one body of men can be equally expert in the raising of produce and in its subsequent disposal.

In the chapter on methods of marketing details are given as to the manners and customs of producers, factors, and distributors which are very interesting even to those readers who are not directly concerned in the sale or purchase of crops. One thing, as usual, comes out prominently—the fatnousness of our system, or rather chaos, of weights and measures. There were, as we learn on p. 41, forty-six different "weighed measures" by which Wheat sales were returned, varying from 52 lb. to 90 lb. per bushel; and a similar diversity obtains in different markets up and down the country in the case of barley and other cereals. The same thing holds good with regard to fruits and vegetables in Covent Garden and other markets.

"A further complication is caused by the remarkable measures used in selling fruit and vegetables in Covent Garden which producers are expected to adopt. The very names are peculiar, and the number of different varieties is great and perplexing. Thus we learn from an article by Mr. W. W. Glenny, in the *Fruit Growers' Year-Book* for 1897, that 'vegetables may be gathered and loaded direct on the waggon, cart, van, or barrow; may be secured in bundles with bass or rods, tied in bunches with rods, arranged in hands, packed in loads, flaskets, crates, hampers, pads, sieves, half-sieves, quarter-sieves, flats, molleys, prickles, feys, pottles, punnets, 2-cwt. sacks, 1-cwt. sacks, pea-bags, ¼-cwt. bags, besides foreign bags of no defined size, and barrels, boxes, trays of innumerable sizes and endless shapes.' Of course, none of these is a legal measure, and in many cases the words are easily recognised as common technical terms, but in other cases they are expected to imply a given weight or number. Thus, according to the same Year-Book, a Seakale punnet measures 8 in. in diameter at the top and 7½ in. at the bottom, being 2 in. deep; while a Radish punnet is 8 in. in diameter and 1 in. deep, if to hold six 'hands,' or 9 in. by 1 in. for twelve 'hands.' A Mushroom punnet is 7 in. by 1 in., while a salading punnet is 5 in. by 2 in. A sieve contains 7 imperial gallons, while a bushel-sieve holds 10½ imperial gallons. After this it is a relief to know that a bushel basket 'ought' to contain an imperial bushel, two-thirds of which is contained in a 'junk.' We next learn that a pottle of Strawberries should hold half a gallon, but never holds more than one quart, and that a 'hand' of Radishes contains from twelve to thirty or more, according to the season. A 'bundle' of Broccoli, Celery, &c., contains 6 to 20 heads, of Seakale 12 to 18 heads, of Rhubarb 20 to 30 stems, according to size, and of Asparagus from 100 to 125. A 'bunch' of Turnips is 12 to 25, of Carrots 15 to 40, of greens 'as many as can be tied together by the roots'! An imperial hundredweight is, of course, 112 lb., but a hundredweight of Kentish Filberts is 100 lb.

Provincial markets are less perplexing, as fruit and vegetables are usually sold by imperial weights. But even here terms are used which are not commonly known. At Sheffield vegetables are sold by the bag; at Nottingham fruit is sold by the pot and by the strike, as well as by imperial weights; while at Glasgow the old-fashioned 'sleek' or West of Scotland bushel is used, though its meaning has been changed so as to connote a weight, varying according to the class of fruit offered.

Truly, the industry of fruit and vegetable growing is a toilsome and perplexing occupation."

The want of system in weights and measures is by no means the only obstacle in the way of the satisfactory disposal of produce. How many there are who can echo Mr. Rider Haggard's statement here quoted—"One of the greatest obstacles with which the little farmer, the small holder, and indeed all agriculturists have to contend is the impossibility of delivering their produce in markets that are eager for it because of the overwhelming difficulties of collection and delivery, and the overwhelming "charges of its transport." Perhaps, says Mr. Haggard, in continuation, "it will not be thought extravagant to say that on the proper organisation of the sale of fruits and vegetables the success of that form of agriculture depends. Some of our readers may remember the means mentioned in these columns by which the producers in Holland and other continental countries have overcome these difficulties, and are consequently able to undersell us in our own markets.

The following extracts will be read with interest:—

"The sale of Potatos in large quantities is of comparatively recent growth, and the markets which are devoted to that purpose are usually quite new. Potatos, moreover, are a bulky commodity, and do not depend on their appearance for their price so much as other kinds of vegetables and fruit. They are therefore sold in markets near railway stations, often in the stations themselves, and where they are sold in the central market, it is more often than not that a sample only is exhibited, the bulk being consigned either from the farm or the depot. They are usually sold by weight, but in the case of new Potatos they are taken by the acre occasionally, in much the same way as fruit.

With fruit and vegetables of other kinds the case is very different, the utmost importance being attached not only to the fresh, attractive appearance of the individual articles that make up the consignment, but also to the neatness and artistic effect of the way in which they are presented for inspection. For this reason skill and care in packing and growing fruit for market is of the highest importance. A publication of the Board of Agriculture and Fisheries on the subject begins with these words:—

'Intensive cultivation has been carried in many places to a high pitch of excellence, and British horticulturists pride themselves, justly, upon their skill as producers. Admirable and necessary as the highest cultivation must always be, yet something more is required to ensure complete commercial success, namely, the conveyance of the produce in the best possible style to the market or to the consumer. It is at this point too many fail, and a material proportion of unprofitable sales is mainly attributable to neglect in presenting goods in the most satisfactory manner. Proofs of this defect are evident in every British market, and commonly the produce of the home-grower may be seen in direct contrast with that of his foreign competitors, to the conspicuous disadvantage of the former.'

As a general rule, producers of fruit simply despatch it to the various markets, where it is sold for their account. It has been largely the habit in Kent for proprietors to sell their crops at auctions, but a large number of them are giving that up now, and are marketing their own fruit; instead of selling their fruit to the little dealer, they are distributing it all over the country, and selling it in the various markets.

Let us therefore return to the traders in the market, taking Covent Garden as the best example we can find. A large amount of foreign stuff is sold there as well as English, but the foreign is usually sold by auction, while the English is generally the subject of negotiation by private treaty. This is probably due to the smallness of the market-place, and the necessity for clearing it rapidly in the case of the foreign goods, which are all sent into the market. The English is often only a sample. Of the two kinds of traders there is no doubt that the merchants are the more prosperous. It is customary with them to go down into the country and buy up whole fields of fruit and vegetables, and whole orchards of fruit, and have such quantities consigned to them as they require. Strawberries are often dealt with in this way; Pears, Plums, and Damsons follow when the soft fruit is over, and Apples are purchased after the others are gathered. Some merchants travel round from farm to farm picking up small quantities, and making their profits out of the reduced railway rates they are able to get when they send the whole of their purchases to London.

* *The Business Side of Agriculture.* By Arthur G. L. Rogers. (Methuen & Co.) Crown 8vo, pages 159.

Such a system may suit the small farmer, but the large important growers naturally wish to get all the profit on their produce, and in their case the fruit and vegetables are consigned to the salesmen, who dispose of them to the high-class shopkeepers of the West-End, who are able to exact a high price from their customers. The volume of trade that passes through the market in this way, the number of persons who consign their goods to the salesman, as well as the number of persons who flock there to buy, must be taken as a proof that the system works satisfactorily on the whole, and it is indeed unreasonable to suppose that a trade could exist for very long if it did not in the main meet the wants of the producers and consumers. But the complaints that are made about it are many and bitter. Stories are rife which tell of fruit and vegetables consigned to a salesman in considerable quantities with no better return than a shilling or two of profit, and a bill showing how the salesman's commission, the market charges, and the cost of carriage and handling have swallowed up the remainder of the price. Consignors assert that they are unable to make out how the market charges are calculated, while the prices quoted in the daily and trade papers are very different to what they received. The answer given is that, owing to the supplies of fruit from abroad, there is often a scarcity one day and a glut the next; that the changes in the weather have an important effect on the demand for fruit as well as on its keeping qualities; that it is impossible to sell small and irregular consignments as profitably and as easily as large and constant supplies; and, above all, that the inferior packing and insufficient grading of much of the English produce compared with the arrivals from abroad lower the selling price of the home-grown article. As pointed out above, attention has repeatedly been called to this last point, and a most notable example has recently been made public. The Silverskin Onions consigned from Bedfordshire to the pickling firms in London would not command any sale at all if they were not carefully graded, and yet in spite of the English farmers' skill the Dutch peasants have succeeded in taking part of their business away. 'The organisation of the brining industry in the Netherlands,' says Mr. Crawford, in his Report on the Dutch brined vegetable industry (p. 11), 'has enabled the factories, by collecting their supplies of raw Onions from a large number of growers, and by the use of improved apparatus, to send to this country large consignments of Onions in brine, possessing greater uniformity in size, shape, and colour than it seems possible to obtain by the methods at present adopted at Biggleswade. It is just this uniformity in the bulk which the great pickling firms in this country desire, and for goods possessing it they are prepared to pay a higher price than for produce which is deficient in this respect."

One other quotation of special interest to our readers, and we may leave them to see for themselves what are the remedies proposed in this thoughtful and lucidly-written book:—"Fruit is of so uncertain a nature that a few days' brilliant weather will yield vast quantities of ripe Strawberries or Plums, which the grower cannot store and is obliged to send to market, only to find, perhaps, an unremunerative price. And all the while there are perhaps hundreds of persons [the author might have said thousands] anxious to buy who are quite unaware of the opportunity offered them."

NEW OR NOTEWORTHY PLANTS.

PRIMULA COTTIA, E. WIDMER.*

THIS plant has only been known in the horticultural world for a few years. The *Index Kewensis* does not mention it (at least in the first edition), nor does Pax in his *Monographisches Übersicht des Primula*, published a year before Widmer described it in the *Flora*. It is a plant peculiar to the Cottian Alps, where it is found on the rocks of the Val Germanasco at an elevation of about 3,250 to 8,125 feet. It was sent out by Dr. E. Rostan of Pinerolo at first as P. villosa, Koch, then as P. hirsuta. Closely akin to P. villosa and P. commutata, it differs in habitat from those species which grow in the Eastern Alps, the special home of the genus Primula. P. cottia is saxatile, the leaves oval lanceolate, slightly, rarely sharply acuminate, the petiole 2—8 cent. ($\frac{3}{4}$—$2\frac{3}{4}$ inches), rarely 10 cent. (3 inches) long by 0·8 — 3 cent. (about $\frac{1}{3}$ — $1\frac{1}{4}$ inch) wide, generally rounded at the summit, sometimes pointed, dentated from the centre, teeth large and obtuse; floral raceme longer than the leaves and bearing 2—11 flowers on peduncles 2—7 cm., rarely 9 cm. long; bracts oval, obtuse, half or a quarter the length of the peduncles, the inferior foliaceous but rarely longer than the others; the calyx 3·5—6 mm. with obtuse or pointed division. All the green parts of the plant are pubescent-glabrous; flowers large or very large (last May I saw one 3½ cent. or about 1¼ inch across), very bright rose-carmine passing to violet when faded; tube 3—13 mm. long, well furnished with glandular hairs outside and at the throat; stamens longer than the style; capsule 5—7 mm. long.

This is a beautiful species seen on its mossy, shaded rocks in the Val Germanasco. It grows in abundance in the chinks, and its flowers are lovely against the green and Ferny background. In the Jardin de la Rostania, recently founded in honour of the botanist who discovered and distributed this plant, it does not flower well, as it is not in a sufficiently cool and shady place. We have built a north wall for it and hope that it will now do better. At the Linnæa, on the contrary, the plants sent twelve years ago by Dr. Rostan, and which we put in facing north, have done well, and bear yearly fine and numerous seeds. At the Jardin d'Acclimatation here we cultivate it in pots and raise seed fairly easily, but it grows slowly and flowers less well than in its natural state. The air here is too dry for it; but perhaps in England, where it is damper, it would do better. *Henry Correvon, Floraire, Geneva.*

* *In Beitrag für Kenntniss der rothblühende alpen Primeln*, von E. Widmer, Flora (T. 72 [1889], pp. 69—74).

KEW NOTES.

CYMBIDIUM GRANDIFLORUM, *Griff.* (C. HOOKERIANUM, *Rchb.*)—This very handsome species is now flowering in the Odontoglossum-house. It was introduced from the Sikkim Himalaya by Mr. Lobb, and first flowered in the nursery of Messrs. Veitch at Exeter, in 1866, and was fully described by Reichenbach in the *Gardeners' Chronicle* in January of that year. The Kew specimen has several fine growths, though having but one spike of flowers; this, however, is a very strong one, being nearly 3 feet in length, and has fifteen fine large flowers and buds, a rather singular feature of this spike being the full expansion of the terminal bud before the lower ones show any signs of opening. The sepals and petals are a rich bright green in colour and very fleshy, having a diameter of fully 4 inches from tip to tip of the petals. The large, showy lip is straw-coloured with a yellow margin, round which are large blotches of rich purple. The species thrives exceedingly well in a cool temperature at Kew. If grown in heat, the buds will sometimes drop off the spikes just when they should begin to expand. Figured in the *Botanical Magazine*, t. 5574.

LYCASTE LUCIANIANI ×.

This is an exceedingly pretty and interesting hybrid, flowering in the cool-house. It is from a cross between L. Skinneri and L. lassioglossa, the former being the seed parent. The habit of the plant is that of L. Skinneri, though the flowers are much smaller, their size being nearer those of the pollen parent, as also is the colour of the sepals, which are light-brown. The petals and the lip partake of the character of the seed parent, being prettily marked with small, densely arranged, bright-red spots, except at the tip of petals and the centre of the lip, which parts are white and unspotted.

BRUNFELSIA CALYCINA VAR. MACRANTHA.

This variety is a great improvement on the type, and is probably the most showy and beautiful of all the Brunfelsias. Like the species it forms a well-branched, woody shrub, with dark-green leaves 5 to 7 inches in length, by 2 to 2½ inches broad. The flowers are produced in clusters of from three to six in the axils of the leaves, and remain in a fresh condition for a considerable time. The colour is a pleasing shade of purple; and the diameter of the flower is nearly 3 inches, the corolla lobes being much undulated. Although Brunfelsias are evergreens it frequently happens that they lose most of their leaves when grown in the vicinity of large towns. Under such conditions it is advisable to give them a rest in early spring in an intermediate temperature for about a month or six weeks. They should then have the branches shortened a little, placing them afterwards in a stove temperature and syringing them in bright weather. This method produces a well-branched plant with a profusion of flowers, as may be seen by the plants now flowering in House No. 9. *W. H., Kew, February 27.*

CHANGES AT WELBECK.

IT was with surprise and regret that we heard recently of the coming retirement of Mr. W. Roberts from the position of gardener to the Duke of Portland at Welbeck Abbey, Notts. Mr. Roberts has been a valued correspondent to these pages, and we hope that the exceptional experience he possesses in practical gardening will enable him soon to find another sphere of employment. On the 16th ult., as we announced last week, a successor was appointed in the person of Mr. James Gibson, who has won fame as a cultivator and exhibitor of vegetables. Mr. Gibson was born at Auchans, Dundonald, Ayrshire, on the estate of the Earl of Eglinton, where his father was steward for twenty-five years. He served an apprenticeship in the gardens at Sundrum, near Ayr, and subsequently was foreman in the gardens of Sir James Fergusson, Bart., M.P., &c. Mr. Gibson's experience as head gardener has been gained entirely in England, in the counties of Kent, Surrey, Middlesex, Buckingham, and for a short period only in Sussex. He is a thoroughly good gardener in all branches, and though known most as an exhibitor of vegetables and fruits, has, we believe, an intimate knowledge of landscape gardening.

MR. JAMES GIBSON.
Whose appointment to Welbeck we announced last week.

Mr. Gibson has won many honours at exhibitions, including the Gold Medal of the Royal Horticultural Society, the Veitch Memorial Silver and Bronze Medals, and quite a collection

of silver cups and miscellaneous medals. He is a member of the Fruit and Vegetable Committee of the Royal Horticultural Society, and of the National Potato Society's Committee. In 1903 Mr. Gibson was a member of the Committee which was responsible for the Gardeners' Dinner held at the Holborn Restaurant on the opening day of the Chiswick Vegetable Show.

As most of our readers are doubtless aware, Welbeck possesses one of the largest gardens in the United Kingdom. The garden staff includes sixty men, and there are 20 acres of kitchen-garden. We congratulate Mr. Gibson upon his appointment to such an important position. He will take with him to Welbeck on March 7 the best wishes of a large number of friends, by whom he is held in very high esteem.

PHALÆNOPSIS AT MESSRS. CHARLESWORTH'S.

From a photograph taken recently in the Phalænopsis-house in the Orchid nurseries of Messrs. Charlesworth & Co., Heaton, Bradford,

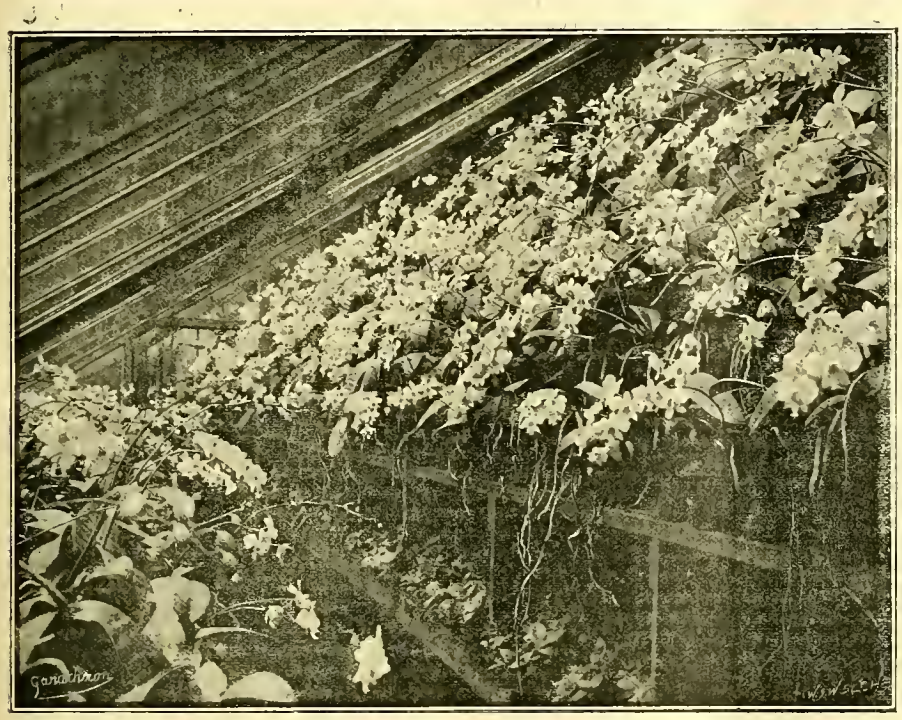

Fig. 54.—PHALÆNOPSIS IN MESSRS. CHARLESWORTH AND CO.'S NURSERY, HEATON, BRADFORD.

Yorks, we are enabled to give an illustration (fig. 54) of the rich display whence Messrs. Charlesworth selected the batch of splendidly-grown specimens which formed the chief feature in their group exhibited at the Royal Horticultural Society's meeting on February 14, and for which a Silver-gilt Flora Medal was awarded.

Considering the reputed difficulty there is in growing Phalænopsis, it is satisfactory to have to demonstrate such success, and at the same time to show that notwithstanding the great space devoted to hybrids the species are not neglected.

COLONIAL CORRESPONDENCE.

LANTANAS A PEST IN QUEENSLAND.

In Mr. Nehrling's description of his Florida garden, much was made of the Lantanas. I do not know if there is frost enough in a Florida winter to kill Lantana, but if there is not, then woe to Florida if ever the plant escapes to uncultivated ground!

My house stands in a 10-acre paddock, 5 acres of which do not belong to me, but I had the use of the land for my cattle and horses. Three years' growth of the Lantana on this 5 acres has so covered it that a dog could not get through, and it is 15 feet high. The plant is filling up all the scrubs and forests, which in a few years will be impenetrable. Most birds feed on the fruit of the Lantana, and their droppings spread the pest wherever they go.

All our worst weeds have been introduced to the colony. Mimosa pudica, and three species of Sida (I know only retusa) are dreadful weeds on grass land. I emptied the soil out of two Wardian cases which came from Kew with seedling [Sugar?] canes, watered it carefully, and had a good crop of Furze (Ulex europæus), Nettle (Urtica dioica), Chickweed (Cerastium vulgatum), &c. The Ulex died, but the Nettle made great progress, soon showed flower, and gave proof that it would be a successful colonist; but my view of the matter was not favourable to this, so I swept off the lot. Vervain (Verbena officinalis) is another introduced bad weed, but is mostly seen in what the sugar-planter calls a "fallow," a 5-feet growth of Vervain, &c., which seeds abundantly and is ploughed in for the next crop. *D. Buchanan, Mackay, Queensland.*

NOVELTIES.

THE TECTUM POT.

Mr. Schwarz sends us photographs of a pot with a loose bottom, and the form is such that the broadest diameter of the pot is below, instead of above, thus accommodating it to the natural tendency of the roots to spread from the centre. Young plants are started in the ordinary way, but afterwards shifted into the "Tectum," with, as is stated, excellent results. The pots may be had from Messrs. Osman & Co., 132, Commercial Street, London, E.

EXPERIMENTAL CULTIVATION.

(*Continued from p. 69.*)

Variety Trials.—No department in experimental work appears at first sight to offer so few difficulties as this, but none in actual practice presents us with so many, if the work is conducted in a scientific manner. Still, it possesses considerable importance, and so much interest attaches to it as well, that such trials should always constitute a part of the operations at any properly organised experimental station. To ensure results of a really useful character, the issues must be narrowed as far as possible, and the closest attention is demanded to secure equality of conditions. The plants submitted to the trials should be from their natural characters and their origin strictly and fairly comparable, the smallest details being fully considered, as some of these have a material bearing upon the subsequent behaviour of the tested plants. The neglect of cultural essentials at the commencement can seldom be rectified afterwards, and perplexing crop results often follow. The preparation of the land, both as to time and weather conditions, should be as uniform as attention and labour can render it; the manuring and the previous year or two's crops should have been identical; and the soil should be free from any marked divergencies, either in chemical composition or physical properties. The land chosen, too, should be level and free from irregularities, both in aspect and altitude. The period for sowing or planting must be selected with the same objects in view, namely equalisation of the conditions for the varieties to be tested.

If these preliminaries are disregarded variety trials are of little value, and imperfect experiments have in this way led to unreasonable condemnation of the whole work. For a considerable time the largest trials of varieties, both of flowers and vegetables, have been conducted by the leading nurserymen and seedsmen in this country and on the continent. It has become a practice amongst inexperienced persons to scoff at these trials as being directed mainly to the exaltation of varieties sent out by each individual firm. That there are defects in the usual systems in seed grounds and elsewhere can be readily admitted, and it would be contrary to human nature to suppose that each firm is not most satisfied when its own products appear to the best advantage. Beyond this I would not go, for a wide acquaintance with and a close examination of the methods adopted by the leading firms have convinced me that the utmost is done to ensure absolute fairness both in the cultivation and the recording of results. If a rival's variety is proved to be superior, the fact is not usually proclaimed to the world, but the fullest advantage is taken of it all the same, so that the public benefit ultimately. This is all one can expect; a firm does not conduct its business for the purpose of advertising the products of rival establishments. But in an official trial the object is to discover the merits of the respective varieties regardless of their owner's interests.

Here, however, another incentive to the greatest care comes into operation. No firm of any standing can afford to stake its reputation upon the transient merits of an unproved novelty. It is entirely in tradesmen's interests to satisfy the public in what they produce; if a novelty prove to be genuine they are substantial gainers, and if it be found to be worthless they are heavier losers than the purchasers. The presumption is, therefore, that before sending out anything as new, or as an improvement upon older sorts, they will submit it to the most rigorous tests which experience has suggested.

Consequently, when an amateur experimenter, possibly of limited practice and imperfect knowledge, takes upon himself the task of comparing

varieties, condemning or praising in accordance with a few small trials, he may be doing a grievous wrong in one direction, while his praises may be equally misleading in another.

Work of this kind must be placed upon a broader basis before it will yield reliable results for general application. For many years the Royal Horticultural Society had at their Chiswick garden admirably arranged, efficiently conducted, and carefully recorded trials of fruits, flowers, and vegetables, which it was my privilege to study closely during a considerable period. But as regards many of these, if it had been possible to have tested the same varieties at several different stations at the same time, the results would have been of still more value to the public, as the merits or defects of the varieties would have been clearly demonstrated. If any similar trials are undertaken in the new garden at Wisley, an extension of the old scheme in the way suggested would be desirable.

Now that the Board of Agriculture is giving some attention to horticulture, it would be quite within their power to organise a system for general experimental work (in which variety trials should form a part), either through the county councils or separately. It is, in fact, only by the action of some central or official body that such work will ever be placed upon a proper basis.

Trials may be classed in three groups according to their special objects, namely—

1. To determine the distinctness and merits of varieties generally. This, in most cases, means a large collection of varieties, old and new, for the purpose of determining those which are either too much alike or identical, and of eliminating those that are worthless. It especially requires a repetition in succeeding seasons, and in different soils or situations, to permit the formation of trustworthy conclusions. Such experiments, too, must not be unduly restricted as regards the number of individuals submitted to the comparison. A few plants and small plots give rise to the same mistakes as occur in general experimental work when conclusions are founded upon insufficient evidence.

2. To determine the relative merit of novelties. Comparison must in this case be made with selected standard varieties of well-known characters, and the trials should be extended over several seasons under different weather conditions. The utmost patience is needed, and undue haste will often result in decisions having to be subsequently revised or reversed. It is not uncommon for varieties of some fruits and vegetables to be under trial for five to ten years before they are placed upon the market, either owing to a want of fixity of character, or to a great susceptibility to seasonal influences. Such a prolonged testing is not subsequently demanded, but two or three seasons should be allowed; and perhaps if the weather conditions be very diverse two may suffice.

3. To determine the fitness of varieties for special situations and districts.

Under this head trials can be conducted by county councils and other bodies of an official or independent character that should be of great local value. It is well known to every experienced horticulturist that both vegetables and fruits display strange peculiarities in their adaptability for certain positions or soils. Some are very restricted in their partialities, while others seem to possess a great elasticity of constitution. Extended records dealing with these characteristics are most valuable guides to cultivators, especially when starting in new localities.

There are several other points which demand attention in variety trials, one of importance bearing upon the restriction of the work, and concentration upon a portion of the subject at a time. Thus in either vegetables or fruits where the forms are very numerous, it may prove advantageous to deal with early, maincrop, and late varieties separately. Perhaps in another case productiveness may be the special object to be studied; high quality is also a subject for a trial; and hardiness is a character that can be tested in a similar way. These are only put forward as indications of the scope of experimental trials, and many others will occur to all who start on the work.

Methods of recording the observations of growers are of great importance here as in other departments, and the more uniformly and minutely such notes can be entered and tabulated the more useful will be the results. In determining the respective value of the varieties compared, the first matter is to set out in full what characters are to be considered, and then to adopt a system of awarding points, as in judging at horticultural shows. Care must, however, be taken to fix a sufficiently high standard at the commencement, as subsequent alterations will lead to confusion. The Royal Horticultural Society has adopted a system of this kind in awarding marks to the varieties under trial, but it has always seemed that the degrees of merit are too restricted; in practice I have found that with a lower standard than six points difficulties constantly arise.

A good example of the details required in variety trials is afforded by the forms issued by the National Potato Society to observers who have conducted county trials. In these, entries are required under the following headings:—Soil; previous crop; manure used; cultural operations; distance in inches between rows and between sets; direction of rows; rainfall during growth; spring frosts; name of the variety; numbers of tubers planted; total weight planted; date of planting; habit of plant; description of blossom; appearance of disease; date of lifting; quantity lifted, ware; quantity lifted, seed; gross weight lifted; flavour; general remarks.

With many fruits and vegetables it is desirable to complete the observations by testing the qualities of the varieties when cooked; and in all cases good cultivation should be provided. Starved or stunted products are not required in such comparisons; on the contrary, it is important to ascertain the full capabilities of the varieties without excessive stimulation. *R. Lewis Castle.*

(To be continued.)

FORESTRY.

QUERCUS PEDUNCULATA & SESSILIFLORA.

The enclosed table, showing the rate of growth of these two varieties of Oak, may be of interest to readers of the *Gardeners' Chronicle*. The acorn of Q. pedunculata was taken from the large Oak at Panshanger, and that of Q. sessiliflora from a tree at Woburn. The two trees are growing here in sandy loam 200 yards apart. An accurate account of their growth has been kept, which I enclose.

	Quercus pedunculata, sown 1811.		Q. sessiliflora, sown 1840.	
Year.	Circumference at 3 ft.	Circumference at 5 ft.	Circumference at 3 ft.	Circumference at 5 ft.
	ft. in.	ft. in.	ft. in.	ft. in.
1865	7 0	6 7	1 10	1 8
1869	7 3	6 10	2 6	2 4
1871	7 6	7 0½	2 10	2 7½
1872	7 8	7 2	3 0½	2 10
1878	8 3	7 9	4 2	3 11
1883	8 7	8 1	5 0½	4 8½
1885	8 9	8 2	5 3½	5 0
1893	8 11	8 6	5 8	5 4
1900	9 7	9 1	8 0	7 7
1904	9 10	9 2½	8 7½	8 1½

From the above table it appears that the sessile variety is rapidly gaining on the pedunculate. *H. Clinton Baker, Bayfordbury, Herts.*

POTATOS.

Soil and Quality in Potatos.—Interesting evidence of the effects of soil on Potato quality comes from Hackwood Park, Basingstoke. Mr. Bowerman, the gardener, is without doubt one of the most experienced vegetable growers in the kingdom, and in the fine open kitchen-garden at Hackwood Park, with a deep and well fertilised soil on a chalk subsoil, he has an excellent opportunity for growing high-class Potatos, and produces annually some of the finest crops of this vegetable; rarely, moreover, is he troubled with disease. For the past few years he has favoured me with a sample of his favourite maincrop Potato, Up-to-Date, to cook and test its merits. It always cooks superbly, and this season it is as good as ever. He writes with regard to two newer varieties, Northern Star and Evergood, both having in other directions very high reputations, "I have fourteen sacks of these, but both varieties are so bad when cooked that I wish I had never seen them." Yet in some other soils these varieties may be of excellent quality. In any case it would seem that owing to the tubers being less dry or starchy, the stocks should be excellent for seed purposes.

Raising New Potatos.

With all respect to so eminent a Potato-raiser as is Mr. Findlay, I cannot for one moment accept his dictum that natural cross-fertilisation has never taken place in connection with Potatos. Were that so, how is it that in years past, when many varieties did produce pollen so abundantly that flowers would give it off almost in clouds, and berries set literally by bushels, that seedlings raised from seed so produced would very greatly vary in character? If Tomatos will cross-pollenise freely, why not Potatos, when pollen is abundant? True, with varieties grown to produce huge crops of tubers pollen is now an exceptionally scarce article in Potato flowers; but thirty years ago it was singularly abundant in many varieties. We have the authority of the late Mr. Clarke, of Christchurch, who raised the famous Magnum Bonum, that it was the product of natural cross-fertilisation. The Early Rose, though a free-bloomer, never did set flower or produce berries. But on one occasion Mr. Clarke found a couple of berries on a plant growing near to a breadth of Paterson's Victoria, and he was confident that a natural cross had been effected. He had never made such a cross. Surprised to find berries where otherwise none had been found, he saved them, sowed the seeds, and raised a batch of seedlings, one of which was the famous Magnum Bonum. Such was the account Mr. Clarke made to me in writing many years ago. In any case no clever artificial manipulation has yet produced a variety fraught with greater value to Potato growers than was Magnum Bonum. In these days, when Potato flowers produce so little of pollen that self-fertilisation is of the rarest, naturally there are no clouds of pollen to be wafted in the air from flower to flower, as was the case many years ago. Then with some varieties it was needful, to check the production of berries, to pick off the clusters of bloom before the plants could become exhausted by seed-pod development. Naturally this sparseness of pollen has made intercrossing to secure new varieties almost an art; all the same, new ones do come in bewildering profusion. I read with amused interest Mr. Findlay's account of the elaborate method he adopts in sowing Potato-seed. I have raised myriads of seedlings in my time, and found no more difficulty in doing so than in raising seedling Tomato plants. Pots or pans filled, as usual, with fairly good sandy soil; holes with the point of a finger a quarter of an inch deep, made equidistant all over the soil; a seed

placed in each, then just covered over. By that way it was ensured that each little plant had its fair share of elbow-room till strong enough to lift and shift singly into small pots, keeping them near the glass, and shifting into 48's before finally planting-out. *A. D.*

CYCLAMEN COUM.

The round-leaved Cyclamen is one of our most valuable of early spring (one might almost say of winter) flowers, for, together with other members of the genus, such as C. Atkinsii and its hybrids, they may often be seen in flower or in bud in winter. I am led to remark on the beauty and the general value of these plants by reason of a greatly admired exhibit of them at a meeting of the Royal Horticultural Society on Feb. 14. As displayed in the boxes in which they were exhibited, the plants gave an excellent idea of what may be accomplished by a free use of them in the garden. One of the best purposes for which to use them is as a groundwork to such plants as Andromeda floribunda, Kalmia, Ledum, Daphne Cneorum, and similar subjects. The soil usually

Fig. 55.—Cyclamen coum var.

employed for such shrubs is very suitable for these hardy Cyclamens, which appear to possess a liking for the shelter and the shade thus afforded. At the same time the plants grow well in sandy loam in which old mortar has been mingled. At Painswick, where the late Mr. James Atkins grew these plants so well, the soil is of a heavy loamy character, and probably to facilitate the drainage more than for any other reason, small limestone chippings of the district were freely incorporated with the soil, and in these the plants thrived with great success.

As plants for the cold-house in winter, Cyclamen Coum and C. ibericum are very charming. The latter species varies considerably, which variation is seen in the flowers and also in the more or less marbled leaves. C. Coum is a small-leaved plant, the leaves being not more than 1½ inch across, of a dark-green colour with reddish under-surface; cordate, and slightly crenated at the margin. The delicate-looking flowers are developed not more than 3 inches above the plant. The corolla is short, with roundish and blunt segments, of a reddish colour, with crimson staining at the somewhat constricted mouth. A white form of this plant was raised by the late Mr. James Atkins. Mixed groups of these varieties are very pleasing in the early days of the year, when they flower with the Snowdrop, Winter Aconite, &c.

In planting the corms should be buried an inch or more beneath the surface of the ground. Imported corms frequently remain dormant for a whole year, although perfectly sound. In the interesting group already noted, which was exhibited by Messrs. Jackman, of Woking, additional interest was given by a curious development seen in a single plant, and which is illustrated in fig. 55. This was virtually a variety of C. Coum album, but possessed seven segments in place of the normal five. The segments were pointed, acute, and horizontally disposed, giving a star-like appearance to the flower. The segments were heavily marked with deep violet at their bases. All the flowers on the plant were identical, and the segments not reflexing as in the ordinary form, presented a novel and interesting feature. *E. H. Jenkins, Hampton Hill.*

THE SPECIES OF EREMURUS.

(*Continued from p. 99.*)

E. h. robustus (E. himalaicus × robustus).—A pretty and vigorous hybrid that may be adequately described as having the habit of E. himalaicus, the larger flowers of E. robustus, whilst the colouring is a blend between that of the two parents—a silvery-blush or white "shot" with tints of pink. It is an effective garden plant, but it has the precocious habit of E. robustus in thrusting its flower-spikes too early for their well-being. *E. himrob* × is another name for it. I think, however, there are hybrids between himalaicus and robustus both ways, these differing more in habit than inflorescence from each other.

E. Olgæ (Regel).—A pretty, graceful Eremurus that one too rarely sees in private collections, though introduced long ago. It has a root-system similar to that of E. himalaicus, but the thong-like roots are ruddy-tinted. The leaves are very long and numerous, glaucous, and very tough, forming a loose tangle a yard through when established. The root-stock is more often two to three-crowned than simple, and the spikes attain to a height of 8 to 9 feet, 6 to 7 feet of which is sparsely covered with short pedicelled flowers that are coloured white internally and reddish-pink externally. The petals are rounded and shell-like, showing many tints of silvery-pink on all surfaces, and they remind one of Apple or Peach-blossom. The spikes are much less crowded than in most of the species of Eremurus, and they are extremely graceful and very lasting. It flowers five to six weeks after E. himalaicus and E. robustus, and is generally the last to bloom of the race. I have measured flowering portions of strong spikes that exceeded 7 feet in length, and a mass of imperfectly developed buds at the tips showed that still greater length is possible. It grows splendidly in heavy clay, and one strong specimen has yielded a dozen flowering crowns in four years. The species varies a little in colour range; some are nearly white, others striped with pink externally, the inner surfaces pellucid and slightly flushed pink; others are almost brick-red externally, but never harshly coloured.

E. robustus.—The finest Eremurus so far introduced, and an exceedingly vigorous plant, surpassed in stately magnificence only by its variety Elwesianus. It is a plant one cannot grow too well, for it prefers a deep sandy loam, and appears to resent soils containing any quantity of chalk and lime, such as would grow E. Bungei well. The root-stock has a conical crown (differing in this respect from Elwesianus) set in a depression of the roots, which ascend abruptly as they leave the root-stock, the thongs being rigid and fleshy, and not more than a dozen around each crown. The leaves are deeply channelled, pale green, 2 feet long or more, ascending for half their length, the tips always drooping when fully grown. The flower-spikes are 8 to 10 feet high, stouter than a man's wrist when fully developed, bearing on the upper third a dense array of soft pale pink flowers, 1½ inch across each, the petals of which are broad and rounded, the anthers reddish, and the ovaries orange-tinted. It is a splendid species, succeeding admirably in a shrubbery clearing and other sheltered place, where its growing spikes would receive some protection. The flowering-spikes of E. robustus are among the first to appear, and they grow very quickly when once started; hence it is not improbable that they may suffer from late frosts in the open border. For such open spaces the variety Elwesianus is the better plant—it is later in pushing spikes, and slower in developing its spikes than E. robustus. *G. B. Mallet.*

(*To be continued.*)

THE PAGOSCOPE.

Under this name M. Bernel-Bourette has introduced an instrument which cannot fail to be of service to cultivators. We take our illustra-

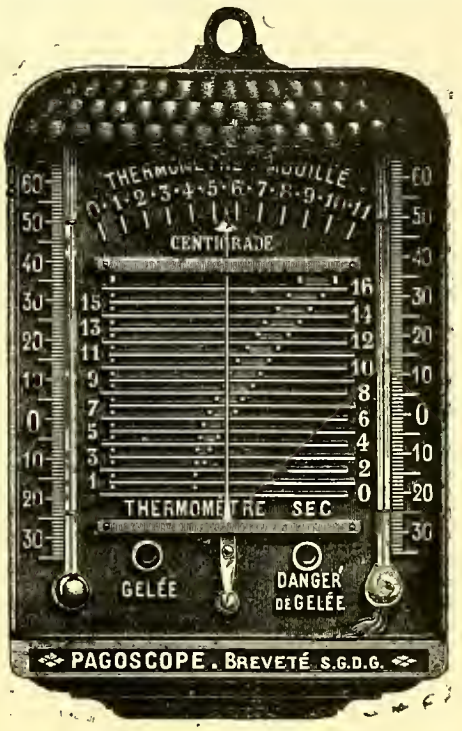

Fig. 56.—Bewar E of the Frost!

tion (fig. 56) from the *Journal de la Société Nationale d'Horticulture de France* for January, 1905, where it is fully described. The object of the instrument is to give timely notice to the cultivator of the approach of frost. The apparatus consists of a dry and of a wet bulb thermometer attached to a plate of zinc, whereon are inscribed certain figures in lines on either side and one in a horizontal or curved line near the top, representing thermometric degrees. There is also a needle, which serves as an index. The plate itself is marked with three bands or stripes of colour, green, yellow, and red, the yellow stripe being relatively narrow.

The thermometric scale represented is the Centigrade, but of course a similar arrangement might be adapted to the Fahrenheit scale. When it is desired to use the instrument, the temperature of the wet bulb thermometer on the right-hand side is first of all noted. Let us suppose it is between 5° and 6°, then the index is moved so that its point becomes placed between 5° and 6° on the curved line of figures at the upper part of the plate; then the temperature of the dry bulb thermometer on the left side is read off; let us suppose it is between 7° and 8°. Having ascertained this, the finger tip should be run along the horizontal line corresponding to that.

temperature till it meets the index or needle. If the point where the horizontal line comes into contact with the index is situated on the portion of the plate coloured green there is no fear of the occurrence of frost; if the junction point is in the yellow band the frost is likely to occur, at any rate it would be prudent to take precautions; lastly, if the point of contact of the horizontal line with the index happens to fall within the red band, frost is absolutely certain to follow. The instrument is patented.

SPRING FLOWERS AT FIR GRANGE, WEYBRIDGE.

W. A. BILNEY, Esq., an active member of the Council of the Royal Horticultural Society, has in a very few years succeeded in making his gardens at Weybridge most varied, beautiful, and interesting. When Mr. Bilney acquired the property a good part of it was still beautified by the Pine-trees peculiar to the district, and his object was to interfere as little as possible with the Pine-wood, but to arrange, with the aid of the existing trees and natural undulation of the sandy soil beneath, a series of pretty gardens connected by seemingly endless walks, and his object has been accomplished in a highly successful manner. It is now a scene of great beauty, the spring flowers being well advanced, and a very great quantity of bloom appearing to keep up the display until the summer flowers come in. Many thousands of bulbs of all kinds have been planted—clumps of the best Pæonies, Irises, and other showy flowering plants, and all have thriven well, despite the sandy nature of the soil, which even now is rather dry beneath the more closely arranged Pine-trees.

Around the commodious dwelling-house a modern garden, with lawn and flowers, is arranged; on one side is a rustic nook surrounded by Rambler Roses running over rustic woodwork. Beneath the windows of the billiard-room a close bank of that most useful of hardy shrubs, Choisya ternata, is arranged, and the lawn in front is studded with innumerable tufts of Crocuses of all colours, which are permanently planted; and from the house and beneath the Pine-trees runs the garden of rockeries, banks, and naturally arranged groups of most of the best hardy plants and shrubs. In the first nook the masses of Crocus Imperati have been in bloom for several weeks, and will last several weeks longer; the hardy species of Cyclamen commenced flowering in January, and are now beautiful objects; and the large clumps of Gentiana acaulis show well for bloom. At another curve is a large mass of Winter Aconite covered with yellow flowers. This seeds of its own accord, and the seedlings are thickly distributed. Beyond, beneath the Pine-trees, is a plantation of Rhododendrons, with banks of Irises beside them, and a small ornamental water for Nymphæas, the rockery around being planted with a complete collection of Saxifrages, some of the earlier of which are in bloom. Then comes a bog-garden with suitable plants, and having Bamboos and other graceful subjects around it. Here, and in several other parts of the garden, clumps of Narcissus minimus are in flower.

Passing through the rock-bordered walk a nook of Hellebores, Snowflakes, Snowdrops, and other spring bulbs are making a fine show, and a small Fern-dell is reached. Beyond is the new Japanese garden, well advanced, and in which it is intended to plant uncommon Japanese plants and shrubs. Quantities of Japanese Lilies are already planted, the uncommon Lilium rubellum being represented by a clump of one hundred bulbs. The continuation of the woodland walk returns to the house again, and is beautiful at many points with the flowers of Scillas, Chionodoxas, Galanthus Elwesii, Hepaticas, Cyclamen Coum, Hamamelis, Primula cashmeriana, and other spring flowers. The whole of the beautiful garden scenes have been carried out on Mr. Bilney's own plans, and his labours have proved a great relaxation to him during an active life.

The walled-in kitchen-garden is in excellent trim; the fruit-trees and general crops are in fine condition. Most things thrive better than would be expected on such sandy soil, though Turnips and some other root-crops are difficult to obtain, and Raspberries refuse to grow or fruit even tolerably.

Under a sheltered wall is the children's garden, managed entirely by themselves. Peaches and Nectarines under glass are in full flower, and in the greenhouse a large batch of Lachenalia tricolor makes a fine show, and the Roses in pots are well set with buds.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Mossing Aërides.—A. Fieldingii, the "Fox-brush" Orchid, has a good constitution, and grows well if suspended from the roof of a Cattleya-house. Once established in a basket, it is not advisable to disturb a plant until the basket has decayed. Associated with this are A. crassifolium and A. crispum, each of which may now have the old sphagnum-moss picked out, and new moss pressed moderately firm in its place. For a month or so after resurfacing any of the plants sprinkle the sides and surface only, but when the roots become active afford water whenever there are signs of dryness. Species which need more heat, shade, and moisture, such as A. affine, A. Lobbii, A. maculosum, A. Lawrenceanum, A. odoratum, A. quinquevulnerum, &c., may be grown in pots. Insert pieces of crock placed upright amongst the roots, and fill in between these with freshly gathered sphagnum-moss. Plants having too much naked stem may be shortened from the base upwards, so as to bring the foliage nearer the pots. The plants should be staged in a position where there is a free circulation of air, and extra care is needed for some time in the matter of watering. Keep the surroundings moist by damping the spaces between the pots, and spraying overhead on all fine days. A. Vandarum, a terete-leaved species, thrives best in a moderately cool house, such for instance as one in which Cypripedium insigne succeeds. In other respects treat the plants in the same way as the other species, except that these should be tied to upright stakes.

Angræcums.—The dwarf-growing species, such as A. citratum, A. bilobum, A. Leonis, A. modestum, A. pallidum, A. Sanderianum, &c., grow best in baskets furnished with a few pieces of crock and a surfacing of moss. Suspend the plants on the shadier side of the East Indian-house, and afford them abundance of water throughout the growing season. A. eburneum and A. sesquipedale being more robust, need pot-culture. For potting these, use a mixture of fern rhizomes, sphagnum-moss, small crocks, and a small proportion of semi-decayed Oak leaves. Place a few pieces of potsherds in the bottom of the pots, and then work in the compost amongst the roots, surfacing the whole with clean, chopped sphagnum-moss alone. Place the plants in a warm house where the shading is not dense, and afford water sparingly, except just when the plants are rooting freely.

Vandas, being of a diversified character, all the species cannot be treated just now, but such as V. insignis, V. Bensoni, V. Denisoniana, V. lamellata, V. Parishii, V. Roxburghii, &c., may have the old moss replaced with new. Suspend them on the shady side of the warm-house, and keep them just moist until they are rooting freely, when copious supplies of water may be afforded them. V. cœrulea is best grown in pots two-thirds filled with drainage and surfaced with sphagnum-moss, which may be renewed now. Place the plants in a light position in a house where an intermediate temperature is maintained, afford ventilation freely, but maintain an abundance of moisture in the air. The sphagnum-moss will not need much water for some time to come; but when the plants are rooting freely, it will be difficult to afford them too much, providing the other conditions are satisfactory. Disease spots may appear on the leaves if there are cold draughts, or if a "stuffy" atmosphere is permitted. To some extent these spots may be arrested by pricking them with a needle or a knife-point.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Primula kewensis ×.—For two months past a batch of these plants has given us a bright display of flowers, but the plants have now ceased to be effective. For winter use there is nothing more serviceable than this Primula if grown well, but otherwise it is of little value. The specimens when arranged in a mass among other flowers are very pleasing, but the flowers, if cut and arranged in glasses, soon drop, and I would not recommend them for this purpose. I have found little difficulty in raising a large number of plants from two I purchased some two years ago for stock; and my method of culture is as follows:—As soon as they have ceased to flower they should be divided (care being taken not to break the young roots during the operation) and repotted. Let the compost consist of good fibrous loam and leaf-soil in equal proportions, one-third of old lime-mortar sifted, and one-third of silver-sand. Very small pots only should be used for the first potting. Place the plants in a warm frame near the light for a few weeks, and provide them with slight shade in bright sunshine. When the weather becomes warmer and roots are forming, remove the plants to cooler quarters, and repot them into slightly larger pots, using similar compost for the second potting. The third and final repotting should be into 5-inch or 6-inch pots at most, and when these pots become full of roots the plants will require feeding with weak manure water. During the summer no place suits them better than in a cool frame directly under a north wall, where they can be shielded from the direct rays of the sun, but derive full benefit from the light. Until the plants become strong the flowers should be removed as they appear.

Lobelia lenuior, figured in the *Gardeners' Chronicle*, Jan. 19, 1901, p. 46, fig. 20, whether grown in baskets or in pots, is extremely valuable during summer and autumn. A pinch of seed should be sown now, and another pinch a little later on to form a successive batch. Sow the seed on a hot-bed, and prick the plants off as soon as they are ready. The seedlings require warmth and moisture, and much light during their season of growth.

Browallia speciosa major.—Insert cuttings or sow seeds of this plant. Pots containing cuttings should be plunged in a mild bottom-heat. Seeds also should be raised under like conditions, and the seedling plants should be grown during the summer on a shelf near to the light in a warm-house.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Raspberry Canes may still be planted. They are gross feeders, necessitating a liberal amount of manure to be worked into the land before planting is done. Suckers make the best plantations and should be planted in preference to dividing old stools. Allow a space of 5 feet between the rows, and 3 feet from plant to plant. Newly-planted canes should be cut down to within 1 foot of the ground soon after planting, reducing this length to almost the ground level when growth has well commenced.

Older Plantations may now have the canes topped, and a good plan is to shorten every alternate cane to within 2 feet of the ground; by this means some very fine fruits are obtained, and the season of ripening is prolonged. I can recommend this practice where the canes are trained to wires. The bundling of five or six canes together is a system practised in some gardens, but in such cases many of the buds fail to grow.

through being so crowded. It is preferable, if neatness is not a consideration, to shorten the canes to 4 feet high and allow them to fall outwards. Not only will the old canes succeed better, but the young ones also; and this simple plan is followed by market growers. Where heavy mulchings have been applied to Raspberries the material may be lightly forked-in below the surface of the soil, remembering that Raspberries are surface rooters, and it is not good practice therefore to dig deeply amongst them. Of varieties, Superlative is the universal favourite, Baumforth's Seedling and Hornet following as red-fruiting varieties, and Antwerp is an old favourite yellow-fruiting variety, but is now superseded by the newer one, Guinea.

Autumn-fruiting Raspberries cannot always be relied upon for a crop. These should be cut down now close to the ground, thinning out the new growths that will presently come from the base to five of the stoutest. October Red and Belle de Fontenay are the best of this section.

Gooseberries.—In some districts where birds are numerous, the work of pruning has been delayed. This should now be finished as expeditiously as possible, covering the bushes afterwards with fish-netting. Bushes from which the fruit will be picked whilst still green should not be so heavily pruned as those of some of the Lancashire and other dessert varieties. Thin out the centres of the trees, cutting back the side shoots of last year's growth to three or four buds, and the leading growths to half their length. If Gooseberries and Red and White Currants are required for exhibition purposes, cut the shoots hard back, leaving five to six eyes on each shoot close to the main stem. They will then produce unusually fine fruits.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

French Beans. — Sow seeds for successional batches according to the demand. Let five seeds be put in each 8-inch pot, and cover them about 2 inches deep with fairly rich soil. They need a temperature of 60° to 65°. Veitch's Early Favourite is a favourite here, and is followed by Canadian Wonder.

Mushroom-beds.—The same preparation of manure for Mushroom-beds is necessary whether for use indoors or outdoors. The manure must be turned over at intervals of a day or two until sufficient is collected to form the beds, but it should never be allowed to become so hot as to cause dryness. The manure when used should be neither wet nor dry, and it is not well to scrupulously remove all the litter from the manure, for the presence of a little litter will help to keep the manure in a sweet condition. Mushroom-beds indoors may be made from 12 to 16 inches deep, and should be equally firm all over. When the heat begins to decline and does not exceed 80°, the pieces of spawn may be inserted just below the surface at distances of 6 inches apart, breaking each cake into six pieces. Be careful to ascertain that the spawn is fresh. A good position for outdoor beds at this season is one behind a north wall. The size of the beds will be determined by the material at command. A width of 3 feet at the foundation is a convenient size, and the bed may lean against the wall 3 feet high, or stand clear, with equal sides, tapering to about the same height. When it is known that the temperature of the bed will not rise above 80°, apply a covering 2 inches thick with rich loam, making this firm and smooth. Let beds out-of-doors be covered also with litter or straw 18 inches deep.

Parsnips.—We have just sown Parsnip seeds in shallow drills 2 feet apart, the ground having been prepared well previously. No rank manure is near to the surface of the soil, as this would prevent the roots from going straight into the ground. To secure perfect roots for exhibition or other purposes it is necessary to bore holes 2 to 3 feet deep, making them 4 inches wide at the top, and dusting the insides with air-slacked lime, afterwards filling up the holes with well-screened soil from below the potting-bench; but any time during March is sufficiently early for sowing this crop. In many gardens, however, this is the only means by which satisfactory roots can be secured, and if the whole crop be treated in this way the result will compensate for the extra amount of labour involved.

Globe Artichokes.—The finely-screened cinder-ashes used here for protection during severe weather will now be removed little by little until the plants are fully exposed. For the purpose of protection ashes have a neat appearance, and there is very little trouble from slugs or decay. Suckers that were potted in the autumn and have been kept under protection will now be gradually hardened and planted 3 feet apart in rows, and spaces of 4 feet allowed between the rows. Suckers afford the best means of increasing the stock, and "Green Globe" is the best variety.

Seakale.—Root-cuttings from 4 to 6 inches in length have been placed in boxes containing fine soil, and placed in a temperature of 60°. In a fortnight or so, and previously to planting the sets, all the sprouts will be rubbed off excepting one or two, and be eventually reduced to one. If this system is not adopted, cuttings may now be planted, in rows drawn with the line and hoe, 2 inches deep, 2 feet apart, and 12 inches between the plants.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Dr. Corbet, Impney Hall Gardens, Droitwich.

Pot Vines which were started into growth in November will now be at the stoning stage, or approaching thereto, when the temperature at night should be reduced to 65°, to be increased to 68° on mild nights. When the berries again commence to swell take advantage of bright sunny days to push forward the crop by closing the house early with sun-heat. Liberal supplies of weak tepid manure-water and occasional sprinklings of Kirk's and Thomson's Vine-manures should be afforded. Allow the laterals to extend a little more at this stage, for if space will allow of this it will improve the size and colour of the fruit. Keep the atmosphere moist by damping the paths and walls in the house, using occasionally for this purpose weak liquid manure. If red-spider makes its appearance, sponge the Vine-leaves at once.

Later Vines.—Let later Vines of Black Hamburgh and other free-setting varieties have a temperature of 65° at night when in flower, and disperse the pollen by gently tapping the roots or by passing the brush over the bunches at mid-day. Thin out the bunches as soon as possible, care being taken not to thin Black Hamburgh severely. Retain six or eight bunches on each Vine, according to the size of the bunches and strength of the Vines. Avoid over-cropping the Vines or the fruit will be sure to lack colour, and the quality will be only second-rate. Pay careful attention to ventilating the house and to the stopping of lateral growths on the Vines, always allowing plenty of room for the principal leaves to develop perfectly.

Cucumbers.—Plants raised from seeds sown as advised in a previous Calendar will now be growing freely, and as the days increase in length more moisture may be given them. Those plants which have been in bearing all the winter may be cleared out as soon as the young plants have become productive. Stop all laterals at the first leaf, and encourage a few early fruits, but do not allow more than one or two fruits to each plant at the commencement, and cut them before they attain to their full size. Afford a top-dressing to the plants when roots appear on the surface of the soil, but avoid over-feeding until the plants come into full bearing, when all superfluous growths should be removed, and the others pinched and tied in when necessary. Afford ventilation when the atmospheric temperature of the house is at 75°, if only for a short time, increasing the amount of ventilation as the temperature rises to 80°. Close the house early in the afternoon with plenty of atmospheric moisture, allowing a further rise to 85° or 90° after closing.

Frame Cucumbers.—Let the materials be got in readiness for these. The bed should consist of two parts leaves and one part of stable litter, well mixed together by frequent turnings before making up the bed. When the bed has been made, form a ridge or place mounds of soil, one to each light generally being enough. Plant out the Cucumber plants as soon as the soil has become warmed through, or at a temperature of 80°, covering up the pits at night with mats. Leave a "chink" of air under each light to allow any excessive steam from the manure to escape.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Herbaceous Border.—To prevent the strong-growing perennial Asters from getting out of bounds, lift the stools at least every second year. Make liberal applications of manure, and replant a portion of the growths taken from the exterior of the clumps. If the early and late-flowering varieties are planted in carefully chosen positions, there will be flowers continuously from July until November. Amongst the taller-growing sorts A. lævis Arcturus, with its black stems, is very distinct and effective. The variety Coombe-fishacre has a very graceful habit. Dwarf-growing early-flowering sorts are most useful for massing, especially A. acris and A. dracunculoides, growing from 2 to 3 feet high; also A. Nova Belgii "densus," with its compact dense heads of deep blue flowers. Aster Thomsoni, a Himalayan plant, is grand for the front row, being of neat and refined habit, and seldom more than 2 feet high. It has large pale lilac-coloured flowers, and may be increased by seeds or by cuttings of the shoots taken in spring. The roots may not be divided. A. Amellus and its varieties, about 2 feet high, are amongst the showiest, and, like A. Thomsoni, do not require stakes. The remarks on lifting quickly-spreading Asters also apply to Rudbeckia "Golden Glow," Helianthus "Miss Mellish," and other similar plants. When the re-arrangement of the border has been completed, fork-in a good dressing of manure obtained (if possible) from a covered yard.

Herbaceous Phloxes require deep rich soil, and if the stools have been planted two years or more lift them for division and replanting. Discard very old stools and plant clumps of newer varieties from reserve quarter in their places. Dwarf-growing varieties that flower late are valuable.

Anemone japonica and the variety *alba* should be afforded deep soil, and may be increased by division.

Wigandia macrophylla and W. Vigieri.—Sow seeds of these plants in heat, and prick off the seedlings as soon as they can be handled. Pot them on when they are ready for this, using rich soil to encourage strong growth. Seeds of Nicotianas may also be sown.

THE APIARY.

By Chloris.

To make Syrup.—Take about 5 lb. of white sugar, either lump or granulated, and place it in three pints of water; boil well so as to get out the air, for air causes sugar to candy. Much has been written about various drugs, which it is claimed will cure or prevent foul brood; but it is to be doubted whether they will accomplish this result, and it will be well to omit them from the syrup, because the bees are never in a hurry to take down such a mixture. Well-fed bees will not leave the hive during bad weather, so we gain in two ways—there is less leakage by death, and breeding proceeds briskly within.

What vessel to use.—Place the warm syrup in a common glass jam-bottle, filling it to the brim; then tie two or three thicknesses of muslin over it. Invert the bottle over the feed-hole and cover up warmly, so as not to allow the heat to escape from the cluster. It will be an advantage to place under the bottle a block of wood about ½ an inch in thickness, with a hole in the centre about 2 inches wide. Some of the books on bee-keeping specially warn us against using any but cane sugar. Personally, I do not think it matters whether the sugar be cane or beet. I have tried both, and can see no difference in the results.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAR. 4 { Société Française d'Horticulture de Londres Meeting.

SALES FOR THE WEEK.

MONDAY NEXT—
Herbaceous Plants, Perennials, Azaleas, Roses, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Palms, Plants, Azaleas, Rhododendrons, Liliums, Roses, Fruit Trees, Border Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 o'clock.—Cases of Lilies from Japan, Azaleas, Roses, &c., at Stevens' Rooms, at 12.30 P.M.

FRIDAY NEXT—
Hardy and Herbaceous Plants, Roses, Azaleas, North American Plants, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Imported and Established Orchids, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —41°4.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March* 1 (6 P.M.): Max. 44°; Min. 35°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 2 (10 A.M.): Bar., 29·9; Temp., 42°. Weather—dull, with occasional sunshine.
PROVINCES.—*Wednesday, March* 1 (6 P.M.): Max. 43°, W. Coast of England; Min. 40°, Scarborough.

Rosa gigantea. *(See Supplementary Illustration.)*

IN 1889 we received from Sir GEORGE KING, then the Director of the Calcutta Botanic Garden, some seeds of this noble Rose, which were distributed among those likely to succeed in its culture. Probably seeds were distributed from other sources also. Mr. GEORGE PAUL informs us that he raised seedlings from this Rose, but that they damped off; and the same fate befell others raised by Mr. LEACH. Some disappointment has been felt at the circumstance that while the Rose grows with the greatest freedom, as at Kew and elsewhere, flowers have only very rarely been produced. Eventually in 1898 Lord BROUGHAM had the satisfaction of flowering the plant in his garden at Cannes. In his "List of Roses now in cultivation at the Château Eléonore at Cannes," published in 1898, his lordship mentions the plant as having flowered in his garden for the first time in Europe last month [April, 1898, presumably]. He gives a photographic representation of it, and describes it as—

"A splendid plant, making growths of 40 feet or more, with rambling branches armed with irregular prickles of moderate size, often in pairs at base of leaves, which are about 3 inches long and glabrous. The flowers are solitary, about 6 inches in diameter—which size will not unlikely be increased when the plant is older and stronger, of a golden-white with yellow centre containing an unusual quantity of pollen. Petals large, broad, imbricated; disc large, styles much exserted, free, villous; stamens long. The most desirable and by far the finest single Rose I have ever seen. It does not seem to be very hardy and is subject to mildew [as it is also here]. The bud is long, larger, but very closely resembles that of Madame Marie Lavallée, and of a pure gold colour. This Rose when in flower should obviously be shaded, as the sun soon extracts the gold from the blooms, leaving behind a substitute of dirty white. At a short distance the flowers bear a close resemblance to a Clematis."

Mr. F. CANT, of Colchester, also succeeded in flowering it, but with such indifferent results that he discarded the Rose as useless for his purposes.

Then came Mr. LEACH, the gardener to the Duke of NORTHUMBERLAND at Albury, Surrey, who succeeded in 1903 in inducing the plant to produce two flowers, the first of which was just on 6 inches across. In February, 1904, the same specimen produced about a dozen flowers, and this year Mr. LEACH had the satisfaction of seeing twenty-eight blooms on his plant, some of which were exhibited at the Royal Horticultural Society on Tuesday last, and secured for the exhibitor the award of a Cultural Commendation and a Botanical Certificate. Mr. LEACH cultivates the plant in a Peach-house, and the shoots are trained down on the wires.

The colour of the flowers exhibited was ivory-white, and the foliage showed one more pair of leaflets to each leaf than is represented in our illustration. A good figure is given in the *Botanical Magazine*, t. 7972 (September, 1904), where the flowers are shown of a pale-primrose-yellow colour, whilst the bud has the golden colour mentioned in Lord BROUGHAM'S description. There is no doubt whatever from the glowing descriptions given by travellers, and such evidence as we now have, that this is indeed a grand Rose and amply deserved the award made to it. In due time we doubt not we shall discover some means of inducing the plant to flower more freely. Up to the present, as Mr. HEMSLEY says, "every possible method of propagation has been tried ineffectually in order to obtain flowers more freely in this country, yet it flowers profusely on the Riviera."

Sir GEORGE WATT was the first to discover this Rose (in Manipur), but the name R. gigantea was first published by the late Sir HENRY COLLETT, who found the plant in the Shan Hills, Upper Burmah. More recently it has been found in South-Western China by Dr. HENRY and others. We may therefore expect considerable variation, whilst the colour of the flowers, about which there has been a diversity of statement, would naturally differ according to varying conditions and diverse stages of growth. Sir GEORGE WATT mentions that the fruit is edible, as large as a small Apple, and that it is sold in the bazaars of Manipur State.

Mr. FITZHERBERT, in our own columns, May 2, 1903, p. 278, mentions the species as hardy in South Devon; and we have heard of it as grown on an outside wall at Reigate, Surrey.

RHODODENDRONS AT SINGLETON, NEAR SWANSEA, AND AT PENLLERGAER.—Some very fine specimens of Himalayan Rhododendrons may be seen in the Singleton Abbey grounds, belonging to Lord SWANSEA. The specimen shown in fig. 57 is a natural hybrid between R. Falconeri and R. niveum, raised from seed sent to Singleton by Colonel SYKES, who commenced his first expedition to the Himalayas in about the year 1848. The tree is 30 feet high, and 20 feet in diameter across the branches. At the time our photograph was taken the plant had 200 heads of flowers, which in size are very similar to those of R. Falconeri, but they are tinged with lilac colour when they first open, passing afterwards to white or nearly white. Mr. JAMES HARRIS, whose photograph appears in the illustration, was gardener at Singleton for many years, and has now a nursery at Blackpill in the immediate neighbourhood. Among the most notable Rhododendrons at Singleton is R. barbatum, 37 feet high and 15 feet through. This tree is wonderful and its effect handsome, even in winter, but when in flower the sight must be one worth a long journey to see. It generally produces about 400 heads of flowers. Of R. Falconeri there is one specimen 28 feet high and 15 feet through, which has produced on one or more occasions as many as 200 heads of flowers. We had the pleasure of visiting Singleton in January, and these marvellous Rhododendrons, so large that their individual characters are well developed, provided us with an unusual treat, the foliage of R. barbatum and other species being so handsome that the absence of flowers was of less consequence than one would have expected. There is also a good Pinetum at Singleton, which contains many fine specimens, including Tsuga Mertensiana (Albertiana), 110 feet high. Lord SWANSEA having resided abroad for the past three years, Singleton is only inhabited by caretakers, but we are glad to find that although little brushing up and such-like work is done in the gardens, the trees are looked after by Mr. HARRIS, who is still retained for this purpose by Lord SWANSEA. The extraordinary climate at Singleton is shown by the fact that we were able to gather beautiful flowers of Grevillea rosmarinifolia on January 14 from a plant growing on the Castle walls exposed to the weather. From Singleton we drove to Penllergaer, the residence of Sir JOHN T. LLEWELYN, Bt. In the beautiful and extensive gardens there Sir JOHN has an exceedingly rich collection of Rhododendrons, including most of the Himalayan species that are hardy in South Wales. The natural undulations at Penllergaer, the immense lake and other features, are remarkable, and the spot is an ideal one for the cultivation of Rhodendrons and Bamboos, which Sir JOHN has made his special favourites. The magnificent Bamboos are a revelation to those who have never seen the effect they are capable of producing in favourable localities, where care is given to the selection of positions in which the plants will have the benefit of shelter. Mr. WARMINGTON, the gardener at Penllergaer, has been at the place so long he has seen most of the rarer plants grow up, and evidently shares the enthusiasm his employer has for their cultivation.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS FOR SCHOOL TEACHERS, 1905.—The Royal Horticultural Society will hold an examination in Cottage and Allotment Gardening on Wednesday, April 5, 1905. This examination is intended for, and will be confined to, Elementary and Technical School Teachers. The general conduct of the examination will be on the same lines as that of the more general examination, except in obvious points to which they would not apply. Intending candidates are requested to send in their names early in March. A Silver-gilt Flora Medal will be awarded to the candidate gaining the highest number of marks, and each candidate will receive a Certificate of the class in which he has passed.

—— GENERAL EXAMINATION.—The Society's Annual Examination in the Principles and Practice of Horticulture will be held on Wednesday, April 12, 1905. A copy of the syllabus, covering both examinations, will be sent to any person on receipt of a stamped and directed envelope. Questions set at the Royal Horticultural Society's Examinations, 1893—1904, may also be obtained at the Society's Offices, Vincent Square, Westminster, price 1s. 6d.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual general meeting of this Society will be held at the Caledonian Hotel, Adelphi Terrace, Strand, W.C., on Monday, March 13, 1905, at 8 P.M. Mr. W. P. WRIGHT will preside.

Early Cabbages.—Messrs. Webb & Sons have forwarded to us the following letter from a correspondent:—"I cut and sold some Webb's Emperor Cabbage on February 18. The seed was sown in July, and planted-out in the open field in September. Is this a record? *F. Edgar, Polden Hill Dairy, Chilton Polden, Bridgwater.*"

The Dean of American Commercial Horticulture.—The *Country Gentleman* gives a portrait of George Ellwanger, founder of the house of Ellwanger & Barry, Rochester, N.Y., now carried on by the sons of the original partners. Mr. Ellwanger was born December 2, 1816, at Gross-Heppach, Wurtemburg, the son of a Grape-grower; studied horticulture for four years at Stuttgart; emigrated to Rochester in 1835, and four years later bought the nurseries of Reynolds & Bateham, gradually adding to them until now the Mount Hope establishment covers over 600 acres. The partnership with Mr. Barry was formed in 1840, and continued until that gentleman's lamented death just fifty years later. In 1846 Mr. Ellwanger married a daughter of General Micah Brooks, one of the pioneers of western New York. Four sons were born of this marriage, who received the advantages of education afforded in the best schools and colleges of this country, and of extended study and travel in Europe.

Colonial Exhibition at the Crystal Palace.—The Trinidad *Bulletin of Miscellaneous Information* for January mentions that an exhibition of Colonial and Indian produce will be held at the Crystal Palace this summer. The Legislature of Trinidad has voted the sum of £1,500 to be devoted to this purpose, and his Excellency Sir Henry Moore Jackson, K.C.M.G., has appointed a Committee to deal with the matter. Professor Carmody has been elected chairman and Mr. J. H. Hart secretary of the Committee. A space of 1,500 square feet has been applied for. Intending exhibitors should communicate with the Secretary at once.

Destruction of Moles.—Carbon bisulphide is an effectual means of destroying or driving away moles. With a sharp spade cut through the mole-hill, and expose the opening of the shaft of the little animal's mine; pour about an ounce of the bisulphide down the hole, immediately replace the earth, and stamp it down firm. This method has proved effectual in ridding gardens of the presence of moles, and should be effective also in pastures. Of course, care must be taken that no naked light be brought near the bisulphide, even a pipe alight might be sufficient to cause an explosion. I have also found bisulphide useful for destroying wasps in their nests. *J. O. Braithwaite, Chingford, January 20, 1905, in Pharmaceutical Journal.*

"The Journal of the Royal Horticultural Society."—Three parts in one, dated December, 1904, have just reached us. Naturally the triple part is very bulky, and the contents are so copious and so varied that neither the time nor the space at our disposal is adequate to do it justice. He would be a rapacious Fellow indeed who did not consider that he got the full value of his subscription in the *Journal* alone. We must confine ourselves to the statement that the present part contains many of the papers read before the Society, and even those discussed at the social gatherings of the Horticultural Club. When we say that in the latter category are included a paper by Sir J. Llewelyn on Rhododendrons, and one by Sir George Watt on Indian Primulas, we shall give our readers an indication of the value of the publication before us. Dr. Cooke's memoir on Plant Pests, with its illustrations, will, we hope, be issued separately. The analysis of current periodicals, which has been so useful a feature in recent issues, is on this occasion crowded out. The celebration of the Centenary, the opening of the Hall by the King and Queen, and the timely gift of the garden at Wisley, are duly recorded, so that this part will have a special historical value as a record. By some mischance the portrait of Robert Fortune at p. 222 is given instead of that of David Douglas; and as it would seem from the legend that the mistake was attributable to the *Gardeners' Chronicle*, we are obliged in self-defence to call attention to the error, and also in order that it may be duly corrected. The amount of work entailed on the Secretary in the preparation of this volume can only be rightly estimated by those who have personal experience of like character. The Society owes him a debt of gratitude that is beyond repayment.

Chambre Syndicale des Horticulteurs Belges.—In the present year the twenty-fifth anniversary of the foundation of the Chambre Syndicale des Horticulteurs Belges occurs. In connection with the occasion the Society has published a pamphlet descriptive of its vigorous life and good work, especially in the advocacy of the abolition of needless restrictions connected with the phylloxera scare, and in the promotion of free trade in horticulture. This is a pleasant souvenir of the Ghent horticulturists, and the portraits contained in it add to its interest.

