ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture III.—Misplacements and Malformations.

[The first two lectures of this course were devoted to the demonstration of the situation of the heart in the thorax, the explanation of the sounds of the heart, and to the demonstration of the mode of examination to be adopted in investigating a supposed case of cardiac disease. These it has not been thought desirable to publish.]

Misplacements.

The heart is not unfrequently found to occupy a wrong position in the chest, and displacements of this kind may be either congenital or due to disease in after life. The congenital misplacements have the terms *ectopia cordis* or *ectocardia* applied to them, and they are divided into the internal and external. Of the internal misplacements, the most common is that to which the term *dexiocardia* has been given, in which the heart is found occupying a very similar position on the right side of the chest to that which it should occupy on the left. This condition may co-exist with transposition of the other viscera, or may occur alone. When the heart is so placed the aorta generally makes its turn to the right side, the descending aorta lies on the right side of the spinal column, and the large vessels also are transposed, the arteria innominata being given off on the left side, and the separate trunks of the subclavian and carotid arteries arising on the right. Such, however, is not always the case. The aorta sometimes makes its arch to the left, the descending aorta occupies its ordinary position, and the large vessels originate in the usual way. The heart in cases in which it is thus misplaced may either be itself quite natural, or its conformation may be more or less seriously defective. Of these several forms of irregularity many instances might be quoted. The malposition of the heart attracted the notice of observers from a very early period. It may readily be supposed that what attracted especial attention was that the irregularity, when unattended with any serious deviation from the natural conformation of the organ, does not appear to be necessarily productive of any serious symptoms. Cases are on record in which the condition existed in persons who survived for many years, and who even attained very advanced ages.

Of the external misplacements of the heart, the most common are those in which, in consequence of imperfection in the sternum, the organ is situated wholly or in part in front of the chest. Our museum contains one very interesting specimen of the kind, which occurred in the practice of Dr. Bain, of Poplar, and is described in the *Pathological Transactions* by Mr. Sydney Jones. In this, as in most of the cases on record, the child only survived for a few hours. In other instances the diaphragm is defective, and the heart is found lying in the abdominal cavity; and in some cases of this kind life has been prolonged for some years, and even a considerable amount of vigour has been enjoyed. The heart, however, when misplaced is often also imperfectly formed.

The congenital misplacements of the heart are, however, rare and interesting rather in a scientific than in a practical point of view; but not unfrequently the heart is displaced as the result of disease in after life. Indeed, the organ very often deviates more or less from its natural position, and especially in connexion with alterations in the condition of the lungs. Some years ago I made, in conjunction with Dr. Lanchester, then House-Surgeon of the Victoria-park Hospital, and now of Croydon, numerous observations on the position of the heart in the chest, and found that the situation of the orifice of the pulmonary artery varied from the level of the upper border of the fourth cartilage to the upper border of the second, and from the middle of the sternum to fully an inch to the left of that bone; the general rule being that the organ was situated at a higher level in cases in which the lung was contracted, and lower down when it was expanded. The heart also may be brought in contact with the parietes of the chest to very different extent in different cases, altogether independently of being itself diseased. Thus, after extensive pleurisy of the left side, the area of dulness is often considerably extended, and the pulsation can be felt and seen over a space much larger than natural. More marked displacements, however, than these often occur. In cases of effusion in the left pleural cavity, the heart is more or less displaced to the right, beating behind the lower portion of the sternum, to the right of that bone, beneath the right nipple, or even to the right of that body. More rarely in such cases the heart is displaced both to the right and upwards, so that in a case of empyema of the left side I once saw it lying beneath the right clavicle. The opposite displacement, in which the heart occupies a position further to the left than it should, is less frequent and less striking; but in a case in which there was extensive effusion in the right pleural cavity, in connexion with growths of lymph-adenoma in the chest, the heart lay at the anterior border of the left axilla. I once also saw a still more rare form of lateral displacement, in which the organ lay quite over on the right side, in consequence of the absorption of the fluid of a pleuritic effusion on the right side, which had completely and permanently compressed the lung, so that it was wholly impermeable to air. The condition was found in the body of an old man whose history was imperfectly known, and the time at which the effusion had occurred could not be ascertained; but, from the excessive thickening of the pleura, and the bony deposits which existed in it in different places, it was evident that the disease was of very long duration. The left lung was very greatly expanded, and had doubtless much assisted in the displacement of the heart. Similar displacements to those which depend on pleuritic effusions may also result from the growth of tumours of different kinds in the chest.

The heart may also be displaced upwards in cases in which there is copious effusion in the peritoneal cavity. I have seen several cases in which the organ has been found in ascites to lie immediately under the left clavicle. In two of these there was a loud systolic bellows murmur heard apparently at the base of the heart, and which was evidently due to the altered position of the organ, as it increased with the advance of the displacement, and no other cause was found on examination after death to explain its production.

Lateral displacement from pleuritic effusion I have never found to cause murmur at the heart, except in the case I have referred to in which the organ was also pushed upwards so that it lay under the right clavicle. This observation is of considerable practical importance, for it occasionally happens that the symptoms of intrathoracic growths resemble very closely those of pleuritic effusions, or the latter may coexist with the former. In such cases, if the heart be displaced, murmurs are of very common occurrence. In any doubtful case, therefore, in which the heart is simply displaced laterally, and in which a murmur is heard, the suspicion may be entertained that there is a tumour, or at least that the malposition is not wholly the result of an effusion in the pleura. Guided by these considerations, in a very obscure case which was not long ago under my care, I ventured to express the opinion that there was an intrathoracic tumour, and the result proved the diagnosis to be correct.

Malformations.

It is impossible in the space of a single lecture, which is all the time that we can devote to the subject, to give more than the merest outline of the various kinds of malformation of the heart.

The malformations of the heart may be classed—first, into those which occur at the early periods of fœtal life, and consist in serious deviations from the natural process of development; and secondly, those which originate at the later period, and are only important by interfering with the changes which should ensue after birth, or by predisposing to disease in more advanced life: and these classes may be again subdivided according as the irregularities chiefly affect the heart itself or the larger vessels.

Of the malformations of the first division, and which specially involve the heart itself, those which occur in the earliest periods of fœtal existence present the circulatory organs in the simplest form. The heart consists of only two cavities, an auricle and a ventricle, and the ventricle gives origin to one vessel, from which both the pulmonic and systemic arteries are derived.

In the next group the process of development has proceeded to a somewhat more advanced stage before having been arrested. The auricles are found to be imperfectly divided, but the ventricle, though it also may present some rudiments of a septum, is essentially single, and gives origin either only

to one vessel for the maintenance of both the pulmonary and systemic circulations, or there may be a distinct pulmonary artery and aorta.

When the deviation from the natural process of development occurs at a still later period, there are two auricles and two ventricles, though these may be imperfectly separated; and there may either be only one artery given off, or two distinct vessels, though in the former case the single vessel can no longer be regarded as the primitive arterial trunk, but rather represents the aorta proper.

In each of these forms the heart is very imperfectly developed; and those deviations which occur at the earliest periods are very rarely seen, and are only compatible with the maintenance of life for a very limited period. When the process of development has proceeded to a more advanced stage the heart is better fitted to maintain the double circulation, and life is sometimes much more prolonged, though the cases in which this occurs are very few in number.

In a fourth group of malformations the development of the heart has proceeded to a still more advanced stage; the auricles, ventricles, and vessels are complete, though the septa which should divide them may be imperfect. This imperfection is generally traceable to the existence of some impediment to the passage of the blood from the right ventricle into the pulmonary vessels, either caused by malformation of the valves of the pulmonary artery, by constriction at the fibrous zone to which the valves are attached, or at the end of the conus arteriosus or infundibular portion of the right ventricle, or by narrowing of the cavity of the ventricle at the commencement of the conus arteriosus, or at the point of union of the sinus of the ventricle with the infundibular portion.

Specimens displaying one or other of these forms of defect are contained in our Museum, and I have several in my own collection at the Victoria-park Hospital, and many similar instances are recorded; indeed, they are the most common forms of congenital defect in the heart. The subjects of these malformations do not generally survive more than some months or years, but occasionally patients live to the period of puberty or to early manhood or womanhood, and still more rarely to even more advanced ages. In a less frequent set of cases the defect at the pulmonic orifice is still greater, the aperture, and often also the trunk of the vessel, being indeed found entirely imperforate, the blood being generally conveyed to the lungs from the aorta through the ductus arteriosus. The septum of the ventricles also is imperfect, or the foramen ovale unclosed. Life, however, is in such cases generally of short duration, though some remarkable instances to the contrary are on record.

Closely allied in their effects to the malformations which have last been mentioned are those in which the impediment to the circulation is situated at one of the other cardiac orifices—the right auriculo-ventricular, the left auriculo-ventricular, or the aortic; and in some very rare instances these apertures are imperforate.

A very small number of cases are also on record in which the foramen ovale is found to have become more or less perfectly closed before birth. A case of the kind occurred in the practice of my friend Mr. E. Pye-Smith, and is described in the *Pathological Transactions*. The subjects of this defect only survive birth for a few hours, death probably resulting from the imperfect expansion of the lungs, from the free outlet for the blood into the descending aorta through the large ductus arteriosus. An analogous form of defect may also involve the ductus arteriosus; or at least that passage, if it be not prematurely obliterated, not unfrequently does not exist. With this condition the pulmonary artery is of small size, and cannot adequately expand to transmit the increased flow of blood which should pass to the lungs after birth, and so an impediment to the circulation is occasioned. The heart may in consequence be defectively developed, or the fœtal passages may remain open after birth.

The development of the primary vessels, the pulmonary artery and aorta, may be arrested or prevented at different periods of fœtal life, either alone or in conjunction with defects in the heart itself. Of the malformations of this kind the most remarkable is that in which the vessels are transposed, the pulmonary artery taking its origin from the left ventricle, and the aorta from the right. This irregularity was first described by Dr. Baillie, and the specimen which he figured is contained in the Museum of the Royal College of Physicians. In these cases either the septum of the ventricle must be imperfect, or the foramen ovale or ductus arteriosus open, and even with these conditions life is generally limited in duration to a few weeks or months, or at the most to two or three years.

In some cases the portion of the aorta between the origin of the left subclavian artery and the entrance of the ductus arteriosus is more or less constricted, and the supply of blood to the descending aorta is mainly transmitted through the ductus arteriosus. More aggravated instances of the same defects occur, in which the ascending aorta only furnishes the supply to the arteries of the head and upper extremities, and the descending aorta is simply a continuation of the ductus arteriosus. Two very interesting specimens exhibiting the slighter form of irregularity, which were formerly in Sir Astley Cooper's collection, and which have been described by Dr. Farre, are in our Museum; and there is also a specimen of the more extreme defect, which was described by Dr. Wade Hicks in the *Pathological Transactions*.

If in the former kind of cases the constriction be at the time of birth only slight, so as not to create any marked impediment to the circulation, the patient may survive for many years. The obstruction, however, may become gradually greater from the thickening and induration of the coats of the artery, and ultimately the canal may in this way become entirely impervious, or it may be completely obstructed by thrombosis, the circulation being carried on by the enlargement of the collateral vessels, and by their free anastomosis. Of this (as it has been termed) *quasi malformation* a considerable number of instances are on record, and our Museum contains one very interesting and beautiful specimen which was obtained from the body of a man which had been injected for dissection. The preparation is described by Mr. Sydney Jones in the *Pathological Transactions*. We have also a specimen exhibiting the same condition which occurred in the practice of Dr. Barker. The malformations which have just been mentioned must be ascribed to the faulty evolution of the pulmonary artery and aorta from the primitive arterial trunk and the branchial arches.

The malformations of the second class, or those which originate at the later periods of fœtal life, are chiefly irregularities in the number and connexions of the valves; but some of those which have before been described, though they probably generally occur at the earlier periods, may originate also at the later. This remark applies even to some of the more serious defects, such as the entire obliteration of the orifice of the pulmonary artery and the premature closure of the foramen ovale. Of the malformations of the valves may be named the blending together of two of the curtains of the semilunar valves, so as to leave only two distinct segments; or the three valves may be united so as to form a simple diaphragm, stretched across the orifice; or the folds of the tricuspid or mitral valves may be blended together. If at the time of birth the constriction of the orifices thus caused be great, one or both of the fœtal passages may be prevented from closing, and all the symptoms of a congenital cardiac defect will arise. Often, however, the malformation of the valves is not immediately a cause of impediment to the circulation, and the symptoms of disease only manifest themselves after the lapse of years, when the orifices and valves, being rigid and unyielding, do not expand with the progress of growth so as to admit of the increased circulation which is required, or when they have become the seat of disease in after life aggravating the original defect.

The more serious irregularities in the conformation of the heart are usually incompatible with the prolongation of life for any lengthened period, and are only seen in infants or young children, and do not therefore often occur in ordinary practice. However great, therefore, their scientific interest, they are not of much practical importance. The less marked imperfections, such as an obstructed pulmonic orifice, with the septum of the ventricles incomplete or the foramen ovale open, are, however, not unfrequently seen, and occasionally in persons of more advanced age. These conditions are generally readily recognisable. Not only does the commencement of the symptoms, if carefully investigated, generally date from early life—or at least there is a history of very prolonged indisposition,—but the actual state of the patient is very characteristic. There is usually very intense and peculiar lividity of the face and extremities, and a loud bellows-murmur is heard at the base of the heart, and is usually propagated in the course of the pulmonary artery, and must be regarded as proving the existence of some source of obstruction in that situation. Often, also, the murmur is heard very loudly in the course of the aorta, and if so, it is at least probable that the aorta communicates with both ventricles. Indeed, either the septum

of the ventricles is incomplete or the foramen ovale open in so large a proportion of cases that the supposition of their existence may fairly be hazarded.

We have not very long ago had two such cases in my own wards in the Hospital. In one of them a boy, 17 years of age, whose case is described in the pathological reports, and whose heart is in the Museum, the condition was correctly diagnosed during life. In the other, also in a boy of about the same age, the diagnosis of the case was sufficiently clear. He left the Hospital considerably benefited, and I have not since heard anything of him.

I have spoken of the lividity in these cases as being very intense and peculiar, and it is so much so as to have caused the terms *cyanosis*, *cyanopathia*, and *morbus cæruleus* to be given to the condition. There has also been considerable discussion as to the cause to which this discoloration is to be ascribed. Morgagni, in describing a case of stenosis of the pulmonary orifice with an open foramen ovale, which fell under his notice, ascribed the lividity to the excessive congestion which must have existed; while Dr. Hunter soon after, in relating a similar case, suggested that the intermixture of the venous and arterial currents of blood was probably the cause of the peculiar lividity. The former view has recently been maintained by M. Louis, while the latter has received the able support of Dr. Farre and M. Gintrac. There cannot, I think, be much doubt that the congestion which obtains in these cases is the essential cause of the cyanosis, for the intensity of the discoloration bears a direct reference to the amount of obstruction, while cyanosis may exist, even to a very marked extent, in cases in which no intermixture of the venous and arterial blood occurs. It is, however, probable that other circumstances influence the peculiar colour which the patients assume in some of these cases —such, for instance, as the long duration of congestion causing extreme dilatation of the small vessels, and the peculiar thinness and transparency of the integuments from imperfect nutrition. When, also, so small a portion of blood is exposed to the influence of the air, the whole mass must assume a very dark colour, and this must intensify the discoloration. It is a curious circumstance that pathologists for a long time almost entirely lost sight of the fact that the imperfection of the interventricular septum, the unclosed foramen ovale, and the open ductus arteriosus are simply the necessary results of the obstruction to the transmission of the blood from the right ventricle by the pulmonary arteries, and that these conditions must therefore be regarded as essentially conservative, and as alone affording the means by which extra-uterine life can often be maintained. This is the more remarkable as the true relation in which the abnormal openings stand to the primary source of obstruction was very clearly pointed out by some of the early observers. It has been thought that there is a special antagonism between the condition of the blood in cases of cyanosis and the tendency to the deposit of tubercle, and Rokitansky denied the possibility of cyanotic persons becoming tuberculous. This, however, is not correct. Cyanosis in the most intense form not unfrequently coexists with tuberculous depositions; and, indeed, if persons who have malformed hearts live for a sufficient length of time, they often die phthisical. It is, however, equally incorrect to assert, as has recently been done, that persons labouring under malformations of the heart almost always become phthisical. I have seen several exceptions to any such rule; and when the two conditions coexist I believe that the deposition of tubercle is not due, as has been asserted, to the irritation of the pulmonary tissue, but to the very defective nutrition which exists in such cases from the imperfect aëration of the blood.

FROM two to seven deaths daily occur from the yellow fever in Rio. In Monte Video the fever has abated.

FROM a statistical account issued by Dr. London, director of the lying-in hospital established at Jerusalem by the Baroness B. de Rothschild, we find that of the total number relieved 48 women were born in Jerusalem, 24 came originally from Russia, and 19 were born in various parts of Turkey. Some of the mothers were very youthful, 2 being but fifteen years old, 3 sixteen years of age, 5 seventeen years old, 9 of the age of eighteen, 4 of the age of nineteen, and 15 not beyond their twentieth year. The report embraces a period of one year.

ORIGINAL COMMUNICATIONS.

DEATH UNDER THE ADMINISTRATION OF METHYLENE ETHER.

By LAWSON TAIT, F.R.C.S.,
Surgeon to Birmingham and Midland Hospital for Women, and Consulting Surgeon to the West Bromwich Hospital.

S. S., AGED 62, admitted to the Hospital for Women under my care for large multilocular ovarian tumour. She had been in perfect and robust health until February last, when the tumour was noticed. There was no complication in the tumour save a cretaceous mass behind the uterus, quite free, and supposed to be either an old cyst degenerated or a calcareous fibroid. A systolic murmur at the base was recognised two days before the operation, but as it seemed to arise in the great vessels, and as no general signs accompanied it, and as there certainly was no valvular lesion, it was not considered of such importance as to form an objection to the proposed ovariotomy.

She was placed under the influence of methylene ether on June 28, about 11 a.m., by the resident medical officer, Dr. Louisa Atkins. She took the anæsthetic readily and quietly, and after five drachms had been administered she seemed so perfectly and satisfactorily unconscious that in a few seconds the operation would have been begun. Suddenly she seemed to be coming out of the anæsthesia, the urine passed out of the bladder, and the eyes opened. I noticed the pupils to be extremely dilated, and the pulse suddenly ceased. Some efforts at respiration were made, and a spasmodic effort as if the patient was about to vomit. Respiration then ceasing, it was carried on by Sylvester's method. Strong ammonia was applied under the nostrils, and a strong stimulant enema given. Other means, as rubbing the chest with a brush, dashing cold water over it, etc., were tried unavailingly. It was evident to the acting staff, who were all present, that failure of the heart was the initial part of the process of death.

The post-mortem examination was made within twenty-four hours, and revealed nothing to account for death. The heart was in such a condition as might be expected in a person of her age: the cavities contained a small quantity of dark blood, there being no difference apparent between the blood in the right and that in the left side. There was no atheroma in the aorta or in the coronary arteries, and the fibres of the heart were not fatty. All the valves were competent, and only in one cusp of the aortic valve was there one minute atheromatous plate, so small and even that it could have been of no consequence. The systolic murmur must therefore have been hæmic. The brain and all the other organs were healthy except the left ovary and a calcareous fibroid tumour pedunculated to the fundus uteri, which could easily have been removed, as it certainly would have been had the operation been performed.

The anæsthetic administered was a mixture of McFarlane and Co.'s anhydrous ether and Hearon, Squire, and Francis's bichloride of methylene, having a density of 1·1, according to Dr. B. W. Richardson's formula. I have now administered it over 200 times, and never with the slightest appearance of risk till the occurrence of this case. It has been frequently administered for my colleagues and for myself in hospital practice by Dr. Louisa Atkins, than whom I never saw a more competent and careful administrator. The day on which this fatal case occurred I gave it or had it given in five cases and in the following order:—

1. For the introduction of a stem pessary in my own consulting-room.
2. For the proposed ovariotomy in the case of S. S.
3. For version in a case of placenta prævia to which my friend Dr. Call Weddell, of Bloomsbury, had summoned me in consultation.
4. For the removal of an external hæmorrhoid.
5. For an examination and operation on a case of stricture of the rectum.

This is sufficient to show that I have by no means lost confidence in methylene ether, for it has great advantages over all other anæsthetics.

It would seem that it is not absolutely safe, though I am of opinion that S. S. would have died under any anæsthetic.

Sulphuric ether cannot be used to any extent where assistants are scarce; and to lay down rules to the end that no

anæsthetic should be given save in the presence of two or more qualified men, would be to limit the benefits of anæsthesia to a most unwarrantable extent.

Methylene ether is such a thoroughly manageable anæsthetic that I am quite certain, in spite of this fatal case, that it, or at least some anæsthetic safer, but as manageable, will come into general use. I am quite certain sulphuric ether will never be the anæsthetic of private practice.

I am not sanguine enough to believe that we shall ever get any agent which shall be absolutely free from risk; just as I am quite certain that numerous deaths occur from the use of ordinary drugs, the effects of which are much less tangible than those of anæsthetics.

One suggestion I should like to make to those engaged in studying the actions of anæsthetics—Should we not look to the state of the blood for an explanation of such cases as this? S. S. had a systolic murmur in the great vessels which must been hæmic. Was the state of her blood the cause of her death? If so, there were no external indications of anything wrong.

NOTE BY DR. B. W. RICHARDSON, F.R.S.

The case recorded above by Mr. Lawson Tait is the first fatal case under methylene ether. The agent had proved so safe under experimental trial, and, hitherto, so manageable, effective, and successful in practice, I had hoped it would have been found more free of evil than any other anæsthetic. It may still hold its place, by comparison, but the proof that it is not free of danger is incentive enough to new research. We must in all such painful positions simply submit to nature, and go on anew, avoiding specially the method of inventing foolish excuses for the agent, or the mode by which it was administered, and trying to extract out of the very calamities it has occasioned some useful lesson.

The case now before us, painful as it is, presents many features that should not be forgotten. *Imprimis*, it elucidated a fact I have for many years taught,—that there exists a small minority of persons who die under anæsthesia as if from some particular and unknown susceptibility to the influence of the narcotic vapours. I believe with Mr. Tait that his patient would have died under any anæsthetic that produces general insensibility. But what is the nature of this susceptibility? Is it a failure in one part of the organism, and always in the same part in all persons, or is it varied. Towards the elucidation of this problem not a single fact, however small it may be, should be overlooked. Mr. Tait's case again is valuable as conveying a fact: I refer to the anæmic condition of blood to which he has drawn attention. The capacity of blood for the absorption of anæsthetic vapours is modified by the density of blood. It will be worth while, in the future, to learn whether absorption under diseased states of blood may be so quickened as to be a cause of immediate danger.

NOTES ON

A CASE OF ANEURISM OF THE THORACIC AORTA,

THE SYMPTOMS AT THE COMMENCEMENT BEING VERY OBSCURE.

By W. I. H. LUSH, M.R.C.S.,

Associate of King's College, London, Resident Medical Officer to St. George's, Hanover-square, Dispensary.

W. F., aged 48, came under my notice on April 12. Had always enjoyed good health up to three weeks previous to the above date. He then for the first time complained of an occasional burning pain on the right side of the chest and back, and running down the arm. He ascribed it to rheumatism, and did not take much notice of it; but as it continued to increase he applied for advice. Patient was a healthy-looking man, but had rather an anxious expression of countenance. No history of syphilis, rheumatism, or of any injury to the chest. The superficial veins of the chest and neck on the right side were distended. He complained of slight cough and dyspnœa, which was increased on taking the least exertion. There was slight aphonia, but no dysphagia; no numbness or œdema of the extremities. On auscultation a distinct systolic bruit was detected, heard plainest two inches above and to the inner side of the right nipple. There was slight dulness on percussion, and pulsation could be felt in the second and third costal spaces. Cardiac sounds at apex normal; apex-beat in normal position. No perceptible difference in the radial pulses. Pulse 78, temperature 98·8°; no tracheal breathing; respiratory sounds normal; pupils equal; urine contained no albumen. He was placed on a nourishing diet, and ordered a mixture containing perchloride of iron and digitalis, and perfect quiet enjoined. As he complained of sleepless nights, chloral hydrate was ordered, commencing with grs. xv., and gradually increasing up to grs. xl. For the first few nights after taking the chloral he slept better, but after this it seemed rather to excite than to soothe him, so on April 25 the chloral was discontinued, and tinct. opii ℥xxx. given.

April 26.—Passed a better night after taking the tincture of opium than he had done for some time. The tinct. opii was gradually increased to ʒiss.

May 5.—Slight œdema of the arms and legs, and puffiness of the face. Cough very troublesome.

16th.—Œdema much increased. Dulness at both bases, and feeble breathing. From this point all the symptoms of obstruction to the circulation became more marked, and the aphonia complete. There was slight dysphagia towards the last, but the pupils remained normal.

He died on June 12.

Autopsy made thirty-six hours after death. I was assisted in the examination by my friend Mr. Charles Vipan. Body very œdematous. Thorax filled with serum. On attempting to remove the sternum it was found to be adherent to a large fusiform dilatation of the ascending portion of the aorta, the size of an orange, which pressed on the recurrent laryngeal nerve, and slightly on the œsophagus. On opening the aneurism it was seen to be filled with a large fibrinous clot stained with the colouring matter of the blood. The walls of the aneurism were covered with atheromatous deposit. The aortic valves were retracted and evidently incompetent. The other valves were normal. The lungs were œdematous, and on making a section of them a quantity of frothy mucus exuded. An examination of the other organs could not be made on account of the objection raised by the friends.

The above case may be of some interest, both on account of the obscure symptoms which it first presented, and also on account of its being one of the cases in which chloral not only failed to produce a sedative effect, but evidently after the first few doses caused increased excitability of the nervous system.

Chapel-street, Grosvenor-square, W.

CASE OF MALIGNANT FACIAL CARBUNCLE.

By FREDERICK IRVING DE LISLE, L.R.C.P.,

Physician to the St. Peter Port Hospital, Guernsey.

Although this case did not differ from others of its kind, yet the happily comparative rareness of this most fatal disease, and the insidious manner in which it commences, so apt to lead astray the unwary or overworked practitioner who sees it in its early stage, may render it interesting to the profession.

A. M. H, aged 19, an actress, about May 25 noticed a small pimple on the upper lip, which caused her some pain and uneasiness. This she scratched, and applied to it eau-de-Cologne, which caused it to smart intensely. On the 26th the pimple had enlarged and was accompanied by throbbing pain. Fearing lest the eau-de-Cologne should have poisoned it, she applied to Dr. F. E. Carey. Dr. Carey observed a good deal of induration about the base of the pimple. Patient had felt depressed and languid for some weeks, and from a bright lively girl had become lethargic in her habits, lying down the whole of the day, just rousing herself to go to the theatre for a rehearsal or a night's acting. During this time her appetite remained good. Ordered a mixture containing one grain of quinine in each dose. A dose to be taken three times a day.

May 27.—The induration had extended and the pain increased. The induration, pain, and swelling continued to increase until May 30, when Dr. Carey detected fluctuation. The part was lanced, and healthy-looking pus issued from the wound. On the evening of this day, as she felt herself getting worse, she was removed at her own request to the hospital, and was seen that evening by my colleague, Dr. Clifford Crewe. I took charge of the case on the morning of the 31st.

31st.—Upper lip greatly swollen and indurated; swelling extends over the whole of the left cheek and closes the left eye; a bright red blush extends all over the swollen part of the face.

Tongue furred, and breath excessively fetid. Is in great pain, and unable to sleep at night. Pulse 140, thin and compressible; temperature 103°. The whole appearance gives the impression of some great depressing cause having been at work. Patient is coherent in her answers, but has difficulty in speaking owing to the swelling of the lip, and does not answer immediately that she is spoken to, as if she required time to understand the question. Ordered—℞. Tinct. ferri perch. ℥x., liq. strych. ℥v., quinæ sulph. gr. j., every three hours. ℞. Pot. permang. ʒj., aquæ ℥xvj., m. ft. lot.; the broken part of the lip to be syringed out with it; a portion of it to be diluted with an equal quantity of water, and used for washing out the mouth. ℞. Chloral. hydrat. gr. xv., liq. morph. mur. ℥xv., aq. cinnam. ad ℥j.; to be taken at bedtime, and to be repeated two hours after if sleep is not induced. Milk, eggs, and wine *ad libitum*. Evening: Has wandered slightly during the day, and the swelling has increased. Does not seem to understand questions when put to her, but on their being repeated she answers coherently. Pulse 140; temperature 103·5°.

June 1.—Pulse 150; temperature 104°; skin hot and dry; a little crepitus heard at the base of both lungs. Slept at intervals during the night. Is quite delirious, and fancies she is in a gutter, and pleads most piteously to be lifted out. Noon: Low muttering delirium. Pulse 155. The swelling has extended to the submaxillary region on the left side, and is of a hard boggy character; it also invades to some extent the right cheek. Evening: Delirium is more violent; patient wishes to get out of bed, and is still under the impression that she is in a gutter; she succeeded in rising when the nurse was at the other end of the ward, and was with difficulty persuaded to return. After taking the night draught she became more composed, but did not sleep; towards the middle of the night the violence of the delirium returned. Pulse 160; temperature 104·5°.

2nd.—Pulse 170; temperature 105°; skin feels cooler, and somewhat clammy, notwithstanding the rise of temperature indicated by the thermometer. Patient lies on her back and picks at the bedclothes; is quite delirious, but now of a quiet kind. The amount of quinine in each dose of her mixture to be doubled. Noon: Pulse cannot be counted. Temperature cannot be taken, owing to the way patient throws her arms about. Patient refuses all food and medicine. Evening: Sinking fast; the symptoms at noon aggravated. Patient slips down off the pillow, and is constantly obliged to be raised. No urine has passed since last night. I introduced a catheter into the bladder, but no urine had been secreted.

3rd.—Died at 7 a.m.

It is probable that in this case death was caused by septicæmia and exhaustion. Although there was no rigor to mark the former, yet I believe that the suppression of the urine was due to blood poisoning. As it is advised to push quinine in these cases until cinchonism is produced, it may be thought by some that the dose of quinine prescribed was wretchedly inadequate; it is therefore necessary to state that, owing to some peculiarity in the climate of this island or other cause, large doses of quinine are badly borne. I have seen well-marked cinchonism even with a very small dose of the drug. My reason for combining perchloride of iron and strychnine with the quinine is the well-known powerful tonic and antiseptic properties possessed by this salt of steel, and the beneficial effects of this alkaloid when administered in cases of depressed nervous energy.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GUY'S HOSPITAL.

AMPUTATION THROUGH SHOULDER-JOINT.

(Under the care of Mr. DURHAM.)

[For notes we were indebted to the dresser, Mr. Lungley, who, it will be remembered, was killed on board the emigrant ship *North Star*, while honourably and bravely employed in the exercise of his profession.]

John W., tram-car driver, aged 42, a strong, healthy-looking man, was thrown from his seat by the slipping of the drag-handle, two of the wheels of the car passing over his right arm, causing a compound comminuted fracture of radius, ulna, and humerus, as high as the middle of the deltoid, which was much lacerated.

On admission (August 9) the patient was in a state of collapse. Recovering from this, Mr. Durham amputated, about four hours from the time of the receipt of injury. On examining the arm whilst the patient was under chloroform, it was found to be completely crushed from wrist to shoulder, and no radial pulsation was perceptible. A key tourniquet having been applied to the subclavian, Mr. Durham made an anterior flap, preserving as much of the deltoid muscle as was uninjured. He then dissected down to the axillary artery, and, passing a ligature round it, drew it out of the way. The joint was next disarticulated, and in doing this the pectoral muscles escaped from the wound, having apparently been torn through by the wheels, the edges being as clean as though severed by the knife. A full posterior flap was then made, and the vessels twisted, including the axillary, after removal of the ligature previously applied. There was but little loss of blood during the operation. The edges were then brought together by continuous suture, and the flaps supported by broad pieces of strapping, and dressed with carbolic oil.

10th.—Slept but little during the night, and complains of great pain, which he refers to the injured hand, not yet realising that his arm had been amputated. Pulse 120; temperature 103·5°.

11th.—Slept fairly well last night, after subcutaneous injection of morphia; less pain. Pulse 110, full; respiration 40; temperature 103°.

12th.—Dressing removed. Healthy discharge from posterior corner of incision; the whole wound, with exception of half an inch in this position, having healed by first intention. Suture removed. Pulse 100; temperature 101·8°; respiration 38.

14th.—The aperture at posterior corner all but healed up, but, the discharge not escaping freely, a small incision was made, and a drainage-tube inserted, passing about three inches in direction from the axillary border of scapula towards glenoid cavity.

15th to 27th.—The wound still freely discharges healthy pus; syringed out daily. Patient eats and sleeps well. Temperature normal.

29th.—Patient has had rigors and sickness. Erysipelatous blush over whole shoulder. Administered an emetic—pil. col. c. cal. gr. x. Temperature 101°.

30th.—Patient feels much better. Redness disappeared. Temperature nearly normal.

From this time he continued steadily to improve, the sinus gradually healing up, until October 15, when he was sent to Bognor, the wound being entirely healed and the patient restored to health.

ABSCESS ON OUTER SIDE OF THIGH (PERIOSTEAL)—RECOVERY.

R. L., aged 12, was admitted into Guy's Hospital on July 20, 1872. While running in the street she fell and struck her hip against the stones; she was able to walk home. Two days afterwards she felt great pain down her thigh, so that she could not walk, and was obliged to take to her bed. She was in bed a week, but finding the pain to be much increased she was brought into the Hospital.

On Admission.—Patient is a very unhealthy-looking child, very thin, and quite tubercular in appearance, fingers slightly clubbed. Has no cough and does not expectorate. Upper part of right chest dull on percussion, and crepitation is to be heard. Some sordes about mouth; tongue clean. The right thigh is considerably swollen and very painful on pressure, so that she cries out directly it is touched. The swelling extends from the knee to the great trochanter. There is no redness in the part, but considerable heat. There is decided fluctuation. There has been no shivering. Pulse 100; temperature 98·9°.

A fortnight after admission, chloroform being administered, an incision was made about four inches long on the outer part of the thigh, under the carbolic acid spray. About a pint and a half of moderately healthy pus escaped. No bare bone could be detected, but it had a peculiar nodular feel. The cavity extended to the great trochanter. Carbolised gauze was placed over the wound, and oil silk over that. Two days later the dressing was removed for the first time; very little discharge was found. Patient's health was much improved. From this time a rapid recovery ensued.

SPINDLE-CELL SARCOMA OF THIGH—REMOVAL.

(Under the care of Mr. DURHAM.)

[For notes we are indebted to the courtesy of Dr. Goodhart, the Registrar.]

T. E., aged 20, labourer, of Gravesend, admitted May 30, 1873. The family history of the patient is good. He has never had any previous disease. Five years ago he was kicked by a horse on the outer side of the right thigh, but this caused him no pain. He was able to walk quite freely till about two years ago, when he first noticed a small swelling in the position in which he had been kicked. Gradually enlarging at first, it has been rapidly growing during the last two months.

When admitted he looked spare, but not unhealthy. On the right thigh is a large swelling, of irregular shape on the outer aspect, and lobulated at the lower part. It is evidently under the vastus externus, so that from the tumour a tendinous ridge may be felt running down to the outer part of the knee-joint. It moves, but not freely, on the bone, and is apparently bound down by the fascial structures. No enlargement of the glands in the groin.

Mr. Durham made a long vertical incision on the outer side of the thigh and exposed the mass. He then enlarged the original cut by two transverse ones, so as to convert the incision into a crucial one. The tumour was then quickly exposed and found to push outwards the vastus externus and protrude from underneath it. The muscle was cut through and the growth dissected out by turning it up from below. The incision was then closed by sutures, except its posterior arm.

The growth consisted of small spindle cells with an immense number of free oval nuclei. It belonged to the type of spindle-cell sarcomata.

With this growth, and attached to it, was removed a piece of the vastus externus muscle. The portion of muscle excised had its longest measurement in the direction of the axis of the muscle, and it was interesting to witness the irritability and contractility of its fibres. As the tumour was being sent round for inspection, it was seen that the muscle was in a state of active and forcible spasmodic movement, which reminded one of the spasmodic movements of choreic patients. We had the opportunity of watching this for forty-nine minutes, and at the end of that time the spasmodic contractions were still going on almost as vigorously as when first noticed. How much longer they continued we have not been able to ascertain, but the fact seems worth recording.

TUMOUR OF SUPERIOR MAXILLA.

(Under the care of Mr. DURHAM.)

John F., aged 49, labourer, was admitted May 20, 1873. Family history good; a healthy man. About fourteen years ago he was very much troubled with bad gumboils from carious teeth, and they used to discharge freely. Thirteen weeks ago he had a slight cold, and noticed a swelling on the right side of his face, which has gradually increased in size since.

On Admission.—The patient is a wasted man; his face is distorted by a tumour, which pushes forward the cheek on the right side and the corner of the mouth. On looking into the mouth a mass is to be seen on the outer side of the alveolar process of the upper jaw, between the gum and the cheek. The surface is ulcerated, and extends from the right canine backwards to about the site of second molar. The only teeth present on this side are one incisor, one bicuspid, and the canine. The surface of the tumour is hard and nodulated, but no shell of thin bone can be felt over it.

June 10.—Mr. Durham operated. An incision was made from the inner angle of the eye downwards by side of the nose through right nostril and through upper lip in the median line. A second was next carried from the angle of the mouth upwards into a curve (whose concavity was upwards) for two inches. Free bleeding occurred, which was arrested by twisting. The flap thus made was dissected up, a tooth withdrawn, and the nasal process of superior maxilla divided with bone-forceps. The palatine process was then divided in a similar manner, one blade being in the nostril, the other in the mouth. The molar process was divided by the saw. The bone and growth were then turned outwards. Several ragged fragments were next removed by the forceps, and, as the growth appeared to invade the palate, a fresh section of bone was taken away by the saw further to the left, close to the septum. Some bleeding still continuing, it was stopped by the hot iron, and the soft parts were then adapted by sutures.

The microscopic nature of the growth has not as yet been ascertained.

EDINBURGH ROYAL INFIRMARY.

PERIMETRITIS POST-PARTUM.

(Under the care of Dr. MATTHEWS DUNCAN.)

[Reported by Dr. J. R. HARDIE.]

J. M., AGED 24, unmarried, was admitted to Ward XVI. of the Royal Infirmary on April 9, 1873, complaining of pain in the lower part of the back in the left iliac, hypogastric, and epigastric regions.

Patient was delivered eleven weeks ago, and was progressing favourably until about seven weeks ago, when, after going out, the pain complained of commenced. The pain was first noticed in the left side and lower part of the belly. She has had rigors and occasional sweatings. Temperature 101·6°; pulse 108.

Physical Examination (April 11).—The lower half of the belly, or, more exactly, all below a line joining the crests of the ilia, is occupied by hardness, greatest and most prominent in the middle. It is everywhere dense and tender to the touch; dull on superficial percussion, but slightly resonant on deep percussion. On introducing the finger into the vagina, the cervix uteri is found to be nearly in its natural position. The cavity of the true pelvis is observed to be unoccupied, except at its upper margin on the left side, where there is a little hardness prominent from above. It is slightly tender, and on bi-manual examination is identified with the external hardness, and presents a doubtful feeling of fluid. The rest of the plane of the pelvic brim presents fulness and tightness, but no marked hardness. The uterus is fixed, and on introducing the probe it is found to be of natural length, but displaced a little forwards. No parametric induration is felt in the pelvis or groins. Poultices were ordered to be applied over the seat of abdominal swelling, and one half-grain of opium to be administered when pain is troublesome.

Progress of Case.—April 26, temperature 100°, pulse 90; 27th, temperature 99·8°, pulse 102; 28th, temperature 99°, pulse 102. The hardness now extends only as high as to a line joining the anterior superior spinous processes of the ilia, and appears to be further diminished at either end of this line. April 29: Temperature 99·5°; pulse 76. May 19: Belly appears natural to the touch. On examination per vaginam there are discovered signs of numerous adhesions at the brim of the pelvis, and also especially a mass of hardness on the left side of the uterus, which is evidently connected with the left ovary. The whole of the organs in the brim of the pelvis are easily displaceable, and almost mobile. 30th: The swelling formerly described on the left side of the uterus cannot now be made out. The pelvic viscera are now movable. Patient has now a healthy look; body well nourished; and she says that she feels quite well. Sent to convalescent hospital.

This was a very simple and characteristic case of perimetritis post-partum, without suppuration anywhere. The perimetritis was extensive, involving the lower packet of small intestine. Neither symptoms nor signs indicated the presence of suppuration, the inflammation being only everywhere adhesive. The rapid disappearance of the hardness and adhesions is noteworthy. There are grounds for believing that early in the disease there was an attack of ovaritis. The pain began in the left groin, and was always severest there. There could always be felt in the region of the left ovary a tender hardness, which as the adhesions disappeared could be identified as this gland. The adhesions about it were the last to disappear, and when they did so the gland could be no longer made out by any kind of examination.

WE much regret to learn that on the evening of Thursday week, the 19th inst., Dr. Robert Law, King's Professor of the Institutes of Medicine in the School of Physic in Ireland, was suddenly attacked with right hemiplegia. The latest accounts are somewhat favourable, the patient being quite conscious, and not losing ground in any way.

"DEDUCTING," says the *Iron*, "railway servants and suicides, the railway system of the United Kingdom costs about 900 lives per annum, out of a passenger traffic of 375,000,000; while, taking an average of the last four years, 122 persons are killed annually by accidents in the London streets."

SATURDAY, JULY 5, 1873.

"A FREE BREAKFAST-TABLE."

A popular cry, professedly in the interests of the labouring and poorer classes, is "A Free Breakfast-Table"; and members of Parliament who wish to win the favour and praise of the masses adopt this cry as a valuable help towards their ambition, professing to see in it something of a principle to be accepted by the Legislature, calculated to confer a great boon upon those classes considered least able to bear taxation. Now, we might examine this cry, or the principle contained in it, from a political point of view, and we believe could show that the classes in question have no just claim for exemption from the incidence of indirect taxation—which is really the only form of taxation that reaches them,—and that their relief from such taxation beyond the point already reached would throw an unfair burden on the income-tax-paying portion of the community. We might further show that the reduction of duty upon various articles of consumption—as, for example, sugar,—although involving a great loss to the revenue of the kingdom and the necessary retention of an income-tax, gives no tangible relief or benefit to the purchasers of the commodity by a corresponding reduction of its price, inasmuch as the amount remitted in duty is intercepted and pocketed by the class of middle-men who intervene between the producer and the consumer.

However, leaving such political discussions to politicians, we would examine the reasonableness of the cry from a hygienic point of view, and in the first place would ask its advocates whether they have duly apprehended its meaning and worth? To demand a "free breakfast-table" is simply to ask for the entire remission of the duty on tea, coffee, and sugar; the other usual accessories to the breakfast-table—bread, butter, bacon, and eggs—are to all practical purposes free. We have, therefore, only the question to answer, whether the making tea, coffee, and sugar—particularly the first, for coffee is comparatively sparingly used, and sugar is already sufficiently cheapened for all domestic purposes—free commodities will be advantageous to the popularly styled "working classes." Our reply is that such a course would not be so; and that when the vast sacrifice of revenue it would involve is taken into account it would be unjustifiable.

The saving to the classes in question accruing from the reductions of duty already carried into effect is not proportionate to that reduction. Its advantages have been principally reaped by the dealers, whilst the increased demand for the articles has fostered adulteration, and introduced into existence compounds under the name of tea, disgusting in character and deleterious in their effects. Before the duty was lessened tea was a much more genuine article than now, and its consumers had the benefits derivable from its use from smaller supplies, and consequently at not much greater cost than at the present day of cheapness and nastiness.

But, apart from such considerations, we hold that tea-drinking should not be encouraged. The teetotalers are urgent in their endeavours to restrict the sale and use of alcoholic liquors, on the plea of their detriment to the health of the nation; and to the same one-sided enthusiasts we may attribute much of the strength of the cry for the remission of the tea duty. On the medical side we contend against excessive tea-drinking as injurious to the public health, and, although without advocating the evil policy of restriction of trade in articles of diet, we raise our voice against measures calculated to increase the evil we deprecate.

No medical man of experience and observation among the poorer classes of society can fail to be impressed with the lack they display of knowledge how to feed themselves. Cookery is an almost unknown art among them, and when attempted is an exhibition of wastefulness. The men generally so take care of themselves as to secure more or less animal food, towards which also they have, as a rule, more avidity and taste than the women, and are vastly indifferent to its culinary preparation. The wives, from natural instincts and from more sedentary occupations, care less for such food, and too often shirk the trouble of cooking from sheer indolence; and their growing tendency for years has been to rely more and more upon a tea and bread-and-butter diet. This diet, too, they enforce upon their children; and no one acquainted with the elements of food necessary to health can fail to recognise that it is an insufficient diet. It is not, therefore, to be marvelled that medical men are now becoming acquainted with its evil results, and exposing them. The wonder is that protests against such feeding have not been heard earlier; but since the counter-blast to excessive tea-drinking raised by Dr. Arlidge nearly two years ago, many physicians have followed in his wake, and exposed the evils of the favourite diet of females of the lower strata of society. At the time some literary periodicals made merry at the idea of the ills of tea-tippling, but the experience of the profession was against them.

Although various communications have reached us on the subject, we have chiefly been led to write on it from remarks occurring in the recently issued Parliamentary report on the hours of labour in factories, which puts prominently forward the ill results accruing from the wide-spread use of the insufficient diet in question. The Commissioners, Dr. Bridges and Mr. Holmes, put sundry questions to the medical men practising in textile factory districts respecting the health of the operatives, the diseases prevalent among them, and their causes. In reply to those questions, the interrogated doctors referred to the prevalence of digestive derangements of an obstinate form, consequent mainly "on the eating and drinking of easily prepared foods, as bread, tea, and coffee, and the neglect of meat and fresh-cooked vegetables."

Distinct individual testimony to the pernicious results on children and adults of this defective diet is borne by Alderman Ferguson, of Bolton, a factory surgeon of wide experience, and by Dr. H. Browne, of Manchester; and the Commissioners

observe, generally, that dyspepsia is one of the most prevalent diseases among the factory operatives, and is attributable to the excessive use of tea.

Defective nourishment, with its attendant dyspepsia, must sap the vitality of the body, and provoke early degeneration and decay. In other words, a population underfed is one that must deteriorate physically and degenerate; and if it be a duty of a Government to restrict or deter from the use of unwholesome food or beverage of any one sort, it must also be so with regard to any other. In fine, the policy of a "free breakfast-table" brings no benefit to the classes in whose interests it is advocated, but encourages the extension of a mode of living inimical to the health of the country. It would be well, indeed, for the poorer population if they could be induced to return to the dietary of their forefathers, and replace the bread-and-butter and tea by meal and milk, and supplement these articles by a modicum of soup, in the use and preparation of which they might get most valuable instruction from abroad.

THE JUDGMENTS OF THE SCOTCH JUDGES ON THE MEDICAL WOMEN QUESTION.

On Friday, the 27th inst., the four judges of the Second Division of the Court of Session gave their decision in the ase of Jex Blake and others *v.* the Chancellor and Senatus of the University of Edinburgh. By a majority of three to one the interlocutor of Lord Gifford was reversed, and the plaintiffs were ordered to pay the costs of the defendants. Previously to giving their opinion the judges formally consulted the other members of the Scottish Bench. It is believed there will be no appeal from this decision.

In a lucid statement by Lord Cowan of the rights demanded in this action, and of the grounds upon which the judges have unanimously given an adverse decision as to the more important points, we find that the plaintiffs demanded as a legal right that women be admitted as students to the classes of any professor in the University on precisely the same footing as male students; that they are therefore entitled to study and graduate in Medicine in the University; and that the medical professors are bound to instruct women either in separate or in mixed classes. On this general question of legal right Lord Cowan did not think it necessary to dwell, "seeing that all the consulted judges without exception had returned opinions to the effect that the legal rights asserted by the pursuers [or plaintiffs] could not be maintained or enforced, irrespective of the regulations adopted by the University Court." In that view Lords Cowan, Neaves, and Benholm concurred. The Lord Justice Clerk (Moncrieff), who, as Rector of the University, was President of the University Court when the regulations were adopted, is also of opinion that "the contention of the pursuers that females were entitled to the same University privileges as males was a hopeless one, against which usage was conclusive." Lord Gifford, too, who in his enthusiastic interlocutor in favour of the ladies, and against which the Senatus appealed, most unquestionably declared his conviction that *vir* in the charters included *fœmina*, just as the word "horse" includes mares, now, in a new opinion, confesses that he was in error. Apart from the regulations, and independently thereof, he is of "opinion that the ladies could not, as a matter of right, demand admission as students into the University." Had, then, the University Court the power to confer this legal right, as regards the Faculty of Medicine? Lord Cowan and the majority of the judges are clearly of opinion that it has no such power, and that the regulations by which the professors were "permitted" to give instruction in Medicine to women were not only beyond the powers of the Court, but were a manifest encroachment on those of the Crown and Parliament. But in so far as the minority of the judges are of opinion that the University Court had this power of permission, nothing is really gained for the medical women, because they are equally of opinion that neither the Court nor the Senatus can compel the professors to instruct women, either in separate or mixed classes. All that is alleged in their favour by the minority of the judges, is that the medical professors may teach women if they please, and that if they do so teach they must also examine for graduation. But the minority do not say that the University Court has the same power as regards other Faculties. In short, a clear judicial deliverance is wanting in all their opinions, and sentimental discussions predominate. On the other hand, the opinions of the majority are lucid statements of the law. We would especially mention that of Lord Ormidale, and referred to by Lord Cowan.

It is to be hoped that the experience the medical professors have had of the "lady" students will serve as a warning to them to abide by the law so lucidly laid down, and that for the future none of them will coquette illegally with the "ladies," however mature, persuasive, or attractive the applicants may be.

THE NEW ARMY MEDICAL WARRANT.

We have received at different times reports of meetings of army medical officers held at the camps of Aldershot and the Curragh, the object being to discuss the new Medical Warrant, and to elicit the opinions of the Service as to the desirability of memorialising the Secretary of State for War, with a view to obtaining an alteration in those clauses which are so manifestly unjust to gentlemen holding commissions in the Army Medical Department. It is not necessary to give *in extenso* the proceedings of these meetings, for the simple reason that we have already, on numberless occasions, placed before our readers a complete list of those grievances which the new Warrant has entailed upon members of the profession doing duty with the army. The salient points are now so well known that it is needless to repeat them; suffice it to say that upon each of the occasions above alluded to a "round robin" was drawn up, signed, and forwarded to the head of the Department, praying for a reconsideration of the obnoxious clauses. Further, we have heard of other meetings for the same purpose at different stations both at home and abroad, and we cannot but think that Mr. Cardwell will by this time have realised the great fact that the discontent with his new legislation for the Medical Department is not simply the expression of feeling on the part of a dissatisfied clique, but rather the forcible protest of a whole body of gentlemen, who feel that their interests have been most unjustly sacrificed to the spirit of parsimony which has pervaded most of the acts, in relation to the medical services, of the present Government. As a matter of fair reasoning and common sense it has always hitherto been the received idea that no alterations should affect men already in the Service to their disadvantage; yet here, upon the debated points, the whole body of medical officers are deprived of advantages which some of them have enjoyed for a period of thirty years. And the policy (if policy it can be called) of such a proceeding is manifestly short-sighted: the small amount which will be saved to the country by the abolition of the forage allowance will be largely exceeded, if the authorities at the War Office refuse to acknowledge their error, by the difficulty which will ensue in obtaining recruits for the Service. The sister island came to the rescue of Pall-mall upon a former occasion; but if the protests of its leading colleges upon the new Warrant are sincere—and of this there is no doubt—Mr. Cardwell must not look in the same direction for assistance to enable him again to coerce the Medical Department.

In conclusion, we would hint to the gentlemen concerned

that no agitation is so powerful or carries so much weight as that which is heard within the walls of St. Stephen's. Meetings such as we have now recorded are useful as instances of universal feeling, but we doubt if the influence they exert on the authorities is very powerful. When an honourable member rises in his place to catechise the Secretary of State for War touching the existing dissatisfaction in the medical corps, fresh evidence is brought to that worthy official's mind that the body for which he has just (in some instances) so unsatisfactorily legislated are possessed of potent friends and well-wishers who are not disposed to stand by and allow them to be wrongfully entreated.

THE WEEK.

TOPICS OF THE DAY.

We have the pleasure of publishing this week the first half of Professor Rolleston's most able and valuable Harveian Oration. Professor Rolleston's Oration fulfils two objects—one is, it gives an account of recent advances which have been made in the anatomy and physiology of the circulation, thus illustrating the fame and reputation of the great discoverer who made such advances possible; and secondly, he has vindicated the claims of Harvey against one of the many persons—Walter Warner, the mathematician—who have been said to have anticipated the discovery of the circulation. Professor Rolleston completely disposed of Warner's claims by reading passages from his MSS. found in the library of the British Museum. The announcement of Professor Rolleston's discovery of the moderator-band in the heart of the Australian cassowary—a band existing in the hearts of Ungulates and in a rudimentary state in the human heart—greatly enhanced the scientific value of the Oration, which, whether as a scientific or literary production, has scarcely been surpassed by former Harveian Orators.

The Royal Colleges of Physicians and Surgeons of Edinburgh some weeks ago presented to the House of Commons a statement of reasons against Mr. Headlam's Bill for amendment of the Medical Acts. This statement is now before us. As there is not the slightest chance of Mr. Headlam's or any other Medical Reform Bill being heard of until a new Parliament has been elected, we do not think it necessary to print the very able statement of the Colleges *in extenso*. Most of their arguments have appeared in some form or other, and have frequently been discussed in our own columns. We think that if the Scotch bodies are determined to oppose—and up to a certain point we believe they are capable of opposing effectually—the cry for fresh medical legislation, they have only to do one thing, that is, raise the standard of examination for the licences of the Scottish Corporations, and thus deprive their opponents of the strongest reason for urging the necessity for a change.

The Edinburgh Royal College of Surgeons has addressed a memorial to the Director-General of the Army Medical Department in reference to the new Army Warrant, which we publish in another column. It seems to us that the memorial should rather have been addressed to Mr. Cardwell, who is the party really responsible for the defects of the Warrant.

A second application from the Ladies' Association for the Promotion of the Medical Education of Women to the Council of Queen's College, Birmingham, for the admission of women to the medical classes has met with a second rebuff. The *Birmingham Daily Post* reports that a counter-memorial, signed by forty out of the fifty male medical students, was presented at the sitting of the Council at which the ladies' petition was received, expressing the desire of those who signed it that women might not be admitted to the classes. After due consideration and discussion, on the motion of Canon Wilkinson, seconded by Professor Clay, the following resolution was agreed to, *nem. con.*:—

"That this Council, having fully considered the subject of the admission of female students to the medical department of this College, begs to refer the Ladies' Committee for the Education of Women for the Medical Profession to a resolution already passed by this Council, as follows:—'The Council, whilst fully recognising the right of women to occupy any field of employment for which they may deem themselves qualified, and desirous to afford any facilities in its power towards the higher education of women, considers that it cannot, under existing arrangements, conveniently admit female students to any of its departments, and is not prepared, at present, to make such alterations as the admission of female students would require.' The Council still regards the practical difficulties in the way of complying with the request made to them as insuperable, and regrets that it cannot further entertain the question at present."

We congratulate the professors and medical students of Birmingham on the wise stand the Council has made in this matter. In the present state of affairs in Edinburgh and Birmingham, and after the strong expression of opinion that has been drawn from the Scottish Bench as to the impropriety of mixed classes, we should hope that if women are still determined to attempt as a profession the practice of Medicine—a calling for which we have still to be convinced that they are physically or mentally fitted,—we say we hope they will see the necessity of obtaining a medical school and an examining board of their own. As long as modesty and decency are valued in England they will never be allowed to participate in the education provided for male practitioners.

Lord Ettrick has done well to call the attention of the Government to the frightful sacrifice of human life in India—amounting to 4000 annually—by tigers and snakes. A correspondent of the *Times* suggests strychnia for the tigers, which has been found so useful in clearing the Australian settlements of prairie dogs. For snakes in India the offer of a sufficiently tempting reward is no doubt the best remedy. Dr. Fayrer, in the "Thanatophidia of India," proves that the natives will readily adopt snake-killing as a means of living if it be sufficiently paid. In the same work there are some valuable hints about the use of carbolic acid and tar in keeping deadly snakes at a distance.

We have the pleasure of recording that her Majesty the Queen has recently conferred the honour of knighthood on two members of our profession. On June 26 Dr. Alexander Nisbet, Honorary Physician to her Majesty, and Inspector-General of Hospitals and Fleets, received that honour; and on the 30th of last month the Queen conferred knighthood upon Dr. Joseph Ritchie Lyon Dickson, Physician to her Majesty's Legation in Persia, who is in attendance on the Shah. Sir Joseph Dickson is the second son of the late Mr. John Dickson, R.N., of Dalkeith, surgeon to Lord Nelson at the siege of Copenhagen, afterwards appointed by the British Government Surgeon-Major and Chief of the Medical Staff of his Highness the Hereditary Pasha of the Regency of Tripoli, at the request of his Highness and on the recommendation of Lord Nelson. In 1847 Sir Joseph was appointed Physician to her Majesty's Legation in Persia, and in 1849 was called to attend the King for typhus fever during the absence of his Majesty's body physician, and received the Commander's Star of the Lion and Sun in acknowledgment for his successful attendance. The Shah requested the British Government to attach Sir Joseph to his staff on the occasion of his Majesty's visit to Europe. Sir Joseph's elder brother is Physician to her Majesty's Embassy in Constantinople.

The letter in the *Times* last week signed "George Burrows, M.D., Physician-Extraordinary to the Queen," and warning tourists against an outbreak of small-pox in the Bernese Oberland, turns out to be a forgery. Dr. Burrows disclaimed any

knowledge of it in the *Times* of Friday last week. In the same paper of Thursday last is a letter from the Agent and Consul-General for the Swiss Confederation, in which it is asserted that there has not been a single case of small-pox in the district, and that there had been but one case of small-pox in the whole Canton during the present year, and that was in a district far removed from Thun, Interlacken, and the Bernese Oberland. The author of such a stupid and mischievous hoax should be sent to spend the holidays in an empty small-pox hospital as a punishment.