The Fruit Industry.—The Departmental Committee appointed by Lord Onslow to enquire into and report upon the fruit industry of Great Britain held sittings on the 21st to the 24th inst. The following members were present:—Mr. A. S. T. Griffith-Boscawen, M.P. (Chairman); Col. Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Monro, Mr. Hodge, Mr. Vinson. Dr. Somerville, Mr. P. Spencer Pickering, M.A., F.R.S., the Rev. W. Wilks, M.A., and Mr. Ernest Garnsey (Secretary). The Committee had under their consideration the draft report prepared by the Chairman.

Fig. 57.—Rhododendron hybrid (R. falconeri × R. niveum) at Singleton, near Swansea.

Height 50 feet; diameter of branches 20 feet. Flowers tinted with lilac at first, but passing to white or nearly white. (See p. 136.)

"THE GARDEN CITY."—We have received a copy of *The Garden City*, the official organ of the Garden City Association. This company has been formed, as many readers know, "to develop an estate of about 3,800 acres, between Hitchin and Baldock," for industrial and residential purposes, with special reference to sanitary and æsthetic requirements. The magazine deals with matters connected with the Association, is edited by Mr. G. H. NORTHCROFT, and can be obtained from SIMPKIN, MARSHALL & Co., 23, Paternoster Row.

GEO. MONRO, LTD., CONCERT.—The ninth annual Bohemian concert was held at the Queen's Hall, Langham Place, W., on the 23rd ult. Mr. Geo. Monro presided, and was supported by Messrs. Assbee, Joseph Rochford, John Rochford, H. B. May, — Pollard, P. E. Kay, and others. The attendance numbered about 1,700 persons, and a very enjoyable evening was spent. The band of the Grenadier Guards, under the conductorship of Mr. A. Williams, Mus.Bac., was present, and the company was also entertained by Miss Carrie Tubb, Messrs. Chas. Saunders, Phil Ray, Walter Graham, Will Edwards, &c. On referring to a copy of the balance-sheet for last year, we find that the receipts were approximately £180, and donations were given to the following charitable institutions:—Gardeners' Royal Benevolent Institution, £6 6s; Wholesale Fruit and Potato Trades Benevolent Society, £6 6s.; the Surgical Aid Society, £2 2s; and Charing Cross Hospital, £2 2s. Grants of £1 1s. each were made to the Geo. Monro, Ltd., Pension Fund, and Geo. Monro, Ltd., Outing Fund. In view of the good work thus done, it is gratifying to hear from the Hon. Secretary, Mr. Baker, that it is expected the recent concert will prove to have been a greater success than any of its predecessors.

TREES AND SHRUBS.

ERICA VEITCHII ×.

ON February 14 last Messrs. R. Veitch & Son, of Exeter, exhibited under this name a shrub at the Royal Horticultural Hall in Vincent Square. It did not seem to me to be quite at its best, for only a few of the flowers were open. But knowing the plant as I have done for the past two or three years, I can testify to its great beauty. It has, I believe, been in the Exeter nursery for a good many years, and no doubt originated there. It was sent to Kew a few years ago to be named, and although it was seen to be closely allied to Erica lusitanica (codonodes) and to E. arborea, it could not be identified with either. As it is in several respects intermediate between those two species, the presumption is that it is a hybrid. Both these Heaths have long been cultivated in the Exeter nursery, and the hybridising was no doubt the work of bees or other insects.

Messrs. Veitch presented a plant to Kew, and this has grown and flowered well. Last spring it was in flower for quite three months, and when regarded as an ornamental shrub may be said to have eclipsed both its parents. The flowers are pale pink, and whilst they are intermediate in shape between the cylindrical ones of E. lusitanica, and the shorter rounded ones of E. arborea, they bear a closer similarity to the former. In habit, on the other hand, E. Veitchii follows the latter. It seems, in fact, to have combined to some extent the greater flower beauty of E. lusitanica with the better habit of E. arborea.

In regard to its hardiness it will, I expect, be at least as hardy as its parents. Neither of these has suffered at Kew since the great frost of ten years ago. But my experience is that 20° of frost or thereabouts, whilst not injurious for a single night or so, are fatal to these species if they are of longer continuance. *W. J. Bean.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

WILD GARDEN.—Gunnera manicata requires a damp but sunny and sheltered situation. It thrives in soil containing much decayed vegetable matter and should be afforded rich top-dressings. Spiræa gigautea furnishes a fine effect in July, with flower and stem from 4 to 10 feet high, and it revels in a moist place. Other vigorous and easily-grown plants are Aralia californica, Bocconia cordata, Cephalaria tartarica, Crambe cordifolia, Echinops in variety, Ferulas, Heracleum giganteum, Inula Helenium, Mulgedium giganteum, Polygonums, Rudbeckias, Rodgersia podophylla, Saxifraga peltata, Senecio clivorum. Telekia speciosa, Acanthus, &c. *W. A. Miller.*

APPLIANCE TO PREVENT DRIP.—Noticing the illustrations and remarks by Mr. Brewer on p. 86, I will give a short description of the method I employ here with the same object in view, as I think that in many ways it is an improvement on the side beadings illustrated as being fixed halfway up the principals or rafters. In our case the sash-bars as well as the principals have been treated, and the light false bottom, specimen of which I enclose (see fig. 58), answers admirably, as it catches and carries off all drip,

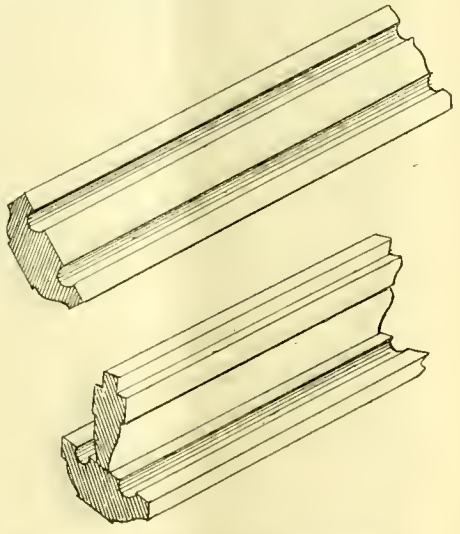

FIG. 58.—ANOTHER APPLIANCE TO PREVENT "DRIP" IN PLANT-HOUSES.

from condensation or otherwise, which may collect at any portion of the bar; and being light in construction and nicely beaded, it adds to rather than detracts from the appearance of a plain sash-bar. Shortly, the contrivance is that a false bottom, beaded on the underside and double-grooved on the top, is fixed to the bottom of the sash-bar, so that the drip on either side the bar has a groove of its own to conduct it to or near the bottom of each bar, where it can drop clear of plants and woodwork and do no harm to anything. Both sash-bars and false bottoms are afforded a coat of paint at the point of junction immediately before the latter are fixed, consequently a water-tight joint is made, and the drip-bars should last for many years in good, condition. *J. C. Tallack, Shipley Gardens, Derbyshire.*

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—In spite of the President's reply to Mr. Elwes' comments at the annual meeting on the issues of the Society's Journal, I think the bulk of the Fellows, unfortunately the quiescent ones, hold with Mr. Elwes that the Journal is unduly large and greatly overdone with matter. So much is this the case that not one Fellow in a thousand can peruse the parts right through, and that neglect to read them which is so common, whilst induced by the exceeding bulk of each issue, is greatly aided by the practice of issuing the books with uncut edges, so that the labour in cutting the leaves is too great for busy people to undertake. What wonder, then, if large numbers of the Journal are put on one side and never looked into. To issue books in that way, however interesting their contents, does not help the Society, nor does it advance horticulture. When the various issues of our fine gardening Press are to hand they are eagerly scanned and read. There is not a wearying excess of matter, it is largely of current procedure, and the paper edges are neatly cut [to the great detriment of the appearance]. No bibliophile asks that these papers be sent out uncut, but in the case of the Journal a few are permitted to dominate the Council, and thus, to the great annoyance of those who would like to read their Journals, the issues, instead of being guillotined, are sent out uncut. The cost of the Journal is also a heavy one. At the annual meeting it was said that only one issue of the Journal took place last year; yet the cost appears in the Expenditure Account as over £1,200, presumably for one issue. If three issues are to come into the accounts for the present year at the same ratio, the cost must be the large sum £3,600. Surely that is far too much to expend on such publications! Two issues yearly are ample, and if of one-half the bulk, so much of the matter being condensed such as busy people could manage to read, the gain all round would be great. *A Fellow.*

APPLE LADY HENNIKER.—Referring to the remarks by "E. M." (see p. 115) on this valuable Apple, I may say that here it was at its best by the middle of November, and by the third week in December it was quite unfit for dessert. The tree here is a standard, and is almost the only tree free from American blight. The soil is a shallow loam resting on mild clay, which is sometimes called soft sand. *F. G. Brewer, Grange Gardens, Brentwood, Essex.*

THE CUCUMBER "SPOT."—Mr. Ward's letter on p. 150 is interesting so far as the theories he advances may be the means of throwing some light on the causes which predispose the plants to an attack of the disease. It is by intelligent and watchful observation of the growth of this plant during the summer by expert and practical growers like Mr. Ward that it is possible to find out the cause of its visitation. Once the cause is found then we may hope with some confidence that a remedy will soon follow. Mr. Ward advances the proposition that the most favourable time for its attack is when the plants have been bearing for nine or ten weeks, and are consequently weakened by the heavy crops they have borne. This is a theory that I think would be endorsed by most practical growers; but unfortunately for theories, be they ever so sound and good, once they come into contact with facts, they often vanish into thin air. [Then they are not theories. ED.] Last summer, visiting a large grower who has been a great sufferer from the ravages of this pest, he assured me that once the fungus had obtained a lodgment in a garden, its subsequent attacks in the following years were considerably earlier each season, irrespective of any apparent condition under which they may be growing. In illustration of this point he showed me some young plants in pots with only three or four leaves on them, and growing in a house well isolated from any other Cucumbers that were suffering from this fatal "spot." After battling against its ravages for two or three years he has been compelled to give up Cucumber cultivation altogether. Mr. Ward further suggests a preventive in the shape of vaporising the Cucumber-houses with sulphur once a fortnight from the end of April until they have done bearing, when he truly says that every particle of leaf and stem growth will be finely and evenly covered with the sulphur deposit. Mr. Ward might have added that so would the flowers of the embryo Cucumber and also the Cucumber itself. This deposit would certainly not help the fertilisation of the flowers, neither would it enhance the selling value of the fruit, so that if the remedy suggested proved effective in preventing an attack the resulting injurious consequences to the crop would more than overbalance any good attained. I agree with Mr. Ward that the directions given by Mr. Geo. Massee for its prevention (which he quotes) appear on the face somewhat fanciful and impracticable, but so have many other scientific researches which have ultimately proved of great value.

One grower I know is carrying out the experiment, the result of which I shall follow with much interest. It seems to me that a subject of so serious import to commercial horticulture in England is well worthy of the serious thought and research of the proposed experimental station at Wisley. *Owen Thomas.*

ARUNDINARIA NOBILIS. — Some time ago you published an article by my friend, Dr. Otto Stapf, of Kew, in which he stated that the plant named by me Arundinaria nobilis is identical with Arundinaria Falconeri. I was abroad at the time, had no means of verifying Dr. Stapf's statements, and, under the attack of so great an authority, could only bow my head meekly and remain silent. I was at Kew last week, and Mr. Bean then showed me the plant from which Dr. Stapf drew his conclusions. It is a plant of Arundinaria Falconeri sent as a gift to Kew under a wrong name, and no more like what Sir Joseph Hooker once called in a letter to me, "your well-named Arundinaria nobilis," than an Elm is like an Oak. *Redesdale.*

CRANBERRIES FOR MARKET SUPPLY. — In reference to "Bramble's" inquiry under the above heading, at p. 126, I may say that I had a bushel or two of surplus Cranberries to dispose of some ten or twelve years ago, and I received a letter from a leading salesman in Covent Garden, with whom I had previous dealings, in reply to one asking if there were a demand for English-grown Cranberries, saying that there was "no sale for them." However, I see in this day's issue of the *Gardeners' Chronicle* that Cranberries are quoted in the wholesale market list (p. 127) at 13s. per box—for American fruit, I suppose. Not knowing the size of the box, one is unable to say whether the price is such as would justify a man in embarking in the cultivation of the Cranberry on a large scale in this country as "Bramble" has intimated his intention of doing, but I should say emphatically, "No." However, if "Bramble" should be the possessor of some acres of low-lying moist bog-land that would not produce anything else profitably, he might plant it with Cranberries this spring and await results. Certainly the initial cost of plants and planting would not be very heavy, and the plants grow and cover the ground quickly when placed in suitable land, the soil being made nice and firm about the individual plants. The gathering of the berries, say in October, is tedious work, but, as a rule, labour is cheap and plentiful in rural districts at that time of the year. The only cultivation required after planting is to keep the ground uniformly moist, pegging down the shoots as they extend their growths in order to keep them close on the surface and thereby induce them to root therein as well as to prevent them being blown about by the wind. No other plants in the shape of Sedge, Heather, &c., should be allowed to grow among the Cranberry plants; they should be pulled up with the hands, not hoed up on any account, as the use of the hoe would be injurious to the surface-rooting trailing shoots of the Cranberry If the plants are set out [in rows ?] about [3 ?] feet apart they will soon cover the intervening spaces. The plant may be propagated by cuttings, layers, and by dividing the roots. The fruit makes excellent tarts and preserves, for which purpose large quantities are bottled annually in the autumn in some private places in this country. Seeing that large quantities of the Cranberry are imported annually from North America there is, after all, a possibility of "Bramble" in the circumstances indicated turning his bog-land to profitable account. *H. W. Ward, Rayleigh.*

SEED-PACKING. — My experience of seed-packing is small in comparison with that of such authorities as Mr. Watson and Messrs. Carter & Co. At the same time I have received seeds from the tropics, collected on the Himalayas of India, the Andes of South America, and some of our West Indian islands, also from well within the Arctic Circle. In each case they were contained in paper packets, afterwards sewn up in calico bags, and they arrived here at various seasons through the post and carried by the steamship companies. In the majority of cases the seeds have germinated successfully. Several varieties of Primula from the Himalayas came up remarkably well. Seeds of Bignonia and allied species lose their vitality more quickly than many on account of the small amount of substance contained in the seeds. Seeds ripened in the tropics have less moisture in them than our own, hence the desirability of thorough maturation and elimination of moisture from seeds sent to those parts from here. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

AN IMPROVED MUSHROOM BENCH. — When calling on Mr. Bannister recently, at Westbury-on-Trym, he showed me his method of supporting his Mushroom beds. Instead of the usual slate or wooden benches in the house, those beds above the floor of the house rested on a wire frame, with a mesh of about 2 inches. With a layer of turf over the wire-work before placing in the manure, he is able, when the beds are in bearing, to pull Mushrooms from the underside as well as from the top of the bed, also from the side near the path in the house. Most gardeners know how Mushrooms will heave themselves through any small space when the spawn "runs," and this arrangement of a wire base facilitates the working through of the Mushrooms, and doubtless increases the yield. *T. H. Slade.*

MANURE FOR PEACH TREES.—Mr. W. H. Clarke stated on p. 119 that trees growing in light or gravelly soils "should be examined, and if the roots are in the least degree dry afford them a soaking with manure water from the farmyard." But if farmyard drainings be applied to roots that are at all dry they are apt to harm the fibres and to excite the growth of the tree too much in spring. Such manure-water is too rich in nitrogen for Peach and Nectarine trees when in a dormant state, and should only be applied after the stoning is completed, and then only if the tree is carrying a full crop of fruit. The trees should then be given a good soaking with clear water, afterwards applying the manure-water. At the same period they may also be given a little chemical fertiliser at alternate waterings. But when the fruits have been gathered no more manure should be given. *A Reader.*

CAMELLIA RETICULATA.—I enclose a flower of this species, which is distinct in appearance of growth and in size to any Camellia grown. The semi-double flowers often attain to 9 inches in diameter; the colour is bright rose, and the numerous stamens add much to their attractive appearance. It flowers very freely when planted in equal parts of loam, peat, and leaf-soil, with a moderate quantity of sand; a little soot is beneficial to the plant. *W. Thorpe, Gardener to J. M. Collett, Esq., Hillfield, Gloucester.*

EARLY PEACHES (see also pp. 55, 91, 106, 129). —Why do early Peach-trees drop their buds? Some gardeners say that it is the result of over-ripening of the wood, and advise shading the trees in the summer after the fruit has been gathered, but sometimes there is the same trouble in the late houses, where it is almost impossible to get the wood ripe enough. My experience leads me to think that bud dropping is caused by insufficient root action. Slow, insufficient root action is brought about in several ways: first, by under-watering; second, by leaving the borders too long without renewing the soil, either or both of which reasons will prevent the trees from making sufficient fibrous roots yearly. Thirdly, by over-watering, which causes the border to become an inert mass of soil, with a temperature that is too low to stimulate the roots into growth. *John Bates, Hanley, Staffs.*

—— I did not mention planted-out trees, for they behave differently to pot trees. We have planted-out trees as well as pot trees, in all some nineteen varieties, but the only ones that fail in pots or otherwise are Alexander, Amsden June, and Hale's Early. With regard to the question of affording plenty of water to the roots of Peach trees during the autumn and winter months, I think every gardener will admit this is necessary. If Mr. Barks will visit these gardens during those months I think he will agree that our trees are supplied with sufficient water. I have in my possession a copy of a paper read before the Royal Horticultural Society on "Pot Fruit Culture," by the best authority on the subject, and if any of my friends would like to see it I shall be happy to let them have it, and they will see that these particular varieties are condemned for early forcing in pots. *Thos. Tomlinson, Tower House Gardens, Streatham, S.W.*

—— The commonest cause of bud dropping is probably dryness at the roots, and the consequent check at some time or other of nutriment to the buds. A badly drained or imperfectly made border containing subsoil of a cold retentive nature is also sufficient to cause the evil, which may be aggravated by over-watering. Another frequent cause is the manner many fruit-houses are, under compulsion, stocked with Chrysanthemums in the autumn and winter months. Not only are these plants watered with liquid containing strong chemical manures greatly injurious to the trees, but the ventilators are partially closed in hard weather, and fire-heat is employed for the purpose of developing the Chrysanthemum-blooms. In early-forced houses this is a most pernicious habit, for this reason, when the plants are cleared the house is immediately thrown open to all winds and weather, with the idea of giving the Peach-trees a rest. During the time the Chrysanthemums were there the trees or roots became active, and the check occasioned by the lower temperature afterwards, in some cases below freezing-point, retards the development of the buds, which had commenced earlier, and when the house is closed again to start the trees, bud dropping commences. Another cause is the sudden change from the resting to the starting of the house: this should be very gradual, especially when the level of the borders is much below that of the surrounding ground. The tops of the trees must not be excited in advance of the roots. Early Peach borders should be raised somewhat above the ground level. In our anxiety to secure ripened growths the extreme of over-ripeness is another cause of bud dropping, and the same evil is sometimes brought about by red spider. A bad attack by these insects causes the trees to lose their foliage prematurely in the autumn, and the wood becomes exposed to the sun's rays, which so hardens it and so dries the buds that both growth and fruit-buds will fail. Grossness in growth will cause this evil, and insecticides used in excess about the fruit-buds is sufficient to cause them to fall. Some varieties are certainly more prone to bud-dropping than others, but if the trees are in good condition and proper culture is afforded, no difficulty should be experienced in securing a crop. Hale's Early, one of the best early varieties, has perhaps not so vigorous a constitution as some other kinds, and does not succeed well in all districts, but well-ripened fruits are excellent. This season I have increased my stock of this variety. In a house 300 feet long here Alexander and Waterloo have produced excellent fruit, and upon the outside walls I have no complaint against them as bud-droppers. Waterloo is the better of the two, and should be grown in preference to Alexander. Early Louise, Early Beatrice and Early Rivers are growing here on outside walls, the fruits, although naturally small, often weigh 8 to 10 ounces. Fruits of Hale's Early have weighed 14 ounces. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

—— I am surprised that no one has mentioned the frequency of stone-splitting in the variety Alexander. I have seen it in several gardens, and in all cases this has been its chief failure, quite one-third of the fruits ripening prematurely owing to this cause. It is however valuable as an early ripening Peach, owing to its not stopping to "stone," and ripening much early in consequence. *F. G. Brewer, Grange Gardens, Brentwood, Essex.*

—— There are three Peach-houses here, and not a bud has fallen this season. The trees in the first house when in flower were so beautiful that my employer wished to have the trees photographed. All varieties of Peaches and Nectarines, whether early, mid-season, or late-ripening sorts, are liable to drop their buds. The trees should never be allowed to get dry at their roots, whether resting or not. Never allow too dry an

atmosphere at any time, but damp the walks, borders, and stages, if there are any, even when the trees are resting. The third, and I believe the worst evil to be guarded against is that of employing too much fire-heat during frosty weather when the trees are resting. Why is heat employed at all when frost is most beneficial to the trees? Sometimes Peach-houses are required for housing plants, but these should be nearly hardy, and only sufficient fire-heat be used to keep out severe frost. The varieties we grow here are Peaches Early Rivers, Dymond, Noblesse, Princess of Wales, Prince of Wales, Barrington, Dr. Hogg, Stirling Castle, Golden Eagle, and Royal George; Nectarines Elruge, Lord Napier, Stanwick Elruge, Newton, Victoria, and Humboldt. *Wm. Fulford, Castle Eden Gardens, Co. Durham.*

SOCIETIES.

THE ROYAL HORTICULTURAI.

FEBRUARY 28.—The display in the Royal Horticultural Hall, Vincent Square, on Tuesday last, was not quite so large or imposing as that made at the previous meeting. Orchids were less numerous on the occasion under notice, but a magnificent exhibit of forced shrubs was made by Messrs. R. & G. CUTHBERT, Southgate, and with other groups of similar plants, also of Cinerarias, Begonias, alpine plants, &c., the space in the Hall was moderately well furnished.

The ORCHID COMMITTEE recommended one First-class Certificate and two Awards of Merit to novelties.

The FLORAL COMMITTEE recommended a Botanical Certificate to Rosa gigantea, and two Awards of Merit to varieties of Lachenalia raised by Mr. F. W. MOORE, Glasnevin Botanical Gardens. The most interesting subject before this Committee was the specimen of Rosa gigantea (see p. 136), which Mr. LEACH has succeeded in flowering a third time at Albury Park Gardens. A Gold Medal was awarded to Messrs. R. & G. CUTHBERT for their group already mentioned, and which owed very much of its effect to the smaller group of Magnolia Lenne in the centre of the display. We are unable to remember an instance when this magnificent Magnolia has been shown in such fine condition, or when the rich purple colour of the flowers was more pronounced.

The only exhibit of importance before the FRUIT AND VEGETABLE COMMITTEE was a collection of Apples from Mr. JNO. WATKINS, Pomona Farm, near Hereford.

In the afternoon a lecture was delivered on "Fruit Growing in British Columbia," by the Agent-General for that Colony.

Floral Committee.

Present: W. Marshall, Esq., Chairman, and Messrs. C. T. Druery, H. B. May, J. Hudson, Jno. Green, R. Hooper Pearson, Jno. Jennings, J. F. McLeod, C. R. Fielder, Ch. Dixon, Chas. Jeffries, Geo. Gordon, C. E. Pearson, R. C. Notcutt, E. H. Jenkins, M. J. James, Geo. Paul, W. Howe, R. W Wallace, J. A. Nix, G. Reuthe, H. J. Cuthbert, and E. T. Cook.

Miss EDITH COLE, West Woodhay House, Newbury, Berks, exhibited a pretty species of Aloe under the name A. somaliensis. The plant was in flower in a 6-inch pot, the inflorescence being nearly 2 feet high, and the flowers of brownish-red colour becoming white towards the open end of the tube. The leaves were light green mottled with darker spots, and with purplish spines on the margins.

Lachenalias were shown by Mr. J. T. BENNETT POË, Holmwood, Cheshunt, and Mr. F. W. MOORE, Botanic Gardens, Glasnevin, Dublin. Mr. BENNETT-POË contributed splendidly grown plants in pots, and Mr. MOORE sent cut specimens only. All the varieties were seedling sorts raised by Mr. MOORE, and Mr. BENNETT-POË'S gardener has found that these seedling varieties grow with more vigour than the older sorts, as L. Nelsoni.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, staged an extensive group of greenhouse plants, including well-flowered pot plants of Clematis, Cinerarias, Primula obconica, P. kewensis, Boronias, Eranthemum pulchellum, &c., the whole being interspersed with choice specimen Ferns (Silver Banksian Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, presented a batch of greenhouse plants and forced flowering shrubs. Clematis were a feature, the handsome deep claret-coloured variety named Ville de Lyon being especially prominent. Occupying the centre of the group was a new hybrid perpetual Rose named Cherry Ripe, a name indicative of its colour.

Messrs. H. CANNELL & SONS, Swanley, Kent, set up a semi-circular group of Eupatorium petiolare, the plants being well furnished with heads of fragrant white flowers. Messrs. CANNELL also staged a few Cinerarias, trays containing flowers of their strain of hybrid mammoth Primulas, and cut flowering growths of Pelargonium "Clorinda," which attracted considerable attention. This plant belongs to the sweet-scented-leaved section, and freely produces large trusses of flowers of rich rosy-pink colour. It was raised by Dr. Bonavia (Bronze Flora Medal).

A batch of Roses displayed by Mr. GEO. MOUNT, Canterbury, was much admired. Considering the earliness of the season, the quality of the flowers was good. The varieties exhibited were Mrs. R. C. Sharman Crawford, Mrs. W. J. Grant, and Mrs. John Laing (Silver Banksian Medal).

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, contributed a miscellaneous collection of plants, including Corylopsis spicata, with its drooping racemes of sulphur-yellow-coloured flowers; the handsome Rhododendron Veitchianum, the showy Camellia reticulata, and well-flowered plants of Atragene (Clematis) austriaca. Messrs. VEITCH again showed Cheiranthus kewensis and Primula kewensis (Silver Banksian Medal).

G. HASLETT, Esq., Woodside House, Wimbledon (gr., Mr. A. Scarlett), staged half-a-dozen plants of Hippeastrums in flower.

An exhibit attracting considerable attention was shown by F. D. GODMAN, Esq., South Lodge, Horsham. This consisted of twenty inflorescences of Rhododendron grande, each inflorescence being accompanied with the large, handsome, farinaceous, obovate leaves. The individual flowers are distinctly campanulate in shape, and of creamy-white colour with a dark base to the cup (Silver Banksian Medal).

Mesars. JOHN LAING & SONS, Forest Hill, London, set up a semi-circular group of pot plants of Begonia semperflorens gigantea carminata. The plants are of tall-growing habit, terminating in the deep scarlet inflorescences that are brought well into prominence against the dark-green foliage (Bronze Banksian Medal).

Messrs. SUTTON & SONS, Reading, filled one of the centre tables with Cinerarias. The plants were of dwarf habit, and carried dense, compact heads of flowers in several pleasing shades of colour. The type is more sturdy than the ordinary florist's strain, and shows indication of the stellata blood. A few plants with reddish flowers were uncommon (Silver-gilt Flora Medal). Messrs. SUTTON also exhibited flowers of a pale yellow-coloured Freesia obtained from crossing a white with a rose-coloured variety. In the new variety the yellow colour was suffused over the whole flower.

Messrs. J. CARTER & Co, 237 and 238, High Holborn, staged a small batch of a dwarf-growing, white-flowered Primula named Carter's Bouquet. The form and size of flower are good.

Mr. RICHARD ANKER, Addison Nursery, Napier Road, Kensington, brought specimens of "Tufa," a substance of volcanic origin, which is eminently suited for constructing rockeries, cascades, wall gardens, &c. A number of pictures illustrating such objects formed with this material was also displayed.

FORCED FLOWERING SHRUBS.

Quite the handsomest group of plants in the Hall was that shown by Messrs. R. & G. CUTHBERT, Southgate Nurseries, Southgate, Middlesex. This exhibit occupied an extensive area on the west side of the building, and consisted of forced shrubs set up in first-class style. Plenty of colour was furnished by such plants as Azaleas, Laburnums, Wistarias, Forsythia suspensa, Staphylea colchica, Magnolias, Ribes, Prunus and Pyrus species, and similar plants that are adaptable for early forcing. Standard-grown plants were worked into the group with good effect, and in the centre was a magnificent batch of Magnolia Lenne, the handsome and richly-coloured flowers of which were remarkably fine. Suitable greenery was furnished by plants of Japanese Maples, small Palms, and various species of Ferns, an edging of the last-named plants forming a suitable finish to the whole (Gold Medal).

Adjoining Messrs. CUTHBERT'S display was a group of similar plants, with the exception of Azaleas, staged by Messrs. CUTBUSH & SON, Highgate, London, N. The group did not present such a display of colour, by reason of the absence of Azaleas, as the foregoing collection, but was meritorious for the variety and interest of its constituents. Wistarias, Lilacs, Magnolias, Staphylea colchica, Spiræa confusa, Pyrus Malus Scheideckeri, &c., with a well-grown batch of Xanthoceras sorbifolia that occupied the centre of the group, furnished the principal features (Silver-gilt Banksian Medal).

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, filled one of the corner sites with a group of forced flowering shrubs, Azaleas, Lilacs, Staphylea colchica, Prunus species, Forsythia suspensa, Laburnum, &c. (Bronze Banksian Medal).

ALPINE PLANTS.

Messrs. THOS. WARE, Ltd., Feltham, Middlesex, presented a group of these plants. The curious-looking Scoliopus Bigelowi, with its Orchid-like foliage, was noticed; also Canarina campanula, Iris fimbriata, Dendromecon rigidum, Corydalis thalictrifolia, and numerous species of Primulas, Saxifragas, Hellebores, Irises, Crocuses, &c. (Silver Flora Medal).

Messrs. CUTBUSH & SON, Highgate, London, N., set up an extensive exhibit of alpine and hardy plants. Among the plants in flower we noted Stylophorum diphyllum, Azalea obtusa, Anemone Pulsatilla alba, Colchicum libanoticum, together with numerous species of Irises, Saxifragas, Hepaticas, Muscari, &c. Messrs. CUTBUSH also exhibited Iris Aschersoni, a new species, with inconspicuous flowers of pale yellow colour prettily veined with purple.

Misses HOPKINS, Mere, Knutsford, exhibited a small collection of alpine plants.

Mr. G. REUTHE, Keston, Kent, staged a collection of alpine plants, including Hepaticas, Crocuses, Saxifragas, Cyclamen Coum, Leucojum, &c. At the back-ground were several species of Rhododendron (Bronze Flora Medal).

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, displayed a number of pots and pans containing alpine plants, Crocuses, Irises, Saxifragas, and Snowdrops. A good type of Primula megaseæfolia named P. m. superba was noticed (Bronze Banksian Medal).

Messrs. GEO. JACKMAN & SON, Woking Nurseries, Surrey, staged a number of alpines, prominent among which was a batch of Shortia galacifolia. Alpine Cyclamen were a feature, and we noticed a white form of the common Celandine, named Ranunculus Ficaria alba.

Messrs. BARR & SONS, King Street, Covent Garden, London, contributed hardy and alpine plants, staging many choice varieties of these interesting subjects (Bronze Flora Medal).

Miss WILLMOTT, Warley Place, Great Warley, showed a batch of Narcissus Bulbocodium var. monophylla. The plants represented forms of this pleasing bulbous flower collected in various localities, and among them much diversity of form was shown. Some of the varieties were greatly superior to others (Bronze Banksian Medal).

AWARDS.

Lachenalia, Brilliant.—The flowers of this variety are of very large size and of rich golden-yellow colour, with the tips of the segments tinted with red. The flower-stems appear to be not more than 6 inches high (Award of Merit).

Lachenalia, Jean Rogers.—This is a very handsome variety of distinct habit, the flower-stems being 13 or 14 inches high. The flowers are less yellow than some other varieties, but before they have become quite open the brilliant red colour of the calyx has a very good effect. Both Lachenalias were shown by Mr. J. T. BENNETT-POË, Holmwood, Cheshunt; and Mr. F. W. MOORE, Botanic Gardens, Glasnevin, Dublin (Award of Merit).

Rosa gigantea (see p. 136 and Supplementary Illustration).—Flowers of this beautiful species were shown by Mr. W. C. Leach, gr. to the Duke of NORTHUMBERLAND, Albury Park, Guildford (Botanical Certificate and Cultural Commendation).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, H. Little, Francis Wellesley, J. Douglas, R. G. Thwaites, W. Cobb, J. Colman, T. W. Bond, G. F. Moore, H. J. Chapman, N. C. Cookson, H. A. Tracy,

W. H. White, H. G. Morris, A. A. McBean, W. H. Young, W. Boxall, J. W. Odell, R. B. White, J. W. Potter, W. A. Bilney, H. J. Veitch, H. T. Pitt, and H. Ballantine.

There was but a small show of Orchids compared with those at recent meetings. The largest group was staged by Mr. J. Cypher, Cheltenham, his speciality of fine Dendrobiums being the chief feature. Among those noted were the delicately-tinted Dendrobium nobile Cypheri, D. n. Amesiæ, D. n. Ballianum, D. n. album, and D. n. Purity. The dark-coloured varieties were D. n. nobilius, D. n. Sanderianum (a model flower of a bright magenta-rose tint), and D. n. Statterianum. In the centre was a finely-flowered specimen of the elegant D. barbatulum, and among the hybrids D. × Ainsworthii intertextum, D. × Cybele nobilius, D. × splendidissimum marginatum, D. × Curtisii, &c. The Cypripediums included C. × Sallieri Hyeanum, C. × S. aureum, and a very distinct C. × M. de Curte (Silver Banksian Medal).

Messrs. Jas. Veitch & Sons staged a group of hybrids, in which were the finely-coloured Cypripedium × Harri-Leeanum, Lælio-Cattleya × Myra, L.-C. × Violetta var. carnea, L.-C. × Antimachus, Lælia × splendens, Phaio-Calanthe × Sedeni alba, and others. The species included a fine specimen of Cypripedium villosum giganteum, Phalænopsis Stuartisana, Lælia flava, and Dendrobium atro-violaceum (Silver Banksian Medal).

Mr. H. J. Chapman, gr. to Norman C. Cookson, Esq., Oakwood, Wylam, was awarded a Silver Flora Medal and Vote of Thanks for a very interesting exhibit of about three dozen beautifully-executed and coloured photographs of some of the leading spotted forms of Odontoglossum crispum, hybrid Cypripediums, Cattleyas, &c. The representations in most cases were of life-size and life-like.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), showed Dendrobium heterocarpum album, with slender stems of cream-white flowers with yellow and purple disc to the lip; and the pretty D. Wiganiæ nobilius.

N. C. Cookson, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), showed the beautiful Phaius × Clive, which had previously secured an Award of Merit; and Dendrobium × orphanum, with yellow flowers having a claret-purple disc to the lip.

Francis Wellesley, Esq., Westfield, Woking (gr., Mr. Hopkins), sent Cypripedium × Colossus Westfield variety, much like an improved C. villosum giganteum; and C. × Allertonense (bellatulum × villosum aureum), with pretty, cream-coloured flowers tinged and densely spotted with purple.

Messrs. Sander & Sons, St. Albans, showed a small group, in which were a handsome new form of Cypripedium insigne of the Harefield Hall class, but with large purple blotches on the fine white upper part of the dorsal sepal. Also the new, white, rose-tinted Cypripedium × Prince Humbert (Mastersianum × niveum), a very richly-coloured Odontoglossum triumphans latisepalum, a good spotted Odontoglossum crispum, and a hybrid of O. Pescatorei with cream-coloured flowers blotched with purple.

J. S. Moss, Esq., Wintersbill Hall, Bishops Waltham (gr., Mr. Kench), sent a very handsome Odontoglossum Pescatorei with purple-spotted flowers.

Messrs. McBean & Sons, Cooksbridge, showed Cypripedium × Grace Ruby (Dayanum × Godefroyæ leucochilum), with a large cream-coloured flower spotted with purple.

Sir Robert Montcreiffe, Bart., Bridge of Earn, N.B. (gr., Mr. Common), sent a good white Odontoglossum crispum. R. G. Thwaites, Esq., Chessington, Streatham (gr., Mr. Black), showed Dendrobium × Chessingtonense (aureum × Wiganiæ) with flowers yellow with a purplish disc to the lip. Also D. × Cybele Ballianum. W. D. Stapleford, Esq., Holly Dene, Coalville (gr., Mr. Mount), sent flowers of two hybrid Cypripediums.

The Right Honble. Lord Rothschild, Tring Park (gr., Mr. Arthur Dye), sent Lælio-Cattleya × luminosa superba and Brasso-Cattleya × Digbyano-Mossiæ. C. J. Lucas, Esq., Warnham Court (gr., Mr. Duncas), sent a good specimen of Cyrtopodium punctatum with three spikes of flowers.

Mr. H. Parr, Trent Park Gardens, Barnet, showed Dendrobium Wardianum album Trent Park variety.

W. Macdonald, Esq., Pitlochry, N.B. (gr., Mr. Gilchrist), sent a small form of Cypripedium × Actæus.

Captain G. L. Holford, Westonbirt (gr., Mr. Alexander), showed Cattleya Trianæ Westonbirt variety, a very large form with broadly-ovate petals. Sepals and petals light rose, disc of the lip chrome-yellow, front purplish-crimson.

Baron Sir H. Schröder, The Dell, Egham (gr., Mr. H. Ballantine), again showed the beautifully spotted Odontoglossum crispum Veitchianum with a fine spike of thirteen flowers, and the original plant of O. × Wattianum Hardy's variety, with a very strong spike. In both cases the plants were superbly grown.

Mr. Geo. Paul, The Old Nurseries, Cheshunt, showed several fine forms of Cœlogyne cristata from imported plants. One had two strong spikes to a bulb, and another was pure white with a faint yellow mark on the lip.

Awards.

Lycaste Skinneri alba var. magnifica, from Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), and Messrs. Hugh Low & Co.—A superb variety, with very large flowers, broad in all parts, the sepals being broadly ovate, pure white with yellow crest to the lip. One of the finest formed Lycastes (First-class Certificate).

Lælia × *Iona nigrescens* (tenebrosa × Dayana), from Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins).—A very beautiful and brightly-coloured form, the handsome, velvety, claret-crimson labellum streaked with maroon being the darkest in colour of any in its section. Sepals light-rose veined with rose-purple; petals purplish-rose, with a darker veining (Award of Merit).

Odontoglossum × *loochristyense Tracyanum* (crispum × triumphans).—A noble natural hybrid with large and finely-formed flowers, the white bases of the segments showing O. crispum, and the yellow outer parts and the labellum in its large chestnut-red blotching indicating O. triumphans. The sepals and petals were finely marked with distinct red-brown blotches. A very handsomely-spotted variety, and the best of the imported O. × loochristyense (Award of Merit).

Cultural Commendation.

To Mr. H. Alexander, Orchid Grower to Captain G. L. Holford, C.I.E., Westonbirt, for a grand specimen of Ada aurantiaca with forty spikes of bright orange-scarlet flowers, from ten to eighteen on a spike.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq., in the Chair; and Messrs. W. Bates, Jas. Gibson, T. Mortimer, A. Dean, Geo. Kelf, H. J. Wright, H. Parr, F. Q. Lane, Ed. Beckett, Chas. Foster, Geo. Reynolds, J. Jaques, O. Thomas, and W. Poupart.

Mr. John Watkins, Pomona Farm Nurseries, Withington, Hereford, displayed thirty-five dishes of Apples. The fruit was remarkable for the high colouring obtaining throughout. A variety labelled de Danzig à Côtes was of very pronounced colour. Other varieties deserving of mention are Wareham Russett, Bess Pool (excellent examples), Hoary Morning, Beauty of Kent, and Gascoyne's Scarlet Seedling (Silver Knightian Medal).

The Lecture.

FRUIT-GROWING IN BRITISH COLUMBIA.

A General Meeting of Fellows was held during the afternoon, at which Sir Albert Rollit, M.P., presided. A number of new Fellows were elected. The Hon. J. H. Turner, Agent-General for British Columbia, gave an interesting paper on fruit-growing in that province. He pointed out that it behoved those interested in fruit-growing in the Mother Country to know more of the conditions affecting that industry in other parts of the Empire. This Colony, he said, was still in its infancy as regards fruit-growing; for it was only a decade ago that the possibilities of the land for agriculture were recognised. Formerly the soil had only been valued on account of its mines and timber. The Colonial Government had lent their assistance in every way. Insect pests were stamped out under competent inspectors backed by legislative enactments, and the introduction of such pests as codlin-moth and woolly-aphis was prevented by a careful examination of all fruit trees and fruit imported into the Colony. Furthermore, the dumping system of the United States, which had flooded the British Columbian markets with surplus crops at any price, so as to keep up the prices at home, was counteracted by an import tax, with such beneficial results that the colonial growers in a very few years were able to grow sufficient fruit not only for all the Colony's own requirements, but also to export some thousands of tons to Manitoba and the North-west Territories. British Columbia was specially adapted for growing Grapes, Melons, Cherries, Plums, Tomatos, Strawberries, and Peaches, in addition to the Apples and Pears which are at present their principal fruit crops. The varieties of Apples principally cultivated are Wealthy, King of Tompkins County, Northern Spy, Cox's Orange Pippin, Baldwin, and Newtown Pippin.

The Government system of "hall-marking" in different grades the cases of fruit exported was also described, under which dealers were satisfied to purchase without opening the cases. Mr. Turner illustrated his remarks by a series of lantern-slides which included pictures of orchards, views of the varying districts at present under fruit-cultivation, typical orchards and homesteads, the methods of packing, and typical trees loaded with luscious fruit.

In moving the usual vote of thanks to the lecturer, Sir Albert Rollit mentioned that he had himself visited many of the places pictured and described, and he recommended the Fellows to do likewise when in search of beautiful spots favourable to fruit and flowers. He stated that an American had once boasted to him of the vast expanse of the Union, bounded on the north by the aurora borealis, and on the other three sides by the ocean, to whom he had replied that the British Empire had no boundaries, but was world-wide.

PROFESSIONAL GARDENERS' FRIENDLY BENEFIT.

The thirty-eighth Annual Report of the above Society is a record of continued success. The amount of sickness has again been very slight, sixteen members only having drawn from the sick funds during the year, being exactly the same number as in the previous year. The total amount paid out of the Benefit Fund was £61 5*s.* 10*d.*, an average per member of 9*s.* 3*d.* The total income for the year amounted to £166 15*s.* 10*d.*, and the total expenditure to £75 11*s.* 8*d.*, leaving a profit on the year's accounts of £91 4*s.* 2*d.*, and making the total funds of the Society £1,290 9*s.* 3*d.* The annual dinner was held at the Green Dragon Hotel, Leeds, on Wednesday, February 8, between forty and fifty being present. The President, Mr. G. Stubbs, occupied the chair, and he was supported by Mr. Haw, the Vice-President, and several honorary members. The Secretary of the Society is Mr. George Carver, 75, Northbrook Street, Chapel-Allerton, Leeds.

BRITISH GARDENERS' ASSOCIATION.

A meeting of the gardeners of Birmingham and the surrounding district was held in Birmingham on the 13th inst. to consider a proposal to form a local branch of the British Gardeners' Association. About 150 gardeners attended, and they were addressed by Mr. W. Watson, the Secretary of the Association, and by Mr. W. P. Wright, a member of the Committee. On the motion of Mr. J. Udale, Horticultural Instructor for Worcestershire, seconded by Mr. W. H. Morter, head gardener of the Birmingham Public Parks, it was unanimously resolved to at once form a branch, and Mr. W. H. Deadman, of Edgbaston, was elected Secretary *pro tem.* A somewhat lengthy report of the proceedings will be found in the *Birmingham Daily Post* of February 14.

Purley.—A meeting of the Kenley and Coulsdon Horticultural Society, held at the Commemoration Hall, Purley, upon February 15, was addressed by Mr. J. Stocks, as a delegate from the Committee of Selection of the Association, his account of the objects and programme of the Association being very well received.

Altrincham.—At a special meeting of gardeners held at Altrincham on the 16th inst. the formation of a local branch of the Association was agreed upon. A committee was elected to carry on the work of local organisation, with Mr. W. H. Jenkins, Wythenshawe Hall Gardens, Northenden, as Secretary.

At Croydon, under the auspices of the Croydon and District Horticultural Mutual Improvement Society, upon the 21st ult. The proposal, adjourned from a previous meeting, to form a local branch of the British Gardeners' Association, was again brought forward, with the result that it was resolved that a branch should be formed. Mr. W. Rowson, Falkland Park Gardens, South Norwood Hill, was appointed Local Secretary, and all local gardeners interested in the Association are requested to communicate with him.

At Plymouth upon the 25th ult., under the auspices of the West of England Chrysanthemum Society, over a hundred local gardeners being present. The meeting was addressed by Mr. C. H. Curtis as a delegate from the Association. A discussion followed, after which A. J. G. Chalice, Nurseryman, Plympton, moved, and Mr. W. Selley, Delamore Gardens, Cornwood,

seconded, "That a branch of the British Gardeners' Association be formed in Plymouth, to be known as the Plymouth and District Branch of the British Gardeners' Association; and this was carried unanimously. Mr. W. S. E. Cholwill, H. G. Lukesland, Ivybridge, was appointed Local Secretary, and all those wishing to join the Association were requested to communicate with him. Over fifty members of the audience responded to the request there and then.

A meeting of the Committee of the Yorkshire Branch of the Association was held at Leeds upon the 25th ult. Among other business it was resolved that the Committee meet monthly, special meetings to be convened by circular, and that a small Sub-Committee be appointed to consider applications for membership. A circular letter drawn up by the Secretary was adopted with slight alterations, and 1,000 copies were ordered to be printed and circulated, together with the Plea, Prospectus, and Form of Application, among gardeners throughout the county.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

February 16.—There was a good display of plants at the meeting held on the above date.

Messrs. J. Cypher & Sons, Cheltenham, staged a good group of plants, consisting principally of Dendrobiums, among which was included a very choice form of D. nobile, called D. n. var. Purity, and that gained an Award of Merit. A Silver Medal was awarded to the group.

A. Warburton, Esq., Haslingden, staged a fine group of Odontoglossums, among which were meritorious varieties of O. crispum (Silver Medal).

S. Gratrix, Esq., Whalley Range (gr., Mr. Cypher), exhibited Cypripedium × aureum var. Œdippe, for which a First-class Certificate was awarded.

M. Vuylsteke, Ghent, was given a vote of thanks for a pleasing display of Odontoglossums, consisting principally of hybrids.

E. Rogerson, Esq., Didsbury (gr., Mr. Blomiley), exhibited Odontoglossum crispum var. Mariæ, which has already been awarded the First-class Certificate of the Society. The same exhibitor showed O. c. var. Edward Roerhers, which the Committee desired to see again.

J. E. Williamson, Esq., Stretford (gr., Mr. Jones), staged a good group of Dendrobiums, including some meritorious hybrids (Bronze Medal).

Mrs. Ardern, Stockport (gr., Mr. Morris), exhibited a very distinct form of Odontoglossum × ardentissimum named "Lawrence." The principal feature of this variety is its pale colour. The flower is well shaped, and is heavily blotched on the petals, but the colouring is faint, while the lip is purely that of O. Pescatorei, a variety which it very closely resembles (First-class Certificate).

Messrs. A. J. Keeling & Sons, Bradford, staged a group of Dendrobiums, some of the best varieties being D. × melanodiscus var. Aurora, D. × Luna, D. × Iris, D. × var. floribunda (Vote of Thanks).

John Cowan & Co., Ltd., Gateacre, presented a good group, consisting principally of Cattleyas and Lycastes (Vote of Thanks).

Mr. P. Weathers, Old Trafford, exhibited a form of Cattleya Trianæ called "excellens," which was voted an Award of Merit. *P. W.*

SHROPSHIRE HORTICULTURAL.

February 22.—The annual meeting of the above Society was held at Shrewsbury on the above date, the Mayor (Mr. H. J. Hearn) presiding. The annual report was read, from which we extract the following:—

"The success of the opening day at the exhibition held in August last was marred by a continuous downpour of rain, which resulted in a serious falling-off in the receipts as compared with previous first-day receipts. The weather on the second day proving propitious, the receipts at the gates (£2,025 19s. 3d.) created a record. The number of subscribers for the past year exceeded that of any previous year. The balance-sheet showed that the takings for the summer show were £4,542 10s., and the expenditure £4,023 14s. 9d., giving a profit of £518 15s. 3d. The total show takings were £4,554 12s., and the expenditure (less donations £75 5s., and estate account £171 4s. 8d.) £4,159 18s., giving a gross profit of £394 14s., and a profit on the actual year's working of £148 4s. 4d. There was credited to the Society: Balance in bank on deposits £400, ditto current account £413 1s., Corporation Bonds £2,500; total, £3,313 1s."

A spring show would be held on April 14 in place of the Chrysanthemum show held in the autumn of last year.

It was resolved that the Committee again consider the question of purchasing the Priory property adjoining the Shrewsbury Quarry. The matter is more urgent than it was when the Society discussed it a year ago, because the development of the Priory as a building site was then only talked of, and now plans for the erection of a number of small houses are actually before the Council.

NATIONAL POTATO.

The National Potato Society, we are informed, continues to make rapid strides. The new members up to February 16, 1905, numbered fifty, with two new affiliated societies. Mr. Walter P. Wright, Postling, Hythe, will forward all particulars post free. A substantial and varied prize list is being arranged for this year's shows.

Messrs. Sutton & Sons have presented 14 lb. of their Superlative Potato to the National Potato Society for its various trial stations.

GARDENERS' DEBATING SOCIETIES.

Addlestone, Chertsey, and Ottershaw Gardeners'.—The monthly meeting of this Association was held at the Red Room, Addlestone, on Tuesday, February 7, the President, H. Cobbett, Esq., occupying the chair. There was a record attendance of members. The lecturer for the evening was Mr. H. J. Jones, of Ryecroft Nurseries, Lewisham, who gave a lecture on "Tuberous Begonias." The lecturer described the cultural details from the time the seed is sown till the plant is fully developed. The plant's adaptability for greenhouse and conservatory decoration, and as a summer bedding plant, were also touched upon, the lecturer advising all who possessed glass structures, however small, to grow these beautiful plants for bedding purposes. *T. S., Addlestone.*

Isle of Wight Horticultural.—The monthly meeting of the above Association was held on Saturday, February 11, when Mr. Tee, Hunnyhill, gave a paper on "The Cultivation of Carnations." Dr. Groves, J.P., presided over a good attendance of members. The essayist detailed his mode of treatment from the time of procuring layers or seedlings to the flowering period, and impressed upon his audience the advisability of purchasing strong plants from a reliable source. The chief adjuncts to success in the cultivation of Carnations were a suitable position and a well-drained soil, which should consist of a good fibrous loam. Little, if anything, was needed in the way of manure except an occasional dressing of soot, which not only stimulated the plants but kept down slugs and other pests. Mr. Cane, the Newport Nurseries, exhibited a collection of plants, including Orchids. Mr. Watts, gr. to Mrs. Renwick, Mottistone House, staged an interesting exhibit in two monster Parsnips, each 4 feet 5 inches in length.

Kingston Gardeners'.—At a recent meeting of the above Society, Mr. Alderman, Morden Hall Gardens, gave a paper on "Vines." The lecturer gave details on suitable structures and aspects for Vine cultivation, the principles to observe in making proper borders, the planting of young Vines, and the treatment necessary for newly-planted and for established Vines, the renovation of old rods, manuring, &c. Well-drained borders that were 2 or 3 feet in depth were recommended, a greater depth being deprecated as conducive to cold and stagnant conditions, often the precursors of shanking in the berries. A shallow border, and one that required watering fortnightly, is best suited to the production of healthy growth and well-finished bunches. The paper gave rise to good discussions on the merits of covering outside borders, the cracking of the berries of "Madresfield Court" (said to be overcome by withholding water after July), and the causes of shanking.

The attraction of a most effectively illustrated lecture on "Ornamental Trees and Shrubs," by Mr. George Gordon, V.M.H., on the evening of Friday, February 23, led to a large attendance of members. After some preliminary observations respecting trees and shrubs, especially flowering ones, Mr. Gordon took for the text of his remarks the various pictures of a remarkable variety of the subjects named, thrown on to the screen, and thus was enabled to present for the evening features of great interest and beauty. Generally the pictures depicted the various trees and shrubs or portions, and thus conveyed to the members valuable information as to the respective habits and dimensions of the plants described. The now usual collection for the Gardeners' Orphan Fund was made, and 5s. 6d. gathered. This, with 8s. 6d. at the first collection and 3s. 6d. the previous week, makes a total so far of 17s. 6d. This means promise of a goodly sum before the close of the session. Other societies should do the same. On a request from Mr. W. Watson, of Kew, it was agreed to have a special meeting on the evening of Friday, March 10, for the purpose of hearing an exposition of the objects of the British Gardeners' Association from Mr. Watson, or other representative.

Reading and District Gardeners'.—At the fortnightly meeting of the above Association, under the presidency of Mr. W. J. Townsend, a paper was given on "The Raising of Flowers from Seeds." The lecturer, Mr. T. Neve, of Sindlesham House Gardens, introduced his subject under the following headings:—Soil, Firmness of Soil, Covering the Seed, Watering, Temperature, Light. The flowers chosen to illustrate his remarks were Begonias, Calceolarias, Cannas, Carnations, Cinerarias, Cyclamen, Gloxinias, Petunias, Primulas, Streptocarpus, Verbenas, Canterbury Bells, Pansies, and Polyanthus. Many of the points touched upon gave rise to criticisms, resulting in a good discussion of the subject. Mr. W. J. Townsend, of Sandhurst Lodge Gardens, staged plants of Primula obconica carrying highly-coloured flowers, also plants of Cyclamen and of Hippeastrum. Mr. A. J. Booker, Coley Park Gardens, staged two dishes of Annie Elizabeth Apple.

(*For continuation of these Reports, see p.* xviii.)

MARKETS.

COVENT GARDEN, March 1.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

— — B., per lb...	3 0-	5 0

Remarks.—Prices for Cucumbers are somewhat lower, while those for Onions still remain high. American-grown Onions are now on sale; these command 15*s.* per cwt. The demand for Rhubarb has improved. Californian Pears of the variety Easter Beurré in boxes containing from eight to ten dozen realise from 30*s.* per case. The Radishes quoted at 8*d.* per dozen bunches are the Jersey-grown "long," while those at 2*s.* per dozen are "round" French. Cape-grown fruit is still arriving. Plums, 6*s.* to 10*s.* per case. Peaches, 3*s.* 6*d.* to 10*s.* ditto. Nectarines, 8*s.* to 12*s.* ditto. Pears, 5*s.* to 7*s.* ditto. Good English Apples are still obtainable; Blenheim Pippin is seen in remarkably good condition, also Wellington, Court-Pendu-Plat, and Golden Knobs, the prices for the two last named ranging from 4*s.* 6*d.* to 7*s.* per bushel.

Potatos.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 55*s.* to 75*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

There was no great change in the pot-plant trade at the end of last week. Business was very dull, but brightened somewhat on Tuesday, although at closing time there were considerable quantities of plants remaining on hand. Azalea indica is prominent; these plants are now very good and there is a moderately good trade done in them, but supplies are unusually large. Genistas are plentiful, and sell well, good prices being maintained for them. Erica Wilmoreana is now of good quality, as are also E. persoluta alba, Boronia heterophylla and B. megastigma. Acacias include A. cordata, A. Drummondi, A. armata and A. verticillata, all of which are well-flowered. Cinerarias are prominent, and have been in more demand during this week. Best plants of Cyclamen sell fairly well, but there are many of second quality which do not sell even at reduced prices. Hyacinths are over-plentiful, but many realise fair average prices. Supplies of Tulips are not so much overdone, and the tendency is for prices to go higher. Marguerites are still numerous: the demand for these is now better, though even now they do not all find purchasers. Azalea mollis is more plentiful, and prices are dropping slightly. Lily of the Valley, both in pots and in boxes, is very good with well-developed foliage. Primula sinensis is seen in better quality, and P. obconica is of good quality, but there is little demand for it. Spiræa (Hoteia) japonica is now plentiful; some of the plants are not well developed. Among Ferns, Palms, and other foliage plants, there is little variation to record. Large quantities of small Ferns remain unsold at closing time. The trade in hardy plants has not assumed any proportions at present, although large quantities are now arriving daily. Some Pansies in flower are seen; but the cold weather has checked these plants considerably.

Cut Flowers.

There has been a moderately good trade for cut flowers during the past week, and for some subjects prices have advanced. Supplies of Lily of the Valley are rather short, and although there are indications of its becoming scarcer, at present the prices have not advanced much. As suggested last week, prices for Lilium longiflorum have risen considerably, and even at higher prices it is difficult to secure good blooms. There is little variation in the trade in Daffodils; but there are now seen many flowers of the Barri section. Roses are fairly plentiful, and do not sell so readily as might be expected. Good fresh blooms of the variety Liberty were noticed unsold at close of the market. Prices for Violets are now down to the lowest ebb. Orchid blooms, especially Odontoglossums and Cœlogynes, are very plentiful; Callas have advanced in price. Tulips vary little; the extra fine double varieties realise up to 2*s.* per dozen blooms. Carnations continue abundant, at usual prices.

Cut Foliage.

Asparagus plumosus is now very good, as is also Smilax; much of this latter is now marketed in full flower. English hardy Fern-fronds are still of good quality, especially Polypodium vulgare and Polystichum angulare. Bronze-tinted Mahonia foliage is good. Maidenhair Fern is plentiful; some is good, but much of the new spring growth is soft. Ivy is plentiful. Large Cycas leaves are procurable; these make up to 2*s.* 6*d.* each. *A. H., Covent Garden, Wednesday, March* 1.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending February 25, 1905.

THE WEATHER IN WEST HERTS.

Rain at Last.—The weather during the past week has been, as a rule, cold during the daytime; but the night temperatures have been only about average. On the coldest night the exposed thermometer showed only 6° of frost. The ground has become colder, and is at the present time at about a seasonable temperature at 2 feet deep, and about 1° colder than is usual at this season at 1 foot deep. Rain, hail, or snow fell on all but two days, and the showers of hail were at times heavy. On the morning of the 27th there was sufficient snow to nearly cover the ground. On the 26th rain, hail, and snow fell to the aggregate depth of between a quarter and half an inch—by no means a heavy fall for a winter month, and yet we have to go back six weeks in order to meet with one as heavy. Of the total fall of the week about three-fourths has already come through the bare soil gauge, and nearly as much through that on which short grass is growing—showing that the soil previously must have been fairly moist. The sun shone on an average for three hours a day, which is rather longer than is seasonable. There were two days altogether sunless, and, on the other hand, two others when the duration of bright sunshine exceeded five hours. The winds were, on the whole, moderately high, but on one occasion 19 miles was recorded in a single hour, direction south; while on another the average rate of movement for the whole day fell short of half a mile an hour. The mean amount of moisture in the air at 3 P.M. was about seasonable. *E. M., Berkhamsted, February* 28, 1905.

[*For actual temperature and condition of barometer at time of going to Press, see p.* 136.]

Obituary.

Thomas Bounton.—It is with deep regret that I record the death of a promising young horticulturist, Thomas Bounton, who met with a serious accident while assisting to extinguish the fire at the Glen House. He fell from the top of a ladder 30 feet high, receiving a fracture of the spine, from which he succumbed on February 19. The deceased was greatly respected by all who knew him, and was a favourite with his employers. He was three years at Ardgowan, one year at Clovenfords, and three years foreman at The Glen. He took a keen interest in horticulture, and was a member of the Royal Caledonian Horticultural Society. His remains were interred at Douglas New Cemetery on the 22nd ult., a large number of mourners being present. *W. McIntyre, The Glen Gardens, Innerleithen, N.B.*

James Epps.—It is with regret we have to record the death of Mr. James Epps, junr., of Norfolk House, Beulah Hill, S.E., which took place recently, in Jamaica. Mr. Epps left England shortly before Christmas, on a visit to his Cacao estates. Mr. Epps was an ardent lover of horticulture, and was much interested in the rearing of economic plants. For many years he had been successful in cultivating and fruiting the "Cacao" tree in his conservatories at Benlah Hill.

Caroline Hogg.—We greatly regret to see in the *Journal of Horticulture* the announcement of the death, at the age of eighty-three, of Mrs. Caroline Hogg, the widow of Dr. Robert Hogg. Many of our older readers will treasure pleasant recollections of the deceased lady.

TRADE NOTICES.

Mr. S. M. Waldram, until recently Manager of the Rose Farm Nurseries, Wrotham, and formerly of Salisbury Nursery, Edmonton, has been appointed Manager to Messrs. A. Bateson, Bashley Nursery, New Milton, Hants.

Mr. F. W. Ashton will terminate on March 4, 1905, his connection with Messrs. Stanley & Co., of Southgate, late Stanley, Ashton & Co., and on March 6 he will enter the service of Messrs. Hugh Low & Co., Bush Hill Park, Enfield, as Orchid representative and traveller.

GARDENING APPOINTMENTS.

Mr. W. Simpson, formerly Gardener at The Grange, Sutton, Surrey, and at present Gardener at Wemyss Castle, Fifeshire, will shortly vacate this latter position, and be open to receive a new appointment.

Mr. Jas. Brown, for the past two years Gardener at Orford House, near Market Rasen, as Gardener to Sir George S. Mackenzie, K.C.M.G., Tempford Hall, near Sandy, Beds.

Mr. J. D. Robertson, Foreman at Shooter's Hill Cemetery, S.E., and previously for four years Foreman of Greenwich Park, has been appointed Superintendent of the Hammersmith Borough Council's Cemetery.

Miss M. Agar, formerly a student at the Horticultural College, Swanley, and afterwards Garden Mistress at Wycombe Abbey School, as Landscape Gardener to the Metropolitan Public Gardens' Association, in the place of Miss Wilkinson, who has lately resigned that post.

Mr. H. A. Peck, late Foreman at Woburn Place, Addlestone, Surrey, as Gardener to J. R. Kelly, Esq., Oaklands, Worplesdon, Surrey.

Mr. C. L. Laurence, for the past four and a half years at Harwood Hall, Upminster, Essex, has been appointed Gardener to H. H. Platten, Esq., at that place. The appointment to date from Nov., 1904.

Mr. Geo. West, late Gardener, Redlands, Broadstairs, as Gardener to F. Ricardo, Esq., The Friary, Old Windsor, Berks.

Mr. R. Greenfield, Gardener to the Birmingham Hospital Saturday Fund at Tyn-y-coed, Llanrhos, N.W., has also taken over the supervision of Marle Hall Gardens.

Mr. P. W. Barnard, recently Foreman at Pyt House Gardens, Tisbury, Wilts, as Gardener to D. Crossman, Esq., Dudbrook House, Brentwood, Essex.

Mr. Chas. Ford, Gardener to Capt. A. H. Thurburn, Hales Hall, Market Drayton, as Gardener to the same gentleman at Cransley Hall, Kettering.

Mr. A. T. Paskett, for the past two and a half years Gardener to Philip Secretan, Esq., Slaugham Park, Crawley, Sussex, as Gardener to Capt. The Hon. and Lady Edith King-Noel, Horsley Towers, Leatherhead, Surrey.

Mr. H. Rodman, late Gardener to H. Formes Coddrave, Esq., Wiscombe, Somerset, as Gardener to Miss Meade King, Taunton, Somerset.

Mr. J. Roberts, for the past ten months Gardener to Major Platt, Chesterford Park, Saffron Walden, Essex, as Gardener to W. Harker, Esq., Blofield Hall, Norwich.

Mr. C. Benns, for the past year and six months Gardener at the Abbey, Aston Abbotts, Aylesbury, as Gardener to W. H. Herbert Esq., Newnham House, Wallingford, Oxon.

ENQUIRIES.

GRASS ON RUSSIAN RAILWAYS.—What is the Grass used along the Russian railways in Amur Daria to fix the sand? and what is the glaucous-leaved shrub used for a similar purpose? *A. B. H.*
[We suggest that the Grass is Ammophila arenaria, and the shrub either an Elæagnus or Hippophae rhamnoides. ED.]

CONTINENTAL LABELS.—What is the composition of the yellow wash used on wooden garden labels used in continental nurseries? *Correspondent.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BOOKS: *G. B.* You do not state sufficient particulars of what you require. Perhaps *Gardening for Beginners* would suit you. Price 16s, 9*d.*, post-free, from our Publishing Department.—*A Derbyite. Veitch's Manual of the Coniferæ*, price 20s. 6*d.* post free from Messrs. Jas. Veitch & Sons, King's Road, Chelsea; or from our Publishing Department.

CUCUMBER PLANTS: *J. R.* Are you certain that no injurious ammoniacal vapours are proceeding from the hot-bed on which the plants are cultivated. If there are no such vapours the injury may be due to the effects of too much artificial heat. Maintain a moist atmosphere in the house and plant the young plants on raised mounds at a suitable distance from the hot-water piping. A temperature at night of 70° would be better than greater heat. If you suspect fungus to be the cause forward specimens to us for investigation.

DAFFODILS: *T. Clift.* We expect you mean the double variety of N. Telamonius (N. pseudo-Narcissus), the common Daffodil, which for some reason or other often shows green colouring in the flowers.

DENDROBIUM: *P. C.* You have given too much or too little water; either extreme would produce the appearances presented.

GARDENERS' ASSOCIATION: *A. P. & L. S.* There is no Society that offers just the aid that you seek. At the same time the Gardeners' Royal Benevolent Institution (Secretary, G. J. Ingram, 175, Victoria Street, Westminster) provides for aged gardeners who are no longer able to follow their profession, and for gardeners' widows. Being a Benevolent Institution and not self-supporting, subscribers cannot demand assistance immediately they are in need of help, but have to await the result of election by contributors to the funds. The Committee however allot votes to candidates for pension, previous to election, according to the amount of subscriptions they may have paid, and this system in practice makes it almost certain that a candidate who has subscribed to the funds of the Institution during the greater part of his life will be successful at the election. To be eligible for a pension it is not sufficient to prove that a candidate has subscribed all his life, or was a life member, but he must also satisfy the Committee that he has insufficient means to maintain himself. The Royal Gardeners' Orphan Fund (Secretary, Brian Wynne, 30, Wellington Street, Covent Garden, London, W.C.) provides for gardeners' orphans, also on the elective principle. The Fund is deserving of hearty support from gardeners, and the funds at present are insufficient to meet the needs now existing. In the United Horticultural Provident and Benefit Society (Secretary, W. Collins, 9, Martindale Road, Balham, London, S.W.) the principle of self-help is stronger, and there is less benevolence. Most of the funds are contributed by benefit members themselves, and during illness any member receives by right weekly payment from the Society. The management of the Society is most economical, and in addition to the sick pay during illness, it provides in a measure the advantages of a bank and of an insurance society. Any gardener would be well advised in joining this Society. In regard to your question respecting payment during the time a gardener is out of employment, there is no organisation that does this at present. If such work should be undertaken in the future it would naturally be by the new British Gardeners' Association (Secretary *pro tem.*, W. Watson, Kew Road, Kew), but even this Association could not possibly undertake such responsibilities until gardeners were thoroughly organised. The Association does not mention the subject in its prospectus.

GARDENER'S NOTICE: *G. D.* You do not state whether you are living in the gardens or in a house belonging to your employer elsewhere. He cannot demand a month's notice from you unless he can prove that you are a menial or household servant, and it has been held that this is not the case unless you are at your employer's service in the evenings as well as during the day. We note that you are paid weekly.

GARDEN PENCIL: *F. S.* We are informed that samples of the wood-marking pencil, described on p. 101, may be obtained from Mr. J. P. Hemming, 39, Noble Street, London, E.C.

GRAPES: *P. C.* The berries have been kept too long, they are decaying naturally.

GUMMING IN PEACH AND APRICOT TREES: *L. F.* Gummosis, as this disease is technically known, appears to be caused by badly-drained soil, a bleak situation, causing undue exposure to cold winds, or to injuries from frost and external wounds. The latest discoveries on the subject point to the presence of bacteria as being the final cause of gummosis.

HEAVIEST BUNCHES OF GRAPES (see p. 96): *J. F. M.* We think you must be wrong in stating that Mr. Dickson showed the bunch that weighed 26 lb. 4 oz., for our information was taken from the report of the Edinburgh Exhibition which appeared in the *Gardeners' Chronicle* at the time, and in the following issue when illustrations of the bunches were published, the names of the exhibitors were the same. Moreover, in Hogg's *Fruit Manual* it is also stated that Mr. Curror, of Eskbank, exhibited the heaviest bunch.

HIPPEASTRUM (AMARYLLIS): *E. A. H.* A good average flower, but of no special merit.

IRIS KÆMPFERI OR LÆVIGATA: *G. W.* This species is by no means one that should not be manured, but on the contrary it requires exceedingly rich soil and heavy mulchings of cow or similar manure. You have not stated whether the plants are growing with their roots actually in water or upon ground that can be flooded when necessary in summer. The mulchings of cow-manure are best applied in autumn.

MUSHROOMS DISEASED: *J. G.* Your Mushrooms are attacked by another fungus, a species of Hypomyces. All the diseased Mushrooms should be carefully removed and burned as soon as they appear. When new beds are prepared, and before the spawn is deposited, spray the soil and walls with a 2½-per-cent. solution of lysol. A high temperature and stuffy, stagnant atmosphere favour the disease.

NAMES OF PLANTS: *W. R.* Probably Veronica Hendersoni.—*G. M.* No. 2 is not a Cupressus, but Juniperus chinensis.—*B.* Lælia superbiens.—*Constant Reader.* 1, Selaginella denticulata; 2, S. Mertensii; 3, S. plumosa; 4, S. umbrosa; 5, S. Wildenovii; 6, S. cæsia; 7, S. caulescens; 8, S. stolonifera. The trailer is Ficus stipulata (repens).—*F. A.* 1, Lælio-Cattleya × elegans; 2, Odontoglossum × Adrianæ; 3, O. Lindleyanum; 4, Oncidium candidum, sometimes called Palumbina candida; 5, Restrepia maculata; 6, Pleurothallis rubens.—*C. E. P.* Eria bractescens.—*J. B. C.* Muhlenbeckia complexa, a good rockery or basket plant.—*J. E.* The yellow flower is Jacobinia chrysostephana. The spots on the Ixora leaves are probably caused by condensed moisture falling on them.—*C. H.* 1, Dendrobium aureum; 2, Stelis ophioglossoides. — *C. J. Ote.* One of the garden forms of Hellehorus caucasicus.—*F.L.H.* 1, Cryptomeria japonica; 2, C. elegans; 3, Abies Pinsapo.—*H. L. N.* You send more than six specimens; and you should therefore contribute a small amount to the Orphan Fund. The list is incomplete, some of the specimens need careful comparison. 1, Cupressus sempervirens; 2, Thuya orientalis var.; 3, Juniperus virginiana; 4, Pinus sp., next week; 5, Juniperus communis var. stricta; 6, Juniperus; 7, Cupressus nootkatensis; 8, Pinus excelsa; 9, Thuya orientalis; 10, Libocedrus decurrens; 11, Cupressus Lawsoniana; 12, Juniperus virginiana.

PALM ROOTS: *P. C.* So far as we can tell from the scrap received, the roots are affected with a scale like Mealy-bug. Wash the roots thoroughly, and steep them in tobacco-water. Be careful not to apply any strong insecticide or you will kill the roots.

PELARGONIUMS: *C. & A. B.* You have apparently coddled your plants too much by growing them in too moist and too warm an atmosphere without sufficient ventilation.

SULPHATE OF IRON FOR ROSES: *C. D.* Dr. A. B. Griffiths recommended, in his *Special Manures for Garden Crops*, a chemical manure composed of ½ oz. of superphosphate of lime, and a ¼ oz. each of iron sulphate and sulphate of ammonia. These quantities were to be put into two gallons of water, and the liquid applied to the roots without wetting the foliage. He also printed a letter from a cultivator in which the writer described in glowing terms the good effects of sulphate of iron upon his Roses. The late Rev. A. Foster-Melliar, M.A., who was a famous Rose grower, declares that his experience was not so favourable to the use of this manure. In *The Book of the Rose*, of which the third edition has just been issued, Mr. Foster-Melliar states that sulphate of iron is said to give a better colour to the foliage, and in some sorts, such as Anna Olivier, to the blooms as well, but he did not place much reliance in this. At the same time he recommends the following mixture, as prescribed by Mr. Tonks upon the the result of analysis of the ash left from the burning of Rose plants:—

Superphosphate of lime	12 parts
Nitrate of potash	10 ,,
Sulphate of magnesia	2 ,,
Sulphate of iron	1 ,,
Sulphate of lime	8 ,,
	33 ,,

This mixture is applied in February and scattered over the previously hoed surface of the bed at the rate of ¼ lb. to the square yard. A second and lighter dressing may be applied at the end of May if heavy rains have occurred. If you refer to the issue of *Gardeners' Chronicle* for March 19, 1904, p. 178, you will find an article by Mr. J. J. Willis on special soils and manures for Roses

VEGETABLES AND THEIR CULTIVATION: *C.* In our notice of this book, p. 117, we omitted by inadvertence to give the name of the publishers. We supply the omission by stating that the book can be had from Messrs. W. H. & L. Collingridge, 148, Aldersgate St., London, E.C.

WOOD-LICE: *G. D.* If you take some pieces of Potato or of Swede and hollow out the under-surface, so as to provide a retreat for these pests, you will be able to destroy a number each morning upon examination of the traps, which afford food for the wood-lice.

HYBRIDISATION OF GLADIOLUS.

A CORRESPONDENT of the *Gardeners' Chronicle* recently asked for information on the cross-fertilisation or hybridisation of the Gladioli. No operation in gardening is more simple, and there are few garden plants that can be raised from seed and flowered with less trouble. Cross-fertilisation is the easiest and most simple process, and for garden purposes the crossing of the many beautiful varieties of G. gandavensis is the most desirable practice, and gives the best results. Suppose a dozen of the best varieties is obtained to start with. They should be planted in rich, rather sandy loam. The flowers will be produced in July and August. The parts of fructification are very prominent. The anthers are balanced on the filaments, and these can easily be removed with the fingers before the pollen-cases burst. After twenty-four hours the stigmatic part of the flower is ready for the application of the pollen. I simply pinch off the filaments on which hang the ripened anthers, and gently touch the stigma with them. The plants must be gone over daily between one and two in the afternoon until the entire spike has been cross-fertilised. It is important that the seed-bearing plant should be one that has well-formed flowers, and the pollen-bearer should also be of good form and of the colours most desired by the operator.

Hybridisation is the crossing of two distinct species, but in Gladiolus the results of this operation are not so certain as the mating of two varieties of one species. There are distinct species that cross readily enough, others do not; but this is a point that the cultivator would do well to study for himself, as there are numerous distinct species in cultivation. Many good and distinct crosses have already been obtained, and as a result many beautiful plants have been added to our gardens; but the field is very large, and not a hundredth part has been accomplished of what may yet be done in this fair field of garden culture. Some useful information for beginners may be obtained from Dean Herbert's interesting book, the *Amaryllidaceæ*.

The chapter on hybrid intermixtures contains his results of hybridising the Gladioli, but seventy years ago the material at his disposal was very inadequate in comparison to that which is now available. The soil in his garden at Spofforth was specially adapted to this plant. He says, "They succeed very well in the natural soil, which is a good yellowish, light loam, suitable for Barley, and also in the artificial borders of peat and sand. These hardy crosses are between G. cardinalis, blandus, carneus, inflatus, augustus, and tristis, and they vary with every shade of colour from white to scarlet, rose, coppery and blackish-purple, and some are exquisitely speckled in consequence of the cross with tristis." Herbert adds, "Clusters of these seedlings stood undisturbed for twenty years by merely covering them with leaves from November to March or April." Certain specific forms would not cross; for instance, G. psittacinus would not cross with any of those species named above. G. byzantinus could not be fertilised with the pollen of G. tristis. Crosses from G. hirsutus, recurvus, and versicolor were found to be delicate in the Dean's garden, being unable to bear the vicissitudes of our variable climate.

There are fifty-five species figured in the *Botanical Magazine*, and thirty-nine of these were introduced before 1830, in which year G. psittacinus was figured; it also flowered for the first time in England in that year, so that Herbert had ample material to work upon. Of course good additions have been made since that date, amongst others G. Saundersii, G. purpureo-auratus, and G. dracocephalus. A very remarkable species is G. sericeo-villosus, collected by Mr. Cooper in Cape Colony for the late Mr. W. Wilson Saunders, and figured in the *Botanical Magazine*, t. 5427. It develops a spike 3 to 4 feet in height, freely set with yellowish flowers, the stem densely clothed with long, shaggy, silky hairs. This distinct species may not now be in existence in gardens, but this and others I have named of recent introduction may well be taken as types to become parents of quite distinct garden plants. Good work has been done already in this direction.

M. Lemoine, of Nancy, managed to cross G. gandavensis with G. purpureo-auratus with excellent results. There are also the G. Childsii and G. nancianus hybrids; these are amongst the most beautiful of garden flowers. When the seed-pods have been formed and ripened, they are gathered as soon as the capsules show signs of opening; the crosses are marked and entered in a book for future reference. The capsules will, if placed in a dry room, speedily burst open. Let the seed be quite dry before it is put into paper-bags, and keep it in a dry cool place until March. Sow the seed in that month thinly in pans or flower-pots, using good potting-soil, as it is intended the plants should remain in these to make their growth during the season. The seed germinates best over a gentle hot-bed; the plants will appear in two weeks. When all of them have done so admit air to the frame rather freely, and as the season advances the lights may be removed. Corms will be formed varying in size from that of a pea to that of a Hazel-nut; and when the leaves assume a yellow tinge the bulbs should be shaken out and placed in dry sand in a cool room from which frost is excluded. They may remain there until March, when they should be planted out in the border in shallow drills 18 inches apart, putting the corms 6 inches distant from each other. Although they are of such small size, they will produce very nice spikes of flower the same season, so that they may be brought to their flowering stage eighteen months from the time of sowing the seed. They require good soil if tall, handsome spikes are to be produced.

For garden purposes the varieties of G. gandavensis are esteemed; they produce handsome spikes of very beautiful colours, and hundreds of singularly beautiful forms are obtained by the cross-fertilsation of these varieties. It would be necessary to purchase the best varieties to start with, and then the result will not be problematical, for I write from my own experience, having raised thousands of seedlings from the G. gandavensis varieties, and never failed to obtain many plants as good as or even better than the parents. *J. Douglas.*

ORCHID NOTES AND GLEANINGS.

THE COLLECTION AT WOODHATCH, REIGATE.

In the *Gardeners' Chronicle* for March 26, 1904, an illustration was given of the Dendrobiums then in flower in the gardens of Mrs. Haywood, Woodhatch, Reigate (gr., Mr. C. J. Salter). Many of those specimens were grown from seedlings and were furnished with seven or eight flowering growths, each 4 feet in length and bearing fifty or sixty flowers on a growth. Some curiosity was felt as to whether plants so grown could be maintained at this high standard, but a visit to Woodhatch this year disclosed the fact that the specimens had even improved on their good condition of last year in every respect. Not a trace of "spot" or disease has appeared on the plants, and their grower may well be proud of them. Most of the specimens are of crosses of the D. × Ainsworthii and D. × splendidissimum classes. These again have been crossed with other species and varieties, the result being great variety and beauty of flower. Some of the most remarkable are D. × Ainsworthii Woodhatch variety, D. × Ainsworthii intertextum (both with a yellowish-white ground colour); D. × melanodiscus Salteri and D. m. gloriosum, two of Mr. Salter's certificated recently; D. × splendissimum Mrs. Haywood (with very large lilac-rose flowers with maroon centres), and D. × Edithæ

superbum. A number of the best forms of D. nobile, D. × Cybele, D. × Schneiderianum, D. × Juno, and others are also in bloom, the whole making a very fine display. In the matter of culture, Mr. Salter regards it as being most simple. Sphagnum moss with a sprinkling of sand is the material used for potting. He gives plenty of pot-room, repotting the plants when roots are proceeding from the new growths, and keeps them during the growing season in a house from 75° to 90° Fahr. Abundance of moisture is supplied and air given cautiously by means of the top ventilators only. The plants are shaded until the growths approach maturity, when in the end of August the blinds are removed and full sunlight and plenty of air admitted. From the end of November to the end of January the plants are kept cooler (about 60°) and dry, only a little water being given to prevent shrivelling. In the beginning of February the houses are kept more moist, and the plants prepared for flowering.

The little warm Phalænopsis-house has a small lot of Phalænopsis, which have been in the gardens for many years, and which have now grown to large specimens and are sending up spikes. In many other gardens these plants grow well when the proper place can be found for them, although they frequently fail when tried in other quarters.

In a similar manner Vanda Sanderiana, with which most growers have a difficulty, has grown well here from the first importation.

The range of cool-houses has a number of good things in bloom, including some grand pans of the white Masdevallia tovarensis, a nice specimen of M. Schroderiana, and some other Masdevallias, good Cœlogyne cristata and its variety hololeuca, Pleione humilis, Ada aurantiaca, Epiphronitis × Veitchii, grown into little bushes bearing a profusion of cinnabar-scarlet blooms; Oncidium cheirophorum with many slender spikes of yellow flowers, Sophronitis grandiflora, and other pretty species.

In the warmer houses are a good selection of Vandas and Aërides, Arachnanthe (Vanda) Cathcartii, and a few others being in bloom or bud. The Cypripediums have large specimens of several hybrids raised at Woodhatch in bloom, and in bud a very promising hybrid between C. × T. B. Haywood and C. bellatulum. Also good Cypripedium Mastersianum, C. × Euryades, and C. × Harrisianum superbum. A large number of Miltonia vexillaria are showing well for flower. Among the Cattleyas in bloom are C. Trianæ and C. maxima, and a good supply of buds showing to continue the display.

The herbaceous Calceolarias, Cyclamen, and some other florists' flowers, for the culture of which Mr. Salter is famed, are in grand condition for flowering; and the great quantity of fruit-trees have smooth, clean bark, pleasant to look at even in winter. *J. O'B.*

Dendrobiums at Burford.

The following Dendrobium species and hybrids are now in flower in Sir Trevor Lawrence's Orchid houses at Burford, which, when grouped together, make an interesting and attractive display of bloom:—

Species.—D. glomeratum, Fytchianum, Wardianum, W. album, fimbriatum, f. oculatum, nobile, n. elegans, n. Ballianum, n. Statterianum, n. Murrhiniacum, n. Burford variety, cruentum, primulinum, p. giganteum, Pierardi, signatum, s. aureum, crumenatum, Harveyanum, Ashworthæ, Kingianum, K. album, specio-Kingianum, aggregatum, sulcatum, æmulum.

Hybrids.—D. Dominianum, Cybele, Wiganæ, W. xanthochilum, W. album, W. nobilius, melanodiscus, chrysodiscus, Burfordiense, Melpomene, Cassiope, splendidissimum, s. grandiflorum, s. delicatum, Juno, Mrs. Haywood, Leda, Apollo grandiflorum, A. album, aureo-Wardianum, Wardiano-japonicum, Sybil, Luna, Blackianum, xanthocentrum, Hebe, Clio, C. superbum, C. Burford variety, Aspasia, Artemis, Ainsworthii, A. Woodhatch variety, A. Hazelbourne variety, The Pearl, Kennith, euosmum virginale, e. leucopterum, Rœblingianum, pallens, Aurora, Myra, Ethel, Euterpe, Euryclea, Strætius. *W. H. W.*

Synanthy in Cypripedium Exul.

A correspondent kindly sent us recently a remarkable flower of this species with two standards (dorsal sepals) and one lower sepal, forming one complete whorl of three segments, alternating with which are three lateral petals forming a second whorl. There are two lips, one partially enclosed within the other, a single column, and two distinct staminodes. The ovarian cavity is single, with three parietal placentas. The obvious explanation is that we have here to do with a fusion of two flowers, but how, when, or why the fusion took place is not apparent. Both flowers issued from the axil of a solitary bract.

Disease in Phalænopsis.

In the *Zeitschrift für Pflanzenkrankheiten*, vol. xiv., pp. 263 — 266, 1904, Prof. Sorauer publishes some details respecting a hitherto undescribed disease that attacks the leaves of Phalænopsis amabilis, and particularly of the variety Rimestadtiana. It shows itself in the form of numerous specks upon the leaves, which range in colour from yellow to black. The diseased portions are at first somewhat wart-like, but at a later stage they sink and form depressions. The cellular contents of the infected tissue disappear almost entirely, and in consequence the cells themselves shrivel up. Isolated in this dead tissue are found the fungoid spores. Herr Sorauer gives a minute description of the changes exhibited in the course of the disease by the cellular matter, and more especially by the chloroplast. According to Sorauer's opinion, the disease is induced by over-stimulation, which can be lessened by a change in the method of the cultivation of the plant. They should be kept cooler and dryer, and besides this an improvement should be made in the soil by adding some lime and small pieces of charcoal.

NEW OR NOTEWORTHY PLANTS.

Rhabdothamnus Solandri.*

To those who interest themselves in the geographical distribution of plants the occurrence of a Gesnerad in New Zealand offers some knotty problems for solution. Did it originate there—or how did it get there? Most of its relatives are natives of tropical or subtropical countries, especially in the Western Hemisphere. To horticulturists, however, it is of more importance to know that it is in cultivation.

Fig. 59.—Rhabdothamnus Solandri: flowers orange.

It is to Mr. Gumbleton that we are indebted for the opportunity of illustrating this interesting plant, of which we append in the foot-note a full description, taken from Sir Joseph Hooker's *Handbook of the Flora of New Zealand*. Its orange-coloured striped flowers are attractive. It would in most cases need the protection of a greenhouse, but

* 1. *Rhabdothamnus*, A. Cunn.—A slender, hispid or pubescent shrub. Leaves opposite. Flowers solitary or in pairs. Sepals five, unequal, persistent. Corolla-tube campanulate; limb 2-lipped; upper lip 2-lobed, under 3-lobed. Stamens four, the fifth rudimentary; filaments slender, arched; anthers cohering cruciately. Disk thin, annular, lobed. Ovary 1-celled, narrowed into a slender style; stigma small, obtuse, 2-lobed; ovules numerous, on 2-lobed prominent placentas. Capsule ovoid, beaked, 2-valved; valves 2-fid, separating from the placentas. Seeds very minute, albuminous.

1. *R. Solandri*, A. Cunn., Fl. N. Z., I. 186.—Shrub 2—4 feet high; branches opposite, hispid, terete. Leaves on slender petioles, broadly obovoid or orbicular, ½—⅝ inch diam., coarsely toothed, harsh to the touch. Flowers axillary or terminal; peduncles slender, ½—¾ inch long. Sepals lanceolate, acuminate, ⅓ inch long. Corolla ⅝ inch long, orange with red stripes. Capsule shorter than the calyx.

Northern Island: from the Bay of Islands to Wellington, Banks and Solander, &c. The foliage somewhat resembles that of Trophis aspera and Carpodetus serratus.

in favoured situations it might even prove hardy. Mr. Gumbleton favours us with the following note concerning it:

"The accompanying illustration (fig. 59, p. 146) gives an admirably faithful and accurate idea of this pretty and most free-blooming as well as botanically interesting little plant, which is known as the shrubby Gesnerad from New Zealand. I obtained my plant early last autumn from M. Lemoine, of Nancy, who, I think, raised it from seed. It was in a very stunted and sickly condition when it reached me, and for some time I feared it would die, but on being planted out in a frame it soon recovered, and is now growing rapidly and assuming quite a shrubby appearance. It began to bloom early in December, and is now covered with flowers and buds. The flowers resemble those of a Tydæa in form, and are of a deep orange colour striped with brown. *W. E. Gumbleton.*"

GARDEN ADORNMENTS.

There are few matters in which greater judgment and more refined taste are demanded than in the introduction of architectural features or statuary into gardens. Those whose fancy leads them in that direction are wont to call attention to such places as Versailles and various gardens in Italy, where architecture or sculpture is allowed to intrude into the domain of the gardener. We cannot say that the result is altogether satisfactory. In many cases it is so much otherwise that the statuary becomes ludicrously out of place, and the often exquisite proportions of the vases fail to attract because of the incongruousness of their surroundings. Nevertheless there is abundant room for the display of individual fancy, and the garden of an eminent anatomist was not disfigured by the remains of extinct animals or the curved outlines of gigantic ammonites. Often too the memory of former travel is pleasantly evoked by some object seen and purchased when the owner was travelling. This may have been the case with the ancient well-head at Tylney Hall, Hampshire, the residence of L. Phillips, Esq., of which we give an illustration (fig. 60) after a photograph by Mr. Mason Good.

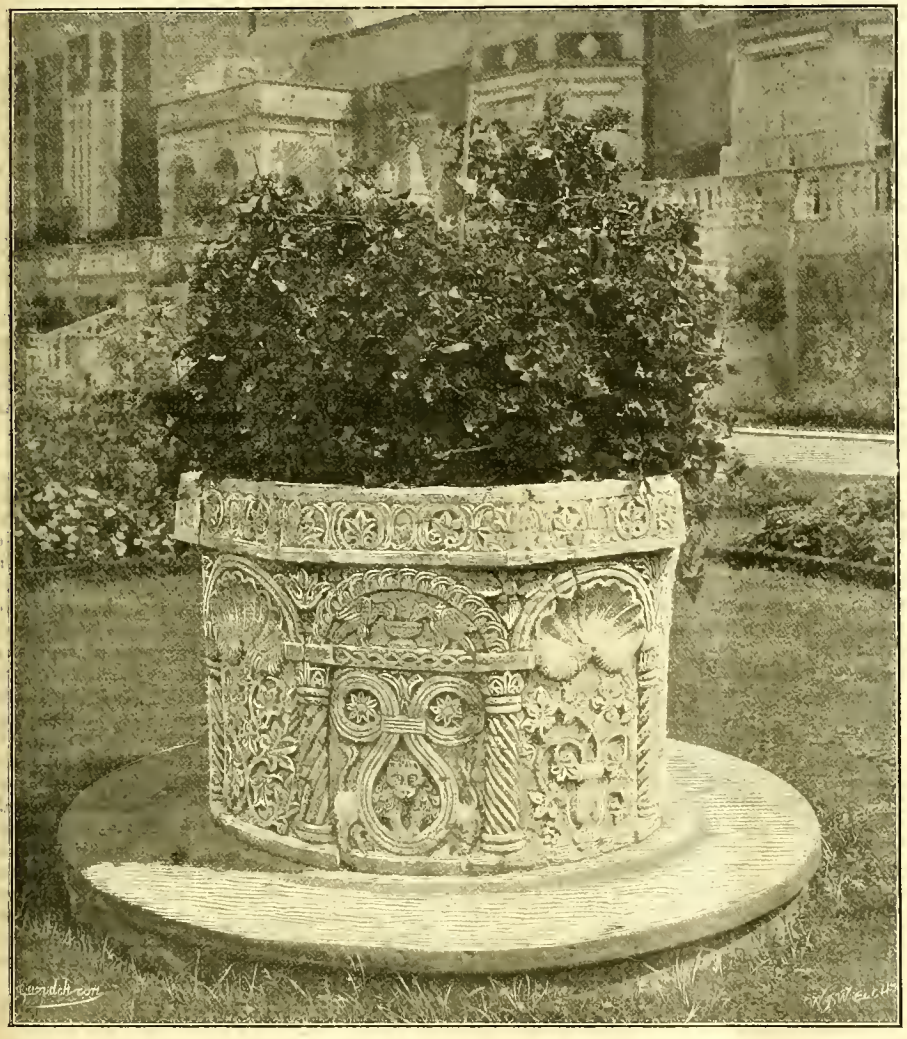

Fig. 60.—Ancient Venetian well-head at Tylney Hall, Hants.

The structure in question is said to be of Venetian origin, and the style of ornamentation seems to point to the Lombardic or Romanesque period, when the severity of old Roman types was becoming modified by a freer and more decorative treatment. In any case the "well head" possesses great interest and no little beauty.

VEGETABLES.

THE ROTATION OF KITCHEN-GARDEN CROPS.

(*Concluded from p.* 123.)

The last subject treated of in the *Gardeners' Chronicle* for February 25 were winter and spring Broccoli. These were planted in the previous July after a crop of Strawberries, which had occupied the land for the three previous years, so that by the time the last of the Broccoli is cleared away the ground will have been continuously under crops for nearly four years without cultivation, other than surface tillage and surface manuring. The time has now come therefore for it to be trenched and manured for the succeeding crops, which should be Seakale and Leeks. The autumn and winter Broccoli will all have been cleared in time for the preparation of the land for these crops, but the latest of the Broccoli probably not until the middle or end of May. These late varieties are valuable in completing the circuit of the year in which they can be had in use, for the early Cauliflowers come in in May, often before the Broccoli is over. The land on which the late section of the Broccoli has stood may be used for a variety of crops, after having been trenched and manured. In the south Tomatos or Marrows would succeed, provided the plants were strong and of good size when planted-out; or early Brussels-Sprouts and early Savoys would be suitable. The land under Seakale and Leeks will have been deeply stirred in digging up these roots, so that very little further cultivation will be needed, but if a moderate dressing of manure can be applied when the land is forked over for the succeeding crops, which should be Brussels-Sprouts, Savoys, and Winter and Spring Kale, the value of these crops will be correspondingly increased.

Roots.

Although roots do not usually occupy a large extent of land in any garden, they are amongst the most indispensable of vegetable crops. The land I have found to be most suitable for the growth of these is that which has been trenched and well manured the year before and on which late Peas have been grown. The only preparation necessary for these crops on such land is to fork the ground over and level the slight ridges left by the rows of Peas. Parsnips should be sown as early in February as a favourable day can be found, Carrots in the middle of March, Chicory, Salsafy and Scorzonera early in April, and Beetroot at the end of that month. If seeds of these root crops are sown too early there is danger of the plants bolting into seed and proving useless. Jerusalem and Globe Artichokes are usually grown in some out-of-the-way corner not far from the Rhubarb quarter.

There are other subjects of minor importance for which it is scarcely possible (or indeed necessary) to find a place in the general order of rotation—such as Turnips, Summer Spinach, Broad and French Beans, Scarlet Runners, Lettuce, Endive in succession, and other salad material. Some of these may very well be grown between rows of Peas if sown at the same time. Spinach is an instance, as this would be gathered before the Peas were in pod. For the others mentioned, spare corners of well-manured land are always available. The subject of the rotation of crops would be incomplete without reference being made to the value of borders having north or even east aspects. The former, especially in hot summers, is invaluable for the growth of Lettuce and other salads, Turnips, Spinach, and similar succulent crops, which it is next to impossible to grow successfully in extreme hot and dry weather in exposed quarters. These cooler quarters of the garden are none the less valuable for

the growth of soft summer fruit, such as Strawberries, Gooseberries, and Currants, in order to prolong the season in which they can be had ripe. *Owen Thomas.*

ALPINE GARDEN.

CROCUS CHRYSANTHUS AND ITS VARIETIES.

In my garden I have generally flowers of some varieties of this species in January, but the time is somewhat prolonged and it is March before they are usually over for the year. Crocus chrysanthus is rather widely spread in its habitats, being found in western Asia Minor, the North of Greece, and in European Turkey, while it is also found at altitudes varying from little above the sea-level to about 5000 feet. Its colour variations are wider than are to be found in most of the Crocus species, and it has been remarked that there is no other known instance of a species with orange-coloured flowers giving a form with lilac flowers. The typical plant, as found near Smyrna, is of a uniform rich, orange colour. In the variety fusco-tinctus the outside of the outer segments is suffused with rich brown, and the variety fusco-lineatus has featherings of the same colour. These are both remarkably pretty forms, and they seem among the first to flower each year. I have had two sizes of these; but a very small one is a charming little flower, opening brightly to what sun we may have in the middle and end of January in average seasons. A white variety, named C. c. albidus, is also in cultivation, but it is not so pretty as the pleasing C. c. cœrulescens, which has lilac flowers. There are a number of other and intermediate shades, such as the sulphur-coloured sulphureus and the delightful, rich-yellow, sweet-scented "Canary-bird," or the fine variety called superbus, which has rich orange-yellow-coloured flowers with bright scarlet stigmata. All are beautiful, and to the flower-lover longing for the appearing of his favourites, they are charming in the extreme. *S. Arnott, Carsethorn-by-Dumfries, Scotland.*

THE SPECIES OF EREMURUS.

(*Concluded from p.* 133.)

E. robustus Elwesianus.—The best Eremurus, and a stately and reliable border plant withal. The root-stocks are extremely large, the roots thick and fleshy, coloured brick-red, the resting crowns very large, not conical but semi-spherical—a character I use frequently to determine this variety from E. robustus—and the rooting system covers a square yard. The leaves are very broad, deep-green, 2 to 3 feet long, sub-erect, never drooping unless damaged, and the spikes appear when the leaves are nearly developed, reaching a height of 10 to 12 feet, the upper third furnished with rose-pink flowers each 1½ inch across, the anthers orange-red, and the ovaries yellowish. The spikes are very symmetrical, tapering a little at the top, whilst in E. robustus they are nearly cylindrical. As the two plants are often confused, I will briefly note that Elwesianus differs from robustus in the semi-spherical, not conical crown, in the descending, not ascending roots (those of robustus ascend for 2 to 3 inches then descend or spread horizontally) in the rigidly-erect leaves, which do not droop at the tips, and in the tapering spike of deeper-coloured flowers. It is the best of the pink-flowered forms of Eremurus, and the root-stocks grow to an enormous size without breaking up or forming more than one crown. It appreciates a liberal soil, but no manure should be placed near the roots. A mulch of decayed manure is helpful as a surface dressing in summer.

E. "Shelford" (E. Bungei × Olgæ).—A very beautiful hybrid, of sterling worth, and just mid-way between its parents in every respect. The rooting system is that of Olgæ, the leaves those of Bungei, whilst the graceful inflorescence is coloured bronze, copper, and bright yellow in an effective and richly-toned blend. The exteriors of the shell-like petals are darker than the inner, whilst the anthers are reddish-tinted, as in Bungei. It was raised at Great Shelford by Sir Michael Foster, and it has already won unstinted admiration, the graceful spikes possessing the good attributes of either parent. It is not harmed by frosts, unless the spikes happen to be half a yard high, when severely cold winds cripple them.

E. Warei (hort. *Reuthe*).—A very beautiful plant from Turkestan, and a great rarity, now finding its way into general cultivation. The root-stock is slender, developing quickly from the seedling to flowering size, becoming finally 18 inches across; the roots thin and black, the crown slender and conical. The leaves are glaucous, very narrow, and persistent till autumn, appearing shortly after the new year, and growing through all weathers without taking much harm. The flower-spikes are slender, 6 to 7 feet long, clothed for one-third of their length with cup-shaped flowers, coloured a bright tint of salmon internally, purplish externally, the outer colouring showing through on the inside, so that a tint of magenta is produced. Seeds germinate well and freely, and it will not be long before this grand Eremurus becomes common. Hybrids between this and other species show great vigour and an extended colour-range. I have heard of plants producing spikes 9 feet long, and it is probable, in a light and sandy soil, to exceed even this. It does not succeed in heavy loam, and even on light soils it prefers to be elevated. E. "Mrs. Reuthe" is a hybrid between this species and turkestanicus, with the habit of Warei. The flowers are borne on slender stems, and are coloured deep sulphur-yellow; the anthers—a very beautiful feature—are coloured orange-red, reminding one of Cimicifuga in their dense array.

Curious Species of Botanical Interest.

E. Kauffmanni (Regel).—A curious species from Turkestan, more closely allied to the Asphodels than any other species. The roots are much thickened, and not more than 6 inches long, the crown conical and small. The spikes average 5 feet in height, and bear dull-coloured purplish-bronze flowers three-quarters of an inch across each, and not more than one-third of the spike is covered with flowers. The capsules are very distinct, being wrinkled and ascending. It increases fast at the root, and seedlings are not difficult to raise. It has no great garden value, and is only grown as a curiosity.

E. turkestanicus.—A dull-coloured species that differs but little from E. Kaufmanni. The roots are a foot across, the flowering crowns conical and generally in pairs, the leaves glaucous, an inch or two wide, and 2 feet long; the flower-spikes are 2 yards high, bearing along half their length quantities of purple-tinted flowers of comparatively small size, the exteriors of the petals being heavily keeled and chocolate-coloured. The seed-vessels are ruddy tinted, have hard rugged exteriors, and the pedicels ascend so that the capsules touch the stems. Grown as a curiosity only, but obviously a useful parent species, in that it has given us a splendid hybrid in E. Mrs. Reuthe. It will grow well anywhere, and increases very freely.

Other species that may be appreciated in a collection are E. spectabilis, a yellow-flowered species closely allied to the preceding; and E. altaicus, a curious species bearing dusky-yellow flowers of poor worth, compared with many others. It is a free-flowering plant. *G. B. Mallett.*

FRUIT REGISTER.

APPLE LORD BURGHLEY.

Of good dessert varieties at this season of the year that known as Lord Burghley succeeds remarkably well in our stiff cold soil. We have one small tree which invariably crops well. The fruits are of satisfactory size, with dull red colouring on the sunny side, and of good quality considering the late season. They keep well, and the skins do not shrivel as they do in most of the late kinds here. I should like to know how the variety succeeds in other northern gardens. I very seldom see its name mentioned, and am inclined to think the variety is not much grown. *J. Easter, Nostell Priory Gardens, Wakefield.*

Some Lesser-known Apples.

Perhaps in our anxiety to obtain new varieties we sometimes cast aside some of our old meritorious fruits, flowers, &c., to make room for something which, after trial, does not excel the old ones. This I am inclined to believe is what is happening with respect to the Apple.

Many individuals are interesting themselves in the production of new Apples, which, if not officially recognised by the Royal Horticultural Society, are still grown by the raisers, and add bewilderment to the already perplexing list.

When collecting specimen fruits for the late Dr. Hogg and Dr. Bull, as they were compiling that beautiful work, *The Herefordshire Pomona*, I had excellent opportunities of examining some of the varieties I am about to mention. These Apples are much valued locally, and with the same care bestowed upon them that is given to many other kinds generally cultivated, they would prove valuable. Isolated as some varieties are in one district, with no one enterprising enough to push them, they are seldom heard of; several of their number have, however, been brought to light and are found in catalogues. Crimson Devonian is one of the highest-coloured Apples grown; it is a heavy cropper and a strong grower. Caldwell Improved is one of the best of kitchen fruits, keeping well until March. It is a good hardy grower, well suited for cold districts. Then there is our old English Codlin, perhaps one of the oldest Apples grown; as an early or midseason Apple I should include it in a collection; its cropping qualities are regular and good. All who grow Apples for exhibition should secure Bodenham Beauty, a fruit of the first size, and equally good for dessert or kitchen use, keeping in good condition until March. British Queen resembles in appearance Blenheim Pippin, but is not equal to it in flavour. Allen's Everlasting is somewhat better known, and is esteemed on account of its late-keeping qualities and excellent flavour.

Only in a few districts, particularly in Norfolk, is Dr. Harvey grown. That it is extensively cultivated in that county is sufficient proof of its hardiness; it is grown chiefly for market purposes. Coker's Beauty is a very handsome Apple, somewhat after the type of King of the Pippins. This Apple, although awarded a Certificate at the Guildhall fruit show, seems to have sunk almost into oblivion.

Lord Burghley (see above), certificated in 1865, is not grown nearly enough, its merits as one of the very best late dessert kinds have only been discovered by a limited number of growers. I have seen it in good condition in May and June; but it is not a kind I should recommend to be planted extensively as a standard. Monmouthshire Beauty is a very pretty Apple, of good quality, and keeps well until January; I have an old tree growing in an orchard, and it seldom fails to carry a crop: it is useful either as kitchen or dessert fruit.

A very old favourite in Herefordshire is Pine-apple Russet, highly appreciated on account of

its peculiar aroma and soft rich flesh; in some localities it is known as Pomeroy. Tewkesbury Baron is another very highly-coloured Apple, surpassing in appearance and cropping qualities many of our better known sorts, and when well grown is valued highly; it is an ideal Apple for exhibition, but the fruits are not of large size.

The Apple orchards in different counties, which I have seen personally, in Herefordshire, Worcester, Somerset, and Devon, contain many meritorious seedlings at the present time. In many instances these have been produced from the Cider "cheese," or experimentally raised from the pip of some favourite variety. Often have I been shown Apples so produced bearing a local name, and possessing first-rate flavour. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

CULTURAL MEMORANDA.

CALADIUMS.

Few plants surpass these for decorative effect from April to September in the warmhouse by reason of the brilliant colour and rich marking of their leaves. Provided the plants are well established and are suitably hardened, an ordinary greenhouse will meet their requirements from midsummer onwards, but it is necessary to place them where they will not be subjected to the influence of cold draughts, and they must be very carefully watered. The season for repotting and, if necessary, for increasing the stock of these plants is now at hand. As the bulbs are taken from the pots each one should be carefully examined, removing any decayed portions that may be present, and should it be desirable to increase the stock, each piece having a growing shoot should either be pulled or cut off with a knife. The cut surfaces should be sprinkled with fine silver-sand before placing the cuttings in quite small pots containing a light soil composed of equal parts loam, leaf-soil, and peat. A sprinkling of sand should be placed under each cutting, which should next be covered with soil. A sprinkling of sand on the surface finishes the potting. The pots should be plunged in a bottom-heat of about 75°, and allowed a day temperature of from 65° to 70°. They will soon commence to grow, requiring very little water except a light spraying from the syringe twice daily. It is advisable to keep the plants near to the glass roof, especially the small-leaved or dwarf varieties, which otherwise would quickly become drawn, thus losing half their decorative value. Although these plants enjoy light it is necessary to apply a thin shading during the brightest part of the day throughout the summer months. As the pots become full of roots transfer the plants to pots of a larger size, an 8-inch size being sufficient for the requirements of specimens of the stronger-growing varieties, while for the charming variety argyrites, 4 or 5-inch pots are of ample size. For the final potting the compost should be coarser in texture, with a small quantity of horse droppings added, and coarse silver or river-sand used in place of the finer sand previously advised. As growth advances and the roots of the plants protrude, weak liquid manure may with benefit be given on two or three occasions each week, that prepared from sheep or from deer-droppings proving excellent for the purpose. Named varieties are now endless, but growers in search of a varied collection cannot do better than visit the Temple Show at the end of May and see the grand exhibits staged by several of the London nurserymen who make a speciality of these plants. *J. Mayne, Bicton Gardens, Devon.*

The Vilmorin Memorial. — The sums received or promised now amount to £1,289, the number of subscribers being 3,112.

SPIRÆA BRACTEATA.

Our illustration (fig. 61) shows a flowering spray from Kew of this very pretty white Spiræa, reproduced from a photograph by Mr. Raffill. It is one of the most desirable of hardy Spiræas, and is useful for forcing purposes. Whilst there is happily no question at all as to the value of the plant, there is very considerable doubt as to what name it should bear. It appears that there is a Japanese plant, and there is another shrub that grows in Austria and Southern Russia. The two are so much alike that it is difficult to tell them apart. Some botanists therefore consider them as separate species; others look upon them as constituting one species extending from Southern Russia through Amur Land to Japan. We cannot pretend to decide the point, but we may add that on February 25, 1885,[1] the Japanese form was figured in our columns, and described by Mr. Nicholson as S. media rotundifolia alba (fig. 62). On June 16, 1894, Mr.

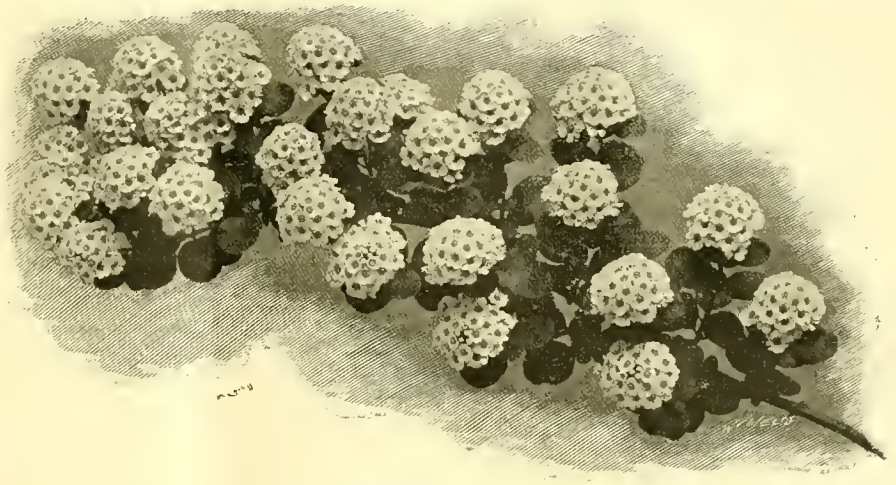

Fig. 61.—Spiræa bracteata from Kew.
(Photograph by C. P. Raffill.)

Fig. 62.—Spiræa bracteata, originally figured as S. media rotundifolia alba.

Hemsley descanted in the *Gardeners' Chronicle* on the Japanese shrub, which he called bracteata, and said that the name media was erroneously applied to it. It was again the subject of a note on July 6, 1895, p. 22. In the same year a figure was given of the Japanese plant in the *Botanical Magazine*, t. 7429, where the flowers are shown of a greenish-white colour. The two species, S. bracteata (Japan) and S. media (with which S. confusa is synonymous), are kept separate in the *Kew Hand-List of Tree and Shrubs* (1902). The distinguishing characters of S. bracteata are to be found in the leafy bracts borne on the flower-stalks just beneath the flowers, as shown in fig. 62, and in the large glands projecting into the interior of the flower from the edge of the calyx-tube.

COLONIAL NOTES.

HORTICULTURE IN CAPE COLONY.

A CONGRESS of the horticulturists of the eastern province of Cape Colony was held on November 22 at East London. The executive reported an increased interest in horticultural matters throughout the whole of the eastern provinces. They were encouraged to believe that there is a genuine awakening to the importance and far-reaching possibilities of the fruit-growing industry of the eastern province of the Cape Colony.

"THE TRANSVAAL AGRICULTURAL JOURNAL."

We have received the January number of the *Transvaal Agricultural Journal*. The contents include papers on The Evolution of the Plough, Government (Forestry) Plantation at Gemsbokfontein, Pan, and many botanical and horticultural notes. We note that this quarterly is illustrated with handsome plates, some of which are photographed from nature by the Government Printing Works three-colour process, and are wonderful reproductions of the fruit and insects represented.

"THE YEAR-BOOK OF NEW SOUTH WALES."

This is the record of the conditions during 1904 of the various government departments, of military, naval, legal and similar affairs. The pamphlet also contains historical information, with reports on the products of the colony, the conditions of immigrants, and a gazeteer. The booklet is in fact of great value to all interested in New South Wales. Under the heading "Forestry" are important notes on each of the principal timbers, while the flora is mentioned in the section devoted to geographical characteristics. The agricultural industry is dealt with from the standpoint of the new arrival, and the most profitable crops are suggested. Sugar-growing, viticulture and other branches of agriculture are also discussed with respect to their relative importance.

The Year-Book is obtainable from the Agent-General (for New South Wales), in London, Westminster Chambers, 9, Victoria Street, Westminster.

ELÆOCARPUS.

I have noted the fine plate of Elæocarpus cyaneus in the *Gardeners' Chronicle* for October 15. By the way E. reticulatus, Sm., is older than E. cyaneus, Ait. It is a small tree, very common about Sydney. The fruits are of an intense Prussian-blue colour. I have never seen them purplish-blue as in your specimen; also the flowers are pendulous when growing wild. It might be worth while to have your specimen examined at Kew to see if it is a variety or an allied species. *J. H. Maiden.*

"FOREST FLORA OF NEW SOUTH WALES."

The thirteenth part, issued in 1904, contains figures and descriptions of Eucalyptus sideroxylon, Aphanthe philippinensis, a tree allied to the Elms; Casuarina lepidophloia, and Heterodendron oleæfolium (Sapindaceæ). The descriptions are by Mr. J. H. Maiden, and include notes on the economic uses of the several trees.

"REPORT FOR 1903 ON THE BOTANIC GARDENS AND DOMAINS OF NEW SOUTH WALES."

The long drought broke in March, 1903, and the year, on the whole, was the best for years. The good season was by no means confined to the coastal districts. Much good work was done in connection with the National Herbarium and Botanical Museum. As regards the gardening work of the several local establishments, Mr. J. H. Maiden reports that they are well kept and reflect credit on the respective staffs."

AGRICULTURAL NOTES FROM QUEENSLAND.

The December (1904) issue of the *Queensland Agricultural Journal* contains much that is of interest. Mr. A. Benson gives diagrams for improved fruit-cases, with a view of packing Grapes and Plums so as to prevent their contact and consequent injury during exportation. There are also articles on Wattle bark (Acacia decurrens), the Forest, Cedar planting at Atherton, as well as others on other branches of agriculture.

"ANNUAL REPORT OF GOVERNMENT GARDENS AND PARKS IN MYSORE FOR 1903—1904."

The season was abnormally wet. Annuals suffered to some extent, but otherwise growth was good and profitable. A piece of a letter signed "Rd. Clive, First Assistant, Political," and dated Fort William, the 24th April, 1819, was recently found and presented to the establishment. It is of interest as dealing with the early history of the Mysore Gardens.

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

The Orchard-house.—The most forward trees in this house will now be approaching (if they have not already reached) the flowering stage, owing to the fact that all fruit-trees under glass this season are in a very advanced condition. Daily attention must be given to the requisite watering of the trees, and especial care in watering will be necessary in the case of those trees that have been freshly top-dressed, seeing that the soil beneath the top-dressing and which contains the active roots is not allowed to become dry, although the surface-dressing appears moist enough. Maintain suitable atmospheric conditions by damping the paths and other available spaces and by lightly syringing the trees overhead on bright days. The night temperature should not exceed 50°, while the day temperature should not be allowed to rise above 65°. Apply ventilation freely in favourable weather. A little ventilation should always be allowed through the top and side ventilators, excepting in very cold weather. Fumigate the house lightly on two occasions before the trees expand their flowers. This is especially necessary in those orchard-houses in which Strawberries have been grown. Avoid having too much atmospheric moisture during the flowering stage, and allow a little heat in the pipes both during the night and the day. Extra heat given early in the morning with plenty of ventilation will greatly assist the setting of the fruit. Peaches and Nectarines set their fruits freely in orchard-houses, but Pears, Apples, Cherries and even Plums are more shy in this respect, and will well repay any extra attention given them. A dry atmosphere is essential for the free setting of these latter fruits, whose flowers must be pollinated daily with a soft brush. Disbudding and pinching the trees must be attended to as often as it becomes necessary in order to encourage an equal flow of sap through the whole tree.

Young Vines that were rooted in small pots as recommended in a previous calendar, will now be ready for shifting into 6-inch pots. See that the latter are made clean before they are used, and that the compost, which should be on the dry side, is suitably warmed. It should consist of rough fibrous loam with a sixth part lime rubble and wood ashes, and a good sprinkling of bone-meal added. When potted place the Vines in a bottom-heat of 75° to 80°. "Cut backs" will now be ready for the final shift into 12-inch pots. The Vines should be watered before being potted, in order to ensure the "balls" being moist. The pots should be clean, well crocked, and the potting process carefully carried out. When potted plunge the pots in a steady bottom-heat until they have well rooted through the soil, after which the bottom-heat should be gradually discontinued. Water should be used sparingly at the roots but maintain a somewhat close, moist atmosphere until the plants are well established, by lightly syringing and damping the paths.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Lælia anceps and its varieties. — The typical forms of this species will now begin to emerge from the resting stage, and be sending out new series of roots. The necessary potting operations should be attended to immediately these develop. If the plants are to be suspended, let them be put into teak-wood baskets. Pieces of crocks should be placed on the bottom bars, and the plant should be fixed in position with good lumps of fibrous peat and sphagnum-moss, used in the proportion of two parts of the former to one part of the latter. In making up new specimen plants remove useless back pseudo-bulbs, and so arrange the pieces that their growing points are toward the centre of the pot. Place the potting material well up to the bases of the last-developed pseudo-bulbs, but do not use more of the compost than is necessary. If pots or pans are used, a larger quantity of drainage material should be allowed, and the surface of the potting medium finished off in a mound. L. Dawsoni, L. Sanderiana, L. Schroderiana, and others of this section thrive best in baskets, and usually produce floral scapes more freely from those growths that project over the sides of the receptacles. When such growths project beyond reasonable limits they should be cut off, and the pieces thus severed made up into new specimens, leaving the old growth to "break" again from lateral buds. Where a separate compartment is not available for Mexican Lælias, the plants should be placed in the lightest and most freely ventilated section of an ordinary Cattleya house. Water must be applied sparingly until the season is well advanced, and nothing should be done to induce the plants to make early growth, for the later in the season the new growths develop the more likely the plants are to flower successfully. Very little shade should be afforded the plants in order to allow them the full benefit of natural sun-heat, as artificial heat should be only applied when the atmospheric temperature recedes to 55°. Spraying overhead and damping between the receptacles should be done as often as is necessary to promote sufficient atmospheric moisture to counteract the drying influences entailed by free ventilation.

Catasetums, &c.—Few of these Orchids are of much horticultural importance, the most valuable being C. Bungerothii. As soon as the young growths of this and of other species are about an inch in length the plants should be set in order for the season, and, as the roots seldom survive for more than one year, annual potting is the best plan to adopt. Use pots or pans in which to suspend the plants, making them three parts full with drainage material. The rooting medium may consist of fibrous loam, peat and sphagnum moss in equal proportions, adding a good sprinkling of sand and small crocks. Place the plants in a light part of the stove, and afford little or no water for several weeks afterwards. Whenever water is applied see that none lodges between the growths. It is only when the the bulbs are nearing their limit of growth that a generous supply of water is needed. A compost of which decaying Oak-leaves form a part appears to suit these Orchids and the members of the two following

genera, viz., Cycnoches and Mormodes. When this material is used afford the plants a greater depth of compost, and apply a smaller quantity of water to the roots. Cycnoches chlorochilon, the "Swan Orchid," should be grown under the same conditions as the Catasetums, but the species of Mormodes that are commonly cultivated should receive Mexican-house treatment, or be given a place on a shelf in the Cattleya-house. The older roots of Mormodes survive for a season or two, hence annual potting should not be practised in their case, it being generally sufficient if the old surface materials are replaced by new.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Wythes, Esq., Copped Hall, Epping, Essex.

Souvenir de la Malmaison Carnation.—To grow these plants perfectly it is necessary to have glass structures devoted entirely to them. If suitable varieties be selected flowers can be had from February onwards. Two varieties, Baldwin and Valetta, may be relied on to yield a number of flowers in this month, but two-year-old plants should be grown for the purpose. To attempt to force "Malmaisons" into bloom is generally to court failure, and only those varieties that have a tendency to produce their flowers early should be tried. During the winter months the atmosphere must be kept dry, the plants themselves allowed to remain on the dry side, and overhead syringing should be strictly avoided. Allow a circulation of air between the plants at all times. A temperature of 40° to 45° by artificial heat will be sufficient under these conditions. The "rust" fungus may be stamped out entirely if care be taken to remove all affected leaves with a knife or scissors. As the days become longer the floors and stages of the house should be damped down frequently, and the plants be afforded more water at the roots. Appearances of red spider should be checked in good time by applications of "Veltha."

Border Carnations.—My practice is to have a number of these layered over and above what are required for planting out, in order that some may flower in pots in May. They should be layered in July, and when the layers have made roots, they should be potted into 5-inch pots in a moderately rich soil. Shade them from the hot sunshine for a few days, but not afterwards. Let the plants stand in cold frames during the winter, protecting in very severe weather, but not coddling them. In February remove them to shelves near the light in late Peach-houses or similar structures, and let them develop gradually; very fine flowers may then be expected in May.

Hippeastrums (*Amaryllis*).—Let bulbs that have laid dormant through the winter be shaken out of their old soil and re-potted, as advised in a previous Calendar. There is no occasion to plunge them in tan or any other material, but place them "pot thick" on a cool base and syringe them occasionally. An atmospheric temperature of 55° by night will be suitable. Admit a little air during the day in bright weather, but close the house before the sun loses its power. As soon as seedlings are large enough to be handled pot them up and place them on shelves near to the light in a hot atmosphere. Seedling bulbs should not be dried off until after they have flowered.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

Filberts and Cob Nuts.—Now that the female blossoms have expanded, pruning may be done without fear of removing too many of them. All bushes should be grown on single stems. Suckers must not be permitted to develop. As the nuts are borne on twigs and spurs, pruning should be carried out in such a manner as to produce these. Strong growths should be shortened during the summer, and the subsequent side growths should be pinched to about six leaves. Where trees are grown as bushes or shaped as cups, any growths that will not be required should now be removed, the extension shoots and spurs shortened back and well thinned out if overcrowded. Only over-tall trees should be cut severely, because close pruning produces strong, unfruitful wood. If male catkins are few, as is the case here, branches may be cut from other trees where they are plentiful and be fixed above the trees in such a manner that the wind may distribute the pollen; or Hazel branches will answer the same purpose. Shy-fruiting varieties may be grafted at the present time on weak-growing stocks, which will in some cases induce fruitfulness. The husk of a Cob-nut is shorter, but that of a Filbert longer than the nut.

Protecting Apricot Blooms.—Many trees growing against warm walls of dwelling-houses and outbuildings are commencing to open their blossoms, so that adequate means must now be taken to protect the flowers. They only need protection from frost, and will set their flowers in a very low temperature, therefore the protecting material should be removed from the trees when there is no frost or cold wind. The practice of tying Spruce branches, Yew and Laurel shoots to the trees is a good one, but double or treble fish-netting, tiffany or hexagon netting is more portable and more convenient. A simple means of covering the wall is to roll the material round a pole, fastening it to one end of the wall first, unrolling it, and lightly hanging it on nails at the summit of the wall at the same time; a considerable length can be quickly covered and uncovered in this way. If there is no coping to keep the material from the trees, poles standing from the top of the wall to the ground are necessary for this purpose. Do not entirely dispense with the covering until there is sufficient foliage to protect the young fruits.

Recently-planted Trees.—All trees planted against walls during this season should now be quite settled in the soil, and may be nailed or tied to the wall. They should be pruned as was advised in a previous Calendar.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Montbretias require a warm aspect, deep, sandy soil, and thorough drainage. Plant the corms in irregular masses, putting them 3 inches deep and 6 inches apart from each other. Such space will allow them to increase if undisturbed for several years. As soon as the plants become overcrowded they will flower less satisfactorily. Upon signs of this lift the corms and transplant the finest, or lift the central patch out with a fork. Amongst the many fine varieties are Golden Sheaf, and Etoile de Feu. They require protection in severe winters by covering them slightly with litter, ashes, or Cocoa-nut refuse.

Bedding Plants.—Plants of Fuchsias, Heliotropes, Aloysia citriodora, and of Plumbago capensis that are used in summer bedding should be pruned and placed in gentle heat in order that they may break into growth. Abutilons that were rooted during last autumn should be given a shift into larger pots. Such varieties of Ivy-leaf Pelargoniums as Souvenir de Charles Turner and Madame Crousse that were placed in 5-inch pots and wintered in a cool-house will now require attention in the matter of staking and tying in order to train them into suitable sized plants for growing as pyramids and as pillar plants. Dahlia tubers should be placed in heat in order that they may make growths to be used as cuttings for propagating purposes. Salvia patens should be treated in a similar manner if it is desirable to increase the stock. Seeds of either may be sown if desired. A sowing of Sweet Peas should now be made in 6-inch pots, placing six or eight seeds in each pot. Stand the pots in a cold frame, and maintain a close, moist atmosphere till the seeds have germinated, when ventilation should be employed in favourable weather. Seedling Hollyhocks should be potted as soon as they are large enough to handle. Place them when potted in a light position in the forcing-house, and when they have established themselves in the new soil remove them to a cooler structure, and one in which ventilation can be freely applied. Seedling plants of tuberous-rooted Begonias should be "pricked-off" when ready. Seeds of Lobelia speciosa, Golden Feather (Pyrethrums), Gaillardias, Iceland Poppies, Salvia Horminum grandiflora violacea, S. splendens, and Œnothera taraxacifolia should be sown in boxes and placed in a moderate degree of heat. Store stock plants of Lobelia compacta that have not been allowed to flower will now have plenty of young, sturdy growths suitable for propagating as cuttings. Half-fill a shallow box with sand, dibble in the cuttings, and then place the box on a hot-bed. Cover the box with a sheet of glass until the cuttings are rooted, when a lower atmospheric temperature must be given in preparation for their final shift into boxes. Alyssum, Verbenas, &c., should be propagated in the same manner.

Shrubberies.—Strong-growing shrubs require judicious pruning in order to keep them in good shape. Remove any "suckers" that may be present on hybrid Rhododendrons which are not upon their own roots. Mulch newly-planted trees and any others that require it with well-rotted manure. Andromeda floribunda, whose spikes of white flowers are now beginning to open, does well in a sheltered situation and in a peaty or loamy soil.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Onions.—Sow seeds of this important crop in the middle of the month. Little difficulty will be experienced in breaking up the soil, levelling it, and making it firm by treading, if this was turned up roughly early in last autumn. If the soil was well dusted with lime last month, soot should now be applied previous to raking the surface and drawing the drills. When the soil is in a dry, favourable condition, sow the seeds thinly, covering them lightly by means of the feet, having one foot on each side of the drill; and afterwards rake the surface down fine. Seedlings raised from seeds sown in August should now be thinned carefully to 9 inches apart, using the hand-fork. If the thinnings be lifted carefully and planted firmly I foot apart each way in mild, showery weather, these plants will make better bulbs even than those which are left standing, and they will keep for a longer time in good condition. This applies especially to such varieties as Ailsa Craig, Giant Rocca, &c.

Turnips.—Sow seeds of the varieties Early Milan and Early Snowball on a south border or other sheltered position where the soil is of a light nature. Let the drills be made 9 inches apart and 1 inch deep. Sprinkle the surface with soot when the young plants appear. These plants will succeed the variety Carter's Early Forcing now growing in frames, and which require free ventilation and frequent root waterings.

Spring Cabbages.—Dust over the surface of the ground with soot before hoeing is done. See if later plants have been loosened by frost; they need to be moderately firm in the ground. We are pricking off seedlings from the first sowing, and making another small sowing of the variety Carter's Model.

Lettuce.—Fill up any blanks in autumn-made plantations by taking plants from the store-beds. Hoe the surface of the ground frequently. Of the plants that have been wintered in frames, three-fourths may now be planted in sheltered positions out-of-doors. Those remaining will soon be fit for use. A good selection of "Bath" or "Brown Cos" stand the winter well, and are excellent in quality. We are pricking off seedlings from the first sowings of Superb Cos and Perfect Gem. Make sowings out-of-doors at intervals of twelve or fourteen days. It will save time if the seeds be sown thinly where the plants are to remain. Especially should this be done on light soils or during periods of heat and drought.

Celery.—We make our first sowing in heat in the second week in March, and about a month later we sow seeds in cold frames for the general and later crops, employing rich but sandy soil. Standard Bearer is the variety chiefly relied upon, of which at the present time we have a good supply here.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAR. 13—United Horticultural Benefit and Provident Society, Annual Meeting at Caledonian Hotel, Adelphi, London, at 8 P.M. Birmingham Mutual Improvement Society's Meeting.

TUESDAY, MAR. 14—Royal Horticultural Society's Committees Meet. National Rose Society's Committee Meeting.

THURSDAY, MAR. 16—Linnean Society's Meeting.

SALES FOR THE WEEK.

MONDAY NEXT—
Hardy Border Plants, Azaleas, Roses, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Azaleas, Palms, Lilies, Roses, Fruit Trees, Herbaceous Plants, &c, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—893 cases Japanese Liliums, Maples, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 3 o'clock.—Roses, Azaleas, Lilies, Gladioli, &c., at Stevens' Rooms, at 12.30.

FRIDAY NEXT—
Herbaceous Plants, Perennials Lilies, Begonias, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—2,100 Vanda cœrulea, 3,500 Odontoglossum crispum, Lælia autumnalis atro-rubens, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —42·4°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March* 8 (6 P.M.): Max. 51°; Min. 38°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 9 (10 A.M.): Bar., 29·6; Temp., 51°. Weather—dull, with occasional showers.
PROVINCES.—*Wednesday, March* 8 (6 P.M.): Max. 50°, Land's End; Min. 44°, E. Coast of England.

British Gardeners' Association.

THERE is now evidence to show that the working gardeners of this country are at length recognising that it is better to combine for purposes of co-operation and mutual assistance than to remain, as heretofore, disjointed units. The meeting at the hall in Essex Street, Strand, in May last, at which the Association was initiated, was practically unanimous in principle. Some points of detail were objected to, but these, as we pointed out at the time, could be readily adjusted when the Committee got to work. The first thing to do then was to replace all the talk and writing of previous years by some scheme which should ensure practical application of admitted principles. This was done, and then came the proposal that when a body of 500 gardeners had signified their adhesion, the preliminary organisation, or Committee of Selection, should be superseded by a Council elected on broadly representative lines, and that this Council should proceed to carry out, as far as circumstances should permit, the objects for which the Association was founded. Meetings have since been held in various parts of the country, explanations have been afforded, difficulties have been removed, and now the Association is in a condition to begin active work. Convinced by long experience of the necessity for improving the position of the gardener, and of raising him to a status more in accordance with the intelligence and the forethought expected of him, and the responsibility he has to assume, we rejoice at the formation of the Association, and we can but feel that if it be judiciously guided by the governing body the benefit to gardeners will be great, whilst the employer will have a guarantee that the man he takes into his service has really something to show that he is what he pretends to be—a gardener. If unfortunately evil counsels prevail, a circumstance we do not in the least anticipate, the Association will collapse. Justice and liberty between man and man, co-operation for the common benefit, can but lead to good results all round. Matters, as we have said, have arrived at such a stage that the Executive Council can be elected. We cannot too strongly urge the exercise of the greatest care in the selection of the most fitting men; nor can we over-rate the responsibilities which will fall on the Council in the execution of their task; but knowing what the leading gardeners are, and how they will rise to the level of their opportunities, we can but look forward most hopefully to the results of their deliberations. The following document has been forwarded to us for publication, and in the interests of gardening and gardeners we gladly give insertion to it:—

"At a Committee meeting held on March 3 it was decided that 500 gardeners having now joined the Association, the election of the Executive Council should be proceeded with. The Council will consist of twelve members who live within easy reach of London, and a representative of every Branch with not fewer than fifty members. To enable all [members] to take part in the election of the twelve, a list of those who are willing to serve on the Council will be posted to every member, who will be invited to mark the names of those he prefers, and the twelve who obtain the highest number of marks will be considered elected. This arrangement appears to be the only workable one that would give satisfaction. The selection of candidates will be representative of all sections of gardening, but the majority will be gardeners employed in private establishments. Gardeners who have not already joined the Association are urged to do so at once, and thus secure the right to take part in the election of the first Executive Council.

Candidates for membership are requested to apply to the secretary of a branch, should there be one near, but those who prefer it may apply direct to headquarters. The expenses of public meetings held in different parts of the country are as a rule provided locally, the fund for the promotion of the movement being too small to do more than help to pay the delegates' expenses. The Committee would be thankful for further help in the shape of donations to the Expenses Fund.

It was also decided to secure an office in London and to engage a permanent secretary as soon as possible.

Up to February 28 the membership amounted to 504. Of this number 211 are head gardeners, 26 'single-handed' gardeners, 183 journeymen gardeners, and 80 various. These are thus distributed: South of England 271, North of England 91, Scotland 42, Wales 78, Ireland 12, Colonies 6.

Meetings have been held in twenty-three gardening centres, including Birmingham, Leeds, Sunderland, Plymouth, Exeter, Bournemouth, Reigate, Swansea, Cardiff, Altrincham, the Isle of Wight, &c., and branches have been established in seventeen districts. Suggestions for holding public meetings from gardeners who are willing to help will be gladly received by the Secretary.

STATEMENT OF ACCOUNTS.

W. Watson, Secretary (pro. tem.)."

PHALÆNOPSIS SCHILLERIANA (see Supplementary Illustration).—The enormous specimens of Phalænopsis which have been in the collection of the Right Hon. Lord ROTHSCHILD at Tring Park (gr., Mr. ARTHUR DYE) for many years have been frequently remarked upon in these columns. This year the show of flowers was even better than previously, and the plants were so fine that on January 9 photographs were taken, one of which, by the kindness of Lord ROTHSCHILD, we are enabled to reproduce in our Supplementary Illustration to this issue. The largest plant of Phalænopsis Schilleriana was purchased at the dispersal of the Burton Constable specimens in 1881, and this winter it bore a spike with seven main and eleven secondary branches, having in the aggregate ninety-nine flowers, each of which measured from 3 to 4 inches across, the largest leaves being 15½ inches long and 5½ inches wide. Other plants also finely flowered had eight or nine leaves each, the largest leaves being 15 by 6 inches. The original plant of Phalænopsis intermedia Portei, purchased about thirty years ago, has again produced a great profusion of rose-tinted flowers. The specimens of P. Stuartiana have flowered well, the handsome P. Stuartiana nobilior and punctatissima being among them. At present the large specimens of P. Aphrodite and P. amabilis are fine, and P. Sanderiana and the pretty little P. Lowii, which blooms regularly at Tring Park, are promising well for flower. There seems to be little trouble occasioned by these plants at Tring Park, where the chief object is to keep a uniform rather warm and moist atmosphere.

THE INTERNATIONAL EXHIBITION IN EDINBURGH.—The schedule of prizes to be offered by the Royal Caledonian Horticultural Society at the International Exhibiton to be held in the Waverley Market, Edinburgh, on September 13, 14, and 15 next, has been issued, and copies may be obtained on application being made to the Secretary, Mr. P. MURRAY, THOMSON, S.S.C., 5, York Place, Edinburgh. We shall expect to see a magnificent collection of fruit at this show. In Class I. for a "Table of Dessert Fruit," five prizes are offered, which in the aggregate amount to £65. Equally liberal prizes are offered in the following classes which include that for a collection of twelve dishes of fruit, the prizes offered for which amount to £51, and another for a collection of eight dishes of fruit, for which £30 is offered. The numerous classes for Grapes will doubtless be well contested, for every Scots gardener prides himself upon his ability to grow good Grapes. In the class for eight bunches, including not more than two bunches of any one variety, the first prize will consist of the Scottish Challenge Trophy (value

50 guineas), a Gold Badge, and £15. The second prize will be £15; third prize, £10; and fourth, £5. There are as many as thirty-five classes for Grapes, including several for seedling varieties. The classes which immediately follow those for Grapes are for other indoor fruits, and some for hardy fruits. We hope that English growers in the Southern counties will make a good display of hardy fruits in Edinburgh, that the Scotch people may become more familiar with the quality of the Apples and Pears obtained in the more favoured districts in this Isle. There are classes for preserved fruits and jams and for fruits which have been grown abroad. There are numerous classes for ornamental foliage and flowering plants, and growers from south of the Tweed will doubtless help to make this section a success. Vegetables are certain to be well shown, for they are always an outstanding feature at the September shows in Edinburgh, and the prizes to be won in these classes are worthy the efforts of the best growers. Every effort should be made to ensure that the classes bearing on the scientific aspect of gardening be well maintained, and that in every section of class 219 it will be found necessary to award a Veitch Memorial Medal. Under gardeners are asked to draw plans to scale showing the best way to lay out a piece of ground 20 acres in extent, and from enquiries we have received it would appear that a number of young men intend to enter the competition. Of the 252 classes the last forty are of unusual interest, and from every point of view it is desirable that the Edinburgh International Exhibition of 1905 shall become an unqualified success.

Linnean Society.—A meeting will be held on Thursday, March 16, 1905, at 8 P.M., when the following papers will be read:—1, "Contributions to the Flora of Liberia," by Dr. Otto Stapf, F.L.S. Exhibitions:—"Penguins and other Birds from the Falkland Islands, and Scratched Rocks from a Rockhopper's Rockery," by Mr. Rupert Vallentin, F.L.S.

The Surveyors' Institution.—The next ordinary general meeting will be held in the lecture-hall of the Institution on Monday, March 13, at 8 P.M., when a paper will be read by Mr. E. Morten (Barrister-at-law), entitled "Surveyors' Reports and Certificates."

Presentation to the Cardiff Public Parks.—At a recent meeting of the Cardiff Parks Committee, Mr. W. W. Pettigrew, superintendant of the public parks, reported that a gentleman who recently died at Whitchurch (Mr. Watson), had left his valuable collection of Cactaceous plants to be handed over to the town. Their value might be anything from £250 to £400. It was decided that the gift should be accepted and that £150 should be added to the current estimate for the purpose of erecting in the beautiful Roath Park, laid out by Mr. Pettigrew, the first instalment of a house to accommodate the plants.

Presentation to Mr. J. Roberts.—The members of the garden staff at Welbeck assembled on Monday evening, the 6th inst., to present for Mr. Roberts's acceptance a testimonial on the occasion of his retirement from Welbeck, as a token of the high esteem in which he is held. It took the form of a "silver tea and coffee set," suitably inscribed. The presentation was made by the senior foreman on behalf of the garden *employés*. The loss of Mr. Roberts is a source of the deepest regret to all who have worked under him, and he carries with him from Welbeck the best wishes of all his men, who have found in him a good friend and kind-hearted master. Since Mr. Roberts has been at Welbeck he has carried out some very much needed improvements in the way of making the young gardeners more comfortable by building a new bothy, which has a well-stocked library attached to it. Wherever he goes it will be with the best wishes of all from Welbeck and district.

Oxford as a School of Forestry.—There is something rather grotesque about this announcement to those who remember Bagley Wood as it was several years ago. The Scientific Department of the University has greatly developed since then, so that the preliminary part of a forester's education might possibly be evolved, but Oxford has still much leeway to make up before it can be considered up-to-date.

The Almond.—The first flowers on the Almond-trees in a favourable locality in the south-western suburbs of London expanded fully on Tuesday last, March 7. The first flowers on the same trees last year opened on March 21.

The Nice Battle of Flowers.—We understand that this festive ceremonial was this year less remarkable than usual owing to the scarcity of flowers, due to the severe weather recently experienced. We could wish, for some reasons, that such use of flowers was more often curtailed.

Flowers in Season.—A box of brilliant Cineraria flowers has been sent us by Messrs. Clibrans, Altrincham, Cheshire. The strain from which these were gathered is evidently remarkable for the clearness and variety of colour, as well as for the large size of the flowers.

Potatos.—Since the memorable "tasting test," when over sixty varieties were tasted on the same occasion, we too have been favoured with samples for trial. Fortunately they have not been very numerous, nor did they all arrive at the same time. The first was "Sir John Llewelyn." Of this we personally could not report favourably; but, as showing how tastes differ, some of the same Potatos made a most favourable impression in the case of other people. "Sutton's Discovery" was the next to be submitted to the test of the cook. This is a variety which is a robust grower, a good cropper, and has gained a great reputation from its relative immunity from disease. When cooked, we found the outer layers flaking off, whilst the centre was a "mass of flour," such as we used to see in Potatos years ago. The flavour was good. "Peacemaker" is an oval kidney with netted skin and shallow eyes. The colour was in some cases blackish at one end, but the tubers were floury and of excellent flavour. "Table Talk" has a rounded tuber with very slightly netted skin, and very deep eyes. When cooked it was seen to be floury, white, and particularly delicate in flavour. The two last varieties were sent us by Messrs. Scarlett, of Market Street, Edinburgh. In the matter of flavour so much depends on circumstances that no great importance can be placed on individual expressions of opinion.

—— Now that Potatos are exciting so much attention we should like to have the opinion of growers upon the cause of the different shapes which tubers assume. Why are some globular or nearly so, others oval or oblong, others flattened at the sides (lapstones)? The netted skin, the shallow or the deep eyes, the purple shoots and other peculiarities are easily accounted for, but the causes regulating the shape of the tubers are not so obvious. Another peculiarity has been pointed out to us in the case of Sharpe's Express, in which the sprouts are very short and sturdy, and thus are less likely to be broken off than are long sprouts, a matter of some importance to market growers. This variety, from the peculiarity just mentioned does not make much visible growth at first, but when favourable conditions arise then they develop rapidly. The retarded growth of the shoots is a great advantage when frost occurs, as the tops are not so likely to be damaged as those that grow more rapidly and expose a relatively greater surface to the action of frost.

Co-operative Grading of Fruit.—At the annual general meeting of the Herefordshire Association of Fruit-growers and Horticulturists which was held on March 1 at Hereford, a committee was appointed to consider the best method of giving effect to co-operative grading and packing, and also the sale of fruit. Mr. H. P. Bulmer observed that the Americans and Canadians were in the right when they decided to grade Apples into sizes, and established brands or marks by which the contents of the barrels of fruit were well known before they were opened. Mr. Joseph Riley was re-elected President. It was stated that the membership was rapidly increasing, and there was a balance of £20 odd in hand.

Caoutchouc and Coffee.—M. de Wildeman, in the latest number of the *Comptes Rendus*, mentions a climbing plant, Baissea gracillima, as a source of "rubber," which is also yielded by Periploca nigrescens, a near relative of P. græca, which is cultivated in our gardens. In the same number, M. Chevalier mentions Caffea excelsa, also a native of the Congo basin, as a source of coffee. The proportion of "caffein" in the seeds is said to be no less than 1·8 per cent. The flavour is also described as "very estimable." Our Colonial friends should take note of these useful discoveries.

Lord Morley.—The death of the Earl of Morley will be keenly felt not only in the House of Lords and in his own county, but also among garden-lovers. He was a keen horticulturist, and had fine collections of rare and beautiful shrubs at his two seats, Saltram and Whiteway, of both of which descriptions from the pen of Mr. Fitzherbert have appeared in our columns.

"Polygonum for Banking."—The Polygonum intended is P. cuspidatum, and by "banking" is meant the preservation of the banks of streams, especially those liable to be occasionally flooded. Our new American contemporary, *Horticulture*, says that it "surpasses Willows for holding streams, and that, once established, it is a stayer." We give currency to this as a valuable hint.

International Botanical Congress, Vienna.—This congress will be held in Vienna from June 11 to 18, together with an International Botanical Exhibition. The nomenclature question will occupy a large share of attention, in addition to which numerous papers on botanical and agricultural subjects are announced. Various excursions are planned both before and after the meetings of the Congress, such as to the summit of the Schneeberg, a trip to Illyria (occupying about a month); similar visits to the Austrian coast, to the Eastern Alps (one month), the lower Austrian mountains and the Valley of the Danube (10 to 14 days). Shorter outings will be made to places in the neighbourhood of Vienna, and visits will be paid to the scientific establishments of the Austrian capital, including the Botanic Garden of the University, that of Schönbrunn and that of Baron Rothschild at Hohe Warte; the Seed Control Station; the Experimental Station of the Hochschule für Bodenkultur; the Forestry Station at Maria-brunn, &c. All communications should be addressed to the General Secretary, Dr. A. Zahlbruckner, I. Burgring 7, Vienna; and during the meeting of the Congress, enquiry offices will be open at the University I. Franzensring, and at the Botanical Garden III., Rennweg 14. Arrangements for lodgings, restaurants, &c., will be made if applications be received before June 1. A lady's committee will endeavour to make the stay in Vienna as pleasant as possible to lady visitors. As if this programme were not full enough the Royal Hungarian Society of Natural Science invites the members of the Congress to make a "collective excursion" for five or six days to Budapest and its neighbour-

hood. Those intending to avail themselves of this most attractive trip should apply to Dr. CHARLES SCHILBERSZKY, Secretary of the Botanical Section, Budapest I., Budafoki-út 13.

MENDEL'S EXPERIMENTS WITH PEAS.—In adverting incidentally to this subject some time since we omitted to state, what indeed we did not then know, that it was Mr. DRUERY who first called the attention of the Royal Horticultural Society to the matter, and it is to him that we are indebted for the translation of "Mendel's Memoir" which appeared in the Journal of the Society, and which was afterwards incorporated in Mr. BATESON'S work entitled, *Mendel's Principles of Heredity*.