THE ELECTION INTO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

The annual election of Fellows into the Council of the College took place yesterday, the 3rd inst., and rarely has there been so much interest excited in the Profession—partly, perhaps, owing to the unusual number of candidates for the four vacancies caused by the resignation of Mr. Charles Hawkins, and by the retirement in the prescribed order of Mr. Richard Quain, Mr. Thomas Turner, and Sir James Paget. The last-named gentleman, however, again offered himself, and was deservedly re-elected, being returned at the head of the poll. The candidates, originally nine in number, but reduced to eight by the retirement from the contest of Mr. Thomas Wakley, were, taking them in chronological order, Messrs. Francis Hird, of the Charing-cross Hospital; Haynes Walton, of St. Mary's Hospital; John Cooper Forster, of Guy's Hospital; Edward Law Hussey, of the Radcliffe Infirmary, Oxford; John Marshall, F.R.S., of University College Hospital; William Scovell Savory, F.R.S., of St. Bartholomew's Hospital; and George Southam, of the Manchester Royal Infirmary. Messrs. Walton, Forster, Marshall, and Savory are Fellows by examination, and Messrs. Marshall and Savory are members of the Court of Examiners. Punctual to the hour appointed (two o'clock) Mr. Hancock, the President, accompanied by the Vice-Presidents, Messrs. Curling and Clark, entered the library, where the election took place, and explained to the Fellows the mode of election, which was by ballot. The voting then commenced, and was not brought to a close until five o'clock, when the scrutiny commenced, and at its close the President declared that the choice of the Fellows had fallen on Sir James Paget, Bart., and on Messrs. Haynes Walton, George Southam, and John Marshall. The numbers polled by the candidates were as follows:—

Sir James Paget . .	200,	including	1 plumper.
Mr. Haynes Walton . .	136	,,	25 plumpers.
Mr. George Southam . .	113	,,	13 ,,
Mr. John Marshall . .	106	,,	5 ,,
Mr. John Cooper Forster .	105	,,	4 ,,
Mr. William Scovell Savory	97	,,	1 ,,
Mr. Francis Hird . .	62	,,	5 ,,
Mr. Edward Law Hussey .	29	,,	0 ,,

In the evening the Fellows dined, as usual, at the Albion Tavern, under the presidency of Professor Humphry, M.D. A large number of country Fellows attended the election, amongst whom we noticed Dr. Harris, of Redruth; Messrs. Southam, Blackmore, Mellor, Railton, Woodcock, of Manchester; Husband, of York; Mathias, of Stockport; Sir J. C. Burrows, of Brighton; Messrs. Harrison, Stubbs, McCheane, Walker, of Liverpool; Cattlin, Rugg, Morgan, of Brighton; and Messrs. Baker, Bartleet, Savage, and Thomas, from Birmingham.

NEW EXAMINERS AT THE ROYAL COLLEGE OF SURGEONS.

At a special meeting of the Council of the Royal College of Surgeons on the 1st inst., to elect two members of the Court of Examiners in the vacancies occasioned by the decease of Mr. Richard Partridge, of King's College, and by the completion of his five years' term of office by Mr. Samuel A. Lane, of St. Mary's Hospital, the choice of the Council fell on Mr. John Marshall, F.R.S., Surgeon to University College, and Professor of Anatomy in the Royal Academy of Arts, for the first-named vacancy; and on Mr. Timothy Holmes, Surgeon to St. George's Hospital, and Hunterian Professor of Surgery and Pathology in the College of Surgeons, for the second vacancy.

THE ANNUAL REPORT ON THE ARMY MEDICAL DEPARTMENT FOR THE YEAR 1871.

The annual Blue-book containing the Report on the Army Medical Department for the year 1871 has just been published. This, the thirteenth volume, is not quite so bulky as its predecessors, but contains a large amount of information compiled by various medical officers belonging to the army. It commences as usual with a statistical account of the health of the troops serving in the United Kingdom during the year referred to, from which we gather that, compared with the results for 1870, there has been a very slight increase in the admissions to hospital and mean daily sick, but a decrease in the deaths. They have all, however, been considerably under the average of the last ten years.

The average strength of non-commissioned officers and men doing duty in the United Kingdom during the year 1871 was 92,667. The admissions into hospital from this force amounted to 75,641, the deaths to 764, and the average constantly non-effective from sickness to 3594. The admissions, therefore, were in the ratio of 816, the deaths of 8·24, and the mean daily sick of 38·78 per 1000 of mean strength. The death-rate thus shown gives a decrease of ·87 per 1000 as regards the preceding year.

A carefully prepared table shows the influence of the different classes of diseases in causing the sickness and mortality, from which it will be seen that there has been a decrease in the ratio of admissions by both groups of general diseases, and in that of the deaths also by the constitutional group. This reduction in admissions has been to some extent counterbalanced by an increase in diseases of the urinary and cutaneous systems, and in accidental injuries. The fluctuations in the other classes of diseases has been very slight.

Eruptive fevers were much more prevalent than in 1870 at all the groups of stations except the camps, the excess being mostly due to small-pox, which prevailed so generally throughout the year as an epidemic among the civil population. The troops in camp did not escape it; but there was a reduction in admissions by eruptive fevers compared with the preceding year, chiefly from the abatement of measles and scarlet fever. There were altogether 213 cases of small-pox admitted into hospital, of which number nineteen died, or 9 per cent. The patients are all stated to have borne marks of vaccination, except one recruit who had just joined. Revaccination was largely performed in consequence of the widespread prevalence of the disease; all men were subjected to it in whom the marks had become indistinct, whenever a case occurred in a corps or at a station where the malady was prevalent.

Continued fevers did not differ greatly from the results of the preceding year. Paroxysmal fevers were less prevalent at all the groups of stations, except the large manufacturing towns, and London and Windsor—the dockyards and arsenals, as usual, furnishing the highest proportion of cases. The relative prevalence of these fevers at the different stations appears to depend on the previous service of the corps doing duty at them, as they are almost always the result of liability contracted in the tropics.

Syphilis was more prevalent than in 1870 at the dockyards and arsenals, and large manufacturing towns, London and Windsor showing no change, and the other groups of stations a decrease.

The admissions from scrofula and phthisis were lower than

in the preceding year at all stations, except the camps, which showed no change. Local diseases exhibited no marked difference, with the exception of a considerable increase in those of the urinary system. Injuries differed little from the results of the previous year, and the proportion of deaths by suicide in the two years was identical.

There are also the usual sanitary reports from the principal districts and large stations, together with the records of invaliding and recruiting for the year 1871 in the United Kingdom, which give most exhaustive and valuable information. These are followed by separate and distinct reports from all foreign stations under British control, including India, containing in each instance similar details to those given for this country; and the first portion of the book terminates with an able summary showing the sickness, mortality, invaliding, and the proportion constantly non-effective from sickness per 1000 of mean strength in the whole of the army at home and abroad for the year 1871, and on the average of the ten years 1861-70.

THE SPREAD OF CHOLERA.

Reports of the spread of cholera continue to reach us from Austria. There is also a report of the death of at least one English lady at Vienna from so-called cholerine. The outbreak of cholera in America, if really of the Asiatic type, bids fair to offer a fine nut to crack on the modern theories as to the propagation of the disease.

ORDERS OF MERIT FOR SCIENTIFIC MEN.

A debate in the House of Lords on an address to the Queen, introduced by Earl Stanhope, and asking the institution of an order of merit for scientific and literary men, ended without a division, as the Government was strongly opposed to any such innovation. It was shown by Earl Granville that the universal decoration of distinguished men on the Continent had led to much abuse and misuse of the titles conferred; and also that the recipients of these honours were more frequently those specially skilful in making themselves popular with those personages who had to dispense the orders of merit than sound men of science; and that the great men of letters, who are as a rule very reticent, would not be likely to press for such distinctions. The *Times* generally disapproves of the measure on the ground that it would be inexpedient and impracticable, inasmuch as the great men of letters and science would hardly have the "push" of less worthy men, all whose doings and purposes are kept prominently before the public with the single object of courting public favour. We consider that it would be difficult to see what valid distinction there is between the man who holds a Government post and the man whose ambition does not lead him to enter the public service, that the former should receive a title for himself and a certain social standing for his family, while the latter, more gifted, more famous, more useful to his own age, and perhaps to ages that are to come, should remain without any such State recognition. Attempts have been made to draw a distinction, but they seem to us futile.

A SCOTCH JUDGE ON MIXED MEDICAL CLASSES.

We have received a legal document entitled "Opinions of Consulted Judges *in causâ* Miss Sophia Louisa Jex Blake and others," etc., in which is recorded Lord Ardmillan's opinion of the conduct of the said Miss Sophia Louisa and others in attending mixed medical classes. Lord Ardmillan observes:—

"I fully and respectfully recognise the high qualities, capacities, and vocation of women. I recognise especially the fact that the elevation of women in domestic and social position is one of the blessed fruits of Christianity. There are few, indeed, who hold intelligent and virtuous women in higher estimation than I do. It is very much for their own sake, and on account of the respect which I entertain for them, that, on this particular point, I feel it my duty to state my decided opinion that the promiscuous attendance of men and women in mixed classes of medical study, such as anatomy, surgery, and obstetric science, with concomitant participation in dissection, demonstration, and clinical exposition, is a thing so unbecoming and so shocking—so perilous to the delicacy and purity of the female sex, to the very crown and charm of womanhood, and so reacting on the spirit and sentiment which sustain the courtesy, reverence, and tenderness of manhood—that the law and constitution of the University, bound to promote, and seeking to promote, the advancement of morality as well as knowledge, cannot sanction or accept such attendance."

Lord Ardmillan's remarks apply ostensibly to the demand by the ladies, referred to above, that the Senatus should compel the medical professors to teach them in mixed classes; but his Lordship surely cannot have forgot that it was precisely the "thing so unbecoming and so shocking," in his opinion, which led to the disgraceful riot of the extra-academical students at the College of Surgeons in Edinburgh, and the never-ceasing abuse of the University therefor. Is it not more than probable that the riotous students anticipated this opinion of his Lordship, and only too rudely expressed it?

The *Scotsman*, the organ of the medical ladies in Edinburgh, has expurgated its report of Lord Ardmillan's judgment by omitting the passages we have quoted, feeling, doubtless, how severe is this reproof of the Scottish judge, not only to the unfortunate lady-students involved, but also to all those who have encouraged them in demanding and attending mixed classes.

A CASE OF MELANÆMIA.

An interesting case of this rare affection is given in the second Heft of Stricker's *Jahrbuch* for this year by Dr. S. Von Basch. The patient was a physician of the Banat, and lived in a malarious district. In 1868 he had an attack of ague, which was cut short by quinine. A second attack was dealt with in the same fashion in 1869; but the attacks were renewed more violently in 1870 and 1871, till in 1872 they appeared in a most aggravated fashion. In May that year he was also attacked by neuralgic pains apparently malarious in their origin. In June he began to complain of pain in the urethra while passing water, and this pain gradually spread upwards till it reached the symphysis pubis. Fourteen days later he had pain in his joints, and high fever, which yielded to water dressings and quinine in large doses. These pains began in the course of the morning and gradually increased in intensity till about four or five o'clock in the afternoon. During the early hours the urine was normal, or with only a slightly flocculent precipitate of mucus; but that passed near the time when the pain was greatest was turbid and milky-looking, depositing a copious dirty-white sediment soluble on the addition of acetic acid. When seen in August by Dr. Basch the patient was markedly cachectic, and the spleen and liver were enlarged. Under appropriate treatment he somewhat improved, but the sediment continued. One day, examining the urine when free from the white sediment, Basch found a scanty reddish precipitate, mainly composed of uric acid crystals, with some oxalates, but containing over and above hyaline masses, some of them like cells, some in fragments, the larger of which were thickly filled with dark brown and finely granular pigment. Further investigation showed that exactly the same kind of bodies were to be found in the blood. The ordinary dirty-white sediment was found to consist of needle-shaped crystals, sometimes solitary, sometimes in rosettes, and were set down as the crystalline bibasic phosphate of lime. The urine itself was acid. The case was so far satisfactory that the patient improved and obtained a considerable degree of health.

The case is imperfect, and we purposely abstain from all comment; but we would invite attention to it for its analogies

in certain points with the cases of hæmatinuria recently so graphically told in these columns by Dr. Druitt. This case, in fact, seems a kind of halfway-house to the more aggravated forms there recorded.

PRECAUTIONS AGAINST CHOLERA.

We are glad to observe, from a reply to an inquiry on the subject, that the Chairman of the Port of London Sanitary Committee said that the Committee were fully alive to the necessity of taking precautionary measures against the possible visitation of cholera to this country.

APPOINTMENT OF NURSES TO HOSPITALS.

Dr. Inglis, one of the honorary physicians of the Worcester Infirmary, has addressed a letter to the committee of that institution, complaining of a change which has lately been introduced, of giving the power of electing the nurses to the matron. We do not endorse the opinions expressed by Dr. Inglis, though undoubtedly there is some force in them. He says the matron, failing to obtain two nurses from the Stockwell Hospital on whom she had calculated, obtained two others through advertising, neither of whom (he says) was fit to be placed in the responsible position of head nurse in an infirmary. No reflection was cast upon them, but they were not competent for the duties of nurses. Dr. Inglis considers it to be a grave defect in the management of the Infirmary that incompetent persons can thus be put in charge of patients. He complains that the medical gentlemen are not consulted, as heretofore, as to the qualifications of persons desiring to be engaged in this capacity, and submits that no one ought to be accepted as a nurse for service in the Infirmary except her qualifications are satisfactory to the medical staff, and that in order to insure this the testimonials ought, as in the case of appointing a house-surgeon, to be referred to the physicians and surgeons.

A (SO-CALLED) MARTYR TO THE VACCINATION ACT.

A Mr. Price, of Ludlow (says the *Oswestry Advertiser* of the 25th ult.), is paying dearly for "conscientious convictions" on the subject of vaccination. He has already been fined £30 for refusing to have his child vaccinated, and last week was again summoned and ordered to have the operation performed within twenty-eight days. Upwards of 300 inhabitants of the town signed a memorial to the magistrates asking them not to impose another fine, on the ground that the objection was a conscientious one.

APATHY OF A VESTRY.—THE ADULTERATION ACT.

A letter was read at the last meeting of the St. George's (Hanover-square) Committee of Works, from the Secretary of the Anti-Adulteration Society, to the effect that they desired the Vestry to co-operate with them in carrying out the Adulteration of Food Acts. An opinion was expressed that the Vestry of the parish was not sufficiently active in the matter. The Committee, however, decided to take no action. The Committee will incur a great responsibility if the Adulteration Act is to be a dead letter to them; and we trust the Anti-Adulteration Society will, although they have not obtained the co-operation of the Vestry, adopt steps to bring under the penalties of the Act tradesmen who vend adulterated articles of food. Supineness in carrying out this important Act of Parliament on the part of the Vestry of such a parish as St. George's, Hanover-square, rather surprises us. We should have expected a ready adoption of measures for the suppression of the evils which the Act was designed to correct, so that the present system of trading might be purged of the taint of fraud by adulteration.

A DANISH FACTORY ACT.

The *Times* in a recent issue contained an interesting notice from its Danish correspondent of the adoption by the Government of Denmark of those general principles of supervising and controlling labour which have so long been in operation and so universally approved in this country. The Act of the Danish Government enforcing these principles bears the wide-reaching definition of "an Act concerning the work of children and young people in mills or great workshops, and the public inspection to be established of the same." It will thus be seen that the measure at once comprehends legislation both for factories and workshops, and therein effects an amalgamation in the work to be performed not yet attained in this country, where several heterogeneous factory and workshop Bills are in operation to the detriment of efficient and harmonious action.

In some of its provisions the Danish Act is more stringent than the English factory laws. It allows no child under ten to be employed; it limits the work of those between ten and fourteen to six hours and a half each day, including an interval of rest for half an hour; and further forbids work to them before six in the morning and after eight at night. Youths between fourteen and eighteen may work twelve hours a day, but not before five in the morning nor after nine at night, and of that time two hours at least are to be given them for rest and meals. The proprietors of mills and workshops are to provide a separate room for the meals of the young people in their employ; and, as far as circumstances will permit, the two sexes are to be kept separate as well during working as during recreation hours. We may add, moreover, to this account from the *Times*, that special provisions are made for the medical inspection of factories and of their operatives, and for periodical returns of the state of health of those employed and of the hygienic condition of the workshops.

FROM ABROAD.—PRIZE QUESTIONS OF THE ACADÉMIE DE MÉDECINE—EXCISION OF THE COCCYX IN IMPERFORATE ANUS—THE NEW MEDICAL FACULTY AT LYONS—MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The meeting of the Académie de Médecine for the distribution of the prizes of 1872, which, after postponements, was held on June 24, passed off very flatly, with a small audience, and an absence of the customary pomp,—why, no one seems to know. The works which received recompense in recognition of their merit were—M. Saint-Vel's "Traité des Maladies des Régions Intertropicales," M. Pellarin's "Contagion du Choléra demontrée par l'Epidemie de la Guadeloupe," M. Labadie-Lagrave's "Contributions à l'Etude de la Dysménorrhée Membraneuse," M. Liouville's "Sur la Généralisation des Anévrysmes Miliares," and M. Lagrelette's "Traité de la Sciatique." For several of the prizes no memoirs have been sent in, and altogether the responses to the invitations to competition seem to have been but feeble.

The list of prize subjects for 1873 was also announced; but as the time for sending in essays for these has passed by, we need only notice those proposed for 1874:—1. The Academy Prize of 1000 fr. is to be awarded for the best unpublished work on Experimental Physiology. 2. The Portal Prize of 2000 fr. for the best memoir on a question of Pathological Anatomy. 3. The Capuron Prize of 1000 fr. for the best manuscript memoir on some obstetrical subject. 4. The Civrieux Prize of 900 fr.; subject, The part played by the Nervous System in the production of Glycosuria. 5. The Barbier Prize of 2000 fr. for the discovery of the means of completely curing diseases reputed as usually incurable, as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera, etc. In the meantime "encouragements" are to be awarded to those who without attaining this end seem nearest to approach it. 6. The Godard Prize of 1000 fr. for the best work on Internal Path-

ology. 7. The Orfila Prize of 2000 fr.; subject, Aconitine and Aconite. 8. The Rufz de Lavison Prize of 2000 fr.; subject, "Establish, by precise and sufficiently numerous facts observed among men and animals passing from one climate to another, what are the modifications or alterations of functions and the organic lesions that can be attributed to acclimatisation." 9. The Saint-Lager Prize of 1500 fr., founded in order to compensate the experimenter who shall have induced a thyroidean tumour as a result of administering to animals substances extracted from the waters or the soils of countries in which goître prevails as an endemic. 10. The Falret Prize of 1000 fr.; subject, Insanity in its relations to Epilepsy. All essays, written in French or Latin, and furnished with mottoes, must be delivered at the Academy before March 1.

At a recent meeting of the Paris Surgical Society, M. Verneuil called attention to the excision of the coccyx as a means of facilitating the performance of the operation for imperforate anus. Ten years since an infant was brought to him with the anus in a state of natural conformation, but having an imperforation at the distance of about a centimetre. As the end of the gut could not be found, Littre's operation was performed. At the autopsy it was observed that an excision of the coccyx would have enabled the rectal ampulla to be readily reached. Since then M. Verneuil has performed such excision in the cases of five boys and one girl, with the result of saving five of them without resorting to Littre's operation. The mere puncture of the ampulla he regards as dangerous, and only to be attempted as a means of diagnosis. Even when not indispensable, the excision much facilitates the operation and abridges its duration; it also facilitates the suture of the intestine to the skin, preventing thus infiltration of fæcal matters and consecutive stricture. When the *cul-de-sac* of the rectum is placed very high, and is but slightly movable, it is to be feared that traction may lacerate its fragile parietes; but after excision of the coccyx the depression of the rectum is less necessary, for it can then be carried more backwards, and fixed to the skin. This M. Verneuil did in three of his cases, and the anus thus carried back performed its functions very well at a later period. There is no incontinence of fæcal matter, there being rather a tendency to coarctation, which may be overcome by the daily introduction of the little finger. There are cases of imperforate anus, however, in which this excision is not required; and the portion removed is usually very small.

M. Trélat and other speakers observed that there were cases in which this would be a needless complication, while in others the ampulla is situated so high up as not to be attainable even after excision. M. Marjolin observed that there are almost as many different cases as there are patients, and there is always difficulty in choosing the best operative procedure. When the ampulla is near the surface, and the skin and mucous membrane can be readily brought together, subsequent dilatation after puncture may prevent stricture. When the case is a simple one, would it not be better to confine ourselves to division of the integuments rather than complicate it by suture of the intestine and skin? M. Verneuil replied that, so far from being a complication, the suture simplified the case by preventing stercoral phlegmon from infiltration of fæcal matter into the cellular tissue. In all cases such suture should be performed. He had never, indeed, met with those simple cases in which the rectal ampulla is subcutaneous. The perineal propulsion is a sign which often deceives. M. Blot wished to know to what height M. Verneuil would think himself authorised in searching for the rectum? He had himself pushed his incisions to seven or eight centimetres, without attaining the discharge of meconium. M. Verneuil replied that he first directs his incisions towards the coccyx, of which he removes the point. He continues to dissect a little further, and if unsuccessful resorts to Littre's or Callisen's operation.

At the meeting of the Conséil Supérieur de l'Instruction Publique, the important question of the creation of new medical faculties was freely discussed. Professor Würtz read a report which he had been appointed by a committee to draw up on the subject. In this he stated that three or four additional faculties were wanted, and the question was in what city should they be located. Nine cities had offered to make the necessary provision for them—viz., Lyons, Bordeaux, Nantes, Lille, Toulouse, Marseilles, Besançon, Limoges, and Rennes. The report proposed striking off the last three of these as not offering sufficient guarantees for the provision of the needs of the faculties. The offers of Toulouse and Marseilles are also rejected, as these cities can very well be embraced within the radius of Montpellier. The claims of the remaining four would have to be discussed; but, as it is only intended to establish one additional faculty immediately, the reporter considers that the claims of Lyons far outweigh the rest, and proposes that they shall be at once acceded to, leaving the other three towns for ulterior disposal. After a long discussion the report was almost unanimously adopted, and no doubt Lyons will soon be recompensed for the slight which for political reasons was put upon it by the preference of Nancy as a substitute for Strasburg. The Municipal Council of Lyons has come forward with the most liberal offers for the establishment and provision of the faculty during the first five years.

The American Medical Association held its twenty-fourth annual meeting at St. Louis in May last, and the proceedings seem not to have been characterised by anything very remarkable. Indeed, it is evident that the leading members of the profession in the United States take little interest in its proceedings, so that it is becoming less and less an indication of their feelings. The numerous projects that are brought forward on different occasions for the reform of its present constitution evidently show that this is not considered to be working satisfactorily. We find from one of the subjects brought before the Association that the Army Medical Corps is as little contented with its position as is our own. In a memorial addressed to the Association, signed by several army surgeons, it is stated that they are on an inferior footing to the other branches of the service, and point to the example set by the British War Office in its new Army Medical Warrant as one which they would like to have imitated. The memorial points to the fact that during the late war a larger number of the Medical Corps of the Army than that of any other staff corps died either directly or indirectly through the performance of their duties, and they cannot acknowledge the justice of keeping them now in a secondary position. The memorial also complains that vacancies are not duly filled up, throwing great labour upon those employed, and arresting the current of efficient supply. The "Nomenclature of Disease" forms a subject of one of the reports. It seems that a thousand copies of the modification of the one issued by our College of Physicians have been circulated at home and abroad, with the view of eliciting the opinions of the editors of journals and practitioners. Two replies only have been received, and the Committee concludes from this that the Profession are so well satisfied with the work as to render comment superfluous. It cannot believe that men of culture and experience would be so apathetic as to pay no attention to the matter. However, the Association did not think it prudent to take so favourable a view of the matter, and, after a discussion, agreed to a resolution that it was inexpedient to adopt this nomenclature, even in its revised form, and that an endeavour should be made to negotiate with the College of Physicians of London an arrange-

ment for the Association being represented on the occasion of the first decennial revision. This is certainly the best course; and let us hope that a more creditable production will be the result of the combined wisdom of the two continents. Whatever may be the opinion in the United States concerning the present "Nomenclature," it can scarcely be lower than that which is entertained among ourselves. From a report of one of the Committees it appears that the cultivation of the cinchona tree in California has begun to occupy much attention, and that the State of California seems disposed to take the necessary steps in emulation of what has been done by the British and Dutch Governments.

PARLIAMENTARY.—RATING OF HOSPITALS—ORDERS OF MERIT.

In the House of Commons, on Thursday, June 26,

Sir R. Baggallay took the opportunity of opening up a discussion upon the rating of hospitals while the House was engaged in amending the law for the levying of rates so as to obtain a uniform system throughout the country. Sir R. Baggallay claimed exemption for St. Thomas's Hospital, with which he is connected, on the ground that the governors would be compelled to close 140 out of the 600 available beds to provide the £3000 demanded of them for parish rates. Mr. Scourfield and Mr. Muntz supported the proposal of Sir R. Baggallay on the ground that it was no new proposal, and that the exemption desired was approved of by the public at large. Mr. Gladstone and the Solicitor-General, in opposing the exemption, showed that the ratepayers of Lambeth—a poor district—would be taxed to the extent of £3000 a year over and above that which they were legally required to pay to the rates if the exemption was enforced. Sir R. Baggallay argued that if the ratepayers did not pay with one hand they would have to pay with the other for the relief of their sick poor, so that the gain to the Hospital would not really affect the ratepayers. Mr. Gladstone explained that some time ago there were two hospitals in London doing exactly equal work —that is to say, each relieved with equal efficiency the same number of persons needing relief. One of these institutions, however, did the work with £15,000 a year, and the other with £30,000; so that the conclusion obviously suggesting itself was that the richer establishment had really a margin equal to the entire revenue of the other.

In the House of Lords, on Friday, June 27,

Lord Stanhope moved an address to the Queen, praying her Majesty to take into consideration the institution of an Order of Merit, to be bestowed upon men who have distinguished themselves in science, literature, and art. He stated that there was no country of any importance but England that had not made some provision for the proper recognition of such claims to public distinction. The recognition of art and science by the grant of decorations had, instead of advancing, actually retrograded in England, and he thought it would be desirable to give to literary men and artists a distinction similar to those Orders which statesmen and military commanders were ambitious to receive. A red riband was formerly granted to men of science, and it added to the dignity with which Sir Joseph Banks used to preside over the Royal Society; but this was no longer the case. This had been strikingly shown by the decoration of the Bath being conferred on Professor Owen, a man of great eminence, who was eligible as the holder of an office in the Civil Service—viz., at the British Museum; while he apprehended that a man of equal eminence, Sir Charles Lyell, would be excluded.

A SHOCKING practice has been discovered in Oude. When Hindoos or Mahommedans die of cholera they are buried immediately; but when the epidemic has abated the corpses are dug up again, and, spite of their frightful condition, are subject to the ordinary ceremonies of burial or burning. The attention of Government has been called to this practice.

THE officers of the Army Medical Department stationed at Gibraltar have laid their views with respect to the new Medical Warrant before the authorities at home. In doing this they have followed the example of their brethren at Aldershot; but, in addition to the points put forth by these officers, the gentlemen in Gibraltar have desired that Clause 5 in the new Warrant shall be replaced by Clause 17 in the old one.

THE HARVEIAN ORATION,

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS, ON WEDNESDAY, JUNE 25TH,

By GEORGE ROLLESTON, M.D., F.R.S.,
Linacre Professor of Physiology in the University of Oxford, etc.

MR. PRESIDENT AND FELLOWS OF THE COLLEGE OF PHYSICIANS,—A man whose lot it is to live away from London may well feel some diffidence in accepting an invitation to lecture before a metropolitan audience; and, sir, when you honoured me by requesting me to deliver this year's Harveian Oration, I felt and expressed this natural hesitation. I wish to record that you pointed out to me that my function in Oxford was to pursue and lecture publicly upon the very subjects with which Harvey occupied himself; and I suggested to myself that what could with any propriety form the substance of a course of lectures in the one place could, *mutatis mutandis*, furnish materials for an address in the other. I felt besides that as the President of the College of Physicians is, by virtue of his office, one of the five electors to the Linacre Professorship, the Linacre Professor might seem scarcely justified in declining an invitation to appear before the learned body to which in part he owed his position; and, though I mention it last, I felt first of all that a wish expressed to me, not so much by the official whom I am now addressing, as by the individual who now more than twenty years ago introduced me to Harvey's Hospital, and has persistently befriended me ever since, was a wish which I ought not lightly to disregard. If now, sir, I follow an example which you have often set me, and, without needless preface or further personal allusions, address myself at once to the business before me, I shall thereby pay you the best of all compliments, by showing you that your teaching has not been wholly thrown away upon your former pupil.

The time allotted to me I propose to occupy, firstly, in expounding with all possible brevity certain advances made in our knowledge of the anatomy and physiology of the circulatory organs; and secondly, in giving the as yet unrecorded history of one of the many attempts to rob Harvey of his rightful rank in the noble army of discoverers which were made in the latter half of the seventeenth century.

Some of the last, if not the very last, of the many fruitful experiments which Harvey performed in the way of interrogating Nature as to the circulation were experiments in the way of injection. If the writer of a work which appeared but some forty-three years ago—Guthrie, "On the Diseases and Injuries of Arteries"—had taken the pains to repeat those experiments which Harvey performed more than 220 years ago, and when in his seventy-fourth year, we should not have had the following statement at page 8 of his book:—"I have conceived that the arteries contain air in an uncombined state, which may assist in keeping them distended, and in facilitating the circulation; but I have not been able to prove it." The fact that Harvey performed experiments in the way of injection may be unknown to many persons who are too well informed to conceive that the arteries may or can, compatibly with the carrying on of any circulation, contain air in an uncombined state; for these experiments are not to be found recorded either in the treatise "De Motu Cordis" or in either of the two letters to Riolanus, which two compositions were, in the older editions of Harvey's works, printed as three parts of a single treatise, under the names of "Exercitatio Anatomica Prima, Secunda, and Tertia," and were, till the appearance of the College of Physicians edition in 1766, the only published, as they are still the best known, records of Harvey's work and labour upon the circulation of the blood. The experiments to which I refer are put upon record in a letter of Harvey's to P. M. Slegel, of date 1651 (see "Harveii Opera," ed. 1766, p. 613; ed. Sydenham Society, p. 597). They were undertaken with the object of giving a final and happy despatch to all the quibbling objections of Riolanus, "omnes Riolani circa hanc rem altercationes jugulare"; and they consisted, firstly, in forcing water from the cava into the right ventricle whilst the pulmonary artery, the "vena arteriosa" of those days, was ligatured—whereby Riolanus's suggestion as to the permeability or porosity of the interventricular septum was shown to be untenable; and, secondly, in forcing water from the pulmonary artery round into the opened left ventricle, whereby the lesser circulation was demonstrated, to use Harvey's own favourite word, *αὐτοψία*; or, to use the very

words employed by him upon this very occasion, by an "experimentum ἄφυκτον a me" (in his seventy-fourth year) "nuper et collegis aliquot præsentibus exploratum." Simple as this experiment may seem to us now, I do not think that any apology is required for the drawing of attention to it; for it is only twenty-eight years ago that Dr. Sharpey, so recently and so fitly decorated with our Baly Medal (see *Edinburgh Medical and Surgical Journal*, vol. lxiii., p. 20), had to perform the very closely similar experiment of injecting defibrinated blood into the thoracic aorta, with the very closely similar object of showing that the force of the heart was sufficient to account for the passage of blood through the intestinal and hepatic vascular systems—nay, to perform an all but identical experiment, adding on to it but the means for estimating and reproducing the force put out by the ventricle concerned. If such experiments as these were necessary in 1845, how much more necessary must have been the still simpler experiments of Harvey in 1651? At that time the prestige of Riolanus the younger "pressed heavily upon mankind." Harvey himself had called that individual "anatomicorum coryphæum" in 1649; and, in the very year and letter we are dealing with, he calls him "celebrem anatomicum." And Pecquet, the discoverer of the thoracic duct, in his work, also of this selfsame year, 1651, the "Experimenta Nova Anatomica," a work spoken of by Haller ("Bibliotheca Anatomica," i., p. 443) as "nobile opus et inter præcipua sæculi decora," has the following remarkable passage:—"Ita sentiunt non vulgaris peritiæ medici Harveius, Veslingius, Conringius, Bartholinus, aliique complures; nec melior ipse Joannes Riolanus (quod mirari subit pro eximiâ viri, quà in rebus anatomicus cæteros anteivit sagacitate). Audi hanc in rem illius sententiam." This, I think, I will spare you; but I will remark that, after this singular—or perhaps, alas! not singular—instance of the blundering judgments which contemporary writers may pass upon each other, no young man, nor indeed any old one—for Harvey was in his seventy-fifth year when he first read Pecquet's work (see "Epistola Tertia," Morison's, p. 620, ed. 1766; p. 604, ed. Sydenham Society)—if his own age, in his own estimation, do him scanty justice. Posterity ordinarily—I do not say always—rectifies these false judgments; it has done so, at all events, in the cases of the men so grotesquely grouped together by Pecquet. See also, I would add, Gregorius Horst, the father of Harvey's correspondent of the same name, in his "Opera Medica," i., p. 83 (1661), where Riolanus is spoken of as "anatomicorum hujus sæculi fere primum"; and Bartholinus himself, who, in his work "De Lacteis Dubia" (1651), refers to "multis Riolani observationibus quibus rem anatomicum immortali nominis celebritate auxit." Haller, at all events, writing in 1774 ("Bibliotheca Anatomica," i., p. 301), speaks of Riolanus as "vir asperos et in nuperos suosque cœvos inimitis ac nemini parcens, nimis avidus suarum laudum præco et se ipso fatente anatomicorum princeps." The duty of attacking and abolishing such a man may, or, indeed, must have been, a disagreeable one to his contemporaries: they appear to have shirked it. It was their duty to have faced it, notwithstanding it might have been disagreeable.

Harvey used for these experiments a somewhat rough injecting apparatus, "quemadmodum in clysteribus injiciendis fieri solet." The modern experiment which I wish first to introduce to your attention rests for its accomplishment upon the employment of the delicate injection-syringe (*for Einstichung*) of Ludwig, and of the fine soluble Berlin blue for the substance to be injected. Here, as in so many other instances, our superiority to our forefathers rests mainly or wholly upon our possession of more delicate, or upon our command of more powerful agents; and the delicate syringe and the penetrating soluble injection-mass help us to discoveries and demonstrations impossible in default of such means, just as the superior lenses of Malpighi and Leeuwenhoeck helped them to the discovery and demonstration of the capillary circulation, unknown to the discoverer of the circulation as a whole. The experiment to which I refer has its results fairly represented in the diagram to which I point, from a specimen prepared by myself at a class-demonstration. It gives a figure of the lacteals injected, by the means just specified, as they exist upon the terminal segment, here widely globular, of the ileum, upon a single disciform patch upon the commencing colon, and finally and chiefly upon and all around the walls of the colossal vermiform appendix of the rabbit. In this latter place it is but what the Germans call, and have called, a *Kinderspiel*, to insert the point of the fine *Einstichung* syringe charged with the soluble blue injection just beneath the peritoneal coat at the cæcal end or elsewhere, when, upon pressing the piston, a reticulation of blue will spread itself over the surface of the tube, enclosing as islands the solid substance of the Peyerian follicles. It needs but a little perseverance in the way of gentle pressure to cause superficial tubular lymphatics to arise into view, and to declare their true character by their contrast with and distinctness from the bloodvessels, as well as by their moniliform character speaking of their richness in internally placed valves. Passing over the convex walls of the appendix, they join larger trunks which run along its mesenteric border; then larger trunks in their turn enter the mesenteric glands, and form in their substance reticulations strikingly like those formed previously in the walls of the intestine around the solid substance of the Peyerian follicle—speaking thus to the naked eye of the similarity, and by consequence of the homology, which the microscopic examination enables us to prove to exist between the lymph-masses and the solid masses they surround in the Peyerian follicles and in the mesenteric glands respectively.(a)

It is the demonstration of the relation of the lymphatic or lacteal vessels, or sinuses, as the case may be, in different animals, to the solid ampulla-like masses in the Peyerian follicles, which the modern method of puncture can claim as being eminently its own attainment; for many years ago—in 1784, in fact—and three years before the appearance of Mascagni's splendid work, with similar figures and histories of similar experiments ("Vasorum Lymphaticorum Historia et Iconographia," 1787), the continuity of the lacteal radicles upon the walls of the intestine with the "lymph-paths"—to borrow a word of later coinage—in the mesenteric islands, and finally, after passing through successive lines of these apparently solid structures with the thoracic duct itself, had been demonstrated by Sheldon, then Professor of Anatomy in our Royal Academy of Arts. These are his words (from page 49 of his work, "Of the Absorbent System," 1784), describing his plate No. 5, a copy of which I have had made and suspended there: "In the fifth plate of this work, upon a portion of human jejunum from an adult female subject, seventeen lacteal vessels are injected with quicksilver, by inserting pipes into them upon the intestine. They were remarkably large and varicose in this subject, and as the quicksilver was poured into the lymphatic injecting-tube to fill these vessels, it frequently ran out in a full stream by the jugular vein, which was opened. This circumstance rendered it evident that the mercury had passed through the whole course of the lacteals and thoracic duct, and had penetrated even into the venous system. It is, I believe, the only instance in which the thoracic duct has been injected from the lacteals on the intestines."(b)

Sheldon's first plate, I may add, when compared with his letter-press on p. 37, appears to show that what he calls "ampullulæ" were really Peyerian glands, and that he had repeatedly seen these glands distended in the way of natural injection with chyle, as it is easy enough to see them distended in an animal, such as a rat, which can be got to feed on fatty food, and can be killed at a proper interval of time afterwards. He appears to have had very serious as well as reasonable doubts as to the existence of any foramen in the apices of these ampullulæ; but the authority of Lieberkühn, whose "Dissertatio Anatomica" (p. 18) he had himself edited, appears to have weighed with him more than his αὐτοψία. Near, therefore, as Sheldon came to seeing the whole truth, he just failed of doing so entirely and completely; and the views which Lieberkühn had put forward (p. 10, *loc. cit.*) as to the

(a) I take this opportunity of expressing my surprise that Henle has not seen his way towards accepting this view of the real nature or *Bedeutung* of the Peyerian follicles. In his "Gefasslehre" of 1868 (p. 404) he refers us back to his "Eingeweidelehre" of 1862, where the absorbent character of these structures is denied, just as it was about the same date by Hyrtl in his "Handbuch der Topographischen Anatomie," 1860, p. 646, and by Teichman, "Das Sangadersystem," 1861, p. 88-91. The view which I have adopted was accepted by a distinguished Fellow of this College, Dr. Burdon-Sanderson, in the Eleventh Report of the Medical Officer of the Privy Council for 1868, p. 96.

(b) I have some pleasure in pointing out, by the aid of another diagram, taken from the plates of the venerable Professor Arnold, of date 1838, that the quicksilver injection could sometimes give as correct results as the "silver method" of modern microscopy for the detection of lymphatics by their epithelium. The diagram shows the fourth ventricle plexus without, the velum interpositum, on the contrary, with, lymphatics injected with quicksilver. The use of the silver method has enabled me to prove that this representation is correct: abundance of choroidal villi can be procured, and very beautiful objects they are when treated with 0·25 per cent. of nitrate of silver from the plexus in the fourth ventricle, but no lymphatic vessels. These can be shown from the velum interpositum by the use of the same reagent.

great number of the Peyerian glands in the lower segment of the small intestines, being a proof that they held relation to secretion or excretion rather than to absorption, prevailed, and have prevailed, even into our own day. These are Lieberkühn's words—"Quare ad finem ilei plures quàm in integro intestino positi erunt? Nonne propter fæces jamjudum exsuccas et indurescentes ut lubricatæ valvulum facile transeant nec lædant?" In Henle's ordinarily and marvellously excellent "Generelle Anatomie," of date 1841, I find (p. 895) the excretory character of the Peyerian follicles taken as something certain, the only thing left uncertain being the question as to whether their contents found their way into the cavity of the intestine by a constantly patent, however small, duct, or by dehiscence, as ova for an ovary. In 1850 the real meaning, the true physiological import, of these glands was proved by Brücke: the method of injection, of which I have spoken, enables us to demonstrate or exhibit what was thus proved, and that with the greatest ease. It is difficult to understand how anyone can now doubt that the Peyerian glands are really but the *pileorrhizæ* of the roots, the glands the tubera, and the thoracic duct the trunk or stem of the absorbent tree.

If any apology be needed for my dwelling so long upon a point of anatomy which has not merely so much historical, but also so much practical, interest—the Peyerian glands being the part of the organism especially affected by the poison of typhoid fever, which I see has, amongst other *aliases*, that of "Peyerian fever" (Walshe, "On Diseases of the Heart," 3rd ed., p. 208)—I would add that I was till recently under the impression that the actual demonstration, the doing, of that which that diagram represents as done, might have been a fitting exhibition for me to go through upon the present occasion, following herein the example of Harvey—"viliora animalia in scenam adducentis." I have, however, learned that this very demonstration on the appendix vermiformis of the rabbit has been often performed in Germany, and, indeed, also in England; and I judged, consequently, that it might be superfluous, as it would not be novel, to exhibit it here and now.

Having been thus disappointed in my intention of demonstrating something new in this direction, I cast about in another for something of the same character. And in the heart of a bird, the Australian Cassowary (*Casuarius australis*), killed at Rockingham Bay, lat. 18 deg., on the east coast of the continent, and sent me by my former pupil, J. E. Davidson, Esq., I came upon a structure which I am well assured has never been either described or figured before. It possesses upon this ground some claim upon our attention; but it possesses stronger claims than any mere rarity could give it, being as it is a structure which, though it has never been seen in any other member of the class Aves, is largely developed, and, indeed, exactly reproduced in the hearts of certain mammals, and does not fail to be represented, at least rudimentarily, in our own. The structure in question is a "moderator" band, holding precisely the same relations to the other parts of the right ventricle in this bird which the band so named by Mr. T. W. King in the *Guy's Hospital Reports*, vol. ii., p. 122, 1837, holds in many, if not in all, Ungulate mammals. This, I presume, is made plain by a comparison of the two diagrams placed side by side, showing, one of them the heart of this bird, the other the heart of a sheep, with the right ventricle similarly laid open in either case. The advantage, which in the struggle for existence, and specially in that very common phase of it which takes the form of a race for food or from an eater, which an animal with such a muscular band passing directly across the cavity of its right ventricle from its fixed to its movable wall, is not a difficult thing for any man to understand who has ever either watched in another or experienced in himself the distress caused by the over-distension of any muscular sac. A band of similar function—I do not say definitely of precisely the same morphological importance—has often been figured as existing in the hearts of most or all Reptilia below Crocodilina; and it serves in them to close up and expel the blood from the pulmonary compartment of their imperfectly divided ventricle.

Such being the function of this moderator band, what is its morphological bearing, and what traces can we find of it in ourselves, tempting us to speculate as to the nature of the secret bond which brings us into relations of affinity not only to the mammalian class, but with an older stock, the many-sided potentialities of which embraced not only mammals, but all warm-blooded animals, and not only all warm-blooded creatures, but warm-blooded animals and reptiles also? The valves of the heart in the higher vertebrata, when regarded from this point of view of development—the safest if not the sole criterion of homology,—may be spoken of as being but trabeculæ flaked off from the inner surface of the wall of a muscular sac, and subsequently made more or less membranous in the way of specialisation and its correlative economy. Thus, as Gegenbaur ("Vergleichende Anatomie," 2nd edition, p. 836) has remarked, the intervalvular space in these animals corresponds to the entire cavity of the spongy walled heart of fishes and amphibia; and the sinuous intertrabecular cavities in the spongy walls of these latter animals correspond with the chief part—viz., the extravalvular part—of the ventricular space in mammals, birds, and Crocodilina. Now, the musculi papillares represent the disposal or destination of the innermost layer of the right ventricle, according to Dr. Pettigrew (see his paper, *Phil. Trans.*, 1864, p. 479); and I would submit that the moderator band is but a specialisation of the next layer in order from within outwards—to wit, Dr. Pettigrew's sixth layer, which he has figured (plate xiv., fig. 33) as proceeding in a spiral direction from right to left, much as the fibres of the moderator bands I have figured do. A study of the heart of the rabbit will put this matter in a very clear light, and further open our eyes to see and recognise the rudimentary representation of this moderator band in our own hearts. If we look at the outer aspect of that very constant musculus papillaris, which passes in man from the outer and movable wall of the right ventricle to distribute its chordæ tendineæ to the two more anteriorly placed of the three segments of its auricular valve, we shall frequently see that its longitudinal fibres are crossed nearly or quite at right angles by a slender fibrous band, so that we have before us an appearance not wholly nor essentially unlike that presented by the striæ longitudinales of Lancisi and the fibres of the corpus callosum when viewed in mutual connexion. This band of fibres can sometimes be traced up towards the conus arteriosus, and be seen not to die away until close upon the point of origin of the most anteriorly or upwardly placed chorda tendinea arising from the septum to pass to the hindermost of the three segments of the tricuspid. The points between which this line of fibres lies may be observed to be the very same as those between which the moderator bands in the cassowary and the sheep stretch as free columns in the diagrams before you. It is not altogether rare to see this band raise itself from the position of fusion, like the ventricular wall, and assume the character of a cylindrical band for a lesser distance, but with no less distinctness as a column, than in the Ungulata. Such a case I had actually before me whilst writing this, and you have it now figured before you.

Every gradation, in fact, exists between the entire obsolescence of the moderator band, which we sometimes see in the human heart, through the typical, and, I should anticipate, constant, but not functionally important, representation of it in the rabbit, up to the important and structurally prominent development attained to by it in the Ungulate mammal, and this solitary instance for the class of Birds, and the sub-class with such generalised affinities, of Struthiones.

And, speaking of the method of gradations, I take this opportunity of saying that its application in the case of the muscular right auriculo-ventricular valve of birds will, in my judgment, put an end to the disputes which have taken place as to its homology with one or other of the two valves in the crocodiles. The two portions of the valve in the *Casuarius australis* are so nearly equal—the larger being but 1·7 inch, as against 1·4 of the smaller—as to do away with the difficulty which might be felt in holding that both crocodilian valves are represented here. There are other reasons for this view, which I reserve for another occasion. But while speaking of the heart of the bird, I cannot forbear pointing out how the structural arrangements of its auricle, differing as they do strikingly from those of the same compartment in the mammalian heart, helps us by that contrast to get a true idea of the working of this latter. Firstly, the walls of the bird's right auricle are relatively thicker, not only as compared with the walls of its own ventricle, but also as compared with the walls of the corresponding auricle in the mammal, the musculi pectinati standing out in as sharp relief as the similarly working muscular ridges in a hypertrophied bladder, and enclosing anfractuosities and recesses almost as deep. But, secondly, and what is of more importance, the bird's auricle is furnished with a large and functionally active valve, protecting the entrance of the great veins, and preventing regurgitation into those vessels just as the auriculo-ventricular

valves prevent regurgitation from the ventricles. It is fair to argue *à priori* that if the mammalian auricle had counted for as much in the action of the heart as the bird's, its force would have been economised by the placing of a large and functionally useful valve in the site of the rudimentary Eustachian—a structure altogether absent in many mammals, and variable, as rudimentary structures very often are, in ourselves. The *à priori* argument of comparative anatomy is abundantly borne out by the appeal to experiment. Marey, in his "Physiologie Médicale de la Circulation du Sang," 1863, whilst referring (p. 36) to other evidence from comparative anatomy than that which I have adduced, cites, in support of the view that the auricle has but an accessory and subordinate *rôle* in the functions of the heart, an experiment of Chauveau's, in which the auricle of a horse, being exposed and irritated, lost its contractile power for a time, during which, nevertheless, the ventricles continued to contract and the circulation to be maintained. Colin, again ("Traité de la Physiologie Comparée," vol. ii., p. 257, 1856), found that the left ventricle continued to be filled with blood even when the corresponding auricle was prevented from contracting by the insertion into it of a finger. And further, Magendie had long ago noted, in experimentation, what many here present may have noted in pathological or clinical observation—viz., that the auricles may remain extremely distended for hours, and, like other muscular sacs similarly conditioned, unable to contract and empty themselves, without the circulation for all that being brought to a standstill. It was Dr. Pavy's paper, treating (in the *Medical Times and Gazette* of November 21, 1857) of the case of a man (E. Groux) with a congenital fissure of the sternum, which first drew my attention to these points; and his summary of what takes place in the dog is so clear that I herewith reproduce it.

"In the dog, the contraction of the ventricles is sharp and rapid, instead of prolonged, as in the reptile, and does not appear to occupy nearly so much time as half the period of the heart's action. The ventricular contraction communicates a sudden impulse to the auricles, occasioning in them a distinct pulsation, which is instantly followed by a peculiar thrill, wave, or vermicular movement, running through the auricular parietes down towards the ventricle. This thrill or wave is coincident with the passage of the blood from the auricle into the ventricle, and takes place so instantaneously after the ventricular contraction, that the one movement appears to run on to continue itself into the other. There is then a pause, which seems comparatively of considerable duration, and which is succeeded by a recommencement of the heart's action, beginning with the ventricular contraction."

Dr. Pavy has very kindly gone to the trouble of repeating the experiment upon which these statements are based; and from a letter with which he has favoured me I gather that the auricular contraction detectable by the cardiographic tracing, as immediately preceding the ventricular contraction, is also detectable, of course during the pause just mentioned, by the eye, unassisted by the cardiograph, and turned simply upon the exposed heart, in which the auricular appendix is seen to become redder or more flesh-coloured at the moment in question. And he further remarks that this auricular contraction, difficult though it be to be observed under physiological conditions, may be exaggerated into considerd prominence in disease entailing contraction of the auriculo-ventricular orifices, and may then make itself known by a presystolic murmur.

I should now be glad to draw attention shortly to a few memoirs which have appeared comparatively recently, and which treat of matters of considerable interest, not merely as scientific problems, but also as practical questions. First among these I would name the paper which appears in the third volume of Professor Ludwig's "Arbeiten," 1868 (having previously appeared in vol. xx. of "Bericht Math-Phys-Klass., K.S., Gesellsch. Wissensch.," Leipzig), by Professor Ludwig himself and Dr. Dogiel. In this paper we have a number of experiments recorded as performed with the hearts of dogs removed from the body, and as nearly as possible emptied of blood; and the conclusion which the authors come to is that the heart of the dog, when removed from the body and emptied of blood, still produces a sound during the systole of the ventricles which is not essentially different from that which is recognised as the normal first sound of the heart. The authors add, however (p. 85), that they do not think these experiments entirely exclude the possibility of the tension of the auriculo-ventricular valves entering as a factor into the production of the first sound; and hereby they would be guarded from coming into contradiction with most English authorities—as, for example, Dr. Walshe ("Diseases of the Heart," 3rd ed., 1862, p. 62). Dr. Guttmann, however, in a paper of no great length, but of considerable merit, published subsequently to the one just mentioned, and in Virchow's *Archiv* for 1869, points out with much acuteness what, when once pointed out, is ever thereafter obvious—viz., that it is, in the nature of things, impossible, with all possible precautions in the way of emptying the heart of blood, to empty the complex phenomenon made up by a systole of the heart, of the condition of tension of the auriculo-ventricular valves. Surely the musculi papillares will contract with the rest of the ventricular walls, and, contracting, will they not stretch the chordæ tendineæ and the valves? For myself, I would say that we are more likely to overrate the share taken by the valves than to underrate that taken by the muscular walls. I need not say to this audience that the fact with which we are all so familiar, of the alteration in the first sound produced by disease of the auriculo-ventricular valves, does not absolutely prove that they produce any part of it during health; and, finally, to my own ear at least, a modification of Wollaston's experiments, which anybody can try for himself by making his temporal and masseter muscles contract at any time of perfect stillness, appears to produce a sound which is scarcely, if at all, different in quality from the first sound of the heart. A judgment, however, upon the nature of a sound, or, indeed, an aggregation of sounds, as in music, is one upon which two observers may very well differ, as neither of them can lay his proof of supposed identity or difference alongside of that which the other may possess, or suppose he does.

It is with much pleasure that I refer to Dr. Rutherford's paper on "The Influence of the Vagus on the Vascular System," which appears in the Edinburgh Royal Society *Transactions* for 1870, vol. xxvi. In that year, having to deliver an address to the Biological Section of the British Association at Liverpool, I made bold to say that the results which Dr. Rutherford had come to, and which were then only known to me in an abstract in the Cambridge and Edinburgh *Journal of Anatomy and Physiology* (May, 1869, p. 402), would prove to be of the highest value and importance. His memoir now published *in extenso*, and extending over forty-two pages, as fully justifies my prediction as it will fully repay anyone who will take the pleasant trouble of reading it. The most important result in a practical point of view is the demonstration which Dr. Rutherford has given of the nerve-circle, whereby, in the way of reflex action, the all-important secretion of gastric juice is called forth. The sensory impulse caused by the ingestion of food into the stomach is propagated upwards by the vagi to the medulla oblongata, where it throws into abeyance the vaso-motor nerve-cells, which, whilst the stomach is empty, keep the bloodvessels of the gastric mucous membrane constricted, but which, when their activity is inhibited, allow the zonular fibre-cells of these bloodvessels to dilate, and allow of the increased afflux of blood thus called for. That relief will result to some of the countless martyrs to dyspepsia out of the demonstration of this physiological relation of vagus, sympathetic, and peptic glands, I do not doubt. Possibly, I would add, Owsjannikow's observations as to the working of hydrate of chloral as a depressor of arterial tension (Ludwig's "Arbeiten," 1872, p. 32), may prove valuable to persons engaged in practice, by pointing out, in however shadowy a fashion, the road to a more rational and systematised, even if less general, use of this drug than that which I am told is now made of it. It may seem a paradox, but it is none the less true for all that, to say that, for the activity of many organs, a paralysing and inactivity of certain nerve-centres in connexion with them is a pre-requisite. The activity of such, indeed of most, organs is but intermittent and occasional, being but intermittently and occasionally called for, whilst the constringing activity of the sympathetic has to be constantly at work to prevent waste of force; the phenomenon of the distinction of the corpora cavernosa, a phenomenon used by Harvey himself in the way of illustration (see p. 129 of the "Epistola secunda ad Riolanum"), I may adduce in the way of illustration also, being, as it is, dependent upon a similar nervous mechanism.

Owsjannikow's paper (also found in Ludwig's "Arbeiten," sixth year, 1871, and in the "Bericht Math-Phys-Klass., K. S., Gesellsch. Wissensch.," Leipzig) just referred to, and published two years subsequently to Dr. Rutherford's, gives, as the result of a number of experiments performed in Professor Ludwig's laboratory at Leipzig on rabbits, and independently at St.

Petersburg on cats, the conclusion that the ganglionic centres of innervation for the entire sympathetic system occupy but a small space at the base of the brain—two strips, to wit, on either side of the median fissure in the floor of the fourth ventricle,—of, in the rabbit, a length of about four millimetres, beginning about four to five millimetres anteriorly to the calamus scriptorius, and ending about one to two millimetres behind the level of the corpora quadrigemina. The title of such a book as Eulenberg and Gutmann's "Die Pathologie des Sympathicus auf Physiologische Grundlage," Berlin, 1873, is an encouragement to those who hope to see fruit arise from such researches as these in the way of additions to our means for meeting, or at least understanding, human disease and suffering.

It has long been known (Budge, 1855) that the sympathetic nerves which supply the vessels of the head and iris do not pass directly or by the shortest possible route to this their distribution, but pass down the spinal cord for a greater or lesser distance, and then turn outwards, and pass from the anterior nerve-branches to bend upwards, much as the recurrent laryngeal nerve does. That other vascular regions receive their vaso-motor supply by this apparently circuitous route, and, till the history of development is taken into consideration, paradoxical route, is from time to time being demonstrated. Dr. Pavy, to whom I have already referred, many years ago identified and mapped out one segment of the road along which nerve-force passes to the liver, and prevents or allows of the occurrence of diabetes. Further exploration of this route we owe to Cyon ("Bulletin de l'Académie Impériale des Sciences de St. Petersburg), cited in the *British Medical Journal*, December 23, 1871; and this same investigator, working still in the same line of investigation, as it is in these days usually necessary for an investigator to work if he will make himself a name as a discoverer, has also shown us (Ludwig's "Arbeiten," third year, 1868) the track along which the vaso-motor nerves of the anterior limbs pass, proving that these nerves pass down in the spinal cord as low as the mid-dorsal region, before leaving it to turn upwards in the sympathetic chain to join the brachial plexus. Of all the results, however, which have been attained to in the line of experimentation now under consideration, those come to by Brown-Séquard and demonstrated by him at the meeting of the British Association held at Liverpool in 1870, and subsequently published in the *Lancet* of January 7, 1871, seem to me to be certainly the most striking, and possibly the most important. Could anything have been more surprising to him whose memory we here this day commemorate, than to have been told that an injury to a particular part of the brain, the pons, called after the excellent anatomist whose life ended in the very year in which his had begun, would produce hæmorrhage in certain parts of the lungs, and anæmia, œdema, and emphysema in others? This is an easy experiment to repeat; it is one which might have been done in the days of Harvey as easily as in those of Bernard, of Budge, of Ludwig, and of Brown-Séquard. But easy though it would have been to perform, I am bold to say it was well for Harvey that he never happened to perform it. For considering that, like Haller, he knew nothing of the contractility of arteries; considering that Hunter had not performed his now well-known experiments with the umbilical arteries; considering, sir, that in that excellent work on "Physiology," the translation of which, in 1838, by our late and never sufficiently to be lamented friend, Dr. Baley, we owe to your suggestion, I find several pages (pp. 202-206) devoted to *disproving* the muscular contractility of arteries; considering that it was not till three years later, in 1841, that Henle's work, already referred to, appeared with its still unsuperseded figures (plate iii., figures, 8, 9, and 10) of the arteries with their circular muscular coat, and with its excellent summary in letterpress of the whole subject (pp. 518-526, and especially pp. 524, 525); when I consider that nothing of all this had been done, to say nothing of other advances connected with names of men yet living to speak for themselves and for us—I say it may have been well that Harvey never came upon the facts relating to the alterations of lung-substance being entailed by destruction of brain-substance, not difficult to be observed and reproduced, which we owe to Brown-Séquard. For if he had come upon them, how could he have explained them in the absence of the entire chain of connecting facts, in the forging of which chain so many successive workers—Purkinje, Valentin, Weber, Burdach, Stilling, and others—have all contributed links? Might not even Harvey, often as he withstood such temptations, have, nevertheless, in default of power to assign the real causes of such a phenomenon, been driven back upon some of those explanations which he himself so forcibly denounces in the words ("Epistola secunda ad Riolanum," p. 116)—"Vulgo scioli cum causas assignare haud norunt dicunt statim a spiritibus hoc fieri et omnium opifices spiritus introducant, et ut mali poetæ ad fabulæ explicationem et catastrophen Θεὸν ἀπὸ μηχανῆς advocant in Scenam." It is a hard thing for any man to abstain from speculating as to the cause of any well-established phenomenon, especially if it be of striking interest and importance; it is a hard thing for any man to do more than keep pace with his own generation; and those who have spent any time in reading the works of Harvey's contemporaries will best appreciate the difficulty he must have had in setting himself free from the influence of the *idola theatri* referred to.