THATCHED ROOFS.—We frequently see in representations of Japanese scenery thatched cottages from the roof of which are growing tufts of Iris tectorum. Mr. H. C. DAVIDSON, in the *Morning Leader*, suggests that a trial should be made with this Iris in suitable situations. We have no doubt many plants might be grown under such circumstances in this country, but we do not think we could manage to grow Pineapples on our thatched roofs, such as were once figured in our columns.

CEPHALIPTERUM DRUMMONDI. — American papers are singing the praises of this West Australian Composite, seeds of which have just got into the hands of Mr. BURBANK, who has raised "improved" varieties by selection. The flower-heads are of a pink colour, which is retained in drying, so that they are likely to be used for ladies' millinery. Mr. BURBANK is quoted as saying "that the largest millinery establishment in the world has, after examining the flower with great care, desired me to hold it for him (*sic*) without regard to price." West Australia and the Cape abound in "everlasting" flowers of a similar character.

"VARIATION OF ANIMALS AND PLANTS UNDER DOMESTICATION."—When the *Origin of Species* was first launched upon a then unsympathetic world it was felt by its author, as by the public, that the evidence upon which the theory of evolution was based should be made public. As a result Mr. DARWIN published two volumes under the above title. These volumes were packed with details from all sorts of sources, arranged with great skill and scrupulous fairness, to support the author's views. Horticulture was very largely drawn upon, and the scattered notes in the horticultural press, especially in the columns of the *Gardeners' Chronicle*, were utilised and co-ordinated in a manner that gave great satisfaction to both the writer and to the editors. A popular edition in two volumes, edited by Mr. FRANCIS DARWIN, has just been published by Mr. MURRAY at a low price, and we cannot too strongly recommend it to the notice of all interested in the philosophy of horticulture. Practical men who concern themselves with facts only will find that these volumes constitute a perfect encyclopædia of facts and of references, set forth with that impartiality and freedom from bias which were so characteristic of the great naturalist.

SEED LIST.—We have received a list of seeds offered for exchange by the Imperial Botanic Garden, St. Petersburg. Those wishing to benefit by it should make immediate application, addressed to Prof. Dr. FISCHER DE WALDHEIM, Director.

STATE HORTICULTURE IN AMERICA. — The General Assembly of the State of Rhode Island has been asked to appropriate 15,000 dols. for a greenhouse at the Rhode Island College of Agriculture and Mechanical Arts at Kingston. At the annual meeting of the Board of Managers of the New York Botanical Garden, Dr. BRITTON called attention to the rapidly-filling greenhouses and to the advisability of planning for the construction of another range of houses, which should have a floor area of at least as great as the present range, to be erected to the eastward of the Bronx River. The report of President H. H. GOODELL to the trustees of Amherst Agricultural College recommends the addition of a number of horticultural buildings, and it is understood that the trustees will recommend to the Legislature immediate permanent improvements at a cost of over 100,000 dols. This includes 3,200 dols. for an addition to the greenhouse of the entomological department; 39,500 dols. for erecting and equipping a new building, and 14,000 dols. for a new greenhouse in the horticultural department; 35,900 dols. for a new building in the botanical department; and enough additional money to connect the botanical and horticultural buildings with the heating plant. *Horticulture.*

"CASSELL'S POPULAR GARDENING" is now completed by the issue of the twenty-fourth part. It is well got up, abundantly illustrated, full of useful hints, and provided with an excellent index, as well as a table of conteuts, the latter rendered specially necessary by the plan of the work.

PUBLICATIONS RECEIVED.—*Agricultural Bulletin of the Straits and Federated Malay States.* Edited by H. N. Ridley, November, 1904. Contents: Layering Rubber Trees, Experimental Rubber Tapping at Singapore, Asclepias curassavica, &c.—*Annual Report of the Bureau of Industries for the Province of Ontario*, 1903. Part I. Agricultural Statistics; Part II. Chattel Mortgages.—From the University of Illinois Agricultural Experiment Station. Bulletins No. 96: *The Testing of Corn for Seed*, by A. N. Hume; and No. 97. *Market Classes and Grades of Swine*, by W. Dietrich.—*Peat and its Products*, an illustrated treatise on Peat and its products as a national source of wealth, by W. A. Kerr, V.C. (Publishers, John Smith & Son, 19, Renfield Street, and 225, Ingram Street, Glasgow).—From the Midland Agricultural and Dairy Institute (Kingston, Derby), Bulletins for 1904. No. 1. *Report of an Experiment with varieties of Potatos at Friskney, Lincolnshire*: No. 2, *Report on Field Trials on the Manuring of Seeds, Hay*: No. 3, *Report on Tests of Varieties of Potatos at Althorpe*: No. 4, *Report of Experiments with Barley in Lindsey, Lincolnshire*: No. 5, *Report on Field Trials on the Manuring of Mangels.*—*Farmer and Stockbreeder Year Book*, being the Farmer and Country Gentleman's Almanack for 1905. We note articles herein on the Rating of Agricultural Land, by T. C. Jackson; How New Varieties of Potatos are Produced, by Mr. Findlay; and the Renovation of English Orchards.—*Transactions of the English Arboricultural Society*, vol. vi., part 1, compiled by Mr. J. Davidson. Contents: Management of Hedges, by Mr. T. Conway; Formation of a Crop of Larch, Mr. Wylam; Production of Coniferous Timber, Mr. Anderson; and Notes on Japanese Larch, by Sir Hugh Beevor and Dr. W. Somerville.—*The Agricultural Journal of the Cape of Good Hope*, February. Contents: Extra-tropical Forestry, Irrigation in the North-West, a Late Cape Orange, &c.—From the Cape of Good Hope Department of Agriculture: *Report of the Government Botanist and Curator of the Herbarium for the Half-year ending June*, 1904. Dr. MacOwan reports favourably upon the progress achieved.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

EPIPHYTES IN ENGLAND.—At the general meeting of the Linnean Society (see *Gardeners' Chronicle* for February 11), in a discourse on "Botanical Collecting," Dr. Augustine Henry, F.L.S., said that the assertion in text-books that epiphytes of the higher types than Ferns do not occur in Europe is too sweeping, and the celebrated traveller gave several instances of epiphytes occurring in our islands. At Pencarrow we have several interesting instances of shrubs growing on large trees. Seedling Rhododendrons, apparently ponticum, occur in two cases: one plant shared with a 2 feet high Yew a fork in an Oak tree fully 35 feet from the ground. A cluster of young plants nearly a foot high is growing on a Catalpa bignonioides. For many years the trunk of this tree was encircled by a large clump of Rhododendron ponticum; four years ago I cut it down, exposing some tiny seedlings on the Catalpa. These have since grown steadily, and are quite healthy. At the time I feared the exposure to sun and air would be fatal. For several years—three at least—a Bramble has been living 20 feet from the ground in the fork of a large Oak. The Bramble, probably Rubus fruticosus, makes luxuriant growth, but does not flower; no doubt the summer shade is too dense. Curiously enough these instances, which occur in a valley alongside a large artificial pond fed by a stream, are within 100 yards of each other. Here there is of course plenty of atmospheric moisture, but it must not be supposed that North Cornwall possesses the "moist, warm climate" of many parts of Ireland and of the West of Cornwall. Here we get but little benefit from the Gulf Stream. Last year's mean temperature was but 48·47° Fah., and the temperature for the past week has ranged from a minimum of 22° to a maximum of 44°. Amid slightly drier surroundings an Ivy is growing on a Plane-tree in a hole made by the loss of a medium-sized branch. In the first instance the Ivy grew up the tree from the ground at its foot; on reaching this moist receptacle for dust and vegetable *débris* it evidently stayed and rooted. Five years ago the Ivy was cleared from around the Plane, and since then this Ivy has had an independent existence. Cotyledon Umbilicus grows abundantly on many hedges, walls, &c.; but except for a few clusters on the stems of some old Currants trained against a north wall, I have never seen it as an epiphyte. Ferns growing on large trees are, of course, very common; but the common Polypody largely predominates. *A. C. Bartlett, Pencarrow Gardens, North Cornwall.*

SWEET-SCENTED SHRUBS.—In addition to Lilacs, Azaleas, and other favourites, the following species are well worth growing:—Clethra alnifolia, C. canescens (thrives in peaty soil or loam), Comptonia asplenifolia (having fragrant leaves, and growing 3 to 4 feet high; it delights in peat and requires slight shade). Calycanthus floridus is hardy here, also Laurus Sassafras. The evergreen Choisya ternata requires in most localities a sheltered place or a wall. *W. A. Miller, Underley Gardens, Westmoreland.*

FRUIT-GROWING IN BRITISH COLUMBIA.—The lecture on this subject delivered to the Fellows of the Royal Horticultural Society on the 28th ult. by the Agent-General for British Columbia, was as remarkable for its omissions of matters of great interest to his hearers as it was for such information as it gave. Specially was nothing said as to the pecuniary conditions under which land was held; what were the average rates and taxes per acre, cost of labour, and general cost of transit per ton per mile for the fruit. The lecturer spoke in strong deprecatory terms of what he in fiscal phrase described as the "dumping" of fruit into British Columbia from the United States. Prior to the expansion of fruit culture in that Colony, he had nothing but praise for the same thing, which he is pleased to term "dumping; but does not call it so when his Colony pours great quantities of fruit into Great Britain. But then, doubtless, to buy is evil, to sell is good. Not long since one of our great fruit-growers and a member of the Council of the Royal Horticultural Society declaimed against this "dumping," and said that only a duty placed on imported fruit would give the home grower a chance. Would it matter one atom to this oppressed person if the "dumping" were of United States or Canadian origin? In a conversation I had with Mr. Turner after the lecture I found that the greater number of the fruit-growers of British Columbia plant on their own freeholds, land having been furnished them free as grants by the Colonial Government. What wonder is it then that fruit can be sent here in great abundance and be sold very cheaply? We have nothing at all in this country so far as fruit-land is concerned that can at all compare with such tenure as exists in British Columbia. Here fruit-land is costly if purchased, and rents are high, whilst conditions of tenure are oppressive or uncertain. Mr. Turner said that a gentleman in the room had paid as much as £30 per acre for land in the colony, and he regarded that a higher price than would be paid in this country. I should like to learn of good fruit-land that could be purchased at that price per acre here. As to labour the few pictures really depicting fruit-growing shown by the lecturer rather indicated that very much less was expended on that element in fruit-growing there than is the case here. Railway transit also is far cheaper in the Colony. But it is evident if our fruit-growers wish to compete with colonial fruit in our markets they must

proceed on lines that will enable them to put into trade fruit superior in size, in appearance, and especially in succulence and flavour, to that imported. Only in that way can the severe competition now experienced be satisfactorily met. *A. D.*

SEED-PODS OF PHYSIANTHUS ALBENS AND JASMINUM OFFICINALE.—I am sending to-day a seed-pod of Physianthus albens from a plant growing in the open in South Devon. I believe the fruiting of this Brazilian climber in the open to be rare, though I have met with it bearing seed-pods in two other cases. When first introduced into this country Physianthus albens, which has also been known under the names of Araujia albens, A. sericifera and Schubertia albens, was treated as a stove plant. Later it was introduced into the conservatory, and now it is found to be perfectly hardy in the open in warm positions in the south-west. The somewhat small, urn-shaped, white flowers are generally borne in the late summer, but the plants remain in bloom for a long time, and the specimen from which the seed-pod was cut was still in good flower in December. The blossoms prove a trap for insects, hundreds of humming-bird hawk-moths being caught by their long probosces during the hot weather. The plant in question is growing on the front of a house on the river Dart, about five miles from its mouth, and faces south. The plant has reached to the eaves, and is annually cut close back in April. It has fruited for the past three years, many of the seed-pods being considerably larger than the one forwarded. I also send fruit of the common Jasmine from the same garden. The fruiting of this species may not be a rare occurrence, but I never remember having met with it before. This has also seeded for the last three years [see figure of the fruit of this species in the *Gardeners' Chronicle*, Jan. 18, 1896, p. 80. Ed.]. The garden is remarkable for the number of plants that ripen fruits. Eugenias, Myrtles (both large-leaved and small-leaved), shrubby Veronicas, and Cotoneaster rigida spring up in numbers from self-sown seeds. It was in this garden that the Mint-scented form of Aloysia citriodora (the so-called Lemon-scented Verbena) appeared. The Mint-scented branch, which has been extensively propagated from, on the original plant is still alive, and its perfume is quite distinct from that of the remainder of the bush. *S. W. Fitzherbert.* [The fruit of the common Jasmine has been figured in the *Gardeners' Chronicle*. Ed.]

FACTS AND FANCIES IN FORESTRY. — The interesting note under this heading at p. 44 leads me to say that the finest specimens of Larch I have ever seen, not excepting the famous Dunkeld trees, were growing in shallow soil overlying limestone of great depth in the Coolbanagher and Corrig (Spire) woods situated some 4 miles apart on the Emo Park Estate, the latter woods towering high above and within a few hundred yards of the Portarlington Station, on the main line of the Great Southern and Western Railway from Dublin to Cork. The hill, owing to its high altitude and conical shape, and to the fact that the spire of some old temple protrudes a considerable distance above the summit, forms a landmark for many miles around. The Coolbanagher Wood also occupies a high situation, the shallow soil of a light, open nature covering the surface of the solid limestone rock to the depth of from 9 to 18 inches. Notwithstanding these apparent drawbacks to tree-growth they have attained to good size and dimensions, the trunks being straight and of great thickness, and in great demand by timber merchants. Larch and Fir are naturally surface-rooting trees, though in the circumstances indicated they had no option to be otherwise. The large number of Fir and Larch-trees met with in the process of cutting peat for fuel in the Irish bogs present in every case a mass of large, horizontal roots attached to the buried trunks, which have remained sound for centuries past. But specimens of the Larch growing excellently under conditions the reverse of those described above may be mentioned. These trees are growing on the banks of the river Barrow, about 48 miles from Dublin, at a point where the river divides the King's and Queen's Counties, some 2 miles east of Portarlington, on the Wilmott-Chetwoode estate. Here the trees occupy a low, moist tract of land, about 300 yards in width, bounded on the one side by the Barrow, and on the other by the canal running from Dublin to Mountmellick; the soil, overlying a gravelly formation, is loamy, moderately rich, and deep, as the fine timber growing thereon testify. These trees I have not seen for a quarter of a century or so, and if they are still standing must be magnificent specimens. Thus, some timber trees will flourish and attain large dimensions under opposite conditions, and separated but a few miles. *H. W. Ward.*

"DRIP" IN PLANT HOUSES.—We enclose a section of the bar (see fig. 63) which we have used for over thirty years, and which has answered admirably for this purpose. You will note that the grooves are worked in the solid, and this we consider essential, as however carefully

Fig. 63.—Messrs. Foster and Pearson's improved glazing-bar.

the drip piece may be put on, it is sure to open at the joint in time and lead to decay. All houses, whether for fruit or plant culture, should be fitted with drip bars. *Foster & Pearson, Ltd., Beeston.* [It will be observed that this method is only practicable when building new houses or replacing roofs. Ed.]

—— Referring to the letters and illustrations which have appeared recently in the *Gardeners' Chronicle* in reference to the question of the prevention of drip, we send you a section through the glazing-bar (see fig. 64) which we have now

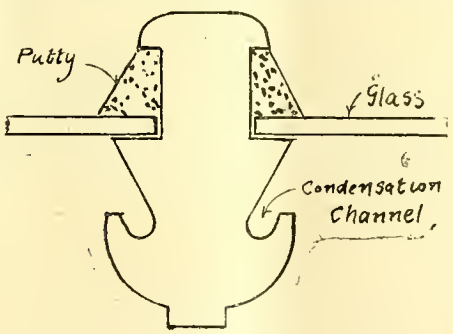

Fig. 64.—Glazing-bar used by Messrs Richardson and Co.

used for a number of years. "Prevention is better than cure," and as you will see we provide a channel which is part of the bar itself, and formed when it is put through the machine for carrying away the condensed moisture from the under side of the glass. You will notice also that a cap is formed on the top of the bar, and the putty is fitted in underneath this cap so that it is impossible for the weather to get to the back of the putty and cause it to shell off. No doubt the devices illustrated by your correspondents are excellent for remedying an existing defect, but in the erection of new glasshouses it is well to see that a bar such as we have described is used so that there need never be any fear of damage being caused to plants by drip. *W. Richardson & Co., Darlington.*

PINUS INSIGNIS (see "Enquiry" on p. 96).—This Pine succeeds best when planted from pots. Those plants received from the nursery with the roots tied up in sacking, and the advice to plant them with the sacking remaining on the roots, was given for obvious reasons—viz., to prevent what soil there was leaving the roots. To plant this Pine without any soil adhering to the roots is to court failure. *T. H. Slade, Poltimore Gardens, Devonshire.*

HIMALAYAN RHODODENDRONS AT SINGLETON. —I was much interested in reading on p. 136 the notes on the beautiful trees at Singleton. Doubtless these varieties are much hardier than they are thought to be by most growers. We have plants of R. Falconeri, R. Thompsoni, R. arboreum roseum and R. a. album, which I brought from Cornwall four years ago. They were planted by the side of woodland walks, where shelter was provided by large masses of R. ponticum. During severe frost additional protection has been afforded by placing branches of R. ponticum around the plants, thrusting the ends into the ground so that the branches lean inwards over the plants. The growth each year has been most satisfactory. If a good Rhododendron soil is provided, and shelter is afforded from cold winds, I feel sure many of these varieties may be successfully grown in the home counties. At the present time we are cutting large branches of R. Nobleanum in flower for decorative uses from plants grown in sheltered nooks out of-doors. *Chas. Page, Dropmore Gardens, Bucks.*

APPLE TOWER OF GLAMIS (see p. 69).—This Scotch Apple succeeds well here also (Hants), and I have had it grow well and crop heavily in Yorkshire and other places. Its habit is somewhat of a semi-weeping character, and is very suitable for cultivation as a standard tree in a grass-covered orchard. Those who require a real good kitchen Apple having fruits of medium size and good quality cannot do better than plant this variety. As Mr. Yates advised, do not prune it much, but allow the branches to grow freely, merely thinning the branches out to admit light and air. *E. M., Bishops Waltham.*

MR. PETER FISHER.—I was pleased to see on p. 121 that my old friend, Mr. Peter Fisher, is still alive and doing well. He came to me from the Duchess of Atholl's gardener in July, 1880, and he stayed with me till November, 1882. He was the most persevering and painstaking young man I have met in over fifty years' experience. These were the days of flower shows, when we were able to grow good specimen plants, fruit and vegetables in London, and I advised him to go into some large place in the country, where he would see vegetables and hardy fruit well grown in abundance. He was sent to Mr. Pease, of Hutton Hall, Yorkshire, where he stayed about two years, he then returned to me having the wish to go to America, and I persuaded him to do so. He obtained a situation at Mount St. Aubern, near Boston, where he stayed a few years. He used to write to me to get him seeds of different things, but he was most anxious about Amaryllis, Carnations, and Cyclamen, which we had at St. Dunstans, I gave him of my best. He then opened the Mount Vale Nurseries at Boston, U.S., called Fisher Brothers, and used to send to me to procure him large quantities of seeds of Cyclamen, Carnation, and Primula seeds; and several years after he wrote to say he had sold his share in the Mount Vale Nurseries, and was opening one at Ellis, near Boston, as a Carnation specialist. Two and a half years ago he paid me a visit of some duration, and brought his wife and family. Mrs. Fisher having formerly lived in St. John's Wood. He was very careful to carry back with him some of the standard Carnations and Amaryllis of twenty years ago. Therefore not only the men, but some of the best seeds have gone to America from London. *Richard Butler, gardener to Lord Aldenham, St. Dunstans, Regent's Park.*

TSUGA MERTENSIANA AT SINGLETON. — Can Mr. Harris state the date when the fine Tsuga Mertensiana (Albertiana) mentioned on p. 136 was planted; also the girth of the trunk at 5 feet from the ground? This I imagine must be one of the finest specimens of the species in this country. We have a fine specimen here, but it is not yet 80 feet high. *C. Page, Dropmore Gardens, Maidenhead.*

FRUIT PROSPECTS AND THE STORAGE OF APPLES.—With me Pear and Plum trees are making a grand show for flower. Some of them are rather dangerously forward, but this spell of cold weather, by keeping the fruit buds back, may possibly be the means of saving them. In this country our prospects of either fruit or no fruit entirely depends on the severity and frequency of frosts during the flowering season. My Apples, which were stored in a cool, dry cellar, have kept splendidly, and I believe a cellar is the very best place for storing them. I know Apples are often placed upon the wooden floors of a garret, especially by farmers who have no proper fruit-room, and where they soon get withered; but many fruit-rooms that I have seen filled belonging to even good gardens were little better calculated to keep fruit in good condition than is the farmer's garret. *W. M., Berkswell, February 27.*

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—The remarks of "A Fellow" upon the *Journal of the Royal Horticultural Society*, in your issue of March 4, move me to leave for once the ranks of the "quiescent" Fellows, for whom he claims to speak. Very probably many Fellows, especially those able to frequently attend the shows of the Society, find themselves amply repaid for the value of their subscriptions by other privileges, and leave their *Journals* unread. If so, they lose much, and the depth of their horticultural interest stands condemned by their neglect. Fellows with a genuine vital interest in horticulture and all that concerns plants are the most worthy of consideration, and they will not be amongst those whose numbers of the "Journal are put on one side and never looked into." Even those whose interest is not sufficiently great to lead them to study the more scientific papers can read the table of contents and select what is to their taste. The various articles are naturally of unequal value, but they are all worth careful reading, and they are not long. Much of the "Extracts from the Proceedings of the Society," &c., are not of a kind to be read through, but are valuable for reference. With regard to the question of cut or uncut edges, uncut seem to me more in keeping with the character of the publication. "Busy people" will "manage to read" about any subject in which they are really in earnest, and if that subject be plants they will find a mine of delight in the *Journal of the Royal Horticultural Society. M. I. W.*

—— "A Fellow," see p. 138, is well within his rights in criticising the Journal. His first complaint is as to the issue of the parts in an uncut state, because "a few are permitted to dominate the Council," and suggests "that the labour in cutting the leaves is too great for busy people to undertake." One can scarcely believe there are such lazy people in existence. It must be too much trouble for them to cut a Rose-bud, or pour water into a flower-pot. I had an uncut copy before me when I read the Fellow's remarks; I sent for a bread-knife and deliberately cut all the leaves in seventeen minutes. I hope more than "one in a thousand" of the Fellows think it a pleasure to cut the leaves of their copies. If the copies were sent out "guillotined," to use "A Fellow's" elegant expression, the Council would be designated barbarians by hundreds of Fellows, and our worthy Editor would have a bad half-hour at the annual meeting. If some of the Fellows know nothing about books, they need not let everybody know it. The December issue of the Journal is full of varied and useful information. Goodness only knows what "A Fellow" would like to cut out! Perhaps he would begin with Dr. Cooke's excellent papers on "Pests of the Shrubbery;" but even Fellows who do not grow shrubs must be grateful to the veteran who is giving us the result of sixty years' labour. Again, who can write so well upon Himalayan Rhododendrons as Sir John Llewelyn, who grows them so well in his own garden? A new writer comes next, Mr. W. T. Hindmarsh, and his paper is so interesting that, like little Oliver Twist, we "want some more." Are there any of us who are not grateful to M. Viviand-Morel for his careful paper on the genus Rosa? Mr. Leake's papers on the Indigo-plant must be of immense value to those interested in the valuable dye obtained from it; and it all adds to our universal stock of knowledge. In fact I have looked through the papers, and have no complaint to make of any of them. Reviews of books and short notes are useful and interesting. I have all the Society's publications, from the first volume of the *Transactions*, published in 1812, until the present time, and do not hesitate to assert that none of the publications in the past is equal to the Journal now being sent out. There is no need to go into the matter of cost; the Council can be entrusted with that. There are three parts in the present issue, and only one part more will be required for the supply of one year. One editor is enough, and I for one sincerely trust that the Rev. William Wilks may long be spared to continue the work in the future he has done so well in the past. I fear if such editors as "A Fellow" were to have any share in the work of cutting down the papers and "guillotining" the leaves of the parts before they were sent out, stormy scenes would follow, and one might safely predict that the present gratifying access of Fellows would not continue; but there will always be a few who cannot let well alone, and must needs find something to talk about, or to ventilate their supposed grievances in the horticultural Press. *Jas. Douglas.*

MANURE FOR PEACH-TREES.—On p. 139 "A Reader" stated that when the fruits have been gathered no more manure should be given to Peach-trees. There is no doubt that trees are greatly benefited by watering with diluted manure-water after the fruit has been gathered, also in the winter months should they require watering. I think the practice of watering with manure-water and washing-in with clear water, or *vice versâ*, is not a good one, it being then most difficult to estimate the amount and strength of the manure-water each tree receives. The most satisfactory way is to dilute, say, 6 gallons of manure-water with 30 gallons clear water, using it stronger or weaker at discretion. *J. S. Higgins, Rug Gardens, Corwen, Wales.*

—— Replying to a note by "Reader" on p. 139 of the *Gardeners' Chronicle*, I may say that I afford Peach and Nectarine trees, whether growing under glass or out-of-doors, root waterings with farmyard manure-water at intervals during the resting period. This practice is followed with the best possible results, and there is not the least injury done to root fibres, although it is only when the manure-water is above its usual strength that we dilute it. I advised that the trees should be examined because of the drynesss of the season, which rendered it imperative that the borders should be examined before the trees came into flower. Manure-water at this time would add much strength to the flowers and vigour to the young fruits. A practical man would not give strong stimulants to an actively growing tree which has become dry at the roots, but at this season of the year there is no risk by doing so. At the same time no one would apply stimulants to a vigorous tree which had not a prospective crop. Manure-water is rich in nitrogen, and that from the stable contains almost double as much as does liquid-manure from the farm-yard. Nitrogen in some form or other is essential to Peach and Nectarine trees, and I have not yet found it to excite the trees to make growth too early. On chalky soils and soils containing sufficient lime, if a dressing of freshly-made wood ashes be applied in the autumn to provide potash, no more suitable manure than liquid from the farm-yard or stable can be found. "A Reader" states that no manure should be given the trees after the crop has been gathered, but I say, on the contrary, that a tree whose vigour has been reduced by perfecting a crop of fruit needs manure to help it to build up and perfect the buds, and render it in a condition for yielding a good crop in the following season. Trees so treated, I believe, yield superior results, but varieties which ripen their fruits late in September should not be treated so liberally afterwards. Apart from the many commercial fertilisers which I use, the following combinations of my own compounding have proved very beneficial. They are applied to the trees four times at least during the season. A mixture of nitrate of soda and superphosphate was followed by a crop similar in all respects to that obtained after using superphosphate and muriate of potash. Nitrate of soda should be used on light sandy loams, and sulphate of ammonia on heavy or retentive soils. The above manures containing potash encourage the formation of fruit-buds, but a certain amount of nitrogenous manure must be added to promote growth, without which bud-formation could not take place. The best all-round fertiliser for Peaches and Nectarines I have yet mixed is one of muriate of potash, superphosphate, and sulphate of ammonia. If "A Reader" will call here he will see that the strength and quantity of flowers the trees now carry, and the size and quality of the fruit that will ripen later, perfectly justify my practice. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

CONTINENTAL LABELS.—In answer to the enquiry on p. 144, I may say that in five nurseries in Germany, Holland, and Belgium where I was employed some years ago, yellow ochre mixed with linseed-oil into a thin paint was used for colouring wooden labels. *Walter Ingwersen.*

CUCUMBERS.—It would be interesting to know the importance Mr. Owen Thomas attributes to the fertilisation of the Cucumber in the production of saleable fruit; compared with that of using sulphur as a prevention for "spot," considering the sulphur proved effective? *G. H. H. W.*

AGAVE AMERICANA CAUSING SKIN IRRITATION [see also p. 158 for note on Daffodils causing similar irritation — in both cases from raphides. ED.].—In the *Gardeners' Chronicle* for January 20, p. 14, there was an article on "Skin Irritation," caused by the incautious handling of certain plants such as Rhus Toxicodendron, Primula obconica, and others. I did not see Agave americana mentioned, and it may not be generally known that the sap or juice of this plant causes intense irritation. On January 20 I had to take down two large Agaves that had recently flowered on St. Michael's Mount, Cornwall, and as they were too large to be brought through a doorway we had to cut them up, for which purpose a small axe was used, and the sap or juice getting on our hands caused intense irritation. One of my assistants who incautiously rubbed his face and neck with his hand suffered severely for a short time. I may mention the height of one of the flower stems was 24 feet. The other plant had evidently received an injury in the centre at some time, for instead of throwing up a single flower-stem, it threw up several small flower-stems from the axils of the leaves, and on cutting up this plant I found the centre ot be rotting. *W. J. P.*

SPICE APPLE.—I herewith send specimens of an Apple, known locally as Spice Apple, which I presume comes from D'Arcy Spice. It is of good flavour, and has been fit for use since Christmas, but is just now going past its best. The variety appears to be little known, but in good seasons bears heavy crops on a standard tree in the orchard here. Wellington, or Dumelow's Seedling, has been good this year from standard trees in the same orchard, and the fruits are in good condition at the present time; I enclose specimens. The highly-coloured Apple sent herewith sells well in the market early in the season; the flavour is poor, but the fruits certainly keep well. It is known locally and in Devon as the Bloody Butcher. Norfolk Beefing is in good condition still, and is also of splendid colour. *Geo. A. Head, Kingsdon Manor Gardens, Taunton.* [The fruits first mentioned by our correspondent are of the true Spice Apple described in Hogg's *Fruit Manual*, not D'Arcy Spice, the fruits of which will keep good much longer. The Dumelow's Seedling fruits are as fresh in appearance as when gathered, whilst those of Bloody Butcher are as useless, owing to their wretched flavour, as they are handsome. ED.]

EARLY PEACHES.—As I wrote to the *Gardeners' Chronicle* some two or three years since giving my experience of the earliness of the Alexander Peach, I should like to say a few more words in its favour. I have grown this variety for many years past,

and have not, up to the present time, found its equal for earliness in ripening its fruits. Planted at the warmest end of the early house, which is generally started on December 15, it never fails to bear a heavy crop of good-sized, well-coloured fruits, which we are generally able to gather from April 15 onwards. This variety is followed by Rivers' Early Nectarine. Next in order of ripening comes Early Louise Peach, which, with us, carries quite large fruits. Then follow Peaches Early Alfred and Early York, succeeded by Lord Napier Nectarine and Condor Peach. These trees are all growing on a curvilinear wire trellis occupying the whole of the front of the house, the back wall being covered with trees, of Royal George Peach and Elruge and Victoria Nectarines. I have tried Waterloo for an early crop, but failed with it. Alexander however never fails to carry a crop of fruit with us. Waterloo planted in a second early house, started January 15, invariably carries a fair crop of fruit. Although these American varieties are liable to bud-dropping, yet I find them retain sufficient to produce a good crop of fruit. Peach-borders never ought to be allowed to become dry at any time of the year, as this is in a great measure the cause of a deal of bud-dropping. After the fruit is gathered, the trees should be exposed and hardened as much as possible in the autumn and early winter months, up to the time of closing the house for forcing. I always apply a good dressing of lime to the borders annually, and this I find is a great help to the trees, enabling them to strengthen and retain their buds, so that we do not suffer from bud-dropping to any great extent. Our second house contains trees of Dr. Hogg, Waterloo, Princess of Wales, Royal George, Barrington, and Noblesse Peaches, Rivers' Orange and Lord Napier Nectarines. Our latest house, which is much longer than the other two, contains almost all the later kinds of Peaches and Nectarines, including Apricots. Even in this cold, wet, sunless district we generally manage to gather Peaches from the middle of April into September from trees under glass. *Edward Ward, Longford Hall Gardens, Manchester.*

—— Mr. Divers, on p. 125, stated that dryness at the roots will cause any variety of Peach to drop its buds. I dispute that statement, and am very doubtful if dryness is the cause, or would be the cause, of any variety dropping its buds. So convinced am I that dryness is not so frequently the cause of bud-dropping as is generally supposed, that only last year I allowed a young tree of Early Rivers Nectarine to get as dry as it could be, until it was almost in flower, and not a single bud was dropped, and the tree ripened 254 good fruits. I do not by any means advocate dryness at the roots for Peaches, and take it for granted that no practical gardener will withhold water during active growth. I believe I have read in the *Gardeners' Chronicle* every year for at least twenty years that dryness was a cause, if not the chief cause, of Peach-trees dropping their buds, and yet we hear as much of the bud-dropping as ever. I have ripened fruits of Hale's Early in the first week of May in Yorkshire, Forfarshire, and Northamptonshire, and I was always troubled with buds dropping more or less. I attribute the dropping chiefly to premature ripening. Hale's Early and Alexander are generally grown in early houses with a south aspect, and the young shoots are regularly tied down to expose the fruits, and to get them to ripen as soon as possible, consequently the wood gets roasted with the fierce sunshine during the latter end of May, June, and July. Some years ago I tried shading the glass as soon as the fruits were gathered, and allowed the shoots to grow without being tied down, and although it did not prevent some of the buds from dropping, I found a marked improvement; but I have not had an opportunity of further experimenting with very early trees. I cannot agree with Mr. Slade that Hale's Early should be classed as only second-rate in flavour. I think a well-grown fruit of Hale's Early is hard to beat. I have obtained as much as 30s. and even 36s. per dozen for them (wholesale) in Covent Garden Market. Several of these fruits were over 10 oz. in weight, and the flavour all that could be desired. *George Duncan, The Gardens, Merstham House, Merstham, Surrey.*

NOTICES OF BOOKS.

THE BOOK OF THE LILY. By William Goldring. (John Lane. 8vo, pp. 98.)

The author of this attractive little volume reminds us that no one, whatever be his qualifications, can know all there is to be known about Lilies. He further alludes to the varied climates and conditions under which they grow naturally, and says that in no part of the world is there a garden where all the Lilies would thrive to perfection—that ideal is not to be realised. However true that may be, there are two factors which come into play in enabling us to make the best of circumstances—one is the natural powers of adaptation possessed by the plant; the other is the faculty inherent in or acquired by the gardener of finding out by experiment and judgment just what those powers of adaptation are and how they may be fostered in practice. From this point of view Mr. Goldring needs to make no apology for writing about Lilies. If he does not know all about them, at least he knows more than most do, and his lengthened experience and balanced judgment render him an authoritative guide. Bulbs with thick fleshy scales, which only cover a small portion of the axis, are more difficult to cultivate and more susceptible to injury than bulbs with thin membranous scales which envelop the whole axis, and thus afford a greater amount of protection to the central bud or axis, and prevent the subjacent scales from drying up by exposure. The formation of a root-stock or rhizome, from which the bulbs are produced in some of the species, and the different manner in which the roots are emitted in different species, are also points that demand the attention of the cultivator. The author takes each species in its alphabetical sequence, gives a condensed summary of its characteristics, but devotes more space to its cultural requirements. The Madonna Lily, L. candidum, the longest known and, taken for all in all, the most beautiful species, succeeds in a cottage garden, whilst it is a failure in many an establishment of greater pretensions. The author attributes the failure, with some hesitation, to some fungoid disease. We do not think there is any reason for doubt as to this point. Further, Mr. Goldring tells us to leave this Lily alone when once established, as it much resents disturbance at the roots. "Cottagers do not disturb the bulbs, and that is why they succeed where gardeners fail." In our own case a tuft of white Lilies has been grown in the same spot for more than thirty years, with as little disturbance as could be experienced in any cottage garden, but only on one or two occasions has any flower been produced. In winter, however, the rich green of the foliage where all around is bare is most attractive. Martagons, ordinary and scarlet and Fortune's variety of tigrinum do well in the same garden, even though subject to more disturbance. For cultural purposes Mr. Goldring divides the Lilies into two groups, according as they require a moderately stiff soil and full exposure to the sun, or a peaty soil and shady situation, whilst a third group includes those that revel in a deep sandy peat soil that is naturally moist but not sodden, and where the aspect is partially shaded.

Some very judicious remarks are made as to the planting of Lilies in the open garden in association with Rhododendrons or other shrubs. This is a chapter particularly worthy of study by those intending to plant Lilies, and a similar comment may be made as to the chapter on planting Lilies, which gives evidence that the natural habit of growth of each species has been carefully noted in relation to the best methods of cultivating it.

The book ends with a complete list of the species and varieties in cultivation. There is a table of contents, which, with the list before given, to some extent obviates the necessity for an index, especially as the arrangement of the species is mainly alphabetical. There are numerous illustrations, so that the book is one which every lover of Lilies will desire to see on the most accessible shelf of his library.

TREES: A HANDBOOK OF FOREST BOTANY FOR THE WOODLANDS AND THE LABORATORY. By H. Marshall Ward, &c. Vol. 2, "Leaves:" (Cambridge University Press—C. J. Clay & Sons).

We are delighted to see that the second volume of this series amply confirms the good opinion we formed of the first. Whether we look upon the leaf from a morphological standpoint and as a most valuable asset in our systems of classification, or whether we consider it from the physiological side as the laboratory and workshop wherein are carried on those intakes and those outpourings, those combinations and recombinations, those buildings-up and those resolutions which constitute essential features in the life of the plant—in whatever way we look at it indeed the leaf is seen to be all-important.

Professor Marshall Ward before now has shown that he is no mere laboratory student, tied down to the intricacies revealed by the microscope or the test-tube, and no mere scrutineer and classifier of forms and dispositions as revealed in the herbarium, but he takes broad, general views, not disdaining or ignoring any department of botanical study, but giving to each, as far as circumstances will allow, its proportionate share of attention.

In the present work we have first a study of the leaf in general, of its form, structure, and functions, and secondly a classification of trees and shrubs according to the characters of the leaves. This portion is specially intended for foresters and gardeners who require to ascertain speedily the name of a particular tree without special reference to its botanical affinities. The classification, that is to say, is in a high degree arbitrary and artificial; thus on immediately succeeding pages we have the Clematis, the Elder, the Ash and the Horse-Chestnut. The juxtaposition of the Gueldres Rose with the purple Willow (p. 179) is likely to confuse a student, as the system of venation is quite distinct, though for purposes of tabular analysis the two come on immediately succeeding pages. All this is in accordance with the exigencies of the artificial arrangement adopted and with the utilitarian requirements of the practitioner. As more volumes are promised in the future, we trust we may have some further explanations of the varying morphology of stipules, and of the reasons for the diversity of form in the leaf, for the occurrence of the same form in widely different groups, and some more detailed account of the sequence of forms in the same tree, from the cotyledon to the fully-developed leaf—a point often of consequence to the practical man and one to which the student of morphology, phylogeny and of fossil plants must needs pay great attention.

The illustrations are numerous and, together with the glossary and index, add very materially to the merits of a book which we should like to see in every garden and forest library.

Obituary.

DONALD M'OMISH.—We greatly regret to announce the death of this nurseryman, which took place very suddenly on Sunday, February 26, at the age of sixty-nine years. Deceased, who was a native of Crieff, learned gardening first under Mr. Mustard, gardener, Ferntower, and later with the late Mr. Roderick Macdonald, Drummond Castle Gardens. He afterwards became gardener to the late Hon. Captain Arthur Drummond, of Cromlix at Inchbrakie. About the year 1868 he commenced business in Crieff as a nurseryman and seedsman, renting the Currachreen Nursery.

PATRICK NEILL FRASER.—The death of this well-known horticulturist, of Rockville, Murrayfield, Edinburgh, is announced in the *Journal of Horticulture*. Mr. Fraser was Treasurer of the Royal Caledonian Horticultural Society for a period of twenty-eight years. He was also a member of the Royal Society of Edinburgh and of the Royal Scottish Geographical and Edinburgh Botanical Societies. He was particularly fond of Alpine plants and hardy Ferns, and cultivated rich collections at his residence in Murrayfield.

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 28.—*Present:* Dr. M. T. Masters, F.R.S., in the chair; Rev. W. Wilks, Dr. A. B. Rendle, Messrs. Saunders, Bowles, Hooper, Worsley, Massee, Gordon, Douglas, Veitch, Holmes, and Chittenden (Hon. Sec.).

Old Age in Plants—A letter was read upon this subject from C. B. LUFFMANN, Esq., of Victoria, Australia, who pointed out that many vegetatively propagated plants were dying out, owing to what he designated as a "prepotent tendency" and a diminishing food supply. It was decided to discuss the question, with reference especially to the Potato, at the meeting on March 28.

Henslow Testimonial.—Dr. MASTERS announced that the testimonial would be presented to Prof. Henslow at the meeting of the Scientific Committee on March 14.

Snowdrop "Sport."—A variety of the common Snowdrop, which had persisted in the same soil for ten years, was sent by Mr. J. M. RAWSON. Mr. BOWLES recognised it as Galanthus nivalis var. poculiformis, Hort.

Daffodil Poisoning (see also note on Agave on p. 156).—Mr. J. LOWE wrote stating that the gatherers of Daffodils often suffered from sore hands, and requesting some information as to a remedy. Mr. J. WALKER wrote stating that usually only those who had chapped hands, or who failed to wash their hands after picking the flowers, suffered from the trouble. The Committee were of opinion that the crystals of calcium oxalate (raphides), which are frequently in abundance in this and similar plants, were the cause of the trouble, and it was suggested that the workers should thoroughly grease their hands with tallow before picking the flowers, or should wear gloves.

Cyrtanthus lutescens.—Mr. WORSLEY showed a colour variety of this plant.

Decayed Crinum Bulbs.—Mr. WORSLEY also brought some decayed bulbs of Crinum, and described some of the organisms found in them. Mr. SAUNDERS undertook to report upon them.

Insects Injuring Pine Shoots.—Mr. WILLS wrote requesting information about a grub, Retinia buoliana, which bored into shoots of Pine and caused their destruction. This was referred to Mr. Saunders.

Leaves Decaying at Tip.—Croton and Dracæna leaves were received which were apparently injured through adverse atmospheric conditions, and a leaf of Asplenium nidus-avis malformed at tip probably through injury in its early stages.

Malformed Mushrooms.—Dr. MASTERS showed specimens of very irregularly formed Mushrooms, which Mr. MASSEE reported to be attacked by a mould Hypomyces (sp.). All such should be destroyed.

Laurel Leaves Diseased.—Dr. MASTERS also showed specimens of Laurel leaves with blisters upon them. Mr. MASSEE undertook to report upon them.

ABERDEEN AND NORTH OF SCOTLAND COLLEGE OF AGRICULTURE.

THE course of lectures instituted by this College, entitled "The Elementary Chemistry of Soils and Manures, with special reference to Horticulturists and Gardeners," was inaugurated on Tuesday evening, February 21. There was a large attendance, the lecture-room being crowded. The course, as intimated in our issue of 18th ult., will consist of six lectures.

The lecturer was Mr. James Hendrick, B.Sc., who said he felt highly gratified by the way they had turned out for that course of lectures. He had the honour of suggesting that course some time ago to the Governors of the college, and they very kindly took the matter up and made the necessary arrangements which enabled him to deliver that course. The reason why he had proposed that course of lectures was that in dealing with gardeners and meeting gardeners he had found that there were certain matters known to the agricultural chemist which might be of use in matters connected with the practical cultivation of plants. Within comparatively recent times a very great number of fertilisers—artificial fertilisers—had been introduced, and he found that very few opportunities were given to gardeners to learn about these, so that their information about them was very limited. He further found that the materials sold to gardeners and others as manures were not always what one would wish them to be. If they had a certain amount of information about these manures they might probably be able to make up manures for themselves much more cheaply, at any rate, and probably also much better than many of those things which were sold in small packages as garden, hothouse, or other manures. As an agricultural chemist, with a special knowledge of the chemistry of materials, such as manures, such materials also as were used for spraying plants, to combat their diseases and to destroy insect and fungoid pests, he came to try to give them some information which might be useful to them about these subjects. That Agricultural College wished to make itself of use to all interested in the cultivation of the soil, whether on a large or a small scale, in the neighbourhood of towns or in the distant country. So far they had been giving lectures in the country, but in this course they wished to bring information to those in the neighbourhood of the city who were interested in gardening. Mr. Hendrick then proceeded to deal with how plants grow, and how they were made up. The lecture, which was largely of a preliminary nature, was of a most interesting character. Mr. Hendrick intimated at the close that his next lecture would deal with manures.

NURSERY AND SEED TRADE ASSOCIATION, LTD.

FEBRUARY 27.—The annual general meeting of this Association was held at the offices of the Association, 30, Wood Street, Cheapside, London, on the above date, Mr. W. J. Nutting (Messrs. Nutting & Sons) being Chairman. The Report and balance-sheet for the last year were approved, and showed that several new members have joined the Association, the total number now being 193; also that the Association had answered 1,068 "status" inquiries, and expended £20 12*s.* 5*d.* in making special inquiries in relation thereto, and had recovered £3,958 (which were virtually bad debts) for the members.

The members referred to the Bill of last year for the prevention of corruption, and to the desirability of supporting any Bill for the same purpose which may be brought forward this year. The question of the sale of poisonous compounds by members of the trade was also discussed.

The financial position of the Association was considerably stronger, and efforts are being made to acquire a reserve fund to assist the members in punishing persons who improperly obtain goods, and for taking up matters which affect the trades represented by the Association.

NATIONAL POTATO.

WE are informed that the President, Sir John T. D. Llewelyn, Bart., offers a Silver Cup, value £10 10*s.*; for competition at the next show; Messrs. Carter & Co., in conjunction with Mr. Archibald Findlay, offer a magnificent Challenge Cup, value £50, together with £12 in cash. Messrs. Sutton & Sons offer £24 in cash prizes for their great Potatos Discovery and Superlative. Mr. E. J. Deal (Messrs. W. W. Johnson & Son, Ltd., Boston) offers a Silver Cup. Valuable cash prizes are offered by the following well-known firms: Messrs. Daniels Bros., Ltd., Norwich; Fidler & Sons, Reading; J. Kerr, Dumfries; Robert Sydenham, Birmingham; S. M. Thomson (Dalmeny agent), Edinburgh; William Deal, Kelvedon; Dobbie & Co., Rothesay; T. A. Searlett, Edinburgh; Professor W. J. Malden, Ham; R. W. Green, Wisbech; J. Bettinson, Wisbech; G. Massey & Sons, Spalding; H. Scott, Warminster, and others. The total value of the prizes is nearly £200, and the schedule is comprehensive and varied.

GARDENERS' DEBATING SOCIETIES.

BARNSLEY PAXTON.—This Society closed its twenty-second season of debate for mutual improvement on Tuesday evening the 28th ult., when a large company was presided over by Mr. J. Henshall, and a paper with specimens was given by Mr. John Parker on "Parsley all the Year Round." The essayist gave a very interesting and instructive discourse on this valuable plant, and marvelled how it was that gardeners did not study and take greater care in its cultivation, so that fine crops all the year round might be assured. That such a thing can be done he lucidly explained, and proved by the handsome specimens he exhibited. He also urged that the roots should have liberal applications of good farmyard-manure, and dressings of lime to prevent canker, and that in the winter months the beds should be protected by shed-screens. The plant, he said, was first introduced into England 450 years ago. A long and interesting debate followed.

PANGBOURNE AND DISTRICT GARDENERS'.—The fortnightly meeting of this Association was held at the Riverside Club, Pangbourne, on Friday, March 3. Mr. W. Grieve presided. There was a record attendance of members. The lecturer for the evening was Mr. Edgar William Dix (gardener to Sir Benjamin Baker, Bowden, Pangbourne), his subject being "Annuals and their Culture." Details of the culture of these flowers from the sowing of seed till the flowering stage was fully dealt with. Mr. F. Tugwood, gardener to Mr. D. H. Evans, staged well-grown Primulas and several dishes of Apples. *T. N. F.*

CHESTER PAXTON.—At the usual fortnightly meeting of this Society held at the Grosvenor Museum on Saturday March 4, an essay on Bee-keeping was given by Mr. John Wynne, of Rowton. Mr. H. G. Little presided over a good attendance. The lecturer gave some valuable hints on the best and most profitable methods to adopt for successful bee culture, illustrating his remarks by the aid of lantern slides. The prevention of disease in Apiaries and our importation of foreign honey were also dealt with.

NORTH FERRIBY AND DISTRICT GARDENERS'.—A meeting of the above Society was held on Wednesday, March 1, Mr. F. Reid presiding over a record attendance. A paper on "Gardening, Past and Present," was given by Mr. G. Wilson, The Gardens, Bishop Burton Hall, Beverley. The essayist dealt with work in the garden in days gone by and of to-day, dealing with and comparing the two in a very able manner. A discussion followed.

REDHILL, REIGATE AND DISTRICT GARDENERS'.—A lecture on "Orchids" was given in the King's Hall, Colman Institute, Redhill, on Tuesday evening, Feb. 28, by Mr. H. J. Chapman, gr. to Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, Northumberland. Mr. Jeremiah Colman, D.L., J.P., occupied the chair. Mr. Chapman said many persons considered Orchids in the light of plants only to be indulged in by those possessing a plentiful endowment of this world's goods. That was a great mistake. Many of the best species which fetch the greatest price are imported into this country, and realise about 1*s.* 6*d.* each. Many Orchids sold for £1,000 were originally bought for about 1*s.* 6*d.*

SCHEDULES RECEIVED.

DURHAM, NORTHUMBERLAND AND NEWCASTLE-UPON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY'S summer flower show, to be held on Wednesday, Thursday and Friday, July 19, 20 and 21, 1905. Secretary Mr. J. B. Read, Dean Street, Newcastle.

GLAMORGAN DAFFODIL AND SPRING FLOWER SOCIETY'S exhibition to be held in the Drill Hall, Cardiff, on Wednesday, April 19, 1905.

BRADFORD AND DISTRICT CHRYSANTHEMUM SOCIETY'S nineteenth annual exhibition to be held in St. George's Hall, Bradford, on Friday and Saturday, November, 17, 18, 1905.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending March 4, 1905.

1905. FEBRUARY 26 TO MARCH 4.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	At 9 A.M. Wet Bulb.	DAY. Highest.	NIGHT. Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-feet deep.	At 4-feet deep.	RAINFALL.	SUNSHINE.	
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr.	mtn.
MEANS	37	35	45	33	26	39	41	43	Tot 0·27	3	8

REMARKS.—On February 28 there was 0·03 of snow.

THE WEATHER IN WEST HERTS.

One Frosty Night.—The past week was on the whole warm, but on the coldest night the exposed thermometer registered 13° of frost, or a lower reading than at any time in February. The ground has again become warm, and is now at about an average temperature at 2 feet deep, and about 2° warmer than is seasonable at 1 foot deep. Rain, hail, or snow fell on four days, but the total measurement was less than a quarter of an inch. Each day some rain-water has come through both percolation gauges, but the amounts have been small. The sun shone on an average for a little over two hours a day, or for about an hour a day short of the average duration of bright sunshine at this time of year. Light airs and calms have prevailed during the week, and the direction of the wind has been very variable. The mean amount of moisture in the air at 3 P.M. exceeded the average by as much as 10 per cent. Chionodoxa Lucilliæ came first into blossom on the 3rd inst., which is

five days in advance of its average date of flowering in the same part of my garden in the previous seventeen years, and six days earlier than last year.

FEBRUARY.

Exceptionally Warm and Sunny, and very Dry.—This was a very warm February. In fact, in the last nineteen years there have been only two other Februaries as warm. On the warmest day the highest reading in the thermometer-screen was 55°, which is in no way exceptional. On the coldest night the thermometer exposed on the lawn at no time indicated more than 9° of frost, which is the lowest extreme minimum registered by that thermometer during the last nineteen years. Rain, hail, snow, or sleet fell on thirteen days, to the aggregate depth of little more than an inch—which is not much more than half the February average—making the past month the seventh dry one in succession. On the morning of the 20th the ground was covered with snow to the mean depth of ½ an inch. About three-fourths of the total rainfall, or nearly 4 gallons, came through both percolation gauges during the month. The sun shone for over two-and-a-half hours a day, or twenty minutes a day longer than is seasonable. There were only four days altogether sunless, which is the smallest number I have yet recorded here in February. The wind was, as a rule, somewhat high, but in no hour did the mean velocity exceed 19 miles. The mean amount of moisture in the air at 3 o'clock in the afternoon was 2 per cent. below the February average.

THE WINTER OF 1904-5.

Remarkably Warm and Sunny and Very Dry.—There have been only four warmer winters in the last nineteen years. The mean temperature of each of the three months was in excess of the average, but December and January only slightly so. At no time did the exposed thermometer show more than 15° of frost, which is an exceptionally high extreme minimum for the season. Each of the three winter months was dry—the total deficiency from the average amounting to 2½ ins. There have been only two other winters in the last nineteen years when the duration of bright sunshine was as great.

Our Underground Water Supply. — Since the winter half of the drainage year began in October the total rainfall has been 7½ inches, or 5½ inches in defect of the average for the same five months. This is equivalent to a deficiency in rainfall on each acre in this district of 126,880 gallons. *E. M., Berkhamsted, March 7, 1905.*

[*For actual temperature and condition of barometer at time of going to Press, see p.* 152.]

MARKETS.

COVENT GARDEN, March 8.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 55*s.* to 75*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

REMARKS.—Prices remain much the same. The Peas quoted are frame-grown and come from Guernsey. Grape fruits per case 16*s.*; Custard Apples, 5*s.* to 10*s.* per dozen; Cape Plums, per case, 6*s.* to 10*s.*; Peaches, 5*s.* to 10*s.* ditto; Nectarines, 8*s.* to 15*s.*, ditto; Pears, 4*s.* to 7*s.*, ditto; Grapes, 7*s.* to 20*s.* ditto. There has been no Argentine-grown fruit during the past week. Apples, English Blenheim, per bushel 6*s.*; Wellingtons, 7*s.* ditto; Golden Knobs, 5*s.* to 6*s.*, ditto. The Easter Beurré Pears quoted are from Calaifornia. New season green Onions, 3*s.* 6*d.* per dozen bundles.

COVENT GARDEN FLOWER MARKET.

AZALEAS continue to make the greatest show; it is questionable if they have ever before been marketed in such quantities as they have been this season; some realise good prices, but many are cleared at a loss. Azalea mollis is not over plentiful. Erica Cavendishii is now to be had in well-grown plants, those in 48's realising 24*s.* per dozen. E. Wilmoreana and E. persolutaare also good. The same applies to Boronias and Acacias. Cinerarias make a bright show. Genistas are plentiful, and sell moderately well. Supplies of Cyclamen still hold out, and good plants of these are obtainable, although many are of second quality. Marguerites sell more readily; if the weather continues mild these will be in demand for window-boxes. Daffodils in several sorts are good. Deutzia gracilis, also Spiræas, chiefly S. japonica, some S. multiflora compacta and S. astilboides floribunda, are seen. Spikes of Polygonatum multiflorum (Solomon's Seal) are very pretty; these make about 10*s.* per dozen. Hydrangea Thomas Hogg is already seen, but the plants are dwarf with several heads of bloom; they were realising 9*s.* per dozen. Plants of Rhododendron Cunningham's White are well flowered, and make from 2*s.* to 3*s.* each. Lily of the Valley in pots is good, at from 18*s.* to 30*s.* per dozen. Begonia Gloire de Lorraine still holds out, but several growers have finished marketing these for the season. Well-flowered plants of the old double white Primula sinensis are seen, but these seem to have gone out of favour, and do not sell readily. Among foliage plants there are still good supplies. Ferns sell more readily, but there is not a great demand for Palms, and it is rarely that growers can clear their stands by closing time, unless they accept prices considerably below ordinary market quotations. For hardy roots, &c., trade has revived; and should a few days' mild weather continue the Pansy trade will be busy.

CUT FLOWERS.

Supplies are very large from all sources, and as is usual early in Lent, trade has fallen off considerably. It is difficult to give even approximate prices, for much of what is now on the market has to be cleared out for what it will fetch. Lily of the Valley, which was scarce at the end of last week, is now plentiful. Lilium longiflorum is down to 4*s.* or 5*s.* per bunch. Roses, especially the variety General Jacqueminot, are considerably cheaper, being down to 2*s.* per dozen. Carnations are also plentiful. We are now getting a great variety in Narcissus, large quantities coming from the Channel and Scilly Islands. Home growers are also sending in large supplies. Tulips are not quite so plentiful, and good prices are maintained. Gardenias are now more abundant and sell slowly at low prices. Supplies of Eucharis are short and prices have advanced. Few Tuberoses are seen. Violets are plentiful, these arrive chiefly from France. English-grown Lilac is abundant. Orchid flowers are not so numerous as they were last week. Few Cattleyas are seen. Supplies of all kinds of cut foliage continue plentiful. Hardy Fern fronds (British) are still good. The uprooting of our native Ferns has started again. They are seen in sackfuls. In the market strong roots that have taken years to establish are sold at very low prices. *A. H., Wednesday, March 8.*

ENQUIRY.

"HARE PIPES."—Can any reader tell me whether this is a form of net used in decoying wild fowl? or a small wooden pipe with which to imitate the cry of a hare and decoy within range of a shot-gun? *HH.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ACACIA DEALBATA: *J. N. H. W.* We believe it is correct to say that the species of Acacia known in Covent Garden Market as "Mimosa" is A. dealbata, but cannot say whence the term "Mimosa" arose, unless at one time Mimosa was made to include Acacias. The true Acacias are Australian. A. dealbata flowers much earlier than July in this country in greenhouses. The French edition of Nicholson's *Dictionary of Gardening* gives March as the flowering period.

ANNUAL GRAPE: *H. L.* This story is a very curious one, but you need pay little attention to it. The Vine seen cropping so well in Wales was probably grown in a pot, and the owner might reasonably have said that he raised a fresh plant for his particular purpose each year, but not from seeds.

ANTS IN GREENHOUSES: *Amateur Gardener.* Find out where their nests are located, and pour boiling water over the spot. There is a remedy known as the 'Ballikinrain Ant-Destroyer," which is said to be very effectual; but it is also a virulent poison, and should not be stored without a Poison label on it.

BEGONIAS: *J. H. P.* You do not tell us under what circumstances the plants were grown. The leaves look as if they had been scorched when damp; or have you been using some insecticide too strong, or fumigating too severely?

BOOKS: *V. C., Paris. Thompson's Gardeners' Assistant*, new edition, by W. Watson. Price, 52s., post free, obtainable from our Publishing Department.—*C. P. A Dictionary of English Names of Plants*, by William Miller, includes those of trees and shrubs. It may be obtained from our Publishing Department, price 12s. 6d., post-free.—*Orchid. The Book of Orchids*, by W. H. White, price 2s. 9d. post-free; or a more comprehensive work is *Orchids: Their Culture and Management*, by W. Watson and H. J. Chapman, price 25s. 6d. post-free from our Publishing Department.

COLLECTION OF ANNUALS: *A. B. C.* In the class to which you draw our attention no species that are not true annuals should be exhibited. An annual is a plant that grows from a seed, flowers, and dies in the same year.

CORELESS APPLES: *H. L.* See *Gardeners' Chronicle* for December 24, 1904, p 446; also February 25, 1905, p. 121.

CRICKETS: *J. G. D.* See answer to "G. W. B." on p. 128 of our issue for February 25.

CYCLAMEN FLOWERS EATEN: *A. S.* The insects you have forwarded are the common weevil. They feed principally in the night, which is the best time to catch them. Trap them with pieces of Carrot or Potato, and examine the traps by the aid of a lantern.

FLOWERING OF FIGS: *Ficus.* The flowering stage precedes that known to gardeners as the "second swelling." The true fruits are what are usually spoken of as seeds in the Fig. The edible portion is not strictly a fruit, but a swollen branch in whose cavity the flowers and fruits are borne. Cut one of the receptacles (fruits) open at various dates previous to the ripening process, and you will find the contained flowers more or less open in some of them. Figs generally are unisexual, but occasionally male and female flowers are contained in the same receptacle, the male flowers near to the orifice at the end of the receptacle, and the female flowers in the concavity near to the stalk. In English fruit-houses fertilisation seldom takes place, and the so-called "fruits" are therefore as a rule seedless. Directly after the flowering stage Figs are apt to drop from the trees, especially when forced early in the year.

HUMEA ELEGANS: *A. B. C.* The leaves are attacked by the well-known fungus disease. If only two of the twenty-four plants are attacked these should be isolated at once.

LAUREL SHOOTS: *G. J.* The blisters are due to an excess of moisture in the soil. The plants are free from insect and fungus pests.

LECTURE ON FRUIT CULTURE: *V. C., Paris.* We expect you mean a lecture which Mr. T. A. H. Rivers delivered before the members of the Horticultural Club in 1902, of which a short report was published in our issue for Oct. 25, 1902, p. 314. A fuller report was printed in the *Journal of the Royal Horticultural Society*, vol. xxvii., p. 625, which may be purchased on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, London. Procure a copy of *Fruit Trees in Pots*, a new work by Josh Brace, price 5s. 3d. post free from our Publishing Department.

"MANNA": *T., Transvaal.* It has nothing whatever to do with Manna. The plant is Setaria italica var. Italian Millet.

NAMES OF FRUITS: *W. R., Sandy.* 1, Gooseberry Apple, not Gooseberry Pippin; 2, not recognised; 3, Hunthouse; 4, Sweet Lading; 5, Allen's Everlasting, gathered too soon; 6, Nelson Codlin.—*H. D. P.* Maltster.—*T. Cross.* Your Apple is Beauty of Hants. It is a type of Blenheim Pippin, and a few trees are to be found throughout the country, especially in Kent, where it is named "Bastard Blenheim." The fruit is distinguished from that of Blenheim Pippin by the eye, which is much smaller; the colour of the fruit is more brilliant, and there is a thin patch of russet round the stem. Its quality for dessert or cooking is quite equal to that of Blenheim Pippin.—*E. N. H.* The fruit was bruised beyond recognition. Send other specimens earlier in the season next year, and pack them more carefully.

NAMES OF PLANTS: *H. G. C.* The big one is Correa speciosa var. Backhousiana, and the small-flowering species C. alba.—*T. C.* 1, Cypripedium × auroreum (Lawrenceanum × venustum); 2, C. × hybridum, two flowers; 3, C. × Sibyrolense (Boxalli × insigne), not a good form; 4, Dendrobium × Ainsworthii. The labels on 2 and 3 were detached.—*J. H. W. Genève.* Miltonia Warscewiczii, often seen in gardens named Oncidium fuscatum and Odontoglossum Weltoni.—*W. B. B.* 1, Nephrolepis tuberosa. You should send fertile and barren fronds of Ferns where possible; 2, Azalea indica, probably Dentsche Perle; 5, Sparmannia africana.—*H. L. N.* It is very difficult to name Conifers without the cones. Your specimens are, however, good ones—a contrast to most that we receive. Some of your specimens were named last week. The others are, we believe, as follows:—1, Cupressus sempervirens; 3, Juniperus virginiana; 4, a Pinus about which we are doubtful—it may be P. cembroides; 5, Juniperus communis var. fastigiata; 6, J. virginiana var. Schotti; 8, Pinus excelsa; 12, Juniperus virginiana.—*G. E. P.* Omphalodes verna, very near to but not the same as Myosotis.—*G. P.* The Fern is Doodya media, the other is the Retinospora stage of Cupressus funebris.—*G. P.* Odontoglossum × Andersonianum, of good quality.

ONION-GROWING ON A LARGE SCALE: *R. M.* If you had furnished us with a few particulars of the land you intend to crop with Onions on a large scale, and informed us whether it had been recently in cultivation, and if so, how cropped, we should then have been in a better position to advise you as to the preparation of the ground for the reception of the seed. However, we will assume that your land was cropped last year and in previous years with roots or cereals, and that it was ploughed up last autumn. This being so, it should now be well harrowed, if this has not been already done. Should the soil be at all lumpy, let it be rolled, and then dress it with artificial manures at the rate of 5 cwt. per acre. These manures may consist of 2 cwt. of guano, 2½ cwt. of superphosphate of lime, and ½ cwt. of muriate of potash. Then harrow the surface again, and afterwards strew fresh soot over the ground in sufficient quantity to discolour the surface, prior to sowing the seed in shallow drills at from 12 to 15 inches asunder. Twelve pounds of Onion-seed will be sufficient to sow an acre of ground for "bulbing" purposes; but should you desire to have the young plants come up sufficiently thick in the rows to admit of their being thinned-out, bunched, and sent to market for salading, 15 lb. of seed per acre will be required. An American seed-sowing machine of the right size should be used for drilling in the seed, afterwards rolling over the ground so as to compress the soil. If the land was given a liberal dressing of farm-yard manure for last year's crop, the artificial manures need not be applied, as a dressing of soot will be ample, for this is not only an excellent purifier of the soil, but is also a powerful fertiliser. But should the ground be in poor condition a dressing with artificial manures as indicated above will be very valuable, the soot being strewn over the land immediately before sowing the seed. This application of soot will probably save the crop from the attacks of the wire-worm and Onion maggot (Anthomyia ceparum). It is too late in the season now to dress land intended for Onions with farmyard manure, and the sooner the seed is put in the better prospect there will be of securing a remunerative crop. We may add that freshly-broken-up meadow land of a somewhat light sandy, loamy nature reduced to the desired degree of finness, and otherwise treated as described above, will yield first-rate crops of Onions, or of any other kind of bulbs or roots for the matter of that. Danver's Yellow, James's Keeping, and Main Crop, are good varieties of Onions to grow for the supply of the market.

PEACH LEAVES: *W. M.* Kindly send us some specimens of the leaves which have become curled.

PINES: *Scots, W. S.* The Spruces are attacked with a gall insect, a species of Chermes. The Pine-trees are attacked by a fungus, the white spawn of which is very conspicuous. Look about and see what fungi are growing on or near to the trees. The fungus is quite sufficient to account for the death of the shoots.

PRIMULA: *A.* The blooms are so small that we do not recognise them for the species you name. The protrusion of the style, "pin eye," is natural in some Primroses. Please send a leaf.

RICHARDIA WITH DOUBLE SPATHE: *R. W. R.* This is not at all uncommon. We receive many specimens every season. The donation has been given to the Gardeners' Royal Benevolent Institution.

SEEDLING OF PTERIS FERN: *A. B. C.* The pretty variegated form you send is nearest to P. Victoriæ, a plant distributed by Messrs. W. Bull & Sons some years ago. Your plant may be distinct, and in that case would be worth keeping.

TARRED BOXES: *A. L.* If tar be used, the boxes should not be employed for some time afterwards, but we should prefer not to use it.

TWINING PLANT: *R. L. P.* The plant you send on the Pelargonium is a Dodder—Cuscuta europæa, a parasitical plant which feeds on the Pelargonium. It probably sprang from seed in the peat.

VIOLET: *C. H. Kent.* The large double light-coloured Violets you send under the name of "Miss Naylor" are extremely pretty and powerfully fragrant, but whether the variety is distinct from all others we cannot say.

VIOLET LEAVES: *J. C.* There is no fungus present, and the bleaching of the leaves, always commencing at the edge and working inwards, suggests some ammoniacal or other exhalation from a fertilizer present in the soil.

CLIMATE AND CULTIVATION.

OUR old correspondent, Mr. Challis, of Wilton House Gardens, is recognised as a first-class, all-round gardener, but it is not so generally known that he has been for years a patient and keen meteorological observer. The remarks that he made at the meeting of the Bath Gardeners' Society last week have therefore a double value. We must, from considerations of space, omit the introductory portions, in which Mr. Challis dealt with the well-known facts of the constitution of the atmosphere and cognate matters, and pass on to his remarks on climate in its relation to practical horticulture.

"The more practical side of this subject will be perhaps better considered, first, with reference to the climate in the open-air; and secondly with regard to the more artificial, because comparatively confined, atmosphere of the hot-house.

In selecting a site for a residence, a gentleman naturally chooses first that which he believes will best contribute to the health and comfort of his family and household, then most probably he will have a thought for horses and stables, and then perhaps for the cows and the dairy, piggery and fowlery, and for his garden, which last is frequently relegated to a position that is neither suitable nor salubrious, either with regard to climate, aspect, or soil; and the poor gardener has to endeavour to surmount difficulties over which he has little or no control whatever. In olden times, when the raising of an efficient water supply for garden use was a much more difficult and expensive operation than it is now, there was reasonable excuse for gardens being located in the valleys near the rivers. Unfortunately, such positions are generally the most unsuitable, as they occupy the hottest, the coldest, and the dampest localities—the hottest, because when the sun shines they are sheltered from the cooling breezes that would otherwise temper its rays; the coldest, because when the sun sets the air near the adjoining hill becomes condensed, and by reason of its increased weight is by the laws of gravitation forced down the sides of the hills into the valleys, where it displaces the warmer and lighter air, and where it remains until it again becomes rarefied by the returning sun. The valleys are the dampest position, because the vapour rising from the rivers becomes condensed by the cold air, and then remains stagnant.

There is ample evidence of these facts almost every day during the autumn, winter, and spring seasons, when a dense fog may be seen remaining in the valleys, while the surrounding hills are comparatively clear and sometimes bright. I have myself frequently found the temperature of the air in a valley to be 28° or 30°, while at the same time that of the air at a moderate elevation, only half a mile distant, was 40° to 45°. We need no longer wonder that tender subjects should be destroyed in the valleys while similar plants on the surrounding hills are perfectly safe and uninjured.

To choose the best position and aspect for a garden is not always an easy task without having had some previous meteorological experience of the locality. Some experts choose a south or south-western slope at a moderate elevation above the valleys, while others prefer a south-eastern slope. Those who favour the former position say that the latter is subject to the sudden changes of temperature by being exposed to the ill-effects of the early morning sun after a severe frost, while the advocates of a south-eastern slope, especially the fruit growers, assert that the fierce south-westerly gales are more to be feared than spring frost. I am rather in favour of the latter view, especially if an efficient protection by trees be afforded against north-east winds during the spring season. I should prefer to risk losing a few exposed buds by frost in spring than have to endure the chance and disappointment of seeing a full crop of fruit swept off the trees by a few hours' fierce gale in autumn.

The climate of a garden may be greatly improved by the erection of suitable brick walls, also by planting Yew, Hornbeam, or Holly hedges, which not only serve to break the force of wind, but also tend to lessen the excessive evaporation of moisture from tender plants by cold currents of air. It is, however, the providing of well-built garden walls, permanently coped with glass and protected in front during the early and late spring frost months with three or four thicknesses of ordinary Strawberry netting, that should be the acme of the gardener's ambition with respect to fruit-tree cultivation. Such structures are not only comparatively economical, but they also at all times supply just the amount of protection required to guard the trees from frost and also from intense sun-heat. From such structures, where the trees are judiciously cultivated, both with respect to the roots as well as the branches, and where the walls are completely covered by the trees, the crop, I may safely say, never fails, for in the never-to-be-forgotten disastrous year 1903 I saw such structures well furnished with an abundance of every kind of fruit, whilst in the open garden and orchard not a single respectable dish could be found or obtained.

Protection from extreme cold, intense sun-heat, excessive evaporation and nocturnal radiation should, I venture to think, exercise the gardener's mind to a much greater degree than it has done hitherto. We should bear in mind that the radiating force of the sun's rays, also the nocturnal radiation force from the surface of the earth, is much greater in this latitude than it is in more temperate or even tropical regions, and as we cultivate plants and trees chiefly obtained from warmer climates than our own, this practice of protection cannot be sufficiently emphasised. That the radiating force of the sun's rays is much greater in this latitude than it is under the Equator has, I think, been fully verified by meteorologists of exceptional repute.

It has been proved that the radiating force of the sun in the tropics seldom exceeds 25° to 30°, whereas in this country it is frequently as much as 45° and 50°, and even 60° and 65°. The greatest force often occurs during the late spring, and if accompanied, as is often the case, by a low atmospheric temperature, the excessive evaporation that takes place under such conditions is exceedingly detrimental to the tender fruit blossoms and foliage, as also to tender plants where unprotected, for instead of there being present in the atmosphere 60 or 70 per cent. of moisture, which is the amount they require, it may be reduced to 10 or even 5 per cent., which must, if of long duration, most certainly prove fatal. Under such circumstances protection is not only necessary to fruit-trees, but it is equally so to tender plants and seedlings in the open garden, especially to those that have been recently transplanted. The shelter of a garden-mat or similar material suspended a few inches above the plants so as to avoid contact with them, and to enclose a still body of air underneath, will almost certainly guard them from injury. Similar protection is equally if not more essential to guard tender plants from the destructive effect of nocturnal radiation.

When after a bright, sunny day the sun has disappeared, the surface of the ground on a calm, cold night radiates its heat into the atmosphere to such an extent that it often becomes several degrees colder than the air immediately above it, so that even in midsummer plants growing close to the ground are liable to be frozen, while the temperature of the air 4 feet above is 4° or even 6° higher.

Meteorologists account for the comparatively weak sun power in the tropics with that in this country by saying that it is chiefly due to the cooling effect of the much larger volume of vapour that is always present there, and more especially to the cooling effect of the extremely elastic condition of that vapour, which simply means

that by a peculiar yet most wonderful law of Nature the sun itself creates a limit to its own destructive powers, otherwise in the tropics vegetation would in a few seconds be destroyed by its perpendicular rays.

With regard to the more artificial climate of the hothouse, which is a subject of the greatest interest and importance, although it is not unattended with difficulties, yet it is much more under the gardener's control than is the climate in the open-air. Gardeners, speaking generally, study and observe one element of climate only—viz., heat. The thermometer is to them the only index to the climate they are so desirous to provide and maintain. Such sticklers are they, and so precise as to this element, that the young gardener in charge had far better never have been born than allow the thermometer to rise one degree higher or sink one degree lower than the prescribed limit.

It is perfectly true that in tropical regions, whence the inmates of our hot-houses are derived, the temperature is much more equable than we in our variable climate can possibly hope to ensure for them. If this be true with regard to temperature, it is equally or even more so with regards to atmospheric moisture. This element therefore should be regulated with the same care and the same scientific precision as that of temperature.

It is generally admitted that alternate periods of growth and rest are essential to the welfare of the occupants of the hot-house, and the temperature is again carefully regulated to that end, but not so with the atmospheric moisture. Water is thrown indiscriminately about the paths and walls, while at other times they are allowed to become too dry, and the results are often visible by the plants becoming spotted and diseased on the one hand, and and shrivelled on the other.

The atmosphere in the tropics during the growing seasons is always highly charged with moisture, seldom less than from 75 per cent., and occasionally 100 per cent.; whereas in our hot-houses, as at present managed, the amount of moisture would, if tested with the hygrometer, often be found as low as 60 or even 50 per cent. for hours together. During the resting periods in the tropics the plants are subjected to lengthened and excessive dryness by day, but as a rule in our hot-houses through the winter or resting season the atmosphere is kept even damper than it is at midsummer. It need then be no longer a matter of surprise that plants which depend to such a large degree during the growing seasons on a specific amount of moisture in the air for their sustenance, and also during their resting seasons on a specific amount of dryness in the air during the day for their solidifications, should so often dwindle and die under the unsuitable, ill-regulated, and unnatural climate that is too often provided for them.

It may be said, "Why trouble about these theoretical scientific questions when good results can be produced by old-fashioned practical gardeners without them?" Does this remark refer to the old-fashioned practical man who one frosty morning was asked by his anxious master if the thermometer in the Orchid-house was all right, replied, "Yaas, meister, he be all right now; he wur a bit low this yer morning, but I blowed on un, and soon fetched un up to scratch"? Or does it allude to the successful, practical gardener, who is a keen observer, a plodding, persevering, methodical man, who works to some extent scientifically, without properly understanding the theory or groundwork of his practice? Why, allow me to ask, are English artizans inferior to the French in designing, and the Germans in finishing of manufactured goods? Simply because we as a nation are just a little too practical, and somewhat deficient in theoretical, scientific, and technical knowledge, compared with our continental rivals.

Practical knowledge is excellent, but when combined with sound theory it is infinitely more so. Above all, then, gardeners should adopt as their guide through life an open hand, open eyes, open ears, open mouth, open mind, and, last though not least, an open heart."

FIG. 65.—THUNBERGIA NATALENSIS GROWING IN THE CAMBRIDGE BOTANIC GARDEN. COLOUR OF FLOWERS PALE BLUE.

THUNBERGIA NATALENSIS.

THIS charming species from S. Africa is not generally known to be hardy, but it can be grown out-of-doors in the south and midland counties if provided with a sheltered position and protection afforded by some rough litter placed about its crown during severe winter weather. The photograph reproduced at fig. 65 was taken last August and represents a plant in the Cambridge Botanic Gardeu growing against a wall of a cool greenhouse facing to the south-east, a position it has occupied for several years. The plant grows about 3 feet high, and is very pretty during the summer when studded with its pale-blue flowers, which have a rich yellow tube. It is figured in the *Botanical Magazine*, t. 5082. A succession of flowers is maintained for about two months or more. It is worthy of a place under glass, and will make a good mass if planted in a cool greenhouse where the sun's rays will reach it. *E. J. Allard, Botanic Garden, Cambridge.*

FOREIGN CORRESPONDENCE.

APPLIANCES TO PREVENT "DRIP."

I THINK still greater improvements in sash-bars are possible than those prepared by Mr. Brewer, p. 86, and Mr. Tallack, p. 138 [which were appliances for preventing "drip" in houses already erected. ED.]. I send you figures representing sash-bars such as have been employed for many years past in America, and are now in common use in Germany and other countries. Even here, in Sweden, we have commenced to use them, but have hitherto had to get them made by hand, as the mills have not found customers enough to induce them to change their machines, or construct machines for this special work. That will not be the case in England; if nurserymen or gardeners demand a new model they will get it at once. I need not say much about the great advantages of this sash-bar—they are apparent to anyone. From a saw-mill they should be obtainable at the same price as the plain ones without grooves. Perhaps some nurserymen and market gardeners will say that drip is of no consequence; but I never saw a figure in *The American Florist* of large Rose and Carnation-growing establishments in America which has not shown grooved sash-bars. There may be more "drip" in America because of the harder winters and consequently more firing; but there seems to be a demand for such a bar in England. *M.P., Jonköping, Sweden.* [The drawings enclosed by our correspondent represent similar grooved sash-bars to those figured in our last issue, p. 155, and can only be used for new houses or when re-roofing old ones. ED.].

Seed Packing.

In the *Gardeners' Chronicle*, February 11, 1905, on p. 90, there appeared a short article on "Seed Packing" by Mr. William Watson, of the Royal Gardens, Kew. Mr. Watson recommended moist cocoa-nut fibre as packing for the transportation of seeds which lose their vitality on drying. There are many seeds which belong to this class, and the method recommended by Mr. Watson is a most excellent one.

Further, Mr. Watson says: "For seeds generally I know of nothing better than paper packets or calico bags; and the more moisture there is in the seeds themselves when thus packed the better. Hermetically sealed tins or bottles should never be used." Carefully-conducted experiments have given results which are diametrically opposed to those set forth by Mr. Watson. By far the vast majority of seeds retain their vitality the better the more thoroughly they are dried. Seeds put up in paper packets or cloth bags may remain germinable for a number of years if kept in a dry climate; on the other hand, seeds put up in the same manner, and sent to places having warm, moist climates, deteriorate very rapidly. But in all cases, excepting the special kinds of seeds which lose their vitality on becoming dry, the best results are obtained when seeds are carefully dried and packed in hermetically sealed containers. When prepared in this manner the seeds must be dried at a temperature slightly higher than any degree of heat to which the sealed containers will be subjected. Seeds prepared in this way will remain viable in any climate. This applies particularly to agricultural and garden seeds of the temperate regions. Many seedsmen now use the hermetically sealed containers for the transportation of seeds, especially those which are sent to tropical and subtropical countries.

The following data, taken from a long series of experiments, will show the advisability of carefully drying seeds and packing in air-tight containers to guard against the entrance of any moisture:—

Cabbage and Onion seed stored at Mobile, Alabama, for 131 days, from December 20, 1901, to April 30, 1902, in paper packages and in sealed bottles respectively, showed the following germination:—Cabbage from the envelope, 60 per cent.; from the bottle, 84 per cent.; Onion seed from the envelope, 19·5 per cent.; from the bottle, 86 per cent. (See Bulletin 58, Bureau of Plant Industry, U.S. Department of Agriculture, "The Vitality and Germination of Seeds.")

Unpublished data are as follows:—Onion seeds from paper packages, after being stored one year in Kingston, Jamaica, germinated only 4 per cent., while seed from sealed bottles germinated 87 per cent. The same from Puerto Principe, Cuba, gave 0 per cent. and 82 per cent. respectively. Lettuce seed stored one year in Manila, Philippine Islands, germinated 0 per cent. and 95 per cent. respectively; Bridgetown, Barbados, 0 per cent. and 94 per cent. respectively from the envelopes and bottles. The greatest factor in causing the loss of vitality in seeds of the field or garden is moisture. *J. W. T. Duvel, U.S. Department of Agriculture, Washington, D.C., U.S.A.*

PLANT PORTRAITS.

Nicotiana Sanderæ ×, *Revue de l'Horticulture Belge*, February.

Arbutus Unedo, *Revue de l'Horticulture Belge*, February.

Musa paradisiaca rubra, *Revue Horticole*, February.

Magnolia hypoleuca, *Mitteilungen der Deutschen Dendrologischen Gesellschaft*, 1904.

Euphorbia (Poinsettia) pulcherrima plenissima, a variety in which the coloured bracts are increased in number though diminished in size, *Le Jardin*, March 5.

KEW NOTES.

Crocus Malyi.—Whilst the genus Crocus contains upwards of seventy distinct species, there are scarcely more than a dozen in general cultivation. The forms of C. aureus, C. biflorus, C. nudiflorus, C. sativus, C. vernus, and C. versicolor are the most common. Of all these species there are numerous forms and garden varieties, which in size and colouring of their flowers are greatly in advance of the types, and constitute the bulk of the Crocuses used for planting in beds. The flowering period of the different species varies considerably, and by selecting these a succession of flowers may be had from October until May.

At the time of writing many of the slopes and mounds at Kew present a lovely sight with various species and varieties of Crocus and other bulbs, and these will be followed shortly by Narcissus, Hyacinths, Tulips, &c. This style of gardening has been a feature at Kew in spring for many years past.

For the decoration of the cool greenhouse or of the alpine-house many of the choicer sorts are

Fig. 66.—Crocus Malyi.

adapted, especially if grown in shallow pans. No species of Crocus should, however, be subjected to any artificial heat during the growing season. This is a frequent cause of the malformation of the flowers when they are grown in pots and pans under glass; another effect is to cause the damping-off of the flowers before they reach maturity. A porous compost of good turfy loam, leaf-mould and sand, with abundance of drainage material, is the best for culture in pots, &c., and the earlier the bulbs are obtained in the autumn and potted-up, the better they will thrive, as many species emit roots shortly after the fall of the leaf.

The illustration of C. Malyi (fig. 66) shows what a lovely effect may be obtained from this species when treated in this manner. C. Malyi was discovered about sixty years ago by the late Herr Maly on Monte Vermay and Monte Orjen in Dalmatia, at an altitude of 7,000 feet, and was named in compliment to its discoverer by Professor Visiani, who described it in the supplement to the *Flora Dalmatica*. It is well figured in Maw's *Monograph of the Genus Crocus*, t. 18, also in the *Botanical Magazine*, t. 7590. The flowers rise to a height of 2 to 4 inches above the soil, and are almost pure white when grown under glass, but develop a slight tinge of purple on the outside of the tube when grown in the open. The tube is 2 to 3 inches in length from the ovary to the throat, and of a dull yellow colour. The throat, anthers, pistil, and style are of a deep orange colour, the large and prominent style being divided into a spreading mass of slightly divided stigmata.

The sheathing-leaves are six to seven in number, scarious, and one-half to 2 inches in length. The proper leaves are four or five in number, appearing with the flowers, and barely reaching to the throat at the time of flowering, elongating after the flowers are over to a length of about 15 inches. C. Malyi flowers under cultivation during the month of March. *C. P. Raffill.*

Coleus shirensis.

This is a species from British Central Africa now flowering in the Begonia-house. It is, I believe, the first time it has bloomed under cultivation. The seeds were sent to Kew by Mr. J. McCleunie at the same time as the recently-flowered and much admired Plectranthus crassus. The seeds germinated freely, the seedlings being very sturdy and freegrowing, and so far as the plant has been tested it appears to be even more robust in habit than the popular Coleus thyrsoideus, which was introduced from the same district. The plant now in flower is a specimen about 2½ feet in height and about the same measurement in diameter, nearly every one of the numerous branches having a fine inflorescence. The square stems are thickly dotted with dark-red spots, the opposite, decussate leaves having a stout petiole 2 to 2½ inches in length; the blade of the leaf is cordate in form, with a coarsely crenate margin, the largest leaves measuring 4½ inches in length by 3 inches in breadth. They possess a very strong and rather pleasant scent. The inflorescences are developed terminally, and have an average length of 6 inches, and are 2 inches in diameter. The large labiate flowers are of two shades of blue, the prominent lower lip being very dark-blue and the upper and smaller lip being of a lighter shade. Owing to the whorled nature of the inflorescence a continuous supply of fresh flowers is maintained, and there are often as many as thirty to forty fully expanded blossoms on each inflorescence. The plant under notice has been in flower for five weeks, and still has a profusion of fresh blooms. This new introduction cannot claim to excel the merits of C. thyrsoideus, but it is a really first-rate companion plant, with much to recommend it to the gardener. The cultivation necessary is similar to that afforded C. thyrsoideus.

Maxillaria ochroleuca, *Lodd.*

A well-flowered plant of this pretty Brazilian species is now a feature of the Cattleya-house. The flowers are borne on slender scapes of from 4 to 6 inches in length; there are usually about six produced on either side of the pseudo-bulbs The petals and sepals are white. The lip is yellow, and rather small. Unlike many species of Maxillaria, this one is very sweetly scented.

Oncidium dichromum, *Rolfe.*

This very distinct and delightful Peruvian species is also flowering in the Cattleya-house, where it has made a bright display for the past three weeks. The growth is similar to that of a small Odontoglossum crispum, with narrow leaves varying in length from 6 inches to a foot. It produces its spikes very freely; they are rather slender, flexuose, and generally from 2 to 3 feet in length. The flowers are rather sparsely arranged on the inflorescence, each carrying from ten to twenty. The sepals and petals are about half an inch in length, and very curiously coloured, probably a reddish-brown would best describe it. The lip has a diameter of 1 inch, golden-yellow in colour. *W. H., Kew, February 27.*

Grafting the Pink on the Saponaria.—M. Poirault advocates this practice as a means of securing it against the attacks of the Fusarium fungus. The scions of the Pink are grafted in spring or autumn on the root-stock of the Saponaria, the buds of which are removed.

NOTES FROM AN ISLEWORTH GARDEN.

THE past year was not noticeable for any great climatic vagaries, and was fairly satisfactory from a gardener's point of view. The fruit crop was generally good.

NEW PLANTS RAISED IN THIS GARDEN AND FLOWERING FOR THE FIRST TIME IN 1904.

Hippeastrum (hyb.) aulicum × vittatum.—One of these hybrids produced a colour sport of an amethystine-rose "self," which I have never previously seen in the genus.

Hippeastrum "Aulic Chief" [aulicum × "Indian Chief"].—A beautiful cross bi-coloured in green and red.

Hippeastrum hyb. Mandevilli [vittatum × equestre major].—A quaint and brilliantly-marked hybrid.

Hippeastrum hyb. aulictre [aulicum × equestre].—Not so beautiful as either parent.

Nerine hyb. Zoroasteri [pudica × corusca].—A fine hybrid, fairly intermediate between the parents, carrying a dozen flowers on a tall scape.

Nerine hort. "Gaimini."—This is an erect flowering form belonging to the sarniensis section, and is the largest-flowered Nerine I have. It bears about ten flowers to the umbel, of a bright pink colour keeled throughout with red, each flower 2 inches across.

Cineraria "Noel."—A light pink self and pleasing.

Canna (hort.) "Sorata."—Crozy type. Bright scarlet, erect and floriferous.

NOTES ON SOME PLANTS NEW TO THIS GARDEN.

Anemone græca bicolor.—This is a glorious plant for the Alpine-house, but is useless in the open near London.

Canna (hort.) "Prof. Troube."—Flaccida type. Flowers striped red and yellow, foliage purple.

C. (hort.) "Roma."—Flaccida type. A very fine form, with extra large yellow and orange flowers.

C. (hort.) "Austria" and "W. Beck."—Flaccida type. Flowers yellow and red.

C. (hort.) "Parthenope."—Flaccida type. Tawny-red flowers.

These four Cannas were kindly sent from the garden of Messrs. Dammann, of Naples.

Iris Milesi.—From the temperate zone of the Himalayas. Takes somewhat after chinensis in general aspect, but the flowers are purplish and whitish, and inodorous. It does well with me, either as a conservatory plant or in the open, and has lived through three winters quite unprotected. The fruit is generically typical, containing about fourteen brown, wrinkled, nearly spherical seeds with minute acute tip.

Clematis "La France" (hort.) is a plant of fine constitution, is a decided improvement on all the older blue forms, and is second to none in intensity of colour.

C. Henryi I regard as the best pure white. It seeds freely with me.

Lobelia tenuior I have grown for three years. It is a charming plant for the conservatory, and should be sown in September to produce the best effect the following summer.

VARIOUS PLANT NOTES.

The value of ornamental Vines for conservatory work is not generally recognised. For instance the old V. heterophylla variegata is undoubtedly one of the best foliage plants in cultivation. Vitis Coignetiæ, which rarely colours well outside in our damp autumns, is a glorious sight in pots, and even the common V. Veitchii (Ampelopsis) is quite worth growing for autumn decoration of the cool-house or veranda.

Two lovely little plants for decorative work in the dwelling-house are Pellionia Daveauana and Saxifraga sarmentosa tricolor, the former of which will stand a long time in a room, not minding the comparative absence of light.

Some of the best Roses among recent introductions are climbing "Caroline Testout" (pink), "Frau Karl Druschki" (white), and the Hybrid Teas, "Augustin Guinoisseau" (blush), and "G. Nabonnand" (cream).

Those who class Cypella cœrulea as synonymous with C. plumbea are in error. The former bears many (or several) flowers from the apex of the same flowering stem; the latter carries but a single flower. C. plumbea reproduces itself quite true from seed, with but slight colour-variations; the seedlings flower in four years after sowing.

Amaryllis Belladonna rarely flowers in the open ground (that is away from a wall) in the London district, but last September, of ten bulbs which have grown for several years under some Poplars, every one flowered. Probably owing to the Poplars drawing all the moisture from the soil, the bulbs ripened.

Crinums in the open.—Only C. Powelli and C. Moorei flowered well in 1904, but C. yemense flowered well under a wall.

AGAPANTHUS UMBELLATUS AND VARIETIES.

Mr. J. G. Baker held that all the Agapanthi (recorded at the time he last dealt with this genus) were varieties of one species, so that in his view the genus was at that time classed as monotypic.

I have examined several forms sent me from various sources under the names umbellatus, Leichtlini, and Mooreanus (two colours), and I have raised seedlings on the forms called umbellatus and Mooreanus [*vide* "Notes from Isleworth" in *Gardeners' Chronicle* of March 21, 1903, p. 181] without being able to discern any specific differences between them.

Mooreanus is more inclined to be deciduous than the rest, and probably for this reason may be left undisturbed at the base of a south wall or in other favoured positions. In such places it will flower in July, not more than a week later than plants which have been housed during the winter.

What I have as the type (umbellatus) is certainly a much finer plant than is generally seen under this name, but my plants are very generously treated, and have grown into "specimens." The same is also true of the variety Leichtlini, and this should be borne in mind in the descriptions annexed.

Umbellatus and Leichtlini are splendid decorative plants for the lawn. Mooreanus is no use for this purpose, but makes a good cut-flower for vases.

Comparative Description.—The leaf-stem is about 3 inches long in the type, longer in Leichtlini and shorter in Mooreanus. The number of leaves to each flowering stem is fourteen, sometimes more in Leichtlini. The maximum width of the fully grown leaf is 2½ inches, but is much less in Mooreanus, which in some cases has leaves only ½ inch wide. The length of the mature leaves is 3 to 3½ feet, a foot more in Leichtlini, and rather less in Mooreanus. The span of the umbel reaches a foot in Leichtlini, is an inch less in umbellatus, or only 7 inches in Mooreanus. The depth of the umbel is about an inch less than the span, but in Mooreanus the umbel is not more than 4 inches deep. The number of flowers in the largest umbels varies from 100 to nearly 150 in the case of umbellatus, and to nearly 200 in Leichtlini (see below). In colour my umbellatus is the most decided blue, and is slightly darker than Leichtlini. Mooreanus will flower from seed in eighteen months, and shows great colour variety, many shades of blue and even pure white coming from one blue parent without any crossing. The individual flowers of my umbellatus are indistinguishable from Leichtlini, but as a garden plant it is distinguishable by its greater compactness and sturdiness. In Mooreanus the whole plant is smaller and more slender, and the umbel is shallower, and carries notably fewer flowers. Leichtlini carries from 116 to 189 flowers in the umbel (average 146 flowers); umbellatus carries from 101 to 135 flowers to the umbel (average 118 flowers) in the case of really well-grown plants. I counted the flowers on six of the best scapes to find the average. Mooreanus has fewer flowers than this, perhaps only half as many. *A. Worsley, Isleworth.*

POTATO-COOKING TEST.

ON Tuesday, March 7, a further cooking test of Potatos was carried out at Marks Tey by Mr. William Deal, Mr. H. J. Jones, and Mr. W. Cuthbertson at Messrs. Dobbie & Co.'s seed farm.

It will be remembered that the judges on the last occasion expressed a desire that a later trial should take place to ascertain the effect of longer keeping on the various varieties and samples. Mr. George Gordon, V.M.H., Editor of the *Gardeners' Magazine*, and Mr. H. Henshaw, of Cambridge University Experimental Farm, again judged along with Mr. Alexander Dean.

Specimens for cooking were supplied by Messrs. Davie & Co., Haddington; Messrs. Bruce & Robbie, Forfar; Messrs. Dobbie & Co., Rothesay; Messrs. T. H. Lincoln & Co., Boston; Mr. R. W. Green, Wisbech; Mr. William Deal, Kelvedon; and Mr. H. J. Jones, Lewisham.

Following the system adopted last time, points were given as under:—

	Variety and Locality.			Flavour	Texture	Appearance	Total.
1	Up-to-Date	...	Forfar ...	...	...	...	6
2	,,	...	Lincoln ...	...	...	...	3

51	Uncle Sam	...	Kent ...	3	3	3	9
52	Kerr's King Edward ...		Kent ...	2	3	2	7

The best dish of each variety was left standing for twenty-four hours after being judged, for the purpose of being then examined and its appearance reported on. Mr. Cuthbertson and Mr. Ireland examined them all carefully, and found Warrior, The Factor, Langworthy, Green's Favourite, Peacemaker, were unchanged, retaining their whiteness and flakiness. The others had all gone off a little.

BAMBOO FOR THE GARDEN.

Many gardeners have used Bamboo canes for staking flowering plants and small trees, but it may not have occurred to all to realise to how many other useful and artistic purposes Bamboo can be applied in the garden. Nature has provided no material that can approach to the Bamboo in its many-sided usefulness to the gardener. Strength combined with lightness, cleanliness, durability, elegance of appearance, and economy of cost are all in its favour.

Dealing first with the Bamboo in its natural state, or at least as regards the kinds which are imported into this country, the Tonquin cane is the most familiar to gardeners. It grows with a smooth, straight stem of a faint yellow colour, is almost of equal diameter the whole length, and nearly solid, weighing much heavier than the ordinary hollow Bamboo. The usual imported lengths are 4 feet, 5 feet, 6 feet, and 7 feet, varying in thickness from $\frac{1}{2}$ inch up to $\frac{3}{4}$ inch; and for staking Chrysanthemums, Roses, Dahlias, Tomatos, and Carnations there is nothing better. Being so smooth, they do not harbour pests, such as greenfly, &c. The uses of Bamboo, however, in the garden extend far beyond stakes. What are known as yellow Bamboo tapers can be put to many uses. These have a natural glossy surface, with knots at frequent intervals, which project more than in the Tonquin variety. They can be purchased in various lengths, from about 7 feet up to 20 and 24 feet long, the butt-end varying in thickness according to the length, say from $\frac{1}{2}$ to $1\frac{1}{4}$ inch. The tops taper off into strong twigs, which can be bent without the aid of heat, and are excellent for tying Carnations. Clusters for training of any height, either in pots or in the ground, are easily made by thrusting three or more taper-twigs into the earth, bending the top and tying them together with galvanised binding wire.

Arcades or rosaries can be artistically formed, an example of which is illustrated in fig. 68, using Bamboo tapers 14 feet long, and sticking them about a foot into the ground and the same distance apart in a line on each side of the path or walk, and fastening to them similar poles horizontally, with the twig-tops cut off. Such arcades can be of unlimited length, it only means extending the length of the horizontal canes by letting them overlap, and binding them together with galvanised wire. For annual climbing plants the structure can easily be taken down and packed away during the winter months, but where a permanent arcade is wanted it is advisable to tar the bottoms of the canes, a process which will materially prolong their life.

Conservatories, greenhouses, and ferneries afford many opportunities for the use of Bamboo. The taper-canes give a good effect when used for the training of light-growing plants. As Bamboo can be obtained up to 6 inches in diameter, flower and Orchid pots made of short lengths are very effective, either hung or stood about where desired. The hollow Bamboo just referred to, and with which everyone is more or less familiar, lends itself peculiarly to all kinds of flower decoration. At each joint is a strong membrane, which divides the cane into a number of water-tight cylinders, and these joints are practically rot-proof

By cutting a series of holes in a length of Bamboo, one between each knot, a very pretty holder for dried grasses or cut flowers is formed. Fig. 67 shows the kind of flower-holder here described, the holes being cut out with a thin-bladed saw, and by making a nail-hole at the back it can be hung up. By using the stouter Bamboos in this way, and planting miniature Ferns in each hole, a very pretty effect is obtained. For Fern or window-boxes, Bamboo can be artistically used in conjunction with virgin-cork. The canes can easily be split in halves lengthways, and will split true, so that shelving can be made more decorative by edging the front with the Bamboo, fixing it on with wire panel pins, taking care to always drill the holes first with an ordinary bradawl.

Arches, porches, porticos, verandahs, arbours, and summer-houses can, with a little practical knowledge, be easily constructed by any gardener, using Bamboo for the principal parts.

Fig. 67.—Flower-holder of Bamboo.

The tools required are but few and the material inexpensive and very durable, the chief thing being to learn how to make a strong and neat joint. By dint of a little practice this can soon be accomplished, after which the scope of ingenuity in the way of ideas is practically unlimited.

The tools chiefly required are: Rasp, fine-toothed saw, brace and centre-bit, light hammer,

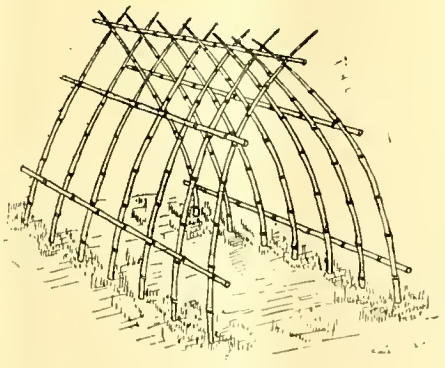

Fig. 68.—Arcade made of Bamboo.

bradawl, and knife (a pen-knife will do). The rasps are distinct from the ordinary wood rasp, being deeper in segment—in fact, quite a semicircle in section. These are sold in various widths from $\frac{1}{2}$-inch to $1\frac{1}{4}$-inch by most tool dealers. A 1-inch rasp is about the best size to have for general purposes. The saw should be of the kind known as a "tenon," or meat saw—a 10-inch need not cost more than 1*s.* 9*d.* *S. W. N.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT FIR GRANGE, WEYBRIDGE.

Orchids are the principal plants under glass in the gardens of W. A. Bilney, Esq. (gr., Mr. Whitlock), and the showy Dendrobiums, both species and hybrids, are the favourites among the Orchids.

The Dendrobium-house presented recently literally a mass of bloom, a large proportion of it being borne on grand specimens of Dendrobium Wardianum, which have stout pseudo-bulbs, many of them 3 to 4 feet in length. This is one of the handsomest of Dendrobiums, but in gardens generally it has a reputation for rapidly declining in vigour. This is not Mr. Bilney's experience, for he still has most of the first plants he purchased, and notably the pretty carmine-tinted D. Wardianum "Fir Grange" variety, for which an Award of Merit was obtained in 1900. Many handsome varieties were in bloom when these notes were taken, and also a plant of the best white form of D. Wardianum with several growths.

The varieties of Dendrobium nobile are also well represented, including the best white forms, and still the best-coloured variety, D. nobile nobilius, in good specimens. Out of a recent importation, however, Mr. Bilney is flowering two of the giganteum type different in shape to nobilius, and very finely coloured. A very interesting specimen of the old D. nobile is also in the collection, whose history has been traced for over fifty years. Of other species there were in flower some good specimens of Dendrobium Findlayanum and D. Brymerianum, and remarkable for extraordinary vigour several plants of D. albo-sanguineum, some of the pseudo-bulbs being considerably more than 1 foot in length, and very strong.

Of the hybrids in bloom were a very fine set of the best forms of D. × Ainsworthii, including the white D. × A. intertextum and D. × A. Hazleborne variety, for which Mr. Bilney received an Award of Merit in 1902; a number of distinct forms of D. × melanodiscus, of which the variety Rainbow is the showiest; good forms of D. × Euryalus Apollo, D. × splendidissimum, and D. × rubens grandiflorum. One of the new forms of this type now flowering has very finely formed flowers, white tipped with carmine-rose and with a fine claret disc to the lip; D. × The Pearl, a very delicately tinted flower; forms of D. × chlorostele, Clio, Aspasia, and Lutwychianum, all hybrids of D. Wardianum; D. × Schneiderianum, D. × Artemis, D. × Hebe, D. × euosmum leucopterum, and several pretty hybrids of the same strain with white flowers with purple disc to the lip, the best of which resulted from D. tortile × Ainsworthii; the fine magenta-rose D. × Harold, the handsome D. × Thwaitesiæ, one of the finest of yellow-petalled Deudrobes, and a great number of other pretty varieties. Of very rare varieties noted was a fine example of D. Falconeri giganteum with large and finely-coloured flowers, which seem to grow here most luxuriantly.

In the other houses was a varied selection of good Orchids, with Cypripedium Rothschildianum and some other Cypripediums in bloom; also a number of the best forms of Cœlogyne cristata, half-a-dozen good examples of Cymbidium eburneum, several of the orange-scarlet Lælia harpophylla, a bright group of Lælia anceps, some good Lycaste Skinneri, Lælia × Mrs. Gratrix, and several other showy kinds, including a very finely-coloured form of Cattleya Trianæ.

The cool-houses, a small range in two divisions, have been more recently completed than the other Orchid-houses, and the specimens of Odontoglossum crispum, obtained out of recent importations, are mostly unflowered, but are fast approaching the flowering stage. A few plants of O. crispum, O. triumphans, O. Rossii, O. pulchellum, &c.,

were in flower, but the main show of bloom in the cool-houses was a number of good specimens of the old form of Cypripedium insigne sylhetense, which is still a very distinct and free-blooming kind, and one of the easiest to grow of greenhouse plants. Moreover, it lasts a very long time in flower. *J. O'B.*

GENYORCHIS PUMILA.

This is the name given by Schlechter to an Orchid which at one time or another has been included under Dendrobium, Bulbophyllum, and Polystachya. It is a pretty little species which encircles the branches of the trees in the Congo district, and which has flowered in the Brussels Botanic Garden and in the Colonial Garden at Laeken, where also another Congolese Orchid, Polystacha polychæte, has produced its flowers. Neither plant is sufficiently showy to attract the notice of Orchid growers in general. They are figured in the last number of the *Revue de l'Horticulture Belge.*

DENDROBIUM FIMBRIATUM OCULATUM.

A healthy specimen of this beautiful species is now flowering in the large conservatory at Cherkeley Court, Leatherhead, the residence of Abraham Dixon, Esq. The plant, standing on a tall pedestal with twenty-seven splendid spikes of rich orange-yellow flowers, is exceedingly attractive. Altogether there are about 300 flowers on the plant, the majority of them measuring $2\frac{3}{4}$ inches in breadth; the large maroon-red spot on the lip is very beautiful, so that it is one of the finest varieties I have yet seen of this lovely Dendrobe. Mr. A. Wilson, the gardener at Cherkeley Court, told me that the plant has been grown in a vinery, standing on the ground a long way from the roof-glass, and in almost full sunshine. During the growing period the plant was kept thoroughly moist at the roots, and was well syringed overhead several times a day. All through the winter months it has been rested with the Vines, the temperature ranging from 40° to 50° by night. In the same house is a healthy batch of Cattleya Trianæ, and all the plants have been in the collection for a great number of years; there are several very pretty and distinct varieties, the most prominent among them being a fine plant of the rare C. T. Backhouseana. For several years past the deciduous Calanthes have grown well under Mr. Wilson's care. These plants are now commencing to push up strong, clean, healthy growths, and will be repotted during the next few days. The plants are grown singly in well-drained pots of moderate size, having good fibrous loam and a little coarse silver sand to root into. *W. H. W., March* 6.

DISA GRANDIFLORA, YELLOW VARIETY.

Of late years the discovery of a fine yellow variety of Disa uniflora, more generally known in gardens as D. grandiflora, has been reported from South Africa, and a correspondent under date February 6 says:—"Last week I saw two spikes of Disa grandiflora with flowers of a beautiful yellow colour, quite pure, and rather larger than the ordinary scarlet form."

Another correspondent sends us a cutting of a Cape paper referring to the event.

Bolus, in *Orchids of the Cape Peninsula*, says:—"There is a variety found near Du Toit's Kloof which has the sepals and galea tinged with orange," and it may be a form of that type which is now recorded.

In the Right Hon. Lord Rothchild's gardens a few, supposed to include yellow varieties, were received three years ago, but only good scarlet varieties flowered, and no yellow form has yet appeared in cultivation.

STAUROPSIS GIGANTEA.

We have on several occasions recorded interesting Orchids grown in an ordinary plant-house by D. Campbell Brown, Esq., Bank of Scotland House, Oban, N.B. Mr. Brown makes no pretensions to being an Orchid-grower, and yet has great success with some reputedly "difficult" plants. The species is generally called Vanda gigantea, and the plant now in flower is stated to have nineteen leaves, each 16 to 17 inches in length, and an inflorescence of seven flowers. The flower sent is $2\frac{1}{2}$ inches across, and the segments, which are very fleshy, are of a clear sulphur-yellow tint irregularly spotted with reddish-rose, the side lobes of the labellum being tinted with rose. It is a very singular and attractive species.

VEGETABLES.

THE BEST PEAS.

HAVING to lecture on edible Peas before the members of our Gardeners' Society, I invited six first-class gardeners, most of whom are also famous exhibitors of vegetables, to furnish me with their special selections of six varieties of Peas, medium to tall in height, suited to furnish a succession for a long season. One gardener, Mr. A. Ward, formerly of Stoke Edith, and now of Ashford, Kent, whilst an eminent gardener is not an exhibitor, and I purposely invited his list, because doubtless his point of view would be that of a domestic supply of Peas rather than for exhibition. Still, no doubt each of the other gardeners, Messrs. J. Gibson, E. Beckett, W. Pope, W. Fyfe, and J. Bowerman, has given full consideration to that object in their selections. Prior to receiving any of the lists, I prepared a list from my own experience of many varieties, and that I will give with the rest.

Mr. A. Ward's selection is:—	
Early Giant	Duchess of York
Centenary	Criterion
Eureka	Autocrat
Mr. E. Beckett's is:—	
Early Giant	Edwin Beckett
Duke of Albany	Alderman
The Gladstone	Autocrat
Mr. J. Gibson's is:—	
Early Giant	Senator
Duke of Albany	Prize-winner
The Gladstone	Autocrat
Mr. W. Pope's is:—	
Early Giant	Edwin Beckett
Acme	Centenary
The Gladstone	Autocrat
Mr. W. Fyfe's is:—	
Early Giant	Peerless
Exonian	Criterion
Alderman	Autocrat
Mr. J. Bowerman's is:—	
Early Giant	Edwin Beckett
Prestige	Criterion
The Gladstone	Autocrat
My own selection is:—	
Early Giant	Senator
Prize-winner	Centenary
The Gladstone	Autocrat

The following show the number of votes given to each of the selected sixteen varieties from seven voters:—Autocrat, 7; Early Giant, 7; The Gladstone, 5; Edwin Beckett, 3; Centenary, 3; Criterion, 3; Alderman, 2; Duke of Albany, 2; Prize-winner, 2; Senator, 2; Acme, 1; Exonian, 1; Eureka, 1; Prestige, 1; Peerless, 1.

I have purposely refrained from giving the names of any firms associated with the varieties, because I do not know in all cases who put them into commerce. Prestige is the only one that is unknown to me. It is significant that there seems to be no Pea more popular as a first early than is Early Giant, and none more so for a late one than is Autocrat. The Gladstone also comes out well, but it may not yet have become so widely known as it deserves. What is most obvious, however, is that we have many varieties of Peas of medium height possessing superb "marrow" flavour and wonderful cropping qualities, of which those named in the list can hardly be excelled. I did think, however, that someone would have named Thomas Laxton, certainly a fine cropper. *Alex. Dean, Kingston-on-Thames.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

The Potting of Dendrobiums presents more difficulties than occur in the potting of most other Orchids, owing to the tenacious character of their roots; therefore, so long as the plants have sufficient room and the drainage is perfect, renovation of the surface materials will keep the plants healthy and vigorous for years. Plants of D. nobile, D. crassinode, D. Findlayanum, and D. aureum, with the many hybrids therefrom, should be overhauled soon after new growths appear, so that fresh material may be supplied in time for the new roots to benefit therefrom. If the plants are grown on a stage, they should be put into pots, and these should be about half filled with drainage material. Work in amongst the roots a mixture of fibrous peat, short lengths of bracken rhizomes, and sphagnum-moss in equal parts, finishing off the surface neatly with peat and sphagnum-moss. Do not press the material very tightly, but make a few of the pseudo-bulbs secure by tying them to neat stakes. If the plants are to be suspended, use good-sized shallow baskets or perforated pans, and employ but little drainage material other than that afforded by the "Fern-roots." This class of Dendrobium needs a moist atmosphere, a moderately high temperature when growing, and moderate protection from bright sunshine, especially in the early stages of growth; afterwards a little more sunlight will not be harmful. When the plants are nearly completing their growth for the season, only a sparing supply of water will be needed, but the atmosphere may be kept moist by judicious damping and spraying. Those allied to D. nobile may be propagated by taking lengths of suitable old bulbs, almost cutting them through between every other node, and then laying them on damp sphagnum moss or other moisture-holding material in a propagating case. When the resultant growths emit roots fix each piece in a small pot and cultivate it in a warm atmosphere.

Dendrobium Wardianum.—Few growers succeed in keeping this grand species in a thriving state many seasons after it is imported, the balance of light and heat being so unstable at the season when the newly-made pseudo-bulbs have to grow and mature. The new growths having made considerable progress root action will soon follow, and before this occurs the necessary cultural details should be given attention. Do not disturb the plants unless there is absolute need to do so, but pick out as much of the old material as possible and replace it with new. In cases where potting is decided upon crack the pot and insert those parts to which live roots cling into the new receptacle. Employ small pans for suspending the plants, afford ample drainage, and a compost of good fibrous peat and sphagnum moss. This species enjoys a high temperature with free ventilation, and when there is young growth on the plants protection from strong sun-light is essential. A light and warm position in a Cattleya-house is a very suitable one for the plants, provided the summer season is at all a good one, because failure generally overtakes plants subjected to a high artificial temperature or a stuffy atmosphere. Speaking generally, Dendrobiums of every class resent frequent waterings, excepting for a short period when in most active growth and root production, and even then the materials should be such that the water will get away easily. In no case do I advise the use of decaying leaves as an addition to the rooting medium for Dendrobiums.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORNER, Impney Hall Gardens, Droitwich.

Pines.— Plants which have been developing their fruit during the winter months will require to have a dryer atmosphere as the fruits approach ripeness, and water should be withheld from them. The fruits on the earliest Queens will commence to swell freely as soon as the flowers have passed, and applications of weak natural manure-water and of guano-water may be given more frequently

in the place of clear water. Remove the surplus suckers from each plant whilst they are small, retaining only one or two of the strongest. All gills that appear around the base of the fruits must be taken away. The weather in March and April being generally very changeable, extreme care is necessary in ventilating the structure, but a little air should be admitted in bright weather when the atmospheric temperature has reached 78°, and is steadily rising. When the weather is mild the temperature at night may be 75°, falling to 70° in the morning. Let the bottom-heat be maintained steadily at 90°. Start the fires early in the afternoon, and by this means and by retaining the sun-heat it will be possible to maintain the required temperature without having to heat the pipes excessively. Until the end of next month cover the pits at night with mats or other protective material. Do not syringe the plants overhead yet, but moisten the surface of the beds and all available spaces at closing time, and damp the paths more frequently, occasionally using liquid-manure for the purpose. Examine that part of the hot-bed near to the hot-water-pipes, and if the material is dry apply water at a temperature of 85°. Secure each of the fruits to two neat stakes, as they require support to keep the crowns straight. Place each stake at about 2 inches from the sides of the pot, they will not then injure the tender roots.

Succession plants which were potted last month into pots in which they will fruit will require to be watered very carefully until they have made plenty of roots and are growing freely. The plants have been kept in a rather close and moderately moist atmosphere, but as they become better established ventilation may be applied more freely. The temperature at night may be 65°, allowing a rise during the day. Repot any plants which were not attended to last month. Pot up suckers as soon as they are obtainable, and plunge them in a bottom-heat of 80° until they have made roots, after which they will require similar treatment to that advised for succession plants.

PLANTS UNDER GLASS.

By A. Bullock, Gardener to E. J. Withes, Esq., Copped Hall, Epping, Essex.

Begonia Gloire de Sceaux.—In order to obtain large specimens of this plant propagation should be commenced as early as possible. Select base or sucker growths for cuttings, and insert them singly in thumb-pots, plunging these in a brisk bottom-heat. They will soon make roots, and should then be given a shift into slightly larger pots before the smaller ones have become so filled with roots as to cause a check to the plants. Let the soil consist of good fibrous loam two parts, leaf-soil and broken lime-rubble one part of each, adding sufficient broken charcoal and silver-sand to keep the compost porous. Do not pot the plants deeply, or they will probably collapse suddenly and for no apparent reason. It is to deep potting and to neglect in adding sufficient lime-rubble to the soil that I attribute such failures. Well-grown plants are of great service from December until April, for apart from the beauty of the flowers the rich bronze-coloured foliage is very effective. Guard the plants at all times against suffering a check, and cultivate them in a warm, moist atmosphere, in a light position, shaded from direct sunshine. Even from the potting stage and until they flower, the plants should be treated with "Quassia Extract" in the manner advised recently for Jacobinia chrysostephana.

Begonia Haageana, when grown in pots in a warm atmosphere, remains in serviceable condition for a long time during summer, but planted against a partially shaded wall in a moist atmosphere the plant grows more luxuriantly, and flowers almost incessantly, the effect of the blooms among Ferns and other greenery being charming. Cuttings may now be inserted, and another batch a little later to form a succession. Good fibrous loam and turfy peat, with a liberal supply of silver sand added, will form a suitable compost.

Begonia corallina is a useful plant for decorative purposes, but should be planted out in a border under glass where there is plenty of heat and moisture, and where it can be allowed to grow up the roof, in order for its fullest effect to be realised. When a plant has become established it makes vigorous growth, and is rarely without flowers. For making cuttings select growths of moderate vigour only, and propagate them similarly to B. Gloire de Sceaux.

Begonia President Carnot may be treated in the same way as B. coralliua. The "trusses" of flowers being large and handsome, they are very effective, especially if grown overhead.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Aston Rowant House, Oxon.

The Loganberry.—This is a hybrid between the Raspberry and one of the American Blackberries. Growers should be particular to obtain plants propagated from reliable stocks, as seedlings do not reproduce themselves true to character. A quantity of these plants purchased from the continent turned out to be quite worthless, all being seedlings. The plant can be grown in various forms, and is adaptable for covering arches, pergolas, and trellis-work; also for forming wind-brakes in the fruit-garden, and for divisions between various parts of the vegetable-garden. Canes that were planted this season may be cut down to within 1 foot of the ground level. The ground previous to planting should be thoroughly prepared and receive a liberal addition of manure. Established canes should have all the old growths removed directly fruiting is over, but if this has not been done proceed with the work immediately, retaining four to six of the straightest and strongest young growths. If these are well ripened they may be allowed to remain their full length. Those plants that are tied or nailed to walls should have their canes trained about 12 to 18 inches apart, and stopped at the height of the wall. North and north-east walls are admirably adapted for the plant's requirements, and the fruit from this situation will be produced later than from those planted in more sunny positions, and thus the season for this fruit will be prolonged. The Mahdi, a new hybrid of similar parentage as the foregoing, requires the same treatment. The Japanese Wine-berry (Rubus phœnicolasius) has little merit for culinary purposes. The foliage and wood are of a very ornamental character, and the plant is adapted for covering bare places, and is effective when allowed to grow wild and as isolated specimens.

Black Currants. — Now that the buds are swelling keep a sharp look-out for the "big bud" disease [mites], and if the diseased buds are not too numerous, hand-picking should be resorted to. This practice, where Black Currants are extensively grown, would necessarily be expensive; in such cases much good will result by spraying the trees with a mixture of sulphur, soft-soap, and paraffin in the proportion of 2 oz. of the first two to 1 gallon of water, adding a wineglassful of paraffin to the whole. Keep the mixture well stirred while it is being applied.

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Peas.—Good breadths of Peas may now be sown, and there will be no danger of their rotting in the ground. Such varieties as Mayflower, Little Marvel, Daffodil, Chelsea Gem, Exonia, Criterion, and Carter's Buttercup, sown here in January, are now well above ground, but in the event of cold cutting winds it will be necessary to draw the soil towards them in ridge form to serve as a protection. Dust with soot to prevent damage from slugs and sparrows. Peas that have been raised under glass, and have been hardened off well, may be planted-out in sheltered positions where the sun's rays will reach them. Then put some branches of Yew about 18 inches high at distances of 3 feet apart, over which stretch nets to afford shelter and protection from birds. It is a good as well as a general practice to sow Spinach between the rows of Peas.

Cauliflowers raised from seeds sown in the autumn should now be planted out in a sunny, sheltered position. If afforded such protection as is advised above for Peas, it is an advantage to get the plants put out early and before they are of large size into rich soil, as there is then less danger of their becoming blind. Plants for affording the first crop we are now putting into 8-inch pots. Seeds of Cauliflower should now be sown in the open, and these will afford a succession to the autumn-sown plants. Such varieties as Early London, Eclipse, Autumn Giant, and Self-Protecting, will form a good succession.

French Beans.—To maintain a supply of this favourite vegetable, any portable frames upon hot-beds that have been used for such crops as Asparagus should be cleared and sown with French Beans. These will provide a supply much in advance of that obtainable from seeds sown out-of-doors.

Potatos which have sprouted under glass may be planted in such frames as advised above for French Beans, and a few may be planted out-of-doors in a sheltered border near to a south wall, where protection can be easily provided in the event of spring frosts, but the soil should have been previously prepared, and should consist of a good proportion of partly-decayed leaf-soil, old potting-soil, road-scrapings, and wood-ashes, well mixed together. By these means a fortnight may be gained in the time of lifting new tubers.

Tomatos.—Sow seeds in gentle heat for raising plants to be cultivated out-of-doors. Place the seeds 1 inch apart in shallow boxes, for if the seeds be sown at all thickly in boxes or pots the danger of allowing them to become drawn is greater. The plants should be kept near to the glass until removed out-of-doors. They need perfect drainage and moderately rich soil, free from stable-manure, but containing wood-ashes.

Seeds of Brussels-Sprouts, Cabbage, Leeks, Lettuce, Parsley, and other herbs, may be sown on well-prepared ground. Sow seeds of Radishes at intervals of a few days.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Seed Sowing.—Seeds of several varieties of "annuals" should now be sown, including China Asters (especially the single varieties), Pansies, Phlox Drummondi, Cannabis gigantea, Cosmos, Coreopsis, Oxalis corniculata, Scabious, and Salpiglossis. Prepare a suitable hot-bed in a frame, covering the surface with a layer of fine, light soil about 12 inches in depth. Sow the seeds in drills about 1 inch deep. Seeds of Acacia lophantha, Daturas, and Erythrina cristagalli should also be sown. Propagate plants of Paris Daisies, and of Campanula isophylla and the variety alba. These Campanulas are especially suitable for growing in vases, &c., or for planting in warm nooks on the rockery.

Lilies require a deep, rich, well-drained soil and a situation that is sheltered from strong winds and from excessive sun-heat. L. auratum and L. speciosum succeed well when planted on slopes facing to the south-east. The present is a favourable time for top-dressing the bulbs with well-rotted manure. The varieties L. s. Crown Princess, L. s. rubrum multiflorum, and L. Schrymakersii, produce their flowering-spikes early and freely. L. candidum, L. croceum, L. chalcedonicum, and L. testaceum thrive well in ordinary borders. The species first-named should be seldom disturbed, or the plants will fail to produce the best results.

Trees and Shrubs. — Proceed with planting shrubs on all favourable occasions. Tall trees recently transplanted must be made secure from injury by wind. An excellent manner of securing freshly-planted trees is to drive three pegs into the ground at equal distances from each other, and 9 feet from the tree. Tie some soft material two-thirds up the stem of the tree, round which fasten stout wire, and secure to the pegs in the ground. Cotoneasters are excellent subjects for planting on rockeries, on walls, and on steep banks in shady places, and all the species are easily grown. Some of the choicer varieties are C. bacillaris, C. horizontalis (with prostrate frond-like growth), and C. congesta (a charming evergreen species, suitable for rockeries). Among deciduous trees and shrubs having conspicuous golden foliage are: Acer palmatum aureum, Catalpa bignonioides aurea (useful in subtropical bedding), Populus canadensis aurea, Quercus pedunculata concordia, Spiræa opulifolia aurea, Ulmus campestris Dampieri aurea, U. c. Roseelsii aurea.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, MAR. 22 { Royal Botanical Society's Show at Regent's Park.

FRIDAY, MAR. 24—Royal Botanical Society's Meet.

SALES FOR THE WEEK.

MONDAY NEXT—
Choice Border Plants and Perennials, Roses, Azaleas, Lilies, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Palms, Plants, Azaleas, Rhododendrons, Fruit Trees, Roses, Herbaceous Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY NEXT—
Gladiolus, Spiræas, Roses, Herbaceous Plants, Begonias, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Orchids in large variety at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —43·4°.

ACTUAL TEMPERATURES :—
LONDON.—*Wednesday, March* 15 (6 P.M.): Max. 56°; Min. 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 16 (10 A.M.): Bar., 29·3; Temp., 51°.
Weather—overcast, with occasional sunshine.
PROVINCES.—*Wednesday, March* 15 (6 P.M.): Max. 48°, Scarborough; Min. 40°, S E. Coast of England.

Some Events of the Week. At a meeting of the Committee of the National Rose Society held on Tuesday last, a discussion arose as to the form which the memorial to the late Dean HOLE should take. Rev. J. H. PEMBERTON, in addressing the meeting, emphasised the necessity of dealing with the matter on broad lines. It would not be enough to found a class in an exhibition schedule, but some means should be taken to excite the sympathies of others besides exhibitors and the members of the National Rose Society. There were hundreds of people unconnected with the Society and with Rose exhibitions who knew Dean HOLE through his books, cherished his memory, and who would, if properly approached, be desirous of testifying to their appreciation of the late Dean's work. A large number of our American cousins regarded him as a public benefactor, and would probably contribute to a permanent memorial if some definite scheme were placed before them.

Dr. MASTERS, complying with the request of the Chairman, afforded some explanations as to the manner in which the Veitch Memorial Trustees used the funds entrusted to them for the promotion of horticulture, and for the recognition of valuable services to it, in any way, without any limitation as to nationality. Lately the Trustees had contributed a most welcome addition to the funds of the Lindley Library. He suggested that the Hole Memorial should be instituted on similar lines. Ultimately a small Committee was appointed to consider the matter further, and it was decided to meet at 2 o'clock on April 11.

The most interesting feature of the meeting of the Scientific Committee, held on the same day, was the presentation to Professor HENSLOW of a handsome tea and coffee service on the occasion of his retirement from the Honorary Secretaryship of the Committee, after a service of more than twenty-five years. Dr. MASTERS, in making the presentation, alluded to the history of the proceeding, and explained that the presentation was made exclusively by the members of the Committee and by some of the members of the Council. Had those who were concerned in the organisation of this memorial sought outside co-operation it is certain the response would have been much larger, but it was felt to be desirable to confine the subscriptions to members of the Committee.

Professor HENSLOW, in acknowledging the gift, alluded to the history and present condition of the Committee, and to the great pleasure he had derived from its meetings. It is satisfactory to know that although owing to change of residence Mr. HENSLOW will not be able to attend the meetings so regularly as heretofore, he will still be enabled occasionally to give his valuable services to the Committee and to the Society generally.

This agreeable function disposed of, Mr. WILKS made two announcements which gave great gratification to the members. The first was that some gentleman whose name was not mentioned had promised to present the Committee with a microscope, and requested some suggestions as to the kind of instrument required, which were thankfully given.

The second intimation was that Mr. MASSEE had undertaken to initiate some experiments at Wisley on the bud-mite of the Black Currant, and also to carry on some investigations on the germination of seeds under certain conditions. To make the beginning of experimental research at Wisley is in itself a hopeful sign and a promise of better things to come.

As we are going to press we receive information that Mr. R. NEWSTEAD, whose work on the Coccidæ has elicited the warm approval of the experts, and who has acted as our Entomological Referee for some years, has been requested to undertake the duties of a special lectureship in economic entomology and parasitology in the School of Tropical Medicine attached to the University of Liverpool.

BOUGAINVILLEA SPECTABILIS IN AMERICA (see Supplementary Illustration).—The following note is from Mr. SIDNEY HOCKRIDGE, manager of the City Nurseries, Redlands, California: "Noticing that illustrations of several Bougainvilleas have appeared in the *Gardeners' Chronicle* recently, I am sending you a picture of a dwelling here (that of Mr. HENRY FISHER), which has attracted the attention of world-wide travellers, because of the remarkable profusion of the Bougainvilleas upon it. The species is B. spectabilis, and four plants were planted in June, 1897. They were hardwood cuttings 9 inches high and barely rooted. The total length of wall surface now covered by these four specimens is 100 feet, and they have attained to a height of 28 feet. Some of the growths doubtless are over 30 feet in length. These Bougainvilleas are never pruned, but have been frequently cut back by frost. On February 14, 1902, they endured a temperature of 25°. On that occasion they were found to be in bad condition however, all soft growth and all firm, ripe wood less than ½ an inch in diameter being killed. In October, when the photograph was taken, the display of colour was wonderful, and to-day, Dec. 27, the colour is very fine, but has faded to some extent and the flowers are dropping fast. On the right side of the picture may be seen a plant of Bignonia venusta. This has established itself and seems likely to contest the supremacy of the Bougainvillea. The Bignonia never fails to give a glorious display from December onwards, and just now is at its very best, furnishing a magnificent display of orange colour. The aspect is to the south."

THE ROYAL SOCIETY. — Among the fifteen selected candidates for election this year are Professor F. W. OLIVER and Lt.-Col. D. PRAIN, the Superintendent of the Botanic Garden, Calcutta.

THE BOARD OF AGRICULTURE AND FISHERIES.—We are informed that Mr. AILWYN E. FELLOWES, M.P., the new President, has appointed Mr. F. L. C. FLOUD to be his Private Secretary. Mr. REGINALD LUCAS, M.P., will act as Mr. FELLOWES' Parliamentary Private Secretary (unpaid).

TESTIMONIAL TO MR. H. ECKFORD. — All who have sympathy with the proposal to present a testimonial to Mr. HENRY ECKFORD, in recognition of his services to floriculture, are asked to communicate with Mr. H. J. WRIGHT, 32, Dault Road, Wandsworth. Our readers are well aware that the evolution we have witnessed in the Sweet Pea has been mainly due to the work done by Mr. ECKFORD at Wem.

THE FRUIT INDUSTRY.—The Departmental Committee appointed by Lord ONSLOW to enquire into and report upon the Fruit Industry of Great Britain held sittings on the 7th to the 10th inst. The following members were present: Mr. A. S. T. Griffith-Boscawen, M.P. (Chairman); Colonel Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Hodge, Mr. Vinson, Dr. Somerville, Mr. P. Spencer Pickering, M.A., F.R.S., the Rev. W. Wilks, M.A., and Mr. Ernest Garnsey (Secretary). The Committee had under their consideration the draft report prepared by the Chairman.

ROYAL BOTANIC SOCIETY OF LONDON.—We are informed that the Society has arranged to hold its second annual horticultural exhibition on Wednesday, Thursday, and Friday, June 7, 8, and 9, instead of June 14, 15, and 16, as originally proposed. This is in addition to the usual monthly shows.

FORESTS, WILD AND CULTIVATED.—Dr. A. HENRY will discuss this subject at the meeting of the Horticultural Club on March 28. The lecture will be illustrated with lantern slides.

PREVENTION OF CORRUPTION BILL.—In the House of Lords on the 13th inst., the LORD CHANCELLOR, in moving the second reading of this Bill, said he had received a letter from the principal bankers of London urging the high importance of this measure to the commercial community, and expressing their earnest hope that the Government would pass it into law. That was a remarkable document, which ought certainly to receive considerable attention. He hoped the Government would take care that the Bill should pass, and should not be lost again at the end of the Session. It dealt with a very serious and crying evil, which, by the confession of all persons, required remedy. Lord AVEBURY

said that the letter to which the noble Lord on the Woolsack had referred was signed by every one of the clearing bankers of London. He would add also that it expressed their thanks to the Lord Chancellor for having on more than one occasion carried the Bill through the House of Lords, and their hope that the Government would carry it through the House of Commons. The Archbishop of Canterbury said that the Bill had the support of a great many people outside the ranks of business men, who were desirous of promoting a reform urgently needed in the interests of the general morality of the country. He earnestly hoped the Bill would be placed on the Statute-Book that session.

The Shamrock.—Messrs. Ramsay & Son, of Ball's Bridge Nurseries, Dublin, have received an order from the commanding officer of the Royal Dublin Fusiliers at Malta, to supply 1,000 sprigs of Shamrock to be worn by the soldiers of the regiment on St. Patrick's Day.

Presentation to a Gardener.—An interesting presentation, consisting of a silver tea-service, was made on Saturday evening, March 11, by the committee of the Rochdale and District Chrysanthemum Society to Mr. E. Hubbard, who is leaving the district to take up the position of head-gardener at Colonel G. Kemp's residence at Lingholm, Keswick.

"Illustriertes Handbuch der Laubholzkunde."—This is the third part of a very valuable treatise on the trees and shrubs which are hardy in Central Europe and a portion of Britain. The text is in German, with numerous contractions, which are embarrassing at first, but to which the reader soon becomes accustomed. The numerous illustrations are very helpful, so that in spite of the language in which it is written the book will be of great service to all students. The author is Mr. Camillo Karl Scheider, and the publisher is Gustav Fischer, of Jena. Any foreign bookseller, such as Messrs. Williams & Norgate, could procure it. We observe that the name Calycanthus is replaced by that of Butneria, which is a very unfortunate change. The present part contains details of many genera specially interesting to gardeners, such as Berberis, Magnolia, Philadelphus, Ribes, Escallonia and Platanus. The author considers Platanus acerifolia, our London Plane, to be a hybrid between P. orientalis and P. occidentalis.

The Chambre Syndicale of Ghent.—We have already had occasion to mention the twenty-fifth anniversary of this Society, which has done such great service in watching over and promoting the interests of commercial horticulture in Belgium. The exhibition held on the occasion (February 5) was the most important of its kind, and was well supported, not only by the Ghent nurserymen, but by exhibits from the Brussels Botanic Gardens, the Marquis De Wavrin, and others. The banquet held in the great hall of the theatre was also a great success.

A New Name for an Old Practice.—Mr. Galton has introduced the name "eugenism" or "eugenics" to connote the selective process employed in selecting the most suitable parents for breeding purposes, whether in animals or in plants. Mr. Groff, of Simcoe, Ontario, Canada, has established a great reputation for his cross-bred Gladioli, and in commenting upon them he is very energetic in pronouncing upon the necessity of making use for breeding purposes of the most highly developed "tame species," as he calls them. He deprecates crossing with wild species—meaning, we suppose, those that are the ancestors of our present races. Of course there is much reason in this, for to do otherwise would be to revert rather than to progress, to start from the same point from which our fathers did, or approximately so. Nevertheless, there may be cases in which it is desirable to go back to the wild form to secure vigour of growth, which may have been impaired by continuous inbreeding. Again, there are dozens of wild species of Gladiolus not yet introduced, but some of which would in all probability prove valuable as the source of new forms, new shades of colour, and so forth. Of course, time would elapse before the raiser could make sure that his seedlings were suitable to new and varied conditions, but that is the case even with the offspring of "tame" species.

Evesham Market Gardeners' Visit to Paris.—The Evesham market gardeners who visited Paris in January have purchased a handsome silver-mounted claret jug, which this week Mr. McKay has forwarded to M. M. Plique, the French gardener who showed them round the gardens at Vitry that memorably cold day when the Englishmen learnt, among other things, that France is even colder than Evesham. The inscription on the jug is as follows:—"Souvenir from the Evesham market gardeners on their visit to Vitry, January 13, 1905."

"The Gooseberry Growers' Register for 1904."—This is a list of the Gooseberry shows held principally in the North of England during 1904. It contains an enumeration of the kinds exhibited, and of the weights of each fruit, and as it also contains a record of the heaviest berries from 1809 to 1904 inclusive, it is really a statistical document of some importance. For the year 1904 we find the heaviest berry was one called Jumbo (red), which weighed 29 dwts. 6 grains; Ringer (a yellow berry) weighed 29 dwts. 4 grains; Surprise was the heaviest green berry, 27 dwts. 8 grains, and Transparent was the heaviest white berry, 28 dwts. 29 grains. "London" still holds the premier position with a weight of 37 dwts. 7 grains in 1852, and for many years in succession it was the heaviest berry. Other berries weighing 30 dwts. and over are Lion, Bumber, Wonderful, Antagonist, Ringer, Macaroni, Garibaldi, Bobby, Rover, Leveller, Dr. Woolley, Stockwell, Ploughboy, and Lord Derby. "No labour, care, or skill is considered excessive that results in producing the monster Gooseberries so often ridiculed, but which are really triumphs of skill and trophies of culture and perseverance." We have shown that the records are of scientific value, and if some further information as to the habits of the bushes, the shape and size of the foliage, and the conditions under which the bushes are grown, the record would be still more valuable. The book can be had from Edward Foulds, Bingley.

Illustrations of Choice Vegetables.—We have received from Mr. Ernst Benary, the well-known German seedsman at Erfurt, the first part of a work that promises to become of first-rate importance to cultivators of choice vegetables. Part I. of *Vegetables Photographed from Nature* includes eight loose plates upon thick art paper, each measuring 20 by 18 inches, and representing types of the following vegetables: Cabbages, Red Cabbages, Borecoles, Endives, Onions (Tripoli), and Radishes. The work is in no sense a seedsman's catalogue, and the names of the varieties appear as a rule without the name of any particular firm as a prefix or affix. On the two plates devoted to green Cabbages, for instance, such varieties are shown as Enfield Market, Oxheart, St. John's Day, Early York, Winnigstadt, Brunswick Drumhead, Fottler's Improved, &c. Some of the varieties, though not all of them, are well known to cultivators in this country, and the reproductions are so excellent that easy comparisons may be made between familiar types and others that are less well known. Interesting differences are shown in the manner in which the leaves are folded over each other to form what is commonly termed the "heart." The Filder or Pomeranian Cabbage, for instance, has a "heart" which represents an acute if miniature pyramid of quite opposite shape to that of the well-known "Drumhead" type. The Red Cabbages, of which six varieties are shown, more nearly resemble each other in form, but there would doubtless be differences in habit, earliness, &c. Seven varieties of Borecole are illustrated, of which the Dwarf Green-curled (extra selected) appears to be a very desirable type with profusely curled leaves. Of the eleven varieties of Tripoli Onions, few of the names would be familiar to our readers, but in other respects the bulbs, like those grown in this country, vary greatly in form, some being quite flat, and others representing perfect globes. The illustrations of Endives are less convincing the plants are difficult subjects to reproduce, and for this reason a leaf of each variety is shown separately. As many as fifteen varieties of Radishes are illustrated, and they represent every modification in shape between the long root and that of Turnip-shape, but, in view of the importance cultivators attach to the amount of top-growth particulars varieties make when forced, it would have been well to have reproduced the plants in their entirety. It should be mentioned that this is an English edition, and although printed in black-and-white, a duplicate plate of the Onions is coloured, in order to show that an edition of the work may also be obtained in which each vegetable is reproduced in its natural colour. One part will be issued every year at the price of six shillings.

Market Grower's Daffodil.—Mr. W. B. Hartland sends us a box of the single Trumpet Daffodil Cervantes, with photograph taken at Christmas from plants grown under glass. This is the earliest period it has flowered in any year with Mr. Hartland, but Mr. Clarence Webb, of Kendal, and others have had it in bloom much earlier. The blooms are pale-straw colour, and in size like those of Princeps. North Star is much smaller, but can be bloomed in November. "The flowers sent herewith are from the open; we have been cutting them for a month. We have plenty of varieties now out-of-doors, including the White Trumpet sort Bishop Mann." Mr. Hartland also sends flowers of Eupatorium vernale, as mentioned in last report of the Royal Horticultural Society, where it received an Award of Merit at the Floral Committee, February 9 1904. It is all that can be desired as a winter-blooming market plant.

Don't Sit on the Bananas.—This instruction should, in the opinion of the Archbishop of the West Indies, be displayed prominently in all schools in the islands, so that the children may learn what not to do. His Grace had observed how good-natured drivers were in the habit of giving a lift to weary travellers, and that very frequently these travellers took their seats on the Bananas as they were being conveyed from the plantations to the quays. The result was that on their arrival in England the fruits were found to be bruised and rotten, and the price obtained was lowered in consequence. Surely some method could be devised of securing the continuance of human kindness without injury to the Bananas!

Forestry in the United Kingdom.—Dr. W. Schlich has done good service by reprinting with additions the substance of various lectures that he has delivered on the subject of forestry, as well as of articles contributed by him to these columns. In these papers he points out (1) the importance of the forestry problem to the nation (2) and the measures which should be taken in this country to insure the benefits offered by forestry, (3) adds notes on the afforestation of surplus land and the treatment of some types of British woodlands. There are many who would be deterred from reading the author's *Manual of Forestry*, authoritative though it be, who

would be glad to peruse the present modest treatise and in some cases to make its perusal preliminary to a careful study of the Manual. We strongly advise all who are concerned in the management of woodlands or in the afforestation of suitable areas to become the possessor of this little book, which is published by Bradbury, Agnew & Co., Bouverie Street, E.C.

Weather Vagaries. — In this country we have had a large and varied assortment of samples so far as weather is concerned, but, on the whole, we cannot be said to have had a severe winter. In Southern Europe affairs have been very different, and even in India the temperature in the northern and central regions has, says *Indian Planting and Gardening*, been as low as 22° Fahr., and even lower. In Calcutta itself the temperature has been as low as 40°, which was felt to be very uncomfortable in "muggy Bengal."

"Botanical Magazine." — The March number contains coloured illustrations of the following plants:—

Romneya trichocalyx, Eastwood, t. 8002. — Nicholson in *Gardeners' Chronicle*, 1902, ii., p. 190. A Californian Poppy with finely-cut glaucous foliage, large white flowers 6 inches across. It differs from R. Coulteri in its densely setose calyx. Kew.

Dendrobium regium, Prain, t. 8003. — An Indian species described by Mr. Rolfe as very like D. nobile in habit. The flowers are nearly 3 inches across, with the perianth segments spreading, rosy-pink, whitish at the base; sepals oblong, petals broadly ovate, lip projecting, convolute at the base, front lobe ovate, acute, rosy-pink with darker stripes; throat and tubular portion of lip yellow. It was sent from Calcutta to Kew.

Rosa Hugonis, Hemsley, n. sp., t. 8004. — A species from Western China raised at Kew from seed collected by Father Hugo. It has straight prickles of various sizes, adnate stipules, pinnate leaves with five lateral pairs of narrow, oblong, serrated leaflets, and one single terminal leaflet; flowers solitary, 2 inches across; sepals linear lanceolate; petals yellow. The shrub is hardy at Kew, and is an acquisition to the "garden" Roses.

Æchmea lavandulacea, C. H. Wright, t. 8005. —Discovered by Mr. Broadway in Grenada, W.I., on rocks overhanging the sea. The leaves are broadly strap-shaped, serrate, and recurved near the top. The peduncles are rose-coloured with lanceolate bracts of the same colour. The flowers are numerous, distichous, that is placed in dense rows one row on each side of the branches of the panicle. The secondary bracts are of a greyish-lavender colour, and covered with whitish, fluffy scales; corolla deep violet. Kew.

Nicotiana Forgetiana, Hemsley, ex Hort. Sander, t. 8006.—This species, which had been previously named but not described, is one of the parents of the beautiful N. Sanderæ ×. As the hybrid is likely to displace the original species, it is satisfactory to have this description and illustration. In itself it is very attractive, though less so than its offspring. It has oblong, acute leaves and loose panicles of rose-coloured flowers on slender stalks. The calyx is slightly irregular, and the lobes of the corolla are ribbed in the centre. One of the five stamens is shorter than the other four. It is a native of S. Brazil, and was introduced by M. Forget to Hort. Sander.

Obituary.

T. M. Crook. — The death occurred on March 8 of Mr. Thomas Miller Crook, Stanley Grange, Hoghton, near Preston, aged forty-five years. Mr. Crook was well known in the district as a cultivator of Orchids.

Mrs. Cocker.—We regret to announce the death, on the 13th inst., of Mrs. Cocker, wife of Mr. Cocker, the well-known nurseryman, Springbill, Aberdeen.

THE FERNERY.

CULTURE OF HARDY FERNS.

Now that Ferns have benefited by a long winter's rest, and are still so far in a dormant state that there is no new growth liable to damage, it is obviously the right time to rearrange, repot, and divide the plants. These operations are best effected in March, and under glass they cannot be undertaken too soon. Out-of-doors, the end of the month is early enough, especially as it is not well to expose the Ferns, which presumably have been protected throughout the winter by their old fronds, dead or alive, prematurely to risk of damage by removing this protection and subjecting them to cold drying winds. Pots, pans, and all similar receptacles should now be overhauled and cleaned, and the contained plants shifted and repotted according to their needs. Fine specimens in large pots often remain in good healthy condition for many years, and if last season's growth was satisfactory they can be left alone, or at most a little mulching of fresh soil may be added. If, on the other hand, they have diminished in size, it is best to turn them out, when quite possibly it may be found that the great mass of soil has gone sour, and the bulk of the roots has perished in consequence. In this case all dead material should be pulled away, and the Fern installed in a smaller pot with fresh compost. The best general compost consists of a mixture of half good yellow friable loam and half brown fibrous peat, with a liberal quantity of coarse silver-sand, the whole being rather lumpy than fine. We must not forget that Nature in Fern habitats uses no sieve and the soil there is generally some such mixture as above, and consequently very open and porous. Sifted soil, on the other hand, is very apt to cake and become sour owing to lack of aëration.