(*To be continued.*)

PROFESSOR HOLMES'S LECTURES AT THE COLLEGE OF SURGEONS.

Abstract of Lecture II.

The Professor, continuing the subject of Carotid Aneurism, observed that the time occupied in the cure of a large carotid aneurism by interrupted compression is usually considerable. The only case recorded in English practice is that under Mr. Sheppard, of Worcester, reported in the *Medical Times and Gazette*, vol. ii., 1863, p. 463. The patient was a policeman of intelligence, and made pressure with his own thumb for half an hour at a time as often as he could. The aneurism disappeared in five weeks.

The lecturer had met with no case on record, nor heard of any in private, where the rapid method of pressure has been tried in carotid aneurism; yet this treatment would be advisable where the aneurism is of large size and contains clot, and the patient is unable to bear pressure without chloroform. The tendency to affection of the brain from compression would, however, necessitate great caution in watching the symptoms while the patient is narcotised. A case of innominate aneurism, under Mr. Cooper Forster, recorded in the *Guy's Hospital Reports* for 1873, illustrates some of the effects of prolonged compression of the carotid under chloroform. It shows the circumspection which must be enforced in any future attempt to cure carotid aneurism by similar means, though the attempt is worth making, and should be made in cases of such a nature and size as to render the cure by compression probable, but after persevering trial compression without chloroform cannot be tolerated.

To sum up present experience of this matter: Five successful cases—viz., Sheppard's, Rouge's, Kerr's, Professor Humphry's, and Mr. Gay's—have been mentioned by the lecturer. In all, except Professor Humphry's, the pressure was digital; the only two others were unsuccessful. Thus, of seven cases of compression five were successful, and in the two which failed the ligature failed also. Thus we see that the trial of pressure for the cure of carotid aneurism is a rational measure, attended hitherto with a large proportion of success in the very few cases on record. There remains the question whether this experience affords a sufficiently favourable contrast to the results of other modes of treatment to justify us in adopting compression as the first resort of surgery in carotid aneurism. To answer this question we must turn to the records of the operations on the carotid artery—first, on the proximal side of the tumour; second, on the distal side; and finally, by the old method.

The treatment of carotid aneurism by ligature of the artery was first attempted by Sir A. Cooper in the well-known case which forms the commencement of the Medico-Chirurgical *Transactions*. The operation was performed in 1805, and proved fatal from inflammation of the sac of the aneurism. The preparation was produced from the museum of St. Thomas's Hospital, and is very interesting in itself as one of the landmarks in the progress of surgery. It shows perfectly the mechanism and effects of inflammation of the sac and cellular tissue around it—one of the usual causes of death after ligature of the carotid below the tumour.

This danger attaches more to Anel's operation than to Hunter's. This inflammation is usually regarded as due to

the deposit of soft clot in the sac as the consequence of the want of any circulation through it, a point on which Broca has laid much stress. But it seems to Professor Holmes equally probable that the proximity of the wound to the tissue of the sac is the real cause of the frequency of its inflammation. This point is not entirely overlooked by Broca, but he notices it in only a very few words. It forms, in Professor Holmes's opinion, one of the great objections to the ligature of the carotid for aneurism of the artery itself, that in a tumour which is at all large no space exists to cut down upon the vessel without great disturbance of the cellular connexions of the aneurismal sac, and much danger of subsequent inflammation.

In Sir Astley Cooper's case the inflamed and enlarged tumour has pressed on the pharynx to such an extent that it only just admits a common bougie, and on the larynx so as almost to close the glottis, and has produced inflammation of the windpipe, with deposit of coagulating lymph on its mucous surface. The coagulum in the sac appears firm enough, and there seems no reason to attribute the extensive inflammation which succeeded the operation to any irritating action of the clot, when so sufficient a cause exists in the dissection which had been carried on in the immediate neighbourhood of the sac. In fact, why should soft clots exercise any irritating effect on the tissue of the sac? We see them constantly in all parts of the body remaining perfectly quiet for long periods of time and then quickly disappearing. We see aneurismal sacs, when submitted to pressure, remaining soft, with hardly any pulsation, then gradually becoming hard and pulseless, and finally rapidly shrinking. Can there be any doubt that in these cases a great part of the sac has first been filled with soft clot, which has gradually given place to laminated fibrine? Instances of aneurism filled with soft clot after the disease has proved fatal by inflammation are by no means rare in voluminous aneurisms in any part, and especially in the thorax. In watching such cases it has appeared to Professor Holmes that the inflammation has been provoked by accidental causes acting on tissues highly irritable from the pressure of the growing sac; that the pulsation did not begin to slacken till the inflammation had manifestly commenced—in a word, that the coagulation was produced by the inflammation instead of the reverse. The neck especially is a part in which inflammation of the cellular tissue is apt to spread rapidly and to cause great infiltration; so that this traumatic cellulitis after ligature of the carotid soon produces fatal pressure on the parts around.

The fact anyhow remains, that the ligature of the carotid near the aneurismal sac is very often followed by inflammation of the latter; and in a case of Mr. Vincent's, reported in vol. x. of the Medico-Chirurgical *Transactions*, in which the inflammation commenced unmistakably in the wound, Mr. Vincent distinctly states that the aneurismal sac was contracted around a firm coagulum, and that its internal surface bore no indication of having been inflamed.

Sir A. Cooper's first case was unsuccessful, but the same volume contains his second and successful case. This was the first instance of a completely successful result in carotid aneurism; for though a Swedish surgeon in 1807 (*i.e.*, between Sir Astley's two cases in 1805 and 1808) tied the carotid for a pulsating tumour, the nature of the tumour seems uncertain, and it recurred fifteen years afterwards. In the second case of Sir Astley's, the aneurism was above the bifurcation and situated upon the internal carotid; and it is remarkable that the ligature did not entirely abolish the pulsation of the tumour, though the artery was tied with two threads and divided between them. The man survived the operation thirteen years, and died of apoplexy.

Exactly parallel to this last case is one recorded by the late Mr. Porter in the *Dublin Journal* for 1840. The aneurism was situated on the internal carotid, as was proved by dissection seven years afterwards; and in this case also it was observed that pulsation returned in the tumour four hours after the operation. In a case by Mr. Syme, reported in the *London and Edinburgh Monthly Journal* for November, 1842, of aneurism of the internal carotid, the tumour continued to pulsate after the ligature of the main trunk, though much less forcibly than before. The patient died thirty hours after the operation.

The records of the Hunterian operation for carotid aneurism are to be found chiefly in the works of Dr. Pitz (Langenbeck's *Archives*, vol. ix.), and M. Léon Lefort (*Gazette Hebdom.*, 1868); these contain those of previous investigators, such as Norris, Norman Chevers, Wood, etc.

The former collection contains eighty-seven cases, of which thirty-one died, which was unaccounted for. The operation is by no means so free from danger when employed for aneurism as has been represented. The danger does not depend perhaps exclusively, or even principally, upon the operation, but on the condition of the aneurismal artery, and very probably on the condition of brain which often accompanies carotid aneurism. It is a remarkable fact that the operation has only been once fatal out of thirty-four times in which it has been known to have been practised for epilepsy, headache, and other nervous symptoms, in which in all probability the artery and brain were healthy or not seriously impaired.

M. Lefort's paper is somewhat more critical, and contains less details of cases than the German surgeon's paper. He mentions fifty-three cases, thirty-five of these being of the common carotid, six of the internal, and twelve of the external carotid and its branches, and he says that out of these thirty-five cases of aneurism of the common carotid less than half have been really successful. He called attention to the great frequency of suppuration of the sac after ligature; this occurred eight times, and in three was the cause of fatal hæmorrhage. M. Lefort in fact can find only sixteen cases of recovery after this operation, and in exactly half of these cases there were complications which endangered the patient's life.

What, then, is the inference to be drawn from this picture of the Hunterian operation for aneurism of the common carotid? M. Lefort says that we cannot avoid those dangers which depend on the obliteration of the artery, since this is necessary for the cure of the aneurism; but that the danger which depends on the suppuration of the sac we can obviate by resorting to the old operation—*i.e.*, after having secured the artery on the proximal side of the sac, incising the tumour, turning out the clot, and tying its distal end. It is clear, however, that the cure by compression does not in the least degree necessitate the obliteration of the artery; and it is to be hoped that surgeons will adopt this plan of treatment more generally, and pursue it more patiently. Sufficient facts, then, prove how great is the danger incurred in tying the common carotid artery on Hunter's or Anel's method for an aneurism involving the trunk of that vessel. This danger increases as the tumour is seated lower on the artery, both because of the greater difficulty of the operation and because of the proximity of the sac to the ligature.

The next point is to consider whether there are any, and if so what, cases in which Wardrop's suggestion of ligature after the manner of Brasdor is admissible. The number of cases in which Brasdor's operation has been performed for aneurisms believed to be of the common carotid artery is eight. The only case, however, in which we have definite anatomical evidence of the existence of an aneurism exactly confined to the carotid, and of its cure by Brasdor's operation, as well as the mechanism by which that cure was brought about, is Lambert's. This case is well known and is described in Wardrop's work, page 36 and following. The way in which Brasdor's operation cures in cases where no branch intervenes between the aneurism and the ligature is clearly seen from this case. The blood is brought to a standstill in the artery and in the sac, the coagulum in the artery extends into the aneurism, obliterating the mouth of the sac and finally filling its cavity. This is strictly analogous to the partial cures which are produced in innominate or aortic aneurism by the ligature, or by the embolism of the common carotid, when the coagulum in this vessel extends down into and obliterates that portion of the sac through which the blood-stream used to pass into the carotid.

Lambert's case proves that an aneurism or an aneurismal dilatation of the root of the carotid may be cured by Brasdor's operation. But cases strictly amenable to Brasdor's operation are exceedingly rare, and there seems no prospect of radical cure by this method except in such a case as Lambert's, where the aneurism is limited to the root of the carotid itself; and these are extremely few. No specimen of the kind is to be found in the museums of this city. Nor can such a case be diagnosed with certainty during life from aortic or innominate aneurism. The practical inference is that the distal operation is justifiable in cases in which symptoms are such as to indicate growth of the aneurism upwards along the course of the carotid with increasing pressure on the trachea; but that it must be held to be a very dubious course. And in any such

case the effect of distal pressure on the carotid should be carefully noted. If it has no effect on the pulsation of the aneurism, this is a discouraging augury for the success of the distal operation, though it is not absolutely a contraindication. If, on the other hand, it materially checks the pulsation, an attempt should be made to treat the aneurism by methodical pressure on the upper portion of the carotid.

It remains to speak of the bold operation carried out by Mr. Syme in a case of traumatic aneurism resulting from a stab which had punctured the left carotid so near the clavicle that no pressure could be exercised below it, even after it had been exposed through the opening of the sac. The case is reported in his "Observations in Clinical Surgery," at page 161. It is an interesting practical question whether a somewhat similar operation ought not to be performed in spontaneous aneurism, where the tumour extends so low that the proximal end of the artery can only be tied close to the sac. It is, however, a suggestion which has not been put, as yet, to the test of practice. M. Lefort's reference to such an operation, as having been carried out by a "surgeon of Leeds," cannot be found recorded.

The experience of surgeons hitherto, then, leads to the conclusion that aneurism of the trunk of the carotid artery may be very often treated successfully by compression, and that the cure by compression frequently leaves the artery unobliterated, and exposes the patient to far less risk of cerebral mischief; that the ligature of the carotid for such tumours is extremely dangerous, and ought not to be undertaken until attempts, well devised and perseveringly carried out, have failed to effect the cure by compression; and that when the surgeon has been compelled by the position of the tumour to place his ligature close to the proximal side of the sac, it is worth very grave consideration whether it would not be better to evacuate the tumour and tie the distal portion of the artery also; finally, that cases do occur in which Brasdor's method holds out a rational hope of cure, but that this operation ought not to be practised except in cases of growing aneurism, where distal pressure checks the pulsation of the tumour, yet has failed to effect a cure.

Now as to aneurisms of the secondary carotids. There are many histories on record of aneurisms of the internal carotid artery; nor are spontaneous aneurisms of the external carotid artery apparently so very rare. No trustworthy diagnostic sign has been pointed out by which the artery affected can be distinguished with certainty—by which it can be determined whether the aneurism is seated on the internal or external carotid, or one of the branches of the external carotid artery, unless it may be the state of the pulse in the temporal, the affection of which would lead to the conclusion that the aneurism did not affect the internal carotid or not this only. But it is impossible to distinguish between an aneurism seated on the external carotid and one affecting one of its branches below the angle of the jaw. Spontaneous aneurisms of such small arteries as these latter are very rare. Nor is the diagnosis practically important. Aneurisms of the branches of the common carotid, primary or secondary, and situated below the jaw, should be treated by measures directed to the common trunk. The close proximity of the reflux stream from the external carotid in aneurism of the internal carotid artery does not seem to interfere with cure after the Hunterian operation. Without going so far as Broca, and saying that a certain amount of circulation through the tumour tends to harden the clot and promote cure, experience shows that such circulation is not inconsistent with the prospect of cure. In spontaneous cervical aneurism situated on one of the secondary carotids, or on one of the branches of the external carotid, persevering efforts should be made to cure the disease by pressure. If pressure fails, the ligature of the common is to be preferred to that of the external carotid artery for an affection of the latter or one of its branches.

The external carotid has hitherto only been tied for wound, hæmorrhage, erectile or cirsoid tumour, for cancer of the tongue or jaw, or as a preliminary to operations. The object of tying the external in preference to the common carotid is the avoidance of cerebral disturbance; so that there seems no motive for preferring the ligature of the internal carotid to that of the trunk. The artery is smaller, truly, but the operation is more difficult, and the ligature is placed nearer the sac.

It is not so certain that the same practice should be followed in traumatic aneurism generally. The prospect of cure by proximal compression or the Hunterian operation depends on the presence of a well-formed sac, which will contract vigorously on its contents when the force of the circulation is removed. If the sac is deficient or thin, and no progress is made by compression, it may be better to treat it after Mr. Syme's fashion.

Aneurisms of the branches of the external carotid in the face or scalp are almost always traumatic. Digital pressure either on the sac itself or on the artery just above it will almost always succeed; if not, the sac may be laid open, and the two ends of the vessel tied, with a confident hope of success.

Aneurisms of the smaller arteries of the neck, such as that of the transversalis colli, are not common enough to require notice; but traumatic aneurism of the vertebral artery is an affection which is common enough to be important, and which can be usually, or at any rate very often, diagnosed, and which, if confounded with carotid aneurism, is treated by means which tend directly to aggravate the danger.

This affection will be treated of in the next lecture.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

No. XXVII.

By J. F. CLARKE, M.R.C.S.

For nearly forty years on the Editorial Staff of the "Lancet."

ESTABLISHMENT OF THE LONDON UNIVERSITY AND HOSPITAL.

(*Continued from page 556, vol. i., 1873.*)

Edward and Richard Grainger—Robert Carswell—Samuel Cooper.—The "Surgical Dictionary"—Copland and his "Medical Dictionary"—Literary Labour in the Morning and at Night—Professional Caligraphy.

The difficulties under which these papers are occasionally written must be my excuse for an error now and then being committed. I have been reminded by a distinguished surgeon who was demonstrator of anatomy at St. Thomas's Hospital when Richard Grainger was lecturer en anatomy at that institution, that the term "ill-fated" could not be justly applied to him. This is perfectly true, and I had found out the mistake before I received the kind communication of my friend. Richard Grainger, on his retirement as lecturer at St. Thomas's, the duties of which he fulfilled to the satisfaction of all, received a high and lucrative appointment under Government, which he retained until his death, having done good service to the public. I had the honour of his friendship for many years. He was an able, energetic, and conscientious public servant, and in private life one of the most estimable and honourable of men. The founder of the Webb-street School was his elder brother Edward, and, certainly, the term "ill-fated" was in every way applicable to *him*. Most accomplished as a lecturer, and idolised by his pupils, his extraordinary success made him the object of the jealousy, and of something more, of some of his rivals in the Council of the College of Surgeons. They threw every possible obstacle in his way, and unquestionably these proceedings acted most injuriously to him. Of a highly sensitive and chivalrous nature, he carried on the contest with indomitable courage, though not without great mental and bodily suffering. The quarrel was long and bitter, but he succeeded in vanquishing his enemies. The victory, however, came too late. He sank in the very prime of life from a disease which had been aggravated, if not produced, by great mental and bodily labour. It was highly to the credit of the *Lancet* that its great influence was brought to his assistance. Mr. Wakley never penned abler or more eloquent articles than those which appeared in the *Lancet* at the time in favour of Edward Grainger. I now return to the staff of the North London Hospital. Robert Carswell was the third physician. Of singularly unobtrusive and retiring disposition, with a soft voice, a melancholy expression of countenance, impressing the observer with the idea that he was suffering from bodily ailment, yet under this modest exterior was a mind of the highest order. He was an accurate and painstaking observer. His lectures and demonstrations in pathological anatomy were most interesting and instructive. His style was simple to the last degree; his diction never rose beyond the ordinary level; he was neither eloquent nor oratorical. His aim was to be a *teacher*, and not a mere talker. His delineations of disease

were marvellous specimens, such as never have been, and probably never will be, surpassed. This is the more remarkable from the fact that from a dissection-wound in early life he had lost the first and second phalanges of the forefinger of the right hand. Carswell was not "cut out" for success in private practice. His sphere was the deadhouse and the lecture-room. He never had a remunerative practice. Owing to the influence of the late Sir James Clark he obtained the appointment of private physician to the late King of the Belgians. Many of the closing years of a comparatively long life he spent in "learned leisure" at the Palace of Laacken, and in the completion of those labours in pathology to which he was so earnestly devoted. At the period when the *Lancet* was publishing the portraits and biographies of eminent members of the profession, I had occasion to visit Brussels, and it was arranged that I should visit my old teacher, obtain his photograph, and learn from him such circumstances of his life as he might wish to put upon record for the benefit and instruction of his brethren. Unfortunately, Carswell was away from Laacken with the King during my short visit, and I was consequently deprived of what would have been a great gratification to me. Carswell died in Belgium. He had the full confidence and earnest friendship of the King, and he left behind him a name associated with every sentiment of regard and affection by all who knew him in that country and in this. Carswell, unlike some of his colleagues in the London University, never mixed in any way with politics; he was content to pursue the "even tenor of his way," far from angry conflicts and personal contentions. The Senior Surgeon to the North London Hospital was Samuel Cooper, the Johnson of medical literature. His great "Dictionary," though of a different stamp, and written with a different object, was to surgeons what Johnson's great work was to English literature: it is a monument to his memory illustrative of marvellous industry and marvellous erudition. The labours of no single man in the literature of our profession can be compared with those of Samuel Cooper in the compilation of his great work. It is true Copland, in his "Medical Dictionary," might be regarded as a worthy rival, and so, to a great extent, he should be; but Cooper, it should be remembered, was almost entirely unassisted in the compilation of his great work—that it was completed in three or four years—that successive editions of it were published to meet the requirements of the time, and, while exhaustive and most methodical, the massive volume appeared in its various editions at astonishingly short intervals. On the other hand, Copland had able assistance; his great work was begun in one generation, and finished in another. From the appearance of the first number of his dictionary to that of the last, a period of thirty years had elapsed: during that long time Medicine had undergone a complete revolution in theory and practice—had been modified or entirely changed by experience. So much was this the case that the publishers of Copland's dictionary induced him to write a kind of "supplement" to his great work, in order that the early subscribers, if any existed, should be brought up by this means *au courant* to the medical literature of the day. For this supplement Copland was paid £1000. It may not be unworthy of notice in these recollections that the labours of Copland began in the "short hours" of the morning and after the duties of the day, whilst Cooper rose early and finished his literary labours before noon. This may account, to a great extent, for Cooper's success in bringing out new editions of his great work at the right time. Pope has said—

> "On morning wings how active springs the mind,
> But leaves the load of yesterday behind."

This is an aphorism not to be treated lightly. Astley Cooper and Benjamin Brodie invariably pursued their anatomical studies and literary labours in the early part of the day, when they could "leave the load of yesterday behind."

I have stated in a former article that Copland broke down in the most important crisis of the publication of his dictionary, with alarming symptoms of cerebral disturbance; in fact, he was incapacitated for a long period in his labours. When Copland had finished his dictionary he invited to his hospitable table many of his literary friends to dinner. I was present. Fortunately or unfortunately, I was the oldest member of the press on this memorable occasion. Those who were ever present at Copland's gatherings may readily conceive what a magnificent feast was spread for us. I had the honour of proposing his health on this occasion. We were in reality celebrating a great event. The wines were of the finest quality. I shall not easily forget the triumph with which a dozen bottles of Johannisburgh were produced on the table. "These," said Copland, "were given to me nearly forty years ago, and I made up my mind that they should not be opened till my dictionary was completed." They were now opened,—half a dozen of them were in good condition, the other half were vinegary and undrinkable.

It is worthy of note that both Cooper and Copland wrote very clear and distinct hands, as also did James Johnson, who for a long series of years edited the *Medico-Chirurgical Review*. Sir Astley Cooper wrote a clear and bold hand; Brodie made a scrawl on paper only to be equalled by the caligraphy of Elliotson. Samuel Cooper was an excellent teacher; his facts were stated with clearness and conciseness. He always lectured from notes, and was in the habit, when giving his clinical lectures, of writing down the main points of the cases and his observations on them in a neat little book about six inches by four, written in the neatest style, and stitched with the greatest care. The little manuscript book consisted of from sixteen to twenty pages, and he always handed this to me after the lecture. These valuable records were published in the pages of the *Lancet* at the time. I seldom found it necessary to alter or to add a word to them. At the bedside Cooper was painstaking, clear in diagnosis, but somewhat heavy and slow. He was a great favourite with the students, and always commanded their attention and respect. In person he was rather above the middle height, stoutly and firmly built; his eyes were a "sagacious grey," indicating power; his mouth was one of inflexible decision and firmness, if not obstinacy. Like Copland and Ryan (two of the greatest compilers of our time), his head was massive, and it might be said "grand." As an operator Cooper was careful, slow, and somewhat clumsy, but sure. He made mistakes, as all great surgeons have done. He had none of the celerity and mechanical genius or the *élan* of his colleague Liston.

(To be continued.)

MR. LOWE AT ST. THOMAS'S HOSPITAL.

The annual ceremony for distributing prizes to the successful pupils of this Hospital was held in the Governors' Hall on Wednesday, the 25th inst. There was a large assemblage of ladies and gentlemen interested in the welfare of the Hospital, who had come to contribute their quota of congratulations to the recipients of the coveted prizes.

Mr. Lowe commenced his address by congratulating the prizemen *en masse*, alluding especially to the House-Surgeon's Prize as one of great practical value for giving the advanced student a thorough insight into the details of practice before he was actually launched upon the world to act upon his own responsibility. He next alluded to a remark which had just fallen from the lips of Mr. Simon, to the effect that "as Medical Officer of the Privy Council he had derived much useful instruction and support from the heads of that department, especially Mr. Lowe, who had always shown himself most ready to promote the interests of the profession as far as he was able." Mr. Lowe regretted, on the other hand, that Mr. Simon had not imparted to him some of his vast store of medical knowledge, to enable him the better to address an assemblage of medical men. One disadvantage of being a prizeman was that he might become unduly elated by his success, and fall into a state of indifference respecting other more important duties belonging to his student career. Aristotle once said that men valued distinction because it confirmed them in their good opinion of themselves. There were other things better than obtaining prizes, such as the acquisition of useful knowledge. It did not follow that he who obtained a prize had done good work. He might have the guinea stamp—but "a man's a man for a' that." All depended upon how he succeeded in discharging the duties of life when he had to undertake them. The verdict of to-day might be reversed by the experience of to-morrow. There were many things necessary to a successful career which could not be gauged by previous prize-winnings; such were habits of industry and observation, which could not be tested by competitive trials. There were also many moral qualities, such as kindness, gentleness, honesty, shrewdness, etc., all which contributed to make a man a successful practitioner. The first object set before us in life is to do something to make ourselves useful, but that object will not be attained if it is pursued in a direction contrary to the career most befitting us. To

alleviate pain is the object and mission which medical men have ever to bear in mind. Even though they should fail to obtain corresponding remuneration, they would have the satisfaction of knowing that they had in a most disinterested way contributed to the relief of their fellow-creatures, and that was a higher object than pecuniary benefit to themselves. If the great object were to alleviate human suffering, doubtless they would prove the truth of the Scriptural maxim, "Seek God and His righteousness, and all these things shall be added unto you." Again, those who had failed to win prizes need not be discouraged, because it may have happened that their abilities were as great, but they did not display the same zeal in competition as their more successful rivals. They might be assured that there was no nobler profession in the world than the medical profession. The longer we lived the more we realised the truth of that observation of Dr. Johnson's, that length of days and great genius are not always necessary to success in life. Some men strove hard to obtain success and benefit themselves in mercantile pursuits, and they had themselves to thank; but no one could fully estimate, still less doubt, the benefits accruing to the world at large from the cure of disease by skilful physicians. The medical profession stood upon a solid basis: it was not subject to the caprice of fanatics; it rested not on the traditions of the fathers or on the writings of our forefathers; its precepts were subject to the unerring decrees of natural laws, because founded upon a thoroughly scientific basis only to be understood by those possessing a scientific knowledge of their profession, and the unalterable laws of nature. He also gave a word of advice to those about to enter upon the practice of their profession. He advised them not to seek to give patients the impression that they were more learned than they really were. The profession must not rest satisfied with present attainments. They would have much to learn as well as to unlearn. Medical men must become more scientific before they could be dogmatic. They should never assert as fact that which they were not prepared to prove. We had not yet arrived at the point when medical witnesses could always give off-hand an opinion that they could assert with the confidence that it could not be challenged. They should also remember that Nature is a kind nurse, and that she often assists one out of his difficulties. There are generally some odds in favour of Nature. They should endeavour, however, to administer remedies, not haphazard, but with a certain knowledge of their power and means of curing disease. Neither should they misuse the influence which they as medical men would obtain in the families attended. Their reputation should not suffer for the sake of self-aggrandisement. There must be real and substantial pleasure and satisfaction in the practice of the medical profession—where men are constantly bestowing enormous benefits upon their fellow-creatures. The talents committed to them should be used with discretion, and with equal regard to the poor as the rich. No one more richly deserved success than the hard-worked, disinterested medical practitioner.

REVIEWS.

Clinical and Pathological Observations in India. By J. Fayrer, C.S.I., M.D., F.R.S.E., F.R.C.P. of London, F.R.C.S. of Edinburgh; Honorary Physician to the Queen; Surgeon-Major Bengal Army; Professor of Surgery in the Medical College of Bengal; First Surgeon of the Medical College Hospital, Calcutta; Member of the Senate and late President of the Faculty of Medicine of the University of Calcutta. London: J. and A. Churchill, New Burlington-street. 1873. Pp. 648.

As a prominent member of the University of Calcutta, and Professor of Surgery in the Medical College of Bengal, Dr. Fayrer's name has been well known to the profession in this country; and his influence as a teacher amongst the Bengalees has been thoroughly acknowledged in the Medical College Hospital of Calcutta. To the pen of this gentleman we are indebted for "The Thanatophidia of India," a description of the venomous snakes of the Indian Peninsula, and of the effects of their poison upon life, which is now going into a second edition; as well as for a volume on "Clinical Surgery in India," published in 1866.

The contents of the present volume are, like those of its predecessor just referred to, of a practical character, being the outcome of several additional years of experience in an extensive field of observation. The book opens with an address on surgery, delivered at the annual meeting of the Bengal Branch of the British Medical Association in March, 1868. The first point the author draws attention to in this address is that certain changes, and the reduction of the number of patients in the wards of the Medical College Hospital, improved the condition of the hospital, especially by causing a diminution in the number of cases of pyæmia and osteo-myelitis. At the same time it is intended to be understood that the application of the antiseptic principle in the treatment of surgical disease has been in no small degree the cause of this decrease in blood-poisoning diseases. A long list of cases in which carbolic acid in some form or other was employed is supplied; but even with this and Dr. Fayrer's excellent remarks upon the cases in particular and the treatment in general, we do not find conclusive evidence of any beneficial results *special* to carbolic acid, and certainly no proof whatever of its acting in the manner imputed to it by its originator and many of its advocates. Another subject of importance briefly referred to in the address is the prevalence of malaria in Bengal; the different ways in which it expresses itself, and its influence in urethral affections after catheterism. Lastly, attention is drawn to an original method of operating for the radical cure of hernia introduced by the author in 1862 as more simple, and at the same time as efficacious a plan as that of Wutzer, employed by the author up to that time. The operation and instruments required for it are described at pages 45 and 46; but Dr. Fayrer wishes it to be understood that he regards the operation as of a somewhat uncertain character as to its results, though it offers a sufficient prospect of success to warrant the surgeon and justify the patient in its attempt. This we consider a fair and impartial as well as a sound opinion upon an important subject—a subject, too, which is clearly a pet one of the author's.

The remarks on "The Pyæmia of Osteo-myelitis" which follow immediately upon the address, are to a great extent combative of opinions expressed by Dr. Braidwood. There is not the slightest doubt to our minds that Dr. Fayrer is correct in stating that osteo-myelitis is often the precursor and cause of dangerous pyæmic symptoms. It may be remembered by some of our readers that an eminent surgeon in writing on pyæmia has lately expressed himself in these terms:—"Pyæmia may properly be considered as one of the natural sequences of osteo-myelitis, inasmuch as in a very large proportion of the cases which terminate fatally pyæmia is present. . . . The relations of pyæmia to osteo-myelitis are rendered more obvious by the fact that pyæmia is almost unknown except in connexion with suppurative inflammations of the bones." Here we have an assertion not only in support of, but going beyond, Dr. Fayrer's own statement; for while Dr. Fayrer fully recognised many other sources of pyæmia, Dr. Hamilton, of New York, whom we are now quoting, first states that pyæmia is a "natural sequence of osteo-myelitis," and then that "pyæmia is almost unknown except in connexion" with it: the inference from which is that osteo-myelitis is almost the only cause of pyæmia. Strong as the association of the two conditions is, this view of Dr. Hamilton's in our opinion unquestionably represents it as existing to an excessive degree; and even in the association, so far as it undoubtedly exists, we cannot go with Dr. Fayrer to the extent of admitting that osteo-myelitis is never the result or sequence of pyæmia, and ought never "to be regarded as merely one of a series of indications of blood-poisoning." On the contrary, we would with Dr. Braidwood place osteo-myelitis in the same category with other pathological changes significant of that morbid state —pyæmia,—though while doing so we would state our conviction that the bone affection more frequently precedes and causes the general condition than it follows as one of the sequelæ of general blood-poisoning. The great importance of determining whether the osteo-myelitis is a consequence or a probable cause of pyæmia in any particular case is of course in reference to the treatment. Both Dr. Hamilton and Dr. Fayrer have stated that the ablation of the affected bone, even after the supervention of pyæmia, is sometimes followed by recovery; whereas if the osteo-myelitis is only expressive of a general pyæmic condition, no operation is likely to be of service.

Another result of blood-poisoning on which Professor Fayrer has written in the *Indian Annals* and other periodicals, and to which he now draws attention in the chapter on "The Pyæmia of Osteo-myelitis," is the rapid formation of firm fibrinous coagula in the right side of the heart, and the consequent apnœa which in many cases proves rapidly fatal. The formation of these coagula takes place, as is well known, in

persons suffering from exhaustive diseases, such as croup, cholera, diphtheria, and others; and it has been often stated that these form either during dissolution or in the stage of these diseases which just precedes death, or as one of the last vital changes in pyæmia itself. But such, Dr. Fayrer asserts, is not the case, for again and again he has seen patients whose recovery had been reasonably prognosticated, and whose wounds were healthy, overwhelmed suddenly and carried off in a short space of time by the formation of these clots of fibrine. The occurrence of plugging of the right side of the heart as the result of blood changes in pyæmia, whether of osteo-myelitis or other sources of septicæmia, is frequently noted in patients in the Calcutta Hospital, and is a condition readily diagnosed in its incipient stages even two or three days before death; for, Dr. Fayrer remarks, "to the ordinary symptoms of pyæmia are added great rapidity and urgency of breathing (whilst at the same time the air is freely entering the air-cells), feeble and irregular pulse, with great restlessness and delirium, which ends in death." But, besides referring to this subject in the place and manner we have mentioned, and in his remarks upon individual cases of osteo-myelitis and pyæmia, the author gives up thirty-five pages to its consideration in a separate section, entitled "Fibrinous Coagula in the Right Side of the Heart as a Cause of Death after Surgical Operations." In this section the details of nine cases are recorded in which death followed upon surgical operations, of different kinds and different degrees of severity, and was caused, as post-mortem examination in each case established, by fibrinous plugging of the heart. The author is at special pains to point out that without the concurrence of ichorous toxæmia, and where, in all other respects saving the effects on the system of the injury or operation, the patient is in good health, these fibrinous clots may form and slowly or rapidly destroy life.

Dr. B. W. Richardson no doubt has had great influence in drawing the attention of physicians to the treatment of fibrinous depositions in the heart, even *in extremis;* and he it was who in 1850 and 1851 raised (to use his own expression) from a silence of nearly a hundred years the subjects of the nature, diagnosis, and treatment of fibrinous coagula during life. But much credit is due to Dr. Fayrer for the manner in which he has brought these same subjects before the notice of surgeons, and for the care with which he has proved that the formation of these coagula in the heart is a danger to be apprehended after any surgical operation. Further, Dr. Fayrer thinks that in not a few fatal cases of wounds or operations in which the cause of death has been attributed to shock or exhaustion it would be found upon a revision of the post-mortem examination that death resulted from the presence of such coagula. The following quotation will convey to our readers the author's views on this subject:—

"Pyæmia, shock, gangrene, tetanus, and secondary hæmorrhage are the formidable complications which, even to the layman's mind, render all surgical proceedings replete with dread; and terribly does the first of these interfere with our success. But that a patient may have recovered from the shock and first effects, and subsequently perish from another cause differing from any of them, yet directly traceable to the operation, is hardly generally known, and even professionally has received but little consideration. The cases I append are good examples of what I refer to, and merit consideration. The chief points of interest are, that in persons previously in fair health a condition of the blood may be induced, as the result of the effects of a severe injury, wound, or operation, which has a tendency to cause the formation of fibrinous coagula in the cavities of the heart, which may and do prove fatal."

With regard to the management of this accident in surgical patients, Dr. Fayrer says that "particular attention should be paid to the diet and the administration of such remedies as may counteract the spanæmic condition, which we may fairly assume to exist when these symptoms appear." The hyposulphites recommended by Polli, and alkalies, and especially ammonia, as recommended by Richardson, and, above all, plenty of fresh air, are the remedies advocated.

In a chapter on "The Uses of certain Articles in Surgery," the great utility of carbolic acid is again enforced, and a brief abstract of a few cases treated by petroleum warrants the author in concluding that it has been applied with benefit, and possesses some, if not all, the advantages assigned to carbolic acid. The use of horsehair sutures is highly spoken of. Well-selected white hair out a horse's tail is, in Dr. Fayrer's opinion, in many respects better than any suture hitherto devised. It has all the advantages of metal in its smooth and unirritating surface; it is not likely to excite suppuration, nor does it decompose; and it can be removed readily without hæmorrhage or pain. For wounds of the face, eyelids, and in plastic operations it is peculiarly suitable.

We could with pleasure and advantage notice each one of the chapters or sections of this book in the same manner as we have done the two or three of the earlier ones, but we can only just name the subjects treated of. There is less reason for us to do more since much of the material of the volume has previously appeared, in some form or other; but Professor Fayrer has done well to collect his separate theses together. The method of the book consists of practical and clinical remarks upon different topics, with the report of cases to substantiate and illustrate the points discussed. In this way are treated aneurism, tetanus, gunshot wounds, fractures and dislocations, bites of animals, diseases of the jaws, tracheotomy, hernia, stricture and urethral fever, elephantiasis of the leg and scrotum, iliac abscess, injuries to the head. Then follows a statistical account of amputations, and afterwards over a hundred pages are devoted to the accounts of miscellaneous cases, with the author's observations upon them.

An interesting chapter on the subject of hydrocele immediately precedes this collection of miscellaneous cases. In this the author points out that the disease in India is one of the many forms in which the influence called "malaria" expresses itself. Hydrocele is frequently found associated with scrotal hypertrophy of a simple or elephantoid character (generally the latter), and is one of the earliest symptoms in many if not all of these cases. In the natives of Bengal, hydrocele, without elephantiasis, sometimes attains the size of a man's head and even larger. In Europeans in India the disease seldom attains so great a size, though it becomes much larger than it is usually met with in Europe. Dr. Fayrer's remarks on the treatment of hydrocele must carry much weight with them, considering the frequency of the occurrence of the disease in Bengal, and the wide opportunities he has had of trying all varieties of plans and remedies.

Altogether, we can strongly recommend the book to the perusal of practical surgeons. In all probability they will derive some ideas which will be new to them, and, at any rate, they will be able to ascertain the results of the experience of a very discriminating and acute observer in their own field of labour.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

Edinburgh, June 23.

The Health of Edinburgh—Rubeola—Typhoid and Milk—Miss Jex Blake and others *v.* the Chancellor and Senatus of the Edinburgh University.

This year has up to the present time been a comparatively healthy one here, notwithstanding the prevalence in our midst for some months of both measles and typhoid fever. The former disease has been for the most part of a very mild type until quite lately, when a number of cases of so-called rubeola or rötheln, with severe throat symptoms, have been met with.

It is a noteworthy peculiarity in the distribution of the disease in the present epidemic, that it has been almost entirely confined to the New Town, north of Princes-street. The poorer districts of the Old Town have escaped wonderfully. At the Royal Hospital for Sick Children there has not been a single application for admission from this cause during the present year. It further appears, from the weekly returns of the Medical Officer of Health for the city, that of ten fatal cases which have occurred during the past fortnight, nine were in the New Town, one in the Old Town, and none in the suburbs.

The districts which have been freest from measles are, generally speaking, those in which small-pox prevailed most last year. Is there any relation between these two facts? Typhoid fever is also amongst us, and seems to follow pretty closely on the beat of certain milkmaids.

Our Medical Officer of Health, Dr. Littlejohn, is engaged at present in inspecting the private wells of various dairies from which the city is supplied with milk. He has already had the

water of four private wells connected with dairies subjected to careful analysis, with the result that they have been found so much contaminated with sewage and other impurities that orders have been given to have them closed immediately. How the poison finds its way from the well into the consumer's system is a question which admits of many answers. I suspect, however, that the unscientific public see only one possible solution of the difficulty, and regard themselves as the latest discovered test for the adulteration of milk.

The judges of the Second Division of the Court of Session received on Wednesday last the opinions of the consulted judges in the case of Miss Sophia Louisa Jex Blake and others against the Chancellor and Senatus of the Edinburgh University. The Lord President, who is Chancellor of the University, being a party in the action, declined to give an opinion. The other First Division Judges, Lords Deas, Ardmillan, and Jerviswoode, concur in the judgment of Lord Gifford; while Lord Gifford's colleagues in the outer house, Lords Ormidale, Mure, Mackenzie, and Shand, are of opinion that the judgment should be reversed.

The consulted judges unanimously consider that the ladies had no right to enter the University prior to the existence of the regulations framed by the University authorities in 1869. They differ, however, in opinion regarding the validity of those regulations—one party holding that it is within the power of the University authorities to frame such regulations; while Lord Gifford's four colleagues in the outer house hold that the University authorities have no such power. However this may be, the regulations have virtually become a dead letter, as the Professors cannot be got to teach separate classes, and all of the consulted judges are of opinion that it is not within the power of the Court of Session or of the Senatus to decide that they should do so.

June 30.

The case of Miss Jex Blake and others against the Chancellor and Senatus of the University of Edinburgh was decided, on Friday, in the Second Division of the Court of Session. Three of the judges, Lords Cowan, Benholme, and Neaves, held that the interlocutor of Lord Gifford, which was in favour of the ladies, should be reversed; while the Lord Justice Clerk concurred in the interlocutor. The majority considered the resolution of 1869 to be quite beyond the power given the University authorities by the statute of 1858, and therefore illegal.

Unless an appeal is made to the House of Lords, and this decision is reversed, the question which has so long disturbed the Edinburgh University may be considered to be at rest for a long time to come.

We have always been hopeful that the good sense of Scotchmen would in the end prevail. The marvel has been that anything so ridiculous should have survived so long here, and that it should have had the support of so many reputed wise.

But, although

"Full oft we see
Cold wisdom waiting on superfluous folly,"

it is well if, in the end, the folly is recognised to be superfluous, and the wisdom weeded of it.

Many—including not a few of the ladies' former supporters—will not be sorry for this last affecting proof of how

"The best-laid schemes o' mice an' (wo)men
Gang aft a-gley."

GENERAL CORRESPONDENCE.

THE CHAIR OF ANATOMY AT KING'S COLLEGE.

LETTER FROM MR. EDWARD BELLAMY.

[To the Editor of the Medical Times and Gazette.]

SIR,—I see a kind notice in your paper of my candidature for the Chair of Anatomy at King's College. I beg leave to state that I have some time since withdrawn my name from the list of candidates, on the understanding that a "pure anatomist" was the *desideratum* of the School. I was misled by the advertisement. I am, &c.,

June 21. EDWARD BELLAMY.

MRS. MOIR, widow of the late Dr. Andrew Moir, Lecturer on Anatomy in King's College, has been nominated to a pension on the Civil List of £45 a year.

NEW INVENTIONS.

LESLIE'S PLIABLE PLASTERS.

WE have received from Messrs. Mackey and Co., of Bouverie-street, Fleet-street, several specimens of these plasters. They appear to have the following advantages:—They adhere well, are limp, and are therefore easily applied to an unequal surface, and they are strong in texture. The pliable adhesive plaster is a very good plaster for ordinary use; the pliable holland plaster makes an excellent strapping to be used after larger operations. The pliable court plaster is spread on silk, and is an elegant plaster for domestic surgery.

OBITUARY.

DAVID MATHIAS, M.R.C.S. ENG., L.R.C.P. LOND., DIED at his residence, in High-street, Cardigan, on the 9th ult., aged 52. Born at Castleygarn, near Newport, Pembrokeshire, he studied at Middlesex Hospital, and obtained the diplomas of M.R.C.S., L.M., and L.S.A. in the year 1853. He entered into partnership with Mr. John Bartlet Bevan, then practising at Cardigan, whose daughter he married. On Mr. Bevan's death, after the long professional career of fifty-two years, Mr. Mathias succeeded to the practice, which he conducted with unremitting energy until within a few months of his death. His professional skill was universally acknowledged, not only by his patients, but especially by his professional brethren at Cardigan, whose esteem and confidence he held until the last. An excellent anatomist, a clever operator, a thoroughly practical man throughout his career; a cheerful, intelligent companion, a sympathising, tender friend to the sick, he was generally beloved by his large circle of friends, and his loss will be severely felt in the town where he resided. The hardships of a medical life amongst the Pembrokeshire hills, a too willing ear to the pressing calls of a terribly exacting community, combined with an unselfish spirit, which led him, utterly regardless of his own health, to constant acts of self-sacrifice—all eventually broke down his constitution. In 1871 he obtained the diploma of L.R.C.P. Lond., and became a Fellow of the Obstetrical Society. He was Medical Officer to District No. 2 of the Cardigan Union and to the Workhouse, Medical Officer of Health for the same district, and Certifying Factory Surgeon.

MEDICAL NEWS.

UNIVERSITY OF DUBLIN.—At the Summer Commencements held in the Examination Hall of Trinity College, on Wednesday, June 25, the following Degrees and Licences in Medicine and Surgery were conferred by the Right Hon. Sir Joseph Napier, Bart., Vice-Chancellor of the University:—

Magister in Chirurgia honoris causa.

Porter, Georgius Hornidge.

Baccalaurei in Medicina.

Bredon, Alexander Macaulay.
Browne, Jacobus.
Clarke, Andreas.
Clarke, Thomas Kilner (*ad eundem Cantab*).
Crowe, Georgius Wyndham.
Foot, Edvardus Carolus.
Frazer, Gulielmus.
Garvey, Thomas Blennerhassett.
Gregg, Rev. Thomas Huband.
Kane, Nathaniel Henricus Kirkpatrick.
Levinge, Edvardus Georgius.
Marmion, Edvardus Johannes.
De Montmorency, Hon. Arthurus Hill Trevor.
Newman, Horatius Townsend.
Oulton, Gulielmus Henricus.
Pearce, Georgius Alonzo Creech.
Porter, Joseph Franciscus.
Stoyte, Jacobus Carolus.
Walker, Johannes.

Magistri in Chirurgia.

Clarke, Andreas.
Stoyte, Jacobus Carolus.
Kane, Nathaniel Henricus Kirkpatrick.

Doctores in Medicina.

Browne, Jacobus.
Clarke, Thomas Kilner.
Gregg, Rev. Thomas Huband.
Hocter, Robertus Barry.

Licentiatus in Medicina.

Hickson, Georgius.

The conferring of the honorary degree of Master in Surgery upon Mr. George H. Porter, Surgeon to the Queen in Ireland, and Senior Surgeon to the Meath Hospital, was the noteworthy event of these Commencements as regards the Profession of Medicine.

THE QUEEN'S UNIVERSITY IN IRELAND.—A meeting of the University was held in the Council Chamber, Dublin

Castle, on Monday, June 23, when Sir Dominic J. Corrigan, Bart., M.P., M.D., Vice-Chancellor of the University, conferred the following Degrees and Diplomas :—

The Degree of Doctor in Medicine.

Atkins, Ringrose, M.A., of Queen's College, Cork.
Corbett, John Lane, of Queen's College, Cork.
Corly, Henry, B.A., of Queen's College, Cork.
Davis, Francis E., of Queen's College, Cork.
Gormley, Joseph Andrew, of Queen's College, Galway.
Heath, Richard, of Queen's College, Belfast.
M'Millen, Hugh, of Queen's College, Belfast.
Mullen, Jarlath J., of Queen's College, Galway.
Pearson, William, of Queen's College, Cork.
Powell, Caleb K., of Queen's College, Cork.
Quinten, Richard Frith, B.A., of Queen's College, Belfast.
Robertson, Joseph, of Queen's College, Belfast.
Smyth, Carew C. Howard, of Queen's College, Cork.
Wilson, John Forsythe, of Queen's College, Belfast.

The Degree of Master in Surgery.

Armstrong, George W. F., M.D., of Queen's College, Cork.
Atkins, Ringrose, M.A., of Queen's College, Cork.
Benson, Phillip Lambert, M.A., M.D., of Queen's College, Cork.
Corbett, John Lane, of Queen's College, Cork.
Corly, Henry, B.A., of Queen's College, Cork.
Davis, Francis E., of Queen's College, Cork..
Gormley, Joseph Andrew, of Queen's College, Galway.
Heath, Richard, of Queen's College, Belfast.
Johnston, David, M.D., of Queen's College, Belfast.
Mullen, Douglas, M.D., of Queen's College, Galway.
Mullen, Jarlath J., of Queen's College, Galway.
Pearson, William, of Queen's College, Cork.
Powell, Caleb K., of Queen's College, Cork.
Simpson, William, M.D., of Queen's College, Galway.
Smyth, Carew C. Howard, of Queen's College, Cork.
Wheeler, John, M.D., of Queen's College, Cork.
Wilson, John Forsythe, of Queen's College, Belfast.

The Diploma in Midwifery.

Armstrong, George W. F., M.D., of Queen's College, Cork.
Atkins, Ringrose, M.A., of Queen's College, Cork.
Corbett, J. Lane, of Queen's College, Cork.
Johnson, David, M.D., of Queen's College, Belfast.
Mullen, Douglas, M.D., of Queen's College, Galway.
Quinten, Richard Frith, B.A., of Queen's College, Belfast.
Rutherford, Wm., M.D., of Queen's Colleges, Galway and Belfast.
Simpson, William, M.D., of Queen's College, Galway.
Smyth, Carew C. Howard, of Queen's College, Cork.
Wheeler, John, M.D., of Queen's College, Cork.
Wilson, John Forsythe, of Queen's College, Belfast.

The Secretary to the University announced that the following candidates had passed the first University Examination in Medicine :—

Allen, James Franklin, of Queen's College, Cork.
Auderson, Adam, of Queen's College, Galway.
Auderson, J. A. S. Fisher, of Queen's College, Belfast.
Balbirnie, Hugh De Vaux, of Queen's College, Belfast.
Burges, William Armstrong, of Queen's College, Cork.
Camac, Robert John, of Queen's College, Belfast.
Campbell, Arthur Robert, of Queen's College, Belfast.
Edge, A. Mathewson, of Queen's College, Belfast.
Ferguson, William, of Queen's College, Belfast.
Fisher, Turner J., of Queen's College, Belfast.
Freyer, P. Johnson, B.A., of Queen's College, Galway.
Gleeson, William, of Queen's College, Cork.
Grew, Francis, of Queen's College, Belfast.
Hamilton, James, of Queen's College, Belfast.
Holmes, John, of Queen's College, Cork.
Irwin, William Samuel, of Queen's College, Galway.
Jennings, William, of Queen's College, Cork.
MacAuliffe, Alexis, B.A., of Queen's College, Cork.
M'Crea, Hugh Moreland, of Queen's College, Belfast.
Maguire, Daniel, of Queen's College, Galway.
Maybury, Anrelius Victor, of Queen's College, Cork.
Martin, Samuel Edgar, B.A., of Queen's College, Belfast.
Murtagh, Edward Joseph, of Queen's College, Cork.
O'Connor, P. P. Fenelon, B.A., of Queen's College, Galway.
O'Sullivan, Daniel J., of Queen's College, Cork.
Pearson, Christopher, B.A., of Queen's College, Cork.
Robertson, David, of Queen's College, Belfast.
Ross, William, B.A., of Queen's College, Belfast.
Ryan, Michael Richard, of Queen's College, Cork.
Sherrard, Cæsar Dudley, of Queen's College, Cork.
Warren, John Monteith, of Queen's College, Galway.

DENTAL SURGEONS.—At a meeting of the Dental Board of the Royal College of Surgeons on the 30th ult., the following gentlemen, having undergone the necessary examinations, were admitted Licentiates in Dental Surgery, viz. :—

Binns, Edmund, Croydon, student of the Westminster Hospital.
Bruce, Peter, Valparaiso, Chili, of the Middlesex Hospital.
Cursetjee Framjee Khory, of Bombay.
Gibbings, Ashley, Chichester, of King's College.
Hepburn, David, Portland-place, of the Middlesex Hospital.
Kissack, Edward Thomas, Douglas, Isle of Man, of the Middlesex Hospital.
Merson, James, South Molton, Devon, of St. Thomas's Hospital.
Merson, William, South Molton, Devon, of St. Thomas's Hospital.
Mummery, John Robert, Cavendish-place, of University College.
Phillips, Arthur Robert, Cavendish-square, of St. Thomas's Hospital.
Richardson, Edwin Joseph, Duke-street, Manchester-square, of St. Mary's Hospital.
Rodway, Henry Aloysius Barron, Torquay, of St. Thomas's Hospital.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a Certificate to practise, on Thursday, June 26 :—

Walker, John Robert, Clifton-gardens, W.

The following gentleman also on the same day passed his primary professional examination :—

Houlbrook, Edward, of the Leeds School of Medicine.

At the recent competitive examination for the Prizes in Botany, given annually by the Society of Apothecaries, the successful Candidates were—

First.—Todd, John, student of University College, London. A Gold Medal.
Second.—Cuming, Charles Henry, student of University College, London. A Silver Medal and a Book.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOSWORTH, J. R., M.R.C.S., L.R.C.P. Edin., L.S.A.—Medical Officer of the Banstead District of Epsom Union.

BIRD, P. H., F.R.C.S.—Medical Officer of Health for the Fylde District.

COLMAN, W. S., M.R.C.S. Eng., L.S.A.—District Medical Officer to the Brighton and Hove Dispensary.

FOX, CORNELIUS B., M.D. Edin., M.R.C.P. Lond., M.R.C.S. Eng., L.M., L.S.A.—Medical Officer of Health for East Essex.

JOHNSTON, RICHARD, M.R.C.P., L.R.C.S.I., L.M.—House-Surgeon to the District Hospital, West Bromwich.

KING, J. B., M.R.C.S., L.S.A.—District Medical Officer to the Brighton and Hove Dispensary.

MACKINTOSH, JOHN INNES, M.D. Aberdeen, L.R.C.S. Edin., L.R.C.P. Edin.—Medical Officer of Health for Caistor.

NICHOLLS, W. H., M.R.C.S. Eng., L.S.A.—District Medical Officer to the Brighton and Hove Dispensary.

NICHOLSON, JOHN METCALFE, M.D., M.R.C.S., L.S.A., L.M.—Medical Officer for the Hunslet Workhouse, Yorks, *vice* J. J. W. Gisburn, resigned.

SPURGIN, FREDERICK WILLIAM, M.R.C.S., L.S.A. Lond., L.R.C.P. Edin.—District Medical Officer to All Souls and Cavendish District, the Parish of St. Marylebone, *vice* Mr. William Clapp, resigned.

NAVAL APPOINTMENTS.

ADMIRALTY.—George F. A. Drew, Staff Surgeon to the *St. Vincent;* Maxwell Rodgers, M.D., Staff Surgeon, second class, to the *Egmont*, for service at the Falkland Isles; Thomas Harvey, Surgeon to the *Argus;* John W. Davis, M.D., Surgeon to the *Sultan;* A. Fisher, Staff Surgeon to the *Jumna;* Matthew F. Ryan, Surgeon to the *Jumna*. Henry Piers, Esq., has been authorised to assume the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, from June 12, the date of his being placed on the Retired List.

BIRTHS.

COLLINS.—On June 26, at Euston-place, Leamington, the wife of C. P. Collins, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

GANGE.—On June 26, at Faversham, the wife of Frederick A. Gange, M.D., of a son.

HOGG.—On June 29, at Ainslie Lodge, Turnham-green, the wife of William Bruce Gordon Hogg, M.B., C.M. Edin., of a son.

HUNTER.—On June 30, at Bridge House, Dartford, the wife of R. H. Hunter, M.R.C.S., of a son.

KING.—On June 28, at 74, Victoria-park-road, the wife of William Talbot King, M.R.C.S. Eng., L.S.A., of a daughter.

MENZIES.—On June 25, at Castellamare, South Italy, the wife of J. A. Menzies, M.D. Edin., of a son.

ROGERS.—On June 26, the wife of Joseph Rogers, M.R.C.S. Eng., L.D.S., of 16, Hanover-square, and Lombardy Lodge, Kensington, of a daughter.

WHITE.—On July 1, at 1, Storey's-gate, the wife of J. Campbell White, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., of a son.

MARRIAGES.

CAMPBELL—WADDY.—On June 26, at Trinity Wesleyan Chapel, Bristol, Donald Campbell, Esq., M.D., of Calne, Wilts, to Emily Martha, daughter of the Rev. S. D. Waddy, D.D., Eadcliffe, Redland, Bristol.

FOSTER—COOPER.—On June 26, at Christ Church, Wanstead, Edward Walker Webb, son of William Foster, Esq., of Dunstall Court, Feckenham, Worcestershire, to Kate Clara, only daughter of William Cooper, M.D., of Martham House, Snaresbrook, Essex.

HEATON—HANCOCK.—On June 26, at the Rectory Church, St. Marylebone, Captain Arthur Heaton, late 15th Regt., son of the late John Heaton, Esq., and the Hon. Mrs. Heaton, of Plas Heaton, North Wales, to Frances Burrow, only daughter of Henry Hancock, F.R.C.S., President of the Royal College of Surgeons of England.

MORTIMER—HEAZLE.—On July 1, at St. Peter's Church, William Mortimer, LL.D., only surviving son of the late Major Mortimer, H.M. 36th Regiment, to Lizzie Heazle, widowed daughter of the late J. H. Sheppard, M.D., Abbeyleix, Queen's County.

NATHAN—WAGSTAFF.—On June 25, at the Church of the Holy Trinity, Weymouth, Henry Nathan, M.R.C.S. Eng., L.S.A., to Emily, youngest daughter of the late Thomas Wagstaff, Esq., of Kensington, Middlesex.

ROBERTS—TOWNEND.—On June 28, at St. John's, Notting-hill, John Kempe C. C. Roberts, M.R.C.S., eldest son of Stephen Roberts, Esq., of Veryan, Cornwall, to Gertrude, second daughter of the late Frederick Townend, Esq., of Clarendon-road, Notting-hill.

SMYLY—GARDE.—On July 1, at the Molyneux Church, Dublin, Matthew John Smyly, Esq., of 35, Upper Fitzwilliam-street, second son of the late Josiah Smyly, M.D., to Katherine Georgina, second daughter of John Davis Garde, Esq., of Fitzwilliam-place.

DEATHS.

BREWSTER, ANNA MARIA, widow of the late Dr. C. S. Brewster, of Paris and Versailles, and sister of Dr. Henry Bennet, of Grosvenor-street, Grosvenor-square, W.

BROWNE, TOBIAS, M.R.C.S. Eng., L.S.A., at 8, North-terrace, Camberwell, on June 29.

DAUBERRY, JAMES, Surgeon-Major (Retired) H.M. Bombay Army, after a short illness, on June 24, in his 53rd year.

WARNE, WILLIAM COLSTON, M.B., M.R.C.S., eldest son of Thomas Samuel Warne, Esq., at 1, Merton-villas, Rochester, on June 25, aged 22.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BASFORD UNION.—Medical Officer of Health. Candidates must be duly qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to R. B. Spencer, Clerk to the Rural Sanitary Authority, Public Offices, Basford.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Candidates must be legally qualified. Applications, with testimonials, to the House Governor and Secretary, on or before July 26.

BRADFORD INFIRMARY AND DISPENSARY.—Pbysician. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, Mr. Charles Woodcock, 65, Market-street, Bradford, on or before July 8.

BROMLEY, CRANBROOK, MAIDSTONE, TENTERDEN, AND TONBRIDGE.—Medical Officer of Health. Candidates must be legally qualified medical practitioners. Applications, with testimonials, to Mr. Joseph Snelling, Tonbridge, on or before July 10.

CHESTER, TARPORLEY, &c.—Medical Officer of Health. Candidates must be legally qualified medical practitioners, and registered under the Medical Act of 1858. Applications, with testimonials, to Mr. Walker, Town Clerk, Chester, on or before July 24.