Ferns may be roughly divided into two classes—those which form crowns round which the fronds are arranged circularly, and those which produce their fronds singly and at intervals on creeping rootstocks. The common Male Fern is a type of the former, and the common Polypody of the latter. Some species, like the Spleenworts, Blechnum, Parsley Fern, and Hart's-tongue, stand in a sort of intermediate category, since, though they really form crowns, they are on a smaller scale, and the fronds are less obviously arranged in circles. Hence, while it is advantageous to those Ferns which form large and definite crowns to be grown singly, and to have their offsets or sideshoots removed, the others are best left to themselves to form those clumps which constitute good specimens, because for one reason their fronds are narrower, and therefore do not interfere so much with each other as do those of a broad and feathery nature when growing in crowded clumps.

For propagating purposes merely it may be stated that every growing crown, large or small, really represents an individual Fern, hence all but those with rambling root-stocks can be multiplied by careful separation, either by cutting the connections or pulling away, when a bundle of independent roots is found to be attached; while with those of the Polypody type, an inch or two of the creeping root-stock, provided with a growing top, a frond and some root-fibres, provides like material in a different form. The large crowns of the Lastræa type produce side-plants or offsets first of all by a protrusion, which is really a large bulbil, and this proceeds to form both fronds and roots, the latter of which soon render it independent of the mother plant, from which it can then be wedged off by inserting a blunt instrument behind it, and so breaking the connection; the young plant is then ready for a quite independent career, and since the subsequent development of itself and its fellows involves a struggle with the old plant, the benefit of removal is obvious. The result is that a Fern which would grow in a stunted fashion, say 2 feet high in a clump, with its special varietal features reduced considerably, would attain nearly double the size when grown singly, and would be far more beautiful and graceful in appearance. Many of the Shield Ferns produce bulbils at the bases of their fronds, and in some varieties profusely all the way up, and by removing these bulbils, with a piece of the frond-stalk to which they are attached, inserting them in soil and keeping them close, numerous typical plants are obtainable much more rapidly than from spores. These should, therefore, be sought for and profited by when shifting and dividing and removing the *débris* of past frondage. Finally, I should add that in writing the above I have in view not the common forms of British Ferns which are hawked in the streets and sold as such by most nurserymen, but the far more beautiful varieties which have arisen from these by sportings, and of which there are hundreds of choice forms. The common forms are only in their place in their native woods and glens, and are quite eclipsed for cultural purposes by their choicer descendants. *Chas. T. Druery, F.L.S., V.M.H.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

The finest Cryptomeria japonica. — I hoped the correspondence on this Conifer would have elicited particulars of some really fine tree, but at present the Pencarrow tree is the largest of which measurements have been given. Some ten years ago two other specimens of this species at Dropmore were as fine as that quoted by Mr. Page. One grew by the carriage-drive, and was the fellow to that just cut down, inasmuch as they were both "a present from the Hon. Mr. Grenville, who assisted in the planting." The other grew near the beautiful Tsuga Mertensiana, then called Abies Albertiana, and was by many considered the finest of the Dropmore Cryptomerias; but it seems that the Pinetum specimens must have latterly outstripped the others, or Mr. Page would have quoted them when enquiring for finer specimens. I have several times noted that Cryptomerias grow away rapidly for many years, and then suddenly make no perceptible development for three or four or even more years. This partial suspension of growth is frequently most noticeable where the trees are in a comparatively dry soil, and I have an idea that this check coincides with an unusually dry year, which would naturally affect a moisture-loving tree such as the Japanese Cryptomeria. But unless annual records of growth and of the rainfall were kept, one can only theorise on these points. I feel convinced that the tree under notice thrives best when growing in a fairly good well-drained loam in a moist situation, and that the last is not the least essential condition. Returning to fine specimens, on p. 89 of the "Report of the Conifer Conference" Mr. Dunn said of this tree: "The finest specimen in England is at Boconnoc, 64 feet in height and 7 feet in girth." That was, of course, in 1891; but since then this tree apparently has met with some misfortune, or Mr. Page, who was so recently in charge at Boconnoc, would have quoted so fine a tree. *A. C. Bartlett, Pencarrow Gardens, Cornwall.*

Early Peaches.—If a census were taken from gardeners I do not think Alexander Peach would receive many votes either for its suitability for cultivation under glass or against the open wall. My predecessor here gave it a trial in the early house for a couple of seasons, but its bud-dropping habit caused it to be removed to an unheated structure, where it proved to be just as bad; and eventually it was relegated to the Peach wall out-of-doors, and even there a full crop was so uncertain on account of the buds falling in early spring that I was forced to discard it altogether. This variety is certainly one of the earliest Peaches to ripen, but, as a

correspondent says, it has another fault, of splitting at the stone even under good cultivation—a fault that would condemn any Peach. Hale's Early is another variety that loses many of its buds in the early house here, and it is seldom we get a good crop, yet we cannot dispense with it, as we know of no other variety that ripens its fruits so early and is as fine and good as this. We have not tried Amsden June for forcing, but on the outside wall it is very satisfactory, and a much better Peach in every way than Alexander. I am inclined to think soil as well as climate has a deal to do with bud-dropping, and I agree to a great extent with what Mr. Divers stated on p. 125, that all the American varieties are the greatest offenders in this respect. I have also found that bud-dropping is more prevalent in comparatively light porous soils than in retentive ones. In regard to the newer varieties, Duchess of Cornwall and Duke of York, it is to be hoped these will prove immune from bud-dropping, but as yet I have no experience of their behaviour. *J. Mayne, Bicton Gardens, Devon.*

VIOLETS FROM SCOTLAND.—I send herewith a bunch of "Czar" Violets, gathered from under a wall out-of-doors facing to the west, from a double row of plants of about 150 feet in length, I have to-day picked eight bunches similar to the one sent, and a week ago I obtained a similar quantity, having been gathering more or less since the first week in February. The plants are given no attention excepting that they are replanted annually in May. We use single-rooted pieces and plant them at 9 inches apart, the soil being previously enriched with decayed leaf-soil. We do not even remove the runners, as we find they flower freely from these. There may be single Violets superior in size of flower and length of stalk to the Czar, but hardly more floriferous or sweeter in perfume. To fill the box I send also a bunch of Double Blue Violets, and some white ones, from frames. *F. Street, Ardwell Gardens, Ardwell, Wigtownshire, N.B.* [All the flowers are of good quality. Ed.]

MACHINE *v.* HAND-CUT BOOK-LEAVES.—Your correspondents appear to have overlooked the fact that the edges of leaves cut by hand are always rough and uneven, especially in the case of such a bulky paper-covered volume as the *Journal of the Royal Horticultural Society*. The book therefore does not shut tightly, and in the course of a year or so becomes laden with dust—to say nothing of possible germs and microbes. In a gardener's house it is impossible to keep all such publications, valuable as they are, in a closed book-case. The *Journal* may be termed an occasional publication, but if our weekly *Gardeners' Chronicle* were to be delivered uncut, I am afraid many a howl would reach the Editor as well as the Publisher. *A. C. Bartlett.*

DAFFODILS AND SKIN IRRITATION.—Though I have been closely associated with the early forcing of Daffodils for nearly twenty years, handling as many as 300,000 in this way in a season, and am also familiar with the produce of many acres from the open ground at a later date, necessitating considerable assistance, I have only known of two instances where any irritation has been caused. The first of these occurred some fifteen years since; the second is an experience of the present season, and by no means so acute or so bad as the first. In both instances not only were the hands and arms affected, but the face or any portion of the body that was touched with the hand also became inflamed in a short time. It appears that the irritation affects the flower-gatherers rather than those who bunch the flowers, the hands of the former coming into direct contact with the exuding juices of the plant. In the first instance the irritation and inflamuation were so severe that I was compelled to take the man from the work. He was the only one affected out of a dozen or more. I am not of the same opinion as Mr. J. Walker, that chapped hands or dirty hands have much to do with the matter, but rather that some persons naturally are more susceptible to these attacks. Of course if a cut or scar exists on the hands, and the juices come into contact with it, there is every reason for the attack. In the instance referred to there were no such scars existing, and the bare arms—for my men usually gather with the sleeves uprolled—were as badly affected as any part of the hand. I have never tried the effect of putting grease on the hands, and from the way much gathering polishes the finger-tips and hands, should doubt its efficacy. If gloves are at all practicable, the finger-tips should be removed. By reason of the quickly polishing and drying effect the gathering of Daffodil flowers has upon my own fingers and hands generally, I frequently hold them in the water-tank and give them a good rubbing together through the water. It is curious to note that the person who suffered from gathering the early or forced blooms were not affected when gathering those grown in the open. It is also interesting to note that while I was probably one of the earliest and worst sufferers in England from the irritation caused by Primula obconica, I have never experienced any discomfort from the Daffodils. Equally interesting is the fact that the person who, years ago, suffered much from the Daffodils could handle the Primula with impunity. It is the same to-day, and the worker who suffers from the Daffodil irritation is not in the least affected by the Primula. Hence I regard the susceptible nature of the skin to be a more or less predisposing cause when cuts or scars are absent. *E. H. Jenkins, Hampton Hill.*

SEED PACKING FOR LONG SEA JOURNEY.—It was my misfortune a few years ago to receive instructions from a South African gentleman to have a quantity of seeds sent out from England to his estate in the Transvaal. I put the order in the hands of one of the most competent British seedsmen, but he gave it to an ordinary packer, and the seeds were sent as if they were only to go a few miles. When they were received in Africa they were perfectly wet and useless. The gentleman was very much annoyed, as there was a season lost in growth before a second consignment could be sent out, and although the seedsman offered to repeat the order free of all charge, the client was so disgusted at what he termed British methods that he would have nothing further to do with the matter. I may say that I have always understood that seeds going a long sea-journey should be sent in hermetically sealed tins; but I may also add to the foregoing that I have received seeds from Africa in good condition when not hermetically sealed. But these would be carried with passengers' luggage, and in specially dry quarters, and not with ordinary freight. *H. R. Whitelaw.*

THE WEATHER AND WATER SUPPLY.—There is a general complaint in this neighbourhood, and I believe also in some other districts, that the ordinary wells are not yielding their usual supply of water, and that field pits and ponds are unusually low. To farmers and gardeners a plentiful supply of water is absolutely necessary, and the present threatened scarcity and long-continued absence of rain seems to encourage a belief or fear amongst them that unless rain comes quickly and copiously we are in for a dry season. Those people who happen to be favoured with a stream flowing through their grounds would do well to lose no time in putting a barrage across it, and thus save themselves sufficient water to tide them over the predicted scarcity. A few slabs or stakes driven into the bed of the brook or streamlet, and these backed by a little puddled clay or some turves, would suffice to form an effective dam. This barrage should be completed and the head of water saved whilst the stream is still in good flow; this neglected, all the water will have run to waste by finding its way down the valley to the nearest sea. This economical and cheap system of providing a rural water storage might be multiplied infinitely all over the country wherever there is a small stream which could be so operated upon. I have had for a number of years this arrangement in my grounds here, which has afforded my cattle a plentiful supply of water through several dry seasons, and thus saved me much trouble and expense. If anyone has the means of putting down a more permanent brick or stone barrage all the better. But these are not the times to suggest expensive work for either landlord, farmer or gardener, if a more temporary and less expensive arrangement will answer the purpose as well. It may be gathered that my reason for advising a timely storage of water is that all the small streamlets in this neighbourhood, and I believe also in most others in the midland counties, become practically dry during seasons of long-continued drought. *W. Miller, Berkswell, Coventry.*

THE BRITISH GARDENERS' ASSOCIATION.—A special meeting of the Kingston Gardeners' Society has been arranged for the evening of Friday the 24th inst., in Fife Hall, close to the railway-station, when Mr. W. Watson, of Kew, will address the members in reference to the objects of the Association. Mr. Watson specially wished to come to Kingston, and the date has been purposely arranged to suit his convenience. As the objects of the Association seem to have aroused considerable interest, many gardeners resident in the neighbourhood not members of the local Society may wish to attend the meeting, and they will be cordially welcomed. Whatever may be the general opinion as to the merits or otherwise of the objects of the British Gardeners' Association, Mr. W. Watson is a distinguished botanist and gardener, and should be given a very cordial reception and a good audience. *Kingston.*

GRAPE-FRUIT.—The Grape-Fruit is generally considered to be a variety of the Pumelo, Citrus decumana. It is so described in the *Century Dictionary*, and in your own columns a contributor identified it as such a few years ago. I have just seen the fruit for the first time, and find its seeds have more than one embryo. This is characteristic of the Orange, but I have never found the Pumelo with more than one embryo in its seed. The other features of the fruit being intermediate between the Orange and the Pumelo, it most probably is a hybrid, and if so its history should be recorded. Possibly some of your American correspondents may know the facts of the case, and place beyond doubt the origin of this interesting and ornamental fruit. *G. Marshall Woodrow.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

March 14.—An excellent display of very varied exhibits was made on Tuesday last in the Royal Horticultural Hall, Vincent Square, Westminster. There were showy groups of Orchids, which included some valuable novelties.

The Orchid Committee recommended no fewer than ten Awards of Merit.

The Floral Committee recommended seven Awards of Merit, including one for Heloniopsis breviscapa, a species probably new to cultivation. Eleven Medals were awarded for groups of plants and flowers of very diverse character. These included an interesting collection of Platyceriums from Messrs. Hill & Sons, and a group of Camellias from Messrs. W. Paul & Son.

The Fruit and Vegetable Committee made no Award to novelties, but some well-preserved Apples were shown in a collection.

The Narcissus Committee met for the first time this season, but little of interest was forthcoming.

At the meeting of the Scientific Committee, Dr. M. T. Masters, F.R.S., on behalf of the Committee, presented Prof. Henslow with a service of plate, in recognition of the valuable services he has rendered to the Committee during the many years he acted as its Honorary Secretary (see p. 168).

In the afternoon over eighty new Fellows were elected, and the Rev. Prof. Henslow delivered a lecture on "Bud Variation," the subject being well illustrated by a number of lantern slides.

Floral Committee.

Present: W. Marshall, Esq., Chairman, and Messrs. C. T. Druery, F. Page Roberts (Rev.), Jno. Green, R. Wilson Ker, G. Reuthe, R. Hooper Pearson, C. J. Salter, Jno. Jennings, C. Blick, C. Dixon, C. Jeffries, C. E. Shea, Ed. Mawley, W. P. Thompson, E. H. Jenkins, W. Cuthbertson, J. W. Barr, Geo. Paul, H. J. Cutbush, Geo. Nicholson, Jas. Walker, C. R. Fielder, and W. Howe.

A new variety of rambling Rose was shown by Messrs. Hobbies, Ltd., Dereham, Norfolk. It is

named "Philadelphia Rambler," being an introduction from America. The flowers appear to be rather fuller and certainly of deeper colour than those of Turner's Crimson Rambler; but the Committee desire to see specimens that have been cultivated out-of-doors.

Lathyrus pubescens, a very pretty and fragrant greenhouse species with pale blue flowers was shown from Lord ROTHSCHILD'S garden, Gunnersbury House, Acton (gr., Mr. Geo. Reynolds). It received an Award on April 21, 1903.

Shortia galacifolia rosea, a variety shown by Messrs. W. CUTBUSH & SONS, has flowers of deeper colour than the variety lilacina, and is the richest tinted form of this very pretty plant we have yet seen.

Magnolia Campbelli (see fig. in *Gardeners' Chronicle*, Feb. 5, 1898, p. 89) is one of the handsomest species. It is a native of Sikkim, but the flowers hitherto produced in this country do not rival those in their native habitat. Richly-coloured flowers were shown on this occasion by Lord ILCHESTER, Abbotsbury, Dorsetshire (gr. Mr. H. Kempshall).

Fritillaria discolor was shown by Miss WILLMOTT, Great Warley, who had several pots full of well-grown plants about 1 foot high. The species obtained an Award on January 11, 1887, under the name of Korolkowia discolor. The flowers are greenish-yellow-coloured, with purple markings at the base of the corolla.

Mr. L. R. RUSSELL, Richmond Nurseries, Surrey, exhibited a large group of forced flowering shrubs, in which considerable variety was represented. The best features were some plants of Rhododendron (Azalea) Anthony Koster, Ribes sanguineum, Xanthoceras sorbifolia, standard Lilacs, standard Laburnums, &c. There was one plant of the new Jasminum primulinum in flower (from a cold house), and several plants of Clerodendron Balfouri in flower.

Messrs. W. CUTBUSH & SONS, Highgate Nurseries, London, N., again made a very large display of forced trees and shrubs, including most of the species shown on the last occasion. The standard specimens of Laburnum were very fine, 7 feet or more high; double-flowered Thorns several feet higher, Staphylea colchica, Ribes, and Rhododendrons. Messrs. CUTBUSH also exhibited excellent plants of Boronia megastigma, Erica gracilis ovata vernalis, Boronia heterophylla, and Mignonette "Cutbush's Giant," there being groups of each of these plants. Messrs. CUTBUSH & SONS also displayed a large collection of alpine and hardy plants, placing such plants as Daphnes, Dwarf Conifers, and other small shrubs suitable for rockeries toward the background (Silver-Gilt Flora Medal).

Messrs. W. PAUL & SONS, Waltham Cross Nurseries, Herts, exhibited a group of Camellias in pots and a number of cut Camellia flowers arranged in boxes. At a time when Camellias are so much neglected generally, such collections of choice varieties as are shown by Messrs. PAUL are specially interesting (Silver-gilt Banksian Medal).

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, exhibited a collection of choice Ferns, such as Polystichum mucronatum, Adiantum cardiochlæna, Lastrea erythrosera, Davallia Tyermani, &c. The remainder of the table was occupied by greenhouse-flowering plants (Silver Flora Medal).

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, furnished the concert platform with a splendid collection of Platyceriums, placing sufficient Ferns of other types among them to give suitable relief to the group. The centre of the display was occupied by a grand plant of P. grande, while on either side were arranged specimens of P. Hilli, P. angoleuse, P. æthiopicum, P. Willinckii, P. Veitchii, P. alcicorne, P. a. majus, &c. (Silver-gilt Flora Medal).

Messrs. SUTTON & SONS, Reading, filled one of the side tables with pot plants of Hyacinths. The display was divided into three batches, with white, blue, and blush-rose coloured flowers respectively, while the whole was pleasingly interspersed with small Ferns. The strain is intermediate between the ordinary Dutch and Roman Hyacinths, the flower-spikes being tall and the flowers highly fragrant, a type suitable for decorative purposes, and said to be especially serviceable for early forcing. They are known as "Italian" Hyacinths.

Messrs. CANNELL & SONS, Swanley, Kent, made one of the brightest displays in the Hall with their vases of Zonal Pelargoniums and of Cinerarias. The Pelargoniums would be hard to surpass for size of petals and for brilliancy of colours. Varieties that especially appealed to us were Sir E. Cassel (scarlet), Sir Thomas Hanbury (deep scarlet-crimson, with exceptionally large petals), Princess of Wales (rosy-red), and Prince of Orange (orange-red). The Cinerarias were of the "stellata" type, and were represented in many shades of colour (Silver Flora Medal).

Messrs. JOHN LAING & SONS, Forest Hill, London, set up two semi-circular groups of plants, the one composed of Clivias (Imantophyllums), the other of Begonias. Both groups were relieved with Ferns and small Palms.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, showed Primula × kewensis, Camellia reticulata, and Rhododendron Veitchii. Messrs. Veitch also showed some excellent forms of Imantophyllums, a batch of Shortia galacifolia, and plants of Senecio auriculatissimus (Silver Banksian Medal).

Mr. S. MORTIMER, Farnham, Surrey, displayed a batch of white Stocks, named "All the Year Round." The fragrance of the flowers was very noticeable. The variety is valuable in that it produces flowers earlier in the season than the ordinary type, while later-sown batches will maintain a succession late in the season (Silver Banksian Medal).

Mr. HENRY LANGSTON, Nurseryman, Marston, Pembridge, Herefordshire, had several vases of the beautiful deep-blue-coloured Violet Princess of Wales.

Mr. G. MOUNT, Canterbury, Kent, put up a similar group of Rose-blooms to that displayed by him at the last meeting, with the exception that a few more varieties were included. The same high-class culture was seen as in the previous display (Silver Flora Medal).

Mr. A. B. WADDS, The Gardens, Paddockhurst, staged some well-grown pot-plants of Cyclamen. Each plant carried numerous flowers, some of which were of the crenated-petalled type (Bronze Banksian Medal).

Messrs. AMBROSE & SON, Cheshunt, staged a miscellaneous group of greenhouse plants, Roses, Cinerarias, Genista fragrans, Mignonette; also Tulips, Narcissus, &c.

Messrs. H. C. PULHAM & SON, 71, Newman Street, Oxford Street, London, showed examples of sandstone, ironstone, and other materials used in the construction of rockeries, water-gardens, &c., with a miniature rock-garden formed of the same material, and photographs of finished work executed by the firm in different gardens.

Mr. RICHARD ANKER, Addison Nursery, Napier Road, Kensington, W., again showed specimens of tufa, and pictures of rock-work and other structures made of this material.

HARDY AND ALPINE PLANTS.

The Misses HOPKINS, Mere, Knutford, showed a small collection of alpine and hardy plants.

Messrs. R. WALLACE & CO., Kilnfield Nurseries, Colchester, showed some excellent plants of Anemone pulsatilla, also Crocuses, Hepaticas, Fritillaria citrina, &c.

Messrs. BARR & SONS, 11, 12, 13, King Street, Covent Garden, London, showed Alpine and hardy plants. We noticed some pleasing forms of Hepaticas, also Sisyrinchium grandiflorum, Iris unguicularis (stylosa), Lachenalias, Scillas, Anemone fulgens, &c.

Messrs. THOS. WARE, Ltd., Feltham, Middlesex, staged Alpine and hardy plants. Among other good things were Sarracenia flava, Trilliums, including T. sessile, forms of species of Primulas, &c. (Bronze Flora Medal).

Messrs. GEO. JACKMAN & SON, Woking Nurseries, Surrey, contributed a large group of Shortia galacifolia. We also noticed Megasea Stracheyi, Fuchsia microphylla, and a splendid spike of Watsonia Ardernei, Anemones, Irises, Saxifrages, and similar plants.

ADELINE, DUCHESS OF BEDFORD, Woodside Gardens, Rickmansworth (gr., Mr. Dickson), set up an admirable display of Hellebores in vases.

Messrs. B. S. WILLIAMS & SONS, Upper Holloway, London, N., staged a number of alpine and hardy plants.

Mr. JNO. R. BOX, West Wickham Nurseries, showed a few alpine plants.

Mr. G. REUTHE, Keston, Kent, showed many good species suitable for the rock-garden, &c.—Snowflakes, Saxifrages, Crocuses, Primulas, Irises, Shortias; Anemone blanda was well flowered (Silver Flora Medal).

Mr. A. J. BRUCE, The Nurseries, Chorlton-cum-Hardy and West Didsbury, showed a collection of flowers of varieties and species of Sarracenias.

Awards.

AWARDS OF MERIT.

Adonis amurensis.—A double-flowering variety of this well-known alpine plant. The flowers have a band of green florets round the central yellow ones, as is occasionally seen in Ranunculuses. Shown by Messrs. W. CUTBUSH & SONS.

Cantua buxifolia (dependens) (see fig. 69, p. 173).—Flowers of this showy and beautiful Polemoniaceous plant were shown by H. J. ELWES, Esq., Colesbourne, Andoversford. It is a very old garden plant from the Peruvian Andes, and bears funnel-shaped flowers having a very long tube. Colour rosy-red, with a little orange colour on the exterior of the tube. The correct name is C. buxifolia.

Carnation General Kuroki.—This is a first-class, bright crimson-flowered Tree-Carnation. The flowers are of good form, with very slightly fimbriated petals, rich colour, non-bursting calyx, and moderately stout stems. Shown by Messrs. W. CUTBUSH & SONS.

Erica × Veitchii.—This hybrid from E. arborea and E. codonoides (Insitanica) was shown at the previous meeting, and has already been described in these pages (see issues for February 18, 1905, p. 106, and March. 4, p. 138). Messrs. ROBERT VEITCH & SON, Exeter, exhibited a fine bush-like plant, literally covered with its white flowers.

Helleborus orientalis Stephen Olbrich.—This variety has very large flowers of deep reddish-purple colour which is very effective. Shown by Sir TREVOR LAWRENCE, Bart., Burford.

Heloniopsis breviscapa.—This little Japanese Liliaceous plant is apparently new to cultivation. The inflorescences were from 3 to 4 inches high, bore seven or eight flowers each, and the peduncle four or five adpressed rudimentary leaves, characteristic of the genus. The flowers are pure white except for the reddish-coloured pistil and bluish anthers. Shown by Messrs. BARR & SONS.

Pulmonaria arvernensis alba.—This is a pure white variety, the typical form having flowers of deep blue colour. The plant was scarcely 3 inches high, and the flowers are borne in clusters. From Messrs. W. CUTBUSH & SONS.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshay, W. Boxall, W. H. Young, W. H. White, A. A. McBean, F. W. Ashton, G. F. Moore, H. Ballantine, J. Colman, R. G. Thwaites, T. W. Bond, W. A. Bilney, and H. J. Veitch.

There was a very good show of Orchids, and ten varieties were given Awards of Merit.

JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), staged a very effective group, in the centre of which was a number of the perpetual-flowering Epidendrum × Boundii, with pretty heads of orange and red flowers. Also in the group at intervals were selections of Odontoglossum crispum, O. triumphans, Lælia cinnabarina, Phalænopsis, good varieties of Cattleya Trianæ, Lælia flava, and Miltonia Warscewiczii. Among albinos was a good specimen of Cattleya intermedia alba (Silver Flora Medal).

Messrs. CHARLESWORTH & Co. had a fine group, principally of hybrids, which included Odontoglossum × Harryano-triumphans, of excellent quality, the larger having the features of O. trimmphans latisepalum; good forms of O. × Adrianæ, Brasso-Cattleya × Digbyano-Trianæ Heaton variety, of an uniform warm rose colour; Cattleya × Empress Frederick superba, very near to the previously certificated variety Leonata; L.-C. × luminosa, L.-C. × Wellsiana albens, L.-C. × callistoglossa, a pretty batch of the yellow-petalled L.-C. × Myra, with variously tinted rose-and-purple labellums, a batch of Phaius × Norman, and other showy hybrids. Among the species and varieties were two good purple-spotted forms of Odontoglossum crispum, good O. cirrosum, Spathoglottis aurea, Platyclinis glumacea, &c. (Silver Flora Medal).

Messrs. J. CYPHER & SONS, Cheltenham, had a very interesting group, which contained some rare and pretty species specially well grown, and a good show of Dendrobiums, including several of the yellow, fringed-lipped D. Brymerianum, some of the best forms of D. nobile, D. Wardianum album, D. crassinode album, D. × Apollo album, and several other fine hybrids of its class; a good selection of Odontoglossums, including a very fine specimen of the true O. nævium majus; good examples of Epidendrum Stamfordianum, Epiphronitis × Veitchii, some good Cypripediums, Lælio-Cattleya × Impératrice de Russie, and other Lælio-Cattleyas, Masdevallias, Cypripediums, &c. (Silver Flora Medal).

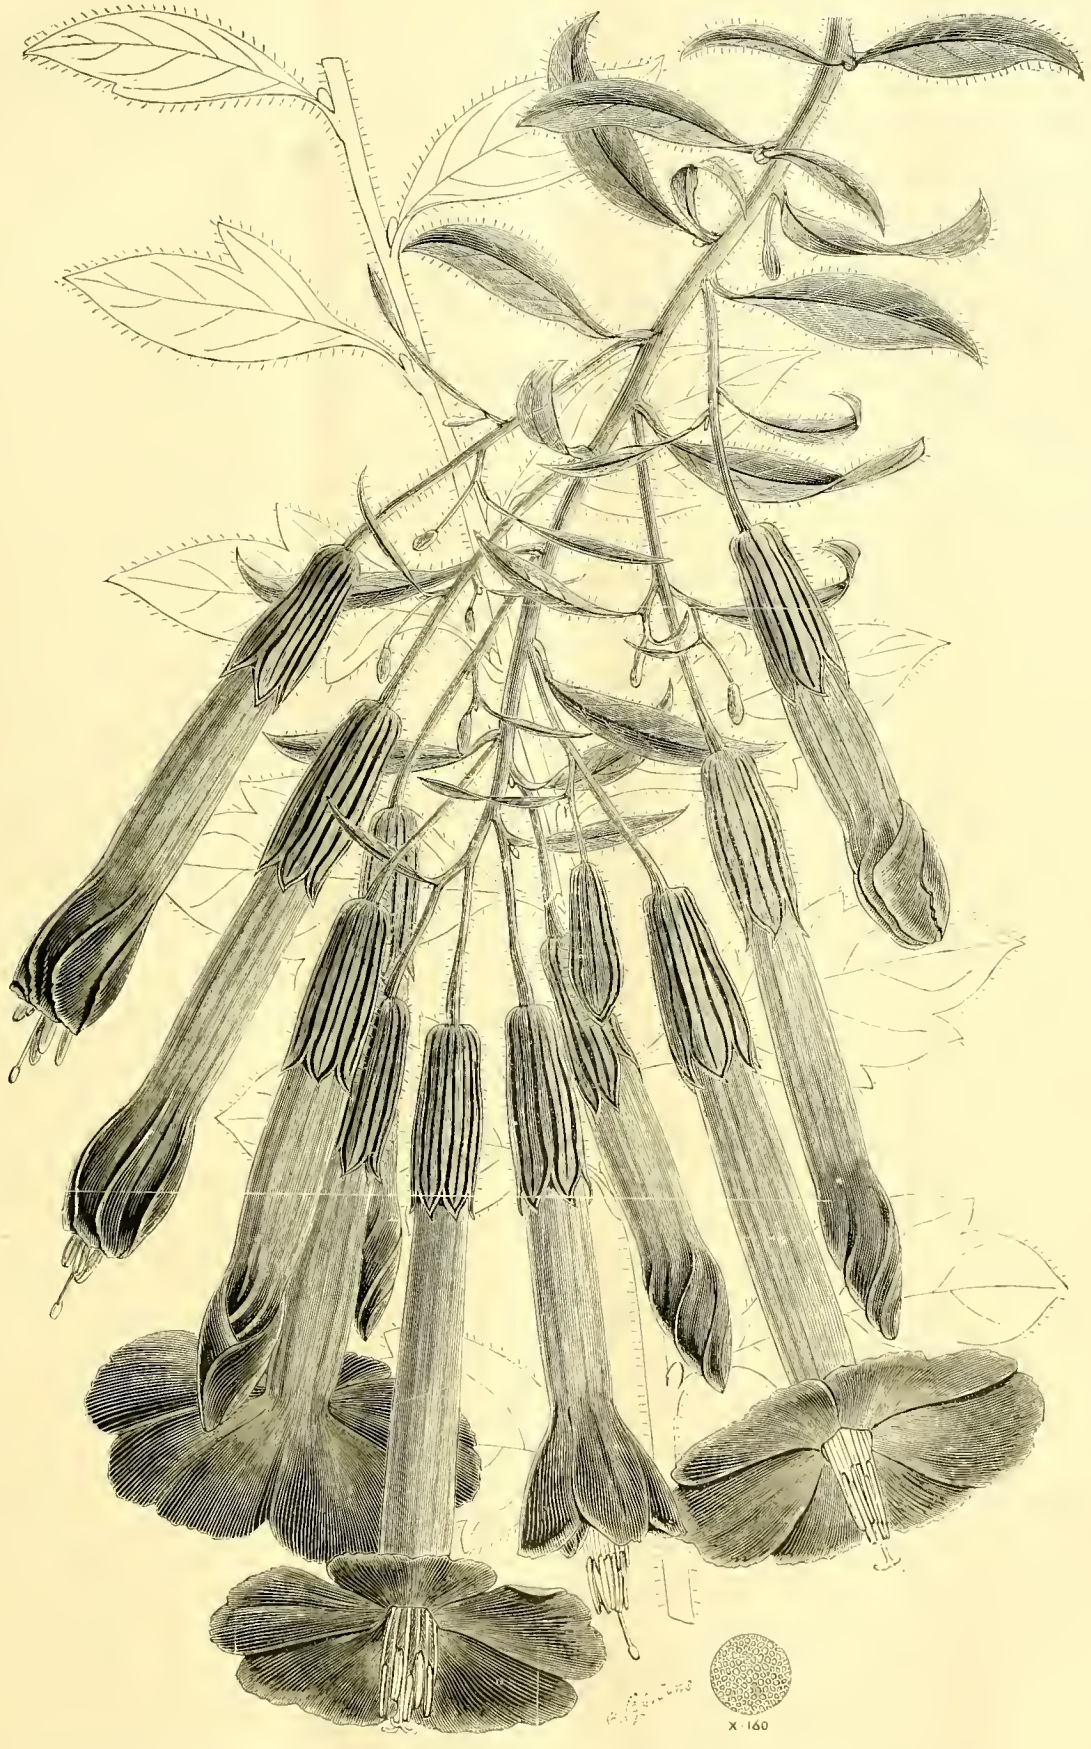

Fig. 69.—CANTUA BUXIFOLIA (DEPENDENS): FLOWERS BRIGHT ROSE-PINK.

Shown on Tuesday last by Mr. Elwes, and recommended an Award of Merit by the Floral Committee. (See p. 172.)

Messrs. Sander & Sons, St. Albans, staged a group containing several good forms of Cattleya Trianæ, and notably one named "Blue Gown," a fine flower with lavender-tinted sepals and petals, and violet-blue front to the lip. Among interesting species were two plants of the rare and singular Odontoglossum stellatum.

The Right Hon. the Earl of Tankerville, Chillingham Castle, Northumberland (gr., Mr. Hunter), showed a small group of rare Orchids, in which were the delicately-tinted Brasso-Cattleya × Digbyano-Schroderæ Tankervilliæ (see Awards), Cypripedium × aureum virginale and C. × a. Hyeanum, a very finely spotted C. × Helen II., C. × Dora Crawshaw (niveum × Charlesworthii), an attractive flower, rose-purple, tinged and veined; C. × Maudiæ, &c.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), showed Dendrobium × Melpomene inversum, a good yellow flower with purple blotch in the lip; spikes of the rare Odontoglossum coronarium miniatum, and the interesting Epi-Cattleya × Gaskello-Parkinsoni (C. Gaskelliana × E. Parkinsonianum), with singularly-formed white flower tinted with rose.

Captain G. L. Holford, C.I.E., Westonbirt (gr., Mr. H. Alexander), showed Cattleya Trianæ Percival, a large rose-tinted flower; and two others (see Awards).

Messrs. Jas. Veitch & Sons, Chelsea, showed Dialælia × Veitchii (Diacrium bicornutum × Lælia cinnabarina), a very remarkable hybrid with fleshy pseudo-bulbs resembling those of Diacrium bicornutum, and erect, 2-feet-long inflorescence, bearing on the upper third portion nine or ten flowers about 2 inches across, and with narrow segments, white tinged with lilac, the younger flowers showing a bronzy tint derived from L. cinnabarina. [This plant, on account of its botanical interest, was awarded a Botanical Certificate by the Scientific Committee.]

Francis Wellesley, Esq., Westfield, Woking (gr., Mr. Hopkins), showed Cypripedium × allertonense magnificum with two flowers.

R. G. Thwaites, Esq., Chessington, Streatham (gr., Mr. Black), showed a selection of Dendrobium × Blackianum (Wigania × Findlayanum) displaying great variation, from white with yellow disc to rose-tinted, one of which was very near to D. × melanodiscus. No two were alike, but varied both in form and colour.

Mr. Jas. Douglas, Great Bookham, sent two plants of Cypripedium × Decdmanianum, and a hybrid of C. Lawrenceanum.

Messrs. Hugh Low & Co., Enfield, showed a fine plant of a supposed natural hybrid between Oncidium Cavendishianum and O. luridum or carthaginense, and named O. Lowii ×; the spike was 7 feet 6 inches in length, with eight branches bearing altogether about 200 yellow flowers spotted with brown.

M. Chas. Vuylsteke, Loochristy, Ghent, sent several good hybrid Odontoglossums, including a finely-flowered O. × ardentissimum (Cultural Commendation).

M. Jules Hye, Ghent, showed Cattleya × Madame Jules Hye (Gaskelliana alba × Mossiæ Wageneri), white with yellow disc, the segments being narrower than in some other white Cattleyas.

F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr., Mr Balmforth), showed Lælio-Cattleya × Gottoiana magnifica, and Cypripedium callosum Sanderæ Shrubbery variety, with much white in the petals and dorsal sepal.

A. H. Houlder, Esq., Hurst Place, Bexley (gr., Mr. Dyer), showed a fine specimen of Cœlogyne cristata Trentham variety.

Alderman William Bolton, Mayor of Warrington (gr., Mr. Cain), sent Cypripedium Chamberlainianum magnificum, a very large flower, the plant having extraordinary vigour.

The Rev. F. Mason, The Firs, Warwick (gr., Mr. Marlow), showed a good Brasso-Cattleya × Digbyano-Warneri.

Awards of Merit.

Brasso-Cattleya Digbyano-Schrodera Tankervillia [?]. From The Rt. Hon. The Earl of Tankerville, Chillingham Castle, Northumberland (gr., Mr. Hunter).—A very delicately-tinted and finely-fringed flower; white with a pearl-pink blush.

Cypripedium × *Chas. Rickman var. magnifica* (barbatum nigrum × bellatulum). From Capt. G. L. Holford, C.I.E. (gr., Mr. Alexander).—Flower large and well rounded; lip dark-claret coloured, the other segments rose with purple dots and veining; the top of the dorsal sepal and petals white.

Lycaste Skinneri utro-sanguinea. From Capt. G. L. Holford.—Sepals white tinged with rose; petals bright magenta-rose; lip dark blood red. A very showy flower.

Dendrobium Wardianum candidum. From J. Newton Mapping, Esq., Headley Park, Epsom (gr., Mr. Beeson).—One of the largest white forms; disc of lip orange with dark chocolate blotch.

Cypripedium × *Haywoodianum* (× T. B. Haywood × bellatulum). From Mrs. Haywood (gr., Mr. Salter).—A large finely-shaped flower tinted with rose-purple and veined with claret-colour, the upper margin of the dorsal sepal being white.

Odontoglossum × *amabile.* From M. Chas. Vuylsteke, Loochristy, Ghent.—Flowers cream-white and formed like those of O. crispo-Harryanum, but the petals bore more numerous and smaller reddish-brown markings.

Odontoglossum × *Lawrenceanum* (triumphans × Rolfeæ).—A fine hybrid with yellow sepals and petals heavily barred with chestnut-brown; lip, white marked with purple. From M. Chas. Vuylsteke.

Brasso-Cattleya × *Digbyano-Trianæ, Heaton variety.* From Messrs. Charlesworth & Co., Heaton, Bradford.—Flower large and heavily fringed, of an uniform lilac-rose colour, with greenish-yellow disc to the lip.

Dendrobium × *Chessingtonense* (aureum × Wigania).—Flowers large, of bright-yellow colour, with chocolate-purple disc to the lip. From R. G. Thwaites, Esq. (gr. Mr. Black).

Dendrobium × *Elwesii* (Hildebrandii × aureum). From H. J. Elwes, Esq., Colesborne, Cheltenham.—An attractive flower of good size; cream-coloured, with a purple blotch on the lip.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq., in the chair; and Messrs. Jos. Cheal, W. Bates, Geo. Woodward, S. Mortimer, Alex. Dean, H. Parr, Geo. Kelf, W. Pope, P. C. M. Veitch, John Lyne, F. Q. Lane, G. Reynolds, Geo. Wythes, Ed. Beckett, G. Norman, H. Markham, and H. Somers Rivers.

Messrs. H. Cannell & Sons, Swanley, Kent, staged a large collection of Apples, including 122 distinct varieties. Many of the fruits showed evidence of having been kept far beyond their proper season, but on the whole the display was admirable, the colouring of the fruits being especially pronounced. We may mention Bramley's Seedling, Gascoyne's Scarlet, Lane's Prince Albert, Bismarck, Calville Boisbunce, and Beauty of Kent as being shown in fine condition (Silver Knightian Medal).

Lecture on "Bud Variation."

Professor Henslow's lecture was richly illustrated by lantern slides and actual specimens. After observing that all plants have an inherent power of varying in response to, if not always in useful adaptation to, changed conditions of life, by which new species are introduced into the world, and that many new forms arise under cultivation by the same means, the lecturer observed that sports only differ from such variations in degree and by the suddenness of their appearance, whether as a part of a plant or as a seedling; so that there is often a difficulty in drawing any sharp line between varieties, sports, and even monstrosities. The immediate causes of sports are often very obscure, but can sometimes be reasonably traced to altered distribution of light, as in the changed position of leaves, or again to the amount of formative material present, as in "cut" leaves, &c., or to heat, as in fastigiation. The examples taken as illustrative and explanative were the fastigiate, fasciate, and weeping types of stems, and spiral torsion and spinescence, cut and crisped forms of leaves, multiform, double, crested, and peloric flowers; the change of form, colour, &c., in fruits, and the dissociation or the separation of characters of the two or more parents in a hybrid or cross.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

March 2.—There was a moderate display of plants at the meeting held on this date.

S. Gratrix, Esq., Whalley Range (gr., Mr. Cypher), exhibited Cattleya Trianæ var. Juno, a fine variety having flowers of good shape and substance, and closely resembling a variety of C. Schroderæ in its uniformity of colouring (Award of Merit).

The same exhibitor had two good forms of Odontoglossum crispum, one of which, O. c. var. "Melba," was voted an Award of Merit.

E. Rogerson, Esq., Didsbury (gr., Mr. Blomiley), received an Award of Merit for Odontoglossum crispum var. "Stanley Rogerson," a pretty variety marked with dark spots. Cattleya Trianæ var. "Our King" came from the same collection.

R. le Doux, Esq., West Derby (gr., Mr. Davenport), sent a few plants, the best of which was a splendidly-grown and fine variety of Odontoglossum maculatum with the varietal name "marlfieldense." This plant obtained an Award of Merit.

T. Statter, Esq., Whitefield (gr., Mr. Johnson), exhibited Dendrobium × whitefieldense, a hybrid of a very prolific nature (Award of Merit).

E. Bostock, Esq., Stone (gr., Mr. Ballance), exhibited Cypripedium × Robsoni, a supposed hybrid between C. insigne Sanderæ × C. × exul.

J. E. Williamson, Esq. (gr., Mr. Jones), exhibited Dendrobium nobile Williamson's var., a pretty and very chaste flower, being very light in colour except for the well-coloured tips to the petals.

The best feature of the meeting was a magnificent display of plants by Messrs. Cypher & Sons, of Cheltenham, which included some lovely Dendrobiums, Cypripediums, Cattleyas, Lycastes, and other plants in season (Silver-gilt Medal).

Votes of Thanks for groups were awarded to Messrs. Keeling, Mitchell, Williamson, Statter, Allen, Parker, Cowan, and Le Doux. *P. W.*

NATIONAL FRUIT GROWERS' FEDERATION.

A meeting of the Council was held on Monday, March 13, at the Royal Horticultural Hall, Vincent Square, the President, Mr. F. S. W. Cornwallis, in the Chair.

Letters were read from the Board of Agriculture stating that a leaflet was under preparation dealing with the disease of Apple and Pear twigs sent to the Board for indentification.

The Railway Services Committee reported that they were negotiating with the Railway Companies concerned for the cheaper conveyance of manure from Birmingham to the Vale of Evesham; that the South-Eastern Company were, at their instance, considering arrangements for an improved connection between their system and those of the Northern Companies with a view to quicker transit of fruit from Kent to the North of England and Scotland. The Committee also reported that a summary of the evidence proposed to be given by Mr. Miskin before the Departmental Committee on Preferential Rates had been duly sent in.

As a suggestion had been made that a Conference of Fruit Growers should be held next autumn under the auspices of the Federation, the Council considered the matter and decided that such a Conference was desirable, and that the preliminary arrangements should be commenced forthwith.

A discussion took place on the terms by which kindred Societies should be allowed to affiliate with the Federation, and the following were agreed to, subject to the approval of the Annual General Meeting, viz.: For any Society whose membership does not exceed 200, an annual fee of three guineas, with representation on the Council by two members. For every hundred members or part thereof above 200, an extra fee of one guinea, with one member of Council to every 100 members. A resolution was unanimously passed declaring the urgent necessity of devising means to prevent the importation of diseased Apples or other fruit, more particularly those affected with the Codlin Moth, such diseased importations being a danger to the orchards and nurseries of Great Britain. The resolution was ordered to be forwarded to the Board of Agriculture.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

ANNUAL MEETING.

March 13.—The Annual Meeting of this Society was held on the above date at the Caledonian Hotel, Adelphi, Strand, London. Mr. W. P. Wright presided. The Annual Report was presented, from which we extract the following paragraphs:—

In many respects the year 1904 has been a record one, no fewer than ninety-five candidates having been admitted to membership, this number showing an increase of twelve over the previous highest number elected in any one year. The membership at the end of the year totals 1,076, made up of 669 paying on the higher scale, and 467 paying on the lower scale.

Sick members to the number of eighty-six have benefited under the Sick Fund, the total paid out during the year being £327 6*s.*, or an average of £3 16*s.* per sick member. This sum has been met by a deduction of 7*s.* 5*d.* from the contributions of the higher-scale members, and of 4*s.* 11*d.* from the lower-scale members.

There are now six members receiving regular grants from the Benevolent Fund, and these amount in the aggregate to £99 6*s.* In addition several members in distress have been assisted to the total amount of £15 4*s.* 7*d.*, and in these cases the help afforded has been most gratefully acknowledged. Contributions to the Benevolent Fund amounted to £130 4*s.* 5*d.*

From the Convalescent Fund £7 has been paid out to members recovering from illness.

Now that the Royal Horticultural Society has acquired a permanent home in Vincent Square, the Committee proposes to henceforth hold the Committee and other meetings of "the United" at the new Royal Horticultural Hall, where accommodation has been promised on particularly favourable terms.

The Annual Dinner held at the Holborn Restaurant on Wednesday, October 12, was again successful.

On the recommendation of the Rules Sub-Committee, the Committee has decided not to call a Special General Meeting to consider the proposed new rules until 1906. The Sub-Committee has met on numerous occasions, and its work, now almost finished, will be submitted to a competent legal authority.

The balance-sheet shows a satisfactory state of affairs, the total receipts from all sources of the Benefit Fund, including a balance of £17,427 8*s.* 6*d.* brought forward from the previous year, amounting to £19,644 19*s.* 7*d.*, with a total expenditure of £529 13*s.* 10*d.*, leaving a credit balance of £19,115 5*s.* 9*d.* The Benevolent Fund also records a balance of £4,232 13*s.*, while that of the Voluntary Convalescent Fund shows £522 4*s.* 9*d.* to the Society's credit.

The Chairman in moving the adoption of the Report congratulated the members upon the condition of the Society, and upon the fact that the number of new members who had joined during 1904 had constituted a record in the annals of the Society. He would like to see the membership number nearer 11,000 than 1,100, and thought much might be done towards this end. He also contrasted the benefits derived from joining this Society with those obtainable from ordinary friendly societies, who had expensive establishments to maintain and a host of highly-paid officials to support. He further counselled all those connected with the Society to urge the claims of the institution upon their fellow-workers. The employment of paid canvassers to undertake this task he deprecated on account of the expense it would necessarily entail, but stated that the Gardening Press was always ready to help forward any good work connected with gardening. The admirable way in which the Society was managed was to be seen in the small amount debited to the Management Fund, which, out of a turnover of over £20,000, only amounted to £265 17*s.* 5*d.*

Mr. Curtis seconded the adoption of the Report, which was carried unanimously.

Mr. A. J. Brown, an old member, regretted the slow progress made by the Society, and suggested that the age limit be lowered in order to encourage a juvenile influx of membership. He also regretted that the Committee was waiting until 1906 before embodying the revised rules as recommended by the Rules Sub-Committee.

The retiring members of the Committee were all re-elected. Mr. Collins was re-elected Secretary.

MARKETS.

COVENT GARDEN, March 15.

Plants in Pots, &c.: Average Wholesale Prices.

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 55*s.* to 75*s.* per ton; seed in variety. *John Bath*, 32 & 34, *Wellington Street, Covent Garden.*

REMARKS.—The Figs quoted above are from Guernsey. There are still supplies of Apples; Bramley's Seedling, 6*s.* to 8*s.* per bushel; Welliogtons, 5*s* to 7*s.*, do.; Norfolk Beefings, 4*s.* to 5*s.*, do.; Custard Apples, 5*s.* to 10*s.* per doz. Cape fruit per case: Plums, 5*s.* to 8*s.*; Peaches, 8*s.* to 10*s*; Nectarines, 7*s.* to 10*s.*; Pears, 4*s.* to 6*s.* Grapes (white and black), 15*s.* to 20*s.* per case. The black variety commands the better prices. Strawberries are now more plentiful. The market is now receiving consignments of Egyptian Onions; these realise from 13*s.* 6*d.* to 14*s.* per cwt.

FRUITS AND VEGETABLES.

GLASGOW, *March* 15.—The following are the averages of the prices during the past week:—Apples, American, 15*s.* to 25*s.* per barrel; do., Canadian, 15*s.* to 30*s.* do.; Oranges, ordinary 420's, 10*s.* to 14*s.* per case; do., large, 11*s.* to 15*s.* do.; do., extra large, 16*s.* to 20*s.* do.: do., large 714's, 12*s.* to 14*s.* do.; Lemons 8*s.* to 15*s.* per case; Bananas, 6*s.* to 11*s.* per bunch; Grapes, 1*s.* 6*d.* to 3*s.* 6*d.* per lb.; Tomatos, 3*s.* to 5*s.* per box; Mushrooms, 1*s.* to 1*s.* 3*d.* per lb.; Onions, 4's, 12*s.* to 13*s.* per case; do., 5's, 14*s.* to 16*s.* do.

LIVERPOOL, *March* 15.—*Wholesale Vegetable Market (North Hay).*—The following are the averages of the current prices during the past week—prices varying according to supply:—Vegetables: Potatos, Bruce, 2*s.* to 2*s.* 4*d.* per cwt.; Main Crop, 2*s.* 9*d.* to 3*s.* 6*d.*; Up-to-Date, 1*s.* 9*d.* to 2*s.* 2*d.*; Turnips, 6*d.* to 8*d.* per dozen bunches; Swedes, 1*s.* to 1*s.* 2*d.* per cwt; Carrots, 3*s.* to 3*s.* 6*d.* per cwt.; Onions, foreign, 10*s.* to 12*s.* per bag; Parsley, 6*d.* to 8*d.* per dozen bunches; Cauliflowers, 1*s.* 6*d.* to 2*s.* 6*d.* per dozen; Cabbages, 4*d.* to 8*d.* do.; Celery, 8*d.* to 1*s.* do.—Fruit: Oranges, Jaffa, 8*s.* to 12*s.* 6*d.* per box; Valencia, 10*s.* to 20*s.* per case; Palermo, 7*s.* to 10*s.* 6*d.* do.; bitters, 3*s.* to 6*s.* do.; Apples, American, 10*s.* to 17*s.* per barrel; Canadian, 16*s.* to 27*s.* do.; Lemons, Palermo, 6*s.* to 11*s.* per case. *St. John's.*—Potatos, 10*d.* to 1*s.* per peck; Cucumbers, 6*d.* to 10*d.* each; Filberts, 10*d.* per lb.; Grapes, English, 1*s.* 6*d.* to 2*s.* 6*d.* per lb.; do, foreign, 6*d.* to 8*d.* per lb.; Pine-apples, foreign, 2*s.* 6*d.* to 3*s.* 6*d.* each; Mushrooms, 1*s.* to 1*s* 3*d.* per lb. *Birkenhead.*—Potatos, 8*d.* to 10*d.* per peck; new, 1½*d.* to 3*d.* per lb.; Celery, 1½*d.* to 3*d.* per stick; Cucumbers, 6*d.* to 8*d.* each; Tomatos, 4*d.* to 6*d.* per lb.; Grapes, English, 2*s.* to 3*s.* per lb.; foreign, 8*d.* to 10*d.* do.; Apples, 2*d.* to 3*d.* per lb.; Mushrooms, 1*s.* to 1*s.* 2*d.* do.; Pine-apples, foreign, 6*d.* to 5*s.* each; Brazil nuts, 6*d.* to 8*d.* per lb.

COVENT GARDEN FLOWER MARKET.

Cyclamen continue plentiful, and good in quality; some of the best plants in 48's have realised as much as 18*s.* per dozen. Cinerarias are also of good quality, but prices for these vary considerably; many are cleared at very low prices. Supplies of Genistas and Marguerites are over plentiful, but these will be needed shortly in larger quantities for use in window-boxes. Daffodils are plentiful, and many remain unsold at closing time. There are good Rhododendrons, Azalea mollis, Prunus triloba, Laburnums, and Lilacs in pots, but they do not appear to be much in demand. Erica Wilmoreana and E. Cavendishi are obtainable in well-flowered plants; E. persoluta and a few plants of E. melanthera are still seen. Boronias are good. Acacias are not quite so plentiful. Callas realise low prices. Lily of the Valley in pots may be had with good foliage. Hydrangea Thomas Hogg in dwarf but well-flowered plants is noticed. Supplies of Begonia Gloire de Lorraine still hold out. Ferns, Palms, and other foliage plants are plentiful, but meet a very slow demand. There is now a better trade in hardy flower roots. Pansies, Polyanthus, Auriculas, and Daisies in flower are seen, and with a few days' continuance of mild weather the market will be receiving large supplies of these flowers. Spring-bedding plants in store boxes are arriving, they include Fuchsias, zonal Pelargoniums, Lobelias, Marguerites, &c. They do not move freely at present.

CUT FLOWERS.

Supplies are very large, especially those from France, Guernsey, Jersey, and the Scilly Islands. These somewhat affect the trade in home-grown produce. Anemones are showy; the St. Brigid, coronaria, fulgens, and the double pink varieties are all abundant. The double crimson and the yellow Ranunculus are good. Violets are plentiful: English-grown flowers of the variety Princess of Wales are very fine. Roses are now over abundant. La France is still one of the best pink varieties, and is marketed in large quantities. Liberty in point of colour is much before General Jacqueminot; the latter fades quickly, but Liberty keeps its colour well for a long time. Marquise de Litta is a good red variety. Captain Hayward is decidedly one of the best varieties for market purposes, although there are few blooms of this in the market. Carnations are cheaper. Winter Cheer is very bright in appearance, but the blooms are small. Madame Thérèse France (pink), Uriah Pike (a good sweet-scented crimson), the American varieties Norway (pure white), Alpine Glow (blush), Fair Maid (a deeper shade than Enchantress), and Floriana (pink), are all worthy the attention of growers. The variety Mrs. T. W. Lawson seems likely to hold its own as the best of its colour. Gardenias are now plentiful. Supplies of Lily of the Valley are again overdone. Lilium longiflorum has gone down in price, but it is not over-plentiful; a few good L. auratum are seen. Tuberoses are seen again. The market is flooded with Daffodils of all sorts. Zonal Pelargonium "Raspail" and varieties in other colours, are plentiful, and sell cheaply. Azalea mollis does not sell readily. Tulips are now over-plentiful; in fact, there are few subjects that are wholly cleared at closing time. *A. H., Covent Garden, Wednesday, March* 15.

GARDENING APPOINTMENTS.

MR. C. C. CHAPELOW, from the Horticultural College, Swanley, as Gardener in the Glass and Vegetable Department at the South-Eastern Agricultural College, Wye, Kent.

Mr. C. W. MUIR, until recently at the Tweed Vineyards, Clovenfords, N.B., as Departmental Foreman at the Horticultural College, Swanley, Kent.

Mr. JOHN REACH, The Royal Nurseries, Craigmillar, Edinburgh, as Gardener to The Rt. Hon. Lord POLWARTH, Mertoun, St. Boswells.

Mr. JAMES BROWN, Foreman at Dunmore Park, Stirlingshire, as Gardener to The Most Hon. The MARCHIONESS OF BUTE, Abbotsford, Melrose.

Mr. R. HARDING, for the past five and a half years Gardener to T. MARTIN, Esq., Treverbyne, Plympton, as Gardener to Mrs. HINNERT, Broadgate, Barnstaple, N. Devon.

Mr. HENRY HENDERSON, for the last ten years Gardener at Cromarty House, Cromarty, N.B., as Gardener and Overseer to F. R. S. BALFOUR, Esq., of Dawyck, Peeblesshire.

Mr. A. L KNIGHT, for the past nine years as Gardener and Bailiff to ROWLAND BROWN, Esq., Oxhey Grove, Harrow Weald, Middlesex, as Gardener to Captain W. H. DAWSON, Ravensdale, Tunbridge Wells, Kent.

Mr. C. COX, for the past four years General Foreman at Ashridge Park, Berkhamsted, as Gardener to C. T. H. TOWER, Esq., Weald Hall, Brentwood, Essex.

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BOOKS: *H. J.* We do not know of a work which deals with the subject you mention, with the exception of *Mushrooms for the Million*, by John Wright. This book, which is out of print, may sometimes be obtained from the second-hand booksellers.

CARNATION, OEILLET REMONTANT LYONNAIS À TIGE DE FER: *Dianthus.* You cannot do better than apply to the grower you mention, and he will get you this variety, if it is obtainable. The significance of the French name is that the variety is a perpetual-flowering variety, and has strong, stiff flower stems (tige de fer—stem of iron).

CUCUMBER AND OTHER PLANTS: *T. C. H.* The diseased appearance of your plants is not due to fungus disease, but the leaves are literally smothered with insect pests. We can detect thrip, scale, greenfly, and red-spider. Adopt measures against these at once by fumigating and spraying with insecticides. The appearance of the Richardia leaves and flower is due to inappropriate culture. Have the plants been watered carefully?

ECONOMIC PLANTS: *Constant Reader.* Apply to Messrs. Wm. Bull & Sons, Nurserymen, Chelsea.

GARDEN POTS: *S. S., Ealing.* If you have only the small unheated conservatory mentioned in your letter, the large number of small and medium-sized pots will be of little use to you. The use for pots is for containing desirable plants, and the opposite view of selecting plants for the pots is a less familar one to us. In respect to the conservatory facing to the north, the Ferns now cultivated are the most suitable plants for the structure, but Orange-trees, Ficus elastica, Aspidistra, Araucarias, &c., would also succeed. If you wish to have flowering plants as well, they will require to be grown in frames and removed to the conservatory when they reach the flowering stage. If you can have such frames erected, a use will soon be forthcoming for the pots.

INSECTS: *G. C.* The mass of minute dark-coloured insects are the so-called spring-tails or ground fleas, Colembola sp. They are often found swarming round newly-made hot-beds, decayed vegetable matter, garden paths, &c., and have been known to attack fungi and the leaves of the Mangold and Potato. Occasionally they have been recorded as injurious, but as a rule they are not so. You can easily destroy them when on the ground with a solution of caustic alkali applied hot. (2) The large, active, grub-like insect is the larva of a beetle belonging to the Brachyletrous beetles. It is apparently of predaceous habits and also a cannibal, as it has during its captivity devoured two members of its own family. Such larvæ are also found in decayed vegetable matter and fungi, but are not known to be destructive to the produce of the garden or the field.

LAND WAITING FOR USE: *C. P.* You might plant Potatos again and get a good and profitable crop this season; or you could sow Clover and other seeds, which if sown at once would furnish a crop after autumn-sown Clover is past, and the ground could be ploughed later on, when the turned-in Clover would benefit the soil considerably.

NAMES OF FRUITS: *W. F. S.* Apple Red Norman.

NAMES OF PLANTS: *Slough* (no name enclosed). 1, Thuya occidentalis variety; 2, Cupressus Lawsoniana aurea; 3, Daphne Laureola (Spurge Laurel).—*J. C.* Primordial (Retinospora) stage and adult forms of Cupressus funebris.—*Strix.* You should number your specimens. The creeper is Nepeta glechoma variegata; the plant in flower is Abutilon megapotamicum; the stove plant is Ruellia Portellæ, and the Fern Polystichum angulare proliferum.—*Hop.* 1, Oncidium maculatum; 2, O. tetrapetalum; 3, Dendrobium tetragonum; 4, Miltonia flavescens.—*V. R. A.* 1, Masdevallia Wendlandiana; 2, M. triaristella; 3, Oncidium triquetrum.—*W. C. S.* Cattleya Percivaliana. —*B. T.* 1, Adiantum formosum; 2, Epidendrum radiatum; 3, Restrepia maculata.—*F. J. R.* Cœlogyne lactea.—*W. U.* Ruellia macrantha.

ORANGE-TREE: *W. H. W.* Unless the plant is in an unhealthy condition or much pot-bound, it will be better to afford a top-dressing now and remove the plant to a tub during next winter, when growth will be less active than it is at this date. If you decide to top-dress the plant, you may remove as much of the surface soil as can be done without injuring the roots, and then apply a compost of rich fibrous loam and leaf-mould in equal quantities, with a little charcoal added. If the circumstances make it desirable to shift the plant at once, be careful not to place it in too large a tub, but one that will afford space for 1 inch or 1½ inch of fresh soil around the old "ball." Use a similar compost as advised for the top-dressing, adding some crushed bones, and keep the collar of the plant above the surface soil, as Orange-trees seldom succeed if planted deeply. Do not disturb the roots more than is necessary, and following the operation spray the plant overhead with water on fine days.

PAGOSCOPE: *D. W. S.*, and others. We have no further information to give you beyond what we have already published. We have done our part. It is for the advertisers to do theirs.

PELARGONIUM UNHEALTHY: *Strix.* The small plant has had its stem buried much too deeply. No plant should be buried below the "collar," or the point at which roots are emitted, whether in a pot or in the open ground. The old stump should have been destroyed long ago. There is no use in keeping such old plants when better and healthier plants may be easily obtained by propagation from cuttings.

PETRIFIED MUSHROOM: *W. F. R.* Without seeing your specimens we cannot say what it is, but we suspect it is a fossil Echinus or something of the kind, and not a Mushroom at all.

PLANTS FOR A BORDER FACING TO THE NORTH: *Amateur Gardener.* You have omitted to state the length and width of the border, but these matters are important when selecting the plants. We give you a selection of plants and state their approximate height, and the predominant colour of the flowers that you may be guided in arranging them. *First set* (plants 3 ft. or more high).—Aconitum napellus grandiflorum (blue), A. Wilsoni (blue), Anchusa italica (blue), Anemone japonica in white and pink varieties; Aquilegia chrysantha (yellow), Campanula lactiflora cœrulea (pale blue), Delphiniums in variety (blue and violet or purplish shades), Echinops ruthenicus (blue), E. sphærocephalus (white), Eremurus robustus (pink), Helenicum grandicephalum, H. autumnale grandiflorum (yellow), H. nudiflorum (orange and crimson), Kniphofia aloides (orange-red), Lathyrus latifolius (rose), L. l. albus (white), Lupinus polyphyllus (blue), L. p. albus (white), Helianthus mollis, H. tomentosus, H. multiflorus pl., H. m. grandiflorus (all yellow shades), Spiræa arnucus (cream), Thalictrum flavum (yellow), Aster cordifolius, A. c. elegans (lilac and white), A. novæ-angliæ rubra (red), A. n. a Mrs. Rayner (crimson), A. n. a. W. Bowman (purplish-blue), A. novæ-belgii Top-sawyer (blue), A. n. b. St. Brigid (rose), A. n. b. Charming (white and purple), *Second set* (plants 2 feet to 3 feet high).—Stenactis speciosa (blue), Spiræa venusta (pink), Campanula grandis (blue), C. g. alba (white), C. persicifolia coronata alba, C. p. fl.-pl., C. p. Mœrheimii (all white), herbaceous Phloxes in white, scarlet, crimson, and rose shades; Oriental Poppies in scarlet and crimson; Incarvillea Delavayi (rosy-carmine), Scabiosa caucasica (blue), Iris aurea, I. Monnieri (both yellow), I. Monspur (blue), I. missouriensis (pale blue), I. pallida (blue), I. Madame Chercau (blue and white), I. Dr. Bernice (crimson and brown), I. l'Innocence (white), I. Queen of May (rose), I. Kæmpferi in rose, blue, and other shades; single and double Pyrethrums in many bright hues, Gaillardias (crimson and gold), Montbretias in orange and yellow, Monarda didyma (crimson-scarlet). *Third set* (plants not more than 2 feet high).—Aster Amellus, A. A. bessarabicus, A. A. Riverslea (all violet-blue), Inula glandulosa (golden-coloured), Megasea cordifolia purpurea (crimson-purple), Campanula carpatica (blue), C. c. alba (white), C. speciosa dahurica (blue), Hemerocallis Thunbergi (yellow), Helenium pumilum (yellow), Lychnis viscaria plena (rose), Lenten and Christmas Roses, Funkias, Doronicums, Anemone sylvestris (white). Heucheras in variety, &c. In addition to the above you could employ as marginal plants any of the alpine or setaceous Phloxes, Aubrietias, such Campanulas as muralis, pumila, garganica; any of the dwarf Achilleas, Hepaticas, Iris pumila in variety, Dactylis, double Arabis, Cheiranthus alpinus, Gentiana acaulis, &c. In the arrangement of the border you will secure a finer display by setting out a selection of the plants given in groups of from 2 to 4 feet across at ground level. That is to say, group several strong plants of each sort together on ground spaces of about 3 feet across. While thus securing a mass of colour from any one subject, the general arrangement will be also bolder and more effective when seen in the distance. At another season Pæonies and many bulbous plants could be planted to enhance the effect. Groups of Lilium tigrinum and L. speciosum in variety could be planted even now in the second set.

VIOLETS DISEASED: *J. W.* Your plants are attacked by a fungus, Ascochyta violæ. Spray the plants every fortnight with potassium sulphide in the proportion of 1 oz. of sulphide to 3 gallons of water. Select a fresh situation and soil for a future plantation, getting new stock from a locality that is free from the disease.

WHITE DEPOSIT ON SOIL: *A. G.* The whitish appearance of the surface soil on your Peach border is due to a deposit of lime, &c., from the water, which is evidently of hard nature in your neighbourhood. The sample of soil you forward appears to us to be of very inferior quality.

BOUGAINVILLEA SPECTABILIS, 28 FEET HIGH, IN FLOWER ON THE DWELLING OF MR. HENRY FISHER, REDLANDS, CALIFORNIA.

From a Photograph taken in October last.

THE
Gardeners' Chronicle

No. 952.—SATURDAY, March 25, 1905.

CONTENTS.

ILLUSTRATIONS.

THE TIMBER VALUE OF EXOTIC TREES.

RECORDS of growth made by various introduced species are given from time to time in the *Gardeners' Chronicle* and elsewhere. Although it does not necessarily follow that these are recorded with any other motive than that of supplying interesting information, yet when any species has made an exceptionally rapid growth it is not unusual for a suggestion to be offered that it will probably prove of value as a timber producer. Such suggestions are, of course, made in good faith, but they seldom emanate from anyone who has any connection or acquaintance with the timber trade of this country, for the simple reason that the timber trade is an industry, while the growing of most exotic species is more or less of a hobby.

Yet it is evident that the constant recommendation of a particular species, even when made by men making no pretence to possess expert forestry knowledge, has a tendency to bring that species to public notice, and may eventually lead to its cultivation on a scale which exceeds the limits of what may be termed "ornamental planting." To a planter who neither requires nor desires to study economy in planting or the home timber supply of the future, the question is not perhaps of great importance, but there are doubtless others who plant with a laudable desire to lay their money out to advantage and confer some benefit upon posterity, and to such the discovery of an apparently valuable species is seldom allowed to pass unnoticed.

No doubt, rapid growth of itself is always an attractive feature in any species, and very few of our indigenous species possess that feature in early youth, the period during which so many exotic trees show to advantage. When, therefore, attention is frequently drawn to a comparatively new but rapidly-growing tree, it is not unusual to find those who value that quality introducing it into their woods and plantations with a view of increasing their value and rate of production. While such a step may be justifiable in some cases, there is little doubt that it has led, and will again lead, to a waste of time and money in others. It is always instructive, and occasionally amusing, to sum up now and again the various species which have been announced as valuable for forestry purposes.

It must not, however, be supposed that the laudation of new species is an innovation. The love of novelty is a human weakness, and is not confined to any particular calling. In 1825 William Cobbett, of Rural Ride fame, wrote the praises of the Locust tree (Robinia pseudo-Acacia) in the following words:—

"I, like all other planters, was in haste. The nakedness of my house called for shelter. I bought large trees, carried them to Botley at great expense, planted them; but by degrees I pulled them all up and flung them away, except a row of them placed against a dead wall merely as a screen. The plantation is, taken altogether, the most beautiful that I ever saw. It consists in part of my Locust-trees, planted in the three years before mentioned, and of these I am now going to give an account. This account will be read hundreds of years hence. The time will come (and it will not be very distant) when the Locust-tree will be more common in England than the Oak; when a man would be thought mad if he used anything but Locust in the making of sills, posts, gates, joists, feet for rick-stands, stocks and axle-trees for wheels, hop-poles, pales, or for anything where there is liability to rot. This time will not be distant, seeing that the Locust grows so fast. The next race of children but one—that is to say, those who will be born sixty years hence—will think that Locust-trees have always been the most numerous trees in England; and some curious writer of a century or two hence will tell his readers that, wonderful as it may seem, 'the Locust was hardly known in England until about the year 1823, when the nation was introduced to a knowledge of it by William Cobbett.' What he will say of me besides I do not know, but I know that he will say this of me. I enter upon this account, therefore, knowing that I am writing for centuries and centuries to come."

One of the "hundreds of years hence" has almost passed, and the Locust has not become so common as the Oak, the men who plant anything else are not thought mad, nor does the nation talk much of William Cobbett's arboricultural introduction. His fate is pathetic; but it is only the common one of most forestry reformers. The thorough trial of a new species is a long business, and requires the experience of more than one man to bring it to a successful issue. Since 1825 many trees have been recommended almost as highly as was the Locust tree by Cobbett, but only to be forgotten again in the course of a few years. Conifers in particular might be named by the dozen which were going to revolutionise English forestry, and make two feet of timber grow where one grew before. Yet when planted outside the shelter of the pinetum or ornamental woodland they were seldom heard of except through the record of their failure. Some failed to thrive except on particular soils or situations, others practically stood still after a few years' rapid growth, while a third class were found to be almost useless as timber when they reached maturity. The few real successes might be counted on the fingers of one hand; the few which have stopped short of complete failure on the fingers of the other. The reason is difficult to see in many cases, especially when a success and a failure have the same country of origin. Take, for instance, two such species as the Douglas Fir and Thuya gigantea. The former develops into a splendid timber tree in this country, while the latter cannot be considered of more than arboricultural interest, although both are known as good timber trees in Western America. Or, again, take the Wellingtonia or Sequoia gigantea and its near relative S. sempervirens. Where can one see a really good specimen of a timber tree amongst the former in this country? Trees of large diameter at ground level are common enough, but at twenty feet from the ground they are little more than poles. S. sempervirens, on the other hand, grows into a well-shaped bole, and carries its girth well up, producing trees with a large volume of timber, although too soft to be of much value. Numerous instances of a similar nature could be given, showing how one species turns out well, and another badly, although both may do equally well for a time.