GREENWICH UNION.—Dispenser. Candidates must be registered under the Pharmacy Act of 1860. Applications, with testimonials, to Samuel Saw, Clerk to the Guardians, Union Office, Woolwich-road, Greenwich, before July 10.

HALIFAX INFIRMARY AND DISPENSARY.—Assistant Honse-Surgeon. Candidates must possess at least one legal qualification. Applications, with testimonials, to Dr. Alexander, Halifax, on or before July 15.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE, W.—Visiting Physician. Applications, with testimonials, to be sent in on or before July 12.

KING'S COLLEGE, LONDON.—Chair of Anatomy. Applications, with testimonials, to the Council.

LEEDS, BOROUGH OF.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to C. A. Curwood, Esq., Town Clerk, on or before July 7.

LONDON TEMPERANCE HOSPITAL.—Visiting Physician and Visiting Surgeon. Candidates must be total abstainers. Applications, with testimonials, to Chairman of Managers, London Temperance Hospital, 112, Gower-street, W.C.

MILE-END OLD TOWN.—Medical Officer for the North District. Candidates must be duly qualified. Applications, with testimonials, to E. J. Southwell, Clerk to the Guardians, offices, Bancroft-road, Mile-end, E., before July 10.

NORWICH DISPENSARY.—Resident Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Treasurer, R. Chambers, Esq., Catton House, Norwich.

ROYAL ISLE OF WIGHT INFIRMARY.—House-Surgeon and Secretary. Candidates must be legally qualified. Applications, with testimonials, to the Secretary, on or before July 14.

ROYAL BERKS HOSPITAL, READING.—Assistant-Physician. Candidates must be medical graduates of one of the Universities of Great Britain and Ireland, and be registered. Applications, with testimonials, to the Secretary, on or before July 14.

ST. THOMAS'S HOSPITAL MEDICAL AND SURGICAL COLLEGE.—Demonstrator of Anatomy. Applications, with testimonials, to R. G. Whitfield, Medical Secretary, on or before July 11.

SEAMEN'S HOSPITAL, GREENWICH.—House-Surgeon. Candidates must be F. or M.R.C.S. Eng. Applications, with testimonials, to the House-Governor and Secretary, on or before July 10.

SEAMEN'S HOSPITAL, GREENWICH.—Visiting Surgeon. Candidates must be F.R.C.S. Eng. Further particulars may be obtained from the House-Governor and Secretary.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must be legally qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to the Chairman of the Committee, on or before July 14.

STOCKPORT INFIRMARY.—Assistant to the House-Surgeon. Candidates must possess some knowledge of surgical dressing. Applications, with testimonials, to the Honorary Secretary, on or before July 12.

STRATFORD-UPON-AVON, ALCESTER, AND EVESHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to J. C. Warden, Esq., 11, Guildford-street, Stratford-upon-Avon, on or before July 19.

TORRINGTON UNION, NORTH DEVON.—Medical Officer for the District of Great Torrington. Candidates must be legally qualified medical practitioners. Applications, with testimonials, to P. B. Glubb, Clerk, Great Torrington, on or before July 11.

VICTORIA HOSPITAL FOR SICK CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD, CHELSEA.—Physician. Applications, with testimonials, to H. B. Scoones, Secretary, on or before July 10.

WEST HERTS INFIRMARY, HEMEL HEMPSTEAD.—House-Surgeon and Assistant-Secretary. Candidates must possess both a medical and surgical qualification, and be registered. Applications, with testimonials, to the Secretary, before July 10.

WESTMINSTER GENERAL DISPENSARY.—Surgeon. Candidates must be Fellows or Members of a College of Surgeons. Applications, with testimonials, to the Secretary, on or before July 14.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House-Governor and Secretary. Applications, with testimonials, to the Chairman of the Weekly Board, on or before July 7.

WREXHAM INFIRMARY AND DISPENSARY.—House-Surgeon. For particulars, apply to Mr. J. G. Buckton, Secretary, 9, High-street, Wrexham.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Carnarvon Union.—Mr. Richard Williams has resigned the Llanrug District; area 26,928; population 10,283; salary £60 per annum.

Hinckley Union.—The Burbage District is vacant; area 11,035; population 4179; salary £60 per annum.

Lichfield Union.—Mr. E. H. Snoad has resigned the Yoxall District; area 7780; population 1883; salary £20 per annum.

Whittlesey United Parishes.—Dr. Thomas R. King has resigned the Workhouse; salary £20 per annum; and the Southern District; salary £60 per annum.

APPOINTMENTS.

Bedford Borough.—Charles Edward Prior, M D. Aber., F.R.C.S. Eng., L.S.A., as Analyst.

Driffield Union.—George G. A. Sutcliffe, L.R.C.P. Edin., M.R.C.S. Eng., to the Kilham District.

Huddersfield Union.—Thomas H. Haigh, M.R.C.S. Eng., L.S.A., to the Golcar District. George Wilson, M.D. Glasg., L.R.C.S. Edin., to the Paddock District.

Nottingham County.—Edgar B. Truman, M.D. St. And., M.R.C.S. Eng., L.S.A., as Analyst.

St. Thomas's Union.—Frederick Wicks, M.R.C.S. Eng., L.R.C.P. Edin., to the Woodbury District.

Towcester Union.—Artbur G. Evans, M.R.C.S. Eng., L.S.A., to the Towcester District and the Workhouse.

AT the *conversazione* at the Royal College of Physicians, on Wednesday, amongst the non-medical celebrities present were a brother of the Shah of Persia, and Archbishop Manning.

MR. STEELE, surgeon, of Ovenden and Halifax, has been appointed Medical Officer of the Todmorden Union.

MR. TALBOT has been elected Medical Officer of Health for the Northern District of the Limehouse District Board of Works, *vice* Dr. Woodford, resigned.

THE Marylebone Board of Guardians last week unanimously resolved to recommend to the Local Government Board that a superannuation of £45 a year be granted to Mr. Clapp, the late Medical Officer. Mr. Clapp was appointed in 1855. Mr. Spurgin succeeds Mr. Clapp as Medical Officer.

THE LONDON AND GENERAL WATER PURIFYING COMPANY.—His Majesty the Shah of Persia having, during his visit to Trentham, expressed a wish to see the process of filtering water adopted by the London and General Water Purifying Company, the Earl of Shrewsbury (the chairman of the Company), accompanied by the secretary, attended on Monday last at Buckingham Palace with models of the filters, and explained the process, with which the Shah seemed much interested.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN JUNE, 1873.—The following are the returns (by Dr. Letheby) of the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	18·40	0·046	0·115	0·001	14·6	3·3
West Middlesex	17·10	0·029	0·126	0·000	14·1	3·0
Southwark & Vauxhall	18·10	0·043	0·104	0·001	14·2	3·4
Chelsea	17·70	0·042	0·115	0·002	14·0	3·3
Lambeth	17·93	0·044	0·105	0·002	14·1	3·4
Other Companies.						
Kent	27·90	0·004	0·243	0·000	20·8	6·0
New River	17·63	0·019	0·147	0·000	14·3	3·3
East London	17·47	0·038	0·165	0·002	14·3	3·6

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was slightly turbid—namely, in that of the Chelsea and the Grand Junction Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 115,893,425 gallons; and the number of houses supplied was 503,562. This is at the rate of 35 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 30·5 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

Mr. Rogers has been appointed Public Analyst for the Limehouse District Board of Works, at a salary of £150 per annum.

School of Physic, Trinity College, Dublin.—The Surgical Travelling Prize, value £50, has been awarded to Mr. Andrew Clarke, scholar of Trinity College.

University of Durham.—At a Convocation held on June 24, the following degree and licences were conferred on the successful candidates at the examination held in the week commencing June 16:—M.B.: George Rowell, Lic. Med., M.R.C.S. Licentiates in Medicine: W. L. Emmerson, M.R.C.S., W. T. Wilson, B.A., Ralph Young, B.A.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

G. S. N.—"Mineral Springs of North America, How to Reach and How to Use them," by Y. Y. Moorman, M.D., Physician to the White Sulphur Springs, Professor of Medical Jurisprudence and Hygiene, etc., Washington University, Baltimore. London: Sampson, Low, and Co.

P. C. S.—His Excellency Sir George Bowen and Lady Bowen are patrons of the Melbourne Hospital.

Inquirer.—The Hôpital St. Louis, in Paris, is specially devoted to diseases of the skin. It is provided with 800 beds.

Geo. N., junior.—It is proposed to secure an annual payment of £50 to Dr. Wolfe, as Ophthalmic Lecturer at Anderson's University, Glasgow, on condition that all the students attending the medical classes have the benefit of his lectures and operations on payinga fee of 5s.

Medicus.—The number of students at Anderson's University, Glasgow, last session, was 2506—an increase of 292 on the previous year.

A Constant Reader.—The next examination of Surgeons in the Royal Navy who are eligible for the rank of Staff-Surgeons 2nd Class will be held at the Royal Naval Hospitals at Haslar and Plymouth on the 15th inst.

The Royal College of Surgeons of Edinburgh on the New Army Medical Warrant.

To the Director-General of the Army Medical Department.

The Memorial of the Royal College of Surgeons of Edinburgh sheweth:

That the Royal College of Surgeons of Edinburgh, having had under consideration the present state of the Army Medical Department, have reason to believe that the Royal Warrant of March 1, 1873, is in several respects unjust and injurious to the Medical Officers of the Army.

That the College consider that only justice would be done if promotion were granted to Surgeons after a stated period of service on full pay (say twelve years—as in the Indian Medical Service), and that this promotion should carry the pay of its rank, as under Clause 3 of the Warrant a Medical Officer may now serve fifteen years as Surgeon, and even then, if not promoted, does not get the additional pay of 2s. 6d. per diem to which he would have been entitled as Assistant-Surgeon under the previous Warrant.

That, as medical officers are now simply attached to regiments for a limited period, their relative rank, as far as regulating choice of quarters is concerned, should place them on the *cadre* of the regiment or corps to which they are at the time attached, according to seniority from the date of commission, and not from the date of joining a regiment. That this rule should not apply to the commanding officer, who of course should always be senior

That the forage allowance hitherto made should not be withdrawn, or, if withdrawn, that a money compensation should be granted in lieu of it.

That promotion from the rank of Surgeon to that of Surgeon-Major should be as stipulated by Royal Warrant of 1858, by seniority alone, excepting in the cases where proved inability forms a positive disqualification against the senior Surgeon on the list standing first for promotion.

That it would be but simple justice that the medical officers who had, previous to the passing of the Warrant, been gazetted to regiments, and paid the usual mess and band subscriptions, should have the same refunded to them, as from the date of the passing of the Warrant they are struck off the regimental list of officers.

That, considering the special work of the medical officers, and the severe strain upon their constitutions in hot climates, where now so much of their service is passed, and especially bearing in mind that when sickness is most rife, and the climate most unhealthy, and consequently their services in greatest requisition, they cannot get leave of absence as regularly as their brother combatant officers—the present scale of half-pay seems to the College so inadequate, that it will be in vain to expect that good men will be induced to join the Service.

That the College, in conclusion, humbly request that the Director-General will take these circumstances into careful consideration, with the view of affording a speedy remedy for the grievances complained of.

Signed in name and by appointment of the College,

Edinburgh, June 19, 1873. Wm. Walker, President.

Rotherham Hospital and Infirmary.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—We are about to build a mortuary in connexion with this Hospital. Our first intention was to build a distinct building apart from the Hospital building (in a corner of the grounds, and as much as possible out of sight); but it has been suggested that it might be made in a cellar underneath the "special ward." This ward is elevated, and the dead-house would be on a level with the ground. This is recommended on the ground of its being so much cheaper; and, as we are poor, economy is a very serious consideration. But I have been told that there are two objections. First, it is very undesirable in a sanitary point of view to have a mortuary and post-mortem room in a hospital or close to it, and in our case there are only the flooring-boards betwixt the roof of the proposed post-mortem room and the special ward, which is for infectious cases. This, as a medical question, I do not profess to understand. The other is a feeling of taste or prejudice, and I object to it because I believe it would have a very depressing influence on the poor patients, who would see the dead-house from the windows of the male ward: and I know how strong the prejudices of the poorer classes are. I am told it is the practice in some large hospitals (ours, of course, is a very small one); but I presume in such cases it is because they have no ground beyond the building. Now, we have plenty, and although, as I said before, we are poor, I would not on that account hurt either the health or the feelings of our poor sick patients.

Will you kindly answer the following questions:—

1. Do you know any hospital where the mortuary is part of the building?
2. Is such place approved or only adopted because no other could be obtained?
3. Would you recommend us to build a mortuary and post-mortem room under our special ward?

I offer no apology for troubling you on a question which appears to me to be so important. I am, &c., The Honorary Secretary.

June 18.

*** We know of no well-built and well-managed hospital where the mortuary is part of the building, or at least where it is in close proximity to the wards. No one in his senses would place a mortuary and post-mortem room immediately under any ward.

Greenway's Limb Suspender.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In reference to my letter on "Mr. George Greenslade's Apparatus for Fractured Leg," and your accompanying note in your issue of to-day, I would beg to remark that when treating a fractured leg with my limb-suspender and convertible splint I never bandage the limb, but merely stay the foot to the foot-piece, and the thigh to the thigh-plate, with a strap and buckle. I do not consider this a "peculiar advantage" of either of the above appliances, but merely a mode of practice which may be carried out when using some of the most simple forms of splints. As regards the hinged side-splints (a very old idea), I consider them objectionable rather than advantageous, as the space between them cannot be altered to suit the limb; with a very spare patient a large amount of padding would be required to make good the deficiency. If necessary, either of my side-splints can be removed without disturbing the limb. When writing my last letter I was not aware you had done me the honour to notice in your issue of the 7th inst. some of my inventions exhibited at the International Exhibition. On referring to your report I find the term "very useful" applied to my "instruments and splints" as a whole. I esteem this a great compliment. I would avail myself of this opportunity to name some of the principal advantages afforded by my unilateral limb-suspender, irrespective of the splint:—The longitudinal trucks and rail, as in Salter's leg-sling, allow the patient to draw himself upwards or downwards in the bed, and prevent motion at the seat of injury or disease during such movement of the body; this action, however, is seldom brought into play. The transverse rail and trucks, the most frequently used, allow the body to be moved sideways, and, in conjunction with the swivel bar, enable the patient with perfect safety to abduct or adduct his limb, or to lie in a diagonal position across the bed. The form of the instrument being unilateral, it can be used for the upper extremity, and a sound leg is not thrown aside from its fellow by any intervening framework, thus preventing distress in the sound limb and obviating other inconveniences. The base of the apparatus being placed underneath the mattress, there is no possibility of the under bedclothes bulging up against the back of the limb and interfering with its free and easy movement. To prevent motion *in* a limb or strain *on* a limb there must be no obstacle to the voluntary or involuntary movement of a limb, horizontally, in any direction, and these conditions are fulfilled by this apparatus. Although the appliance was originally designed for suspending fractured legs, it is evident it would be equally useful in any case requiring the removal of the "dead-weight" of a limb from the bed, as in certain diseased joints, important wounds, gout, etc. Apart from its use in the actual treatment, it is also a luxury to the patient. By removing the foot-piece and thigh-plate from my convertible splint, the remaining portion can be applied to the upper extremity; and by entirely removing the iron plates from the splint-holder, almost any other form of splint may be substituted as the surgeon may see fit. I am, &c.,

Plymouth, June 21. Henry Greenway.

The Bangalore correspondent of the *Madras Times* says that the junior medical officers of the British service are much dissatisfied at "some new warrants," which have removed them from their regiments and placed them on a general staff list. Of twelve doctors who in January formed an actual and component part of the European corps and regiments stationed here, four only remain in April. Bistoury, of the Fleet Hoofs, now with his regiment at Malariabad, says that by this removal he loses some thousand rupees, which uniform, saddlery, chargers, band and mess contributions and subscriptions, cost the erudite disciple of Parkes and Maclean, of Netley, but a few months ago. Worst of all, the disconsolate Bistoury is deprived of the prestige, status, society, and home which his being in a crack corps gave him; and now he is a wanderer on the military-medical face of the earth at the nod and beck of the Director-General.

Comments on Medical Matters.—Medical Polity.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As an Edinburgh graduate, I think I have some title to express an opinion on matters relating to the organisation of the practitioners of the arts included under the head of medical practice in the British dominions. I see with great regret the general wish to reduce all medical practitioners to a dead level of Procrustean uniformity; as also I think it monstrous to oblige all physicians to qualify in Surgery and all surgeons to qualify in Medicine. No doubt it is convenient that the general principles of the two sciences should be reciprocally possessed; but if anything more is required the result will be a useless mediocrity and a degeneration of both Medicine and Surgery. The mental and moral qualifications for distinction in these sciences are not to be found in the same individual; and if they were, rare is the intelligence capable of mastering both. The revolutionary spirit has everywhere striven to bring about this amalgamation, and even in Brazil carried its point; but here the

course of study occupies six years, and the matriculation examination is most severe, and embraces all the subjects of the *Trivium* and *Quadrivium*. Efforts are, however, being now made to obtain the creation of a second order of practitioners, who will amalgamate better with the less educated and less wealthy classes, and will fix their residence in remote districts. The same want is also felt as regards pharmaciens, —those actually coming out of the schools being educated up to too high a standard for the conditions of existence in the country. The system which produced the great physicians and great surgeons of the seventeenth and eighteenth centuries ought not to be despised. What I would much desire to see created in the world-known and honoured University of Edinburgh is a chair of the "History of Medicine," and also of travelling fellowships, with the onus of passing one year in study at Montpellier. How many of our high-pressure London graduates could explain extemporarily the differences between the vitalist doctrines of Montpellier, the materialism of Paris, and the spiritualism of St. Thomas d'Aquinas, and their influence on points of practice? I am heartily glad to see that the Obstetrical Society proposes to care for the education of midwives. I think that as a rule midwifery practice may be left to educated midwives. Here in Brazil physicians only interfere in rare cases where operative procedure is required, notwithstanding the fact that the majority of midwives are negresses. My nine children, and numerous children on my estate, were all introduced to the world by such midwives. The Brazilian midwives are especially skilful in practising version by external manipulation. This practice is secularly traditional here, though only lately spoken of in Europe. I hope that in Ireland and Scotland measures will be adopted for a supply of good midwives; and it would be well if the Liverpool School of Medicine provided instruction for Welsh midwives. I am, &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin.,
Campinos, S. Paulo, Brazil. Brazilian Citizen.

APPOINTMENTS FOR THE WEEK.

July 5. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

7. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

8. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

9. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

10. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

11. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, June 28, 1873.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·89 in. The highest was 30·06 in. at the beginning of the week, and the lowest 29·70 in. on Tuesday evening.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE ON CASES OF PERITONEAL STRUMOUS DISEASE.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

Gentlemen,—I have thought it well to bring before you the following cases on account of their bearing upon topics that have lately, as you know, been much discussed:—

Case 1.—J. J. T., aged 44, painter, admitted Augnst 18, 1865. He had been ill near five months. Had pain first at lowest part of abdomen. Feet have never swelled. Abdomen now much enlarged; girth over umbilicus thirty-six inches and a half. Flnctuation distinct. Snperficial veins enlarged. Size of liver normal. Urine scanty; specific gravity 1015; not albuminous; deposits a large amount of lithates; high-coloured from presence of bile. Is not a spirit drinker. Heart's sounds normal. O. diet.

Augnst 26.—Right side of chest dull, almost to clavicle; breathing laboured, rather frequent; is jaundiced; hands cold; pulse extremely feeble. Died same evening.

Post-mortem.—Abdominal eavity contained a large amount of yellow serum. The peritoneum was everywhere roughened with a coating of lymph, which was very slightly rongh, and presented minute whity spots, but no trace of distinct tubercle. The omentum was shrunk up into a thick, firm cake at the upper part of the abdomen. The mesenteric glands were not enlarged. The liver was covered with fibrine, which formed areolated false membranes between it and some adjacent viscera and the diaphragm. The fibrine was soft and easily broken down. The liver, when cut into, presented a dark ground, with numerous bright yellow spots and patches of various sizes, none larger than a threepenny-piece; these were not tubercles or eancer nodules, but portions of altered hepatic parenchyma in a state of fatty atrophy. The intermediate tissue presented numerous whity ramifying streaks, evidently derived from the ramifications of Glisson's capsule. The hepatic cells appeared shrunk and wasted, and less granular than normal; it seemed as if the lobules were traversed by a sort of fibroid woof, thongh very few distinct fibres could be seen; some of the cells contained yellow matter. The spleen and kidneys were large, but normal. The left testis was enlarged and hard, and contained a large tubercular deposit, which had softened down into a purulent cavity in its interior. Two glands in the corresponding groin were also large and hard, and presented, on being cut open, masses of suppnrating tubercle. The heart was healthy as to its valves, and flaccid. The lungs were quite free from tubercle, bnt the right was much compressed by a large amount of yellow serum, which filled the pleural cavity. There was cretaceous deposit in the bronchial glands. On minute examination the whitish spots in the peritoneum were noted to be rondish, well defined, not bigger than the head of a very small pin, and to consist of nuclear corpuscles. They were not raised above the level of the serous membrane. I could not positively affirm that they were tubercles, but they seemed to be of that nature histologically.

Case 2.—B. C., aged 38, had been attending as out-patient several weeks, but on March 23 was taken very ill with severe pains in abdomen. When admitted he was in a state of collapse. He was pnt to bed, and stimnlants given; but he quickly sank, and died in eight hours.

Post-mortem (March 24, 1869.)—Peritoneum matted together by extensive adhesions. There were numerous firm oval or roundish whitish bodies of varying size in the serons membrane, some as small as a pin's head, others almost as large as a pea; they were single or in groups. The capsular surface of the left lobe of the liver presented numerous spots and streaks of greyish thickening. The intestinal mucous membrane was dark, and traversed by whity, prominent, firm ridges here and there, which looked very much like tubercle. The supra-renal capsules both contained degenerated caseous masses. In the apex of the right lung there were distinct remains of old semi-cretaceous tubercle, and in the left these were still more evident; and there was besides a cavity as big as a walnnt, lined with cretaceous deposit. The deposits in the peritoneum were firm, semi-translucent, and consisted of a fibroid basis substance embedding a few elongated nuclei. The lnngs were hyperæmic, but not consolidated. The bronchi were inflamed, the larger containing mucns, the smaller yellow pus. Bronchial glands were not enlarged; appeared normal.

Case 3.—T., aged 28, a short and spare man, admitted April 27, 1854. He had received a blow seven or eight years before on left side of face. Two or three months afterwards a lnmp appeared of the size of a pea; this grew to the size of an egg, and other lumps of like nature appeared. When admitted there was an enormous tumour on left side of neck, filling it np and throwing the head backwards. Went out June 23; re-admitted November 17 in very bad health, with constant cough and night-sweats. Tumour was wonderfully smaller—only one-third of its former size. He died December 3. Death was preceded some days by great pain in stomach, colliquative diarrhœa, and inability to take food.

Post-mortem.—Body exceedingly emaciated. Kidneys, liver, and heart healthy. A large mass of glands in neck had supnrated at various points. The pus was of good qnality. Thin sections of the glands were remarkably transparent, exhibited but few vessels, and consisted of a low, slightly fibrillated basis snbstance, embedding nnmerons nnclear corpuscles. Here and there small yellow foci were seen, without the least hyperæmia around them. On fnrther examination two of these were found to be simple deposits of yellowish or grey firm fibrine, and not pns. Microscopic examination showed the yellow stuff to be fibrine fattily degenerating; it was tolerably firm, made up of a consistent, semi-homogeneous, semi-fibroid stroma, embedding multitudes of corpuscles, chiefly of nnclear character, and a vast deal of punctiform oily matter. Tubercles were deposited all over the peritoneum; they varied from the size of a pin's head to that of a small seed or shot, were firm, feeling like sand or grits, semi-translucent, and lay in the membrane, whose translucency in the immediate vicinity they did not impair. Some of them, however, in the mesentery were raised from the serous surface, and hung at the end of a short pedicle into the cavity; some were more nearly sessile. In structure they consisted of a small amount of granular matter, with pretty numerous pale, dim, spherical nnclei, having less marked envelopes, less glistening contents, and much less trace of nucleoli than normal nuclei. When treated with acetic acid the tubercle appeared to be made up of multitudes of nuclei aggregated together by a faint, dim, uniting substance, the envelopes became better marked, and the cavities clearer. The tubercle substance appeared to be essentially identical with that of the enlarged glands. The lungs contained numerous miliary tubercles throughout their whole extent; there was no cavity in either lung.

Case 4.—Miss ——, aged 18. Not at all anæmic. Her first ailment was mumps, which occurred about six months ago; before that she had been very healthy. About the same time she had been kept in a state of alarm and semi-sleeplessness for several weeks, while residing in an old conntry house. Her parents were both healthy, and all their other children, but I think an aunt had died of phthisis. Last two months had suffered with abdominal uneasiness, with occasional darting pain. This pain has rendered riding intolerable; it is especially felt now before and after micturition, and was last night, when it woke her up, quite in the region of the bladder. Stools are natural; there is no diarrhœa, or rarely. At the right iliac fossa there is great tenderness; she cannot bear even the slightest pressure; turning in bed causes much pain. Similar tenderness, but not so great, extends over the abdomen, diminishing towards the left flank. During all the last two months the abdomen has been more or less tender. She has much flatulence. Tongue red and dryish; the midpart some time ago was quite raw, and very tender, just as if it had been scalded. Her appetite is good, but the digestive power is weak. She feels a craving for food, bnt after a few mouthfuls gets distended and uneasy. Has great thirst some days. She is much emaciated, but not more so the last month, nor has she lost strength. On account of the disorder of digestion she has been kept to a milk diet with much benefit. Lately her diet has been improved, and cod-liver oil has been given. The chest fronts moved fairly well and eqnally in full inspiration. Good breathing could be heard all through the lungs, though it was sometimes weak, and in the right apex a crepitation was heard at the end of inspiration several times. No cough; no expectoration; pulse 117; nrine pale, alkaline, not albuminous, deposited phosphates; weight, 74 lbs. For a time under treatment considerable improvement was obtained: her weight increased to 84 lbs.; she was able to eat a beefsteak without indigestion. On January 23 her weight was 87 lbs. 6 oz.,

but after this date she declined rapidily, had constant sickness, diarrhœa, consuming thirst, extreme emaciation, red aphthous tongue, and so sank away and died on February 23.

Post-mortem.—Peritoneum presented numerous old adhesions between the liver and parietes; in the pelvis there were several ounces of sero-purulent fluid; no general peritonitis. The mesenteric glands were greatly enlarged, and full of yellow tubercle, which seemed to be disintegrating. There were numerous tubercles, some of rather large size, under the serous membrane of the intestines, especially of the small; and in two places these formed dense groups, and had occasioned so much contraction of the canal by inflammatory thickening of the coats that in one spot I could only just introduce my little finger. In these places the mucous lining of the intestine was greatly inflamed, softened, and ulcerated. The stomach was quite pale and normal in appearance, both within and without; the upper part of the small intestine also appeared healthy; the chief seat of disease was the lower part of the small. The mucous lining of the cæcum was extensively ulcerated. The lower part of the large intestine was healthy internally; uterus normal; Fallopian tubes at outer parts both much enlarged and distended with cheesy tubercle; ovaries enlarged, their interior occupied by a pale, whity, lax fibroid tissue; kidneys healthy; liver pale, fatty-looking. Both lungs contained in the back parts of upper lobes largish masses of opaque crude tubercle, most advanced in left; right lung attached to ribs by adhesions, which were of some standing.

Remarks.—The foregoing cases seem to me undoubtedly *au fond* of the same genus, but they present some remarkable differences. Let us shortly compare them. In the first there was copious serous effusion into the peritoneum, with recent fibrinous false membrane about the liver. There was some amount of cirrhosis, but it seems to me very doubtful whether this was the cause of the ascites. There was similar effusion into the right pleura; and I suspect that both were produced by a like cause—viz., strumous inflammation. There was no positive tubercle of the peritoneum, but I have little doubt that the formations described were essentially of that nature. The lungs and the mesenteric glands were exempt, but the bronchial, two left inguinal, and the left testis contained unquestionable tuberculous matter. These latter strongly marked changes afford the key to the interpretation of the others. The patient is by them clearly proved, ἰος ἔμοιγε δόκει, to have been the subject of a special diathesis, and I shall therefore designate his peritonitis as strumous, though not positively tubercular. The tubercles were so small and latent that I do not think they could have evoked the peritonitis by the irritation they caused. Inflammation in a peculiar state of system gave rise, I believe, to the serous effusion, to the fibrinous, and the quasi-tubercles. Let it be noted that the cheesy deposits in the testis and glands produced no miliary tubercles. The disease seems to have been chronic throughout. Case 2 was a well-marked example of tuberculous peritoneum, and I cannot doubt that the deposit in the intestine was of the same kind. There was clear evidence that tubercle had formerly existed in the apices of the lungs and had become obsolete; but there was no miliary tubercle in them at the time of death: so that the cheesy masses in the supra-renal capsules had not produced pulmonary tubercle, even if they be thought to have generated peritoneal. Neither had the bronchitis, though affecting the small tubes with purulent inflammation, caused the deposit of recent cheesy masses. As I read the case, the man had the tuberculous diathesis, which originally manifested itself in limited pulmonary disease, probably in early life; this after a time retrograded, but the same disorder subsequently attacked several of the abdominal organs and destroyed life. Case 3 was a remarkable instance of lymphatic gland hypertrophy (false), occurring from slight provocation, such as one may reasonably conclude would have had no such effect in a non-predisposed system. It was what is now termed an adenoid growth, and it is worth a remark that I should have noted nearly twenty years ago its essential structural similarity to the peritoneal tubercle. Both had this in common—that they were low fibroid formations, but the lymphoma had much more power of growth in it than the tubercle. The miliary tuberculosis may have been dependent on the absorption of infective matter from degenerating patches in the lymphoma; and the history rather favours this view, as his health greatly deteriorated while the tumour was wasting. The connexion, however, I rather think, between the two events—the shrinking of the growth and the deposition of tubercle—was only of time and not of cause. Case 4 was simply one of rapid tuberculosis, manifesting itself, however, first and most prominently throughout in the peritoneum and abdominal organs. The tubercle in this instance was cheesy everywhere; it showed no tendency to retrogression, but to softening and decay. There was no reason whatever to regard it as derived from some pre-existing focus; it seemed to be of the same age in every part. In such an instance it must be admitted the tendency to a special form of disease—the tuberculous diathesis—was far stronger than in Cases 1 and 2. Nevertheless, it seems to have existed evidently in both, and I can see no ground whatever for divorcing the peritoneal affection from the associated strumous, and making it a separate disorder, with the title of granular peritonitis. Regarding the peritoneal lesion for the moment as one of whose nature we are ignorant, we have to try to ascertain its affinities. We may judge of these partly by its structure, partly by the co-existing lesions in other parts. Its structure is more like that of tubercle than of any other morbid formation, in my judgment. The co-existing lesions may be accidental and without relation to the peritoneal; but, unless this is shown to be the case, the presumption seems to me decidedly the other way. The gist of the cases is, I think, to show (1) that peritoneal tubercle may vary histologically from the most thoroughly cheesy quality to the most purely fibroid, the latter being the more usual condition, and that which betokens the least tendency to destructive decay; (2) to corroborate the old view as to the essential affinity of tuberculous and of strumous disease.

ORIGINAL COMMUNICATIONS.

ARE MORBID FUNCTIONAL STATES OF THE CEREBELLUM, MEDULLA OBLONGATA, AND SPINAL CORD CAUSES OF ALBUMINURIA AND BRIGHT'S DISEASE?

By THOMAS LAYCOCK, M.D., etc.,
Professor of the Practice of Medicine and of Clinical Medicine in the University of Edinburgh.

A YEAR ago an interesting polemic arose in the Royal Medico-Chirurgical Society as to the nature and causes of certain pathological changes in the minute arteries of the body in general, and in the kidneys in especial, found in cases of chronic Bright's disease. Differences of opinion were expressed by eminent physicians whose views will be always welcomed by the Profession, both as to the facts and the theories involved. A committee of the Society was appointed to judge between them, but it resigned office, and the whole matter is still undetermined.

Looking at the questions in dispute as a spectator anxious to derive useful knowledge from the very vivid discussions at the Society and in the lectures subsequently published to elucidate and round it off, I find the controversialists agreed as to this general fact of observation—that there is a change in the structure of the smaller arteries throughout the body generally, as well as in the kidneys, in a certain class of cases of Bright's disease. The difference in opinion was as to the nature of the change. Sir William Gull and Dr. Sutton reported it to be a hyaline-fibroid or fibroid thickening of the arterial wall, whereas Dr. Johnson held that it was a muscular hypertrophy. The obvious method of solution of this part of the question is that each observer should prepare demonstrations from the same subject, for if they be from different subjects it is quite probable that in the one may be hyaline-fibroid and in the other hypertrophic. In the absence of this procedure, it is fair to conclude at least that both observers may be correct.

But the polemic extended far beyond the anatomical facts to the causes of the changes observed. Dr. Geo. Johnson is an earnest humoral pathologist, and affirms that Bright's disease is not a mere local malady, and that "the proximate cause is in all probability a morbid condition of the blood." In proof, he observes that the disease is bilateral, and that it "occurs in association with morbid states in which a morbid condition of the blood may be confidently assumed to exist. Albuminuria, varying in degree and in duration, has been found more or less frequently associated with scarlet fever, measles, small-pox, erysipelas, pyæmia, typhus and typhoid

fever, rheumatic fever, malarious fevers, cholera, purpura, scurvy, diabetes, syphilis, certain forms of pneumonia, pregnancy, the absorption of secretions from the interior of the uterus after parturition, gout, the abuse of alcoholic liquors, excessive eating, certain forms of dyspepsia—resulting, as may be supposed, in the passage of crude materials into the circulation,—a poor and insufficient diet, purulent and other discharges, and, lastly, suppressed action of the skin by exposure to cold, and especially to cold and wet combined."(a)

It will be observed that in this copious exposition of causation, albumen in the urine, or "albuminuria," is taken as identical with, or necessarily leading to, Bright's disease. Further, that while in all these varied diseases the nervous system as well as the blood must be involved—in some more primarily than in others—it is wholly ignored in causation. And exciting causes of albuminuria traceable directly to the nervous system—viz., that kind following upon excessive brain-work, and due to lesions of the medulla oblongata and spinal cord—are omitted. In short, I do not find in Dr. Johnson's papers any reference whatever to any morbid state of the nervous system in general, or of that of the kidneys in especial, as an antecedent to the morbid changes in the kidneys or to those of the blood, which are supposed, "in all probability, to be their cause."

In reference to this omission of an important element in causation I may also refer to the recent discussion as to influence of "alcoholic" drinks on the production of Bright's disease. Neither Dr. Johnson nor the other disputants seem to realise the fact that the drinks of the drunkard are not all "alcoholic" in a definite meaning of the term, but contain other agents of a poisonous or injurious character, as fusel oil, bitters, etc., and that these have all a direct and primary action on the nervous system, and so their use leads to morbid conditions thereof which may be predisposing causes. Lead is another of these neurotic causes. What Dr. Johnson dwells upon is the series of diseases of the nervous system which coincide with, or are consecutive to, chronic Bright's disease, but which, according to his humoral pathology, also depend on a poisoned state of the blood, poisoned by the retention of uriuary excreta, and known by the term "uræmia." Yet he states a well-known clinical fact, which is of itself sufficient to upset the current theories of uræmic poisoning. "Let me add," he observes in one of his lectures, "that in some cases, notwithstanding the scantiness, and ultimately the almost complete suppression, of urine, uræmic symptoms are almost entirely wanting."(b)

But how, according to the humoral theory, is the arterial degeneration or hypertropy of the small arteries generally caused? and how the coincident hypertrophy of the heart, noticed by Bright? "About six years ago it occurred to me," Dr. Johnson observes, "that the hypertrophy of the left ventricle of the heart in cases of contracted kidney might be a result of increased contraction of the small arteries throughout the body, this contraction being excited by the abnormal quality of the blood."(c) And this kind of arterial change is also the cause of the neuroses in certain cases of Bright's disease—excessive contraction of the arteries of nerve-centres, "excited by the presence of impure blood," leading to arrest of supply of blood to the nerve-tissue. Here, again, it is observable how entirely the vaso-motor nervous system is ignored. Sir William Gull differs wholly, and I think rightly, from Dr. Johnson in respect to his humoral pathology.

For many years past I have directed attention to the influential part which the nervous system plays in all tissue changes whatever, showing the facts both systematically in my college course and at the bedside. I have drawn the conclusion from a large and varied series of facts, that the cerebellum, with its connexion downwards along the medulla oblongata and spinal cord and upwards into the hemispheres, is the great trophic centre; and that this centre is put into functional activity, not only by afferent impressions from the body, whether consciousness be coincident or not, but also by afferent impressions from the vast periphery of the hemispheres, and in this case also whether consciousness be coincident or not;—in short, that the hemispheres are not functionally restricted to intellectual processes, as is generally held, nor the cerebellum to muscular co-ordinations, but that both conjointly influence the whole of the organic processes in a way which physiologists and pathologists have, so far as I know, wholly overlooked. It is in accordance with these views that I regard the changes in the vascular system in general described by Dr. Johnson as due to concauses having their seat in the cerebellum, medulla oblongata, and spinal cord; that a special neurosis of the renal nervous system is a concause in all cases of albuminuria and consecutive structural changes in the kidneys; and that the dropsies, thirst, cardiac, vascular, lymphatic, pulmonary, gastric, and other phenomena must be reconsidered from this point of view to understand in any reasonable degree the true pathology and the prevention and cure of this large and common group of diseases. Hence I have put for consideration the question at the head of this note—Are morbid functional states of the cerebellum, medulla oblongata, and spinal cord causes, predisposing and exciting, of albuminuria and Bright's disease?

ON THE SEASONAL PREVALENCE OF SOME ERUPTIVE FEVERS IN INDIA.

By JOHN MACPHERSON, M.D.,
Inspector-General of Hospitals (Retired).

Having been called on suddenly to produce a few notes on some subject that might invite a little discussion at a meeting of the Society,(a) that of the influence of season on the diffusion of some of the eruptive diseases in India has occurred to me. I have not much of absolute novelty to offer; still, facts on the subject have accumulated of late years, and a restatement of those facts and of their general bearing may be not without its use. On the whole, it has been considered a characteristic of contagious diseases in Europe that they are not much affected by season. This is certainly not the case in the East.

Small-pox.—Avicenna expressed the opinion that this disease was most prevalent and most fatal in the early months of the year. The contagion, he thought, was multiplied by dry weather and by southern winds. This statement is confirmed by the result of observation in India, as would appear by the following extracts from some recent reports:—

Punjaub Report for 1871, p. 26:—"The progress of the disease from month to month has followed what registration has now shown to be its regular and almost unvarying course in the Punjaub."

"It seems evident from the tables that I have prepared that the progress of the disease is very much dependent on the weather for its arrest or development. It commonly commences in February, and the sudden rise in May is no doubt owing to the increase of heat; but, either in consequence of the intense heat of June, July, and August, or as the result of the law by which rapid increase is followed by rapid decline, the descent during these three months is so precipitate that it generally sinks to near the place from which it had taken the previous six months to ascend."

Punjaub Report, 1870, p. 10:—"The period of maximum intensity would appear to be earlier the farther south we go, being affected no doubt by the earlier onset of the intense heat, which appears to destroy its power."

It is to be remembered that in either case the intense heat is the precursor of the rains.

Moving a little further south, we come next to the Central Provinces, which in all essentials agree with the Punjaub as to the period of prevalence of small-pox, always making allowance for some difference of climate.

Report of Central Provinces for 1871, p. 28.—"The chief small-pox season is March, April, May; and there, as elsewhere, it decreases to a minimum in the rainy months." "With respect to the rapidity with which small-pox spreads at different times," Dr. Townsend considers "that it is probably mainly dependent on variation in the seasons, and the drought of 1869 appears to have been favourable to its diffusion."

The facts in Calcutta have been long known, and are very striking. Taking a series of twenty years, 15,768 deaths occurred in the first six months of the year, 1821 deaths in the second, or scarcely one-eighth so many in the last as in the first half. The minimum prevalence of small-pox is in Calcutta during the rainy season, especially at its end. A few cases show themselves in the cold weather, but its epidemic prevalence is

(a) Read before the Epidemiological Society.

always in the spring or hot season. The advent of the rains seems to check it—at least, with their arrival epidemics cease.

Dr. Morehead and Mr. Leith showed, many years ago, that the same general law prevailed in Bombay as in Calcutta. Dividing the year into quarters, they found for the city of Bombay the following ratio of deaths by small-pox:—

In 1st quarter,	from February 1 to April 30 .	11·15	per cent.
2nd „	„ May 1 to July 31 . .	6·24	„ „
3rd „	„ August 1 to October 31 .	1·19	„ „
4th „	„ November 1 to January 31	1·36	„ „

Taking up accidentally the first return respecting Bombay that I can find, the same result appears for the year 1865—

1st quarter.	2nd quarter.	3rd quarter.	4th quarter.
368	111	21	66 deaths

Proceeding further south, we are supplied with information by Dr. Cornish's valuable reports.

The curves of small-pox mortality in Madras are not nearly so marked as in Northern India; still there is a distinct preponderance in the early months, and this is most marked in the northern districts, such as Ganjam and Vizagapatam, not differing widely in latitude from Calcutta, the Central Provinces, and Bombay. Cornish's Report, p. 195:—"The seasonal development of this epidemic was very marked in all the talooks. The largest mortality occurred in the month of February, but all through the dry months of the year the disease prevailed with great intensity, and it began to decline rather suddenly with the approach of the rainy season."

From Dr. Cornish's tables it appears that the further south one goes, and as the climate is less extreme, the less marked is the variation in the seasonal prevalence of the disease.

There is, therefore, a wonderful amount of accordance of observation in most parts of India on the season of prevalence.

Varicella.—If we come now to chicken-pox, the accounts of it in India are not very full or satisfactory. There is no necessity for our discussing its relation to small-pox; but there is sufficient evidence, both in Calcutta and Bombay, to show that it follows mainly the same laws as small-pox: it usually commences in the end of the cold weather, and attains its maximum in the hot weather. I have seen it during small-pox epidemics, but perhaps oftener at other times.

Measles.—It might be desirable to have fuller evidence respecting the season of diffusion of this disease. Still, there is abundant proof that the first half of the year is its favourite time of prevalence—indeed, tho Arabs would not have experienced such difficulty in distinguishing it from small-pox, had the two diseases prevailed at different seasons. Returns for Calcutta and Dinapore, and of a recent epidemic at Boorhampore—Dr. Morehead's evidence for Bombay—the fact of the prevalence of measles at Bombay and Madras early in the present year—all serve to show the same general law of prevalence as small-pox does. Thus it may be assumed that small-pox, chicken-pox, and measles all occur chiefly in the first half and in the second quarter of the year.

The *artificial propagation* of the variolous and the vaccine virus follows the same rule. The native inoculators commence their operations at the season of the year when small-pox spreads most readily. They have ascertained in Lower Bengal that this is the conclusion of the cold weather and commencement of hot. They accordingly conduct their operations with a success at this period which they know they could not obtain at other seasons.

The course of vaccinia is remarkably in accordance with all this. It is perfectly regular in Calcutta from the end of November to the middle of March; it falls off during the intense heat. As the rains set in, it degenerates, and crusts do not form; but when the rains have ceased, the vaccine improves again, and vaccination runs its usual course.

It has thus been shown that in the case of the ordinary prevalence of the purely contagious diseases, such as are believed to spread mainly by contact, or still more by emanations from the bodies of patients, certain conditions of heat, dryness, or moisture have very great influence either on the poison of the disease itself, or on the susceptibility of individuals to be affected by it. Of the two, the former is far the more probable, seeing that the non-susceptibility to artificial variola or to vaccinia is exceedingly rare. It would also appear that moist heat, which has so long enjoyed the character of favouring the development of contagious diseases, is decidedly inimical to that of several of them.

Some have attributed the annual reappearance of small-pox in India to the operation of the inoculators; but this idea is pretty generally abandoned now that it is known that small-pox follows the same course where inoculation is not practised.

But all that has been said does not touch on the great problem, why eruptive fevers are widely epidemic in one year and not in another; why, for instance, small-pox is always to be found in India, but is only epidemic once in four or five years; why, as Sydenham puts it, one and the same disease at one certain time attacks an infinite number and becomes epidemic, at another it is contented to attack one or two individuals, and to spread no further; why there should be what is called an explosion of an eruptive fever—for instance, in Calcutta measles arise much more suddenly than small-pox, which usually indicates its approach by an increased number of cases in the months preceding the outbreak.

Causes brought forward to explain outbreaks of other diseases—such as the state of drains, privy emanations, ground sodden with excreta, polluted state of drinking-water, conditions of ground-water, soiled clothes, opening of old graves—are not wanted where a markedly contagious disease like small-pox is endemic; and only the two last of these causes have at times been thought necessary to account for small-pox. Some of these causes may assist in producing individual predisposition, and doubtless aid the spread of the disease.

No one believes in the generation *de novo* of eruptive diseases, even if in the present case it were necessary to suppose it. Importation is scarcely required, where the disease is always present; and in Calcutta I never traced the spread of small-pox to imported more than to other cases.

Whatever result the study of the causes enumerated may have in other diseases, we have no reason from the history of the past to expect that they will throw much light on the history of eruptive fevers, or more particularly on the cause which determines an epidemic outbreak. But we have one fact of an encouraging nature—that the same conditions of weather that influence the ordinary occurrence of eruptive fevers, in an equal degree influence the progress of epidemics of them, a fact which tends to show that epidemic may, in some respects at least, be not very different from seasonal influence.

Meantime, while it is still uncertain how far these apparent effects of heat and moisture in India are reconcileable with what is observed of them in other parts of the world, I am far from assuming that what we know of the influence of temperature or moisture supplies an explanation of the *tertium quid* of epidemic influence, which, although its nature is unknown like that of malaria, has still, like it, been generally required to round off our theories. No doubt—as to the causation of disease—we have not made much of real discoveries, such as that of ozone, or of more doubtful ones, as that of vegetable or other miasms; yet the greatest hope of solving such large questions would seem to rest in a more minute study than has been hitherto carried out of atmospheric agencies, including electricity and atmospheric pressure—of which we know so little, even in the rough,—combined, of course, with clinical observation of the phenomena of disease, and aided by chemical and microscopic research. It is no doubt a slow and tedious process,—many years may elapse without any positive results. But we must remember that "*ars longa*" has always been a true saying in the history of Medicine. Meteorology is only in its infancy, as studied in its relation to disease; and Drs. Ballard and Morris and others have indicated the way in which such laborious investigations should be pursued. It is gratifying to observe how much attention meteorology is receiving in India, the reports from which country are so creditable to the service that has produced them. They are becoming of much value in the study of the more general questions connected with the generation and propagation of disease.

Homœopathy in the University of Michigan.—The Bill establishing two chairs of homœopathy has become a law. So far as the present Faculty is concerned, the question is simply, Shall they abandon their posts (which will result in placing the whole school in the hands of the homœopaths, and so ruin one of the best institutions of the country), or shall they maintain their ground and continue to teach truth right in the face of error, and without respect to the punctilious etiquette, miscalled ethics, which would make them turn tail to a mere shadow, and desert their proper work and duty. We say to them, as Sumner said to Stanton, "Stick!"—*New York Medical Record*, June 2.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

LONDON HOSPITAL.

A SERIES OF CASES ILLUSTRATIVE OF CEREBRAL PATHOLOGY: CASES OF INTRA-CRANIAL TUMOUR.

(Under the care of Dr. HUGHLINGS-JACKSON.)

(*Continued from page* 493, vol. i., 1873.)

Case 7.—*Convulsions beginning in the Left Great Toe—Syphilitic(?) Disease of the Lower Part of the Ascending Frontal Convolution—Indurated Patches—No Optic Neuritis.*

THIS is the case referred to in the footnote "b" to Case 2, in which case epileptiform seizures began in the left thumb. (See November 30, 1872, p. 597.) The present is the only case I have seen in which a very local lesion has been found associated with convulsions beginning in the foot. And unfortunately there was so much disease in the brain that the case does not supply any certain evidence as to localisation of movements. Such cases have their interest much widened by the recent researches of Dr. Ferrier: the artificial production of convulsions by galvanising the convolutions.(a)

I did not diagnose that this patient's brain disease was syphilitic. I do not see how such a diagnosis could have been arrived at.

Emily B., aged 45, a domestic servant, was transferred to my care by my colleague, Dr. Woodman, April 18, 1872. She had convulsive seizures beginning in the left foot. Her earliest symptoms occurred three years before I first saw her. She then had severe pain in her head in the morning, and she felt exhausted, but these symptoms passed off when she threw up a little clear water. In November, 1870, she had her first fit. When about to wash a frock, her eyes closed and she could not open them; then her left leg seemed to be getting bigger, and she felt as if going up to the ceiling; next, she lost consciousness. She had fits of this degree of severity—*i.e.*, attended by loss of consciousness—at intervals of about two months. In these she foamed at the mouth, but did not bite her tongue. But she had numerous partial seizures. All her fits, severe and partial, began in the left foot and in the great toe of that foot. She called the partial fits "cramps." She had constantly a strap on her leg ready for tightening to dissipate the spasm. This had been advised by my colleague, Dr. Ramskill.

I took great interest in her case, and I very often asked her as to the mode of onset of her fits. The account was always the same—the big toe was the part first seized in every attack. The fits, I took for granted, pointed to disease of the right cerebral hemisphere, although I had had no autopsy on a patient with fits of this sort. The only doubt was as to whether it was a coarse or a minute change, or, as it is inconveniently put, functional or organic disease. As the history shows, she had had severe pain in the head three years before I saw her, but on the first of her attendance on me she had none. There was no optic neuritis. For the reason that these two great signs of gross disease were absent, I thought there was no tumour. But later I concluded that there was a tumour, because she had then severe pain, and that of the *right* side of her head. She had no optic neuritis at any examination, nor were there any relics of it, so far as careful indirect examination showed.

From her manner I and all who saw her concluded that she was very weak-minded; her manner was silly.(b) However, her friend, a very intelligent woman, said the patient's memory was bad, and yet affirmed that her mind was good, and certainly as good as it ever had been. She spoke indistinctly towards the end of her life. About October she began to talk more indistinctly still, and her tongue was visibly tremulous; the articulation was not syllabic, it was thick rather. She became thinner—haggard-looking—but still conducted herself with a kind of jaunty silliness. Nevertheless, although I saw her in this worse condition on November 7, I was surprised to hear that she died on November 9, after a few hours' illness. She had been out the day before. I was not surprised to hear that this illness was at first considered to be hysteria, for she did, when in the out-patient room, conduct herself in a way which led to inquiries if the case was not one of hysteria. Nay, possibly she was hysterical as well as suffering from severe brain disease. She died so suddenly that an inquest was held. By the kindness of Dr. Riley I obtained the brain for an examination, which my colleague, Dr. Gowers, was so good as to make for me. The lesions are so various, that the clinical history loses much of its value. From the naked-eye appearances of the growth I supposed there was syphilis, and this inference Dr. Gowers' examination confirms:—

"In the brain I received from you on November 12, a small hemispherical tumour was attached to the dura mater, and projected into the right hemisphere in the lower part of the anterior ascending parietal ('transverse frontal') convolution, its lower margin being about one inch and a quarter from the lower extremity of this convolution in the bifurcation of the fissure of Sylvius. Dimensions—from before back, one inch and a half; above down, one inch; depth in most prominent part, one-third of an inch. No softening in neighbourhood. An area of softening about two-thirds of an inch wide, and one-third of an inch from above down, existed over the posterior cornu of the left lateral ventricle, extending back to within three-quarters of an inch of the posterior extremity of the hemisphere. Softening not recent. Softened tissue separated from the cavity of the posterior cornu only by thickened ependyma. Several areas existed in which the consistence of the brain-substance was considerably increased. The largest of these was situated outside the right optic thalamus, in the white substance: dimensions, about an inch from before back, and half an inch from above down. Another existed in the inferior portion of the right corpus striatum. (This was not discovered until the brain had been much cut about in ascertaining the position of the other changes, and its exact relations were somewhat doubtful.) A third caused a slight projection, about a quarter of an inch in extent, on the left hippocampus major, opposite the extremity of the optic thalamus. A fourth small area was placed outside the left lateral ventricle, opposite the descending cornu, below and outside the anterior extremity of the softened area.

"*Microscopical Appearances.*—The tumour attached to the dura mater was composed almost entirely of fusiform cells lying side by side, some long and narrow, others wide and short. In length they varied from $\frac{1}{1000}$ to $\frac{1}{250}$ inch, and in width from $\frac{1}{2000}$ to $\frac{1}{5000}$ inch. In all the wider cells a nucleus occupied the broadest part, containing one or two nucleoli. A few round and oval cells were seen, about the diameter of the fusiform cells, and with similar nuclei. In the longest narrow cells no nucleus could be distinguished, but one or two dark dots occupied its position. No fibres could be seen, except those formed by the elongated cells, nor any intercellular material. The growth at its edges could be seen to be invading the brain-tissue, extending chiefly along the vessels. The structure of the growth, though not characteristic of, was quite consistent with, and the mode of extension was very suggestive of, its syphilitic nature. The differences of structure of the firmer areas of the brain and the adjacent structures of normal consistence were very difficult to determine, on account of the post-mortem changes. The chief change seemed to be that throughout the firmer areas the nuclei of the neuroglia were increased in number, and mingled with them in varying proportions were other cells, mostly round or oval, with delicate outlines $\frac{1}{2500}$ to $\frac{1}{5000}$ inch in diameter, all occupied by a nucleus about half their own diameter, and containing one or two nucleoli. Apparently free nuclei, resembling those within the cells, were in some places grouped in aggregations of four or five. The cells were nowhere so numerous as to compose

(a) Dr. Ferrier has given a very brief statement of his main results in the *Brit. Med. Jour.*, April 26, 1873. A full account of his researches will appear in the forthcoming volume of Dr. Crichton Browne's West Riding Asylum Reports. Ferrier's facts, and those of Fritsch and Hitzig, to which he refers, are especially interesting to me as confirming the views I have long taken of the nature of epileptic and epileptiform seizures. I have already briefly remarked on this elsewhere (*Brit. Med. Jour.*, May 10), and shall do so more fully in an article in the next volume of Crichton Browne's Reports.

(b) The interest these facts have to me will appear if I give a quotation from a paper published several years ago. In the St. Andrews Graduates' *Trans.*, 1870, I wrote—"I think it of importance to consider the side of the body in which the spasm starting in the leg sets in. My reason is this, that mental defect (imbecility) sometimes occurs with hemiplegia in which the leg suffers more than the arm, and I believe that it occurs oftener when the left is the side paralysed. I fully admit that my facts on this matter are very few, and I therefore ask others to help me in this part of the investigation." My facts are still few, and I still ask for help. Trousseau, I believe, considered imbecility more likely to occur in cases of hemiplegia where the leg suffers more than the arm. I think the "imbecility" is really as *special* a defect as "aphasic" symptoms are; it is a loss of power to *recognise* (not to *see*) things.

tracts of tissue, but were seen to be scattered among the nerve-fibres. Here and there were a few fusiform cells, but these were not numerous."

Case 8.—Epileptiform Seizures beginning Unilaterally—Double Optic Neuritis followed by Atrophy—Very Large Head—Acute Cerebellar Symptoms—Enormous Tubercular Tumour of the Left Cerebral Hemisphere—Small Tumour of the Middle Lobe of the Cerebellum.

This case is interesting from many points of view, and not least from the occurrence (on February 5) of what I have called in the title "acute cerebellar symptoms." It was during life inferred from these symptoms that the boy had disease of the cerebellum, but its nature was not predicted,—it might have been localised meningitis. The peculiar position of the arms and the retraction of the head made me conclude that there was disease of the cerebellum.

J. S., aged 5, was brought to the London Hospital, March 30, 1871, for epileptiform seizures. It would seem that he had had different sorts of seizure at different ages.

First Variety of Convulsive Seizures.—When ten months old he had a series of fits over a period of about two hours; his gums were lanced. He was soon apparently well, and had no further attack until the age of two years.

Second Variety of Convulsive Seizures.—He then (at the age of two years) complained *occasionally* of his right foot. He said it hurt him, and he seemed to be in much pain, but all passed off when his mother rubbed the foot. The attack would last about five minutes. It may seem trifling to speak even so shortly of these attacks, but when it is added that after a while he had attacks in which the right leg would "jerk," and the "working" would go up the side and affect the right arm, the significance of the seizure is more obvious. Plainly they were epileptiform attacks, especially as we shall see he had other attacks, after which he became paralysed of the side occasionally convulsed.

Third Variety of Convulsion.—About ten weeks before admission (before March 30, 1871) he had another variety of convulsion. He had no convulsion of the second kind (the foot-beginning ones) for two months before the first of this, the third set. The first (a severe one) his mother did not see, but he had since been subject to slight seizures in which spasm affected only the *right side of his face, and in which his speech was lost during the continuance of the spasm.* The following note was made the day of admission:—He is not unconscious in the fits, knowing all that is said to him. He tries to speak; the mother supposes to, as he makes a noise "with his lips." He has had these partial seizures many times since the severe fit ten weeks ago. Sometimes he misses a day or two, and sometimes he has the attacks "all day long." After frequent attacks he talks badly; but, as usual in these cases, it is impossible to obtain precise information as to the kind of defect of talking. He "drawls his words," and it is sometimes "impossible to understand what he says." Another fact is that the right arm is useless for a while—about five minutes, she says—although no spasm is ever observed of it. I have noted this several times in cases of epileptic spasm limited to the face. I suppose the powerlessness of the arm depends on sudden cutting off of blood (by arterial spasm) from nerve fibres, the convulsion of the face being the result of discharge of grey matter.

When there is temporary loss of speech in a convulsion, there being no loss of consciousness, the spasm usually begins in the right cheek or tongue. Sometimes there is defect of speech after fits beginning *in the hand*, and when so it is, I think, defect of a higher kind—*i.e.*, the patient gets out a good many single sentences. The defect after fits beginning in the face or tongue is more often "an ataxy" of articulation. I must not attach much importance to such symptoms in a child. Besides, I saw several seizures, and in these his speech was not affected. I do not think this disproves his mother's statement, as the fits I saw were slight. The fits I saw, although they only affected the cheek, were clearly epileptiform. They affected that part of the face which suffers most in the common form of hemiplegia. Those I saw did not spread to the orbicularis palpebrarum. I have witnessed fits so limited in patients who have had at other times convulsions which (beginning in the cheek) spread all over the body. Sometimes a patient who is hemiplegic will have occasional spasm of the *paralysed* part of the cheek or of the hand.