No doubt many causes contribute to these apparant anomalies. Fickle springs, cold summers, and wet autumns, may all aid in exerting their influence unfavourably upon the development of certain exotic species, while they have little effect upon others But the chief factor in converting a normally tall tree into a comparatively dwarf one must probably be sought in our relatively cold and sunless summers, which check height growth after the first vigour of youth is over. Very few of our exotic trees, apart from European species, add much to their height after the first fifty years, and the majority of them fall off quickly before then. This seems especially marked in the case of many North American and Japanese species, although amongst the former several notable exceptions may be found. But probably as great a defect, from a commercial point of view, in many of these trees is their badly-shaped boles. The Wellingtonia, Thuya, Cupressus, Cryptomeria, &c., all exhibit the same failing in this respect, being characterised by stems of comparatively great girth at the base, but which fall off quickly a few feet above the ground. The specimen of Cryptomeria at Dropmore measured by Mr. Page showed this feature in a marked degree. Compare

such a stem with one of Scotch Pine, Spruce, or Silver Fir, and it will at once be seen how superior these latter are if given fair conditions of growth.

But the worst feature about the timber of most of these coniferous trees from abroad is its poor quality. Judging the timber of most of them on its merits, it cannot be said that it is superior, if it is even as good as that produced by European trees. If Pine timber be judged by comparing it with that of Spruce or Silver Fir, the only tree which comes out of the ordeal at all creditably is the Douglas Fir. No American Pine can surpass either the Scotch or Corsican Pines for quality of timber, nor can they equal the latter in rate of growth. The common Spruce is as good as any amongst the Piceas (Spruces), while the European Larch stands at the top of all coniferous timber that can be grown in this country. Owing to the liability of the latter to disease and its more or less uncertain growth, however, it has recently been regarded as a doubtful species, although good reasons against its continued use have not yet been given. That it has proved a failure in many cases is beyond doubt. That it will prove a failure in those about to be formed none can say with certainty, apart from soils which are known to be inimical to it. But although it has by no means been discarded by planters, there has been a tendency during the last few years to replace it by the Japanese species (Larix aptolepis), chiefly on account of the supposed immunity of the latter from fungoid disease and insect pests. As a matter of fact, however, the Japanese Larch is neither immune against the blister fungus nor the Larch aphis. The disease has been reported from several quarters, and Mr. Forbes tells us that he has found the fungus fairly common on the Japanese Larch growing in the experimental forest plots at Cockle Park, although the typical blister has not yet had time to appear. Many of the same species were also badly attacked by the Larch aphis last summer, which, if Mr. Massee's conclusions are correct, should alone predispose them to Larch blister.

Just as one swallow does not make a summer, so one diseased or aphis-infested Japanese Larch does not render that species a failure. But the fact that the European Larch showed the same freedom from disease for many years after it was introduced renders it worth while considering whether the new species is sufficiently superior to the old to make its extensive cultivation a profitable undertaking. Its rapid growth, to begin with, may be an advantage, or it may not. As yet we know little or nothing about the quality of its timber when grown in Britain, but it is well known that the European variety often grows too fast for the production of hard, durable timber, and the same cause may produce the same effect in both species. With rapid growth alone to recommend it, and the possibility that this growth may suddenly drop off after the first twenty or thirty years, without any guarantee as to quality of timber or freedom from disease, the planting of Japanese Larch for commercial purposes must be regarded as speculative an operation as the planting of nine-tenths of the trees introduced during the last hundred years, including Cobbett's Locust tree. Mr. Elwes, who has studied the Japanese Larch both in Japan and in this country, believes that it will not prove superior to the European variety in the long run, while the frequency with which it loses its leading shoot is a serious defect in an ordinary forest tree. In any case the wisest policy seems to be a waiting one, both in the case of this and many other exotic trees. *A. C. Forbes*

FIG. 70.—HELONIOPSIS BREVISCAPA
Entire plant; natural size.
Section through flower, magn. 2 diam.; pollen-grains elliptic, 1-furrowed, magn. 120 diam.
Recommended an Award of Merit at the last meeting of the Royal Horticultural Society.

NEW OR NOTEWORTHY PLANTS.

HELONIOPSIS BREVISCAPA.

THIS Japanese Liliaceous plant is so like the North American Helonias that at first sight it is not easy to distinguish them. The most easily recognised point of distinction is the single undivided style of the Japanese plant as compared with the three styles of the American one. Heloniopsis breviscapa, of which we give an illustration (fig. 70), from a specimen exhibited by Messrs. Barr, is a Squill-like plant, about 6 to 8 inches high, with a thick root-stock, broadly-lanceolate tufted leaves, and an erect, leafy stalked raceme of whitish or pale-lilac bell-shaped flowers, each about half-an-inch in length, supported by a pedicel rather shorter than itself. Perianth segments six equal, oblong-obovate, tapering to the base. Stamens slightly longer than the segments, connate at the extreme base with the segments filaments white, anthers two-lobed, innate, extrorse; ovary three-lobed, with a stout deep-violet-coloured style, capped by a cushion-like whitish stigma; ovules horizontal, very numerous. The plant is quite hardy, and is an interesting addition to our spring-flowering plants. H. japonica, a nearly-allied species, has nodding, loosely-flowered racemes, and was figured in the *Botanical Magazine*, t. 6986; and another species from Formosa (H. umbellata, Baker) is cited in the *Kew Hand-List* as in cultivation in that establishment. *M. T. M.*

CALTHA ELATA, *Duthie**.

A tall, handsome plant, similar in many respects to C. polypetala, Hochstetter, but the cylindrical petioles at once distinguish it from that species as well as from the common Marsh Marigold (C. palustris). It was raised in the Royal Gardens at Kew from seeds obtained by my plant collector in Hazára during 1899, and flowered in the rock garden last July. C. polypetala was also in flower at the same time. It agrees with the latter in the overlapping of the basal lobes of the leaves, but the leaves are more rounded and the marginal teeth are very acute; it also differs by having rather smaller flowers, more numerous stamens, and shorter stigmatic lobes; the follicles also are erect (not spreading), and their beaks are much shorter. It is a taller plant than C. palustris, and comes into flower considerably later. Some specimens in the Kew Herbarium, collected by Falconer in Hazára in 1837, and in W. Tibet in 1838, I think undoubtedly belong to this species. *J. F. Duthie, Kew.*

CEANOTHUS THYRSIFLORUS.

THE genus Ceanothus contains about thirty species of hardy or half-hardy shrubs, all of which are natives of North America. About twenty species have been introduced into cultivation in this country. The prevailing colour of the flowers is blue in its varied shades, but there are several species with pure white flowers, also several garden forms of C. azureus which have pinkish flowers.

The majority of the species are sufficiently hardy to withstand our winters if given the protection of a wall, a position for which they are admirably adapted, as may be readily seen by reference to the illustrations at figs. 71, 72. The species figured (C. thrysiflorus) is a native of California, where it is known as the "Californian Lilac." It was introduced to British gardens in 1861, but does not appear to be at all well known; possibly this is due to the fact that it is

* *Caltha elata, Duthie, sp. nov.*—Caulis elatus, atro-viridis et interdum rubescens. Folia suborbiculata, argute serrata, inferiora longe petiolata, lobis basilaribus imbricatis; petiolo cylindrato, haud sulcato. Flores 1—1·7 poll. diametro. Stamina plurima. Lobi stigmatici breves. Folliculi erecti, rostro brevi.

not sufficiently hardy to stand the winter in the open without some slight protection. As previously mentioned, this is easily afforded by treating them as wall plants. When cultivated in this way they never fail to produce quantities of blossom during the early summer months. The flowers are produced on the ends of the branches of the previous year's growth, in dense compound panicles, and are of a lovely shade of lavender-blue colour. The leaves are variable in size and shape, being from 1 to 3 inches long and ½ to 1 inch in diameter. The species of Ceanothus thrive in almost any soil, but prefer a porous sandy loam, with good drainage. They are readily propagated in early autumn by cuttings of thin, half-ripened shoots cut to a joint, dried at the

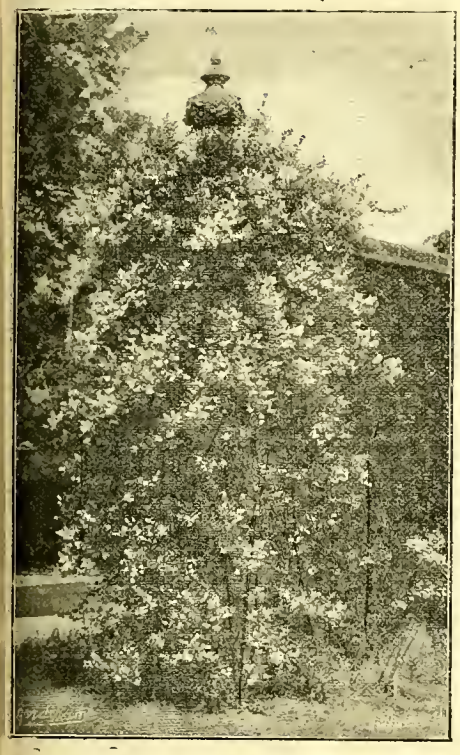

Fig. 71.—Ceanothus thyrsiflorus in flower against a wall at Kew.
(*Photograph by C. P. Raffill.*)

base and inserted in sand in a cold frame or bell-glass; or by layering the branches in spring. The majority of the species flower on the ripened shoots of the previous years' wood, for this reason any pruning which may be necessary should be done immediately after the flowering season is over, and the plants be encouraged to make a strong vigorous growth again ready for the following season's bloom.

The garden forms of C. azureus and C. americanus have long been favourite garden plants, and are sufficiently hardy for general culture in the open border. When grouped together in masses they are very effective when in flower in late summer and autumn, and keep up a succession of flowers for several months. The variety known as "Gloire de Versailles" is one of the finest and hardiest of these, with flowers of a bright blue colour, and they are produced in profusion in late autumn, when many other shrubs have long been past their best. These garden varieties all flower on the ends of the shoots of the current year's wood, and for this reason any pruning which they require should be done in spring before growth commences. *A. P. Raffill, Kew.*

[In 1896 Mr. J. Burtt Davy, then of the University of California, now of the Agricultural Department of the Transvaal, sent us a sketch of a flowering shoot of this species, which was cultivated many years ago at Chiswick, but was afterwards lost to cultivation, or, at any rate, was rarely met with. Ed.]

POTATOS.

Express Culture by an Amateur — An "Eldorado" Tuber weighing 2 oz. produced over 3,717 times its own Weight. — A good deal has been said on the subject of Potatos within the past twelve months. In fact, the great Potato boom has been the chief topic of conversation at all the markets for some time past. Not only have farmers and market-gardeners taken up the "craze," but hosts of amateurs who possess a little knowledge of horticulture have bought tubers at a high price, partly to make experiments and test the different kinds and qualities, and partly in the hope of increasing the family exchequer.

Of all the new kinds of Potatos that have been brought out of late (and their name is legion, although it appears likely that several old varieties have been given new names), none has received the same amount of attention as the now famous "Eldorado," which was produced in Scotland by Mr. Findlay, the noted raiser of many of our best varieties.

The fame which this variety has attained is, I consider, thoroughly well deserved, as I am sure my readers will agree when I have related my own experience in the art of propagating them.

In January, 1904, I purchased an "Eldorado" tuber weighing barely 2 oz. from Messrs. Dean Bros., of Dowsby Hall, near Bourne, Lincs., for which I paid £20. It was a beautifully-formed little tuber (about proper seed size), and had

seven eyes. I kept it in a room with plenty of air and daylight until the beginning of March; then I placed it in the greenhouse and left it in gentle heat to throw out sprouts for about three weeks. When each eye had commenced to grow, I cut the tuber into six pieces (two of the eyes were too close together to divide), and set each piece into a 6-inch pot in leaf-mould and sand, and placed them in a small propagating frame which I had built in the greenhouse. These very quickly commenced to grow, and in two or three days' time I took off their first sprouts, and kept taking off sprouts every other day until the middle of July, when the cut pieces of Potato suddenly collapsed and were gone in a day, leaving only the dry skin, not a bit of substance being left.

I had procured by this time 179 sprouts and twenty-eight cuttings, and I took other rooted cuttings which the plants threw up from their roots until August 10, and so I obtained 250 plants altogether. I commenced to plant out in the garden on June 3, when I set forty-four sprouts; on June 11, forty-four; June 16, twenty-six; June 21, twenty-six; June 26, twenty-six, and kept on setting late plants until August 20 I had 150 really fine plants, but from the remaining 100 I expected very little, as some went wrong and the others were so very late. I have found that neither the earliest nor the latest plants grew and produced so much as those set between the two—that is, those that were grown straight ahead and were not checked in growing did far and away the best.

I was unfortunate in completely spoiling twenty of my best plants owing to the ground having been dressed too thickly with lime, and I lost fifteen of my late ones as they were eaten by slugs and broken by the wind.

My best fifty plants averaged in weight about 4 lb. of tubers each, and the best 150 plants averaged nearly 3 lb., the last plants, being so very late, averaged little over ½ lb. per plant. Anyway the total produce of the 2 oz. tuber weighed 4 cwt. 1 st. 2 lb. 3½ oz.—that is, the produce of one tuber yielded over 3717 times its own weight of beautiful Potatos. The best root yielded 6 lb. 6 oz., and the heaviest tuber weighed 1 lb. 2 oz.

I was surprised that the cuttings did so well. I only took twenty-eight (in the same way as you take Pelargonium cuttings, without any root), and they averaged 3½ lb. per plant. I could have taken scores more, but I thought they would do very little good, and I was afraid of injuring my plants, but I feel sure it would have paid me well to have done so.

I think the above testifies to the value of this variety, and it is a fine, handsome and prolific sort. Its foliage, flowers and habits are very distinct from any other variety. It is a marvellous producer, rapid grower and a disease resister; it is of fine quality, I am told, as a cooker. What more can one want?

My readers will I feel certain agree that my results were not bad for an amateur; and if I an amateur can attain such good results, what should a professional gardener achieve? I have heard of one in this neighbourhood who produced nearly 35 stones of "Eldorados" from a tuber weighing 1 1/16 oz., and of another who dug a root which weighed over 12 lb., and this a sprout.

It has been said that Potatos raised from sprouts are not so good as those grown from the tuber, but I fail to see this, as in all other plants the higher they are cultivated the better they become. For example, the budding of Roses and the grafting of Apples, the results of which are acknowledged as finer and better than when grown on their own stocks. The only advantage, I think, in growing from tubers is, the plants get a rather better start, as they have something to feed on in their earliest stage; but when sprouts once start no one could tell the one from the other, as I had both growing side by side.

My garden is not good land for Potato-growing, but I gave it a fair dressing of farmyard-manure, and at the rate of 12 cwt. of artificial to the acre, composed of three parts superphosphate of lime, two parts kainit, and one part sulphate of ammonia. I also sprayed my Potatos three times with "Strawsonite," a mixture prepared by Messrs. Strawson & Co.

It has been said that some "Eldorados" came out amongst the "Northern Stars," but the odd sports that I have had grow among my "Northern Stars" are entirely different, so I think this is only an old woman's tale.

I think my "Eldorado" was a very good investment, as although they have come down in price lately to little over 10s. per lb., I shall get a very good percentage on my original outlay of £20.

In my opinion nothing can equal the "Eldorado," and if this last season had been a bad Potato year, as the previous two seasons were, there would have been a great demand for it, even greater than there is. In time, when it is cheaper, it must come to be the chief main crop, and take the place of the Up-to-date, as I feel certain its own merits will obtain for it the first place in the crops of Potato-growers. *Rev. G. W. Ridley, Bratoft Rectory, Burgh R S.O., Lincs.*

Cooking-Potato Tests.

The second or deferred testing of cooked Potatos at Marks Tey served to bring out several facts in connection with Potatos. The first thing to be noted is that whilst some tubers maturing late, as Scotch tubers do, further mature or develop starch in their composition when stored for a few months after being lifted, equally may it be assumed that southern-grown Potatos, ripening much earlier, are at their best up to the end of the year, then commence to deteriorate. Thus we should assume that as food, southern-grown Potatos should be utilised up to the end of December, the northern-grown tubers following till the spring. If these variations do really take place in northern and southern-grown Potatos, and of course the assumption is open to question, may it be admitted as a basis for that unquestioned fact that northern-raised tubers give, when planted in the south, much better growth and crops than southern-grown tubers as a rule do? Then another and certainly more well-grounded assumption derived from the Marks Tey cooking test is that soils do greatly affect edible quality. Taking Up-to-Date for instance, the variety specially cooked first to present a point or judging standard, there was the widest possible difference between the best sample and the worst. Two dishes at least were speedily discarded as close, wet, and tasteless, whilst the best dish showed really capital quality in texture, appearance, and flavour. It is easy to understand what a low opinion of Up-to-Date would be formed by those whose inferior soils produced tubers of the worst quality. But those whose soils would produce the best quality would naturally be elated. The same strange difference in quality arising from diversity of soil was found in every case where there were three or more dishes or samples of any one variety cooked.

All the samples were boiled in their skins. That may be very good practice whilst the skins remain fresh, or have been well kept from exposure to the air; but later it is without doubt best to remove the skins, as is commonly done, as nothing can well prevent the coats from absorbing from the air a certain amount of astringency, and that element necessarily imparts its unpleasant taste to the Potato. *A. Dean.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM HYBRIDS, &c, AT WALTON GRANGE.

Perseverance is a characteristic of the Orchid hybridist, and when pursued intelligently success is obtained. One section of Orchids after another has been conquered by him, but until very recently the Odontoglossums occasioned the greatest difficulty. Such, up to a certain point, was the experience in the collection of W. Thompson, Esq., at Walton Grange, Stone, Staffordshire, under the management of Mr. W. Stevens. But most marked success has resulted from the experience gained by former failures, and the method by which thousands of plants of many interesting crosses of Odontoglossums have been obtained may be of interest.

The seeds are sown on the surface of the potting material in which the other plants are growing, and they grow successfully in several houses. But the greatest and most rapid success has been in a small sunk house, in which a cool, moist atmosphere always exists.

On the staging in this house are large numbers of freshly-imported plants of Odontoglossum crispum, potted up in the usual manner, and kept continually moist. These are used as foster-parents for the cross-bred seedlings, the seeds being sown on the imported pseudo bulbs and rhizomes, and in a less degree on the surface of their pots. Invariably the first seedlings to germinate are those on the bare moist pseudo-bulbs. This seems to have distinct bearing on the "mycorhizas" of Orchids, an article on which was published in the *Gardeners' Chronicle*, September 22, 1900, p. 218. Later those on the peat germinate, and last of all those on the sphagnum-moss. But the differences in the surface on which the seeds are sown give other results. Those germinating on the pseudo-bulbs are the most likely to be reared, those on the peat or pieces of crocks come next, and those on the sphagnum-moss are the least likely to be brought up, their constitution being more delicate from the first. The first object is to prick the little seedlings off into dwarf thumb or "thimble" pots, a dozen or so in a pot. These store pots are placed in batches of two dozens or so in shallow wooden boxes about twice the depth of the pots, and with holes in their sides for ventilation. Squares of glass are placed over the boxes, and they are put on a narrow shelf in a cool, moist house within a foot of the glass of the roof. When a quarter of an inch high, or before if necessary, the little plants are potted singly or three or four together in "thimble" pots, and returned to the shallow boxes on the shelf, and covered with glass until they have got over the shift, when they are gradually acclimatised to the air in the house and the glasses left off.

In the main seedling-house it is a pretty sight to see the thousands of seedlings, including a few crosses between Cochlioda Noezliana and Odontoglossums, and among them nice little plants of the beautiful Odontioda × Vuylstekeæ, which was the "sensational" plant of last year's "Temple" show (see *Gardeners' Chronicle*, June 4, 1904, p. 360). Crosses with a fine form of Cochlioda vulcanica have also been successfully made; but these Cochlioda crosses are not so plentiful as others between fine spotted forms of Odontoglossum crispum, O. maculatum Thompsoni (a gigantic form), O. Harryanum, O. Hallii, fine varieties, and generally the best procurable types.

It is interesting to follow the plants from the germinating stage to the plant in flower, as they can be followed at Walton Grange. On the shelf the little plants in boxes are graded, the smallest being at the end of the house and the largest near the door. Later they take their places on the staging in the same house, and as

the space is needed pass out into another cool sunk-house, now three-fourths full of Odontoglossum hybrids. On one side is a batch of O. × loochristyense, raised at Walton Grange between fine varieties of O. triumphans and O. crispum. This batch affords a striking example of the variability of hybrids, for it contains good forms of two sets, the one the yellow-ground chestnut-blotched type as imported, and others varying between it and the purple-brown blotched O. × Vuylstekei, the lips being very dissimilar. Another instance of variation is in O. × waltoniense (polyxanthum × crispum), the members of which generally have finely formed canary-yellow flowers, with sometimes large red-brown blotches, but one of which now in bloom has fine cream-white flowers (showing much of O. crispum) with a slight yellow shade and distinct brown markings.

There are several houses of finely-grown established Odontoglossum crispum, a number of which are in flower or bud. Some handsomely blotched forms have appeared at Walton Grange, and others of the best have been acquired. Grouped together in one house is a batch of sturdy plants of remarkable varieties, including O. crispum Lindeni and O. c. Luciani (two of the finest blotched forms), O. c. The Earl, O. c. Stevensi, O. c. Robert McVittie, and O. c. Victoria Regina, all handsome spotted forms which have received honours at the Royal Horticultural Society when shown by Mr. Thompson. With them are O. crispum Thompsoni (a very remarkable form) and O. crispum Solum, which appeared at Walton Grange and which is one of the most remarkable variations yet seen, its lip being wholly claret-purple in colour with but a bare white margin at the apex, an occasional dark purple blotch also appearing on one of the other segments.

Other famous varieties present are O. crispum heliotropium, O. c. Annie, O. c. Capartianum, O. c. The Bride, and O. c. Cleopatra (a fine white flower), O. c. William Stevens (a good blotched form raised from true seeds of spotted O. crispum), O. × Crawshayanum (Hallii × Harryanum) (one of the showiest of yellow and red-brown hybrid (a fine form of which was in bloom), O. × Wendlandianum, O. × Ruckerianum ocellatum (very handsome and distinct, O. × excellens Thompsoni and O. × excellens eugenes, the latter specially interesting as being parts of the plant shown from Trentham as O. eugenes which obtained a first-class certificate in 1883.

In another house is a batch of Odontoglossums, out of which some good O. × Adrianæ are flowering, one large white heavily blotched form being very close to O. crispum; also O. Hunnewellianum and a great quantity of O. Pescatorei, one being a prettily spotted variety, and another a large specimen with thirteen spikes, while at one end is a batch of free-flowering O. Pescatorei raised true from seeds. One fine old plant of O. × mulus had probably seventy or eighty large bulbs and eight branched spikes of flowers.

In another cool-house with many Odontoglossums on a shelf is a lot of O. Rossii majus in bloom, pans of scarlet Sophronitis with thirty to forty flowers, large baskets of Vanda Kimballiana, and, on the stages in bloom, Cymbidium eburneum and various Dendrobiums, and a fine collection of Miltonia vexillaria are showing well for flower.

The hybridising of Dendrobiums is also in progress and some pretty things are in flower; and of Cypripediums the plants in bloom are represented by C. × Thompsoni, C. × Hera (of a very fine colour), C. × aureum Hyeanum, C. × Miss Louisa Fowler, and a few other good hybrids.

In a rather lofty house, the stage in which is filled with good specimens of the useful white Eucharis × Stevensii raised at Walton Grange, and which is said to be perfectly proof against mealy-bug, which sometimes attack other Eucharis, are suspended a nice collection of Phalænopsis, which have been so grown for some years.

The largest houses are lofty, and the staging is carried up proportionately nearer the glass than in most places, and the basements are planted with Begonias, Clivias, Tradescantias, and other free-growing plants, which seem to have a salutary effect on the Orchids. The use of decayed leaves for mixing in the compost for Orchids has been abandoned at Walton Grange.

BELVEDERE, ST. LAWRENCE, I.W.

(See Fig. 73 and Supplementary Illustration.)

In the Supplementary Illustration to the present issue is presented a view of Brunsvigia gigantea, or more properly B. multiflora, in flower out-of-doors in Lord Walsingham's garden at Belvedere. This garden is situated about 2 miles out of Ventnor, on what is known as the Undercliff, on the south coast of the Isle of Wight. Brunsvigias are generally described in the text-books as "showy greenhouse plants from the Cape of Good Hope," and in most situations in these islands they undoubtedly require the protection afforded by a glasshouse, not only to obtain in them satisfactory growth, but to ripen the bulbs sufficiently to produce flowers. It is therefore quite an exceptional circumstance to have B. multiflora flowering so grandly, as shown in the Supplement, at the base of an outside rockery in July last. Its effect can best be imagined when it is stated that the inflorescence was 37 inches across. The perianth of this species, which was introduced to Britain in 1767, is rosy-pink inclining to red in colour, and a good figure may be seen on reference to the *Botanical Magazine*, t. 1619, prepared from a plant which flowered in one of the hot-houses of Messrs. Loddiges & Sons, at Hackney. A very long list of synonyms is given, from which it appears the plant has been described as a Crinum, Hæmanthus, Amaryllis, and even as a Narcissus.

Within a foot or two from the plant of B. multiflora there is another one representing B. Josephinæ, figured in the *Botanical Magazine*, t. 2578, and of which we present on illustration on p. 186. The plant has made a very large bulb, and will be likely to flower this season if there is as much sunshine as last year. In fig. 73 may be seen better than in the Supplement the surroundings amid which the plants are growing, and we may point out that they are exposed directly to the south, only a very short distance from the sea, whilst the rockery, as well as the general incline of the ground and the high cliffs behind, shelter the plants from the north.

Taking into consideration the natural conditions affecting the site of this most interesting garden, and also the additional shelter provided by hedges and rockeries, &c., it would be difficult to imagine a garden which, being out-of-doors, could offer better facilities for the acclimatising of tender species of plants than exist at Belvedere. The results obtained, nevertheless, are more startling than might be expected, and success has followed some of the most daring experiments.

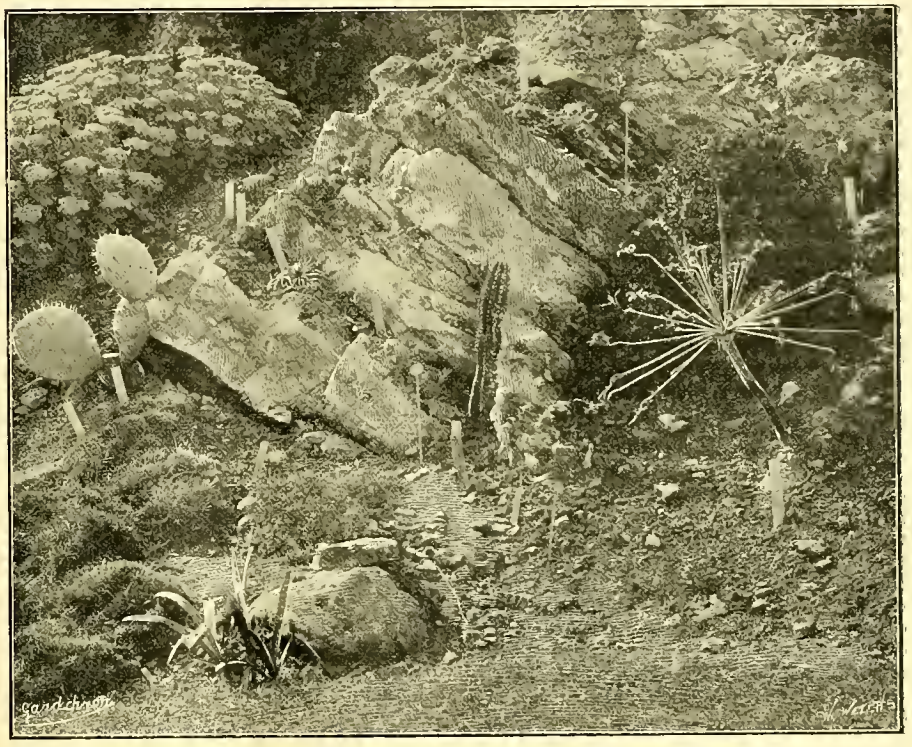

Fig. 73.—View of a portion of the rockery in the garden at Belvedere, St. Lawrence, I.W.

(From a photograph by J. M. Allen, Ventnor.)

We have only seen the garden as it appeared at the end of January, when many of the choice bulbs would naturally be little in evidence, but if we enumerate the names of some of the plants that we noted, it will afford some idea of the collection of tender plants which grow there in the open air, most of them very successfully:—Romneya Coulteri, Nerium Oleander luteum, double-flowered variety; Fabiana imbricata (3 to 4 feet high, just coming into flower), Iris stylosa in bloom, Gardenia globosa (planted in September and partially protected during winter by an upturned bottomless basket), Eupatorium petiolare, planted three years since, and showing flowers; Tulbaghia violacea, Digitalis obscurus, Campanula Vidali, protected with basket; Lonicera fragrantissima, in flower; Veronica Hendersoni variegata, 2 feet high, and in flower; Calceolaria rugosa (integrifolia), a shrubby species from Chili, which, as we were informed by Mr.

Murrell, the gardener, produces its yellow flowers until the month of November; Eleagnus macrophyllus, a bush 5 feet high and more than this in diameter; Hedysarum multijugum, 4 feet high and 6 feet in diameter; Hakea suaveolens, 4 feet high, and Cestrum (Habrothamnus) elegans (this showy greenhouse plant is growing on the west side of a hedge running north and south; it gets cut back a little by the cold, but recovers and flowers freely); Bowkeria triphylla, 9 feet high, flowers of which from this plant were figured in our Supplementary Illustration, Dec. 10, 1904; Plumbago capensis, also on the west side of the hedge, Polygala chamæbuxus var. purpurea, P. oppositifolia (always in bloom), P. Dalmaisiana, Datura (Brugmansia) sanguinea, a large shrub, which flowers each year; Abutilon vitifolium, two years planted, and protected in winter by an upturned basket; Asparagus (Myrsiphyllum) medeoloides, A. Sprengeri, A. graveolens "grata," Desfontainea spinosa, a plant that at present does not make satisfactory growth; Agave americana in large plants; Eucomis punctata, which flowers well each season; Odontospermum (Asteriscus) maritimum, bearing some of its yellow flowers in January; Eugenia Ugni, Leucodendron argenteum (protected by basket), Strophanthus capensis (protected by basket), Exogonium purga, its great bulb, which flowered last year, still visible through the soil; Indigofera Gerardiana floribunda, 5 feet high; Coronilla glauca, 3 feet high, presenting a mass of flowers in January; Anemone fulgens in bloom in the same month; Sophora (Edwardsia) microphylla, 3 feet high; Citrus trifoliata (triptera), Nertera depressa on the rockery, Acacia Drummondi coming into flower, protected by upturned baskets; A. armata, A. verticillata, 10 feet in diameter and nearly as much in height, forming an umbrella-like top; Coronilla viminalis, protected; Lasiandra macrantha, protected; Leonotus leonurus, Sutherlandia frutescens, Cassia corymbosa, Diplacus glutinosus, which flowers, but at the time we saw the plant quite devoid of the stickiness so characteristic when grown indoors; Agathea cœlestis, in flower; Bouvardia triphylla, B. "Alfred Neuner," out all winter; Diosma gracilis, its tiny white flowers open in January; Illicium religiosum, Leptospermum bullatum, Clianthus magnificus, 4 feet high and 10 feet in diameter, its numerous inflorescences partly developed in January; Geum Heldreichii in flower; Melaleuca styphelioides, Gazanias in flower, having been planted six years; Sparmannia africana, 4½ feet high (protected by basket); Cypripedium insigne, on banks near stream; Agapanthus umbellatus, Cantua dependens (see illustration in our last issue), a large shrub which flowers close to the residence. Under partial shelter from the residence are also Lapageria rosea, Mandevilla suaveolens, Bignonia grandiflora, and Swainsona galegifolia alba. Aloysia citriodora grows finely in beds.

On the margins of most of the borders thick lines of Freesias were about 3 inches high, and in their thousands must make a very pretty and fragrant feature when in flower. Sparaxis and similar Cape bulbs are cultivated in groups on or adjacent to the rockery. There are hardy Opuntias and other species of Cactaceous plants succeeding well, some of which may be seen in the illustration at fig. 73. The photographs are from Mr. J. M. Allen, Ventnor.

FRUIT REGISTER.

THE HERMANN'S APPLE.

A MEDIUM-SIZED, Pearmain-shaped fruit with a short stalk and depressed eye. The skin is of a rich red colour with occasional stripes of a deeper tint. A coloured illustration is given in the March number of the *Garden Flora*.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Calanthes of the deciduous section should be repotted when the new growths attain to the length of an inch or so, and before the new roots have become sufficiently long to be in danger of receiving injury during the process. Prepare a compost of good fibrous loam and peat in equal parts, sphagnum-moss one-fifth part of the whole, and a small portion of dried cow-dung, adding sufficient sand and small crocks to make the whole porous. Allow this compost to become warm before using it. Prepare clean pots, making them rather more than one-third full with drainage material. The pseudo-bulbs should have the old soil shaken from their roots, shortening these to about 2 inches. Place some rough material over the new drainage, and holding the bulbs in the hand, proceed to fill in with the compost to near the rim of the pot, pressing the soil moderately firmly, and just covering the bases of the coming growths. Place the plants in a low-roofed house where the atmosphere is maintained hot and moist, shading the plants from strong sunlight during the early period of their growth. Apply no water to the roots for two or three weeks, and take care not to wet the young foliage. Afterwards, when water is needed, apply it very sparingly and infrequently until the roots reach the sides of the pots, then, if favourable conditions prevail, dryness should no longer be permitted. C. Veitchii, C. Turneri, C. Regnieri, and hybrids therefrom may be propagated by taking off the apical portion of the constricted bulbs and inserting them in moist sand. Place these in a propagating-pit, and when young growths appear fix the bulbous portion in small pots and cultivate them in considerable heat. In the early stages of growth these Calanthes must not be subjected to any fumigant, or the foliage may suffer disfigurement.

Phaius grandifolius and others of a like nature will need attention a week or two after the spikes have been removed. Excepting in the case of small plants, which may be potted on without suffering much root disturbance, these are somewhat difficult to re-establish. Specimens will keep in good condition for several years if afforded an annual resurfacing with good fibrous loam, peat, and sphagnum-moss mixed together in about equal parts, sprinkling in a few crocks during the operation. Should, however, repotting be necessary, carefully remove the rooted portions from the old soil and crocks, and re-insert clean crocks amongst the roots in a new pot to about half its depth, filling to near the rim with the above mixture. Place the plants on a moisture-holding stage in a warm-house, and apply very little water for a considerable time after such disturbance. To keep the convolute growths free from injurious insects, spray them over every other week with some safe insecticide. The "Cooksonian" hybrids now flowering should be kept fairly dry until the new growths are somewhat advanced. P. simulans and P. tuberculosus, also flowering, will need a partial rest until they commence growing again. Spray the leaves frequently to keep them free from insect pests.

Daily Operations, consisting of damping, watering, ventilating, and shading, should be carried out with the utmost care. Atmospheric moisture should now be abundant in most houses, and to promote this a thorough damping of the floors and stages is necessary early in the day. Watering should follow when the temperatures are on the rise, and, in the case of pseudo-bulbous Orchids, should at this season be only done when growing plants are approaching dryness. Ventilation should be afforded gradually, never opening the ventilators and applying shading simultaneously; but first afford a little air, then, if needed, employ shade; but when the temperature again rises admit more air. The use of shading early in the day is much more necessary than it is later, even if the sun remains bright. Gradually increase the temperatures in the warm houses as the season advances, but be very chary of much fire-heat.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Shading.—Attention is now necessary to the shading of houses. Bright sunshine occurring suddenly and followed by cold and heavy storms renders ventilation a very difficult matter, therefore the necessity of shading in good time is obvious. Tiffany blinds on rollers are always to be preferred to permanent shading. If such blinds were removed from the houses in the autumn, as they should have been, they will now need to be overhauled, and after being made good where necessary should be fixed to the houses. When this has been done, a feeling of security may be entertained that the changeableness of the weather, so common at this time of the year, will not cause injury to the plants.

Recently-propagated Plants, including seedlings, will require careful watching, and when air is necessary it must be admitted very carefully, in order to prevent checks to the plants. A high temperature by solar heat, with shade and moisture, will be safer than a lower temperature and injudicious ventilation. The syringing overhead and damping between the pots on stages and floors of houses containing fine foliage plants, &c., should be done more frequently as the days grow longer and the sun becomes more powerful.

Codiæums (*Crotons*) propagated by "ringing," as advised in a previous Calendar, should have made roots in the moss by this time, and may be detached from the old plant by breaking them carefully with the thumb and finger, in preference to cutting with a knife. Let these rooted shoots be potted and placed in a propagating frame or under a bell glass for a few days.

Seedlings of Begonias, Gloxinias, &c., being now ready for handling, should be "pricked off." This work requires the expenditure of time and patience to accomplish it successfully. Use well-drained pans filled with finely sifted loam and leaf-soil in equal parts with a liberal dash of silver-sand, which should be placed in a warm-house for a few hours previous to being used.

Gloriosa superba.—This plant may be easily cultivated, but it requires much heat during the season of growth, and following this a long period of rest. Dormant bulbs should now be potted in a compost of loam and peat in equal parts, adding a little broken charcoal and silver-sand. Pot them up in the pots in which the plants will flower, and place them on stages near to the light. Several growths from each pot should be taken up the roof of the house until the flower-buds have formed. In this manner they may be allowed to remain and flower, and are very effective; or otherwise they can be trained on wire to any shape desired for specimens. Gloriosas may be easily increased by offsets obtainable from the old bulbs previous to being potted. After they have flowered and ripened their growth water should be entirely withheld, and the plants stood underneath a stage in a house where the temperature will not fall below 60°.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Earliest Permanent Vines.—The earliest Vines which were started in December will now be at the stoning stage, and will shortly require liberal supplies of stimulants. The amount of feeding, however, should be determined by the crop and vigour of the Vines, and should never be given to excess, or it will cause the Vines to make gross growths and the fruits to "shank." Stop all strong laterals, remove any seedless berries, and otherwise regulate the bunches before the berries change colour. The border may be lightly mulched with short stable-manure, and as the Grapes approach ripeness the temperature at night should be gradually reduced to 60°, slightly increasing the ventilation at night, and reducing the atmospheric moisture generally.

Succession Vines.—Syringing must be discontinued as soon as the bunches are visible, and the necessary atmospheric moisture supplied by damping the paths, walls, and other available spaces. Examine inside borders, and if they are dry, apply weak liquid manure in a tepid state to old

Vines, or clear water only to young, strong-growing Vines. Draw the points of the shoots by degrees from the roof-glass, but do not attempt to tie the shoots in position yet, because when later the Vines are in flower the shoots may be brought down with more safety. Stop all shoots at two or three leaves beyond the bunch, according to the space there is for the leaves, always avoiding overcrowding. Remove all surplus bunches before the Vines come into flower. Disbud later Vines as they require it, or as soon as it can be seen which buds promise to make the most compact bunches. Much depends upon whether the Vines are grown on the short-spur system or on that in which a moderate degree of extension is permitted. By allowing a young rod upon an old Vine to come up occasionally from as near to the base as possible increased root action will be encouraged, and the health of the Vines and quality of the fruit will be improved. Gradually increase the temperature at night to 65° by the time the Vines come into flower, allowing 5° higher for Muscats. A high temperature at night and a too close atmosphere should be guarded against in cold and sunless weather. Strong, healthy foliage is encouraged by moderately low night temperatures, and as free ventilation as the condition of the weather will allow. Thinning of the berries should be commenced on free-setting varieties as soon as the flowers have set perfectly, but Muscats and other shy-setting varieties need to be allowed more time. The latter should be carefully gone over each day with a rabbit's tail, using foreign pollen, in addition to tapping the rods. Do not delay reducing the bunches to the number that the strength and vigour of the Vines, the size of the bunches, and the length of rods render desirable. Unduly light cropping of healthy Vines should be as much guarded against as the over-cropping of weak ones. Thinning of the bunches should be carefully carried out, and the operator should have a good knowledge of the characteristics of the different varieties, which can only be acquired by experience. No two bunches require the same amount of thinning. Commence to thin at the bottom of the bunch, using a short forked stick to steady it, and remove the seedless and inside berries first, afterwards thinning and regulating the outside berries according to the variety, so as to form a solid and compact bunch. Afford the border a good watering as soon as the bunches are thinned if the soil is at all dry, and sprinkle the paths and borders occasionally with weak liquid manure and guano-water.

Fruit-room.—Grapes in bottles have kept in much better condition with us this season than last. I am sending you a small bunch of the variety Appley Towers, which was bottled on November 22, and is now in firmer condition than Lady Downes'. Mrs. Pearson, bottled the same date, has also kept in good condition. [See p. 185. Ed.]

THE KITCHEN GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Wantage.

Asparagus.—As the crowns are now starting into growth, it is the best time to make new beds. I have been most successful with seedlings of one year, and it is an advantage when the roots are grown near to where they are to be planted. The actual process of planting is the same, whether the plants are put in raised beds or placed on the ground level. In the latter case plant in two lines, allowing 18 inches between the lines and the same distance between the plants, with a space of 3 feet between each pair of lines. If raised beds are employed, plant in three lines instead of two, and let the intervening spaces be the same as those on the ground-level. Make the trenches 8 or 10 inches deep, and spread the tender roots out carefully, leaving the crowns about 3 inches below the surface. Cover the crowns with fine soil drawn over them with the hand, and make them moderately firm. If not already done, sow seeds of Connover's Colossal—a good variety.

Globe Artichokes.—When the protection has been wholly removed and the plants subjected to exposure for a time, if inadequate provision was made in the autumn for forming a new plantation by having subjects lifted in sufficient quantity, the separation of some of the strongest shoots from the plants should now be made, keeping as many roots attached to each shoot as possible. Plant the shoots in well-prepared soil, and to prolong the supply plant them in different positions with varying aspects.

Carrots.—To provide a succession to those sown early on hot-beds, seeds may be sown on a warm border when the soil is in good condition. Do not make the drills too deep, for this is a very common cause of failure, the seedlings being then unable to force themselves through the soil. Sow stump-rooted varieties, such as Early Nantes, Early Gem, and Scarlet Model.

Beetroot.—For the supply of early summer salads sow seeds on a warm border. Carter's Crimson Ball Beet comes into use early, and is of fine quality. Sow the seeds thinly in rows 1 foot apart, and thin the plants as soon as they are large enough to 6 inches apart, stirring the surface of the ground with the hoe in order to encourage early growth. The safest remedy against sparrows is that of netting.

Onions.—Gradually harden off Onions which were raised early for planting out.

THE FLOWER GARDEN.

By W. A. Miller, Gardener to Lord Henry C. Bentinck, M.P., Underley Hall, Westmoreland.

Ixias are now showing their new growth and will require protection from cold winds. Heather or Bracken Fern spread on branches will serve as a suitable wind screen. Beds of Alstromerias should be given a dressing of rich manure. Established beds of these produce an abundance of flowers in summer time.

Eremuri thrive in well-drained, deep, rich, sandy soil; they also require a sunny, sheltered situation, and when established are fairly hardy. They will soon be actively growing, when their foliage will require protection from spring frosts and from cold winds. A supported hand-light placed over them will afford them the necessary protection. See that slugs do not injure them. Eremurus himalaicus and E. robustus are two good species.

Commelina cœlestis is an old garden plant with flowers of a gentian-blue colour. The fleshy roots of these plants that were stored in leaf-soil last autumn should now be placed in moderate heat to hasten their growth. Seeds of this plant may now be sown.

The Rose Garden.—Prune the summer-flowering varieties and the hardiest of the H.P.'s. Cut out old hide-bound wood, small spray branches that cross each other and those that point inwards to the centre of the plant. Remove gross pithy shoots, selecting in preference those that are thoroughly ripened; leave six or seven buds on the shoots of vigorous growers, and prune to a point just above a bud that will grow outwards. Leave fewer buds on moderate and weakly growers. If pegging-down is desired, choose pliable varieties that have stiff flower-stems; Moss Roses are often trained in this manner. Fork in a good dressing of thoroughly decomposed manure, or, should the borders be already well supplied with humus, loosen the surface of the soil with a hoe, and apply artificial manures. Prune and train Roses growing against walls, laying-in the best shoots. Do not uncover tender Tea varieties just yet. Rose-cuttings that were inserted in pots last autumn will be ready for potting into 5-inch pots, using rich soil; keep them under glass until they have become established, and plant them out in June.

Box Edgings can now be replanted, but in doing this see that correct levels are obtained. Divide the old plants, making them of a uniform size, in order to get a regular thickness of hedge about 3 inches above ground. If the soil is very stiff place a little leaf-soil around the roots.

Other Plants as "Edgings."—Gentiana acaulis is an excellent plant for forming edgings, but must be given a sunny situation, or the plants will not flower freely. Arabis lucida variegata is a dwarf, golden-leaved plant of great value for forming lines and edgings. The plants may be divided and transplanted now. They grow best in rich loamy soil. Vinca major variegata makes a good edging if kept within bounds by repeated prunings. Cerastium tomentosum can be planted in lines like Box, or dibbled in beds. Ivy edgings and bands may be rearranged and planted. Other useful "edging" plants are Golden Thyme, Pinks, and Thrift (Armeria vulgaris).

Violas.—Have the beds intended for Violas well and deeply worked, mixing in a quantity of well-rotted hot-bed manure. If a layer of leaf-mould be strewn on the top of the bed prior to planting, it will help the Violas to withstand a period of drought. Planting may be commenced towards the end of the present month.

THE HARDY FRUIT GARDEN.

By W. H. Clarke, Gardener to Sir William Plowden, Astou Rowant House, Oxon.

The Fruit-room.—Examine the fruit-room periodically, and use first those fruits which show signs of deteriorating. Many Apples, when kept past their season, are wasted. Fruit-rooms constructed with thatched roofs and sides cannot be improved upon for keeping the fruit plump and in good condition for a long period. I have Apple Worcester Pearmain in good condition at the present time. The floor of our fruit-room is formed by the bare ground, and this is damped occasionally.

Figs.—Gradually remove the protection afforded during the winter to trees on walls. If the trees have commenced growth it will be necessary to inure the branches to sunlight and air gradually by the partial removal of the covering daily. When this has been done hang treble fish-netting in front of the trees until all danger from frost is past. If pruning was done directly the leaves fell, secure the branches to the wall, allowing plenty of space between them, so that the foliage will not densely shade the fruit and branches during the summer. It is not too late to remove useless and exhausted branches. If there are trees which are not restricted at the roots, and which made exuberant growth last season, dig an encircling trench a distance of 3 to 6 feet from the main stem, severing all roots during the operation, and filling up the space thus made with stones, broken bricks, or any non-rooting medium. Better results follow from trees planted in a restricted area. In such cases where the soil has become exhausted, a top-dressing of mortar rubble, loam, and bone-meal may now be given. Figs may still be planted against walls having a south or south-west aspect, and a restricted rooting area be formed by building a retaining wall varying in size in accordance with the amount of wall-space to cover. Allow ample drainage, and employ a compost of good loam, old mortar-rubble, and small nodules of chalk, the whole of which should be well mixed together when in a dry condition. In making the border the soil should be made very firm, in order to secure well-ripened, short-jointed growths. Where glass copings are employed to protect the trees they may now be put in place; these also greatly assist the ripening of the crops during the summer.

Peach and Nectarine-trees are now expanding their flower-buds, and means should be taken to protect them. If glass copings are used they should be erected at once. Along the front of the copings here runs an iron rod; the curtains have rings attached to them with tape, which hang from the rod, and the individual lengths of curtains are fastened together with tapes also, and secured to the ground by the same means. In the daytime the curtains are pulled along the iron rod, and made secure, thus exposing the trees to the influence of sun and air.

Grafting Materials may now be got ready. Clay which has been ground is preferable, being free from stones; this should be mixed with cow or horse-manure to make it more adhesive and less liable to be washed by rains. If grafting-wax is to be used the following formula is an excellent one for the purpose:—Boil 8 lb. of resin in an iron pot until melted, then add 3 lb. of Russian tallow and 3 lb. of yellow or red ochre; boil for one hour; then add 1 lb. of Burgundy pitch while cooling; grease a tub and empty the whole in the tub. In this state it will keep for years; portions can be broken off as required, and heated to a liquid state for use as will be advised next week.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAR. 28 — Royal Horticultural Society's Committees Meeting, Scientific Committee, at 4 P.M. Horticultural Club Meeting and Dinner.

WEDNESDAY, MAR. 29 — Liverpool Horticultural Society's Spring Flower Show (2 days).

THURSDAY, MAR. 30 — Royal Horticultural Society's Exhibition of Colonial Fruits and Vegetables (2 days). Torquay Flower Show.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Hardy Border and Herbaceous Plants, Roses, Liliums, Begonias, &c., by Protheroe & Morris, at 67 and 68, Cheapside, E.C., at 12.

TUESDAY, WEDNESDAY, THURSDAY, and FRIDAY NEXT—
Absolute Clearance Sale of the whole of the Nursery Stock, under Deed of Assignment, at Edelweiss Nursery, Acock Green, near Birmingham, by Protheroe & Morris, at 12.

WEDNESDAY, NEXT—
Azaleas, Rhododendrons, Palms, Roses, Perennials, Liliums, &c., at 12 o'clock; 330 cases of Japanese Liliums, &c., at 3 o'clock, by Protheroe & Morris, at 67 and 68, Cheapside, E.C.—Orchids, Lilies from Japan, 5,000 Roses, &c., at Stevens' Rooms, at 12.

FRIDAY NEXT—
Vanda Sanderi, V. cœrulea, and 3,000 Odontoglossum crispum, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —44·6°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March 22* (6 P.M.): Max. 62°; Min. 40°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March 23* (10 A.M.): Bar., 29·8; Temp., 54°.
Weather—Fair, with occasional sunshine.
PROVINCES.—*Wednesday, March 22* (6 P.M.): Max. 56°, Guildford; Min. 43, North of Scotland.

Degeneration of Florists' Flowers.

IN anticipation of the discussion to be held by the Scientific Committee on Tuesday next, at 4 P.M., on the alleged degeneration of varieties, especially those reproduced by tubers, cuttings, or layers, the following observations of Mr. DOUGLAS on the Carnation will be read with interest:—

"A Potato-plant, an Apple-tree, or any other member of the vegetable kingdom is liable to degeneration after a certain number of years, in consequence of the conditions of cultivation being more or less of an artificial character. The Carnation, for instance, is usually cultivated in rich, deep garden loam, or, if it is grown in pots, the plants root into even richer material, such as rich loam, manure and leaf-mould, added to which some cultivators add powdered or dissolved bones, blood manure, and other preparations of which they know nothing except that the bag is labelled in large letters 'Carnation Manure.' For something like three or four hundred seasons at least a succession of Carnations has been treated to the artificial conditions of English flower gardens; and these conditions were even more artificial in the past than they are now. The most popular book on the Carnation in the early years of the last century was written by Mr. Thomas Hogg, of Paddington Green, Middlesex, and his potting compost is described as follows: 5 barrowloads of loam to 8 or 9 barrowloads of stable-manure, and one of coarse sand. For surface-dressings subsequently the chief ingredients were sugar-bakers' scum, soap-boilers' waste, night-soil, dung of pigeons, deer and sheep, blood, &c. I am quoting from the sixth edition.

A list is given of 390 varieties of bizarre and flake Carnations, with 113 varieties of white-ground Picotees. Not one of these is now in existence; indeed, it would be a wonder if they lived more than a very few years. The original plant is found in a wild state, living and thriving on old Norman castles, such as Rochester Castle in England, and others in Normandy, living and thriving on decaying stone and mortar, where it cannot obtain any of the luxuries so freely bestowed upon it by the old florists.

The stock of cultivated Carnations has been maintained by a succession of seedlings. The flakes and bizarres were the only types of the Carnation desiderated by the old florists, and the acme of perfection was evidently reached more than a century ago. Hogg figures a very finely-formed and well-marked bizarre Carnation, but it is no better than one figured in the *Botanical Magazine*, t. 39, fifty years earlier under the name of Franklin's Tartar.

The early *Botanical Magazine* plates were usually certainly not exaggerated, and this variety, raised by an ingenious cultivator who had his garden in Lambeth Marsh, is perfect in its kind, and quite equal to the best now in cultivation. The white-ground Picotee type of Carnation came in later, but even thirty years ago the varieties grown in gardens at that time were quite equal to the best of those now in cultivation. A Mr. Norman, of Woolwich, some thirty to forty years ago, produced new varieties of white-ground Picotees of superb quality. Where are the fine varieties of these, the true florist's type of Carnation? Those of the late eighteenth-century period are gone long ago. Not one of the 500 varieties mentioned by Thomas Hogg is now in existence. The late Mr. E. S. Dodwell introduced many very fine varieties in quite recent years; he enumerates 119 varieties of bizarres and flakes, and eighty-six white-ground Picotees, most of them of his own raising; the list is contained in the third edition of his book, *The Carnation*, published so recently as 1892, but many of them have already passed out of cultivation. I often held a conversation with Mr. Dodwell on this subject, and he told me that his experience led him to the conclusion that the average life of a variety Carnation was fifteen years.

My own experience with the Carnation under many phases of culture in England and Scotland extends over a period of about fifty years.

There are doubtless several causes which tend to reduce the vitality of the Carnation. Over-propagation may be instanced as a probable cause. Any plant that is forced beyond its natural capacity must suffer to a certain extent. The most natural way to increase the stock of any variety of border Carnation is by layering; but some growers, not content with this, continue to take cuttings, and force them on in bottom-heat in a close atmosphere and in a high temperature.

Over-feeding is certainly a fertile source of disease, and as soon as disease takes hold of any plant it must be weakened thereby. Over-feeding also induces for the time a strong, sappy, but unwholesome growth, which can only be maintained for a very few years.

Over-flowering will also weaken Carnations to a greater extent than many cultivators are aware. One large double Carnation flower will reduce the vitality of the plant to a greater extent than a dozen or a score of single flowers. The single bloom is of a very fugacious character; it rapidly develops and in two or three days the petals drop off, whereas the large double flowers develop slowly and last in full beauty for ten days or more, to the rapid exhaustion of the plant. Anyone can test this. Let an equal number of plants of the same size be grown together, allow one set to carry all the flowers; in a second set let them be reduced in number, whilst a third lot should not be allowed to produce flowers at all. The extra vigour of the last-named batch will cause surprise. The vigour even of the flake and bizarre varieties may be maintained for a much longer period if a number of plants for stock purposes is grown without being allowed to flower for one year, and layers are taken from them. The colouration of the foliage has a good deal to do with the continued vigour of the plant. The darker the green the greater is the vitality.

Keeping still to the bizarre and flaked type, a notable instance may be recorded in the scarlet bizarre 'Admiral Curzon,' which is still grown in every good collection, and has been in cultivation for the long period of sixty years. This Carnation has been grown under a greater variety of conditions than any other, as almost every amateur grows it, and it has been freely exhibited north and south every year since its introduction. No exhibitor would care to be without so valuable a variety. May not its continued vigour therefore be accounted for by the growers giving a few of their plants a rest in alternate years? The same remark may apply to another favourite in the pink and purple bizarre class, 'Sarah Payne,' produced from seed in 1844, the same year as 'Admiral Curzon' was raised. It has always been valued as the leading flower in its class, and has kept its vigour. 'Sportsman,' a very fine scarlet flake, is also of the same age as 'Admiral Curzon,' from which it sported in Mr. Hedd rley's garden in 1855. It still often comes out at the head of its class. These three are the only varieties known to me that have maintained their vigour for such a long period, a circumstance which I attribute to the practice of resting the plants from the efforts of producing flowers for one season. I am inclined to the belief that over-flowering is one principal cause of degeneration, and this can easily be tested by anyone who will take the necessary trouble.

The yellow-ground Picotee is a form of the Carnation much valued by amateurs, but great care is necessary in selecting varieties with good constitutions. The yellow colour of the flowers is plainly foreshadowed in the foliage of many varieties, others are of a deeper green, and the yellow colour is not so apparent. The pale-foliaged varieties are seldom worth placing in commerce, and ought to be rejected, for however high may be the quality of the flowers, if there is not a good constitution to start with, no satisfactory results can follow; and greater mischief is likely to accrue subsequently if weakly constitutioned varieties are used to breed from. This is certainly a cause of degeneration.

As far as the Carnation is concerned the remedy for degeneration is the selection of vigorous, healthy varieties both as

seed and pollen bearers. There should be no great hurry to get up a stock of plants; but they should be propagated in a [more or less] natural manner. Over-stimulating manures should be avoided; the plants should be grown in good garden soil, using no stimulants but decayed farmyard manure, which should not be allowed to come into immediate contact with the roots. Some of the plants should have a year's rest from flowering, and layers should be taken from the rested plants. Wild plants do not degenerate, and if more natural conditions were allowed to prevail, cultivated Carnations would be free from it.

The old crimson Clove has existed in gardens for a longer period than the florists' types I have mentioned. The old Malmaison is still as vigorous as ever it was, for although disease and death may overtake it in some collections, it still holds bravely on in others; in this instance it is not necessarily the survival of the fittest, but the survival of those which have been most carefully protected, and, let me add, most naturally cultivated."

Royal Horticultural Society's Examinations, 1905: School Teachers' Examination in Cottage and Allotment Gardening, April 5; General Examination in Horticuture, April 12.—Intending candidates for the above examinations are requested to send in their entries as soon as possible. The Royal Horticultural Society is willing to hold an examination in as many different centres in Great Britain and Ireland as circumstances may demand. A capitation fee of 5*s.* will be charged for every student in order partially to defray the expenses of the examination. A Silver-gilt Flora Medal will be awarded to the candidate gaining the highest number of marks, and each successful candidate will receive a Certificate. A copy of the syllabus covering both examinations, with entry forms attached, will be sent to any person on receipt of a stamped and directed envelope. Copies of the questions set at the Royal Horticultural Society's examinations 1893—1904 may also be obtained at the Society's Offices, Vincent Square, London, S.W., price 1*s.* 6*d.* W. Wilks, Sec., R.H.S.

—— The next meeting will be held on Tuesday the 28th inst., when a lecture will be delivered by Mr. Frank Pink on "Bananas." At 4 P.M. the members of the Scientific Committee will discuss the question of the alleged degeneracy of varieties re-produced vegetatively, *e.g.*, the Potato. The Society will hold a show of Colonial Fruit and Vegetables, both fresh and preserved, on March 30 and 31.

Well-preserved Grapes. — We have received an excellent bunch of the Black Grape Appley Towers from our Calendar writer, Mr. F. Jordan, Impney Hall Gardens, Droitwich. The bunch was cut from the Vine on November 22 last, and the fruits have therefore been preserved for a period of about four months by the detached portion of the Vine being immersed in water in a stoppered bottle. The present condition of the fruit is very good, there being no sign of the skins withering, whilst the flavour and sweetness of the flesh are perfectly preserved.

"The Horticultural Directory."— We find that nearly the first quarter of the present year has elapsed without our having called attention to this publication. It is, in fact, so indispensable that it seems superfluous to mention it, but it may be well to remind some folk that it may be had from 12, Mitre Court Chambers, Fleet Street, or from our Publisher.

The Cucumber "Spot."—A well-known grower claims to have discovered a certain means of eradicating the trouble, even after it has got established in a house, and he is offering to sell his secret for the sum of £1,000. A large number of growers, we are told, met at the Tavistock Hotel on Tuesday, March 21, to consider the matter. It was suggested that the cultivators should combine and pay the money over to a trustee, to remain in his hands until a Committee has made experiments and fully proved the efficacy of the remedy. It was suggested that the minimum payment should be £2 2*s.*, this to be made by those with 500 feet run of houses and under, and those with more glass at a proportionate rate up to £25, which would be the maximum; or if it was found that sufficient money could be raised at a lower rate, the amount would be reduced. There were about fifty "market men" present. The meeting was conducted by Mr. G. Tucker, of *The Fruit Grower*. The Committee selected were Messrs. Harrison (of Cragg, Harrison & Cragg), Edney and Larsen. At the close of the meeting it transpired that it was Mr. Ladds, of Swanley, who possesses the secret. A circular has also been issued by Mr. J. Head, of Worthing, who likewise claims to have discovered an infallible remedy for the same trouble. This is a work that would be much better carried out by that properly equipped and officered experimental station at Wisley we are all hoping for.

The Henry Eckford Testimonial. — A Shilling Fund. — A Committee meeting to launch this project was held at the Hotel Windsor, on Monday the 20th inst., Mr. Percy Waterer presiding. It was resolved that the Fund should be a shilling one, so as to embrace not only the large growers, but also those whose appreciation of the work of Henry Eckford is none the less sincere because it is expressed in a modest way. Mr. Percy Waterer was unanimously elected Chairman; Mr. Walter P. Wright, Treasurer; and Mr. Horace J. Wright, 32, Dault Road, Wandsworth, London, to whom all correspondence should be addressed, Secretary. It is the particular desire of the Committee that the testimonial shall have universal expression, and to this end it is anticipated that the Shilling Fund will substantially contribute. In the meantime the Secretary will be pleased to hear from those who sympathise with the movement of conveying to Mr. Henry Eckford the thanks of the horticultural world for his work in the evolution of the Sweet Pea.

Scab in Potatos.—In an article on this subject in the *Journal of the Board of Agriculture* for March it is pointed out that the disease (Oospora scabies) is quite superficial, and does not affect the quality of the Potato. Nevertheless, as appearance and consequently the market value of the tubers are much deteriorated, it is recommended that seed Potatos affected with scab be immersed before planting in a solution consisting of 1 pint of formalin to 36 gallons of water. There will then be no fear of the disease spreading. Potatos should not be grown on the same land that has produced scabbed Potatos.

The Beech Coccus.—Mr. Newstead, in the *Journal of the Board of Agriculture* for March, has a paper in which he describes and illustrates the white scale which is so destructive to Beech-trees. The remedies he recommends are paraffin emulsion prepared by mixing a solution of soft soap in boiling water with an equal quantity of paraffin, thoroughly mixing and churning the mixture, and adding, when required for use, twenty times the bulk of water, churning and mixing as before. This mixture is to be applied with a scrubbing-brush diligently used on the smooth bark, and as far as possible in all the cracks. A handful of sulphur and a pint of turpentine may be added with advantage. Caustic alkali wash may also be used, made as follows:—Dissolve 1 lb. of commercial caustic soda in water, then add 1 lb. crude potash or pearl-ash, also dissolved in water; then add ¾ lb. soft-soap, with sufficient water to make up to 10 gallons. This wash may be employed as a spray in winter or in spring. Two or three sprayings at intervals of two or three days will be necessary. As the mixture is of a very caustic nature, closely-fitting rubber gloves should be worn by the operator.

Azalea indica "Hexe." —The *Revue de l'Horticulture Belge* for March gives a coloured illustration and a description of this form of A. amœna. According to M. Van den Heede, this is the result of a cross between A. amœna var. Forsteriana and the variety A. indica known as Duc Adolphe de Nassau. It appears that the hybrid is much used in Germany and in Belgium as a stock, but it has claims also upon the attention of horticulturists by reason of its rosy-carmine flowers larger than those of the ordinary amœna. Not only is the corolla coloured, but the calyx also, so that the appearance is that of two flowers one within the other. A. "Hexe" crossed with "Deutsche Perle" and with "Charles Enke" has given origin to a whole series of hose-in-hose Azaleas, the flowers of which last longer than in the case of the ordinary forms.

The Bulb-mite is the subject of an illustrated article in the March number of the *Journal of the Board of Agriculture*. The bulb-mite, Rhizoglyphus echinopus, has been studied by Mr. Michael, of whose researches we in these columns have repeatedly availed ourselves. The mites attack sound bulbs as well as those which are diseased. The measures recommended are—1, to burn affected bulbs; or, 2, wash and spray every affected bulb with paraffin, repeating the operation after a fortnight; 3, wash the bulbs in sulphide of potassium (liver-of-sulphur), 1 oz. to 3 gallons of water; 4, fumigation with bisulphide of carbon, in order to do which place the bulbs in an air-tight receptacle, and on the top of the bulbs put a saucer of the bisulphide and let the bulbs remain in the vapour for forty-eight hours. It must be remembered that the vapour is poisonous and inflammable, so that no light of any description should be brought near the fluid.

The Swanley Horticultural College.— A satisfactory report of this College, which is now wholly devoted to the instruction of women, has reached us. Up to the end of 1904 the students were markedly successful in obtaining scholarships and other awards and in obtaining posts as gardeners. The colonial training branch has an equally good record, as in eighteen months' initial work twenty-five students have been trained. The subjects undertaken are garden work botany, horticultural science and rural economy entomology, book-keeping, manual training, bee and poultry-keeping, dairy work, fruit preserving and flower arrangements. The College has good and influential supporters, and we notice among the list of lecturers the names of Messrs. R. J. Tabor (botany, vegetable pathology), F. J. Baker (horticultural science and rural economy), and Miss Turnor (gardening).

The Rainfall and the Wheat Crop.—A very instructive note, accompanied by a diagram, is given in last week's issue of *Nature*. The note was read by Dr. W. N. Shaw before the Royal Society on February 2, and gives a concise indication of the average amount of rainfall for the three autumn months, September, October, and November respectively, in each year from 1884 to 1904 inclusive. On the same diagram is noted the amount of Wheat in bushels per acre during the same years. When the curve representing the total rainfall of the autumn is compared with that denoting the yield of the

Wheat-crop in the succeeding year, the correspondence of the two curves is shown to be extraordinarily close. "The yield of Wheat in any one year seems to depend mainly on the absence of rainfall in the previous autumn, and but little on any other factor." The Wheat is, of course, an annual with a very great root development. It would be very interesting to procure information of a similar character not only with reference to annuals, but to perennials and to fruit-trees. Gardeners attach great importance to the "ripening of the wood" as a factor in the production of a fruit crop, and that is affected probably as much or more by the temperature as by the amount of moisture. Accidents such as the time and duration of spring frosts have also to be considered.

Fig. 74.—Brunsvigia josephinæ: flowers rosy-pink.
See article on "Belvedere," p. 181.

"Flora and Sylva."—The March number has a sensible article on Apple-culture, and one on the Yew, in which is a beautifully executed wood-cut purporting to represent the "Buckland Yew, recently destroyed." This can scarcely be the famous tree at Buckland, near Dover, as that is much less decrepit and more "furnished" than the tree figured, and although moved from its original position some years ago, under the superintendence of the late Mr. W. Barron, it is (or was till last year) in a flourishing condition. There is a valuable descriptive list of hardy Water-Lilies, which are now very numerous; and a similar enumeration of the species of Meconopsis, in which attention is called to the fact that the wonderful M. integrifolia has so far failed to set seed in this country, though artificially pollinated. We believe, however, there is a large supply of Chinese seed in the hands of Messrs. James Veitch & Sons.

The Liège Exhibition. — The Exposition Universelle in Liège is likely to prove very successful. International horticulture will be represented by permanent exhibits as well as by temporary shows, and under very favourable conditions, and these will be held on the Cointe plateau, which is picturesquesly situated and commands a fine view. The flora of the world will be represented; aquatic plants will be found in a lake, and alpine vegetation arranged on a rocky situation; a sunken track will be planted with many hardy Ferns. The various sections of the horticultural exhibition will be united into a pleasing whole by the skill of the landscape gardener, M. L. Vanderswaelmen. A large glazed hall, the "Palais des Palmiers," will contain the large exotic plants. A special building is reserved for the Orchids. One section will be devoted to the installation of all kinds of glass-houses, horticultural accessories, and warming apparatus. A special place on the Cointe plateau is reserved for Japanese plants, and thousands of flowering bulbs will enliven the scene in their season. A "Mountain of Flowers" is to prove an attraction. Another portion of the ground is to be set aside as nurseries for fruit-trees and as a trial-ground for market crops.

—— A Conference will deal with questions relating to different branches of horticulture, and any matter connected with these, even if not specified on the programme, may be put upon the minutes conformably with the arrangements of the organising Committee. Each country represented will form a Committee of Patronage, and already M. Philippe de Vilmorin (for France) and Dr. L. Wittmack (for Germany) have accepted the positions of Presidents. The following is a list of the questions to be discussed at the Congress:—

First Section: *Floriculture.*—1. Flower and shrub-planting of walks, boulevards, squares, gardens, and public parks. Choice of species and varieties. Distribution and succession. Landscape gardening. 2. Which plants (*a*) are most valuable for forcing; (*b*) best bear transport; (*c*) are most in demand for exportation. Each point to be treated separately as regards trade in plants and trade in cut flowers. 3. Improvements in forcing plants (heat, refrigerating systems, etherisation, &c.).

Second Section: *Market Gardening.*—4. The best methods of market gardening (*a*) in the open ground; (*b*) under glass. The subjects to be treated separately. 5. Tools. 6 Manures. 7. Preserving vegetables.

Third Section: *Fruit Culture.* — 8. Species and varieties of fruits best suited for exportation into different countries. 9. Industrial value of fruits. 10. The protection of insectivorous birds, abolition of snares, traps, and nets, &c., international co-operation pursuit of cock-chafers and butterflies.

Fourth Section: *Instruction.*—11. Programmes and methods of horticultural instruction in its various forms. In conferences and public classes, primary and secondary schools, sectional and professional schools. 12. Means for encouraging a taste for horticulture in all classes of society. Exhibitions for amateurs, conferences for ladies, room decorations, the workman's plot, students' conferences, &c. 13. Diffusion of instruction and horticultural publications, treatises, libraries, leaflets, magazines, &c.

Fifth Section: *Trade.* — Markets in different countries, stalls, auctions, &c.; their regulation. Vegetables, fruit and flowers in request, arrangement, selling prices. 15. Exportation of horticultural products; species and varieties in demand in different countries; packing, forwarding, easy and rapid transit, tariffs and freights, commercial customs, intermediate agents, selling prices.

Sixth Section: *Societies.* — 16. Horticultural societies from a professional and commercial standpoint. Unions, syndicates, co-operative societies for purchase, protection, and sale of produce, credit, &c., insurance schemes, &c.

The Bed of Osiris.—An account in the *Times* of the recent discoveries made at Thebes by Mr. Theodore Davis includes an inventory of the many and wonderful treasures enclosed in a royal tomb of the 18th dynasty. Apart from a chariot, costly furniture, and fittings of gold, was the following curious and symbolic relic:—"A mat of Palm-fibre on which the figure of Osiris was delineated in soft mould. Seeds were then sown in the mould, and in the green grass which sprang from them after the tomb had been closed and sealed the Egyptians saw an imago and earnest of the resurrection. A similar bed of Osiris was found in the tomb of Amon-hotep III."

Over-sea Supplies: February. — The cheapening of Cotton has reduced the value of imports, but the rise in the value of exports is remarkable—over a million and a quarter sterling in excess of the value in February of last year. According to the Trade Returns for February the value of the imports was £42,844,937, against £44,110,519 for the same period last year—a decline of £1,265,582. Concerning the value of vegetable products in the national account, we give the following classified summary of values:—

Imports.

Class: Description of Produce.	1904.	1905.	Difference.
	£	£	£
Class I. — Cereals, and other field crops — Wheat, Barley, Oats, &c.	5,296,165	4,675 226	—620,939
Class II.—All other food cultures — Tea, Coffee, Fruit, &c.	3,475,816	3,467.620	—8,196
Class III.—Used in manufactures — clothing, household goods, &c....	7,619,814	5,546,210	—2,073,604
Class IV. — Miscellaneous — including seeds, flowers, &c.	3,005,348	2,736,293	—269,055
Values of Produce...	19,397,143	16,425,349	—2,971,791

The value of the wood and timber imports for last month was £665,171, which, compared with the value for February in last year (£927,192), shows a reduction of £272,021. Under a somewhat long-continued phase of depression the suggestions of some interested in providing more employment for our workers in the planting up of all waste or poor lands with suitable timber may receive attention from large owners and Government officials. By the way the prospect of an enlarged supply from Scandinavia is not encouraged by reports to hand from Stockholm. Throughout Norway there has been a great shortage of snow during the past winter, interfering in a marked manner with the haulage of logs from forest to mills, and the rainfall of last year was so curtailed as to interfere with the amount of water-power.