This patient was slightly hemiplegic of the right side, but it was simply impossible to make precise observations, as he was indocile and slightly feeble-minded. There was only a little weakness of the side.

So far evidence has been given only to show that there was disease of the left side of the brain. On this point there could be no doubt at all. Further, the convulsive seizures rendered it almost certain that the *surface* of the brain was diseased, not that the disease was limited to the surface. The word "disease" is vague, but we could easily go a step further and say that there was instability of the grey matter of the convolutions of the left side of the brain. To say that there was such instability is to utter a truism, for that there was a discharge was manifest, as certain muscles were occasionally put in motion. But the important question remains, By what pathological process was this local instability produced? This is a distinct question. There are probably many ways in which instability of grey matter is produced, but the point of practical importance is this—Is it produced by the action of an adventitious product or not? or, as it is sometimes put, Is the fit "caused by" organic disease? This question, in most cases, admits of easy answer.

Let us first recapitulate. 1. The fact that the right face, arm, and leg were affected showed that the part (organ) diseased was the left side of the brain. 2. The fact that the motor affection was, although only in part, a mobile one—viz., spasm of the right side of the face—rendered it certain that the disease was such that grey matter was unstable, for there was a discharge now and then. After this recapitulation we take up the next question—Was there an adventitious product (foreign body, "coarse disease," etc.)?

The common signs of organic disease are severe headache, vomiting, and optic neuritis. It is very remarkable that to this stage of the illness he had had scarcely any pain in the head, and no vomiting, nor had he got thinner; but he had double optic neuritis, and this, considering there were one-sided motor symptoms, was enough to make it certain that the disease in the left cerebral hemisphere was an adventitious product. Now, the reader is asked to bear in mind that there was no evidence that his sight was defective,—nor was there until his death. His mother, and afterwards the hospital nurse, considered his sight good. It may have been defective, but it was impossible to test it even roughly. Unless the ophthalmoscope had been used we could not have guessed that there was anything wrong with the nerve. However, as there was no headache, the instrument was of the greatest value in diagnosis. The eyes were examined by Liebreich,(c) Hermann Pagenstecher, by my colleague Dr. Gowers, and by many others. I concluded, then, that there was an adventitious product of *some kind.* But there still remains the question, Of *what* kind?

At first I thought it probable that there was a cerebral abscess. This would have accounted for the symptoms. My reason for thinking so was that he had had discharge from the left ear at the age of two years. But he had not recently had any discharge, nor had he had earache; the aural discharge had been from the ear on the side of the brain disease. It was simply impossible to test hearing: the boy was too careless and dull. Another reason for thinking that there was an abscess was that the boy's head was large. I thought myself that it had probably got large recently, and, as the sequel will show, this supposition was no doubt correct; but his mother was convinced that it was no larger than it had been before his illness. Nearly always mothers think similarly until a child's head is of a very large size. Hence we must not let their opinion be decisive; we must consider the *shape* of the child's head, on which more later.

The child attended as an out-patient, and was in hospital some weeks, but no notable changes occurred; he used to pass his time pleasantly, being only slightly paralysed. I then lost sight of him until October 28, 1872.

His mother brought him again to the Hospital on October 28, 1872. His head was larger than before; this, as his mother now admitted, was obvious. He was still hemiplegic on the right side, and the paralysed parts—hand and foot—had undergone slight rigidity. His speech was not obviously affected, but he seemed apathetic, and spoke little.

He was admitted into the children's ward. He seemed dull, but the dulness was more like that of ordinary lack of intelligence. He had pain in the head now and then, and once had diarrhœa. A note of his condition taken on December 7, 1872, will suffice:—He is sitting up in bed playing with pictures.

(c) On May 5 Professor Liebreich examined the eyes, and declared the discs to be in the after stage of neuritis. He pointed out, also, some small spots on the retina, near the macula. They looked to me like bits of gum, and not like the dots usually seen in cases of chronic Bright's disease, and now and then, but rarely, in cases of cerebral tumour.

He can see so well that neither his mother nor his nurse have supposed that there is anything the matter with his sight. When asked they say his sight is good. He would call to the nurse to let her know that the cat was going into the cupboard. But to test his sight carefully was impracticable; he would take no notice of our requests. He has atrophy of both optic nerves; there are still at the macula in each eye the little dots mentioned previously. His sense of smell is not lost: he said oil of cinnamon was nice, and promptly and vigorously expressed disgust at asafœtida. His hearing to ordinary observation was good, but careful testing of it was impossible. There was hemiplegia of the right side; no obvious distortion of face or tongue. He kept the head well up, although it was very large. The arm was rigid; the leg also was rigid, and he walked (when assisted) on his right toes; he could not walk without help. Speech, articulation, and voice were good. His head was very large, and especially prominent above the ears. The anterior fontanelle was soft, and the sutures were beginning to gape slightly.

There is nothing of importance to narrate until the onset of certain acute symptoms shortly before his death. But as these symptoms have an importance almost apart from the rest of the case, I will recapitulate once more.

The position of the disease was the left cerebral hemisphere. The functional nature of the change of the nerve-tissue was instability. That instability was the result of the "irritation" of a tumour. All these things were simple obvious matters. And on his second admission there was clear evidence that his head was not only enlarged, but enlarging—there was gaping of the sutures. So we got further, and felt certain that the adventitious product *was a voluminous one.* There could be only one difficulty in such a case. It was the old one—Of what nature was the voluminous product? The fact that the mass was evidently voluminous made me think chiefly of two things—a large hydatid cyst and a vast cerebral abscess. But I went no farther than the diagnosis of a voluminous adventitious product, and I confess it did not occur to me (as it would do in future) that the mass was a scrofulous tumour.

Nearly the whole of the following notes are by my then clerk, Mr. (now Dr.) Lechler:—

February 5 (from statements of nurse).—Patient is worse to-day. Yesterday morning he said he was much better, but soon after complained of pain in his head, put his hands to his head, and said he was going to be bad. During the day he looked flushed and feverish. About eleven at night he began to scream, and when the nurse went to him she noticed that his head was retracted, that he was trembling all over, and that his right side was convulsed. He was quite unconscious.

This morning he is lying on his left side, *with his head retracted;* his right arm is rigid, flexed, and the hand is drawn up to the shoulder. The right leg is in an almost constant state of tremor. Every now and then he suddenly begins screaming; then the tremor increases, he jerks his right leg about, and moves his right arm. The right arm moves at the shoulder, and is kept in the position before mentioned. During the "convulsion" the fingers are flexed—the thumb bent across the palm with the nail pressing firmly on it.

6th.—Continues in the same state. The fits of screaming and the "convulsion" occur more frequently, and are now almost constant. He is unable to swallow, and had no food yesterday. He has had a little wine this morning, but a teaspoonful remains in the mouth for some minutes and causes constant gurgling sounds. Motions and urine are passed involuntarily. Temperature 101·2°.

7th.—A little better this morning. Lying on his back, *with head retracted.* Breathing quick, and somewhat stertorous; voice a little hoarse. *Both* arms are now flexed, and the hands are placed on the shoulders. There is a constant tremor of the *left* arm, and occasionally of the whole body. The right hand is constantly moved backwards and forwards, and the hand is spasmodically closed. He still cries out at intervals, but his voice is not so loud. The convulsive seizures observe no regular order; most of them first affect the left leg, then he begins to scream, and then his hand is convulsed. Is conscious this morning; knew his mother; protruded his tongue when asked to do so. Is able to swallow better; has taken nothing but wine. The intervals between the crying fits and convulsive movements are much shorter; the latter are almost constant, and the former weaker. Temperature 101·2°; pulse 90; respirations 32.

Note made about 4 p.m.—Lying partly on his back; his chest very prominent, and apparently as if fully expanded. Belly quite soft except occasionally, when, as it seems, he is holding in his breath. His head is thrown back, and is twisted on the trunk, so that the right side of the occiput touches the shoulder, which is raised to meet it. His face looks upwards to the left, and the left side of his head and face rests on the pillow. The right sterno-mastoid is stiff, but not very; the left is not. The finger cannot be inserted without force betwixt the shoulder and the back of the head. The right leg is supple; arms placed as described in previous note; the left hand is in form somewhat as in tetany. 9 p.m.: Since six o'clock he has been in almost constant convulsion, which affects trunk, lips and chin, and left side. It commenced by frothing at the mouth, then universal twitching of muscles, movement of body laterally being the chief movement.

8th.—Has been very restless all night. Convulsions mentioned at last note ceased about ten last night. Mother says he was convulsed at intervals during the night. Is lying half on left side and half on back. Head much more retracted; occiput almost touching upper part of back; back more arched. Right arm extended down back; hand closed; left arm lying at side and extended. Eyeballs turned to left, oscillating up and down; conjunctiva sensitive. Shows no sign of consciousness; has not screamed since yesterday morning. Respiration rapid, entirely abdominal. Pulse 132, small and fast; respirations 52.

9th.—Died at 3.30 this morning.

Post-mortem Examination.—The head was very large. The bones of the cranial wall—*i.e.*, those sawn through—were soft and very thin; the left side of the skull was markedly thinner than the right. There was slight separation at the interparietal sutures, and also at the left coronal. In two places, each of about the size of a sixpence, the bone was gone. The enlargement of the head was seen to be the result of an enormous tumour of the left cerebral hemisphere. It occupied the middle region, extending from the deepest part of the Sylvian fissure, involved the convolutions of its upper wall, and reached the surface of the brain at the middle line. The frontal convolutions were pushed forward. At the uppermost part, and at the outer side, the dura mater was attached to the mass; in other parts there was a thin layer of brain-matter over it. Except where the dura mater was attached, the tumour was easily turned out, the brain-matter being soft about it. The corpus striatum was soft, and in parts diffluent. The tumour on section was of a grey-green tint; it felt tough and elastic; its edge showed growing tissue. *It weighed more than eleven ounces.* The rest of the encephalon was normal, except that there was a mass, the section of which was of twice the area of that of a pea, of a grey-green tint, in the lower part of the middle lobe of the cerebellum, about the position of the uvula. The tumour was altogether about the bulk of two peas. There was no change of importance in any other part of the body. Tubercles, caseous matter, etc., were carefully looked for in the lungs and other viscera, but no such products were found, nor anything like them,—nothing any way abnormal.

Dr. Moxon was so kind as to examine the tumour for me. He gives me the following note, enough for my present purpose:—"The tumour has the characters of tubercle. Its size renders it a most unusual and interesting example. Its substance is caseous in nearly all parts, so that it generally shows only traces of structure. The outer layer, for a depth varying from one-tenth to one-quarter of an inch, shows signs of having spread by the formation of new foci being made up of small granules resembling ordinary tubercles. This lymphoid structure of the recent parts is like tubercle in its characteristic form."

Académie des Sciences.—Sir Charles Wheatstone has been elected a Foreign Associate in place of the late Baron Liebig, by the votes of forty-three of the forty-five members of the Academy who were present.

Spontaneous Expulsion of the Entire Uterus.—Professor Gallard republishes, in the *Union Médicale* for July 5, a case originally published in the *Journal de Médecine de Toulouse* for 1844-45, which, as far as his researches have extended, is unique. In consisted in the expulsion of the entire uterus of a woman 35 years of age, the cervix of the organ having been destroyed by cancer. She died twelve days afterwards from peritonitis, which was produced by contact of urine. The expelled organ was carefully examined and laid before the Toulouse Medical Society.

SATURDAY, JULY 12, 1873.

THE PROPAGATION OF CHOLERA.

The news of the spread of cholera in Austria has aroused attention as to the propagation of this fatal malady, and certain intelligence which has reached us from the East, if possible, heightens the interest we must all feel as to what might be called its natural history. All through the winter and spring cholera has lurked in Poland and Galicia, and now, with the weather most favourable for its propagation, it has begun to spread north by the Vistula to Dantzic, and southwards into Northern Italy, as well as lower down the Danube at Rustchuk. Fortunately for us, it has shown little tendency to spread westward, and so we may possibly again escape this year—the more so that the disease does not show the same tendency to rapid and extensive outbursts it has previously exhibited when about to become widely epidemic. We have reports of cholera from America, but these must in the meantime be received with caution until more exact details are known.

It is, however, from Russia that the most alarming intelligence reaches us. As is tolerably well known, the Russian State authorities, with Pelikau at their head, differed considerably in their conclusions as to the recent outbreaks of cholera in that country and Eastern Europe from those of most other nations. They concluded that these outbursts were not new importations, but were due to the seeds of the disorder having remained latent from former epidemics, even as far back as 1852. They have now sent to this country the evidence on which this opinion is founded—evidence which seems fairly irrefragable, and as a consequence of which we are fain to confess that in all probability cholera is now fairly naturalised as an endemic malady in Eastern Europe. We had already been compelled to assent to the statement that cholera had become naturalised in Persia, but we were hardly prepared for the same disquieting fact as regards Europe; but that being so, all information as to the mode in which it spreads assumes an increased importance, and we have seen nothing of greater importance on the subject than an abstract of modern views on the subject by Professor Parkes in the appendix to the recently issued Army Medical Report.

This deals at some length with the views of Pettenkofer, as recently enunciated by him in a somewhat modified form in reply to adverse criticisms from Sander and Küchenmeister. There is no denying their importance, not only from the weight of Pettenkofer's authority, but from the influence they exercise on the minds of many, both in this country and abroad. They have materially modified modern research in the matter, and should they turn out to be wrongly founded, this influence must have been most pernicious. The foundation of Pettenkofer's theory rests on the assumption that the cholera contagium is mainly or entirely propagated outside the human body; and thus the malady, from his point of view, though readily carried by human beings, and in the main following the lines of human intercourse, is not strictly speaking contagious, but rather miasmatic. The quantity of this contagious matter, according to his views, undoubtedly tends to increase, but it does so in the surroundings of the individual, not in himself; and the most important of these foci of new growth is the ground itself; and on peculiarities of soil he holds that the development of cholera mainly depends. He rejects *in toto* the theory of propagation by drinking-water, which he says in many instances he has investigated was impossible. Shipboard has been selected as a telling instance, where neither soil nor ground-water could be imported into the case, and has by some been considered utterly fatal to the ground theory of cholera. This Pettenkofer does not admit, and yet is compelled to acknowledge that cholera has broken out in ships in epidemic fashion, though it is most frequently brought from the shore. Here he tries to import some new factor into the case analogous to the ground on shore, but seems to fail. Direct contagion, without any interference on the part of the soil, seems to be only too well established, yet Pettenkofer rejects it entirely. Nevertheless, in all probability the ground has some influence, though what it is seems as yet not quite clear; nor does it seem to be exercised in all cases. It is always a misfortune if a man resolutely blinds himself to any side of a question save that on which he himself is intent.

At all events, all recent facts tend to support the belief in the agency of man in the spread of cholera; and Bryden's theory of wind-spread is at a discount, except in so far as the prevailing winds affect human intercourse. The theory has been, moreover, tested by the light of certain known cholera movements in Madras, and found wanting. On the other hand, the facts tending to support the theory that cholera is often propagated by the agency of food and drink, as well as by more direct contagion, are increasing in number; and as they are more strictly examined now than formerly, they are becoming more valuable. Thus we have in Dr. Parkes's report a record of a localised outbreak among a single caste at Delhi, nearly all of whom had attended a funeral feast in the house of one who had died of cholera. Some, too, were affected who did not attend, but ate of the food which had been spread on the floor over which the discharges from the deceased man had flowed. A similar outbreak, where probably the water was the means of propagation, is also recorded as occurring among the 24th Hussars at Secunderabad, which is dead against Pettenkofer's theory, though the evidence in favour of the water theory is not so strong as it might be; but in a localised outbreak among the artillery at Morar, in Gwalior, there seems to be no room to escape from the belief that water was the means of disseminating cholera among the men. Thus it is true that Pettenkofer's theory sometimes helps us to an explanation of the localisation of cholera, but in others it completely breaks down. The whole question as to how cholera is spread is not yet ripe for final decision; but the fungoid theory so popular some time ago has completely collapsed.

THE PHYSIQUE OF THE BRITISH ARMY.

The statements put forward in the House of Lords last week by the Duke of Richmond on the subject of recruiting for the British army exhibit a terrible amount of mismanagement on the part of some person or persons in authority, and give rise to grave apprehensions as to what is likely to be the sort of *physique* to be met with in the bulk of our troops in the future, unless some of the past blundering is amended, and wiser counsels are allowed to prevail. The dearth of recruits during the past year or two has been so great that men—or it would perhaps be more correct to say boys—presenting themselves for enlistment without possessing the requisite chest measurement of thirty-three inches have been accepted, and by an order of the Inspector-General of Recruiting returned as up to that standard. Again, the standard of height has been gradually lessened till from five feet eight inches it has finally got so low as five feet five inches. The returns for the year 1871 show that of first year's recruits 13·19 per 1000 were invalided during that period, while of the men examined for attestation about 6000 out of every 10,000 were under the age of twenty. These facts cannot be looked upon as satisfactory, and, taken into consideration with the short service system instituted by the present Government, would appear to justify the remark made by Earl Forteseue during the debate, that at no distant period, and by the help of the means now employed, the British army would consist almost entirely of boys, instead of seasoned soldiers. In the present age of destructive and death-dealing missiles, any close encounter, such as a bayonet charge, is a thing almost unheard of; yet in future wars, should such a contingency occur, it would be somewhat mortifying to learn by actual experience that our old Peninsular *prestige* for solidity and weight had deserted us, or that our men had been driven back—not by superior pluck, but by sheer brute force, because we had neglected to obtain the same hardy and stalwart class of soldiers who had fought for their country in our forefathers' time. The Government representatives who took part in the discussion can scarcely be said to have been very warm in defence of the present system, and it would almost appear as if a mistake had been made somewhere, as in the case of the new Army Medical Department Warrant. It is an undoubted fact that the number of recruits presenting themselves is far below the number required to fill the vacancies in the ranks; whilst so far from the new system having attracted a higher and more intelligent class of men to the service, as was expected, results show that the *matériel* is still furnished by what Viscount Hardinge happily termed "the waifs and strays of society." If even this latter contingent are to be accepted of an inferior strength and stature, would it not be wise on the part of Mr. Cardwell and his advisers to pause and reconsider their plans before running the risk of subjecting England to defeat in the future through a dogged adherence to a policy which fails to charm even themselves? Our individual province may not be to deal with the military portion of this question; but we raise a protest against sweeping in the stunted and badly-developed boy, whilst the hardy stalwart man is shut out from the army because the pension he might formerly have looked forward to at the termination of his service has been withdrawn.

THE WEEK.

TOPICS OF THE DAY.

Mr. Simon has issued a "Minute on the Precautions to be observed against Cholera," which is drawn up with commendable clearness of expression. Mr. Simon teaches the public that cholera is but little contagious in the sense that small-pox and scarlatina are contagious, but that it has a peculiar infectiveness of its own, which, when local conditions assist, can operate with terrible force and at considerable distances from the sick. He then goes on to explain that it is in the infective power of choleraic discharges that the danger lies; and he warns against the contamination of water and clothes, and the danger of breathing air foul with effluvia from the same source. He gives clear general directions for meeting the danger. Up to the present time we have heard of no case of cholera in England. The deaths from diarrhœa rose last week to sixty-eight, but the corrected average number for the corresponding week in the last ten years is 130. There were three deaths referred to infantile cholera. Of the other zymotic diseases hooping-cough was most fatal, having caused forty-three deaths, whilst from small-pox there was only one, and eleven from scarlatina.

We hear that Mr. Jonathan Hutchinson has resigned the Senior Surgeoney at the London Hospital.

The collections in connexion with Hospital Sunday now amount to £27,000.

There is a rumour that there will be a vacancy before long in the Chair of the Institutes of Medicine in the University of Edinburgh, through the retirement of Professor Hughes Bennett. Dr. Rutherford, of King's College, London, and Dr. McKenrick, Professor Bennett's present assistant, are spoken of as probable candidates.

On the occasion of the recent visit of the Shah of Persia to St. Thomas's Hospital, that potentate was, it is said, particularly interested in the cases of eye disease which he saw in Mr. Liebreich's wards. One paper goes so far as to say that the Shah constituted himself a *pro tempore* out-patient. He asked, it is said—

"Was it well for him to read much? Ought he to abstain from writing? Well, if the Professor said that one might with glasses properly adjusted to weakened sight, and with the book or paper held at a proper distance from the eyes, read or write with impunity, what was the proper distance, and what the best position to stand or sit in? Was it a good thing to put your face in water, and let the cool water 'get into your eyes'? These and other questions of similar purport the Royal out-patient, with great animation and earnestness, put to the Professor, his Majesty speaking in Persian and Dr. Liebreich carrying on the conversation with the interpreter in French, and in the course of the consultation received advice which, it is to be hoped, will be attended by beneficial results."

A COMFORTABLE NIGHT'S REST IN A RAILWAY CARRIAGE.

Those of our readers who have undergone the misery of the night journey in winter to Scotland—the fatigue, the cold feet, the cramped muscles, the uneasy snatches of sleep, the futile attempts to read by the miserable light, the close irrespirable air when the windows are up, and the bitter draughts when the windows are down; the petrified condition in which you at last are deposited on the platform, and your utter unfitness for enjoyment, unless it be the enjoyment of a warm bed, the next day—those, we say, who have undergone all this will appreciate the value of any reasonable proposal to furnish our English railway carriages with comfortable and suitable sleeping compartments wherein a quiet night's rest between clean sheets and a good wash in the morning may be had for a moderate extra charge. The Americans have long ago obtained these luxuries, which, in fact, become necessities when a railway journey lasts a week. In England we have from time to time talked of them as most desirable; but we continue to shiver, catch cold, contract all sorts of congestive diseases depending on checked action of the skin and emunctories, without any attempt to mend our condition. The wealthy can get no better appliances than a stuffy "first-class" and a foot-warmer; those whose purses are not so long have to be content with bare boards and their plaids. Men in our own profession who have to take long journeys on short

notice, know by personal experience, and have plenty of opportunities of learning from their patients, how great is the demand on the vital power made by a night journey by rail. We therefore hail the prospect held out by a company which has been started for providing our trains with Colonel Mann's railway sleeping-carriages. Colonel Mann is an American engineer, and his carriages are, we believe, shortly to be introduced on most of the great "through routes" on the continent of Europe. His cars, besides excellent sleeping accommodation, provide lavatories and all other necessaries for personal comfort. They are well ventilated and warmed, and means are taken to deaden sound by double floors, sides, and roofs, the interspaces being packed with sawdust. We hope that we shall on our next journey north be able to avail ourselves of the sleep-compelling invention of the countryman of Rip Van Winkle. "Blessed is the man who invented sleep," said Sancho Panza. We think it was Charles Lever who added, "Thrice blessed that he did not keep the invention to himself."

DIFFICULTIES IN SANITARY LEGISLATION.

A LETTER from the Committee of Management of the Homerton Hospital was read at the last weekly meeting of the Poplar Board of Guardians, calling the attention of the guardians to the case of a young man, aged 19, who was admitted to that institution on May 30 last, and died from small-pox sixteen days afterwards. The youth had been vaccinated; only one vaccination mark was perceptible upon his arm, and that was imperfect. In connexion with this matter, Mr. Smith, the vaccination officer, reported that he was not aware of small-pox existing in the house in question until May 30, and he then took steps for the immediate removal of the patient to Homerton. In all cases of contagious diseases he caused the patient, if a pauper, to be removed within twenty-four hours of the report reaching him; and if the person was not a pauper he gave immediate notice to the sanitary inspector. The vaccination officer added there was great reluctance on the part of persons not paupers to send their relatives to the Hospital, and consequently they did all they could to conceal the fact of their being afflicted with the disease from the relieving officers and the sanitary inspector, and he was sorry to say that many of the medical practitioners connived with them in order to enable them to do so. A copy of this report was ordered to be sent to the Hospital. Whilst we admit the justice of Mr. Smith's remarks in the main, we think that he was neither courteous nor just in using the word "conniving" with respect to the conduct of any medical practitioners, be they few or many, as to the isolation of cases of small-pox. We feel assured that no respectable member of our profession would "connive" for the purpose of the non-isolation of a patient affected with a contagious disease. He would take every means to prevent the spread of the disease. He would *de facto* so isolate the affected person as would make him, in a private house, as harmless to spread disease as if he were in a hospital. We know that amongst the poorer classes this isolation is all but impracticable; but a very different state of things exists in the higher and middle classes. It is to the public interest that the law regarding the isolation of affected persons should be rigorously carried out, but Mr. Smith himself will, we are sure, acknowledge on reflection that it would be neither wise nor just to carry out these provisions when they were really not necessary.

THE WIMBLEDON CAMP.

WE have received the following medical intelligence from the Camp:—Staff-Surgeon Temple and Dr. Mayo are in charge. The Camp is slightly fuller than usual, but all are healthy. Moule's earth-closet apparatus is working well. Up to the present time there have been no accidents.

DISTRIBUTION OF PRIZES AT ST. MARY'S MEDICAL SCHOOL.

THE annual distribution of prizes at St. Mary's Hospital Medical School took place on Wednesday, July 2; Sir Dominic Corrigan, Bart., M.D., M.P., presiding on the occasion. There was a very large attendance of students past and present, and of others interested in the School and Hospital, the company including an unusual proportion of ladies. The Dean, Dr. Cheadle, read a highly satisfactory report of the progress of the School during the past twelve months, which showed that the increase in the number of students continued, and that out of eighteen students who had gone in for the recent primary examinations seventeen had been successful. The prizes were then presented to the successful students by Sir D. Corrigan, who afterwards delivered a very eloquent and interesting address. He commenced by pointing out the advantage which men of science possessed in being able to follow out the search for truth without being trammelled by the ties of party or sect, like the politician or the theologian—without being bound by the commands of superiors like the soldier—or having to snatch a verdict by special pleading like the lawyer. Men of science alone were free in their pursuit of pure and simple truth. The speaker then proceeded to combat the fallacy which he contended was still rife, that a medical man must resort to artifice in order to gain practice, and quoted numerous examples to prove that the public were on the whole good judges of the qualifications of their doctors, and sought those who knew their work best and could best supply what was required of them. Good, honest, hard work was the usual means of success, and the only certain road to it. Sir Dominic then spoke of the imperfect appreciation of the value of medical knowledge in its relation to questions of the highest importance to the well-being of the State, urging the necessity for the fuller representation of the Profession in the House of Commons, and concluded by impressing upon its younger members the duty of working for the public good rather than for the narrow end of their own personal and private advancement and reward. The address was listened to throughout with most profound interest and attention, and was warmly applauded by the audience.

DUTIES OF SCHOOL MEDICAL OFFICERS.

DR. MCDONNELL, the Medical Officer of the Schools, having refused to obey the order of the Schools Visiting Committee of the Guardians of the Parish of St. Marylebone to make a weekly examination and report of the children, application was made to the Local Government Board for Dr. McDonnell's removal from the office; Dr. McDonnell also addressed the Local Government Board on the subject. A copy of the Board's reply to Dr. McDonnell was laid before the Guardians at their meeting last week, and was to the following effect:—The Board stated that Dr. Bridges, their inspector, had reported to them his conference with the Schools Visiting Committee of the Guardians, and they consider that the position taken up by Dr. McDonnell in declining to give effect to the directions of the guardians, except under the stipulation that he should receive additional remuneration in respect of services required of him, was untenable. The Board further stated that it was his duty, under Articles 53 and 59 of the Order of June 1, 1860, to comply with all the reasonable and lawful orders of the guardians and with the regulations of that Board which may be issued from time to time; that they could not allow the orders of the guardians to be set at defiance so long as those orders were reasonable and lawful; and that unless he was prepared at once to discharge the duties imposed upon him it would be imperative upon the Board to call for his resignation of the office. We think the Local Government Board have arrived at a just conclusion in this case. The "extra duties" which the Schools Committee requested Dr. McDonnell to per-

form would have involved so little trouble and time that it is to be regretted he declined to perform them. We hope, however, a proper understanding has been arrived at, and that ultimately harmony will prevail.

A PLEA FOR SAILORS.

SOME sensible, pertinent, and at this time very seasonable remarks, instigated probably by the recent revelations of the hardships and cruelties practised upon our sailors, which have been brought before the public by the untiring zeal of Mr. Plimsoll, appear in *Frazer's Magazine*. It may be that the article is written in view of the Committee of Inquiry of the House of Commons now sitting on the subject, whose attention might well be called to the laxity of our maritime laws in respect to the causes of deaths at sea, and to the important suggestions contained in the article in question. The writer, urging medical registration and coroners' inquests in cases of deaths at sea, the same as if they had occurred on land, quotes the old maritime law—

"*Item*. Lett inquiry be made concerning the death of a man whoe hath beene killed in a ship, vessell, or boate, or apparrell of any ship, how and whoe killed him, and whether by the ship's apparrell, by what apparrell, *and unto whome the ship did belong*."

Such was the ancient sea law of the dark ages, as recorded in the "Black Booke of the Admiralty," in an addendum to the "Inquisition taken at Queenborow by the command of our Lord King Edward the Third." We live, however, in more civilised times. "How and whoe killed him? . . . and unto whome the ship did belong?" would in these days be very troublesome and awkward inquiries for living men: they might interfere sadly with the principles of free trade. True, landsmen bear the burden of such inquiries when they concern seamen with equanimity, inconvenient as they must be to modern commerce.

THE JEWS AND POOR-LAW MEDICAL RELIEF.

IT has been determined by the Jewish Board of Guardians that out-door medical relief be discontinued for a period of three months from August 1, on the grounds that the Jewish poor are able to obtain gratuitous medical relief when it is to be had; that many persons avail themselves of this charity who are able to pay for it; that many apply for and obtain medical relief who from a medical point of view do not require it. Our Hebrew brethren have shown a wise discretion by passing the above resolution. It is valuable in itself as a step in the right direction; but it is doubly valuable as emanating from a body of men by whom, when charity is really required, it is dispensed in a generous and "open-handed" spirit, which occasionally contrasts most favourably with the conduct of some Gentile boards.

A SAPIENT BOARD OF GUARDIANS.

THE *Wakefield and West Riding Herald* of Saturday last states that the Guardians of the Dewsbury Union were engaged for a considerable time the day before in discussing the propriety of appointing a vaccination inspector. It was ultimately agreed to send up a notice to the Poor-law Board with twenty reasons against the appointment of such an officer.

PRECAUTIONS AGAINST CHOLERA.

WE are glad to observe the vigilance shown by the chief municipal bodies of the metropolis with respect to the adoption of precautionary measures in view of the approach of cholera in the metropolis. The Metropolitan Board of Works have ordered the greatest possible dispatch to be used in completing the works connected with the Pimlico pumping-station for filtering and deodorising sewage before its discharge into the river. The works are now kept going day and night. The Board of Works resolved at their last meeting to refer to a committee the questions as to whether any additional sanitary precautions were advisable.

FROM ABROAD.—DISPOSAL OF THE SEWAGE OF PARIS—DIMINUTION OF THE NUMBER OF STUDENTS AT BERLIN.

IN an article on the sewers of Paris, in the *Révue des Deux Mondes*, July 1, M. Du Camp describes them as unique and as surpassing any construction of the kind in ancient or modern times. The paper has evidently been written in ignorance of the system of sewerage which constitutes one of the marvels of London, but we are noticing it here only in order to make known the results which he says have attended the experiments in utilisation of the sewage. Although in so imperfectly a drained town as Paris, and one so much less in size than London, the mass of this which has to be dealt with is infinitely less than in our own capital, yet the information of what has been and is about to be effected is of great interest.

The drainage, then, of Paris, as far as this has been accomplished, is prevented entering the Seine by means of two huge "collecteurs," situated one on each side of the river; but this is accomplished only for a short distance, as the sewage is poured into the river again below Clichy and St. Ouen. Here it causes such an obstruction to the navigation of the river as to require the annual removal from its bed of 120,000,000 kilog. of solid matters, at an expense of from 100,000 to 150,000 francs. Quite recently, this expensive waste of useful material has been sought to be in part prevented, with great success. The Seine, by the enormous bend it makes from Neuilly to Chatou, encloses a vast area of sandy land, known as the plain of Gennevilliers, which has long been proverbial for its utter sterility, and even at the very gates of Paris only fetched from 78 to 86 francs per hectare per annum, some wretched specimens of beetroot being all that was produced. In this apparently blasted spot a change as if by magic has been worked, for the sewage-water led on and distributed has given rise to a wonderful fertility. The experiment has only been continued during four years, but the result is regarded as entirely decisive, and the land so treated now lets for 600 francs per hectare. A celebrated Parisian perfumer has set up his factory amidst his flourishing scented herbs, and finds that the peppermint which he had always had to import from England can be advantageously grown. Asparagus, which in ordinary soils demands from three to five years to attain perfection, here scarcely requires two years; and beetroots, which formerly were looked upon as marvels if they attained to 800 grammes, now usually reach eight kilogrammes, and may even attain to fourteen. Artichokes, cabbages, rhubarb, and lettuces become colossal. Fruit-trees thrive apace, and a gardener transporting his espaliers from Montreuil has found his peaches attaining most unusual sizes. These advantages had to be forced upon the inhabitants of this sterile spot, they declaring that they were made the victims of the tyranny and selfishness of the Parisians, who were getting rid of their poisonous refuse at the expense of their neighbours. The only way to deal with such opponents was to purchase some of the worst spots and treat them with sewage; and when they saw the flinty soil rapidly converted into a flourishing market-garden they at last consented to accept the precious product which was gratuitously offered. They were knowing enough, also, to not infrequently profitably dispose of to others that which had been given to them for nothing—always, however, maintaining that the Parisians were the really obliged by having been allowed to eject their filthy fluid on other peoples' land: a privilege, in fact, which by right ought to have been paid for.

After so successful an experiment, the municipality soon saw its way to its expansion, and has voted the money necessary for its execution. Large steam-engines have been erected,

and in the course of two or three years the whole 2000 hectares of this sandy plain will have its vegetable products ready close to the Parisian market. The Seine will then be entirely freed of its impurities and the present expensive dredging discontinued. As soon as the entire sewage is thus diverted from the river, the sewers will be made to communicate with private houses, and the fearful stenches and lumbering night-carts, with which visitors to Paris are only too familiar, will disappear. How vast the improvements hence resulting will be may be judged of by the fact that there are at the present time 85,775 *fosses d'aisance* in Paris, 52,128 of which necessitate the labours of nightmen.

It has been suggested that the sewage would accumulate in the reservoirs in quantities so considerable as to render it materially impossible that it should be utilised, and that the surplus quantity would still have to be poured into the Seine again. This is to a certain extent true, but the procedure will be unattended with any danger, as the water will have become restored to its pristine purity. Again and again have attempts been made in vain to purify sewage; but MM. Chatelier and Durand-Claye have at last entirely succeeded in solving the problem by precipitating all solid matters held in suspension by the foul stream. A kind of "clarification" is effected, and in fact the contents of a sewer may now be as certainly and more speedily clarified than a pipe of wine. A diluted solution of sulphate of aluminium is employed for this purpose; a litre of this falling drop by drop will precipitate all solid matters of 2000 litres of sewage. The purifying basins are thus filled with clear and insipid water, and when this has run off there remains a bed of greyish, compact, homogeneous mud, which is shovelled out into heaps, and constitutes the valuable manuring agent, and is given gratuitously to all who apply for it. The water is limpid and absolutely inodorous, while 1000 kilos of the dried deposit have been found by eminent chemists to be composed of—

Azote	16·01
Organic matters	263·61
Phosphoric acid	5·85
Lime	119·20
Magnesia	3·46
Various mineral substances	591·87
	1000·00

It constitutes a most fertilising manure. The cost price of the azote and phosphoric acid would give it a value of 34·63 francs, while a cubic metre produced from sewage does not cost one quarter of that sum. In a few years the whole of this sandy plain, covered by a market-garden, will not be recognisable; and there will be a factory of dry manure, which, if required, may be forwarded all over France.

Some time since (*Medical Times and Gazette*, March, p. 231) we noticed the diminution of the numbers of the medical profession which is taking place in Prussia, and in a recent number (June 16) of the *Berliner Wochenschrift* the subject is recurred to, the diminution of the number of the students at the Berlin University being characterised by the strong epithet of "terrible." That it is considerable is seen from the fact that the whole number of matriculated students for the present summer semester only amounts to 1590, while in the preceding summer semester they amounted to 1990. In the winter semester of 1872-73 they numbered 1918, and in that of 1871-72, 2603. The medical students have diminished from 450 in the summer semester of 1872 to 340 in that of 1873. The entire number of students for the present semester has sunk below that of the year 1862, when it was 1704.

In seeking for the causes of so rapid a diminution, this certainly cannot be solely explained by the much greater expense of living at Berlin compared with formerly, although this may have much to do with it. It is more profitable to inquire whether there are not causes of degeneracy existing in the University itself, than to close the eyes to these, and seek for reasons of its diminished popularity in other directions. If students are expected to undergo the greater trouble and cost of studying here in preference to other places, they must be assured that abundant opportunities of acquiring a thorough education will be offered them; and, in fact, no other university can show greater teaching power or more scientific work. If such teaching power has not proved attractive, this has arisen from the defective division and arrangement of the teaching material. Laboratories are wanting, and clinical teaching is defective. There is no want of patients; but in place of distributing these so that they may be utilised for the students' benefit, the plan is followed of concentrating them in a few hands, so that no real benefit results. Of what use can it be for a hundred students to be crowding around a patient's bed if they have not the opportunity also of regularly watching them in smaller subdivisions and learning how to observe their cases? That fertile principle, the division of labour, is set at nought, the costly material supplied by the State institutions remaining unemployed for the purposes of science and education; while professors and docentes are wasting their energies in striving with insufficient means, deprived of the position and assistance which the interests alike of science and the University should extend to them. What is it that attracts students and young practitioners in such numbers to Vienna? Is it that the teaching power is so much stronger than at Berlin? Certainly not. It is the much-envied General Hospital that there attracts the industrious student from every side. There the rich material is rendered accessible and profitable for education. There flourish special clinics, which have never been thought of in Berlin, or have pined away. Clinics, which in Vienna are attached to the hospital for every special branch of knowledge, have in Berlin to be carried on by private persons with very insufficient appliances. The small universities, of course, only can deal with limited material, but this is well chosen and carefully employed; and the more abundant material in the larger institutions is not of more avail, for want of sufficient subdivision. It is not the rare cases, which, of course, are of more frequent occurrence in a large university, from which most is to be learned, but those which are met with daily, providing that the student is taught to set sufficient store by them.

However, better hopes may be entertained for the future. All are agreed that the great defect of the University of Berlin is that it has no great hospital attached to it. Beyond a most defective surgical and obstetrical clinic, it has entirely to depend upon the Charité Hospital for the supply of cases. This establishment, however, has to supply the wants of the military medical school, and is under the direction of Ministers, who are not, perhaps, sufficiently aware of university necessities. A large university hospital is in the course of erection, which it is expected will supply every need, whether of general or special clinics. Meanwhile, polyclinics (dispensaries) for various special affections are also set on foot, and laboratories for pharmacology and experimental physics are being erected. Altogether, it is hoped, by these and other exertions, that Berlin will recover ere long the power of attraction it once possessed.

It is to be observed, however, that the number of medical students has diminished throughout Prussia. At Bonn, which is liked as a summer residence, they are fewer than last year, and at Greifswald they have diminished from 346 to 298. And, indeed, is this not to be expected? Prussia has entered on a new and expanded career, and with increased wealth numerous pursuits will hereafter enter into competition with the medical, and will absorb many who heretofore would have entered the profession, either as practitioners or professors.

PARLIAMENTARY.—HEALTH OF THE PORT OF LONDON—SANITARY AFFAIRS IN IRELAND—THE CHOLERA—SEDUCTION LAWS AMENDMENT BILL—PUBLIC HEALTH BILL.

In the House of Commons, on Monday, July 7,

Mr. Stansfeld, in answer to Mr. Cadogan, said there had no doubt been some delay on the part of the Corporation, who were the sanitary authority of the port of London, in fulfilling their duties under the Public Health Act of 1872. But some arrangements had now been made by the sanitary authority. One of her Majesty's ships had been placed at the disposal of the Corporation by the Admiralty for the purpose of a hospital ship, and would be moored off Gravesend. A duly qualified medical practitioner had been appointed to the command of that ship, with authority to appoint other medical officers, and two ship-captains would reside on board with their wives. In cases of emergency the directors of the Seamen's Hospital at Greenwich were prepared to receive a limited number of cholera cases. Arrangements had also been made for the treatment of dangerous infectious diseases.

The Marquis of Hartington, in reply to Mr. Bruce, said the Local Board of Ireland was aware of the necessity of having similar digests of sanitary law for Ireland as had been prepared for England, but it was necessary to postpone framing this digest until Ireland had been divided into districts for sanitary purposes.

Mr. Stansfeld, in reply to Mr. Dent, said that plain directions as to the precautions to be taken for preventing the spread of cholera had been prepared, but it was not proposed to do what had never been done before—namely, to give directions to the medical men in the various localities as to the treatment of cholera.

The House went into Committee on the Seduction Laws Amendment Bill, and the following clause was agreed to:—"Whosoever shall unlawfully and carnally know and abuse any girl under the age of twelve years shall be guilty of felony, and, being convicted thereof, shall be liable at the discretion of the court to be kept in penal servitude for life, or for any term not less than five years, or to be imprisoned for any term not exceeding two years, with or without hard labour." Mr. Wharton moved a clause providing that whipping may be added to other punishment if the girl is under twelve years old, which was carried.

On Tuesday, July 8,

Sir C. Adderley, in moving that the House do go into Committee on the Public Health Bill, stated that its main object was to consolidate the law relating to the public health, and make certain amendments in various parts of the existing law which the Commissioners, in their report, had declared to require alteration. The amendments of which notice had been given were not numerous or hostile to the Bill. If the House went into Committee he should not press any portion of the measure against what he found to be the sense of the Committee.

Mr. Corrance opposed the motion. He thought the Bill wholly insufficient for its objects, while it increased the public burdens, and added greatly to the powers taken by the central government. He believed he was entitled to ask the right hon. gentleman to withdraw this Bill, as he thought it had no chance of passing this session.

Other members also opposed the motion.

Mr. Stansfeld said that his right hon. friend (Sir C. Adderley) was the chairman of the Sanitary Commission which sat for two years, and whose invaluable report was the basis of the measure which the Local Government Board passed last year. The rest of the report of the Commission was embodied in the clauses of the present Bill. He had been obliged, in reply to a question in an earlier part of the session, to state that the time at his disposal was not sufficient to justify him in bringing in a measure this session, but that he was bound to offer all the assistance in his power to his right hon. friend, who was entitled to place this Bill before the House, and to demand the support of the Local Government Board. He maintained there was no clause in the Bill which would add one farthing to the local rates in any sanitary district, and he would therefore appeal to the House to allow it to go into Committee.

A Committee was appointed to meet on Friday, July 11, to discuss the clauses of the Bill.

The Court of Common Council have resolved to appoint a medical officer for the port of London at a salary of £400 a year.

THE HARVEIAN ORATION,

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS, ON WEDNESDAY, JUNE 25TH,

By GEORGE ROLLESTON, M.D., F.R.S.,
Linacre Professor of Physiology in the University of Oxford, etc.

(*Concluded from page* 18.)

I pass from this reflection to an exposition of the claims which have been put forward on behalf of Walter Warner, the editor in 1631 of Harriot's "Algebra," to the discovery of the circulation of the blood; and I do this by a natural transition, Walter Warner having been a man in whose mind, all his mathematics notwithstanding, the *idola* in question greatly abounded. Warner's claims are alluded to by Dr. Willis in a note to his excellent "Life of Harvey" (see p. lxiv.) They are put forward by Anthony Wood, upon the authority of Dr. Pell, a man distinguished as one of Oliver Cromwell's diplomatists, and afterwards as an assiduous supporter of the then young Royal Society; and upon that of Dr. Morley, some time Dean of Christchurch, and afterwards Bishop of Winchester (see Wood, "Athenæ Oxonienses," i., 461, ed. 2nd of 1721, vol. i., p. 302, ed. Bliss). Aubrey, a contemporary of Wood's, appears, from a note at p. 417 of the second volume of his "Lives of Eminent Persons," to have had the same story from Izaak Walton, who gave Dr. Morley again as his authority; and Aubrey repeats the tale with certain additions, and notably with that of Dr. Pell's authority, at p. 577 of the same volume. The same story was pointed out to me by one of the officials in the Bodleian Library as being given in an anonymous biographical miscellany to be found in the Rawlinsonian Collection, B 158, p. 152-153. This MS. appears to be of the latter half of the seventeenth century, and its legend runs to the following effect:—A certain Henry, Earl of Northumberland, being imprisoned in the Tower, did, for the better passing of his time, get several learned persons to live and converse with him; one of these men—whom Aubrey tells us (*l. c.*, p. 368) the world called the Earl of Northumberland's magi—was "Mr. Warrener." And the MS. proceeds: "He was the inventor, probably, of the circulation of the blood, of which subject he made a treatise, consisting of two books, which he sent to Dr. Harvey, who epitomised and printed them in his own name; he usually said that Dr. Harvey did not understand the motion of the heart, which was a perfect hydraulik. . . . . Dr. Pain, that very ingenious and learned canon of Christchurch, told me that he had seen and perused this book of Warrener's." Finally, the excellent "Biographia Britannica" has embalmed Wood's and Aubrey's story, in the articles "Harriot" and "Harvey," pp. 2542 and 2550, ed. 1757. Many *à priori* improbabilities will be seen at once to attach to this story, and it is easy enough to discredit more than one of the witnesses. But I have better than indirect evidence to bring forward, and I will have the agreeable mental exercise of excogitating it to the ingenuity of my hearers, which ingenuity will be sharpened, no doubt, by their regard for their own Harvey, and strengthened by the belief that

> "Whatever records spring to light,
> He never shall be shamed."

I may be asked, after this quotation, why I should have thought it worth while to investigate Walter Warner's claims at all. I will shelter myself, in the first instance, behind the example of Sir George Ent, who, feeling and acting by Harvey as Launcelot in his better days felt and acted by Arthur, took similar pains to set aside the similar fable as to Harvey's indebtedness to Father Sarpi. And, in the second place, I will remind my hearers that it was but as recently as 1838 that an article appeared in the *London and Westminster Review*, in which the claims of the Italian monk just mentioned were once again brought forward with surprising confidence, plausibility, and ignorance.

It was possible, I thought, that the same paltry but evil spirit which animated Dutens in writing his "Inquiry into the Origin of the Discoveries attributed to the Moderns" (1769), and in coming to the conclusion that every great man in modern times had been anticipated by somebody or other in ancient ones, might still be going about in dry places, and

might wholly enter into and entirely fill up the soul of some small antiquary, who, coming under such inspiration and guidance upon the passages which I have collected, might proceed to instruct the literary public as to Warner's claims. Whilst considering what indirect evidence might be brought together to rebut this possible attempt at detraction, I came upon what led me to the discovery of the direct evidence I have promised to lay before you, in the shape of a clue which brought me, after a somewhat tortuous course, upon Walter Warner's actual autograph MS. I found, whilst following up Dr. Pell's history, scattered through Dr. Birch's unindexed "History of the Royal Society," that Dr. Birch had procured a number of MSS. of Mr. Walter Warner's for that Society mixed up with Dr. Pell's (see vol. 2, p. 342; vol. iv., p. 447). Coupling this statement with the voucher for Warner's claims, ascribed by Wood and Aubrey to Dr. Pell (who, however, is never reported in Dr. Birch's "History," so far as I found, to have given currency to this statement), I thought that by these MSS. I should be able to test the truth of these statements. But the librarian of the Royal Society knew nothing of any MSS., either of Pell's or of Warner's; and, as the result will show, it would have been odd if he had—at least, in his official capacity. I then made inquiry of the Duke of Northumberland, in whose library the MS. of Warner, once a pensioner of his house, might possibly be preserved; but Mr. J. E. Martin informed me that this hope was a vain one. I found that Sion College had once possessed one MS. of Warner; but I learnt from the Rev. W. W. Milman that they had lost it, and much besides, in the great fire of London in 1666. Finally, when taking the register of Merton College up to the British Museum for the purpose of comparing the entries made in that volume during Harvey's wardenship with his one authentic autograph MS. now in the national collection, I bethought me of making, at the same time, some inquiries as to Warner and Pell; and at last, when I least expected it, and had long ceased to hope for it, I came upon Walter Warner's MS., contained in Dr. Birch's collection, which, according to him, had been made over to the Royal Society, under the title "4394, Birch Collection," numbered on in continuation of the "Sloane Collection."

Mr. E. Maude Thompson, by the employment of various scientific methods, the observation of which went some way to compensate me for the tedious labour entailed upon me by the result to which they brought him, identified the MS. as being really Warner's, and even in bringing its date down to the same, close upon 1610—half a dozen years or so, therefore, before Harvey first lectured at the College of Physicians. The MS. being thus identified, I set myself down to look through its 416 folio pages, the average number of lines in a page being thirty-three or thirty-four; the average of words (many of them idle ones) being eight or nine in a line. I do not think it is very likely that I have missed any clearer exposition of Warner's views than the one which I am about to read from page 138; nor do I think that, by choosing it, I can in any way misrepresent them, for they are stated elsewhere in the "Treatise" in very much the same words, *e.g.*, p. 137. These, then, were his views:—"By this spontaneall pulsatory motion the bloud is continually extracted from the vaines (propter fugam vacui) as well originally exsuctory as secondarily circulatory and propelled into the arteries (propter fugam penetrationis), but with some diversity in the distribution, some part thereof being propelled up into the head by the internal jugular arteries, ad plexum choroideum for spirito-faction, the rest into all the rest of the arteries in universum corpus for organo-faction. Out of that part of the blood that is propelled by the jugular arteries up to the head, the spiritus confusus or immersus thereof being expressed and segregated in plexu choroidi, either by excussion or exhalation, and animal spirits, thereof made by the self-operation of the præexistent in somno, it is again distributed as before, one portion thereof being still derived and transmitted to the heart, ad motum spontaneum pulsationis ciendum, and so about again, perpetuâ circulatione durante fabricâ corporeâ, and all violent destructions or impediments abstracted."

It is, perhaps, needless to dwell further upon Warner's claims—certainly I do not propose to trouble you with reading to you any more of his speculations and conclusions. I have, however, had a copy made of folio pages 140, 141, 142, 194, and 185, and, though the gift may not seem a very valuable one, it will enable any fellow of Harvey's College to satisfy himself abundantly, and within our own walls, as to the real merits of the claimant before us, if the College will allow it to find a place in their library. In the words of Harvey's favourite poet,

> "His saltem accumulem donis et fungar inani
> Munere."

In all seriousness it is something to know what a contemporary of Harvey, and he a mathematician of some eminence, could write only some ten years before the actual demonstration of the circulation of the blood was given to the world.

Let me say, however, that I do not think it by any means impossible that Harvey may have read this treatise of Warner's, hard though the labour must have been to him, and little though he could have profited by it; for, in many parts of Harvey's treatise, "De Motu Cordis," we meet with phrases which seem as if they had been used with a special reference to Warner's views. And his dissertation has at least this claim upon my gratitude, that it has made me think that I understand Harvey's meaning the better for having read it. I fancy, in fact, that I recognise such phrases in Harvey's words ("De Motu," p. 58; p. 56 ed. Willis), "Absque dolore vel colore *vel fugâ vacui*," and in such words as "longè plus est quàm partium nutritioni congruens est." He might have been alluding to almost any page of Warner's MS. in his repudiation (p. 116, see "Epistola Secunda ad Riolanum") of the hypothesis of various sorts of spirits. But there is one of Harvey's many noble and candid, whilst measured and well-balanced utterances, which seems to me to be admirably suited to serve as a text for an exposition, which perhaps some future Harveian Orator may undertake, of the exact relation which his discoveries held to the knowledge and the ignorance, not only of Walter Warner, but of all others of his contemporaries or predecessors. These words run thus ("De Motu," p. 34 ed. 1766, p. 33 ed. Willis)—"Sed et hoc" (namely, the transmission of the blood by the action of the heart, from the veins into the arteries, through the ventricles of the heart into the whole body), "omnes aliquo modo concedunt et ex cordis fabricâ et valvularum artificio positione et usiu colligunt. Verum tanquam in loco obscuro titubantes cœcutire videntur et varia subcontraria et non cohærentia componunt et ex conjecturâ plurima pronunciant ut ante demonstratum est." This may be translated thus: "But it may be said, that all competent persons accept these views in a more or less modified form, and have been convinced of the truth of them from the structure of the heart, and the contrivance, position, and use of the valves. But they seem to me to make as little use of their eyes as men do who are stumbling about in a dark place, and their account of the matter is made up of heterogeneous, contradictory, and incompatible statements, and very much of it is pure guess-work, as I have already shown." These words—the Latin ones, not my translation of them—were published, if not written, nine years (see p. 5, "Harveii Opera," ed. 1766, *Dedicatio*) and more after Harvey had first proved the facts of the circulation, and from them we gather that his discovery had, even so early as that date, got out of the stage in which a discovery is considered to be untrue, and got into that in which it is said that everybody knew it before. In no subject could it have been easier to make out a plausible case than in this of the circulation of the blood. Piccolhomini (an acquaintance with whom I owe to Mr. Walter Warner, see his treatise, pp. 194, 200, and 201), had given a diagram—it is there before you, copied from the copy of his work in our library—of the junction of the portal and hepatic twigs, incorrect enough, no doubt, and obtained by a false method (see Harvey, "Epistola Prima ad Riolanum," p. 105, ed. 1766), but still something in the way of a working hypothesis (see Piccolhomini, "Anatomicæ Prælectiones," Romæ, 1586, p. 117). Servetus had speculated, but rightly, as to the lesser circulation; so had Cæsalpinus; and on Harvey's own showing (p. 15, "Opera," ed. 1766), Realdus Columbus and Walter Warner, p. 132 (4394, "Birch Coll. MS."), had spoken of the heart, in 1610, as being "a mere muscle, very strongly and artificially woven, and contrived with omnimodal nerveous fibres, direct, transverse, and oblike, as it were of purpose for dilatation and contraction, according to the fashion of other muscles." And of the action of the auriculo-ventricular and arterial valves, Harvey himself, *nivcâ animâ*, with untarnished sincerity, repeatedly (see "De Motu," pp. 14, 51, 53, 67, 81) speaks as of something known to all men, "id omnes norunt" (p. 44). What, then, it might have been triumphantly asked, was there left for Harvey to discover, when the action of the valves of the heart, its muscular character, and so much else, was already to be found in the writings or teachings of his

predecessors? To all this we can answer, as, indeed, it seems probable, was practically answered even within Harvey's lifetime,—what was left for Harvey to discover was nothing less than *the circulation itself*. His predecessors had but impinged, and that by guesswork, upon different segments of the circle, and then gone off at a tangent into outer darkness, whilst he worked, and proved, and demonstrated round its entire periphery. His demonstrations and direct proofs were all new, and his indirect arguments nearly all new. Whenever he made use of anything already known, he most punctually acknowledged it. Of his demonstration in the way of injection I have already spoken; of his demonstration of the use of the valves in the veins, and his proof that they are similar in function to the arterial, a fact previously unsuspected (see p. 65, *loc. cit.*), the thirteenth chapter of the Treatise "De Motu" speaks with figures; of his indirect, but irrefragable argument, in the eighth chapter, from the quantity of blood thrown out by the heart at each pulsation, an argument which a mathematician such as Harriot or Warner might have hit upon, but, so far as I have found, did not, he speaks himself as being "adeo novum et inauditum ut verear ne habeam inimicos omnes homines"; and finally, the argument, which, though only indirect, every morphologist will allow to be not only most exquisite, but also most convincing, for the circulation in the adult warm-blooded animal, drawn from the relations held by the venæ cavæ to the efferent arteries in the embryo, and in all animals with but a single or an imperfectly divided ventricle, "unus dumtaxat ventriculus vel quasi unus," and of which I would recommend everyone who is not already acquainted with it to gain a knowledge from the seventh chapter of the same book, was his, and his alone. With regard to all these points—with regard, that is, to the circulation as a whole,—with regard to the actual demonstration and exhibition of it as opposed to mere guessing about it,—with regard to all, or nearly all, sound reasoning as to any large portion of it,—Harvey might have said with Lucretius,

> "Avia Pieridum peragro loca nullius ante
> Trita solo."

or, in the words of a poet of another country and a later age—

> "We were the first that ever burst
> Into that silent sea."

I do not wish to assert that Harvey was wholly independent of the works of his predecessors; he himself would, as his repeated references to them show, have been the very last man to make any such claim for himself; nor would I say that he owed nothing to the times

> "The spacious times of great Elizabeth,"

in which he lived. It is true, I think, in science, as it is also true in morals and polities, that the times make great men as much as great men make the times. Many metaphors have have been used to express this latter half-truth. Such is the metaphor (an acquaintance with which I owe to Mr. Pieton's new and striking work "The Mystery of Matter," p. 265) used by St. Augustine, in which great men are compared to great mountains, dwelling apart in loneliness, and sending floods of blessings down upon the little hills and plains at their feet. Such, again, is the metaphor used by Wordsworth in apostrophising Milton:

> "Thy soul was like a star, and dwelt apart."

Such is the metaphor used by Sir Coutts Lindsay, in his poem on the "Black Prince," where a hero

> "Stands like a beacon, throwing light far out
> Over the rippling tides of centuries."

Now, all these metaphors strive, and profess to express, but half a truth, and they are imperfect even for this imperfect purpose, as they are borrowed from inorganic nature and the arts, and are unfit to be used as illustrations of the complexities of life and thought. I would venture to suggest a metaphor which has struck me, during this investigation, as being more appropriate and close-fitting, even if less beautiful, than those which I have quoted. A group of horsemen are attempting to cross an arm of the sea, up which the tide has been running, and obscuring the ridge, or spit of sand, by which it is fordable. They form themselves into a line, and advance slowly: rider after rider flounders off into deep water, and, if wise, retires towards the rear of the cavalcade of his companions, who still feel and advance upon the bottom beneath them. The line by degrees narrows into a column, and the column, after a longer interval, narrows into a single file. To the foremost horseman courage is necessary, as imagination is to the discoverer, and, impelled by this feeling, he may put a wide interval between himself and his companions, and, reaching the opposite bank long before them, may have leisure to look down upon them, may be looked up to by them and by the rest of the world, whilst for some time in solitary occupation of that vantage-ground. Such I conceive to be a fair representation, in the way of metaphor—the best and shortest way, perhaps, of representing such complex relations—of the relations held by Harvey, and indeed by most or all discoverers, to their contemporaries, to their compeers, and to the conditions whereby they are surrounded.