From trees to flowers is but a step, and in this connection it is interesting to note a reduction of £17,143 on last month's value, as compared with the same period last year—i.e., £31,027 against £48,170. It is pleasant to note that amid the horrors now being enacted in Russia, the experiment of Tea-growing in the Caucasus continues to give satisfaction and encouragement. The record of fruit and vegetable imports during the past month is as follows:—

Imports—January.	1904.	1905.	Difference.
	£	£	£
Fruits, raw—			
Apples	267,916	127,673	—80,243
Apricots and Peaches	3,036	644	—2,392
Bananas	61,316	76,422	+15,106
Grapes	1,984	3,324	+1,340
Lemons...	35,105	18,996	—16,409
Nuts—Almonds ...	26,298	33,760	+7,462
Others used as fruit	20,303	33,237	+12,934
Oranges...	263 739	240 593	—23,146
Pears	1,919	1,033	—886
Plums	1,264	527	—737
Unenumerated ...	12,544	10,615	—1,929
Vegetables, raw—			
Onions ... ...bush.	93,782	93,457	—325
Potatos ... ... cwt.	200,195	26,344	—173,851
Tomatos ... ,,	33,269	54,973	+21,704
Unenumerated ,,	39,553	35,008	—4,545
Totals ...	1,002,513	756,608	—245,937

In the figures concerning the output of dried fruits in California last year as compared with the preceding year, we learn that the Raisin product was 75,000,000 lb. against 120,000,000 lb. in 1903, the Prune output is put at 97,000,000 lb. against 165,000,000 lb. in the preceding year. As regards canned fruit, the "pack" for the year is placed at 2,800,000 cases, the figures for 1903 are given as 2,730,000 cases. The dried fruit imports for last month are—Currants, £27,333, against £19,304 for February, 1904 — an increase of £8,029; whilst Raisins footed up £16,807, against £8,141 for the preceding period — a gain of £8,666. Since our last notes on the subject of fruit imports from the Cape, the Union Castle Steamship Company have landed here some 6,913 cases of fruit as follows:—Peaches, 2,135; Plums, 2,023; Pears, 1,994; Nectarines, 300; Grapes, 37; Tomatos, 4; Apples, 20. The

Exports

for the month—to complete the trade details—furnish very satisfactory figures. The value is placed at £25,269,063, which, compared with the total for February, 1904 (some £23,894,813), show an increase of £1,374,250. How the total is reached need not here be stated, but it may interest some to know that foreign and colonial goods of all descriptions figure for £7,619,723—an increase of £214,382 over February, 1904.

THE APIARY.

THE NATURAL HISTORY OF THE BEE.

In order to handle bees intelligently, it is very necessary to know something about the natural history of the bee.

The Queen.

Every prosperous colony will soon contain one queen, a number of drones or males, and a very large number of workers or neuters. Of these, the queen or mother-bee is by far the most

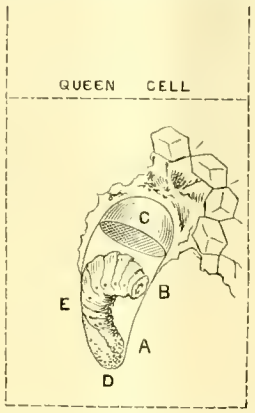

Fig. 75.—A, D, the queen-larva spinning its cocoon; A the head with the "spinnerettes" fastening the silk to the sides of the cell, and forming the respirator at the end shown at D; D, the end of the larva resting against the side of the cell, and by pressing its back against E the larva is enabled to move its head and neck on all sides of the cell, and gradually working upwards it is enabled to finish and rest upon its back with its head downwards: whilst the white "queen jelly" C fills one-fourth of the interior space, and keeps up a moisture for the growth of the larva and expansion of the abdomen, which nearly touches the jelly.

important, for on her fertility the whole success of the stock depends. She lays all the eggs that produce future queens, drones, and workers. If by careful selection the bee-keeper can produce queens that are more fertile and produce workers with more lengthy proboscides or tongues, this will be a decided advantage to the community. We sometimes hear that a queen is known to be present in a certain hive, but there is little or no brood. If the apiarian will search her out, he will perhaps find that the queen is ill-developed, or in some cases she is wingless. In such a case it will be well to destroy her, and introduce another in a manner to be described later.

The queen is produced from the same kind of an egg as a worker, but the difference between them is due to difference in the food. The grub hatching from the egg is fed on a larger supply of better food, termed "royal jelly," which is a milky food, formed of partially digested honey and pollen. The cell, too, differs from the others. Queen cells are acorn-shaped, hanging downward in the lower corners of the frames. In sixteen days a queen emerges, and in five more days she will probably leave the hive on her marriage trip to meet the drones. The queen is only once fertilised in her life. In about another week or ten days her life's work of egg-laying is commenced. She is in her prime during the second and third summers, and during the height of the honey-flow lays 2,000 to 3,000 eggs per day; after this her egg laying properties become reduced and she is of little value, though she might, if left alone, live for five years.

To produce the best results, the bee-keeper will be wise if he produce queens, and, when their fertility has been tested, use them to replace queens which have reached their third season. During manipulation it sometimes happens that a queen is accidentally killed; if there are eggs in the worker cells, the bees will at once commence the construction of queen cells, and remove eggs from worker cells to them, and thus rear queens.

The Drones.—These are the males; they are larger, possess no stings, and lead a happy, careless life. They are produced from eggs which have not been fertilised. It is well known that eggs from hens which are not kept in the company of a cock will produce no chicks; but if a queen be prevented from meeting the drones, her eggs produce drones only. Drones are only found in the hives from about April to the end of August, when they are driven out by the workers to die of starvation. If the supply of outside food fall off in the spring it is no uncommon sight to see the larvæ of the drones lying on the alighting board, and this is a sure sign that the food supply is very low.

Workers. — These are really imperfectly developed females. Their work is that of feeding all larvæ, gathering and defending the stores, building the comb, and following a life of unceasing labour. After leaving the cell, which is on the twenty-first day after the egg is laid, they act as nurse-bees for fourteen days. Then they leave the hive to work in the field, gathering pollen (which is carried on the two hind legs in the pollen basket) and nectar. In the busiest part of the season their life lasts from six to eight weeks, so heavy is the work that their wings are worn out and they fall to the ground to perish. Those hatched in September and October live into the next spring, as their work is not of such an exacting nature. "*Chloris.*"

LAW NOTE.

LEEMAN *v.* LINDEN & Co. (see p. 92).

The Brussels Tribunal of Commerce has been considering a case in which the plaintiff alleges that some Orchids purchased by him from the defendants for a large price on the strength of some coloured representations shown to him by them, were inferior to what he had been led to expect from an inspection of the drawings, and it was therefore contended on the plaintiff's behalf that the sale should be annulled. Questions of much interest to Orchid growers are involved, and three experts, M. Jules Hye, of Ghent; M. de Bièvre, Head of the Royal Gardens at Laeken; and M. Stepman, nurseryman, of Brussels, have been appointed to answer certain enquiries, such as whether under other methods of cultivation these particular plants would have produced finer flowers than those obtained by the plaintiff, and whether such flowers would ever be similar (*semblables*) to those shown in the drawings which formed the basis of the sale. May 12 has, we learn, been fixed as the day for the reception of the decision of the experts. Until then the final judgment will not be given.

ADONIS AMURENSIS.

A PLANT that is native to Manchuria is just now invested with additional interest. A. amurensis is a perennial attaining to a height of 18 inches, with very much divided leaves, the ultimate segments being more or less linear and toothed. The "double" flowers are about 2 inches across, bright yellow, the petals being greatly increased in number at the expense of the stamens. In the specimen figured (fig. 76) some of the inner segments were more or less leafy, forming a ring of green segments, as is found in some of the cultivated forms of Ranunculus. This green condition is, we are told, not permanent. The plant is almost, if not quite, hardy, and flowering at this early period is very acceptable. Our illustration was drawn by Mr. Worthington Smith from a plant shown at the Royal Horticultural Society by Messrs. W. Cutbush & Sons, Highgate. It is figured in the *Botanical Magazine*, t. 7490.

FIG. 76.—ADONIS AMURENSIS, A MANCHURIAN PLANT: FLOWERS YELLOW.
(Award of Merit, Royal Horticultural Society, March 14.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE CUCUMBER "SPOT."—Three-parts down the second column of my letter on this subject, printed in the issue of the *Gardeners' Chronicle* for February 18, p. 105, I stated "that in my opinion the cause of 'spot' appearing on Cucumber-leaves is not to be attributed to the composition and condition of the soil in which the plants are growing under expert management; but to the unfavourable external as well as internal atmospheric conditions occurring at a time when the vigour and energies of the first batch of plants have become nearly exhausted through the production of heavy and continuous crops of fruit during the previous ten or twelve weeks, the plants under such circumstances being more likely while in that condition to experience a check from a sudden and unfavourable change taking place in the weather after fire-heat has been dispensed with than a batch of young plants just coming into bearing would be." Mr. Thomas says on p. 138 that "most practical growers would endorse this statement," adding "but unfortunately for theories, be they ever so sound and good, once they come into contact with facts they often vanish into thin air." I beg to remind Mr. Thomas that the above-mentioned remarks were not put forward as theories but, on the contrary, as conclusions based on the results of close practical observations, and I may add that the young plants referred to above as just coming into bearing in a separate house at the time the "spot" might put in an appearance on the leaves of nearly exhausted plants, would most assuredly be in a better position, being in the full vigour of life, to resist the attacks of this disease—that is, when the atmospheric conditions, externally and internally, favourable to the production of "spot" are present than young plants just set out on the ridges, also in a separate house, would be. I think Mr. Thomas's fears regarding the bad effect that the vaporising of Cucumber-houses with sulphur might have on the fertilisation of the flowers and the subsequent sale of the fruit need not be seriously entertained, as I do not for a moment think that the sulphurous vapour as distributed by one of Campbell's vaporising machines would have any bad effect on the Cucumber flowers, though probably it would put a deposit on the fruit, which, if considered necessary, could be easily and effectually washed off with clean water applied from the hose or garden syringe a few hours before cutting the fruit for market, without in any way damaging the sale of the fruit. The vaporising of the houses could be done on the Friday evening, the fruit having been cut pretty hard for market in the morning, no more being cut as a matter of course until the Monday following. I may add that I was not unmindful of the above-mentioned contingencies at the time (December 26) I penned the article which appeared on February 18, p. 150. I may also add that I experienced no inconvenience or unpleasant sensation by remaining in the Cucumber-house while it was being filled with the sulphurous vapour, and that should the suggested remedy for "spot" in Cucumber-leaves prove effective, the apparent drawbacks suggested by Mr. Thomas are by no means alarming. To the results of scientific research when subjected to and approved by practical tests we as a nation owe and expect much. But all the same I completely fail to see in what possible way the carrying out of Mr. George Massee's prescription can effect a cure, or even act as a preventive for "spot" on Cucumber-leaves. Assuming that Cucumber-houses in which the plants growing therein had been badly affected with "spot" last summer and autumn had been thoroughly cleansed during the months say of November and December, and that every particle of the soil forming the ridges had been removed, the brickwork washed with hot liquid lime, and wood and glass with soft-soapy water and petroleum (one small glassful to the gallon), the ground floor saturated with ammoniacal liquor, finally each house filled densely with the fumes of burning sulphur, then it would be impossible for any insect or germs of disease, fungoid or otherwise, to survive the operation. Clean, fresh, loamy soil, to which a like quantity of short stable-manure had been added and well mixed together, should be then wheeled into the houses and formed into ridges in which to plant the Cucumbers towards the end of December or early in January after the compost has become fairly warm, and the plants have attained the desired size. The Cucumber seeds are in the meantime sown in 3-inch pots filled with the above-mentioned mixture in a fine state. Well, what has science told us to do with a view to prevent "spot" appearing in the Cucumber leaves months later? "To water the young plants when a fortnight old every third day with a solution consisting of 1 oz. sulphate of copper dissolved in 50 gallons of water, and after the plants have been thus treated for six weeks, to commence watering every fourth day with a solution of 1 oz. sulphate of copper in 35 gallons of water." In connection with the advice given above, I should very much like to know what justifiable ground there can be for assuming that the compost prepared as indicated above contains the germs of disease—"spot" or otherwise. I am sure that all practical cultivators—including, of course, your much-esteemed correspondent Mr. Owen Thomas—would like to have a satisfactory answer to this question. I do not think that it can be asserted that the application of the solution mentioned above to the soil renders it more nutritive to the plants. In the issue of the *Gardeners' Chronicle* for January 7 last, p. 13, Mr. J. J. Willis gives a long list of so-called remedies that had been tried and failed in a large market nursery in the neighbourhood of Harpenden. A reference to Mr. Willis's article and mine (written about the same time as his) printed on February 18, will show that we are very much in agreement as to the futility of the various supposed cures and remedies for "spot" on Cucumber leaves recommended from time to time in various publications. As a Cucumber grower, I wish to thank Mr. Owen Thomas for the kindly interest which he has, and is still, taking with a view to ascertain the cause of and cure for the dreaded "spot," which is the cause of so much anxiety to all classes of Cucumber growers, especially those who have only recently invested their hard-earned savings in the business. In conclusion, I should like to say that, in my opinion, it is only in places where Cucumbers are grown specially for market that the cause of and cure for "spot" is likely to be ascertained. When fire-heat is dispensed with, say some time in June, extra care and watchfulness should be exercised in the matter of airing and distributing moisture in the houses in the afternoon, as this is the time from which it may be said danger may be scented from afar. *H. W. Ward, Rayleigh.*

CRYPTOMERIA JAPONICA.—In reference to Mr. Bartlett's letter on p. 170, I may say that the Cryptomeria japonica which was cut down in the pinetum here was a much finer specimen than the one growing close to the Tsuga Mertensiana (Albertiana). The growth of the former tree has been more than double that of the latter during the four years I have been at Dropmore, owing to the latter tree being in a very poor gravelly soil. Philip Frost, in his "Conifer Book of the Dropmore Trees," calls this part of the grounds "Hunger Hill." I attribute the more rapid growth of the pinetum specimen to its being in a better site, and possibly to its receiving more attention as it was growing in the pinetum proper. The specimen mentioned by Mr. Bartlett as growing near to the carriage-drive I have just measured, and find it to be slightly the largest of the three trees. The dimensions are—height 59 feet, girth at 5 feet from the ground 6 feet. This is a very healthy tree, and being in a sheltered position will doubtless grow into a very fine specimen. Regarding the specimen growing at Boconnoc, Cornwall, this tree increased very little in height during the eight years I was at Boconnoc, it having already outstripped the neighbouring trees, and thus was exposed to the strong south-west winds which are so prevalent there, but I imagine it would be equal to the Pencarrow tree in girth. *Chas. Page, Dropmore Gardens, Bucks.*

CANTUA BUXIFOLIA (DEPENDENS).—Referring to the note and illustration in the last issue of the *Gardeners' Chronicle*, allow me to say that this old climbing plant is certainly very beautiful when planted-out in a border and trained over an arch fixed in a light position in a cool-house, where it will attain to a height of 9 or 10 feet. Only the main branches should be fixed in position, allowing the flowering shoots to hang down, as herein lies its beauty. After flowering, the side shoots may be pruned back, leaving an inch or so of the previous year's wood. When the new growths are an inch or two long, thin out the weakest of them to prevent overcrowding. If grown in a dry atmosphere the plant is subject to attacks of red-spider and thrips, but given the above treatment, and occasional syringings, good results will follow. The illustration showed a very strong corymb of flowers, the more usual number being nine to eleven. Cantua buxifolia may be considered hardy in sheltered situations in the southern maritime counties. *James Baxter, Gorddinog Gardens, Llanfairfechan.*

ALPINE GARDEN.—Polygala chamæbuxus purpurea has been in flower most of the winter through; the magenta-purple blossoms are very beautiful. Pulmonaria angustifolia (azurea) has its deep blue-coloured flowers open, also Primula pulcherrima, which blooms here a little too soon, therefore the flowers are liable to damp off. Of the Saxifrages, S. oppositifolia, with purplish-rose-coloured flowers, are very bright. The yellow flowers of Dondia Epipactis are to be seen. Hepaticas, Alyssum, and hardy Cyclamen are bright. Aubrietia "Dr. Mulus" will soon be a mass of flower. Spots in the alpine garden that are to be planted should be indicated by labels, and composts that will be necessary should be put in readiness, so that there need be no delay when planting time arrives. *A. B. Wadds, Paddockhurst, Sussex, March 13.*

ROYAL HORTICULTURAL SOCIETY'S JOURNAL.—It is undoubtedly teasing to a busy man to find the pages uncut. Let him hand the volume to his printer, who will in two minutes put the matter all right by putting the book under his cutting-machine. *W. B. S.*

HIMALAYAN RHODODENDRONS (see pp. 136 and 155).—R. Falconeri is represented here by several established healthy specimens, which receive no protection whatever, and have withstood the frosts of several winters. We have a splendid collection of these Rhododendrons, and they are establishing themselves in different positions. R. argenteum seems to be one of the most tender, and should be protected, or the fine leaves get crippled with the frost and are unsightly all the summer. When planting the large-leaved varieties, such as R. Falconeri, R. Hodgsoni, R. barbatum and others, positions should be selected where they are sheltered from strong winds, but frost does not seem to injure them at all. We have been cutting flowers of R. Nobleanum since the first week in February from plants growing in an exposed position; also R. præcox, which has been, and is at present, a beautiful display of flowers. There need be no timidity in planting these Rhododendrons in sheltered places if the soil is suitable. *A. C. Smith, Lydhurst Gardens, Haywards Heath, Sussex.*

MR. NEWSTEAD.

WE have already alluded to the appointment of Mr. Robert Newstead, the Curator of the Chester Museum, as special lecturer to the University and School of Tropical Medicine, Liverpool, and now have pleasure in presenting his portrait. He will be engaged in giving practical demonstrations and lectures to the students connected with the School of Tropical Medicine, the veterinary department, the agricultural department, and the University. Mr. Newstead, who began his career as a gardener, came to Chester in May, 1886, about a month before the opening of the Grosvenor Museum. The whole of the work of classifying

MR. R. NEWSTEAD.

and arranging the extensive collections has been carried out by him, and he has mounted and prepared practically the whole of the objects now in the Museum. Mr. Newstead has, in addition, done much work in connection with the Chester Natural Science Society, and a few years ago he was awarded the Kingsley Memorial Medal; while at the Chester Paxton Society's last exhibition he received the Silver Medal for a large collection of injurious insects. Archæology has also claimed a considerable share of his attention, especially in relation to pre-historic man and the Roman and Saxon periods, and he has frequently contributed to the Archæological Society's journal.

Especially in the departments dealing with general agricultural and horticultural subjects, Mr. Newstead has been closely connected with the work he will now take in hand. A long list of publications has come from his pen, among which the chief are the two elaborate volumes on the scale insects and mealy bugs (Coccidæ), published by the Ray Society. Mr. Newstead has also made the destructive pest, the Black Currant mite, a special feature of his investigations, while another important branch of his work during the last thirty years has been the food of birds in relation to agriculture and horticulture. His records have not been published, but we believe he has made several thousand post-mortem examinations, which are of great interest to scientists. Mr. Newstead was very closely connected with the late Miss Ormerod, and during the last years of her life acted as her assistant. He prepared the exhaustive index to the whole of her publications, which extended over a period of twenty-three years.

To those who have had the pleasure of his companionship in a country ramble, says a Chester paper, his keen observation and his deductive reasoning are a constant source of delight. In the late autumn Mr. Newstead and the writer were passing a stubble field, from which a flock of linnets and finches rose. "Hungry little beasts," remarked the curator, and he was over the wall in a moment, and ranging the field like a pointer quartering partridges. "Aye, this is it," he said, as he returned with a handful of dried stems. "Look at these Charlock-pods. See how exquisitely one side of the pod has been stripped away as if clean cut with a knife. There are no seeds, though you can see the cavities from which they have been extracted. The birds know what these pods contain, and they must have eaten countless thousands of the seeds of this pestilent plant. This is nature's little way of remedying farmers' carelessness and neglect. Next year this field would have borne a splendid crop of Charlock but for the birds."

Obituary.

FARQUHAR MACRAE.—We find in *Horticulture* an announcement of the death, on February 21, of this nurseryman. Like so many other American business men, Macrae was of British origin, having been born in 1844 in Ross-shire. He emigrated in 1869, and rapidly took a prominent position in his vocation. Latterly he had become famous as a Chrysanthemum grower.

EDWARD A. SANDERS.—There has just passed away, in his ninety-third year, one of the best-known men in the county of Devon, Mr. Edward Andrew Sanders, of Stoke House, Exeter, the senior partner of the Exeter Bank (now amalgamated with Smith, Prescott, and Dimsdale). For more than sixty years he took an active part in county affairs, and was Mayor of Exeter over half a century ago. He was a generous patron of horticulture, and at one time a frequent exhibitor at the Exeter flower shows. In 1864 he was President of the Devon and Exeter Horticultural Society, and up to the time of his death was an honoured and beloved President of the Devon and Exeter Gardeners' Association. Mr. Sanders was a fine illustration of the old English gentleman. Incidentally it may be mentioned that he was a brother-in-law of Judge Hughes, the author of *Tom Brown's School Days. A. H.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 14.—*Present.*—Dr. M. T. Masters, F.R.S., in the chair; Drs. M. Cooke, V.M.H., and H. Muller; Revs. W. Wilks, G. Henslow, and G. Engleheart; Professors G. S. Boulger, and G. F. Scott-Elliott; Messrs. Douglas, Veitch, Elwes, Holmes, Walker, Odell, Baker, Güssow, Bowles, Saunders, Massee, Hooper, and Chittenden (hon. secretary).

Henslow Testimonial.—Dr. MASTERS, on behalf of the committee, after referring to the great interest Prof. Henslow had always taken in the work of this Committee, and after expressing the great regret felt by all on his resignation, presented him with a silver tea and coffee service, bearing the following inscription:—"Presented to Rev. Prof. G. Henslow, M.A., V.M.H., by the members of the Scientific Committee of the Royal Horticultural Society, in grateful remembrance of his valuable services as secretary, and as a token of friendly association during a period of twenty-five years." Professor HENSLOW, in replying, referred briefly to the history of the Committee, with which he had been associated for a quarter of a century, and thanked its members for the support they had always afforded him, and for the mark of their regard with which they had presented him that day.

Pine Bud Moth.—In reply to a request for information concerning this, Mr. SAUNDERS reported as follows: "The shoots of Scotch Fir are attacked by the caterpillars of a small moth belonging to the genus Retinia, which contains several species whose caterpillars live in the shoots of Firs; the commonest species is R. buoliana. When by the appearance of a shoot it is suspected that there is a caterpillar within, it is best to cut it off and burn it. In July, if a number of yellowish-red moths, measuring about an inch across the open wings, appear, it might be worth while to catch them in a butterfly net."

Injured Crinum Bulbs.—Mr. SAUNDERS also reported: "The bulbs were attacked by Dipterous larvæ, probably Lonchæa vaginalis, in large numbers, by the 'bulb mite' Rhizoglyphus echinopus, of which there was one large colony, and by one of the

'Springtails,' Lipura ambulans. It is difficult to say which of these pests began the work of destruction. The grubs of the fly would no doubt be more destructive than the others. The centipedes which were found were probably Lithobius forficatus, which I believe to feed entirely on animal food; they were probably feeding on one more of the pests." A vote of thanks was accorded to Mr. SAUNDERS.

Hybrid Orchid.—Mr. H. VEITCH showed an interesting bigeneric hybrid, now flowering for the first time, Dialælia Veitchi×, between Diacrium bicornutum and Lælia cinnabarina, which showed clear evidence of the influence of both parents. A Botanical Certificate, proposed by Dr. Masters and seconded by Mr. Elwes, was unanimously awarded.

Scientific Research at Wisley.—Mr. WILKS announced that some experiments had already been commenced in the gardens under the direction of Mr. G. Massee, V.M.H., who had kindly undertaken to superintend them. The experiments are:—1, to ascertain whether the Black Currant bud mite can infect the Hazel and *vice versâ*, and 2, to discover what is the effect on germination of soaking seeds in various solutions.

Formation of Fruit-buds.—A communication concerning the date at which blossom-buds were first formed on fruit-trees, and the conditions influencing their formation, was received from Mr. J. DUNLOP, F.R.H.S. After some discussion, in which the Chairman, Professor HENSLOW, Rev. W. WILKS, Mr. BAKER, and others took part, the matter was referred to the Secretary.

Daffodil Poisoning.—Referring to this matter, which came up at the last meeting, Mr. SAUNDERS said it seemed probable that the crystals of calcium oxalate in the leaves acted as inoculation points, causing a small wound which allowed the entrance of the poisonous substance which is known to occur in the leaves.

Disease of Cucumbers.—Mr. HANS GÜSSOW showed drawings and cultures of a fungus causing disease in Cucumbers. The young fruits are covered with a velvety growth of blackish-green fungal filaments, and it is reported by Prof. Mazé that the leaves also are attacked, forming spots similar to those produced by Cercospora melonis, Cke.; the spores, however, of the fungus are quite different. Mr. Gussow proposes the name Corynespora Mazei for this fungus, establishing a new genus and species (see *Journal of the Royal Agricultural Society*, 65 (1904), p. 270-272, figs.). Mr. Massee and Dr. Cooke both stated that the disease was well known in the country, that the fungus was probably the conidial stage of a higher fungus, placed by British fungologists in the genus Alternaria.

Scale Insects.—Mr. WALKER showed specimens of a scale insect which had occurred outdoors on the following shrubs: Escallonia macrantha, Trachelospermum jasminoides, and Cratægus Pyracantha. Mr. Newstead, who determined the insect to be Lecanium hesperidum, stated in a letter that the insect was very rarely met with outdoors, though known in greenhouses.

Effect of Hail.—Mr. G. WOODWARD, F.R.H.S., of Maidstone, sent branches of fruit-trees showing large, partly healed wounds, many of them 2 inches in length by 1 inch in width, caused by the hailstorm which occurred three and a half years since.

Capnodium on Oranges.—Leaves of Oranges almost covered with Capnodium were received from Lisbon from Lady DENISON-PENDER. This fungus lives on the honeydew secreted by aphis, &c., and may be checked by killing the insects as soon as they appear by spraying with a resin wash.

Diseased Spanish Iris.—Plants of Spanish Iris diseased were received from Mr. LOWE, and Dr. COOKE kindly undertook to examine and report upon them.

Amaryllis Bulbs Diseased.—These, from Mr. BAXTER, were referred to Dr. COOKE and to Mr. SAUNDERS to examine.

"Stag's Horn" Ash.—Mr. BURBIDGE, V.M.H., sent specimens of contorted and fasciated twigs of this curious and little known variety of Ash. "The tree," says Mr. BURBIDGE, "is propagated by grafting on the common Ash as a stock. It forms a low-spreading tree 15 to 25 feet in height, and as the tip or apex of every twig is contorted and fasciated, it is very peculiar-looking when its leaves fall in autumn and winter. There is a very good example of this 'Stag's Horn' variety on the lawn at Kilmacurragh, co. Wicklow."

NATIONAL SWEET PEA.

WE are requested to announce that the *Sweet Pea Annual* is so far out of print that no copies can be supplied except to those joining the Society. No fewer than ninety new members have paid subscriptions since the commencement of the New Year. The secretary, Mr. Horace J. Wright, 32, Dault Road, Wandsworth, London, will send full particulars of the Society and its work upon application.

BRITISH GARDENERS' ASSOCIATION.

West Hartlepool.—At a meeting held recently at West Hartlepool it was unanimously resolved to form a local branch of the Association, and a committee was elected to carry this resolution into effect, Mr. T. Smith, Grantully Gardens, West Hartlepool, being appointed local secretary.

Beckenham.—A meeting of gardeners, called by Mr. Mark Webster, was held in this town on March 10, Councillor J. Neville in the chair, and was addressed by Mr. W. Watson. It was decided to form a committee and establish a branch of the British Gardeners' Association in the district.

ROYAL DUTCH BULB GROWERS'.

HAARLEM, MARCH 17—21.—The seventy-fifth annual exhibition was opened on Friday, March 17, by the President of the Society, Mr. J. H. Wentholt, and was continued until the 21st.

Many thousands of people visited the exhibition, including a great number who were brought in from Amsterdam by the new electric tramway running from that city. They were brought to and from Haarlem, including entrance to the exhibition, for the sum of eightpence!

The show was held in the Societeit Vereeniging, the largest Club in Haarlem. The large Hall was laid out as a garden, the floor being laid with turf, and having spaces cut out for beds, the paths being made on the natural floor. The various exhibits were placed in the beds, which, with Palms and other decorative plants, made a very fine effect. The gallery, as well as a large room in the Club-house, were also used for staging exhibits.

Medals were presented for competition by the Queen of the Netherlands, the Queen-Mother, the Prince Consort, and a large number of Societies and private individuals.

The classes were over 100 in number, and comprised competitions for Hyacinths, Tulips, Narcissi, Crocuses, Amaryllis, Astilbe, Clivia, Chionodoxa, Convallaria, Cyclamen, Eucharis, Dicentra, Freesias, Fritillarias, Lilies, Galanthus, Gloxinias, Helleborus, Hepaticas, Irises, Tree Pæonies, Callas, Scillas, and a great variety of spring-flowering plants. We cannot specify all the prize-winners.

The HYACINTHS were arranged on staging in a temporary building adjoining the large Hall. These presented a very striking effect, those grown in glasses being exceedingly fine. A very striking feature in this class consisted of thirty pans made up with ten Hyacinths in each pan. These were the finest we have ever seen exhibited in this manner. In this section the principal prizes went to Messrs. ANT. ROOZEN & ZOON, J. H. KERSTEN & CO., W. ROOZEN and J. C. GEHRELS. In many of the classes there was no competition.

The various TULIP classes were well represented, especially by a very fine collection of Darwin varieties. Tulips, both single and double, were very effective. Messrs. VAN WAVEREN & ZOON, J. J. DE LANGEN, VAN SCHAIK, C. G. VAN TUBERGEN, BLOM & ZOON, E. H. KRELAGE & ZOON, and others achieved success in this section.

For NARCISSUS Messrs. J. SCHOEHULIS was awarded a Silver Medal, and among other prize-winners were HEER J. W. DAUDEY (Spiræas), P. H. TEUNIS, and A. KERS (Clivias), Heer EGGINK and K. STEIJN for Lilies of the Valley.

Next to the Hyacinths we consider that the feature of the show was the AMARYLLIS. There were several exhibitors in the classes for 36 and 24, and there was very keen competition; indeed, the jury had a considerable amount of trouble in deciding the Premier Award.

We must also refer to the splendid miscellaneous varieties of bulbs, such as Iris, Lachenalias, and hardy Orchids. These were well worth a visit alone.

The jury was made up of leading horticulturists from Belgium, Germany, England, and France, with many of the Dutch bulb growers, among whom were:—

President.—A. Truffaut, Paris.

Belgium.—K. J. Kuyk, Mont St. Amand, Ghent; Ch. Pynaert, Ghent.

Germany.—Fr. Benary, Commerzienrat, Erfurt; M. Buchner, Munich; C. Kommer, Bremen; Aug. Siebert, Frankfurt-on-Maine; W. Swoboda, Berlin.

England.—P. Rud. Barr, London; Herbert J. Cutbush, London; George Gordon, London; R. Wilson Ker, Liverpool; Alfred H. Pearson, Lowdham; John Pope, Birmingham; Walter T. Ware, Bath.

France.—Henri Martinet, Paris; Albert Truffant, Versailles; Ph. Levêque de Vilmorin, Paris.

The foreign visitors and members of the Press were treated with the greatest kindness and hospitality. Banquets, receptions, concerts, and other entertainments were offered to the guests; and an official welcome was tendered them by the Burgomaster, Mr. J. W. G. Boreel van Hogelanden.

ROYAL BOTANIC.

MARCH 22.—The first of the Society's shows for the present season took place on the above date, a bright display of flowers and plants being arranged in the corridor and in the conservatory.

Messrs. J. HILL & SON, Lower Edmonton, staged a splendid group of Ferns. Among the collection we noticed Polypodium aureum giganteum, Nephrolepis exaltata, Dicksonia Scheidei, Pellea robusta, Platyceriums, Brainea insignis, Woodwardia orientalis, &c. Osmunda Hilli, a variety of the North American O. gracilis, is worthy of mention (Gold Medal).

Mr. G. REUTHE, of Keston, put up a very bright group of hardy spring flowers (Silver-gilt Medal).

Mr. J. MAY, Gordon Nursery, Twickenham, staged a splendid group of about 125 plants of Cyclamen. The colours of the flowers were bright and varied, and the plants themselves of sturdy growth (Large Silver-gilt Medal).

Messrs. AMBROSE & SON, Cheshunt, had Daffodils and Carnations. Among the latter the variety Flamingo was awarded a Certificate of Merit (Bronze Medal).

Miss ADAMSON, South Villa, Regent's Park (gr., Mr. Kelf), put up a good group of flowering and foliage plants, Cinerarias, Daffodils, Hyacinths, Tulips, &c. (Large Silver-gilt Medal).

Messrs. J. LAING & SONS, Forest Hill, showed Begonias and Anthuriums arranged with Palms and Ferns (Bronze Medal).

Mr. S. MORTIMER, Farnham, Surrey, staged a fine group of a clove-scented Stock named "All-the-Year-Round," to which the Committee awarded a First-class Certificate (Large Silver Medal).

Mr. J. BOX, West Wickham, had a pleasing group containing plants of Begonia Gloire de Sceaux and of alpine plants in flower (Silver Medal).

Messrs. T. S. WARE, Ltd., Feltham, put up a large group of Daffodils, hardy Primroses and other spring flowers, including Conandron ramondioides that received a first-class certificate (Large Silver-Gilt Medal).

Mr. G. H. SAGE, Richmond, showed flower displayers and horticultural sundries.

Mr. J. WILLIAMS, Oxford Road, Ealing, had some pretty flower-holders of various patterns.

GARDENERS' DEBATING SOCIETIES.

CARDIFF GARDENERS'.—The usual fortnightly meetwas held at the Sandringham Hotel, Cardiff, on Tuesday, March 7, Mr. Tom Clarke presiding. Mr. R. Mayne, Park Place, Cardiff, delivered a very instructive and practical lecture on "Pot Strawberries." The lecturer explained in detail the modes of propagation and varieties suitable for the purpose: also the proper treatment necessary to maintain a succession of fruit. Mr. Collier opened a discussion. The Chairman announced that the nineteeth annual General Meeting will take place on March 21st next.

BRISTOL AND DISTRICT GARDENERS'.—A meeting of this Association was held at St. John's Rooms on Thursday, March 13, Mr. Garnish presiding. The lecturer for the evening was Mr. Cane, gardener to Drs. R. and W. Eager, Northwoods, the subject being "Cyclamen." The lecturer recommended growing plants from seed each year, and showed how they could be had in flower from November to May. Details were given on sowing, suitable composts, potting, and on general treatment for the whole season. A discussion followed. The competition for three plants of Cyclamen was keen, the 1st prize being awarded Drs. R. and W. Eager (gr., Mr. Cane). The next meeting is an exchange visit from the Reading Association, when Mr. Winsor will lecture on "Sprays and Buttonholes."

HEADLEY GARDENERS'.—A lecture illustrated by lantern-slides was given on Wednesday, March 14, by Mr. Bunyard on "Birds of the Garden," Mr. J. Murray presiding. The lecturer, before describing the various birds in detail, gave methods of preventing the increase of birds generally, and also methods of attracting them. To attract useful birds, it was necessary to provide nesting-boxes, about 9 inches square and 5 inches deep, with a sloping roof to keep out the rain. The lecturer deprecated the so-called sparrow clubs as upsetting the balance of Nature, and proved that though the sparrows did much mischief in destroying buds, they destroyed thousands of injurious insects, and the seeds of noxious weeds. Even the bullfinch, the most destructive of all garden birds, was partially insectivorous. As examples of birds to be especially encouraged, the lecturer mentioned the missel-thrush, robin, blue-tit, fly-catcher, swallow, and starling. Some very interesting specimens of nests and eggs were exhibited. *H. A.*

ADDLESTONE, CHERTSEY, AND OTTERSHAW GARDENERS'.—A meeting of the above Association was held at the Village Hall on Tuesday, March 7. The President, H. Cobbett, Esq., occupied the chair. The subject of the lecture was "The St. Louis Exhibition." The lecturer, W. F. Reid, Esq., F.I.C., F.C.S., gave a most interesting discourse, which was splendidly illustrated by lantern slides. The principal features of the Exhibition were explained and pictorially represented, especially those features that were of horticultural interest. *T. S., Addlestone.*

DEVON AND EXETER GARDENERS'.—At the fortnightly meeting of the above Society held in the Guildhall, Exeter, Mr. Fry, Dulford House Gardens, Cullompton, gave an address on the "Cultivation of Apples and Pears." The lecturer dealt with double grafting of Pears, with summer pruning of fruit trees, which should be performed after August, and with various remedies for destroying insect pests.

CROYDON AND DISTRICT HORTICULTURAL.—The members of the above Society assembled on Tuesday, March 7, to hear an illustrated lecture from Mr. M. E. Mills, who contributed an interesting account of "Coombe House and its Gardens." In the extensive grounds are many features worthy of note, especially the old Cedars and Beeches, and a very old well of great depth used by the pilgrims years ago when passing.

READING AND DISTRICT GARDENERS'.—At the last fortnightly meeting of the above Association Mr. Barks, the representative of the Redhill and Reigate Association, read a paper on "Vegetables for Home Consumption." Mr. Leonard Sutton presided. The culture of the best sorts and varieties of vegetables was clearly dealt with, after which a good discussion followed. There were interesting exhibits displayed, including a curious specimen of Kale bearing the name of "Perennial Daubenton Kale," and some excellent blooms of Camellia reticulata.

BRIXTON, STREATHAM, AND CLAPHAM HORTICULTURAL.—At the annual general meeting of the members of the above Society it was decided to add mutual improvement meetings to the programme of the Society, which has hitherto been content to devote its energies to the holding of an annual autumn exhibition. The Society is one of the oldest in the London district, having been inaugurated close on fifty years ago, and it has continued its work with varying degrees of success ever since. The first meeting of the new movement was held in the hall of the British Workman's Institute, Ostade Road, Upper Tulse Hill, S.W., on Tuesday, March 14, the President, the Rev. C. S. Nicholl, M.A., in the chair, when Mr. J. Gregory, of Croydon, gave an interesting and instructive limelight lecture, entitled "Some Gardens I have Visited," which was very much appreciated by a large audience. Mr. Gregory supplemented his lecture by giving the members of the Society some good advice out of the plenitude of his experience *re* the successful management of the new movement. The President was supported by Mr. Wm. Roupell (vice-president), Mr. Lake, and others.

LANCASTER AND DISTRICT HORTICULTURAL IMPROVEMENT.—This Society has been successfully inaugurated, and the first lecture was given on Saturday evening in the Storey Institute before a large attendance, by Mr. Chas. Paul, of the Royal Botanical Gardens, Manchester, and Secretary of the Manchester Horticultural Improvement Society, his subject being "The Vegetable Covering of the Earth." The Mayor of Lancaster, Councillor Heald, presided. The many excellent lantern slides, by which it was illustrated, were much appreciated. Lord Ashton has accepted the presidency of the Society, and Mr. H. L. Storey High Sheriff, the vice-presidency. Mr. W. Shaw (Ryelands) has been appointed chairman of committee. The hon. secretaries are Messrs. J. W. Pring (New Street, Lancaster), and W. H. Shaw (Westfield); and the hon. treasurer, Mr. J. G. Shand. About 100 members have been enrolled. The Corporation have granted the lecture theatre at the Storey Institute for the use of the meetings, which will be held fortnightly during the winter months. The summer programme will include visits to places of special interest to horticulturists, and for cottagers and amateurs it is proposed to hold demonstrations at the various allotments, with addresses on the phases of gardening applicable to their needs.

NEW INVENTION.

A TURF-CUTTING MACHINE.

THE illustration at fig. 78 represents the Optimus Turf Cutter, a patent machine for cutting turf. The cutter comprises a handle or frame, having towards the front a wheel adapted

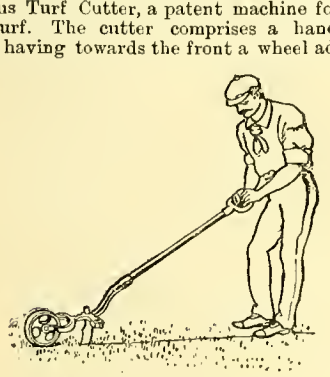

FIG. 78.—THE OPTIMUS TURF CUTTER.

to run upon the surface of the grass, and having behind it an adjustable cutting blade, which, when pushed forward, is said to effectually make the desired division of the turf. Messrs. Corry & Co., Ltd., Finsbury Street, London, E.C., to whom we are indebted for the illustration, state that the knife can be regulated by screw-action to suit any required depth, and also to suit the convenience of the operator. It can also be converted into an edging machine for grass verges, by simply removing the knife and fixing it to the side-arm provided for the purpose.

REMARKS.—The Alicante Grapes are from France. The Cape Grapes, both red and white varieties, are "Hamboorgpoots"; they are known in the market as "Honey Pots." They command from 10*s.* to 15*s.* per case of from 10 to 16 lb. weight. Cape Plums, 5*s.* to 7*s.* per case; Peaches, 3*s.* to 6*s.* ditto; Nectarines, 7*s.* to 10*s.* ditto; Pears, various sorts, 5*s.* to 8*s.* ditto; cases of French Apples, 6*s.* to 11*s.* each; Australian (Victoria) ditto, 12*s.* to 18*s.* per case; these latter are not of good quality. Cauliflowers in variety are now to be had, including these from Kent, Cherbourg, St. Malo, and Cornwall.

POTATOS.

Dunbars, 80*s.* to 90*s.*; various, home-grown, 50*s.* to 70*s.* per ton; seed in variety. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

WITH brighter weather the trade has improved somewhat; supplies are still over-plentiful. In flowering plants Indian Azaleas sell for rather better prices. Best Cyclamen also sell well. Mignonette of good quality is seen from several growers. Supplies of Genistas are over-plentiful, but best plants maintain good prices. Cinerarias are remarkably good in quality, but they do not sell readily. Marguerites are plentiful, some extra fine plants of these are obtainable. Plants of zonal Pelargonium "F. V. Raspail" are good, and realise from 6*s.* to 8*s.* per dozen; some of the variety King of Denmark are seen, but these at present are not very good. Hydrangea Hortensia and the variety Thomas Hogg are seen in dwarf plants, the first-named being well coloured considering the earliness of the season. Intermediate stocks are already coming in, but the white variety only is seen at present; these are good plants and command 5*s.* per dozen. Well-flowered plants of Cheisya ternata are seen. Erica Willmoreana and its white variety are remarkably well flowered this season; E. persoluta alba and E. Cavendishi are also of good quality. Acacias are almost over. Boronias are still seen. Hyacinths, especially the pink variety, are of good quality. Daffodils do not sell very readily. Some fairly good plants of Clematis are in flower. The hardy deciduous flowering shrubs do not sell readily. Lilacs, Laburnums, Prunus triloba, and Azalea mollis are seen; the latter sell fairly well. Spiræas are now plentiful, and Lily of the Valley in pots and in boxes, with good foliage, may be had at moderate prices. All kinds of foliage plants are plentiful, with little variation in prices. Hardy plant roots are now a feature—Pansies (for which 3*s.* per box containing two dozen is made for best quality plants), Polyanthus, Primroses, Daisies, &c. Spring bedding plants in store boxes are arriving. Lobelia, Marguerites, Fuchsias, Zonal Pelargoniums, and Calceolarias may all be had at low prices.

CUT FLOWERS.

Prices generally are if anything lower. Roses are over-plentiful, and cheaper now than they will be later on. Carnations are also abundant; there are some good flowers of the old favourite variety Miss Joliffe to be had. In American varieties, Norway (a fine white), Alpine Glow (blush pink), Floriana (a deeper shade), Adonis (scarlet), and Enchantress are still good. Good pink Malmaisons are obtainable. Lilium auratum is now plentiful, while L. longiflorum is to be had

again at normal prices. Callas are very cheap. Tulips continue abundant. Some good double varieties are seen. Supplies of Narcissus of all sorts are over-plentiful; best quality bicolors probably command highest prices. Gardenias are over-plentiful, and are offered at low prices at close of market. Eucharis are also abundant. Lily of the Valley is again down in price, supplies being more than equal to all demands. Violets are also very plentiful. Anemones in several sorts are very good. French Ranunculus are bright, and maintain good prices. The ordinary Mimosa is now nearly over, but other sorts of Acacia are coming in. Large branches of Double Peaches, Almonds, and other deciduous flowering shrubs are seen. To give a correct price list is most difficult, the fluctuations in prices being so great. *A. H., Covent Garden, March 22.*

ANSWERS TO CORRESPONDENTS.

BEECH BARK: *J. R. P.* The bark is infested with the Beech-coccus (Cryptococcus fagi), an insect allied to the mealy-bug. This coccid feeds exclusively upon the Beech, selecting the tree trunk, and occasionally ascends to the main branches. It will in time cause the bark to peel off, and the tree to decay and die. The young larvæ hatch about September, and although active, many never see daylight, but work their way under the old felted sacs and the dead bodies of their parents. They insert their beak into the hard bark sufficiently far to enable the insects to suck up the juices of the tree. The trunks of specimen or ornamental trees that are attacked by this pest should be thoroughly scrubbed with a mixture of soft-soap and water in the proportion of 8 oz. of the former to 1 gallon of water. In all cases it is best to dissolve the soap by boiling it in a quart of water, afterwards adding the full quantity. If it is found impossible to scrub the bark, spray with a mixture of paraffin, soft-soap and water kept well stirred. [See also p. 185.]

BEGONIA GLOIRE DE LORRAINE: *A. R. B.* You do not say if your propagating-bed is provided with glass lights. If it is not you had better place a shallow frame with lights on the bed, or make a rough temporary frame with narrow boards, and lay a light on this. Your bottom-heat of 70° is rather low, but the cuttings will probably root satisfactorily in that temperature. You will require quite five dozen good plants in 5-inch pots for stock. Fibre will be better than sand for making the cutting-bed. Young shoots will already have started to grow at the base of the old plants, and when they are about an inch and a half long, take them off and dibble them into the fibre in the cutting-frame and water them. You will have to take several batches of cuttings to get one thousand plants, and cuttings rooted as late as the end of May will make useful plants. As soon as the cuttings have rooted pot them into small pots, using a compost of two parts sandy loam and one part leaf-soil, peat, or fibre. Keep the atmosphere of the house in a moist condition, and shade the young plants from direct sunshine. When the plants have become well established shift them into 5-inch pots.

CLIVIA CROSSED WITH HIPPEASTRUM: *T. P.* The flowers you send are specially fine in colour, and seem to show variation in this respect as described by you. It would be very interesting to try to cross them again as you suggest.

CONIFERS: *E. C.* (1) The report of the Conifer Conference was printed in the *Journal of the Royal Horticultural Society*. Write to the Secretary, R. H. S. Hall, Vincent Square, Westminster, who will inform you if copies may still be purchased; (2), *A Manual of the Coniferæ*, published by Messrs. Jas. Veitch & Sons, Ltd., Royal Exotic Nurseries, Chelsea.

DAHLIA SOCIETY: *Eight Years' Subscriber.* The Secretary is Mr. F. J. Bateman, 34, Clarendon Road, Hornsey, N.

FLOWERS FOR TRAVELLING: *N. of D.* You are quite right in your suggestion respecting cultivation. If the flowers are produced in as low a temperature as is compatible with the proper growth of the plants, they will travel better and last longer after being cut than they would if grown in a greater degree of heat. In addition to the plants mentioned, you might try Freesias, Mignonette, double-flowered Primula sinensis, double-flowered Stocks, Streptocarpus, Anemones, Clivia miniata, Richardias, all the species of Acacia, Tuberoses, Roman Hyacinths, Carnations (one of the very best winter flowers for your purpose), Camellias, Eucharis, Gardenias, numberless varieties of Orchids, particularly of Cypripediums and Dendrobiums, Violets, Bouvardias, Hippeastrums, Roses, &c.

FRUITS FOR MARKET: *Old Reader.* We cannot undertake the responsibility of recommending which of the new varieties of Apples, Pears, and Plums are most suitable for market culture. You even mention those introduced in 1904; but a little reflection should convince you that it is impossible for some years after distribution to determine whether the growth of the tree and its cropping qualities will be such in a given locality as to warrant the planting of trees on a large scale even when the questions of appearance, keeping qualities, and flavour of the fruit have been settled. During the past few years there have not been many new Pears or Plums introduced that are likely materially to affect market-growers, but of the large number of new Apples, some ought certainly to be valuable for their purpose. You should procure one tree of each variety, and after trial in your own district you will be more likely to avoid making costly mistakes than you would be if guided by experience obtained elsewhere. The best of the older varieties for general planting were well brought out in our Apple census, published in the issues of the *Gardeners' Chronicle* for October 29 and November 5, 1904.

LIME-TREE: *F. R.* The pieces you send are dead. The bark is covered with a small alga, but this has not been the cause of death. Unless you can furnish us with more particulars we cannot assist you. The trouble is probably to be found at the roots.

NAMES OF FRUITS: *J. J. E.* 1, Catshead; 2, Old Nonpareil. The Pears are Winter Nelis.—*F. F.* The Apple is Graham or Kentish Deux-Ans.

NAMES OF PLANTS: *F. E. G.* Odontoglossum crispum, spotted variety, of slightly better value than the ordinary form, but of no great merit in its class unless it improves under cultivation. — *A. H. P.* Daphne Laureola (Spurge Laurel).—*T. G.* Reinwardtia trigyna, sometimes called Linum.—*A. W. G.* 1, Ophrys fucifera or a near ally; 2, Alonsoa incisifolia; 3, Santolina incana. — *Anxious.* 1, Crinum amabile angustum; 2, Xylophylla latifolia; 3, cannot be determined from the specimen received; 4, Sericographis (Jacobinia) Ghiesbreghtiana.—*G. G.* Odontoglossum × Adrianæ, a very good variety.—*C. E. A.* 1, Cypripedium × siamense, first imported as a natural hybrid. *W. G. S., Lancaster.* Cattleya Schröderæ.—*A. B.* 1, Cypripedium × Charles Canham; 2, Cypripedium villosum, specially good variety.

NARCISSUS "STELLA" AND "FIGARO": *A. Willis Can.* These are tall-growing varieties, their normal height when properly grown being 18 to 21 inches, but in pots they would be a little less tall. If you have seen them as dwarf as 6 inches, it could only be owing to bad culture or the result of employing very weak bulbs.

PICEA: *F. S.* The specimen is a very fine one of Abies Webbiana. The other plant is Podocarpus chilina.

PRIMULA MEGASEÆFOLIA: *A.* The flowers you sent us are correctly described as belonging to this species. The reason for your ill success in cultivating the plants is, we think, due to their having been grown in a greenhouse. The species is a hardy one in most districts, and if you keep the plants in pots they should be placed in a cold frame or house, and in a position close to the roof-glass. An excellent illustration of Primula megaseæfolia was given in the *Gardeners' Chronicle* for April 6, 1901, p. 223.

ROSES: *H. Y.* If liquid cow manure was applied every week over a period of some months, it is very likely that a coating was deposited over the surface of the soil that would almost prevent any aëration at all. When such manure-water is applied so frequently and over so long a period, the surface-soil should be removed occasionally or at least stirred.

SHRUBS: *Few Tree, North-west Staffordshire.* — Shrubs always look best in gronps or masses—*i.e.*, each sort being represented by three or more plants in a group, as the good qualities of each are then seen to the best advantage. The following flowering shrubs are likely to succeed in your district. We have enumerated suitable evergreens, and must defer a list of deciduous species until our next issue. All points considered, Berberis stenophylla is perhaps the best hardy yellow-flowered evergreen shrub. It is of free growth, graceful habit, and is unusually floriferous; the flowers are small, rich yellow, borne on the undersides of the long arching shoots in April. B. Darwinii is of sturdy growth, and bears orange-yellow flowers freely. Buddleia globosa, the orange ball-tree from Chili, not only grows freely, but flowers abundantly in the midlands if planted in a position exposed to the sun, but one protected from cutting winds; its orange-coloured flowers are borne in round heads in May. In severe winters it may be killed to the ground. The common white Broom (Cytisus albus), yellow Broom (C. scoparius), C. s. Andreanus, and the hybrid named præcox cover themselves with flowers each spring. Hypericum oblongifolium, a late, free-flowering species, is of excellent growth, perfectly hardy, and very pretty when displaying its substantial yellow flowers. Leycesteria formosa, from the Himalayas, bears a great number of white flowers shaded with purple, in long pendulous racemes, in summer, and these are succeeded by attractive purple berries in autumn; hard pruning should be practised with this so-called Himalayan Honeysuckle. Ligustrum sinense represents the best of the Japanese Privets, and as its white flowers appear in loose terminal panicles towards autumn (a time when flowers in the shrubbery are on the wane) it has great value; it is sub-evergreen, and succeeds in poor soil. The New Zealand Daisy Bush (Olearia Haastii) is one of the most reliable of small-growing evergreens; it has light-green, Box-like leaves, and produces great clusters of small white flowers towards the apex of the branches in summer. Skimmia japonica, with its shining green foliage, looks well all the year round, and when displaying its racemes of white, sweet-scented flowers at about the end of March, it is particularly pleasing. This is one of the best of small-growing evergreens for the Midland Counties, and a first-rate subject for murky atmospheres. For planting on hard, dry, hungry soils few subjects create a more gorgeous effect than Ulex europæus fl.-pl. (Double Gorse). It is nearly always in blossom. In well-drained soil free from lime hybrid Rhododendrons will flourish amazingly in the same district, as may be seen in the Botanical Gardens at Edgbaston. Another shrub, Pieris (Andromeda) floribunda, also grows freely and produces enormous quantities of drooping Lily-of-the-Valley-like flowers when planted in peaty soil and screened from biting winds. Cratægus pyracantha (Evergreen Firethorn) should be included by reason of the abundance of beautiful orange-red berries borne in autumn. It is a grand shrub in the neighbourhood of Birmingham.

SOIL: *Grimsby.* The sample you send appears to be of a desirable quality. We cannot undertake to analyse soil, but if you are a Fellow of the Royal Horticultural Society you can send it to the Society's chemist and have it analysed on payment of a small fee.

VIOLET-LEAVES: *J. C.* The compost you use appears from the sample sent to be excellent in every respect. No fungus disease is present, and we think your inference may be correct in attributing the condition of the plants to the presence of peat-manure in the soil. The peat absorbs a great amount of ammoniacal liquid whilst in the stable.

SHELTER.

IT may be taken as a fixed law in gardening that continuous success only comes to the man who knows the ways of his plants and cultivates them accordingly, giving them sunshine or shade, moist soil or dry soil, just as they may require. In laying out a garden a very important point, and one with which neither artistic effect nor financial considerations need necessarily clash, is to ensure adequate shelter for the plants that want it, and to know those from which it may safely be withheld. Before, however, our knowledge of this subject can advance beyond the empirical stage, it is necessary to examine in some detail the effects produced by shelter.

I shall consider the question in its two aspects, as it affects the soil and as it affects the plant, and it will be most convenient for my present purpose to begin with the soil.

Plant growth does not usually take place below 33° or 34°, and the best temperature for our common outdoor plants is from 70° to 80° or 90°. It is therefore obviously desirable that the soil should be warmed up as quickly as possible after we want the plants to move. For open-air cultivation the most important source of heat is the sun, which either directly, or indirectly by warm winds or showers, furnishes the gardener with practically all the heat he gets. Uncertain as is the supply, it is beyond our power to increase it, nor can we entirely prevent the great amount of loss that invariably goes on, but by good management the wastage can be diminished, and hence the amount actually available in the garden becomes greater.

I need not now discuss the devices, such as ridge cultivation, dressings of soot, &c., used to increase the amount of heat absorbed by the soil. We are more concerned with the losses, to see to what extent they can be reduced. The heat entering the soil is spent in three ways: it raises the temperature of the soil, it raises the temperature of the water in the soil, and it evaporates the water. The amount required for the last process is many times greater than that required for the second, which in turn is four or five times greater than that spent on the first. Indeed, we may take it that the temperature of a soil depends to a greater extent on the amount of water it contains than on anything else. So long as the water does not evaporate it simply stores up the heat absorbed, and saves it for the colder months; a moist soil is cooler in spring and early summer than a dry one, but retains its heat further into the winter. This explains the common observation that plants grow longer and delaying ripening more on a moist soil than on a light dry one, though on the dry soil they start earlier into growth. On the other hand the heat lost in evaporation is permanently lost to the garden; it will, of course, be recovered when the vapour condenses as rain, but that may fall miles away, and someone else will gain the benefit, just as our western shores owe their increase of temperature over the eastern counties to the heat liberated when rain is produced from the water evaporated out of the ocean. The heat lost by the ocean during the process is transferred to our west coast districts.

The main loss of heat, then, is evaporation of water from the soil. No good gardening end seems to be served by the process, the water and heat lost can ill be spared, and our best efforts in cultivation should be directed towards keeping it in check. Of all the methods by which this can be done, shelter in one form or another is one of the best.

It is quite obvious that any shelter, be it ever so slight, that keeps off the wind will check evaporation, but it is astonishing how great the effect is. King at Wisconsin found that a scanty hedgerow acted for a distance of 150 feet, and more surprising still, a crop of Clover sheltered a neighbouring field for about 300 feet. The most convincing thing of all is to try the experiment; select a plot in the open, shelter part of it with a miniature fence about 2 feet high, and leave the rest exposed; put the thermometer 5 or 6 inches into the ground, and take the temperature occasionally for a few days. The students at Wye College usually find the sheltered part 2° or 3° warmer than the unsheltered. A wooden fence, a hedge, a row of tall or bushy plants, a row of Beans or Peas, even a row of Pea-sticks, if judiciously placed to keep off the prevailing wind or ground draught, improve the prospects of the rest of the garden by increasing the temperature and the amount of water in the soil. A brick wall is sometimes not so good in spite of the warmth retained by the bricks; it may cause eddies, and the little whirlwinds thus produced do much damage. Especially is this the case in some of the old-fashioned circular walled-in gardens, which seem to get the wind no matter whence it blows. In these cases it is advisable to try running out little wind-breaks at right angles to the wall.

A mulch of dung, straw, and other organic matter has substantially the same effect. If applied in the autumn it prevents the loss of much of the stored-up heat; it checks evaporation of the soil water, and ensures that the plants shall start growing early. But the plan is not without its risk—slugs and vermin of many kinds are harboured, the soil does not get aërated, and the early growth may end disastrously if a spell of frost comes on. If we try to avoid these dangers by mulching in spring, the ground is sheltered from the drying winds and its moisture is conserved; the plant is also sheltered, and may make an early start, but the scanty sunshine of the early months cannot get through the mulch to warm the ground.

No general rule can be given; it is, in fact, one of the most interesting points of the gardener's profession that his own judgment must be his chief guide in balancing the probabilities and evolving safe rules of conduct to fit his own particular case from general principles as enunciated above. Plants like Strawberries and Roses on Briar stocks, that must have water in abundance if they are to do well, and have been so long in cultivation here that they are inured to our climate, are perhaps most advantageously mulched in spring; but more tender plants, which cannot spare any of the autumn heat, must be mulched before the winter sets in if they are to remain in the ground at all.

Whilst shelter in the form of wind-breaks or mulches can generally be arranged to check evaporation and so conserve the heat in the soil, there is a source of loss which has not yet been very successfully dealt with—I refer to the loss by radiation. On still clear nights in spring and autumn the ground gives out its heat very rapidly, the temperature falls, and the moisture in the air condenses, forming dew; finally this freezes. In this way are produced the spring frosts which do so much damage in our fruit gardens, at times causing large growers a loss of some hundreds of pounds in a night. The danger is greatest in valleys; the cold air from the hills being heavier than unchilled air, sinks into the valley and displaces the warmer air, which, flowing up to the higher ground, keeps it warm. A late spring or early autumn frost will for this reason generally appear on lower ground, and not on higher ground half a mile away. Standing on a hill when the dew is falling, we can observe the places where this cooling action is greatest, because it is here that the dew forms first; slight irregularities in the ground, scarcely noticeable in the daytime, can be detected in this way. Mulching may reduce this action, but cannot prevent it, nor will any system of wind-breaks; the shelter must be overhead. A blanket of smoke obtained from bonfires has been used with advantage; the Americans devised a scheme for spraying over the garden water distributed from tall jets placed ten to the acre, the man in charge being wakened at the proper time by an electrical thermometer. Another method not uncommonly adopted by them is to

cover the crop with cheese-cloth spread on light wooden frames. We do not as a rule adopt these overhead shelters in England, but either grow under glass or put up with the loss; an exception is, of course, the practice of shielding exhibition Tulips. Yet the problem is a very important one, and might with great advantage be attacked in some experimental garden.

Turning now to the effect on the plant, shelter ensures an increased temperature; but whether this is always beneficial cannot *à priori* be decided. Unfortunately we do not know definitely the most favourable temperatures for all of our garden plants, but experience soon shows whether in a particular garden a given plant requires more or less shelter. Too much may do harm by keeping off sun and air; if the shelter is a living plant it may do further harm by taking away water. At the Woburn fruit farm it is found better, even on a small scale, to have fruit and vegetables separate than to mix them. On the other hand, if the plant is too much exposed and gets a severe check early in life, it may never recover. Moreover, a rather high temperature is necessary for making chlorophyll, and exposed young crops are apt to look very yellow in bleak cold weather. The mechanical injury done by the wind is also of importance; if the plant is badly blown about the stems get twisted and the foliage becomes sere. This reacts on assimilation and affects both growth and root development. A wind-bruised Rose-tree is indeed a sorry spectacle, and even if recovery takes place to such an extent that presentable blooms appear in July, the spray of leaves behind the flower so dear to the heart of the exhibitor is conspicuously absent.

But it must not be forgotten that too much shelter is bad for the plant. A soft, watery growth is induced; the plants become liable to every disease that happens to be about, and the gardener must be prepared with sulphur to check mildew, and with his various washes to keep down other pests. In the East Kent hop-gardens sheltering has become a fine art, and probably nowhere is more attention necessary to prevent diseases getting a foot-hold. And as if the summer troubles were not enough, soft, sheltered plants may be cut down by autumn frosts much sooner than hardy, unsheltered ones.

Experiment and observation alone can decide how far it is safe to go, and when the disadvantages of increasing the shelter begin to outweigh the advantages. *Edward J. Russell, D.Sc. (Lond.)*

HELIAMPHORA NUTANS.

THIS interesting insectivorous plant was discovered by the brothers Schomburgk in 1839 on the mountains of Roraima, in British Guiana. It was refound by Burke (an English Orchid collector) in 1881, who brought plants of it to Messrs. Veitch & Sons, one of which flowered in 1889, and from which the *Botanical Magazine* figure (t. 7093) was prepared.

The illustration at fig. 79 represents a specimen growing in the Cambridge Botanic Garden. It was composed of about thirty fully-developed pitchers, and bore nine flower-scapes. The largest pitchers were about 6 inches high, pale green in colour, slightly tinged with red, and clothed with hairs on the inside similar to the Sarracenias, to which it is allied. The pitchers are not nearly so highly coloured as those represented in the *Botanical Magazine*. The flower-scapes are bracteate, from 12 to 15 inches high, slightly hairy, and brightly tinged with red towards the top, the strongest ones producing a fair-sized pitcher about 3 inches from their base. The perianth is bell-shaped, composed of usually four, rarely five pure white sepals, which after a time become spreading, and change to pale-green, and seem to be more or less persistent. I have tried several times to get good seed by crossing, but have failed, owing no doubt to the necessity of having pollen from a distinct individual, as all our plants originated from one piece.

A good specimen is not often seen, and it is considered rather a difficult plant to cultivate. This specimen has been grown from two single crowns during the last four years, and from which several pieces have been taken from time

FIG. 79.—HELIAMPHORA NUTANS.
(Much reduced.)

to time. Our plants are started from single crowns in small pots in a mixture of peat, sphagnum-moss, and sand, and given a surfacing of sphagnum-moss. They are then plunged to their rims in a pan of moss, covered with a bell-glass, and placed in a light position where a minimum atmospheric temperature of 60° Fahr. is maintained. They require copious supplies of water both at the roots and overhead, especially during the summer months. *E. J. Allard, Botanic Garden, Cambridge.*

NORTH AMERICAN OAKS.

[SEE SUPPLEMENTARY ILLUSTRATION.]

IN their native country the North American Oaks contribute very greatly to the beauty of the landscape. This is more especially the case in autumn, just before the fall of the leaf. I am not one of those who have been fortunate enough to see the deciduous vegetation of eastern North America in its autumnal glory, but the richness of the colour effects is, I believe, never equalled in this country. To this wealth of colour the Oaks contribute in no small degree.

In the British Isles the most ornamental of the American Oaks belong to the group known collectively as the Red Oaks. To this group belong Quercus coccinea, Q. rubra, Q. velutina (tinctoria), and Q. palustris. There is nothing finer among all our deciduous trees as regards autumnal colour than the best forms of Quercus coccinea or the "Scarlet Oak." From the Knap Hill nursery in particular there has been distributed a magnificent form of this Oak, which Mr. Waterer has named "splendens." This form is not only particularly rich in the crimson colour of its decaying leaves, but it is remarkable also for the length of time the foliage lingers on the tree. In ordinary years it does not fall much before Christmas, and retains much of its colour all the time.

Quercus rubra, the "Red Oak," has been largely planted in this country, and some fine specimens exist. It grows quicker, perhaps, with us than any other American Oak. At Kew there is a tree of this species with a trunk 14 feet in circumference. Usually its foliage turns a dull purplish-red. I think, however, this matter of autumn colour is influenced by the soil and possibly other local conditions. In the beautiful and picturesque grounds of Arley Castle, near Bewdley, a large number of trees of the Red Oak were planted by Lord Mountnorris in the early decades of the last century. These usually turn a rich crimson in autumn, and at their best afford one of the most gorgeous colour effects that can be seen in England.

Quercus palustris, the "Pin Oak," is a tree of denser, less open habit than the Red or Scarlet Oaks. Its leaves are more deeply lobed than those of either, and in some places are said to colour finely in autumn. I have not myself seen this, and I believe there is some confusion between this species and Q. coccinea.

The White Oaks of North America, of which three or four species are in cultivation, possess little value in this country. Quercus bicolor and Q. macrocarpa are perhaps the best of them, but I have not seen a really fine specimen of either. Still there may be some in old-established gardens.

The "Willow Oak," Quercus Phellos, thrives well in the South of England. There are several fine specimens in the neighbourhood of London. Two specimens at Kew are worthy of mention: one is about 80 feet high; the other, of more rounded habit, has a trunk 12 feet in circumference. This species is, when in full leaf, one of the most distinct and graceful of the New World Oaks; its leaves are narrow, Willow-like, and glossy green. They remain on the tree late in autumn, but do not colour well. Quercus heterophylla is supposed to be a natural hybrid between Q. Phellos and Q. velutina. It is a quick-growing, handsome tree.

The "Water Oak," known best, perhaps, as Quercus aquatica, is properly the Q. nigra of Linnæus. It has green, obcuneate leaves, and is chiefly noteworthy in its leaves remaining fresh and green on the tree till Christmas or New Year. Like several other North American trees which occur wild in swampy ground, it appears to require in this country only such moisture as a deep loamy soil naturally affords.

It has been observed that the Oaks of Western North America approximate more closely to the European Oaks than the (geographically nearer) Oaks of the Eastern States do. Two good examples of this are Quercus agrifolia and Q. Wislizeni, both Californian species and both very much resembling some forms of the European Holm Oak, Q. Ilex. A third species, also Californian, is noteworthy for the tawny-yellow under-surface of its leaves, and may be compared with the Golden Oak of Cyprus, Q. alnifolia. It will no doubt thrive best in the warmer parts of our islands; in Cornwall and such places it ought to make a fine and interesting tree.

A fourth Californian species, Quercus densiflora, is distinct from any other Oak in cultivation.

There are two healthy specimens at Kew, but I do not know of its existence elsewhere in this country. The leaves are 3 to 4 inches long, ovate-lanceolate, and of stiff texture; they are dark-green above, but the lower surface is covered with a felt-like substance, which, although it becomes tawny with age, is beautifully white when the leaf is young. I fear there has not been in late years such a demand for species of Oak as to encourage nurserymen to pay much attention to them. Still, I think it is a pity that an effort is not made to introduce so distinct and interesting a species as this in quantity, especially as it is becoming rarer every year in its native country.

The "Live Oak," Q. virginiana, or Q. virens, is the only truly evergreen Oak of the Eastern States that has been introduced. Although in the Southern United States it is a very valuable and ornamental tree, it is not hardy in this country except possibly in the extreme south-west. The large specimens of the Live Oak mentioned by London as existing near London fifty to sixty years ago were of some other species, probably Q. Ilex. *W. J. B.*

TREES AND SHRUBS.

LONICERA FRAGRANTISSIMA.

This plant, though not very showy, is of value as a sweet-scented, winter-flowering shrub. The flowers open from January to March whenever the weather is favourable, and are borne in pairs on short pedicels at the base of the young growths. They are small, white, and in shape like those of a Honeysuckle, with a short tube and a deeply-cleft, reflexed corolla, having a strong scent resembling that of Daphne Mezereum. In habit the plant is a rambling shrub with long, thin shoots which can be trained so that the plant may be used as a low climber, for which purpose it is worthy of more extended use. It is only partially deciduous in the open, and against a wall the leaves are usually carried throughout the winter. Any ordinary soil seems to suit this Honeysuckle provided it is not too wet, and a sunny situation suits it better than shade. If a frost occurs during the flowering period the plant merely loses the blooms that are open, the later buds developing as soon as the weather becomes milder. Propagation is effected by cuttings, which can be made from half-ripened wood, and rooted in a cold frame in August, or pieces of ripe wood inserted outdoors in a sheltered place in winter will make roots readily. It is a native of China. *J. C., Bagshot.* [A figure of this species and of the allied L. Standishii was given in our issue for Febrnary 23, 1889.]

SAPINDUS MARGINATUS.

We are indebted to Mr. George Paul for a fruiting spray of this American tree. As it is a native of the Southern States near the coast, and extends westwards to Southern Arizona and Northern Mexico, it is not likely to be hardy in this country, except in our south-western counties, the Channel Islands, and South-west Ireland. In our South African and Australian Colonies it would be likely to succeed. It is a tree attaining to a height of 40 to 60 feet, with pinnate foliage, with six or more pairs of narrow lanceolate leaflets, and a terminal one of the same form. The flowers, which are numerous, small, inconspicuous, and arranged in loose pyramidal panicles, are succeeded by globular berries, each the size of a small Cherry, amber-coloured, with a translucent skin. These berries remain attached to the branches for a long period, so that the attractiveness of the tree depends in a large measure on them. The berries are, it is said, eaten by cattle and deer. If so, "their taste is not the same as ours," for a trial did not induce us to make any further experiment. Naudin, in his *Manuel de l'Acclimateur*, p. 487, mentions the plant under the name of S. emarginatus, and tells us that it is hardy in Algeria, where the durability and beauty of its wood render it valuable. The berries contain "saponin," and are employed in the removal of grease from woollen materials and in the manufacture of soap. Two good illustrations are given in vol. ii. (1891) of Sargent's *Silva of North America*, t. lxxvi., lxxvii.

CYPRIPEDIUM × HAYWOODIANUM.

This fine hybrid Cypripedium has been raised in the gardens of Mrs. Haywood, Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), and when shown at a meeting of the Royal Horticultural Society on the 14th ult. it gained an Award of Merit. The hybrid is rom a cross between C. × T. B. Haywood and C. bellatulum, and, as will he seen from the illustration, it has large flowers of excellent form. They are tinted with rose-purple, and veined with claret colour, the upper margin of the dorsal sepal being white.