It may be expected perhaps that, coming from Oxford, and having been recently elected a Fellow of the College—the wardenship of which Harvey held for something more than a year (April, 1645-46, midsummer)—I should have made search for whatever records there may be left of him unpublished in Oxford, and especially in Merton College. After diligent search, I have to report that there is but little to be learned of Harvey's history from any unpublished document which I have been able to find in Oxford. The Merton College Register gives an account of his election, from which it appears that, having been nominated by a majority of the Fellows—of whom the distinguished John Greaves was one—to King Charles I., who exercised the functions of visitor after the execution of Archbishop Laud, he was duly elected on receipt of the King's letter, after a dispute, of which it is needless to give an account. A couple of days after his admission to the office (on April 11, 1645) Harvey summoned the Fellows into the hall, and made a speech to them, to the effect that it was likely enough that some of his predecessors had sought the office of Warden to enrich themselves therefrom, but that his intentions were quite of another kind, wishing as he did to increase the wealth and prosperity of the College. (I would here remark that it was well perhaps for the College of Physicians that Harvey was, by the success of the Parliament, forced to vacate the office of Warden; otherwise he would, no doubt, have kept his word, and Merton College would have gained what the College of Physicians, or some others of his legatees, would have lost.) He finished his address to the assembled Fellows with an earnest appeal to them to cherish that mutual concord and amity amongst themselves which recent occurrences, we may suppose, had tended to weaken. In the other pages of the Register for the period between April, 1645, and the midsummer of 1646, I find the name of Charles Searborough, the *protégé* of Harvey, and afterwards frequently an office-bearer in this College; but there is little or nothing of special interest to us in the rest of the record, beyond the fact that Harvey appears to have attended the College meetings, and so to have discharged his duties, amongst which the providing for the contingency of a siege and famine was one. Dr. George Paget has put on record, as has also Mr. Pettigrew, the fact that Harvey's signature is to be found in the *Liber Computorum* of Merton. The College Register, however, is not so enriched, as I can state upon the authority of Mr. E. Maude Thompson, who compared the pages relating to Harvey's wardenship with the autograph MS. in the British Museum, when I took the Register up to London for that purpose.

Of Harvey's, as of Berkeley's sojourn in Oxford, we know little; little, indeed, has been recorded, with the exception of the somewhat uncertain gossip of the gossipping Aubrey. But what we do know of the place during those years which elapsed between the battle of Edgehill in 1646, makes us certain that scientific, and, indeed, any other work, must have been carried on in it under great disadvantages. We read of the plague, and of the "morbus campestris," described by a former Harveian Orator and Linacre lecturer as desolating the town and driving people out of residence. It was, besides, a centre for military operations; and military life has been shown, by the experience of all ages (though this experience appears to have been lost upon the carelessness and ignorance of this), to be out of harmony with the habits of men, old as was Harvey then, young as our undergraduates are now, who are or who ought to be devoted to study. Whatever else of Aubrey's tales of Harvey I may disbelieve, I can believe that the words addressed to Charles Searborough, "Prithee leave off thy gunning, and stay here," were his.

If, however, we wish to have a real and truthful picture and image of Harvey before us, we must do by him as we have to do by Shakespeare, by Aristotle, by Butler, and several other great writers: we must lay our minds alongside of his, as it is revealed to us in his works. It is only the writings of great men which will bear or repay such treatment: no commentary nor any biography can give us the real and vivid

sensation of having the men before us which we get from a perusal and reperusal of their books. Having used for this purpose what Mr. Tom Taylor has recently spoken of as "the invaluable three hours before breakfast," I have come to persuade myself that I have obtained something like a trustworthy idea of what Harvey really was. Previously, however, to doing this, I gave Christian burial to much of what Aubrey has left on record about him, feeling more and more strongly, as I grew better acquainted with Harvey, that—

"These were slanders: never yet
Was noble man but made ignoble talk."

I will speak first of his scientific *character*, though it may seem strange to speak of scientific *character*, as *character* implies, perhaps, a moral element; and science, so far as it is really science, and based exclusively upon sound reasoning, has no moral element in it; reasoning, so long as it is sound, being of one kind always, and devoid, therefore, of all distinctive or personal factors. Still, the times in which a man lives, even if we do not regard them as making up some considerable part of the man, justify us at any rate in adding something to our quantitative estimate of him if he be seen to have been superior to the disadvantages of an unfavourable, or to have attained just results without the help of a favourable, environment. I do not forget that Harvey was but eighteen years junior to Bacon,

"Whom a wise king and Nature chose
Lord Chancellor of both their laws."

But neither do I forget that the "Novum Organum" was published in 1620, subsequently to the discovery and actual demonstration of the circulation (see *Dedicatio* to the treatise "De Motu Cordis"), if not to the publication of the "Treatise on the Motion of the Heart"; and that the Royal Society, with its motto, "Nullius addictus jurare in verba magistri," was a foundation of a much later date; and consequently, I think, we may feel justified in saying that, so far as the purely scientific factor of a man's nature can be said to have any distinctive or personal character at all, independence, or robustness, or manliness,—whichever word we may like to choose,—as shown in superiority to mere authority and the weight of great names, was a distinctive character of Harvey as a man of science. With Riolanus in full vigour, and Van der Linden growing towards maturity, as champions of antiquity, it required not a little manliness to assert, "contra receptas vias per tot sæcula annorum ab innumeris iisque clarissimis doctissimisque viris," (Riolanus is often thus spoken of), "tritam atque illustratam" (*Dedicatio*, p. 5), the claims of simple nature "quâ nihil antiquius majorisve auctoritatis" ("Epistola Secunda ad Riolanum," p. 123). This element of real manliness shows itself again, I think, in Harvey's power of abstaining from suggesting a *rationale* of what he felt he did not understand; as, for example, in what is known (out of England, at least) as the "problem of Harvey" (see "De Partu," p. 549)—a problem, which, I think, could not have been answered till the "works and days" of Bernard; and in the cases of several other problems instanced by himself (p. 132, "Epistola Secunda ad Riolanum"), and hidden then, to use his own metaphor (p. 630, "Epistola Prima ad Horstium"), in the well of Democritus.

For the culture which Harvey had bestowed upon his literary faculties we have better evidence than Aubrey's, better even than that of two more trustworthy witnesses than Aubrey—Bishop Pearson, to wit, and Sir William Temple—we have the evidence of his own writings as to his familiarity with one of the greatest writers of antiquity. Bishop Pearson, as Dr. George Paget has reminded us (see page 15 of his "Notice of an Unpublished Manuscript of Harvey," 1850), and Aubrey (see page 32 of "Life," by Dr. Willis, prefixed to the Sydenham Society edition of his "Works," 1847), have told us of Harvey's high appreciation of Aristotle's writings; but in his own writings he refers to the Stagirite more frequently, I think, than to any other individual. And as regards Virgil (the Latin author whom probably, if but one Latin author's works could be saved from destruction, most men would choose to be that one, as Aristotle's works would be the similarly-to-be-chosen Greek), Sir William Temple ("Miscellanies," part ii., "On Poetry," p. 314) has told us that "the famous Dr. Harvey, when he was reading Virgil, would sometimes throw him down upon the table and say he had a devil." It was a similar spirit which dwelt in Sir Philip Sidney, who never heard the famous ballad of Percy and Douglas without feeling his "heart moved more than with a trumpet." It is but a small matter to vindicate for our great discoverer claims to a familiarity with Greek. Still, anyone who will look at such passages as the one in the "Exercitatio De Partu," p. 553, where he speaks of the mischief done by meddlesome midwives, or other passages (pp. 116, 129, and 123, "Epistola Secunda ad Riolanum"; p. 613, "Ep. ad Slegelium"), will see, I think, that he had Greek in abundance at his command, and used it just when it helped him to express his thoughts more clearly and concisely than any other words at hand at the moment. He used it, in fact, like a man of sense and real learning, when the use of it would save him time or trouble—two things, of one of which he had all too little, whilst of the other he had all too much for his and our good. Let me add, that in the one authentic MS. which we now possess of Harvey's (No. 486, "Sloane Coll.," British Museum), a MS. never intended for publication, and consisting but of rough notes for lectures to be delivered, I find that he employs Greek words in several places—*e.g.*, p. 656 and p. 87.

His style has been spoken of as being more or less inelegant and unadorned; and the Latin tongue, which he used, lends itself but grudgingly and awkwardly to the purposes of science, being strictly a political language, habituated and framed to describe the march of the legions, the disputes of the forum, or the denunciations of the moralist. Still Harvey's style has always an impressiveness and solidity of its own; and sometimes—as, for example, in the glorious eighth chapter, "De Motu Cordis"—it rises into real eloquence where a great occasion justifies the use of repetitions, of antitheses, and abundance of metaphors. But, though the use of stilted phraseology was common enough among Harvey's contemporaries, and though his imagination was vivid and active enough, his study (for to this I would ascribe it) of the excellent models mentioned saved him, as such a study can save a man, from falling into the use of false or extravagant imagery.

Harvey, besides the advantages accruing from acquaintance with the great minds of the past, enjoyed also those which may be gotten from familiar intercourse with great contemporary minds. These advantages constitute in themselves a second education; and they were at Harvey's command for a period of more than forty years, during which he was prominently before the public. It is recorded of John Greaves (see "Life," by T. Smith, 1699, p. 44), the once celebrated astronomer and antiquary, and a man whom, as a Fellow of Merton, we can well believe, though I know not that we can prove, to have done more than give a silent vote for Harvey when he was chosen Warden, that he was one of the friends of Harvey. His well-known connexion with the Court must have constantly brought him into relation with the statesmen of those stormy times. His legacy to his "good friend Mr. Tho. Hobbs, to buy something to keepe in remembrance" of him, is touching, even if trifling, evidence in the same direction.

Travel, which even in our days confers a kind of culture peculiar to itself, must have been doubly necessary in days when, in the absence of the steamship and the railway, an insular position must have kept its inhabitants very nearly as inaccessible to "the thoughts that move mankind" as it had happily kept them to the Armada. Sir George Ent's interesting and entirely trustworthy account of the interview with Harvey which resulted in the publication of the treatise "De Generatione," will show anyone who will consult it that Harvey had drawn from his opportunities an insight into what might be expected, and what since his time to some extent has been realised, from enlarged opportunities of observing not only "men, manners, cities, climates, governments," but also the wonderful facts of the unequal allotment, in the various parts of the earth, of useful inorganic products, and of that mystery of mysteries, the distribution of organic life. (See "Works," ed. 1766, p. 162; ed. Dr. Willis, p. 146.)

Having been thus fortunate in securing for himself all the advantages which the various educational agencies of his age would furnish, he added on to all that they had effected, or could effect, the yet more elevating and glorious discipline of long-sustained and finally successful labour. He attained a position of mental dignity in which he could feel neither unduly anxious for the applause of his compeers, nor unduly moved by the reproaches and misrepresentations of his enemies (see *Dedicatio*, p. 164; "Epistola Secunda ad Riolanum," p. 109); the impact of these opposite forces resulting, however, in much benefit for mankind, as without them Harvey might, it is likely enough, have delayed the publication of his works indefinitely. Being self-contained without being self-conscious, he was yet, like all

men of real genius, large-hearted and sympathetic. Whilst he could, in a spirit of perhaps a little over-strained charity, make excuses (see p. 614, "Epistola ad Slegelium") for the irrepressible and pestilent Riolanus, he would, we may be also sure, have felt an emotion of gratitude upon each of the many instances in which his own true-hearted adherents, Sir George Ent and other Fellows of this College, fought his battles for him, and vindicated for him successfully and during his own lifetime his own irrefragable claims. And I can believe that, answering to the character of the dignified and stately man so well drawn by the author whom he often quotes, and considering himself worthy of great respect, being worthy of it, he would not have looked disapprovingly upon our attempt to show him respect by the Tercentenary Memorial to which you, sir, have lent the sanction of your name. I can further conceive of Harvey as entirely sympathising with the men who have now in their hands the torch of knowledge which once passed through his, of applauding without any shadow of jealousy the work of the many workers who in these days are going over the ground trodden by him under far less favourable circumstances and with far less assistance from ancillary sciences and their various and still novel instruments and methods. The same spirit which caused him repeatedly to say (as, for example, to Sir George Ent, p. 163; to Horstius, p. 630), "hæc cum mirâ, ut solet, promptitudine effundens," that he doubted not that much now hidden in darkness would be brought to light by the indefatigable industry of the coming age; the same spirit which dictated the provision in his will bidding "his loving friend Mr. Doctor Ent" sell certain of his "books, papers, or rare collections," and "with the money buy better," would have caused him, could he have been amongst us, to point out, as a matter for congratulation, in how many directions his discoveries had been extended and added to, and how well replaced had been the many works the loss of which had been so "crucifying" to him.

There was not in Harvey's mind that defect in the way of a deficiency of interest in theological questions which constitutes in the minds of some eminent scientific, and some eminent literary, men such a lamentable void. He has, on the contrary, in several places taken pains to state his views upon this highest of subjects. To one of these passages (from the work "De Generatione Exercit. Quinquagesima," p. 385, ed. 1766; p. 370, ed. Dr. Willis), as Mr. E. B. Tylor has pointed out to me, Professor His of Leipzig, a worker whom Harvey would have hailed as a colleague, has referred to it in one of his always excellent papers, published in the *Archiv für Anthropologie*, Bd. iv., 1870, p. 220, on "Die Theorien der geschleitlichen Zeugung." It is just in the investigation of the problems indicated in these last words that, as has often been remarked, the question of the existence of other than purely material forces presses itself most closely upon the mind; and hence, perhaps, the repetition by Harvey of his views regarding it, more than once or even twice, in his treatise just referred to (see "Exercit." 49, p. 370; Ex. 50, p. 385; Ex. 54, p. 419-420.) These statements are all to the same purposes. I have chosen one of them—the last one of the three just cited (not the one quoted by Professor His)—to repeat here, because, besides its philosophical and other interest, it has some literary claims upon our attention, it being not quite impossible, considering its line of thought and arrangement of words, that Pope, who borrowed on all sides and made acknowledgments on none, may have had it before him when he composed his Universal Prayer. It runs thus:—

"Nempe agnoscimus Deum, Creatorem summum atque omnipotentem, in cunctorum animalium fabricâ ubique præsentem esse, et in operibus suis quasi digito monstrari; Cujus in procreatione pulli instrumenta sint gallus et gallina. Constat quippe in generatione pulli ex ovo omnia singulari providentiâ, Sapientiâ divinâ, artificioque admirabili et incomprehensibili exstructa ac efformata esse. Nec cuiquam sane hæc attributa conveniunt, nisi omnipotentirerum principio; quocunque demum nomina id ipsum appellare libuerit: sive mentem divinam cum Aristotele; sive cum Platone Animam mundi; aut cum aliis Naturam naturantem; vel cum Ethnicis Saturnum aut Jovem; vel potius, ut nos decet, Creatorem ac patrem omnium quæ in cœlis et terris; a quo animalia eorumque origines dependent, cujusque nutu sive effato fiunt et generantur omnia." (From Harvey's "De Generatione Animalium," Ex. 54, p. 419, ed. 1766; p. 402, ed. Willis.)

I have detained you far too long; but, feeling that my praise of Harvey has been all too feeble, I am anxious, in ending, to use words in his honour, the singular appropriateness of which is only less remarkable than their beauty and force—

> "Remember all
> He spoke among you, and the man who spoke;
> Who never sold the truth to serve the hour,
> Nor paltered with Eternal God for power;
> Who let the turbid streams of rumour flow
> Thro' either babbling world of high and low;
> Whose life was work, whose language rife
> With rugged maxims hewn from life;
> Who never spoke against a foe.
> . . . . . .
> Whatever record leap to light,
> He never shall be shamed."

SURGICAL INSTRUMENTS AT THE INTERNATIONAL EXHIBITION.

(*Continued from page* 693, vol. i., 1873.)

Mr. Matthews shows several of Sir William Fergusson's instruments for stone, among them a model neatly carved by himself in oak for the rack and pinion movement, as now in general use for lithotrity instruments; Dr. Playfair's flexible intra-uterine probes; also a continuous stream enema.

Messrs. Arnold and Sons send a portable and convenient obstetric case; also Dr. Greenhalgh's metrotome; and Mr. Greenslade's fracture cradle, a full description of which appeared in a recent number of this journal.

We were reminded of the bales of lint manufactured by the ladies of England out of their old sheets, etc., for the wounded in the Franco-Prussian war by the case of lattice-cloth exhibited by Messrs. Maw and Son as a substitute for lint dressing. The special advantages of this method of dressing are that openings are left for the escape of pus from the surface of the sore, and there is no chance of loose portions of the cloth adhering to the sore.

Messrs. Blaise have sent several varieties of *bistouries cachées*; some of them are very ingeniously constructed. Also the combination of scissors and forceps used for skin-grafting.

The instruments sent by the College of Surgeons from the Hunterian collection are very interesting, such as Frère Corni's *bistourie caché;* a lancet attached to a finger-ring for opening abscesses secretly (such an instrument would be found useful at the present day: the incision could be made as soon as the customary *tactus eruditus* was completed, without the terrifying effects and suspense accompanying the usual display of cold steel); a Maltese bleeding instrument, shaped like a cross-bow, the knife being thrust forward by the rebound of the bowstring. John Hunter's lithotomy-knife is also shown; it must have been very badly cared for since it was last used by him—the edge is more like a saw than a knife. Lemere's fistula-knife is shaped like a sickle, the point of which is prolonged into a flexible probe. In this way the fistula can be divided with one sweep of the instrument. We noticed also in this case lithotomy-forceps with four blades, and a great variety of cutting gorgets; among them Pagola's gorget with a concealed blade. Also some circular saws for amputations.

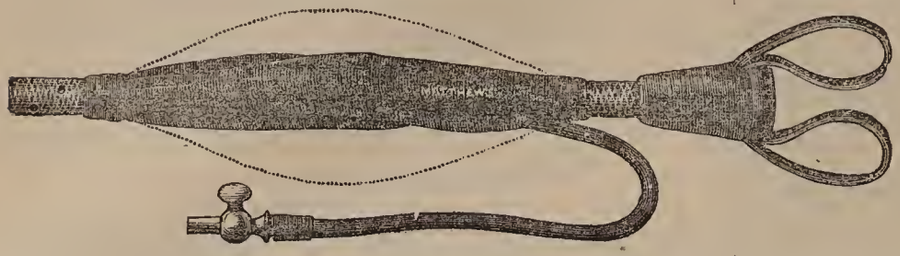
In the College of Physicians' case are several old instruments, including a bullet-extractor made like a corkscrew for boring the bullet and then extracting it. The bullet-forceps would probably in every case be found more serviceable.

Professor Lazarewitch, of the University of Karkoff, has sent a case of obstetric instruments. Among them are pelvimeters for external and internal measurement; and Professor Castellani has a collection of ancient Roman surgical instruments found in Italy.

Mr. Winchester exhibits the model of an invalid bed, so arranged that the mattress can be removed from under the patient without disturbing him. The body is suspended by broad strips of linen, fixed to the sides of the bedstead during the time that the mattress is being changed. In the same case is Mr. Jabez Hogg's demonstrating ophthalmoscope. The advantages which he claims for this instrument are that, instead of the usual biconvex lens, he has fitted a pair of plano-convex lenses into an adjusting tube, for the purpose of correcting spherical and chromatic aberration.

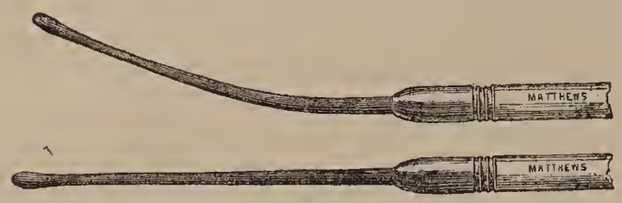
Sir William Fergusson shows a collection of lithotrites in Matthews's case. This collection includes the earliest as well as the latest forms of this beautiful instrument. There is shown the model of a screw lithotrite made by Sir William Fergusson himself—a feat which we presume is unique in the annals of surgery.

An admirable lithotomy-tube is here depicted. Round an ordinary lithotomy-tube is bound a thin bag of indiarubber, in which iced water is injected. Any amount of cold and pressure



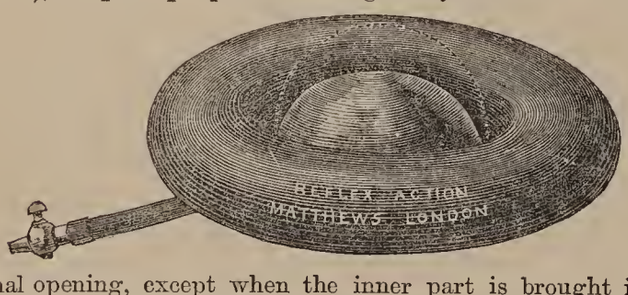
is induced by this means, and the hæmorrhage is much more under control than by the usual expedient of plugging around the tube.

Dr. Playfair's probes for the treatment of chronic uterine catarrh are also exhibited. They are made of flexible metal;



the probe portion being engine-turned, to allow the cotton-wool to be bound round them more readily and safely, for the application of solution of carbolic acid or anything else the obstetrician may deem advisable to use.

The reflex action pad for umbilical hernia (registered) is a very ingenious invention of Messrs. Matthews, and consists of an elastic pad in two compartments, the outer of which reflects the action of the abdominal muscles on the inner (shown by the sketch), the principal pressure being always *around* the abdo-



minal opening, except when the inner part is brought into action by any exertion of the abdominal muscles—such as coughing, sneezing, etc.,—under which circumstances the inner pad advances, so as to be in immediate apposition to the opening itself, thus effectually checking any tendency of the hernia to protrude caused by the additional exertion. The pad is secured to a well-fitting abdominal belt with a centre strap, so as more directly to control the pressure on the pad. It has been used with much success in adult cases as well as with children, carrying out Mr. John Wood's principle of marginal pressure.

Matthews Brothers' guarded perforator is worthy of being extensively adopted by the profession, the point and edges of

the instrument being perfectly protected during its introduction, and readily withdrawn by a movement of the forefinger. The simplicity and handiness of this perforator deserve special notice.

Messrs. Matthews exhibit Mr. John Wood's handy little saws,—the same kind as are constantly used at King's College Hospital; as also Wilcox's forceps, which, by their arrangement of teeth, are exceedingly useful in operations where large flaps are made, being less tiring to the operator than the ordinary dissecting-forceps, and less likely to loosen their grasp. These forceps are invariably used by Sir William Fergusson.

In the University College collection are several of Professor Liston's instruments, among them a pair of old-fashioned bellows for injecting the intestine in intussusception, also an apparatus called a seringotome for dividing fistulæ, and a lithotomy-scoop made like a fishing-net, having an indiarubber bag for catching the stone or removing grit from the bladder.

Mr. Robson, of Newcastle, sends a photo-perimeter, designed for the purpose of measuring the field of vision, and thus ascertaining the amount of sensibility of the peripheral portion of the retina. In the same way the different meridians for astigmatism and relative position of the two images in diplopia may be accurately determined by this instrument.

Dr. Allen has sent a small case of instruments for aural surgery—Eustachian catheters, ear douches, and Politzer's apparatus for dilating the tympanum. The novelty in this case is a convenient form of plug, consisting of a cone of cotton-wool surrounding a thread of silk. The plug can be passed to any distance with the certainty of being easily withdrawn. Much harm has resulted from the insertion of plugs of cotton-wool and their retention for an indefinite time, giving rise to irritation from the discharge being pent up.

The apparatus used by Professor Lister for the antiseptic treatment of wounds is exhibited by Mr. Macfarlane, of Edinburgh, including gauze steeped in the carbolic solution, so that the interstices are filled by it; also boric lint, a more recent dressing for the antiseptic treatment of superficial wounds or sores, but not for cavities. It is found to be less irritating than carbolic acid. In aseptic cases the sore is to be washed with a saturated watery solution of boric acid, and a protective of oiled silk the size of the sore overlays that; one or two layers of dry boric lint should be laid over all. There are also in the same case bottles containing carbolised catgut ligatures ready for use; also carbolic lac plaster and Lister's spray-producer.

Mr. Robert Ramsay, of Great Malvern, shows some artificial velums and casts for the treatment of cleft palate without operation.

Mr. Tufnell proposes to treat stricture of the rectum by constant pressure, with the view to promote absorption, as is frequently done for urethral stricture. The rectum bougie is tubular. A guiding rod is first to be passed through the stricture—the exact situation of the stricture ascertained—and then the bougie is passed over that, and retained till the stricture is cured. The contents of the bowels are passed by the tube.

Mr. Napier has an ingenious instrument for the detection and removal of vesical calculi. The detector—an ordinary bougie made of tin pigmented at the end with nitrated silver—gives ocular instead of aural demonstration of the existence of a calculus by scratches upon the surface. For a complete description of this instrument *vide* the *Medical Times and Gazette*, June 14, 1873.

Lynch and Co., besides exhibiting trusses, pessaries, specula, etc., have some double-channel catheters for washing out the bladder; also Mr. Durham's many-jointed tracheotomy tubes of various sizes.

In addition to the instruments sent by Mr. Hawksley, and described in our previous notice, we may mention a useful speculum vaginæ designed by himself to avoid corrosion from acids or alkalies. It is made of papier maché of the ordinary shape and is lined with mica. The illumination of the interior of the vagina is effected as well with this as with metallic instruments. Dr. Bristowe's gynæcological solid stethoscope with a globular end is also in this case.

Testimonial to Dr. O'Keeffe.—A very flattering mark of the respect in which Dr. P. O'Keeffe is held by the people of Cannaway, among whom he performed his arduous duties as a painstaking and attentive public servant for several years, was bestowed upon that gentleman yesterday, when a number of his friends assembled at the Victoria Hotel and presented an address and a purse containing 110 sovereigns. The address was read by the Very Rev. Canon Murphy Ovens, in the absence of Sir Augustus Warren, Bart. About thirty gentlemen sat down to a *déjeûner* on the occasion, and the proceedings were marked by the warmest wishes on the part of all present for the success of Dr. O'Keeffe in his new sphere of duty as Medical Superintendent of Spike Island.

UNIVERSITY OF LONDON.

Proceedings of Convocation.

In consequence of a resolution passed by the Annual Committee, requesting the Senate to summon a meeting of Convocation to consider the report of the Committee upon the alterations in the Matriculation Examination consequent on the vote of the Senate of February 12, 1873, a general meeting was held on Wednesday, July 2, at the University Building, in Burlington-gardens. The Chairman took the chair at five o'clock, when the report of the Annual Committee was presented, and its reception moved. The following were the principles (as stated in the report) which served as the basis of deliberation of the sub-committee specially appointed to report upon the subject of the Matriculation Examination:—

"(i) That the difficulty of passing the Matriculation Examination should be lessened (*a*) by the admission of optional subjects, (*b*) by the entire removal of one subject from those now ('prior to the resolution of the Senate on February 12, 1873') required from candidates; but that the aggregate amount of work should indicate an equal degree of intellectual acquirements.

"(ii) That the examination should introduce the plan of 'bifureation' of studies, and should adapt itself to the two classes of degrees to which it is preliminary, and to the classical and modern forms of many leading schools.

"(iii) That in the compulsory portion of the examination equal weight should be given to the side of literature and language, and to the side of mathematics and science; but that a choice should be offered to candidates between an extra scientific subject and an extra language.

"(iv) That one modern language other than English should be required from all candidates."

The special subjects which had occupied the attention of the Committee before submitting their report to Convocation were the following:—

"(*a*) The necessary alternative of Greek.

"(*b*) The introduction of optional subjects, and the omission of Chemistry or French.

"(*c*) The 'Natural Philosophy' examination.

"(*d*) The necessary changes in the arrangement of the examination."

As the result of deliberation upon these points, the adoption of the following resolutions was recommended in the report:—

"(A) That in the opinion of Convocation candidates at the Matriculation Examination who do not select Greek should be required to pass an examination in German.

"(B) That in the opinion of Convocation it is desirable that at the Matriculation Examination candidates who are examined in Greek should be required to pass an examination in either French or Italian.

"(C) That in the opinion of Convocation it is desirable that at the Matriculation Examination candidates who are examined in German should be required to pass an examination in either chemistry or botany.

"(D) That in the opinion of Convocation the examination in chemistry at matriculation should not include questions on 'heat.'

"(E) That in the opinion of Convocation it is desirable that every candidate for matriculation who selects either chemistry or botany should be required to pass a practical examination in the selected subject.

"(F) That in the opinion of Convocation it is desirable that the examination in "natural philosophy" at matriculation should consist of elementary questions in mechanics, hydrostatics, heat, and light, contained in two papers, to each of which three hours should be allotted."

All these resolutions were adopted by the general meeting of Convocation, except the last—viz., that the questions in the examination in natural philosophy should be contained in two papers, the time for answering each of which should be three hours.

It will be seen that the Committee endeavoured in their recommendations to accomplish several important objects which have been under the consideration of the Senate and of Convocation for the last few years, and which may be briefly stated to be—1. To lessen the numbers of subjects required and of the candidates rejected at the Matriculation Examination. 2. To adapt the requirements of the University more closely to the modern changes in school education and to its own examinations for degrees. 3. To require of the candidates a more exact and thorough knowledge of all the subjects of the examination.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

No. XXVIII.

By J. F. CLARKE, M.R.C.S.

For nearly forty years on the Editorial Staff of the "Lancet."

ESTABLISHMENT OF THE LONDON UNIVERSITY AND HOSPITAL.

(*Continued from page* 21.)

Robert Liston as Lecturer and Operator.

It would be difficult to find in the history of Surgery two men who were so diametrically opposed as Cooper and his colleague. The fame of Liston had preceded him in his career as a London surgeon. He was second to Cooper in the Hospital, and there can be no doubt that his great reputation as an operator did much to exalt the fame of the North London School. In teaching Liston had no method: his clinical lectures were most unsatisfactory, meagre, and uninteresting—in fact, they were a mere burlesque on surgical tuition. After an operation he would make a few disjointed remarks upon the case, sit upon the operating-stool, look round the theatre to recognise his friends, and make a bow of acknowledgment to them. He would then say—"Gentlemen, you have seen the operation, and I think the patient will do well. I am not your lecturer upon surgery; you get full instruction on its principles, at least, over the way. Whatever may be said of operations as the 'opprobria of Surgery,' when they are necessary I think you will agree with me that they should be quickly and efficiently performed. I have done my best to fulfil my duty. I hope you are satisfied." He would then jump off the stool, and make his bow amid the enthusiastic applause of always a crowded audience. He always prided himself upon the celerity with which he operated, and no doubt to a great extent justly so. To see a patient placed upon the operating-table for the removal of a limb and carried to his bed at an interval of less than two minutes perfectly astonished the students. The dressing and the securing of small arteries was left to the after-treatment of his assistants. He was a consummate actor, but no one who knew him would deny he was one of the greatest and most successful operators of our time. Celerity in operations at this period was unquestionably a most important item for consideration. Ether and chloroform were unknown, and the saving of even a few minutes in the performance of a painful operation deserved to receive, as it did receive, the approbation of surgeons and students. The late Mr. Wakley, who was once, and only once, at my solicitation present, at probably the most important and successful of Liston's operations, remarked to me afterwards—"He is the greatest surgeon that I have seen operate, but he employs too much physical force to make him a perfect operator." This remark was just, and indicative of the shrewdness of the man who made it. It was something almost dreadful to see the great hand, which was compared not inaptly to a leg of mutton, wield the great bone-forceps in cutting through some large bone in a second of time instead of employing the saw, which would have been equally effective, though slower, in obtaining the desired end. I must confess, though I admit the force of the remark of Mr. Wakley, I never saw any case in which the use of the bone-forceps appeared to have been injurious to the patient, but I recollect many instances in which the operation was materially shortened and the sufferings of the patient consequently mitigated. Liston was a man of action; he was deficient in the higher qualities which constitute a great surgeon. He was deficient in the reflective faculties. He seemed to arrive at the diagnosis of the case under him almost by intuition; but having arrived at his diagnosis he acted with the greatest decision. This led him to make great successes; but it led him into more than one lamentable failure. I have recorded in these "Recollections" more than one case in point.

It is due to his memory that I should mention certain instances in which his great sagacity entitled him to the highest admiration. One of the most interesting cases with reference to his success was that of a man who was admitted into the wards with what was believed to be a syphilitic node on the shin-bone, and had been treated as such in several of the London hospitals. On learning the history of the case from his house-surgeon, Liston, who always studied effect, said, "Give me the trephine." It was handed to him; he applied it with the effect of evacuating a quantity of matter from the tumour. The effect of this proceeding upon the students may readily be imagined. He said nothing, but, with the greatest *nonchalance*, went to the bed of the next patient under his care. The case, however, that decided what may be called the fate of Liston was that of a girl named Sarah Griffiths. I believe I am right in stating she had been turned out as incurable from most of the London hospitals. The operation on this poor girl was that one of Liston's cases at which the late Mr. Wakley was present. It was certainly a most extraordinary case. I reported it at the time in the *Lancet*, with an illustrative woodcut. This report and the illustration were subsequently embodied in Liston's great work on "Practical Surgery." The girl was suffering from a fibrous tumour of the upper jaw. It involved both bones of the superior maxilla, forming a large tumour, which so affected deglutition and breathing as to imperil her existence. Liston decided on its removal. It is not necessary to enter into the details of the operation, but it was mainly effected by means of the scalpel and the bone-forceps. In ten minutes the entire tumour was removed, and no one anticipated at the moment that the case would be a successful one; but it was. An artificial palate was made by Mr. Hunter, then the dental surgeon to the Hospital, and the girl presented an appearance afterwards which was truly remarkable. As far as I know, she is living at the present time, affording an illustration without a parallel of the beneficent powers of operative surgery. Liston at this time had all but made up his mind to try his fortune in America. He was prevented from taking this very doubtful step by the following article, which, as it bears so much on the career of the great surgeon, I offer no apology for reproducing in these reminiscences:—

"In the report of the formidable operation which was recently executed by Mr. Liston in the University Hospital for the removal of an enormous tumour of the mouth, and the bone to which it was attached, we have to record one of the most splendid triumphs which operative surgery has ever achieved. Nor was the profoundly scientific and masterly mode of accomplishing the operation the most prominent trait which the ability of the surgeon presented. The sagacity displayed by the pathologist in forming a correct diagnosis belonged possibly to a higher class of merit than did even the tact and dexterity which were evinced by the operator in the theatre. Eighteen months since, when the tumour was comparatively small and the roots of its growth could be accurately traced, the sufferer was discharged—not only as incurable, but as an unrelievable object of affliction—by the surgeons of Guy's Hospital. The opinion of Sir Astley Cooper, the consulting surgeon of that institution, was not once solicited on the case of the unfortunate patient, so utterly destitute of hope was the miserable condition of the woman in the estimation of the surgeons of Guy's Hospital. Eighteen months since, she left that once-renowned institution, with a mind frenzied by agony and despair, whereas she is now about to be restored to her friends, relieved from a mass of diseased growth, which, whilst it rendered her an object of hideous and unsightly deformity, hourly threatened her with death in two of its most terrific forms—starvation and suffocation."

From this time Liston's practice increased, and he told me himself that his receipts rose from £3000 to £7000 a year. This was the highest sum that he ever received, and he succumbed to an insidious disease at the time he had arrived at the zenith of his great reputation. Liston was a man of great physical power and energy; his frame was Herculean. Exercise of a severe character was a necessity to him. In Edinburgh he hunted constantly. In the season it was no uncommon thing to see the great surgeon pursuing his duties in the wards in his red coat and top-boots. When in London he was in the habit of rising at an early hour, and taking very long walks before breakfast. His favourite route was up to the Swiss Cottage on the road as far as Hendon and back. Some of the more athletic of his pupils would occasionally accompany him, but it was only a very limited number who were able to keep up with him. Sometimes he would propose in these early excursions a "steeplechase" to some object in the distance, and it was in the strict sense of the word a "steeplechase." Away went he and his companions over "hedges and ditches," and, if necessary, through "ponds of water." He was generally the first at the goal. One of his companions, in his walks at least, was my friend, John Churchill. Churchill told me that on one occasion when walking with Liston they met Anthony Todd Thompson in the inner circle of the Regent's-park. Thompson expressed his pleasure at having met his colleague on that occasion, and regretted that, as Liston took his morning walks, he had never met him before. "If you want to meet me," said Liston, "you must come into the outer circle or far beyond it; the inner circle of the park does not afford sufficient space for me." On arriving at home Liston used to take a bath, and partook of a breakfast worthy of the times of Queen Elizabeth,—a quart of strong beer, with mutton-chops or beefsteaks, furnished his morning meal. Liston was a free liver, and after dinner drank his port out of tumblers. "Small glasses," he would say, "were only made for children, and not for men; I could not sip my wine out of them." Liston was a member of the celebrated Beefsteak Club, which was then held at the Lyceum Theatre, of which the late Mr. Arnold was the proprietor. At this club the fashion of eating substantial food and of "drinking deeply" was kept up. It is only a few years since that the club ceased to exist, and its famous utensils were sold by auction. Liston had an earnest affection for all dumb animals. He buried his famous hunter at Edinburgh in the erect position, as a mark of his estimation of his worth. His favourite when in London was a huge black cat, who was his companion in his consulting-room and in his carriage rounds. Those who did not understand Liston thought him selfish and cold. This was a great mistake: I can testify to many instances of necessitous patients, to whom, instead of receiving a fee for his services, he would generously give a fee. I have said that Liston had a Herculean frame,—he was upwards of six feet high, strongly knit, and with a face denoting great intellectual power; a forehead broad and massive; grey eyes beaming with intelligence; a nose such as the First Napoleon thought essential for success in his marshals; a mouth and chin denoting decision and power. What were Liston's claims to be estimated as a surgeon of the foremost rank? I think he was deficient in some of the higher mental faculties. He had much more perception than reflection. He formed his diagnosis too quickly: a few short questions as to the history of the case, an examination short and always decisive in its results. This rapid mode of arriving at an opinion impressed some people with the idea that there was a certain amount of carelessness about him. This to some extent may be true, and will account for some of the great mistakes he made, but these were counterbalanced in the eyes of the students by some marvellous instances of correct diagnosis when other surgeons had failed. I do not believe that Liston was a profound thinker: he was wearied by long descriptions and with what may be called with all due respect "minute and unnecessary details." Like Astley Cooper, as I have before said, Liston studied effect. Those who have watched him, as I have done on hundreds of occasions, could not fail to be struck by his simplicity—by his grasp, as it were, at the moment, of the salient points of a case. I do not believe that he was hasty or careless. He was earnest in all he did, as was manifested by the steadfast observation of his truly sagacious eyes. He had a thorough contempt of "physicians," and used to say in his lectures that "a physician treating disease was like a blind man with a club—he might hit the disease but was just as likely to hit the patient." Yet, with all his assumed contempt of medicine, he was always foremost (at least, in surgical cases) to try the effects of new remedies. I believe he was the first surgeon in the metropolis who employed ether in what he used to call "operative procedure." He used belladonna in erysipelas when it was first recommended. He was not scrupulous in the opinions which he expressed with regard to the practice of other great surgeons, and more than once he got into difficulties in consequence. With a great deal of the "canniness," he had an amount of impulsiveness which appeared to ignore that characteristic of his countrymen. I have seen all the great operators of Liston's time, and, with the exception of Aston Key, I have never seen anyone to excel him. In the most delicate operations, as well as the most formidable, his "leg-of-mutton fist," as somebody termed it, was equal to all emer-

gencies. I recollect on one occasion, when witnessing a delicate operation on the eye, a provincial surgeon exclaimed "Why, his hand is like the tusk of an elephant!" "Yes," said a bystander, "it is, but it has all the intelligence of the elephant's trunk." This was true. Liston succumbed to an aneurism, no doubt brought on by the extraordinary bodily exertions to which I have alluded. To the last his courage never failed him. A few days ago I was talking to John Churchill, senior, respecting Liston's last illness. Churchill was one of the earliest friends of Liston when he came to London, and that friendship continued to the last moment of the great surgeon's life. Churchill called upon his old friend two days before he died.

"I found him," said Churchill, "sitting in the chair inhaling from a tube to allay the irritation of his throat. He welcomed me thus—'Well, old Bibliopole, you have come to see me; I suppose they all say I am dying.' Taking a note from the table, and looking out of the window, he said, 'I will keep this appointment to-morrow': it was for a consultation to a lady of title." In about forty-eight hours Robert Liston had ceased to exist.

Such is, I believe, a just account of a great surgeon—a man who has left his mark upon the time. Only one portrait of his fine intelligent face, as far as I know, is worthy of him; it was one, half-length, painted by Sir F. Grant. It has been engraved and printed. Liston was the author of the "Elements of Surgery" and "Practical Surgery"—the first a great, cumbrous, ill-written, and soon-forgotten volume; the second the very opposite. Liston for a short time lectured on surgery at Lane's School; but he did not succeed—in fact, he could not bear the "formal drudgery of systematic lecturing."

(To be continued.)

ANNUAL DINNER OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

The annual dinner of the Fellows of the Royal College of Surgeons of England took place under the presidency of Professor Humphry, M.D., of Cambridge, at the Albion Tavern, Aldersgate-street, on Thursday evening, July 3, after the election into the Council of the four successful candidates for that honour, whose names we mentioned last week—viz., Sir James Paget; Mr. Haynes Walton, of St. Mary's Hospital; Mr. George Southam, of Manchester; and Mr. John Marshall, of University College Hospital.

No fault could be found with the dinner arrangements, which were very complete, with the exception of the absence of all music whatsoever. This want was commented on by Sir J. Cordy Burrows, who could not help regretting that the strains of sweet music had not been added to the entertainment to heighten thereby the harmony of the evening. Professor Humphry made an excellent and genial host, and proposed the various toasts which fell to his lot in terms of great good taste and appropriate enthusiasm.

Sir William Fergusson, in proposing the toast of "The Medical Council," the youngest but the leading medical institution, remarked that as yet we have had no great novelty resulting from the meetings and discussions of this body. He said that, with all proper respect and deference to the gentlemen who composed the Council, nothing of any importance to the profession, with the exception of the Pharmacopœia, had emanated from this institution. What the Council lacked was, Sir William Fergusson thought, a little more effrontery, so to speak, and then he was quite sure it would do more good. It would be well if a friendly collision were to arise every now and then with the old institutions—the Colleges of Physicians and Surgeons. In speaking of the comparative value of education and examination as a guarantee for a man's fitness for the profession, Sir William was strongly of opinion that the method and mode of education ought to stand before examination. It would take two or three years to examine a candidate so as really to know whether he was fitted for the responsibilities of practice; so that examinations without the guarantee that the candidate had been properly and regularly educated would be unsatisfactory and insufficient.

Dr. Paget, of Cambridge, whose name was coupled with the toast, replied in an amusing speech to the friendly and courteous strictures of Sir William Fergusson.

Mr. Charles Hawkins proposed the toast of "The Medical Corporations," coupling the names of Dr. Burrows with the College of Physicians, Mr. Hancock with the College of Surgeons, and Mr. Thorn (the Master) with the Society of Apothecaries.

Mr. Hancock, in returning thanks as President of the College of Surgeons, said that the profession need have no apprehension or misgiving that any step would be taken by which the College of Surgeons would ever relinquish its prestige or cease to control the surgery of England.

Mr. Erasmus Wilson proposed "The Provincial Schools," coupled with the name of Mr. Harrison, of Liverpool. Mr. Wilson had expressed a hope that the watchword of these schools would continue to be, as it had been, "Work."

Mr. Harrison, in replying, said that there was ample evidence of the manner in which many of the provincial schools were giving earnest of their intention of vindicating this watchword.

Mr. Bartleet, of Birmingham, proposed the toast of "The Metropolitan Schools and Teachers," coupled with the name of the distinguished teacher who had that day been elected into the Council of the College—viz., Mr. Marshall, of University College.

Sir James Paget, in a polished and cheery speech, gave "The Health of the Chairman," whom, he said, he regarded with great esteem as one of his first pupils, and as a friend of more than thirty years' standing; and with admiration for the manner in which he fulfilled his position in the University of Cambridge, being at the same time a teacher of surgery in its minutest details, and of anatomy upon its broadest basis.

Professor Humphry, in returning thanks, observed that he was the youngest Fellow who had ever had the honour of occupying the position he then held as Chairman, as well as the youngest Fellow ever admitted to the Fellowship of the College of Surgeons. He received that honour before the statutory age of twenty-five, and was for a long while designated by the *sobriquet* of the "Baby Fellow." He admitted to owing his success to a good and early start, and this start was chiefly through the kindness and friendship of Sir James Paget himself.

The toast of "The Stewards" was proposed by Mr. Procter, and responded to by Mr. Paget, of Leicester.

The Chairman then proposed "The Health of Mr. Carr Jackson, the Honorary Secretary," upon whose exertions the enjoyment of the evening and the success of the dinner had so much depended.

A very large gathering of London and provincial Fellows was drawn together on this occasion. The interest taken in the proceedings of the morning, and the anxiety evidenced by many of the provincial Fellows to insure the election of Mr. Southam as their representative on the Council of the College of Surgeons, had no doubt much to do in swelling the numbers at the dinner. While we congratulate the country Fellows on the attainment of their desire to secure Mr. Southam's return, we must protest against the distinction which it has been attempted to draw between country and London Fellows. It might almost be supposed, from much that we have heard upon this subject, that the interests of the provincial Fellows were adverse to or different from the interests of the London Fellows; that, in fact, the whole body of the Fellows might be grouped into two opposite sects—provincial and London,—as the House of Commons is into Liberal and Conservative. No such distinction, however, exists, or can exist. The interests of the provincial, as of the London Fellows, are the interests of the profession—viz., the advancement and improvement of all surgery and the honour and dignity of all surgeons; together with the guardianship of the library, and of that treasury of knowledge and monument of surgical and anatomical researches—the Hunterian Museum of the College. If, then, this is the case, is it not raising a false cry and establishing a radical misunderstanding and error to declare that country Fellows require special representation by one of themselves, and that the London Fellows who are elected on the Council do not represent their *provincial* as well as their London brethren?

The men whom the great body of the Fellows should elect as Councilmen are those of their number who, from their position in the profession, may well be considered leaders of Surgery, and who from their characters as men are fitted to represent and have a share of the control over a learned and

honourable profession. These requirements, we are proud to admit, are not limited to London, but can be easily found amongst the Fellows in the provinces. There is, however, another desideratum for a College Councillor, and without which the good qualities we have mentioned cannot be brought to have their proper influence: we speak of *regularity of attendance* at the meetings of the Council.

Now, there are some, but not many, leading country Fellows whose time and whose engagements will permit of the frequent visits to the metropolis which the meetings of the Council require. The expense and loss of time must be very considerable, and must tend to have the effect of limiting the number of attendances of those residing at a long distance. For this reason we cannot hope to see any increase in the number of country Fellows on the Council. We will not say country representatives, because, as we have shown, all members of the Council are as much country as London representatives, though we can heartily congratulate the Fellows upon those provincial gentlemen who now hold seats on the Council.

REVIEWS.

Human Longevity: its Facts and its Fictions. Illustrated by Examples. By William J. Thoms, F.S.A. London: Murray. 1873.

We have been a good deal entertained and amused by Mr. Thoms' book. It is on a subject which interests alike the physiologist, the historian, and the genealogist. Of course Mr. Thoms is, as everybody knows, a co-disbeliever with the late Sir G. C. Lewis and the late Mr. Dilke in the generally accepted cases of human longevity. But it strikes us that his book has done more to place the fact of human beings occasionally attaining the age of a hundred years and more on an irrefragable basis than any other which has yet seen the light. In the first place, he himself records instances of it attested by unimpeachable public documentary evidence; and, in the second place, although he has certainly proved that some of the claimants to centenarian honours have been impostors, he as certainly attacks others by a process of special pleading which we are sure will convince many readers of the truth of conclusions exactly opposite to those to which Mr. Thoms would lead them. That numbers of people live to upwards of ninety no medical man for a moment doubts; that some live to a hundred Mr. Thoms himself has most clearly proved. There is, therefore, nothing like improbability or impossibility in the matter. Of course, the opponents of centenarianism have hitherto had the comparative uncertainty of baptismal registers on their side of the argument. The present system of registration of births has not been long enough in existence to throw the light which it hereafter must throw upon the subject. The present generation, therefore, must be content to rest on Mr. Thoms' admissions and on popular testimony. The amusement, however, which the book has afforded us has been derived from the Quixotic fervour with which Mr. Thoms has thrown himself into the controversy. Society is no doubt obliged to him for cutting off a few years from the weary roll of a few poor old soldiers. Well, truth is always valuable; but we almost doubt whether the result is worth the pains,—considering that, as we have said, there have been and no doubt are people of a hundred years old who are *not* impostors. With regard to the case of Henry Jenkins, we think the old peasant's story of his carrying arrows to "Flowden Field"—considering his social position and the improbability of his inventing such a story—one of the most remarkable pieces of evidence that could have been conceived. With regard, again, to old Parr, the question is simply whether old Parr's contemporaries are not better worthy of credence than Mr. Thoms' "reasonings;" especially as Mr. Thoms' facts at least prove that a hundred years is not the limit to human existence.

NEW BOOKS, WITH SHORT CRITIQUES.

Tablets of Anatomy and Physiology. By Thomas Cooke, F.R.C.S. Crown 8vo. Longmans.

*** These "Tablets" are intended to assist the student in revising what he has already learnt. They present in as few words as possible a co-ordinate analysis of all the important points, and show at a glance the general outline of the subjects they treat of. The Anatomy treats in thirteen tablets of the eye and the ear, the minute structures of the cochlea included. The Physiology treats in twenty-six tablets of circulation, respiration, and animal heat, and is the first of the three parts which are to complete this portion of the work.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

July 8.

The Public Health — Ventilation of Sewers — Fatal Practice by a Midwife.

Never, for many years past, has the health of Liverpool been so good as during the first half of 1873. Week after week the deaths are very many less—sometimes more than 100 less—than the average weekly number during the years 1861-70, estimated, of course, on the probable difference in the population. From an average of 30 and over per 1000 per annum, which was often reached last year, they had fallen during the twenty-first week of the present one to 21·2, thus giving to Liverpool the unexampled place of fourth on the health-list of eleven of the largest towns of the kingdom, London, Oldham, and Bradford alone excelling it.

Taking advantage of this breathing time, the Health Committee of the Town Council is seriously entertaining the question of the condition and ventilation of the sewers, and has received and adopted a report from the borough engineer on the matter, which, it is presumed, will be acted upon if not too costly. The following are among the recommendations, viz.:—"That, the system of drainage having been put into good condition, gratings be fixed on the man-holes in the streets, or, in the absence of man-holes, that ventilating shafts in the streets be constructed at distances not greater than 100 yards; that advantage be taken, where practicable, of any tall shafts, as upcast shafts; that in very confined spaces, where, owing to special difficulties in connexion with the condition of the sewer, mephitic air is expected to accumulate unduly, Archimedean screw ventilating shafts of the largest size or similar shafts, without the screw, be used if practicable. . . That immediate consideration be given to the practicability of requiring owners of existing property to ventilate their drains by pipes carried up to the tops of the houses; that the regulation with respect to compelling owners of property about to be built to wet-trap their drains, and thus cut off air communicating with the sewers, if they refuse to ventilate them, be added to the form of permission to drainage at present in use," etc. Dr. Trench, the Medical Officer of Health, objected, and, as it seems to me, very justly objected, to several of these recommendations. He informed the Committee that twenty years previously the plan of ventilating from gully-holes had been tried, but that so great a nuisance had been created thereby as to render it absolutely necessary that the holes should be thoroughly trapped, and he was unable to see why ventilating through one hole should prove a nuisance, while ventilating through another, which the report proposed should be made within a few feet of it, should not,—assuming that the sewers and sewer gas were not very different in the two cases. But it seems to me that these recommendations are somewhat contradictory among themselves. If tall upcast shafts are to be used wherever they can be found to hand, and if the owners of property are to be compelled to ventilate their drains by pipes carried up to the tops of the houses, then the superiority of one of the principles urged by the Medical Officer of Health—viz., that the diffusion of the sewer gas should commence above, and not immediately underneath the noses and lungs of the street traffickers—seems to be conceded; and there seems to be no valid reason, except it be that of cost, which is not mentioned, why it should not be adopted altogether. The Medical Officer further objects to having openings at a less distance than twenty feet from any house, for the very practical reason that at the present time he receives repeated complaints—and that, too, from inhabitants of the least crowded parts of the town—of the nuisance caused by the ventilation from gully-holes, which are on an average more than that distance from any house. Why, too, the alternative of compelling owners to wet-trap their drains should be recommended—when the much simpler and more efficacious one of demanding absolute disconnexion between

the house-drains and those of the street might be insisted on,—does not seem clear. Free ventilation of the sewers seems to us to be absolutely necessary, but then that ventilation should be rendered as innoxious and as little of a nuisance as possible; and scarcely less necessary seems to be the necessity for absolute disconnexion of all house-drains from the street sewer, where such disconnexion is practicable. For it has yet to be proved that sewer gas is quite insoluble in water, and that the very best wet-trap may not by first holding it in solution in its contents serve as a means of slowly conveying some little of it into the house; as also that in many confined places, especially where ventilation is not very free, there may not easily be produced such a difference in barometric pressure between the air of the sewer and that of the house as to enable the former to force its way easily through the water in many of the wet-traps most commonly in use. At any rate, it is not at all uncommon to hear people, who have sculleries with fireplaces and lighted fires in them, complain of bad smells emanating from sinks, the pipes from which have every appearance of being well trapped. The Town Council of Liverpool is a most enlightened and liberal body, and it is to be hoped that they will eventually adopt only such a system of sewer ventilation as shall tend to maintain the present healthfulness of the town.

An important inquest was held by the borough coroner on the 17th ult., which possibly reveals a practice more common than it is supposed to be. The newly born son of a Mrs. Humphreys being thought to be tongue-tied, a midwife named Charnock undertook, as it seems, *de proprio motu* to remedy the defect; for, on being asked what she had done, as blood was seen oozing from the child's mouth on the conclusion of her washing him, she replied, "The little rascal was tongue-tied, so I have cut it a bit with my scissors, but they must have slipped." Surgical aid was obtained, but the hæmorrhage continued for several days, when the infant died. The jury in their verdict strongly deprecated the performance of such an act by any but a qualified medical man.

Joseph Croslett, a butcher, residing in Paddington, Liverpool, was fined £20 on the 4th inst. for exposing bad meat for sale; and still more recently Edward Jones was sentenced to three months' imprisonment, without the option of a fine, by the Wrexham magistrates for a similar offence.

BIRMINGHAM.

July 1.

THE LADY-STUDENTS—THE GENERAL AND QUEEN'S HOSPITALS—THE LOCAL BRANCH OF THE BRITISH MEDICAL ASSOCIATION—THE UNIVERSITY OF LONDON MATRICULATION EXAMINATION.

THE persistency of the ladies in their masculine endeavours to obtain admission to the medical classes of Queen's College is not at all remarkable, considering that amongst the many delightful attributes which they possess that of pertinacity is not the least striking. In exemplification of this we have only to mention that, notwithstanding the strong opposition which has arisen to bar their entrance as medical students into Queen's College, they persist in dunning the authorities with applications for a re-hearing of their case; and at last it has been settled, but in a way which, we fear, fails to give them satisfaction, for the Council have wisely decided not to grant their request. Hence, if the ladies are still determined to dabble in physic, they had better build a college of their own.

The rivalry which used to exist between the Clinical Professors of the General and Queen's Hospitals has subsided, and resolved itself into a warm and close-fisted amity. The respective teachers have combined in their operations, and the result will be highly beneficial to both teachers and teachee. Students will now have the opportunity of attending the classes in either Hospital, and, the lecturers having all things in common, there will be more harmony and unity among them.

The members of the Branch of the British Medical Association dined together at the Great Western Hotel last week. There was a large company, and the event passed off with considerable *éclat*. Mr. Jordan favoured the company with a *résumé* of his surgical career, which met with an attentive hearing. The affairs of the Branch appear to be in a satisfactory condition.

The matriculation examination of the University of London is now going on at Queen's College; there are about thirty candidates. "Young Hopeful" tells us that the papers and examiners are unusually stiff and strict.

LEGAL INTELLIGENCE.

GUILDHALL SECOND COURT OF COMMON PLEAS.

(*Sittings at Nisi Prius, before Mr. Justice* HONYMAN *and a Common Jury.*)—*July* 8.

CLARIDGE *v.* RUMBOLL.

MR. HUDDLESTON, Q.C., and Mr. Roland Vaughan Williams appeared for the plaintiff; Mr. W. Grantham and Mr. R. G. Glenn for the defendant.

This was an action brought by a confectioner residing in George-street, Hoxton, against a surgeon residing at 91, Shepherdess-walk, for negligence as an accoucheur, whereby the plaintiff's wife died in her confinement. The real question in the case was whether a Mr. Westcott, the person who actually attended Mrs. Claridge, the plaintiff's wife, was the defendant's assistant. It appeared that Westcott was unqualified to practise in any way, and that he had at one time acted as assistant to the defendant, and that at the time he was called in he was living at 118, Kingsland-road, at a house where the defendant's name appeared on a brass plate on the door, and where the defendant had certainly recently practised, but where, in December, 1872, the name of Westcott had been painted over a shop window in which the drugs were exhibited. It was also proved that Mr. Rumboll was carrying on business at other places where he had for managers unqualified assistants.

It was not disputed that the death of Mrs. Claridge was caused by the negligence and unskilfulness of Mr. Westcott.

The jury found a verdict for the plaintiff for £100.

OBITUARY.

JOHN SOPER STREETER, F.R.C.S.,

WAS born in Drury-lane, where his father was in general practice for many years. He entered his medical studies at the united Hospitals of Guy's and St. Thomas's. Having passed his examinations at the Hall and College in 1823 and 1824, he joined his father in practice, and continued to carry on the business in the same house until a few years ago, when he removed to Harpur-street, Red Lion-square, where he died last week in his 71st year. Mr. Streeter was one of the pupils of Spurzheim, and attended his lectures on phrenology with great assiduity. He was a warm adherent and advocate of that science during the remainder of his life, both when it was flourishing and when it was under a cloud. He was a man above the ordinary standard, both in intellect and acquirements, and found time in a laborious practice to read and to write. He devoted himself chiefly to obstetrics, and translated "Icones Obstetricæ of Moreau." He also published "Practical Observations on Abortion," in which he recommended the free use of opium. He was author also of "A Folio Atlas of sixty plates, with Editorial Remarks and Obstetric Statistics." Mr. Streeter was much esteemed by his brethren, and for many years was a constant attendant at the Medical Societies of London and Westminster, at which he was a frequent speaker. His speeches were delivered in a clear and somewhat didactic style. It was evident that he seldom spoke off-hand, and he was one of the few who did not address an audience without careful preparation. He served the office of president in both these societies, and conducted himself in the chair with urbanity and dignity. Though fully impressed with a sense of his own importance, he was one of the kindest and most inoffensive of men. I recollect no instance, during a period of thirty years, of his having ever uttered an offensive word. During the last few years of his life, being in independent circumstances, he became what may be called somewhat of an idle man, devoting himself to reading, which was mainly confined to works on medical subjects. He was very fond of chat, and was apt to hold his hearer by "the button." No matter how urgent was the business of his friend, or whatever excuse he might make to be released, Streeter always managed to arrest him for a time in a manner which was really comical. I may safely affirm that he has left no enemy behind him. The circle of his friends was large, and they

will lament his loss. He was buried on Monday last in the family vault at Thornton's-heath. In addition to the works above specified, Mr. Streeter was the author of papers "On Small-pox and its Combination with Pregnancy," "On Hooping Cough," and "On Statistics of Cholera of 1832 at St. Giles's." In person he was above the middle height and of robust frame. He had a remarkedly intelligent face, and a head which, with some trifling exceptions, might have been moulded into a phrenological model. J. F. C.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, July 3:

Barrow, Frederick, King's College Hospital.
Gibbs, Robert, Redcliffe-road, Brompton.
Griffith, Alfred Vavassour, Fenton, Staffordshire.
McKay, Henry Kellock, Guy's Hospital.
Reid, Matthew, Free School-street, Horselydown.

The following gentlemen also on the same day passed their primary professional examination:—

Cory, Fredk. Wm., London Hospital.
Hardwick, Edward Arthur, Charing-cross Hospital.
Hind, Henry Joseph, Guy's Hospital.
Sargent, Arthur Francis, St. Mary's Hospital.
Sworder, Horace, St. Mary's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BROWN, GEORGE, L.S.A.,—House-Surgeon to the Charing-cross Hospital, *vice* Lewis J. Newnham, M.R.C.S. Eng., resigned.

BERKART, ISIDOR B., M.R.C.P. Lond.—Physician to the Training Hospital Tottenham, N.

HALL, JOHN, L.F.P.S. Glasg., L.S.A.—Medical Officer of Health for the Urban and Rural Sanitary Districts of the Leigh Union, Lancashire.

RAILTON, THOS. C., F.R.C.S.—Medical Officer of Health for Chorlton Rural Sanitary District.

ROECKEL, W. J., M.R.C.S.—House-Surgeon to the Royal United Hospital, Bath, *vice* Mr. H. C. Hopkins, M.R.C.S., L.R.C.P. Edin., resigned.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—Dr. Henry C. Woods, Surgeon, to the *Enchantress;* George H. Madeley, Surgeon, to the *Duncan;* James Thomson, Staff Surgeon, 2nd class, to the *Amethyst;* H. Cox, Surgeon, to the *Amethyst;* Hayman Thornhill, Surgeon, to the *Duncan*.

WAR OFFICE.—MEDICAL DEPARTMENT.—Staff Assistant-Surgeon John George Thornley, M.D. (half-pay), resigns his commission.

ARMY HOSPITAL CORPS.—Apothecary to the Forces John Andrews, to be Captain of Orderlies; Apothecary to the Forces William Amphlett Moss, to be Lieutenant of Orderlies.

BREVET.—Surgeon-Major Charles Hamilton Fasson, retired upon half-pay, to have the honorary rank of Deputy Surgeon-General.

BIRTHS.

DEMPSTER.—On July 2, at Duncannon, co. Wexford, the wife of J. Carroll Dempster, M.D., Deputy Inspector-General Army Medical Department, of a son.

HANSON.—On July 2, at Presteign, Radnorshire, the wife of William Hanson, L.R.C.P. Edin., L.R.C.S., of a son.

MILSOME.—On July 3, at Addlestone, Surrey, the wife of John R. Milsome, M.D., L.R.C.P., M.R.C.S., of a son.

PRINGLE.—On July 2, at Northfield, Annan, N.B., the wife of Surgeon R. Pringle, M.D., H.M.'s Bengal Army, of a daughter.

SNOW.—On July 2, at Bournemouth, the wife of William V. Snow, M.D., of a daughter.

TICEHURST.—On July 1, at Silchester House, St. Leonard's-on-Sea, the wife of A. R. Ticehurst, M.R.C.S., of a son.

MARRIAGES.

ANDERSON—HALL.—On July 3, at St. Marylebone Church, William Anderson, F.R.C.S., to Mary Margaret, eldest daughter of Walter Hall, Esq., late of Gayton, Norfolk.

BEATSON—STONE.—On July 7, at Saint Bartholomew's, Coffinswell, South Devon, William Burns Beatson, M.D., Surgeon-Major to H.M. Indian Army, Civil Surgeon of Napore, Central India, to Anna Maria Louisa, second daughter of the Rev. Meade Nisbett Stone, M.A., retired Senior Chaplain, Madras Establishment.

KILNER—NEWPORT.—On July 3, at Ardmore, co. Waterford, W. J. Kilner, M.D., to Margaret Catherine, daughter of the late Rev. Francis Newport, of Kilboy, co. Cork.

MATHIAS—LLOYD.—On July 5, at Holy Trinity Church, Southport, John Edward Mathias, F.R.C.S., of Beaufort Villa, Lord-street, Southport, to Annie Maria, only daughter of Morgan Lloyd, Esq., of Aberystwith.

O'MEARA—SNOOK.—On July 2, at the parish church, Colyton, Devon, Frederick Augustus O'Meara, M.D., son of the Rev. Eugene O'Meara, rector of Newcastle, co. Dublin, to Hester Maria, youngest daughter of the late John S. Snook, M.R.C.S., Colyton.

POPHAM—BAGEHOT.—On July 3, at St. Andrew's Church, Carry Rivel, Somerset, John Francis Popham, Esq., of the Middle Temple, barrister-at-law, only son of John Popham, M.D., of Cork, to Florence Eveline, younger daughter of Watson Bagehot, Esq., of Heale, Curry Rivel.

SHRUBSALL—WELCH.—On July 3, at St. Michael's, Handsworth, W. C. Shrubsall, Esq., Peninsular and Oriental Company's Service, to Mary Maunder, daughter of Francis Welch, F.R.C.S.

SPICKERNELL—PASKETT.—On July 7, at St. Simon's Church, Southsea, George Eastcott Spickernell, M.A., Ph.D., Principal of Eastman's R.N. Academy, to Alice, widow of William Paskett, late Surgeon-Major of H.M.I.S.

SWAN—HARPER—On July 2, at the parish church, Holbeach, R. Jocelyn Swan, M.R.C.S. Eng., L.M., of Northlcach, Gloucestershire, to Ann Elizabeth, eldest daughter of R. Harper, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A,, of Littlebury House, Holbeach.

TOWNSEND—WALKER.—On July 1, at St. Mark's, Peterborough, Henry Milne Townsend, Esq., son of the Rev. T. J. M. Townsend, Vicar of Searby, Lincolnshire, to Helen Gertrude, youngest daughter of Dr. Walker, J.P., of Peterborough.

TURTLE—TAYLOR.—On June 8, at St. Jude's, East Brixton, S.W., Frederick Turtle, M.D., of Clifton Lodge, Woodford, Essex, to Sarah Jane, eldest daughter of John Taylor, Esq., of Brixton.

WATTS—BÖHN.—On July 2, at Frankfort-on-the-Maine, Henry, son of William Watts, M.D. Edin., M.R.C.S. Eng., L.S.A., of Vassal-road, Brixton, to Marie, daughter of the late Valentin Böhn, of Frankfort-on-the-Maine.

WHITEHEAD—MARTIN.—On June 26, at Holy Trinity Church, Ventnor John Livesey Whitehead, M.D., of St. Andrew's Villa, Ventnor, to Sophia Charlotte Jarvis, only daughter of the late George Anne Martin, M.D., of Belgrave House, Ventnor.

DEATHS.

BREMNER, JAMES, of the New Corn Exchange, son of the late John Bremner, Surgeon Royal Navy, at his residence, 107, Grosvenor-road, Highbury, on July 8, aged 52.

CARMICHAEL, WILLIAM SCOTT, F.R.C.S. Edin., of 22, Northumberland-street, Edinburgh, at Aberdour, Fife, suddenly, on July 2, aged 54.

FAGGE, CHARLES BRISCOE HILTON, only child of Charles Hilton Fagge, M.D., F.R.C.P., at 11, St. Thomas's-street, S.E., on June 30, aged 4 months.

HURD, JULIA MARY, wife of James Hurd, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., and daughter of the late Rev. Thomas Whalley, Wickham, rector of Horsington, Somerset, at West Lodge, Frome, on July 2.

KNIPE, CATHERINE, wife of John Copeland Knipe, M.R.C.S., Surgeon H.M.'s 36th Regiment, and eldest daughter of the late Captain Martin Hunter Hailes, 10th Bengal Cavalry, at Meean Meer, Punjab, India, on May 30, aged 31.

MASH, HARRIET, wife of James Mash, F.R.C.S. Eng., L.S.A., St. Giles's-square, Northampton, on June 30, aged 70.

MEADOWCROFT, MARGARET, wife of William Meadowcroft, M.R.C.S. Eng., L.S.A., and last surviving daughter of the Rev. John Robertson, late vicar of Great Bentley, Essex, at Great Bentley, on July 3.

MEISSNER, ELIZA M. A., only surviving daughter of the late A. F. Meissner, surgeon, late of Tottenham, at the house of her nephew, H. T. Fotherby, M.D., 3, Finsbury-square, E.C., on July 5, aged 74.

ORWIN, ADELINE MARY, youngest daughter of James Orwin, M.D., M.R.C.S., L.S.A., of Brixton, at Dovercourt, on June 7, aged 22.

PALIOLOGUS, WILLIAM THOMAS, M.R.C.S. Eng., Staff Surgeon, at Isleworth, on July 5, aged 44.

STREETER, JOHN SOPER, F.R.C.S. Eng., L.S.A., at 20, Harpur-street, Bloomsbury, W.C., on July 3, aged 71.

THEOBALDS, ENITH KATHLEEN, infant daughter of Surgeon-Major J. R. Theobalds, Madras Army, at Jubbulpore, Central India, on June 5.

TYRRELL, WALTER RAIKES, infant son of Staff Assistant-Surgeon W. J. Tyrrell, at Kamptee, on June 6.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BASFORD UNION.—Medical Officer of Health. Candidates must be duly qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to R. B. Spencer, Clerk to the Rural Sanitary Authority, Public Offices, Basford.

BIRMINGHAM, BOROUGH OF.—Surgeon to the Borough Prison. Applications, with testimonials, to Messrs. Gem and Hebbert, Magistrates' Clerk's Office, Moor-street, Birmingham, on or before July 21.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Candidates must be legally qualified. Applications, with testimonials, to the House Governor and Secretary, on or before July 26.

BRADFORD INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to W. C. Woodcock, Secretary, 65, Market-street, Bradford, on or before August 4.

CHARING-CROSS HOSPITAL.—Assistant-Physicians. Candidates must possess a degree from one of the Universities recognised by the General Medical Council, and be Fellows of the Royal College of Physicians of London. Applications, with testimonials, to Henry Woolcott, Esq., Secretary, on or before July 22.

CHESTER, TARPORLEY, &c.—Medical Officer of Health. Candidates must be legally qualified medical practitioners, and registered under the Medical Act of 1858. Applications, with testimonials, to Mr. Walker, Town Clerk, Chester, on or before July 24.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to John Binks, Esq., Hon. Sec., Wakefield, on or before July 21.

HALIFAX INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must possess at least one legal qualification. Applications, with testimonials, to Dr. Alexander, Halifax, on or before July 15.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE, W.—Visiting Physician. Applications, with testimonials, to be sent in on or before July 12.

KING'S COLLEGE, LONDON.—Chair of Anatomy. Applications, with testimonials, to the Council.

LONDON TEMPERANCE HOSPITAL.—Visiting Physician and Visiting Surgeon. Candidates must be total abstainers. Applications, with testimonials, to Chairman of Managers, London Temperance Hospital, 112, Gower-street, W.C.

NORTH STAFFORDSHIRE INFIRMARY, HARTSHILL, STOKE-UPON-TRENT.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before July 23.

NORTHUMBERLAND COUNTY LUNATIC ASYLUM, MORPETH.—Assistant Medical Officer. Candidates must be unmarried, and be duly qualified and registered. Applications, with testimonials, to Mr. Wilson, Medical Superintendent, on or before July 15.

NORWICH DISPENSARY.—Resident Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Treasurer, R. Chambers, Esq., Catton House, Norwich.

PORT OF LONDON.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to the Town Clerk, Guildhall, E.C., on or before July 15.

ROYAL ISLE OF WIGHT INFIRMARY.—House-Surgeon and Secretary. Candidates must be legally qualified. Applications, with testimonials, to the Secretary, on or before July 14.

ROYAL BERKS HOSPITAL, READING.—Assistant-Physician. Candidates must be medical graduates of one of the Universities of Great Britain and Ireland, and be registered. Applications, with testimonials, to the Secretary, on or before July 14.

ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, QUAY-STREET, MANCHESTER.—Medical Officer. Candidates must be legally qualified. Applications, with testimonials, to the Secretary, on or before July 18.

SEAMEN'S HOSPITAL, GREENWICH.—Visiting Surgeon. Candidates must be F.R.C.S. Eng. Further particulars may be obtained from the House-Governor and Secretary.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must be legally qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to the Chairman of the Committee, on or before July 14.

STOCKPORT INFIRMARY.—Assistant to the House-Surgeon. Candidates must possess some knowledge of surgical dressing. Applications, with testimonials, to the Honorary Secretary, on or before July 12.

STRATFORD-UPON-AVON, ALCESTER, AND EVESHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to J. C. Warden, Esq., 11, Guildford-street, Stratford-upon-Avon, on or before July 19.

WESTMINSTER GENERAL DISPENSARY.—Surgeon. Candidates must be Fellows or Members of a College of Surgeons. Applications, with testimonials, to the Secretary, on or before July 14.

WEST RIDING ASYLUM, WAKEFIELD.—Clinical Assistant. Applications, with testimonials, to Dr. Crichton Browne, on or before July 18.

WREXHAM INFIRMARY AND DISPENSARY.—House-Surgeon. For particulars, apply to Mr. J. G. Buckton, Secretary, 9, High-street, Wrexham.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Christchurch Union.—Mr. J. S. Morrill has resigned the Eastern District; area 14,311; population 4,321; salary £70 per annum.

APPOINTMENTS.

Altrincham Union.—James G. Purcell, L.R.C.P. Edin., M.R.C.S. Eng., to the Knutsford District.

Bellingham Union.—Wm. Oliver, L.R.C.P. Edin., L.R.C.S. Edin., to the Fourth District.

Martley Union.—Louis G. Blyth, M.R.C.S. Eng., L.R.C.P. Edin., to the Martley Union.

ROYAL COLLEGE OF SURGEONS.—The annual election of President, Vice-Presidents, Professors, and other officials took place on the 10th inst., when Thomas Blizard Curling, F.R.S., of the London Hospital, was elected in the vacancy occasioned by the retirement of Mr. Henry Hancock; and Mr. Frederic Le Gros Clark, F.R.S., of St. Thomas's Hospital, and Sir James Paget, Bart., F.R.S., of St. Bartholomew's Hospital, were elected Vice-Presidents of the College for the ensuing year. The following re-elections took place:—Mr. Timothy Holmes, as Hunterian Professor of Surgery and Pathology; Mr. William Henry Flower, F.R.S., as Professor of Comparative Anatomy and Physiology; Mr. Erasmus Wilson, F.R.S., as Professor of Dermatology; and Mr. George William Callender, F.R.S., Surgeon and Lecturer on Surgery at St. Bartholomew's Hospital, was elected Lecturer on Anatomy and Physiology in the vacancy occasioned by the retirement of Professor Humphry, of Cambridge. Mr. Henry Hancock, late President of the College, was elected a member of the Dental Board in the vacancy occasioned by the decease of Mr. Partridge. At this meeting the recently elected Councillors—Sir James Paget, Mr. Haynes Walton, Mr. George Southam, and Mr. John Marshall—were sworn in, and took their seats. The following Members of the College having been elected Fellows at a recent meetings of the Council, were admitted as such, viz.:—Messrs. Thomas Stainthorpe, M.D. St. And., L.R.C.P. Edin., and L.S.A., Battle-hill, Hexham, Northumberland, diploma of Membership dated June 1, 1838; and James Armstrong McDonagh, L.S.A. Dub., Mornington Villa, Hampstead-road, diploma of Membership dated October 21, 1842.

DR. LANKESTER, in his report last week to the St. James's (Piccadilly) Vestry, stated that during the last fortnight the deaths were nineteen—the mortality having been lower than the average of the last twenty years.

NEWS from Bombay to the 13th ult. states that small-pox was reported to be prevalent in the villages in the neighbourhood of Murree.

THE Local Government Board have awarded to Mr. T. Torkington Blease, Public Vaccinator for the Altrincham district of the Altrincham Union, £22 7s. for satisfactory vaccination.

IN consequence of the appearance of cholera in Venice, the authorities of the city have determined to issue sanitary bulletins daily. Fifty-five cases, according to an official report, have occurred in the district of Dresden since June 25, twenty-nine of which were fatal. There have been no cases in Laskowitz since the 28th ult. Several fatal cases have occurred in the villages of Burgk and Lobtau.

THE Holmesdale Infirmary, Sevenoaks, has just been finished at a cost of £922, leaving £110 in hand towards the expense of furniture, surgical appliances, boundary fences, etc., estimated to require another £250, which the Committee hope will be subscribed before the opening.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting on Monday, July 7, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, Colonel Charles K. Bushe, Matthew Greene, Esq., and Walter Raleigh Trevelyan, Esq., were elected Members of the Royal Institution.

THE ULVERSTON COTTAGE HOSPITAL.—This Hospital, which has been erected mainly through the exertions of Dr. H. Barber, was opened by Lord Muncaster, M.P., on July 4. The building is of stone, and provides accommodation for twelve patients.

SUPERANNUATION ALLOWANCE.—Mr. Henry Gent has been awarded a superannuation allowance of £40 per annum upon resigning the office of Medical Officer for the Knutsford District of the Altrincham Union, after nearly thirty years' service.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The following prizes and certificates of honour were presented on Wednesday, July 2, 1873, by Sir D. J. Corrigan, Bart., M.D., M.P.:—*Scholarships:* 1872.—Open Scholarship in Natural Science, Mr. Alfred Tilly; Exhibition in Natural Science, Mr. W. H. Weddell; Scholarship in Pathology, Mr. B. Schlesinger. 1872-73.—Assistant Demonstrator of Anatomy, Mr. J. Jackson Gawith; Prosectors, Mr. Musgrave and Mr. Walsh. *Prizes:* Summer Session, 1872.—First year.—Botany and Materia Medica, Mr. G. M. J. Giles; Practical Chemistry, Mr. Alfred Tilly, Mr. Heübeck (extra prize). Second year.—Midwifery, Mr. Knowles. Winter Session, 1872-73: First year.—Anatomy and Histology, Mr. T. W. Watkiss; Chemistry, Mr. Garbutt. Second year.—Anatomy and Physiology, Mr. E. J. Edwardes. Third year.—Medicine, Mr. W. V. Lindsay; Surgery, Mr. F. Tyrrell. Third and fourth year.—Clinical Medicine, Mr. B. Schlesinger.

RAPID REVIEWING.—The *Deutsche Klinik*, June 17, contains a review from the pen of a well-known London physician of the first volume of Mr. Spencer Wells's "Diseases of the Ovaries," published in 1865. The reviewer gives a short analysis, reserving a more comprehensive appreciation of the whole work when the second volume appears. This, of course, it will never do, as the necessity for it has been superseded by the new work on the subject which appeared in 1872, the preliminary review of which will probably appear in the *Deutsche Klinik* some time in 1880.

KING'S COLLEGE.—The Principal and Professors of this institution gave a very interesting *soirée* on Tuesday evening. The halls and various rooms were handsomely decorated, and illuminated with the new magnesium light. Some charming paintings by Turner, Landseer, Stanfield, Holman Hunt, Ansdell, etc., were exhibited, as also specimens of glass and bronzes—Roman, Chinese, and Mediæval. In the Natural History Museum were a series of portraits, photographs, etc., and a curious collection of specimens of work done in our convict prisons. Among these were many fine models, especially one showing the works at Chatham. There

were also specimens of tesselated pavement, rugs (plain and coloured), clothing, stained glass, basket work, gabions and fascines, and boxes containing everything necessary for the *Kriegspiel*, or new German war game, contributed by Major Du Cane, the official head of the Convict Department. A collection of objects relating to John Howard, the great prison reformer, who was appointed Sheriff of Bedford just one hundred years ago, was also shown.

Sulphuretted Hydrogen in the Urine after Perforation of the Intestinal Canal.—Dr. H. Emminghaus, of Jena, calls attention (in the *Berliner Klin. Wochenschrift*, 1872, pp. 477, 491) to the presence of hydrogen sulphide in the recently passed urine in two cases of fatal perforation of the intestinal canal. One of the patients lived thirty-one days, the other seventeen days. In the first case the perforation was attributed to a copious meal of boiled rice, with sugar and melted butter, taken by a patient with a chronic ulcer of the stomach. This mixture, so rich in starch (82 per cent. in rice) by a partial conversion into grape-sugar, and the presence of decomposing albuminates, with cane-sugar also, no doubt generated large quantities of lactic acid; hence the perforation. The hydrogen sulphide is present only in very small quantities in normal intestinal gas, although traces of it can always be demonstrated. (Hoppe-Seyler, "Handbuch der Physiol. und Pathol. Chem. Analyse," p. 56; see also Planer's and Ruge's analyses.) But it is constantly present in considerable quantities in putrid abscesses. In the urine it occurs after decomposition has gone on for some time. (In one of Dr. Emminghaus' experiments he found that the urine of a patient suffering from gangrene gave no traces till the third or fourth day.) Dyspnœa (not merely mechanical), dilatation of the pupils, torpor, delirium and convulsions, faintness, slowing of the heart's action, diarrhœa, meteorism, and borborygmi, urgent desire to pass water, and cyanosis, with cold extremities, were the principal symptoms.

Improved Diet of French Soldiers.—Up to the present time the daily ration of meat has been fixed at 300 grammes in time of war and 250 grammes during peace. The meat has been bought by the respective regiments in the markets, and, in consequence of the rise in prices, good meat has been obtained with great difficulty for the sums assigned for its purchase. The Government has decided that from July 1, 1873, it will undertake the supply itself, and that every soldier in active service even during peace shall have 300 grammes of good meat daily. It has entered into large contracts, the first of these having been taken, it is said, at 1·23 fr. per kilogramme.—*Gaz. Heb.*, July 4.

Domestic Pepsin.—Dr. Folsom writes—"I am using what I call 'domestic pepsin,' consisting of the insides of the gizzards of chickens, turkeys, ducks, or geese, or the stomachs of calves or little pigs. Dry them in a stove on a plate and then bruise them, and give a third of a teaspoonful of the powder in syrup a few minutes before eating. Some country people dry the gizzard itself, and then grate it and give the powder in the same way for dyspepsia. I think this crude, inelegant, domestic pepsin far superior to that made from macerated pig's stomach, and it costs next to nothing. I direct the patient to obtain and dry these 'skins' and then bruise them."—*Boston Journal*, June 5.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Professor Vanzetti, Padua.—Enclosure received.

Associate, King's College.—Sir William Fergusson was created a baronet in 1866. He is a magistrate for Peeblesshire. His family consists of three daughters and two sons.

A Fellow, London.—Mr. Southam was one of the earliest ovariotomists; he contributed some interesting cases to the *Medical Gazette* so long ago as 1843.

An Old Member, Greenwich.—Although the Council of the College of Surgeons invite the members of the British Medical Association to the forthcoming *soirée*, members of the College *not* being members of the Association are also invited. The admission, we believe, will be by tickets not transferable, to be obtained by personal or written application.

O. N., Northampton.—There are fifteen general hospitals in London, and ninety special hospitals, surgical societies, etc. The united incomes of thirty-eight of the special hospitals amount to £137,000; the total income of all the hospitals of which returns have been obtained is £357,000 a year.

The International Exhibition.

to the editor of the medical times and gazette.

Sir,—Your reporter on "The Surgical Instruments at the International Exhibition," page 693 of your last week's journal, has inadvertently given to Mr. Thomas Wormald the credit of exhibiting "Some Ancient Instruments for Lithotomy used by a Native Surgeon of the North-west Provinces of Bengal," belonging to, and exhibited by Your obedient servant,

1, Bedford-square, July 2. Jabez Hogg.

F. H. D.—*Medical Times and Gazette*, March 11, 1871.

C. W. P.—The relative amount of medical care bestowed upon the poor by the Poor-law systems of England and Ireland respectively is roughly indicated as follows:—The cost of medical relief constitutes only the twenty-seventh part of the gross outlay on the poor in England, Wales, and Scotland, but it constitutes one-sixth part of the whole in Ireland.

A Provincial Student.—You are too late in your application; the written portion of the primary examination takes place this day (Saturday). Messrs. Holmes and Marshall are the new examiners. Your brother will receive an announcement of the result of the recent Arts examination in about three weeks.

A Metropolitan Fellow.—From inquiries made there is no doubt of the correctness with which the votes were recorded at the recent election of Fellows into the Council of the College; indeed, it is only due to Mr. Stone to state that his report has never been questioned until the present occasion. Several gentlemen who checked the votes gave the result as published last week in the *Medical Times and Gazette*. After the official declaration by the President there is no appeal; had the votes been equal he would probably have decided in favour of the senior candidate.

Greenslade's Fracture Apparatus.

to the editor of the medical times and gazette.

Sir,—At first I did not intend to reply to Mr. Greenway's remarks respecting his "limb suspender" in conjunction with my apparatus, but, on second thoughts, I think I must ask you to kindly allow me a small space in order to correct a few errors which Mr. Greenway is evidently labouring under respecting my instrument. He says:—"As regards the hinged side-splints (a very old idea), I consider them objectionable," etc. This "very old idea" was, I believe, first introduced by my brother-in-law, Mr. Walter, some twenty-five years ago, and my method is an improvement on this; and I beg to call Mr. Greenway's attention to the fact that the "space between the splints" *can* be altered to "suit the size of the limb." The longitudinal trucks and rail in conjunction with my suspending bar not only allow the patient to draw himself upwards in bed, but, having done so, also permit him to shift sideways to a large extent,—as has been intimated to me by many patients and medical men who have proved its usefulness. I also think that Mr. Greenway will agree with me that perforated metal splints are preferable to wood.

A few days ago I took an opportunity of going to the Exhibition to see Mr. Greenway's "limb suspender," which I certainly think is a useful one,—so much so, that I shall not think of making any uncalled for depreciatory remarks respecting it. I may add that my apparatus was introduced nearly four years ago, the *late* improvements being the facility with which it can be packed in such a very small space. Many medical men have expressed their high approval; one in particular, an eminent surgeon, whose letter I find is dated 1870, pronounces it to have "afforded the greatest relief in one of the worst cases," etc.

I shall not again, Sir, trouble you in this matter, as I think it hardly necessary to be continually "crying up" my own apparatus, but, not having yet taken a part, I trust you will excuse my thus intruding on your valuable space. I am, &c.,

Martock, Somerset, July 7. George Greenslade.

The Medical Officers of the Guards.—We have received a letter signed "Fides" from a medical officer of the Guards, in explanation of a communicated paragraph which appeared in our number of June 28, on the subject of promotion in the Brigade. "Fides" explains that—

"Before the Warrant of 1858 came into force the senior surgeon of each regiment occupied the position of principal medical officer to his regiment, and was styled 'Surgeon-Major.' He received a pay that accorded to his rank, together with 5s. a day as charge money; after thirty years' service he could retire on a pension of £1 1s. 1d. In 1858 a Warrant was issued giving increase of pay and other privileges to the army medical officers. The medical officers of the Brigade of Guards were never asked if they were willing to be placed under the terms of that Warrant—or, in other words, they had to accept it. Not so with the senior ranks—viz., the three regimental surgeons-major—they were occupying at the time a higher status than that accorded by the Warrant, and consequently could not be interfered with."

Two of these gentlemen have since retired, but one still remains to stop promotion—on the plea that he does not come under the terms of the Warrant of 1858. Hence the dissatisfaction amongst the medical officers of the Brigade.

A Death from Chloroform.

to the editor of the medical times and gazette.

Sir,—On the morning of June 28, 1873, Ann T., aged 45, wife of a gamekeeper, came to my surgery by appointment, to have her right arm, which she had fractured twenty-five days before, and which had received no treatment, put upon a bent splint.

Her account of the accident was that on Whit-Tuesday, June 3, whilst running up a hill, she fell, and struck her right elbow. She applied to a chemist, who gave her some "oils" to rub in, but had no further advice till, finding that she did not regain the use of her arm, she at length came to me. I found the arm fixed in a fully extended position, the elbow deformed in consequence of the external condyle of the humerus being broken off by a fracture running through the joint, and the head of the radius being separated from its articulation, and the joint moveable only to a very small extent. It was intended to place the limb on a bent splint in order that it might be of more use to her if anchylosis of the elbow-joint

should take place than it would be when quite straight, and as any movement of the joint caused great pain, chloroform was given. She sat in an arm-chair, her clothes were loosened about the neck, and the chloroform was given on a folded handkerchief by Dr. C. She at once began to struggle and to try to take the handkerchief away from her face, but her hands were held, and in about two minutes, the first portion of chloroform having evaporated, and the woman not being in the slightest degree insensible, a second portion, about one drachm, was poured on the handkerchief. When this was held to her face, she struggled more violently than before, kicking, and moving her head from side to side to escape from the handkerchief. In about two minutes from the time when the second portion of chloroform was poured out her struggles ceased, the pulse remaining good. The handkerchief was removed from her face, and the arm was taken hold of to examine it thoroughly, and to reduce the dislocation of the radius, two pulls were given; when I noticed the woman's face was livid, and her pupils widely dilated. No pulse could then be felt at the wrist, and the breathing had also ceased. She was laid on the floor, her tongue drawn out by forceps, galvanism was at once applied over the phrenic nerve and the diaphragm, a vein in the arm was opened, and artificial respiration—during which air entered and escaped from the chest freely—was kept up for half an hour, but there was not the slightest sign of life from the moment when the lividity of the face and the dilatation of the pupils were first noticed. The galvanism only caused a few muscular contractions in the neck. The bottle from which the chloroform was poured was graduated; it holds sixteen drachms when full, and fourteen drachms were found in it after the woman's death. The unfortunate woman was not noted for sobriety. An inquest has been held, and a verdict was returned that the death occurred from the administration of chloroform, to which the jury appended a rider to the effect that no blame was to be attached to either of the medical men concerned. I am, &c., Δ

COMMUNICATIONS have been received from—

Dr. Heginbothom; Dr. Dempster; Dr. Cheadle; Mr. J. W. Groves; Mr. J. Sampson; Mr. Blease; Mr. J. C. Renton; Dr. A. L. Mease; Dr. Whitmore; Dr. David Nelson; Dr. Burder; Dr. Macpherson; Mr. T. E. Amyot; Mr. C. S. Jeaffreson; Mr. J. Chatto.

BOOKS RECEIVED—

Bourgeois on the Passions in their relations to Health and Disease, translated by Damon—Dalby on Diseases of the Ear—Army Medical Report for the year 1871—Volckman on the Prevention of Poverty—Griffiths' Posological Tables, second edition—The Half-yearly Abstract of the Medical Sciences, vol. lvii.—Roth on the Mineral Springs of Wiesbaden, translated by Benson—Valentine on Medical Missions—Constable on Doctors, Vaccination, and Utilitarianism—Tyndall on Light—Annual Report on the Sanitary Condition of Birkenhead—Whitmore's Monthly Report on the Health and Meteorology of the Parish of St. Marylebone.

PERIODICALS AND NEWSPAPERS RECEIVED—

Allgemeine Wiener Medizinische Zeitung—L'Union Médicale—Manchester Guardian—Gazette des Hôpitaux—The Obstetrical Journal of Great Britain and Ireland, No. 4—The New York Sanitarian—Gazette Médicale—Gazette Hebdomadaire—Le Mouvement Médical—La France Médicale—Lincoln Journal—L'Union Médicale—Pharmaceutical Journal—La Tribune Médicale—Indian Medical Gazette—Philadelphia Medical Journal, June 14, 21—Cork Daily Herald—Ulverston Mirror—Westminster Review—Hancock on the Anatomy of the Foot and Ankle-Joint—Le Progrès Médical—Medical Press and Circular—London Medical Record.

APPOINTMENTS FOR THE WEEK.

July 12. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

14. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

15. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

16. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

17. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

18. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Microscopical Society, 8 p.m. Conversational Meeting, for the Exhibition of Specimens, etc.

VITAL STATISTICS OF LONDON.

Week ending Saturday, July 5, 1873.

BIRTHS.

Births of Boys, 1088; Girls, 1063; Total, 2151.
Average of 10 corresponding years 1863-72, 1992·1.

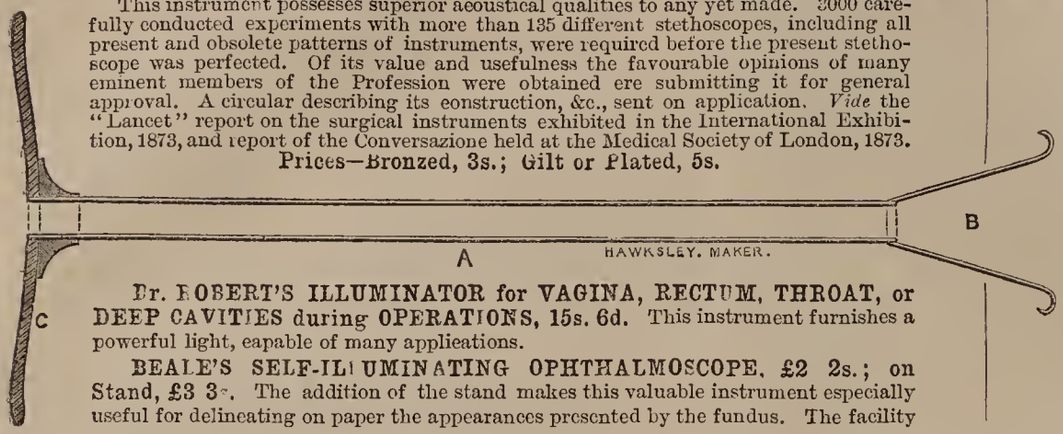
At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·72 in. The highest was 29·88 in. on Wednesday morning, and the lowest 29·55 in. on Friday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

NEW INVENTIONS.

HAWKSLEY'S PATENT DURABLE STETHOSCOPE.



This instrument possesses superior acoustical qualities to any yet made. 3000 carefully conducted experiments with more than 135 different stethoscopes, including all present and obsolete patterns of instruments, were required before the present stethoscope was perfected. Of its value and usefulness the favourable opinions of many eminent members of the Profession were obtained ere submitting it for general approval. A circular describing its construction, &c., sent on application. *Vide* the "Lancet" report on the surgical instruments exhibited in the International Exhibition, 1873, and report of the Conversazione held at the Medical Society of London, 1873.

Prices—Bronzed, 3s.; Gilt or Plated, 5s.

Dr. ROBERT'S ILLUMINATOR for VAGINA, RECTUM, THROAT, or DEEP CAVITIES during OPERATIONS, 15s. 6d. This instrument furnishes a powerful light, capable of many applications.

BEALE'S SELF-ILLUMINATING OPHTHALMOSCOPE, £2 2s.; on Stand, £3 3s. The addition of the stand makes this valuable instrument especially useful for delineating on paper the appearances presented by the fundus. The facility with which anyone may learn to use it and obtain excellent inverted images, is a great recommendation. The spirit now used with the instrument is almost free from smell, and has superior illuminating power. The instrument may be converted into a Laryngoscope, Otoscope, and Endoscope by the following additions, viz.—

For a Laryngoscope, 3 mirrors with wire holders, and adapter to the instrument	£0 15 6
For Otoscope, 3 Toynbee's specula, plated, and adapter to the instrument	£1 1 0
For Endoscope, 3 urethra tubes, 1 bladder-tube, porte caustique, sponge or lint holder, and adapter to the instrument ...	£4 10 0

By removing the lens-tubes the instrument may be used as a powerful illuminator for vaginal or rectal examinations.

HAWKSLEY'S PATENT DURABLE VAGINAL SPECULUM.

These Specula have been made to remedy the defect of the ordinary glass-silvered Ferguson's Specula—viz., their liability to fracture The Patent Instrument is made of papier-maché, japanned on the outer side, and lined inside with silvered mica, which will resist the effects of acids or alkaloids, and always preserve an untarnished appearance. They are made in four sizes, and with the usual bevelled end to facilitate introduction. Price 7s. 6d. each. *Vide* the "Lancet," April 19th and 26th, and report of the Medical Society's Conversazione in the "Lancet" of May 10th, 1873.

HAWKSLEY, Surgical Instrument Maker, 4, Blenheim-street, Bond-street, London, W.

F. WALTERS & CO.

(SUCCESSORS to the late J. MILLIKIN),

7, Southwark-street, Borough, & 12, Palace-road, Lambeth,

SURGICAL AND ORTHOPÆDIC INSTRUMENT MAKERS,

Beg to inform the Medical Profession that they keep their Stock always complete with EVERY DESCRIPTION of CUTTING and BLUNT INSTRUMENTS of the best make and of the most modern and improved construction. A large assortment of Splints, Crutches, and Bed-rests, &c., always on hand.

FOR GREAT EXCELLENCE OF MANUFACTURE

Fr. GUSTAV ERNST,

80, Charlotte-street, Fitzroy-square, W.,

INVENTOR,

Orthopædic, Anatomical, and Gymnastic Machinist,

MANUFACTURER OF

SURGICAL INSTRUMENTS, ELASTIC BANDAGES, &c., &c.

By appointment to the National Orthopædic Hospital, &c.

OF NUMEROUS ORTHOPÆDIC INSTRUMENTS.

GUY'S AND ST. THOMAS'S HOSPITALS.

CAUTION.

J. MILLIKIN, Surgical Instrument Maker to the above Institutions, begs to announce that he has NO CONNEXION whatever with Nos. 7, Southwark-street, and 12, Palace-road, and that all communications intended for him must, in order to insure prompt attention, be addressed to

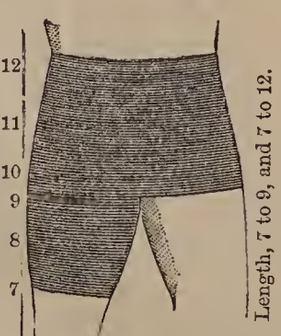
3, ST. THOMAS'S-STREET, BOROUGH,

where he is now conducting his business of Manufacturer of every description of Surgical Instrument and Appliance, Artificial Legs, Arms, and Hands, Trusses, Bandages for Prolapsus Ani, Uteri, Pendulous Abdomen, Moulded Leather Splints, Spinal and Orthopædic Apparatus, &c., Dissecting, Pocket, Amputating, and Minor Operating Cases.

HOOPER'S SPIRAL ELASTIC BANDAGES.

The Measures should be taken next the Skin, as follows:—

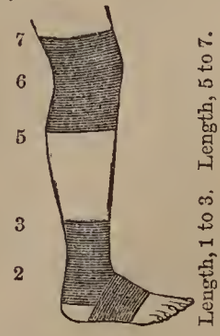
Stocking.



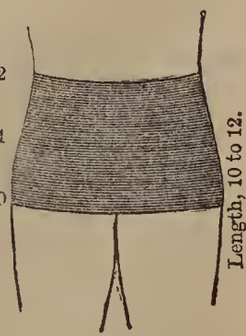
Abdominal Belt & Thigh-piece.

1, Round thickest part of instep.
2, Round ankle-bone.
3, Round small of leg.
4, Round thickest part of calf.
5, Round leg just below knee.
6, Round knee-cap.
7, Round leg just above knee.
8, Round middle of thigh.
9, Round top of thigh.
10, Round body at hips.
11, Round body at umbilicus.
12, Round waist.

The Length should also be given.



Knee-cap & Ankle-sock.



Abdominal Belt.

HOOPER, Manufacturer, 7, Pall-mall East, and 55, Grosvenor-street, London.

ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture IV.—Injuries.

The heart is liable to be overstrained by long-continued hard work, or by sudden and violent efforts, and the foundations of disease may thus be laid, the cavities becoming dilated or the valves incompetent. Independently, also, of these conditions, the walls or valves of the heart may be torn during severe muscular exertion. Accidents of this kind have been known occasionally to occur since the time of Corvisart, though the number of recorded cases is very small. Dr. Quain at the first meeting of the Pathological Society exhibited a heart in which two of the aortic valves were torn from their attachments, and I have seen two similar cases in the hospital practice, of which the preparations are preserved in the Victoria-park Museum. The aortic valves are, indeed, as might be anticipated, those which are most frequently injured, though the tendinous cords and fleshy columns of the mitral and tricuspid valves may also be torn. Of seventeen cases which I collected some years ago, in ten the aortic valves were probably injured, in four the mitral, and in three the tricuspid. When the aortic valves are lacerated it may be that the angles of one or more of the segments are torn from their attachments, or the convex edge of the valve may be separated from the fibrous zone, or the curtain may be torn through. When this accident has happened the patients have generally been using great exertion. One of my own cases occurred in a sailor who was racing up the shrouds of a ship against another man; another patient was pulling at a heavy cask, when his hand slipped, and struck him a severe blow on the chest; a third person was endeavouring to force open a door; and a fourth was striking with a heavy sledge. When the accidents occur the patients experience a sense of something having suddenly given way in the chest, followed by a severe pain in the region of the heart, extending through to the back and shoulders and down the arms, and they become faint. Faintness is indeed a special symptom in cases of injury to the aortic valves, while sense of oppression at the chest and of suffocation occur when the mitral valve or its attachments are torn. In some instances spitting of blood has been occasioned, and in two cases of injury of the aortic valves the patients complained of hearing after the accident peculiar sounds in the chest, neck, and ears.

After injuries of the heart the patients may quickly die, or the symptoms may, after a time, partially subside, but usually all the effects of the corresponding valvular disease more or less rapidly ensue. In cases of aortic valvular injury the patients are recorded to have survived from three weeks to three years and a half, and two were living five months and five years after they had sustained the injury. Dr. Wilks has related a case in which the patient only lived three days, but in this instance there was also serious direct injury to other parts. When the mitral valve has been ruptured the patients have survived from nine days to two years. One of the cases of injury of the tricuspid valve occurred during a violent fit of coughing in a phthisical patient, who lived twenty-eight days. Another person in whom the tricuspid valves were torn during violent exertion only survived between four and five days. In cases of rupture of the aortic valves, if the patients live for any length of time, very rapid and great increase of size takes place in the left ventricle, and indeed it is only by such an occurrence that life can be much prolonged. The sailor whose case I have mentioned afforded a striking example of this, and he was able, after the occurrence of the accident, to perform a long voyage to the East, and during a portion of this time, though with the aortic valves very incompetent, he did the duty of an able seaman. In the class of cases which I have now mentioned, the heart is supposed to have been sound before the occurrence of the accident, or at least not to have been seriously defective. Were there is, however, any alteration in the structure of the valves or muscle from atrophy or fatty degeneration, the injury would doubtless be much more readily produced. Indeed, it is not uncommon in hearts previously diseased for those parts to be torn during some slight effort or exertion; and this is especially apt to occur with the cords or fleshy columns of the mitral valve. I met with a remarkable case of the kind some time ago at the Victoria-park Hospital, which is related in the *Pathological Transactions*.

In some cases the muscular walls of the heart have been found partially lacerated from accidents. Thus I have seen the lining membrane of the right ventricle and a portion of the subjacent muscle torn, though the pericardium was entire, in a case in which a man was crushed and several of his ribs fractured; the laceration of the muscle being thus evidently due to violent action at the time of the accident. Cases are also on record in which the valves were torn from direct injuries.

Carditis, including Peri-, Endo-, and Myo-Carditis.

Pericarditis is seldom, if ever, an idiopathic affection, but generally occurs during the progress of some other form of disease. Thus it is seen in by far the largest proportion of cases as a complication of rheumatic fever. It occurs also in cases of renal disease, and occasionally in scarlet fever, though it is then probably usually rather the secondary result of the renal complication than an attendant on the fever itself. Pericarditis may also occur in phlebitis and tuberculosis, and may be caused by the pressure of tumours, aneurismal or otherwise, on the heart, and it is sometimes the result of direct injury.

The late Dr. Taylor, at that time Physician to University College Hospital, published some years ago, in the *Medico-Chirurgical Transactions*, an exhaustive investigation into the causes of pericarditis. He states that in his own practice it occurred as a complication of rheumatic fever in 8 per cent., or 1 in 12·5 of the cases. We have already gone very fully into the complications of rheumatism when treating of that disease, but as I spoke rather of the prevalence of cardiac complications of all kinds than of pericarditis in particular, I may again occupy your time for a few minutes with the subject. Of the 146 cases of rheumatism upon which I reported in the first paper published in the Clinical Society's *Transactions*, there were 16 in which pericarditis either existed alone or in combination with endo-carditis; those complications therefore occurred in the proportion of 10·95 per cent., or 1 case in 9·1. In the second paper, published in our own Hospital Reports, there were the same affections in 20 out of 87 cases, or in 22·9 per cent., or 1 case in 4·35. Taking the two sets of cases together, of 233 cases of rheumatic fever, there existed pericarditis in some form in 36, or 15·45 per cent., or 1 case in 6·47. This, it will be seen, is a considerably larger proportion than is given by Dr. Taylor; but the differences between our observations are probably partly due to my having included in the calculation cases of rheumatism with old disease of the heart complicated by pericarditis (which does not appear to have been done by Dr. Taylor), and partly to the number of cases analysed by Dr. Taylor being much fewer (only 75) than my own collection, and consequently being more liable to accidental error. In the paper in the Reports I have shown that the proportion of cardiac complications varies very much at different periods, and that trustworthy results can therefore only be attained by analysis of a considerable number of cases extending over a prolonged period of time. I should, however, mention that though the proportion of pericarditis alone which obtained in my cases was greater than that deduced by Dr. Taylor, the total amount of cardiac complication was less. Dr. Taylor states that he met with some form of disease of the heart in 1 in every 2 cases. I found it only in 1 in 2·56 cases.

The circumstances conducing to the occurrence of pericarditis in rheumatism are, according to Dr. Taylor,—

1st. That the rheumatism shall be of the fibrous form.
2nd. That it is a first attack.
3rd. The early age of the subject.
4th. Probably the intensity of the disease.
And 5th. Probably the patient not being previously in a good state of health.

There is no doubt of the correctness of his first inference. Synovial rheumatism is a very passive form of affection, and is generally seen in young persons of the strumous diathesis. It is by no means so common as fibrous rheumatism, and in the

comparatively few cases which I have treated I do not recollect to have ever met with cardiac complication.

My own observations do not, however, confirm the supposed greater liability to pericarditis in first attacks of rheumatic fever. Thus, I find that of the cases included in the first report the proportion of previous attacks of rheumatic fever where there was cardiac complication was 47·1 per cent.; while in the other cases there had been previous attacks in only 34·2 per cent. In the second report this subject has been more carefully investigated, and it appears that, while in cases of first attack the proportion of recent cardiac complication was 11·3 per cent., or 1 case in 8·8, in the cases in which there had been one or more previous attacks of rheumatism the proportion was 45 per cent., or 1 case in 2·2.

I can, however, entirely confirm Dr. Taylor's inference of the greater liability to cardiac complication when rheumatic fever attacks young persons than when it arises in those of more advanced ages. Thus, of 112 cases in persons of 20 years of age and under, the number of cases in which recent cardiac complication occurred was 43, or 33·3 per cent.; of 109 cases between 20 and 40, 32, or 29·3 per cent., were so complicated; and of 12 between 41 and 53, 1 only, or 8·3 per cent., had cardiac affection. These calculations refer to all forms of cardiac complication, but I have no reason to doubt that they are equally applicable to pericarditis alone.

Dr. Taylor speaks doubtfully as to the effect of the intensity of the disease in conducing to pericarditis, though expressing the opinion that the complication is more dangerous when it occurs in severe cases of rheumatism. In the latter view he is doubtless correct, but it is very striking how frequently pericarditis occurs in slight cases of rheumatism. I have many times known it arise in cases of a very trivial character, and I might, indeed, say that it is comparatively rare that the pericardium becomes affected in severe rheumatic fever. Thus, of fifteen cases of pericarditis which are referred to in my last report, in only one was the rheumatic attack an intense one, and in several it was very slight. The liability to endocarditis differs in this respect from the susceptibility to pericarditis, that complication being apparently much more common in severe than in slight cases—its frequency being, indeed, apparently in direct relation to the severity of the attack.

On the influence of the previous state of health of the patient in predisposing to the occurrence of cardiac complications in cases of rheumatic fever, I have no specific facts to offer, but it certainly appears that a previously impaired condition of the general health adds to the severity of most acute diseases, and to their liability to complication, and makes the recovery more difficult and more prolonged, and I certainly think that it operates unfavourably, not only in encouraging the tendency to cardiac complications in rheumatic fever, but in adding to their danger.

To the remarks which have been made as to the causes conducing to the occurrence of cardiac affection in rheumatism, it should be added that probably men are more prone to the complication than women, although the difference in this respect is not very marked.

The occurrence of cardiac affection in rheumatism is, I suppose, due to the large amount of fibrous tissue in the pericardium and valves of the heart. The development of the disease cannot, however, be ascribed to metastasis, as was supposed by the older physicians. The heart generally becomes involved very shortly after the commencement of the affection of the joints, and the cardiac affection generally proceeds *pari passu* with it; but every medical man of much experience has met with cases in which carditis has been developed before the external parts have become affected, and others in which the heart disease has come on after the joints have become quite free.

It is probable that in the development of the cardiac affection the exposure to cold is influential, and that this is the reason why certain joints suffer more frequently than those which are better protected. I have known pericarditis to occur in a patient labouring under rheumatic fever, apparently from his having taken cold in being removed to the hospital.

As to the occurrence of pericarditis as a complication of renal disease, I have no personal observations to give you, but there is no doubt that it very often arises in the advanced stages of Bright's disease; Dr. Taylor found it in 10 per cent. of all the fatal cases. Of the other causes which I have named as conducing to pericarditis, I have several times seen the disease in cases of pyæmia, from uterine phlebitis and accidents and surgical operations. I have also two or three times known it occur in cases of tuberculosis; and in one instance that occurred at the old hospital, London-bridge, there was fatal pericarditis from the puncture of a needle. It has also been supposed that the pericardium may become the seat of inflammation extending from the pleura or lungs, but of this I do not know that any decided proof can be given. Pleurisy and pleuro-pneumonia are certainly very often met with in cases of rheumatic pericarditis, but I have always regarded them as coincident effects of the common cause; and I do not recollect to have seen pericarditis occur in any case of idiopathic pleurisy, even though, as often happens, the pleura covering the pericardium be affected.

The general symptoms which attend pericarditis are very indecisive. Pain especially is a very uncertain symptom. In a large proportion of cases no complaint is made of pain, though generally, especially when the inflammation is intense, there is a feeling of uneasiness or oppression in the region of the heart, and sometimes decided pain. Occasionally, also, when there is pain in the region of the heart in rheumatic fever, it is not from the existence of pericarditis, but from rheumatism of the intercostal muscles and integuments. Tenderness is an equally uncertain symptom: sometimes by pressure between the cartilages or beneath the false ribs some uneasiness is caused; but in other cases there is nothing of the kind. It has been thought that when pain is felt in pericarditis it is in consequence of co-existing pleurisy; but I do not think that the pain can be ascribed simply to the pleurisy. Pleurisy itself is very often latent, and attended with very little pain or uneasiness. The presence of pericarditis is also not necessarily indicated by the existence of dyspnœa. Often in the early stages the breathing is very little affected, though it generally becomes short and hurried when there is active inflammation or when any considerable amount of effusion has occurred; and not unfrequently under such circumstances it is so urgent as to compel the patient to sit upright in bed. With the commencement of the local affection the pulse is generally quickened, rising to 110 or 120, and with the advance of effusion it may be very rapid and irregular or intermittent. The only symptom which is, however, I believe, invariable, is that the temperature rises considerably with the occurrence of the pericarditic affection. This is often very striking in cases which had previously been of a slight character. Thus the temperature, which was before not more than 100° or 101°, with the occurrence of pericarditis will rise to 102°, or 103°, or 104°, or more. Sometimes also there are symptoms of cerebral disturbance during the progress of the disease—such as delirium, more or less active, choreic symptoms, etc.

The diagnosis of pericarditis can only, however, be effected by the physical signs. The first peculiarity which is observed in a case of rheumatic fever when the pericardium is becoming affected is often a modification of the systolic sound to which I have heard the term "tension-sound" applied, and I do not know that I can give a better name to it. It gives the impression that the muscular contraction of the heart is performed with undue energy. To this a slight rustling sound succeeds in some cases, or, in others, that sound occurs as the first sign. At first the rustle is only very slight, barely detectable, and is heard indistinctly, or is only, perhaps, audible when the patient distends the chest with air, and is so short as only to occupy a small portion of the cardiac action, and is not sufficient to mask the natural sounds of the heart. The rustle is often first heard at the sternum and towards the upper part of the præcordial space; but it increases in intensity, and gradually spreads over the whole region. At length there is a distinct double *bruit de frew-frew*—as it is termed by the French—which entirely masks all other sounds. The first rustle probably only indicates the dryness of the serous membrane; the decided friction, the occurrence of solid exudation. The friction murmurs are characterised by their peculiar superficiality. They give the impression of a sound produced quite at the end of the stethoscope, as if by the rubbing of the instrument upon the skin. They are also heard only in the præcordial space, or at least are equally extended from it in all directions. The characteristic friction-sound is as I have described it—double; but often towards the apex only a single sound, which accompanies the systole, is heard. The period during which these murmurs are heard varies very greatly. Sometimes the sound will never extend beyond the slight rustle, and will rapidly subside: it may be heard at night, and may be quite gone the following morning. In other cases it will be very persistent, continuing three or four days or longer; and I have known it continue for fifteen days.

When, however, the friction is very persistent it is often combined with some old disease and enlargement of the heart, the outpouring of liquid effusion being probably in such cases prevented by the pressure on the surface of the pericardium. In the same way in pleuro-pneumonia the friction-sound often continues for a long time, the effusion of fluid being apparently prevented by the solidified lung being incapable of compression.

When the friction-sound ceases, it may be by disappearance of all the signs of disease, but it is more frequently in consequence of the effusion of serum. The area of dulness is then extended, and especially in the vertical direction. The friction, however, generally ceases gradually, disappearing first below and last at the upper part and right side of the præcordial region. It may also sometimes, if the fluid effused be not in large quantity, be reproduced by making the patient draw a full breath or lean forward; or, in children, by making somewhat firm pressure in the præcordial region with the stethoscope. When the effusion is considerable, the heart's sounds are often much muffled or masked; but sometimes the sounds will be heard quite distinctly and naturally, even though there is a large quantity of fluid in the cavity. When also there is a large amount of effusion, the area of dulness is very greatly extended, rising above to the second or even to the first inter-cartilaginous space. It has also a peculiar pyriform shape, being wider below and narrower at the upper part; and often also there is very obvious prominence in the præcordial region. The duration of this stage is also variable—the rapidity or slowness of the absorption being probably much affected by the greater or less intensity of the inflammation and the larger or smaller proportion of fibrine which is contained in the effused fluid. The fluid may rapidly accumulate, and equally rapidly disappear, so that the whole may pass away in a few days, and the heart may entirely recover its natural condition. Most generally, however, the absorption is more gradual, the dulness diminishes from above downwards, and, as the fluid disappears, the friction-sound returns, being first heard at the upper part and right side of the dull space, and gradually falling to a lower level. The returning friction is, however, usually less general and of a harsher note than that which is first heard, though the term *bruit de frew-frew* still well represents it. At the apex also it is often a single systolic sound. After a time, a distinct creaking or stretching sound sometimes may be heard, the *bruit de cuir neuf* indicating that the effused lymph is becoming organised. Finally, after a longer time, all morbid sounds may disappear, though, when adhesions have formed between the two layers of pericardium, there may be a peculiar jogging or tumbling kind of movement of the heart, and at the apex the integuments may be retracted with the back-stroke. Generally, if not always, also, when there has been decided friction, and that has been of some duration, so that the surfaces of the pericardium become more or less adherent together, the area of dulness remains permanently larger than natural. Often also there is a systolic murmur at the apex still heard as long as the patient remains under treatment, but whether this is exocardial or endocardial is not easily decided. Certainly I have known this murmur go entirely away after a long time has elapsed; and this seems more likely to be the case with an exocardial than an endocardial murmur. The diagnosis of pericarditis is not generally attended with much difficulty. The superficial seat of the sound, its peculiar character, and its limitation to the region of the heart or equal diffusion in all directions from that space, distinguish it from an endocarditic murmur. Sometimes, however, the existence of cardiac friction-sound in cases of pleurisy may be liable to be mistaken for a friction-sound connected with pericarditis; but the pleural sound can only be heard on the left side of the præcordial region, whereas the pericarditic sound, if it be not heard over the whole præcordia, is more likely to be heard on the right side at or about the sternum. The pleuritic friction-sound will also be heard with the respiration, and there will be other obvious signs of pleurisy; and these peculiarities will readily distinguish the two sounds.

The Monkwearmouth and Southwick Dispensary has just been opened under very influential patronage, and is to be governed by an Executive Committee of twenty-five. The following have been appointed the medical officers—viz., Luke Blumer, M.D. St. And., James Smith, L.R.C.P. Edin., William H. Dixon, M.D. Edin., Robert Ayre Smith, M.D. Glasg., and George Bolton, L.R.C.P. Edin. The Rev. James H. Hancock, M.A., is Hon. Secretary.

COMMENTARIES ON DISEASE IN CHILDREN.

By EUSTACE SMITH, M.D. Lond.,

Physician to His Majesty the King of the Belgians,
Physician to the East London Hospital for Children,
Assistant-Physician to the Victoria-park Hospital for Diseases of the Chest

IV.—Pleurisy.

(*Continued from page* 651, *vol.* i., 1873.)

Emma W., aged 5, a delicate-looking child, with small features, fair hair, and a thin transparent skin, had had a cough more or less for two years—ever since a severe attack of pertussis. There was a little dulness at the right supra-spinous fossa, and the breathing there was high-pitched and harsh, with prolonged expiration. She was still under treatment when (on May 30) she had an attack of measles. The disease ran its usual course, but the cough was very severe. On June 7 she began to complain of pain in the right side; she still coughed a great deal, seemed languid, had no appetite, and was very hot at night, perspiring freely. She was seen on June 14 looking pale and weakly, but could walk well (she had, indeed, come on foot to the Hospital), and was not at all prostrated by her illness.

On examination of the chest the front of the right side was found to be completely dull from apex to base, with greatly increased resistance. The dulness did not extend into the axillary region, but ceased laterally rather abruptly at a line drawn downwards from the anterior fold of the armpit. The breathing above and just below the clavicle was bronchial; over the lower two-thirds it was very loud and tubular, without any rhonchus. Over the area of dulness the resonance of the voice and cough was unnaturally strong. At the right back there was no dulness, with the exception of that at the supra-spinous fossa already referred to, but the respiration from apex to base was bronchial, with a fine subcrepitant rhonchus towards the end of inspiration. Temperature in axilla, 99·2°; pulse, 136, unequal; respiration, 50.

On June 21 the subcrepitant rhonchus had disappeared from the back, otherwise the signs remained the same as on the previous visit. The cough was very troublesome, the appetite poor, and she perspired very much at night. Temperature, 99·6°; pulse, 148; respiration, 42.

The child improved but slowly, and it was not until July 31 that any notable change was observed in the physical signs. By this date the child was fatter and looked pretty well, although pale, and she slept well at night, but was sometimes disturbed by her cough. The dulness was now less complete than before at the right front, and below the clavicle was rather tubular. The breathing was cavernous from apex to base, without rhonchus, and the vocal resonance bronchophonic. At the back the supra-spinous fossa alone was dull, and the breathing there cavernous, as in front; lower down the respiration was bronchial, and at the base merely harsh. No rhonchus was heard at the back, and the vocal resonance, except at the apex, was natural.

After this the patient was not seen again for six months. By this time she had become fat, and looked very well. There was a little flattening of the right mammary and infra-mammary regions; the right nipple was a little lower than left; and the spine was slightly curved, with concavity to right. The chest measured at the level of nipple on the right side ten inches and one-eighth, on the left ten inches and a half. There was no dulness anywhere about the right side; the supra-spinous fossa even was quite resonant, and the breathing everywhere healthy. About the right nipple a faint superficial crepitating sound was heard with the latter half of inspiration. This was no doubt pleuritic, and was the only indication left of the foregoing disease. The child was said to cough sometimes in the morning on first rising, but not afterwards in the day.

The treatment throughout consisted of quinine and cod-liver oil.

In this case the limitation of the principal physical signs to the front of the chest furnished a possible source of error, which it required a careful consideration of the general symptoms and of the whole aspect of the case to avoid. Dulness limited to the front on one side, combined with tubular breathing and increased resonance of the voice, suggested the presence of pneumonia, and this view was supported by the hurry of respiration, which on the first visit reached the number of fifty in the minute. The dead, flat

character of the dulness was, however, very different from the incomplete dulness of pneumonia; the resistance to the finger was also greater, and the area of dulness was rather abruptly marginated towards the axilla. The entire absence of rhonchus of any kind from the front of the chest was a phenomenon rarely to be met with in a case of inflammation of the lung, and itself suggested pleurisy. Such a condition is, however, occasionally found where the pneumonic consolidation is very complete, but it rapidly passes away, seldom persisting longer than two or three days. In the present case rhonchus was absent throughout. It is unfortunate that no mention is made in my notes of the presence or absence of vocal fremitus, nor of the position of the heart. These are two important omissions, which deprive us of what might have been of great assistance in the diagnosis.

Besides the physical signs, the general symptoms were very decidedly opposed to the pneumonic view of the case. The child, although pale and delicate-looking, had not the aspect of one seriously ill, and she had been able to walk without assistance to the hospital. This point is of very great importance, and tells very strongly not only against pneumonia, but also directly in favour of pleurisy. That a child with caseous deposit at the apex of one lung, who had but just passed through an attack of measles, and who presented *recent* physical signs such as those described, should be able to walk from her home to the hospital without apparent suffering, could only be possible in a case of pleurisy. Had the disease been pneumonia, consolidation of such extent, especially when succeeding to measles, would have been attended by a degree of prostration sufficient to put such an effort out of the question. Besides this, the temperature of the body was little higher than natural (99·2°), and at night she perspired freely.

There can be little doubt, therefore, that the case was one of circumscribed pleurisy. The subcrepitant rhonchus heard at the back was due to accompanying bronchitis, so common during and after an attack of measles; and the bronchial breathing heard posteriorly was no doubt conducted from the front of the chest. The hurry of respiration must be attributed to the exertion she had just undergone.

The diagnosis was confirmed by the after progress of the case. The long persistence of the physical signs without notable change, and especially without the appearance of rhonchi, was very significant; and the moderate retraction of the side found six months after the attack afforded a final proof that a correct estimate had been formed of the nature of the disease.

The removal of the small consolidation of the right apex is a point to be noted in passing. This was probably of some standing, and may have dated from any time subsequent to the attack of pertussis two years before, during all which time the child had remained pale and thin, with a frequent cough. The deposit, however, was undergoing no active change, and while thus indolent there is always in young subjects the possibility that absorption may take place. Its removal appears to have been complete, for at the last examination no signs were left to indicate that the apex of the lung had ever been the seat of disease.

The limitation of the liquid effusion is in most cases owing to the presence of old adhesions, the previous occurrence of a pleuritic attack having left the adjacent surfaces of the pleuræ adherent to one another in certain spots. In this case, however, there was no history of any previous attack, although such might have occurred and been overlooked.

The mode of termination of pleurisy is the same in the child as it is in the adult. Absorption of the fluid may take place with or without retraction, or the fluid may be purulent, and the case become one of empyema. In children, cases of empyema are very common, for the fluid becomes purulent at an earlier period with them than it does with the adult.

In the following case the fluid, although purulent, was being gradually absorbed, and some retraction of the side had taken place:—

John C., aged 3½ years, was admitted into the East London Children's Hospital on August 29. Has always been weakly and very subject to coughs. Five weeks ago the child was seized with a fit of convulsions. On recovery he complained of pain in the left side, and was very feverish and thirsty. He soon began to cough, and his breathing was very shallow and rapid. He was seen by a medical man, who treated him for "inflammation of the membranes of the brain." Since that time he has been very weak and low, and has been troubled with a frequent cough.

August 31.—Child pale and thin. Ends of long bones enlarged; ends of ribs nodular. Fingers distinctly clubbed; legs very small and thin. Can stand, but is barely able to walk without assistance. Skin not particularly harsh. Spleen much enlarged; liver normal in size. Left shoulder and scapula lower than right; and spine slightly curved, with concavity to left side. Heart's impulse felt at the left side of ensiform cartilage. Left side of chest moves very little with inspiration. There is dulness over the whole of the left half of the chest, both back and front, with greatly increased resistance; in the first and second interspaces the note is rather tubular. The respiration is loud and coarse in left front as far as the nipple, becoming at that point rather tubular in quality. In the left axilla the respiration is blowing, and becomes tubular in the infra-axillary region. At the back the breathing is tubular at the base; higher up it is diffused blowing, and remains so as far as the supra-spinous fossa. No friction or rhonchus can be heard, and the vocal resonance is only slightly increased, not at all ægophonic. Temperature yesterday evening, 100·4°; this morning at 9 a.m., 99·4°. The chest was punctured posteriorly on the left side, about two inches below, and in a line with, the angle of the scapula; and a small quantity of thick purulent fluid was withdrawn with the pneumatic aspirator. The temperature the same evening was 101·6°.

On September 3 five drops of tinct. ferri perchlor. were ordered three times a day, and one ounce of wine was added to the diet, which consisted of milk and bread, with meat and broth on alternate days.

September 10.—Sweats very much about the head and neck; skin of those parts covered with milliaria. The child is fretful when touched, but does not seem in pain; eats heartily; cough short and loose.

Percussion of the left half of the chest gives pretty much the same results as before. At the extreme base, both before, behind, and laterally, the note is tympanitic from transmission of the stomach note; elsewhere the percussion-sound is dull, except just below the clavicle and in the axilla, where it is tubular. The respiration at the back is now only bronchial, without any tubular or blowing quality. It is also bronchial in front, and in the axilla is cavernous. The vocal resonance is everywhere on the left side bronchophonic, and as heard at the angle of the scapula the quality of the voice is rather ægophonic. Temperature, 6 p.m., 100·2°; pulse, 154; respiration, 58. Since August 31 the temperature has seldom been over 99° in the morning; in the evening it has varied from 101° to 102°.

The physical signs remained very stationary from this date until the end of the month, although the heart was gradually drawn back to its natural position.

On October 1 the chest measurement at the level of the nipple was on the right side 9½ inches, on the left 9⅞ inches. Half a teaspoonful of ol. morrhuæ was ordered to be taken three times a day in addition to the iron mixture.

October 9.—Percussion is now natural in front of left side, and the left supra-spinous fossa is resonant. Over the scapular region the percussion-note is tubular, and at the posterior base it is dull. Respiration is bronchial at the base behind; superiorly it is harsh, with prolonged expiration. All over the upper half of left back is a peculiar clicking sound like very small bubbles, not at all superficial. In front the breathing is merely harsh; in the axillary and infra-axillary regions it is slightly bronchial and is accompanied by a faint crepitating friction.

From this date the physical signs became gradually more and more healthy, and on November 5 the least possible dulness remained at the left base behind, but the breathing there and everywhere else was perfectly natural, without friction or any other abnormal sound. The child became quite fat and strong on his legs. The spleen, however, did not diminish in size, but remained very large, reaching as low as the level of the umbilicus.

The history of the attack in this case was very characteristic, and the distortion of the left side of the chest (lowering of the shoulder and scapula, with slight lateral curvature of the spine), inconsiderable though it was, combined with the physical signs, rendered the diagnosis of pleurisy an easy matter. Absorption of the effused fluid was evidently far advanced, but the elevation of temperature seemed to imply that the presence of purulent matter in the pleura was injuriously affecting the system; and it was therefore thought advisable to remove what little there might be left without delay. The after progress of the case, although slow, was satisfactory, and the speedy improvement which followed the administration of cod-liver oil is to be noted. The oil might indeed have been given with advantage at an earlier period. The child was the subject of rickets, and in such cases the influence of this drug in

furthering nutrition and improving the general condition is very striking. The enlargement of the spleen, one of the consequences of the rickety state, did not appear to impede recovery, although the size of the organ remained unaltered. Such cases, indeed, generally do well.

ORIGINAL COMMUNICATIONS.

SLEEPING SICKNESS.

By JOHN W. OGLE, M.D., F.R.C.P.,
Physician to St. George's Hospital.

In a clinical lecture at St. George's Hospital, in which the results of pressure upon contiguous nerves and bloodvessels by tumours, aneurisms, etc., in the neck were alluded to, Dr. Ogle brought before his class the following communication, which in 1869 he had received from Dr. M'Carthy, Staff Assistant-Surgeon, at Accra in West Africa, and which, he observed, bore upon the various views as to the mechanism of sleep which had been entertained. Referring to a paper which appeared in the *Lancet*, March 20 of that year, containing the history of a case of ligature of the carotid artery, Dr. M'Carthy wrote as follows:—

"In a note to your clinical observations on the case you describe, you state that you intend preparing a paper containing the results of arrest of circulation in the vessels from pressure of tumours, etc., as regards cerebral symptoms produced by such conditions; and as the following facts of a very peculiar disease bear more or less on the subject you are about to write on, I send you the particulars, with a hope they may be of some little interest to you.

"The malady I write of is called by the natives of this country the 'sleeping sickness,' from the fact that by day as by night the patient shows an extraordinary tendency to drop off to sleep—in fact, cannot remain awake unless some particular cause keep him from sleep.

"The first case of this disease I happened to meet with was on the Island of Buluma, in 1867, and as those I have since seen and heard of correspond exactly in symptoms, cause, etc., with it, I think the subject not unworthy of your consideration. In the first place, I must tell you that I have seen but one patient suffering from the complaint, and as he refused to have an operation performed on him, and has since gone into 'the bush,' I know no more about that case. All the other cases I have seen were patients on whom the operation had been performed, and I give you the history, treatment, and result entirely from their accounts, and from the stories of many natives of the country to whom I have spoken on the subject.

"In every case of 'sleeping sickness' there is invariably a chronic thickening of the deep cervical glands of the neck—I mean those glands commonly called the 'glandula concatenata,' and which form a chain from the base of the skull to the clavicle. The treatment adopted by the native 'doctors' consists in removing those thickened glands. I have never seen the operation performed, but it is said to be always followed by cure. In one man I counted no less than thirteen cicatrices in the neck.

"The above disease is not uncommon at Buluma and on the banks of the neighbouring great rivers, and was supposed to be nearly confined to those places, but I have seen a few patients who had been operated on near this place—*i.e.*, the Gold Coast. I have spoken to many of the natives of Accra, but they appear never to have seen or heard of the disease; and the few cases I have met with here I found in what are called 'bushmen,' so that probably the disease exists in the interior and not on the coast of this part of the country.

"I am under the impression that the sleeping symptoms are caused by pressure on the vessels leading to the brain, and by consequent diminution of the supply of blood to that organ, causing a tendency to sleep. We know that those deep cervical glands are particularly numerous at the division of the common carotid artery, and the pressure on the internal carotid may account for the symptoms alluded to. How those so-called native 'doctors' extirpate the glands from such a site is more than I can account for. They are perfectly ignorant of anatomy, and yet I have never heard of a fatal case resulting from the operation."

CASE OF FATTY OR CHYLOUS(?) URINE, WITH OBSERVATIONS.

By THOMAS E. AMYOT, F.R.C.S.

The appearance in the *Medical Times and Gazette* of June 21 of Dr. Gopal's paper on the interesting subject of fatty or chylous urine, induces me to offer a few notes on a case which has occurred very lately in my practice, but which I might not otherwise have thought it advisable to publish at present, as I have as yet had but one single opportunity of examining the urine. No second chance, however, seems likely to present itself.

In several important particulars my case appears to resemble that related by Dr. Bramwell in the *Edinburgh Medical Journal* for 1858, but which Dr. Roberts, in his admirable book on "Urinary and Renal Diseases," puts aside as a case of possible imposition, on the ground that the urine did not coagulate spontaneously, nor with the aid of heat or nitric acid, and that it contained visible fat-globules. Now, in my own case the facts are precisely the same; but first, imposition was out of the question, as I saw the urine passed into a clean vessel, and took it away with me—my reason for doing so being that, according to the unasked statement of an intelligent nurse, the child's urine had very frequently been thick directly after passing, both during his present and previous illness. Secondly, the urine did not coagulate spontaneously. Thirdly, heat and nitric acid, both of which I tried before and after filtration, failed to cause coagulation. Fourthly, fat globules were visible in abundance.

Dr. Roberts states that "chylous urine is invariably coagulated by heat and nitric acid,"—and certainly one would suppose that it always must be so if true chyle be present; but Dr. Bence Jones, in the narration of a case in the thirty-sixth volume of the *Medico-Chirurgical Transactions*, notes on four occasions the presence of chyle without albumen, while Dr. Golding Bird speaks of the coagulation in such cases being often prevented by the existence of a "large proportion of fat." The occasional visibility of the fat globules is abundantly attested. I now proceed to give a few particulars of my case.

Master R. W., aged 6 years, a very intelligent child, of spare make and active disposition, had a sharp attack of bronchitis at the latter end of January and the beginning of February last, which pulled him down greatly, but from which he rallied with great rapidity, so as to be quite well and (for him) strong by the beginning of April. On the 9th of that month, however, after some exposure to cold and fatigue, he complained of pain in the left shoulder, chilliness, and great lassitude. I was not sent for till the 14th, when I found him suffering from pain in the left hypochondrium, great weakness, total loss of appetite, and difficult and hurried respiration. He had but little cough, but I was astonished to find the whole left side dull on percussion, a total absence of respiratory murmur over the lower and back parts of the lung, and but little, and that imperfect, in the subclavicular region. There was no râle or rhonchus anywhere. The symptoms arose, I suppose, from pleuritic effusion and pressure on the bronchi, though the intercostal spaces were clear. The tongue was clean and moist, the alvine secretions well coloured, there was no great pyrexia, and no heat of surface till the 20th, when the temperature in the axilla was 104° Fahr., and the pulse 136. He was very restless and impatient of being disturbed, but had still little or no cough, and the pain in the hypochondrium had been relieved by local applications. On inquiring about the urine, which was not preserved, the nurse told me that it was frequently milky-looking when passed, and that it had been so during his illness in January. She had also observed it so that very morning. I therefore got the child to pass about an ounce in my presence, and took it home with me. The following was the result of my examination:—Urine passed at 7.30 p.m.: Turbid and milky, but not throwing down any sediment; no urinous smell; acid reaction; not affected by heat or nitric acid either before or after filtration; not affected by acetic acid, ammonia, or liquor potassæ; not coagulating spontaneously, but yielding abundance of fat on agitation with ether, and showing fat globules in plenty under the microscope. They closely resembled milk globules in size and appearance. Besides these there were also present in the field a multitude of extremely minute and less regularly shaped bodies (which,

by the way, I am not sure I observed until the day after the first examination), well defined with a power of 800 linear, and possessing a power of motion not unlike the steady movements of some of the naviculæ, which they retained, even when mounted and cemented under a cover-glass on a slide, for several days. There were no casts or crystals of any kind. After standing the night the fat rose like a cream to the surface of the urine. I should also add that a drop of the secretion, placed on white paper, left after drying a transparent (greasy) ring at its circumference.

Under small doses of calomel with antimonial powder and continued counter-irritation by liniments, the boy improved. Respiration and resonance being slowly restored, the temperature fell to 99·7° by the 22nd, and the pulse to 120. The fatty condition of the urine has not returned, but urates are occasionally abundant, with a rather large amount of bladder (and kidney ?) epithelium.

At the present date the child is still improving, and is indeed as well and lively as usual. He is taking cod-liver oil and Hooper's pancreatic emulsion with much relish, and apparently with great benefit.

On April 22 Dr. Copeman, of Norwich, saw him with me by my request, as I doubted about perfect recovery, and as the life is a precious one. I ought to add that this paper is drawn up from full notes taken during the illness.

Diss, Norfolk.

ON THE USE OF RESIN-CLOTH, IN THE PLACE OF CERE-CLOTH, IN THE TREATMENT OF WOUNDS.

By EDWARD LUND, F.R.C.S.,
Surgeon to the Manchester Royal Infirmary.

To those who practise the system of dressing wounds advocated by Professor Lister, the use of the carbolised gauze which he employs, as far merely as expense is concerned, is a matter for consideration. This perhaps is the case more in hospital than in private practice, because in the former, at the present time, the gauze is largely used to test the value of the antiseptic method, and economy should be observed as far as possible. Moreover, beyond the cost, there is a difficulty in the preparation of the gauze, for the mixture of paraffin and acid with which the fabric is saturated must be applied to it in a heated liquid state, and, unless a certain temperature be maintained during the whole process, the gauze will be of unequal thickness and imperfectly porous. I have tried to make the gauze myself according to Professor Lister's recipe, but I have often failed to do so in these particulars. In the paper in which he first described this dressing (in the *British Medical Journal* of January 14, 1871, p. 30), Professor Lister refers to a very curious property possessed by carbolic acid—namely, that it can be combined with resin, and resinous matters generally, with great facility, and when so blended nearly all its irritating acrid properties are neutralised, while the compound so formed retains the power of evolving an antiseptic vapour at the temperature of the body. It is well known that to touch the mucous membrane or even the skin of the lips with a fragment of pure carbolic acid occasions pain and excoriation, in some subjects more than in others. But when we experiment in the same way on a mixture of the acid with five parts of resin, we find all the acridity is destroyed; the acid is still present, but it is stored up and rendered harmless by this new combination.

Having verified this fact by numerous observations, I came to the conclusion that we have here a method of forming easily, without the aid of heat, an application for antiseptic purposes, in surgical practice, of great value. All that is required to carry out the idea is to saturate very thin calico gauze with such a mixture of resin and acid dissolved in methylated spirit, press it powerfully, spread it out to dry quickly so that it may become quite porous and absorbent, and it is ready for use. Yet the resin and acid thus left upon the threads of the calico after the complete evaporation of the spirit would be found too brittle and adhesive to the skin for a wound-cover and air-filter if something else were not added to impart flexibility. The substance which I employ for this purpose is castor oil, because it is the only fixed oil easily accessible which is quite miscible with spirits of wine. All samples of castor oil, by reason of adulteration, do not show this property of perfect solubility in alcohol, as stated by Pereira ("Materia Medica and Therapeutics," 1865, p. 251), and therefore I am content to use the oil if it will unite perfectly with twice its bulk of rectified spirit. The exact composition of the solution is as follows:—Carbolic acid crystals, melted, two fluid ounces; castor oil, two fluid ounces; purified resin, sixteen ounces by weight; methylated spirit, forty fluid ounces,—mix.

To dissolve these ingredients easily we must add them together in a certain order. To the resin, liquefied by heat and removed from the fire, add gradually one third part of the spirit; when these are well mixed, put in another third of the spirit, in which the oil has been previously dissolved; and lastly, the acid in the remaining portion of the spirit must be slowly added to complete the mixture. The whole must be agitated until all the constituents are thoroughly incorporated, and afterwards passed through a muslin filter to get rid of any extraneous matters. Unless this plan be adopted, the resin will concrete into a mass at the bottom of the vessel, and it will be extremely difficult afterwards to get it perfectly mixed. When thus prepared, the solution is of a dark colour, clean and free from any deposit, and it can be kept unchanged in a well-corked bottle for a long time. It is, in fact, a sort of thick varnish. To make the resin-cloth—as I term it, for the sake of distinguishing it from the cere-cloth dressing for wounds which I described in a paper read at the Leeds meeting of the British Medical Association in 1869,—it is needful to select a very thin, cheap, porous calico, or calico muslin, known in the trade as "mull," which costs at wholesale price about 4s. per piece of twenty yards. This divided into strips, each about nine inches wide and six yards long, is reduced to a convenient form for general use. The calico should be unbleached and free from stiffening; and each of the strips should be carefully folded up, so as just to lie flatly in the press, as I am about to explain. An ordinary square tincture-press may be used to press the cloth, or such a press as is sold for copying letters, to which a tin box has been adapted, so that the plates of the press can work in it; and in this box the folded calico is placed, the solution being poured over each successive layer so as to wet perfectly every part of it. There should be an aperture at the bottom of the box, with a tap by which the superfluous fluid can be removed, collected, and used a second time. The press being brought into action, the pile of calico should be squeezed as dry as possible, all the fluid drained off, the resin-cloth taken out, laid over a few lines of string in a warm room with good ventilation, and, in an hour or two, when all traces of smell of the methylated spirit have been dissipated, the cloth may be rolled up and kept in tin cases ready for use.

It is difficult for me to state the exact cost of resin-cloth made by this process, for I have not yet bought the materials for its preparation at such wholesale prices as could be paid if it were to be manufactured in large quantities; but, allowing for some slight reduction where six or eight twenty-yard pieces of calico are bought at a time, and the solution made by the gallon, I find it comes to a fraction less than 3d. per yard of average width of forty-four inches. In using it as a dressing for wounds, I deal with it precisely as I would do with Professor Lister's antiseptic gauze, for which it must be taken as a cheap and ready substitute. I generally apply ten folds of it over the face of a wound (as in an amputation), and perhaps six folds higher up the limb for some distance, and I cover it with the mackintosh hat-lining, so as to distribute the serous discharges through the breadth of the resin-cloth thus covered. I have never found it to irritate the skin in any degree beyond what the oil-silk protective, liberally used, could control, except once, when, in the hurry of preparing the resin-cloth, I had neglected to dry it thoroughly, and it was applied still moist with the methylated spirit; the naphtha in it seeming to be the chief cause of the skin irritation. But if this precaution be observed I believe this resin-cloth will be found a very useful addition to our means of treating wounds and abscesses on antiseptic principles.

MULTIPLE BIRTHS IN FRANCE.—According to some recent researches of M. Albert Puech, during a period of eight years (1858-65) there took place 8,292,226 simple births, 83,729 double births, 1005 triple births, and 4 quadruple births. If the map of France be divided into three transverse regions, it is found that twin births are most frequent in the northern of these regions and least frequent in the southern region.—*Lyon Médical*, June 22.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

REMARKS ON THE DOUBLE CONDITION OF LOSS OF CONSCIOUSNESS AND MENTAL AUTOMATISM FOLLOWING CERTAIN EPILEPTIC SEIZURES.

(By Dr. HUGHLINGS-JACKSON.)

REMARKS on Epileptic Mania and other post-epileptic phenomena (the whole of them being included under the general term Mental Automatism) were delivered by Dr. Hughlings-Jackson during a recent charge of the clinical wards *àpropos* of several cases of nervous disease. They are reported with additions. The principle here to be enunciated in some detail has already been sketched in this journal (Nov. 30, 1872, p. 597). It is—that in the cerebral part of the nervous system there are from different degrees of gravity of lesions (1) different degrees of involvement of nervous processes in the order of their speciality, and (2) correspondingly different depths of "reduction in automaticity." The expressions 1 and 2 are complementary; they are different faces of the same thing. So far as cases of different degrees of hemiplegia and of affections of speech show, the principle applies, Dr. Hughlings-Jackson believes, very closely. But it applies also to mental symptoms *par excellence*.

We shall illustrate the principle by a set of comparatively simple phenomena, before we speak of mental symptoms. In the ordinary specimen of Speechlessness there is loss of the most Special form of Language, with conservation of the more General—*i.e.*, loss of speech without loss of emotional manifestations. This is but a single illustration from one very important, but yet subordinate series. Now, let us pass to mental symptoms. When a patient in petit-mal *loses consciousness*—that being the first thing in his seizure—he has *lost the use of the most special of all nervous processes whatsoever. This is the definition of loss of consciousness.* He has undergone a loss in the series which is evolved out of all lower series strictly analogous to that loss illustrated by the case of the speechless man; the speechless man has lost the most special processes of a *subordinate* series—the language series. Putting the above in complementary expressions, the patient after petit-mal "is reduced to a more automatic condition of mind"; the speechless patient is "reduced to a more automatic condition of language."

"Reductions" occur, of course, in all degrees of depth, although for simplicity of illustration we have taken arbitrary degrees. There are no *abrupt* demarcations betwixt special and general processes, or, taking particular cases for illustration, betwixt involvement of intellectual and emotional language (every intellectual process casts a shadow of emotion), or betwixt loss of consciousness and coma.

Different degrees of depth of "reduction" will now be illustrated with regard to mental symptoms. If a patient loses the use of a few or the *most* special of all nervous processes only, he may, the speculation is, simply do odd things afterwards. His reduction in automaticity is to a slight depth; there is but a slight departure from healthy action; he will act dreamily. If the "reduction" be deeper his more animal disposition comes out; he may rave and act furiously. (These active "symptoms" are involuntary exhibitions of *himself*, or of the lower "strata" of himself.) The deepest reduction is beyond those processes which we arbitrarily segregate as mental. There is coma,—the most automatic of all processes of the body *are reached;* there are stertor, alterations of respiration, circulation, &c. From loss of some only of the most special of all processes (from slight limitation even of what may be called the "area" of consciousness) to involvement of the most automatic of all nervous processes there are (following petit-mal or haut-mal) all degrees. In both dreaming and drunkenness the state of things is closely analogous. The deeper the reduction the more does the natural disposition come out. People are said to be more immoral in their dreams: strictly, their immorality is not kept under; they are reduced in automaticity; only their lower processes are active.

As will be inferred, Dr. Hughlings-Jackson does not now believe, as he used to do (see this journal, December 14, 1867, p. 642), that the Mental Automatism of epileptics—epileptic mania, for example—is the result of the discharge of any part of the brain; that is to say, *not the direct result*. The duplex condition is found, he considers, when the discharge is *over*. The Mental Automatism is one of the *indirect* results of the discharge. It is true that in some cases of sudden mania a prior seizure (a fit) is not witnessed. Hence, some say that mania occasionally "replaces" an epileptic fit. (This is the very opposite of the view now being stated.) The patient in epileptic mania is by *some process* suddenly reduced to the double condition. There *is* loss of consciousness, and "under this" mental automatism goes on. The following explanation applies, at any rate, to the mode of production of this double condition in a considerable number of cases:—

As before said, the principle holds good both in "physical" and "mental" symptoms. We begin, then, by an illustration from a convulsion followed by temporary paralysis. Dr. Hughlings-Jackson believes that the double mental condition after a fit of, for example, petit-mal is strictly analogous to the condition of the patient who has epileptic hemiplegia after a severe attack of unilaterally-beginning convulsion. The patient after the convulsion is reduced to a more automatic condition, so far as certain physical processes go; the most special sensori-motor processes of a subordinate series are temporarily put *hors de combat* by a strong discharge; the more automatic processes are conserved;—he is, in short, in a double condition, physically. One element of this double condition is negative, the other positive. The negative element is the paralysis of the most voluntary or special parts of one side of the body (hemiplegia); the positive is the conservation of all movements more automatic. Similarly, in the series of series (those underlying consciousness) the discharge puts the most special of that most special series *hors de combat*, and leaves them so temporarily; it produces temporary loss of consciousness; under this automatic (mental) action goes.(a) The negative symptom, loss of consciousness, is analogous to the epileptic hemiplegia; the positive one, mental automatism, is analogous to the conservation of all movements more automatic than those of the face, arm, and leg.

We must, in recapitulation, bear in mind that there are many varying factors concerned in the production of the Mental Automatism of such cases—1. Depth of reduction (compare degrees of intoxication—*see* "The Anatomy of Drunkenness," Macnish). 2. The kind(b) of person *to whom the reduction comes* (consider the effects of drink on the sentimental, on the quarrelsome, and on the greedy—*see* Macnish especially on this matter). 3. The influence of external circumstances of the patient when he is reduced (consider here the accepted theory of dreams). External objects may give a turn to the patient's mental automatism, or possibly the aura (*e.g.*, of smell, sight, etc.) may do this, or even muscæ volitantes—for they are practically external. 4. Loss—especially, it is probable, sudden

(a) An epileptic discharge—that is to say, a sudden, rapid, and excessive discharge—of a part of the "organ of mind" would *not* rouse even incoherent successions of ideas (not rouse ideas at all) nor produce even caricatures of normal action; it would, if strong enough, produce that clotted mass of movement which we call spasm; it would develope strongly and in vast numbers those movements which are the anatomical substrata of ideas; it would produce, also, what, for want of a fit word, must be inaccurately expressed as volumes of "sensation."

(b) It is under this head that hereditariness may most methodically be spoken of. Dr. Hughlings-Jackson does not believe that nervous *diseases* (as epilepsy, chorea, etc.) are hereditary, nor that they "replace" one another, any more than that hemiplegia or apoplexy is hereditary. He takes the very different view—(1) that there is inherited a tendency to certain tissue-changes. Under this tendency there may occur a pseudo-transmission of symptoms or diseases (*e.g.*, hemiplegia from cerebral hæmorrhage occuring with bad arteries, Bright's disease, etc.). (2) That (this applies especially to the so-called inheritance of insanity) a small brain (not merely physically but functionally small) is inherited—a brain easily "reduced." This fails easily under very numerous circumstances of strain (mental or physical), and in diseases as epilepsy, chorea, etc. (compare failure of vision in those who inherit a functionally imperfect eye—hypermetropes). The *facts* of "transmission of disease" are not denied, but a very different *interpretation* of them is suggested. There is now attending the out-patient room a boy who is manifestly the subject of congenital syphilis, and whose mind has failed several months. One sign of mental failure has been a magpie-like hiding of tools. It would be, Dr. Hughlings-Jackson thinks, unmethodical to call this lad's mental condition "Syphilitic Insanity"—obviously grotesque if, going into details, we should say that hiding his fellow-workmen's tools was a syphilitic symptom. The boy's father died insane in Colney Hatch. This boy has received as his father's share in his development not only a syphilitic taint, but a nervous system the higher division of which is easily "reduced." It *so happens* that the reducing agent has been in all probability syphilitic disease. The inheritance was not of insanity, but of a brain ready to fail on comparatively slight provocation of any kind: one probably easily upset by drink or excitement (easily excited, rather). No doubt anything which involved even slight damage to the cerebrum would in such a brain have "caused" insanity—from so-called "alteration" of disposition up to insanity as the term is commonly used.

—or special processes leads to increased action of those processes just more automatic. After section of the spinal cord, reflex action is increased. Of this Bernard says ("Leçons de Pathologie Experimentale," 1872, p. 205)—I draw especial attention to the words I have italicised:—

"Nous trouvons, dans ce phénomène, un fait pathologique qui mérité d'être sérieusement étudié, *d'autant plus qu'il est applicable au système nerveux dans toute son étendue.* Tout nerf séparé du centre dont il émane acquiert des propriétés spéciales, qui ne diffèrent cependant de celles dont il jouit à l'état normal que par un excès d'intensité."

These several factors are, however, to be considered most especially in the investigation of cases of insanity, commonly so called. It is, indeed, as an instrument of investigation of mental diseases that the principle illustrated throughout these remarks is likely, Dr. Hughlings-Jackson believes, to be of most medical service. If the method is really correct, it will be a means both of investigation and of classification—classification as distinguished from mere arrangement. It will thus, he trusts, help to bridge over the chasm in our studies of the "mental" and "physical" diseases of the nervous system. There is no loss of consciousness in cases of insanity as the two terms are commonly used; but there is a limitation of the area of consciousness ("loss of judgment"). (Loss of consciousness is not coma; very few mental processes are excited at any one time.)

Many illustrations of the law above illustrated could be given. Very careful analysis is required before we can decide whether the principle does or does not apply to certain symptoms. Dr. Hughlings-Jackson believes it will be found to apply to the order of symptoms of locomotor ataxy; he believes this is really a paralysis as much as the so-called ataxy of articulation is. There is, he supposes, loss of the most special movements of the legs in walking. Of course there is here the prior difficulty of finding what the most special ("delicate," balancing) movements of walking are. One of these is probably that in which the peroneus longus is especially concerned. This muscle is concerned in giving the last impulse to propel the body forward over the other foot. (See Humphry, "Hand and Foot," p. 93.)

It will have been observed that the cerebellar series has not been spoken of in the above remarks. Probably the order of representation is not the same in this part of the encephalon as it is in the cerebrum. Dr. Hughlings-Jackson believes it to be just the opposite order, so far as the large movements go. The so-called disorder of co-ordination in disease of the cerebellum—the reeling gait—is, Dr. Hughlings-Jackson believes a veritable palsy first of the muscles of the spine; it is chiefly on account of this palsy above that the legs underneath act erratically. Again, in these two disorders of locomotion (locomotor ataxy and the cerebellar reel) there are doubtless *secondary effects* of the palsy—viz., (1) *over-action of associated non-paralysed parts* (analogous to the secondary deviation in ocular palsies), (2) *erroneous "projection"* (analogous to apparent displacement of objects in ocular palsies). These secondary effects hide the essential state of things, and render methodical investigation and classification difficult. The term "disorder of co-ordination" is, indeed, used very vaguely; it is sometimes even used as if there were a "faculty" of co-ordination. Chorea and the reeling gait of cerebellar disease are often spoken of as if they were fundamentally alike. They are utterly different things—different not only in being results of affections of different parts of the cerebro-nervous system, but in that the former is the result of *discharge* of nerve-tissue, and the latter of *loss of function* of nerve-tissue—one is a hyperkinesis, the other an akinesis (or result of one).

GUY'S HOSPITAL.

STRANGULATED UMBILICAL HERNIA—HERNIOTOMY—INTESTINES NOT EXPOSED—RECOVERY.

(Under the care of Mr. BRYANT.)
[Reported by Mr. BINGHAM.]

ELIZA B., aged 47, a married woman, the mother of seven children, was admitted into Guy's, under Mr. Bryant's care, on August 3, 1871, with a strangulated umbilical hernia. She had been ruptured for seven years, and had never worn a truss. A portion of the contents of the sac was always down. Three days before admission the tumour became larger, and vomiting appeared. One day before, taxis had been repeatedly applied with violence without effect.

Under chloroform Mr. Bryant employed the taxis, but with no good result. He then operated, opening the sac only at the upper border of its neck to allow of the introduction of the hernia director. He then divided the neck, and reduced the hernia, or rather the part that had redescended. The intestine was neither seen nor felt.

Pain left her after the operation, but some vomiting continued. The wound rapidly united, and the woman left the Hospital well a month after admission.

STRANGULATED SCROTAL HERNIA—HERNIOTOMY—FÆCAL ABSCESS AND FISTULA—RECOVERY.

(Under the care of Mr. BRYANT.)

George M., aged 46, a brickmaker, came into Guy's under Mr. Bryant's care on February 22, 1864, with strangulated right scrotal hernia. He had been ruptured for twenty years, and had worn a truss. He had been vomiting, and had had local pain for thirty-six hours.

When admitted the right side of the scrotum was much enlarged; it was red and œdematous. Forcible taxis had been previously applied to it for two hours.

Chloroform was given, and herniotomy performed. The sac having been opened, the intestine was found to be black from effused blood; omentum was also contained in the sac, and was of the same appearance. The intestine was returned into the abdominal cavity, and omentum ligatured and cut off. Opium was freely given, both by the mouth and anus. Much relief followed the operation, vomiting disappearing, and good sleep following.

On the 25th, or second day, however, vomiting reappeared, a brown fluid being brought up. Pulse 100; abdomen tender; bowels have not yet acted. Ordered brandy ℥vj.

On the 29th (sixth day) the bowels acted, and the vomiting became less. There was still, however, much fulness about the neck of the sac. The sac itself was contracting naturally.

On March 10 diarrhœa appeared, the wound at this time healing rapidly.

23rd.—Wound had nearly closed.

30th.—Pain reappeared in the right side of the abdomen, above the neck of the hernial sac (that is, thirty-seven days after the operation); some thickening was felt in this region, and constitutional disturbance. The bowels at this time were acting regularly.

The local swelling gradually increased, and an abscess formed above the seat of wound, and on April 29 it burst, discharging fetid air and pus. On the 30th fæces escaped through the wound made by the abscess and the operation.

Great relief followed the discharge of the abscess, all local pain disappearing on May 22. Three weeks later both wounds were closing. The discharge of fæces ceased. By May 30 the wounds had both nearly healed. On June 25 the man left the Hospital cured.

ST. MARY'S HOSPITAL.

ENTERIC FEVER ASSOCIATED WITH APHASIA.

(Under the care of Dr. C. HANDFIELD JONES.)

L. R. S., AGED 14, admitted April 5, 1873. Ill two or three weeks with violent cold and loss of appetite; has had diarrhœa. Is very weak; has some cough. Temperature on admission 103°, though hands and feet were cold; some time later 103·4°. Pulse very weak, 110. Several typhoid spots on abdomen. Tongue dry in median stripe. Very marked malar flush on right cheek. Abdomen not at all distended. Spoon diet;—beef-tea, milk, egg. Ammon. carb. gr. iij., tinct. cinchon. ℥j., dec. cinchon. ℥j., quaten die.

April 6.—Temperature 104·6°; pulse 108. Much diarrhœa about noon, quieted by opiate enema. During the eleven succeeding days there was nothing remarkable observed; his temperature varied from 103·8° to 100°—the difference depending partly, it may be, on the observations being made at different times of the day. His pulse was mostly about 108. Some slight delirium occurred, and some diarrhœa. Brandy ℥ij., was given on the 8th, and increased to ℥iv. on the 14th, when also nitric acid was substituted for the bark and ammonia. The urine at this date contained no albumen, but plenty of chlorides, and gave a notable precipitate with tinct. gallarum.

On the 17th his temperature was 102·2°, his pulse 108; his tongue was cleaning; the bowels were open, but there was no

diarrhœa. The second pulmonary sound was noted to be very loud—much louder than the aortic. The resonance in the fronts and backs was pretty good, but the breathing weak, with much obstructive mucous râle in both backs. The nurse now informed me that he had not spoken for more than a week; he made signs, and sounds like "ah," but could not utter a word.

18th.—Was noisy last night, calling out repeatedly for his father and mother. Cannot or will not speak to-day; when I ask him to show me where he has pain he puts his hand to his forehead. He puts out his tongue when asked; it is cleaning and moist. Temperature 99·7°; pulse 96.

21st.—Continues speechless, but conscious. Temperature 98·6°; pulse 90.

On the night of the 19th called out "Father" and "Mother."

22nd.—Pulse 84; temperature 97·8°. Pupils of medium size; contract well in light. No paralysis of limbs.

28th.—Urine palish, alkaline, with whity sediment of acicular phosphates; pulse more distinct. Begins to utter more articulate sounds, but his vocalisation is still very imperfect. A red patchy and papular rash has appeared on the sacral region.

29th.—Can speak much more intelligibly to-day; has a lichenous rash and patches of erythema all about him.

May 1.—Can talk well now. The eruption has increased, and is very extensive; it is most marked on the dorsum of the feet, where it somewhat resembles that of measles. A bed-sore is forming on right trochanter.

5th.—Is going on well. The eruption has disappeared

12th.—Is quite convalescent, but cannot stand yet.

He left the Hospital early in June.

Clinical Remarks.—So much "talkee-talkee" has been made about aphasia, that one is almost disposed to think that for the present the less is said about it the better. Cases as facts are, however, always of some value, and so I have related the history with the bare remark that, like other instances of the same following fever, the disorder seems to be generally, if not always, a *functional paralysis*, and so deserves to be carefully distinguished from that depending on manifest lesion of the brain-tissue or embolism, which, as a rule, is permanent and incurable. This, after all, is the most practically important thing to be said about aphasia. Trousseau's chapter on the subject occupies fifty-four pages, of which nine lines are given to treatment. The functional character of the paralysis is further evidenced by the circumstance that the patient could utter some words, and, as it would seem, pertinently, when delirious—*i.e.*, when his brain-cells were unusually, though morbidly stimulated.

Académie des Sciences.—At the meeting on July 7 the three vacancies among the corresponding members of the section of Zoology were filled up by the election of Drs. Steenstrup, Dana, and W. B. Carpenter.

The German Association of Naturalists and Physicians.—The forty-sixth meeting of this scientific body will be held this year at Wiesbaden, from September 18 to 24. Communications are to be addressed to Drs. Fresenius and Haas Senior.

Naval Medical Supplemental Fund.—At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on the 8th inst. (Sir Edward Hilditch, Inspector-General, in the chair), the sum of £94 was distributed among the various claimants.

Tetanus in Children.—In the *Gazette des Hôpitaux*, Nos. 46 and 47, M. Bouchut relates an interesting case of idiopathic tetanus occurring in a child twelve years of age. So rare is the disease in France that M. Bouchut, during his large and long practice, has only met with four cases of its occurrence in children as distinguished from young infants. One remarkable fact is that the temperature constantly oscillated between 38·1° and 38·9°, while, as is well known from the observations of Wunderlich and others, tetanus is the disease in which abnormal temperature usually reaches its highest limits, rising to 42°, 43°, or even 44°. In this case it had not reached beyond 38·3° twelve hours prior to death, but mounted up to 40·3° after death. With respect to the use of chloral in tetanus, he observes that the evidence is too contradictory at present to allow of any conclusion being drawn, and that most of the cases in which it has succeeded have been examples of the subacute and chronic forms.

SATURDAY, JULY 19, 1873.

MEDICAL ACT AMENDMENT (UNIVERSITY OF LONDON) BILL.

It may be remembered that in April last we announced the intention of the supporters of the Conjoint Examination Scheme to entrust Sir John Lubbock with the task of conducting a Bill through the House of Commons to enable the University of London, the Apothecaries' Society, and all other of the examining bodies which might require such aid, to join in the Conjoint Examination movement, all existing charters and Acts of Parliament notwithstanding. We said at that time that the Bill could not be passed without the aid of Government; and it was soon made evident that the Government aid was not to be obtained under a certain price, and that price was the submission of the plans and details of examination and of the scale of fees to be paid by candidates to the control of the Privy Council, or at least of some Governmental or Parliamentary power. A moment's consideration will show that, in asking this, the Government acted on intelligible principles. At present a man can be registered as a medical practitioner in England with a diploma which costs £6, and the diploma in question is known to be a guarantee of no small amount of medical knowledge. The proposed scheme would close all avenues to the profession in England except one, and the entrance-fee to that must necessarily be a considerable one. It was not to be expected that a Government having a due regard to the medical service of the country would sanction the formation of a monopoly of medical examination and licence without at least stipulating that it or Parliament should have some control over both the character of examinations and the fees demanded. From the Governmental standpoint such a demand seems perfectly reasonable. On the other hand, it cannot be denied that such Governmental supervision would be an interference with the internal constitution of the medical profession such as that profession has never heretofore permitted, and on that account the proposal of the Government has met with no favour from many who were, nevertheless, most anxious that an enabling Bill should be obtained. As neither party would

give way, this state of affairs has led to the abandonment of the original proposal, and instead of an enabling Bill, which would have opened the way for the union of all the examining bodies, we are presented with a compromise—a dwarfed and almost useless measure—which during the past week has been hastily smuggled through the House of Commons. The Bill only refers to the University of London, and leaves the other bodies in the same legal position as heretofore. It gives the University the necessary powers to join other bodies in forming a conjoint examination, but subjects the scheme to the sanction, not of the Privy Council, but of one of her Majesty's principal Secretaries of State; that Minister having already, according to the existing charter of the University, the right of approving or disapproving its regulations for examination. Our readers will find the Bill reprinted in another column; at the time of our writing it has passed through Committee in the Lower House.

We regret that we cannot see in this measure, which bears the names of Sir John Lubbock, the Chancellor of the Exchequer, Sir Philip Egerton, and Mr. R. Fowler, any substantial benefit. It cannot for one moment be supposed that the examinations of the University of London will be improved by it; neither does it seem to us a measure calculated to help forward the scheme of uniformity of examinations even in England. The establishment of a Conjoint Board, including the two Royal Colleges and all the universities with a high fee on the one side, and its competition with the Apothecaries' Society, demanding a much lower fee, and the Scottish bodies on the other, is not, we think, a desirable prospect. The distinctions between medical men possessing the different diplomas will be productive of infinite harm, and it may reasonably be expected that the English medical educational institutions will suffer, whilst the Scottish will gain. If a Conjoint Board in each division of the kingdom can be established, by all means let it be done. But these piecemeal attempts at legislation are only calculated to increase existing evils. They will divide the profession more distinctly than it has been hitherto divided, and draw more clearly the lines of demarcation between professional classes. Behind all there is the certainty of prolonged litigation, should the Royal College of Surgeons persist in its determination to refuse to examine Licentiates of the Society of Apothecaries independently for its Membership.

THE ASHANTEE WAR.

The intelligence which has reached us from the West Coast of Africa by the last mails is not of a reassuring character—indeed, if officially confirmed, it would seem more nearly to approach the disastrous. The total loss of the mail-packet *Nigritia* is announced, having on board war *matériel*, provisions, and medical stores, shipped under great pressure in this country for the force appointed to oppose the Ashantees. These stores, if saved (as the Government statement in the House of Commons on Monday would lead us to believe), will be long delayed in reaching their destination, and must moreover have suffered considerably by immersion and hasty removal. The mail-packet appears to have steamed full on to a dangerous reef of rocks one hour and a half after leaving Sierra Leone, and only a quarter of an hour after the pilot had left her. The existence of this reef would seem to be perfectly well known, and the occurrence (so far as the particulars have reached us) appears to be totally inexplicable. The same account further chronicles the loss of a second and preceding mail-packet, the *Yoruba*, which is stated to have had on board the stores of all descriptions intended for Cape Coast Castle which had been previously despatched from England. If this latter circumstance be true, the importance attaching to the news can scarcely be over-rated; but, as the stores in question were not sent off from Liverpool in the *Yoruba*—unless they were transhipped into that vessel from the mail-packet in which they left this country,—the report cannot refer to the supplies prepared and despatched in the mail-packet which left the Mersey on May 24 last.

No lives appear to have been lost by the stranding of the *Nigritia*; and as Deputy Surgeon-General Home, V.C., C.B., is reported to have been on board the vessel at the time, on his way to the seat of war, there is every reason to hope that the earliest information to facilitate the replacement of the medical stores thus lost will be forwarded to the authorities at home, who will doubtless take instant steps in the matter.

The guns and ammunition lost or rendered useless are not in our eyes of so much importance as the medical stores: these latter will, if the accounts now sent home are to be relied on, prove of the utmost importance. The town of Cape Coast is said to be inundated with Fantee fugitives, over 30,000 people having sought refuge there. Great distress is reported to exist amongst them from the scarcity of food and water. The rains are unusually late, being nearly three weeks behindhand. The only drinking-water safe to use on the Coast is the rain-water, which is stored in large tanks; these have now run so low that only a few inches remain for consumption, while the water procured from the wells has a reputation for producing dysentery, the most deadly of all diseases on the Gold Coast and to Europeans. The sanitary condition of the place is described as dreadful, from the sudden and unexpected influx of such a large number of strangers, and, in addition to much sickness, there were, when the report left, over 140 cases of small-pox in the Civil Hospital, with dysentery of a very malignant type showing itself.

This latter news alone would show the absolute necessity of replacing with the utmost rapidity any medical stores which may have been lost, as the reinforcements which must by this time have reached the Coast will be plunged into a hot-bed of disease; and it is of vital importance that nothing for the treatment of sickness should be wanting with a batch of unacclimatised troops suddenly subjected to malarious and other pernicious influences.

It is no secret that the Ashantees now hold the entire country right up to Elmina and Cape Coast, and have recently burnt a village about a mile from Cape Coast Castle itself. They have again defeated the Fantees in a battle which is said to have lasted two whole days, and up to the present time would seem to have carried on their incursion almost without a check. It is sincerely to be hoped that the Government has not under-estimated the extent of their resources, and that the reinforcements ordered to the scene of action are sufficient to establish our *prestige* on the Coast by administering a severe lesson to these daring savages. The Administrator of the Government on the Coast is spoken of as a person possessing great skill and experience, but his position in this emergency must be a difficult one, and the most sanguine believers in his resources are said to be looking for the assistance which is to be sent with the most anxious anticipation. We shall ourselves be glad to hear to what extent the medical requirements prepared for the war have suffered, although we have no doubt that the head of the Medical Department will lose no time in meeting the unexpected emergency which has so unfortunately occurred.

Since writing the above, intelligence has arrived of the bombardment of Elmina and an engagement between the British forces and the Ashantees on June 13, in which the latter were repulsed with a loss of 300 men killed and many hundreds wounded, and when the mail-packet left the Coast on the 23rd ult. the arrival of the *Himalaya* with the West India Regiment on board was eagerly anticipated. Deserters from the Ashantee camp aver that Cape Coast Castle itself was to be assaulted on the 28th ult., 30,000 blacks being encamped in close proximity. The *Himalaya* was not even

due until the 5th inst. It is in no alarmist spirit, therefore, that we ask, What news will the next mail bring us? The small handful of seamen and marines have potent weapons, and will fight as Englishmen always do fight, but the odds are fearful to contemplate, and, should any disaster occur, the indignation will be loud and general at the mismanagement which will have permitted a catastrophe to happen, involving at one and the same time a reckless expenditure of human life and a humiliating reverse to the British flag.

THE PHYSIOLOGY OF THE SECRETION OF BILE.

A VERY extensive series of investigations upon the physiology of the secretion of bile has recently been conducted by Dr. Röhrig, of Kreuznach, in the Pathological Institute at Vienna. Our knowledge of this subject has been hitherto very limited, and probably inaccurate, and had reference rather to the functions of bile, and especially to its digestive properties, than to its secretion and the influence of the blood and nervous system upon it. Whatever may be the use of the bile in the alimentary tract, practical therapeutists are generally agreed that the liver can be "unloaded," and the amount of bile secreted artificially increased, and that there are certain drugs which so far possess this power as to deserve the name of cholagogues. Röhrig's investigations were made solely upon the discharge of bile,—in respect of the amount of the secretion in narcotised animals; the effect upon it of alterations in the vascular supply within the liver; irritation of the different parts of the alimentary tract; the presence of fluid in the intestines; the administration of certain drugs, especially purgatives; as well as the influence of various conditions of the nervous system. The results obtained by Röhrig, after experiments upon hundreds of animals, are detailed in Stricker's *Jahrbuch*, 1873, part ii. We will here notice the most important of them.

The mode of experimenting was simple:—A dog or rabbit was narcotised with curare, and an incision made in the abdominal wall from the ensiform cartilage to near the umbilicus; the under surface of the liver was then brought to the opening by the hand, and a glass tube with a pointed vertical arm tied into the bile-duct, while the cystic duct was mechanically closed. The bile as secreted escaped drop by drop from the capillary end of the tube, and the rate of secretion was estimated by the number of drops per minute. It was first determined that after the operation, and under circumstances otherwise normal, the flow of bile steadily diminishes.

There could be little doubt *à priori* that the secretion would be affected in amount by alteration of the blood-supply to the liver, and such was found to be the case. Compression of the trunk of the vena portæ markedly diminished the secretion, but did not completely suppress it; obstruction of the hepatic artery alone diminished the rate of flow slightly; while complete arrest of the hepatic circulation by ligature of both these vessels was followed by entire cessation of the biliary secretion and speedy death. Diminution of the rate of flow was likewise the result of ligature of the ascending cava near the heart, and of ligature of the aorta above the diaphragm; while ligature of the latter vessel below the cœliac axis caused a slight increase in the amount of bile discharged. These last two results are very significant when studied together. Since ligature of the ascending cava in the thorax, and of the aorta below the origin of the hepatic artery have an exactly opposite effect upon the amount of bile secreted, and an exactly similar effect upon the hepatic capillaries,—namely, a rise of the pressure within them,—it follows that the amount of bile does not depend alone on the height of the blood-pressure in the liver. The influence of the amount of blood upon the secretion is further seen after section of the splanchnics and after section of the cervical portion of the spinal cord—both operations being followed by increased flow of bile. On the contrary, irritation of the cervical cord (reflexly through a sensory nerve) diminishes the flow. No noteworthy effect was observed by Röhrig of irritation or section of the vagi sympathici. Anæmia induced by phlebotomy and injection of warm water into the circulation reduced the secretion in amount until it finally ceased.

More interesting to the practical physician are the results observed by Röhrig of the introduction of different substances into the alimentary canal. Chyme injected into the gut markedly increased the amount of discharge—a result exactly in agreement with those of former experiments on the condition of the liver during digestion. Similar injections of tepid water and bile caused a temporary increase of the discharge. The most striking results were obtained after the administration of several of the so-called purgatives, and are worthy of our careful attention, even should the action of the various drugs be different in man. The substances employed were croton oil, colocynth, jalap, aloes, rhubarb, senna, sulphate of magnesia, calomel, and castor oil; and the cholagogic power of these was found to diminish very much in the order in which they have been enumerated. Croton oil decidedly induced the most abundant flow of bile; castor oil had the least action of all. In all the cases the increased biliary flow was preceded by hyperæmia of the intestine, and followed—never preceded—by diarrhœa. Röhrig concludes that "these substances undoubtedly excite the production of bile." Less is said of the effects of mercury upon the secretion than might have been desired. It was found that large doses of calomel (twenty grains for a dog) are seldom able to excite the flow of bile if it is quite stopped previously; but if the secretion is simply diminished it may be increased by the administration of the drug. The greatest action was observed about three hours after administration; it then speedily ceases. There is almost no doubt that the effect of purgatives upon the liver is not to be referred to their immediate action upon the intestine, but to their absorption into the circulation. This is almost proved by two experiments of Röhrig. On the one hand, he found that irritation of any portion of the alimentary canal from the mouth to the anus (including the duodenum), or of the peritoneum, either by mechanical, electrical, or chemical stimuli, had apparently no certain effect upon the secretion of bile. Even when the electrodes were sunk deeply into the substance of the liver no effect of galvanism was observed. On the other hand, the injection of infusions of senna and rhubarb into the veins immediately and greatly increased the amount of bile secreted.

A more difficult investigation was that of the effect upon the secretion of bile of interference with respiration, and the results obtained were somewhat variable. In many instances there was at first a decided diminution of the quantity of bile, and this was found to correspond with a fall of the general blood-pressure, and was believed to be probably due to it. These phenomena were soon replaced by an increase of the quantity of bile secreted and diminution of the blood-pressure, to which it is probably to be referred. And, finally, there supervened a decline of the discharge and a venous condition of the blood in the body, which also probably stand to each other in the relation of effect and cause.

Röhrig investigated the action of four other drugs upon the liver as far as it is a bile-secreting gland—namely, strychnia, acetate of lead, carbonate of soda, and opium. Strychnia was found to diminish the secretion—a result which was to be expected in view of the last-mentioned experiment, for strychnia is known to raise the blood-pressure. Acetate of lead was tried on account of its recognised action on the blood-vessels; when injected either into the intestine or into the

veins it diminished the secretion. A similar result was observed after the administration of a solution of carbonate of soda in the same way. Opium increases the secretion of bile; it would appear, therefore, that opium constipates not by arresting the alimentary secretions, but by its action upon the muscular coat of the intestines. Finally, the experimenter confirms Schmulewitsch's observation—that defibrinated blood injected into the portal vein immediately after the complete separation of the liver from the body, causes the secretion of some drops of bile, while a similar injection of salt solution has no effect. The conclusions at which Röhrig arrived are thus briefly stated by himself:—"From all the experiments which I have described it appears to result that the quantity of fluid which escapes from the biliary vessels of curarised dogs and rabbits is dependent on (1) the vascularity of the abdominal viscera, and (2) the quality of the blood."

THE WEEK.

TOPICS OF THE DAY.

After the opposition which his Public Health Bill has met in Committee, it is not a matter of surprise that it should have been withdrawn by Sir Charles Adderley on Friday last week. The real cause of the opposition has no doubt been a fear that it would lead to an increase of local taxation, although, in the opinion of the promoters of the measure, it would have had the effect of diminishing the rates. Mr. Peel attributed the opposition to the Bill to the new powers it would have conferred on the medical officers of health. We have often remarked that sanitary reform requires the stimulus of panic. Of such objections we should have heard less had the cholera broken out in a few of our filthy villages and manufacturing towns. However, little or nothing more in the direction of legislation for health can now be accomplished until the opening of next session, when Sir Charles Adderley will reintroduce the Bill, excepting Clause 8; and he indulges the hope that the consolidation of the existing sanitary laws will be effected in the same year.

The despatches from Lieutenant-Colonel Festing and Captain Fremantle, giving an account of the bombardment of Elmina and the action with the Ashantees, which were published in Tuesday's *Gazette*, record the distinguished conduct of the medical officers serving with the marines and sailors. Lieutenant-Colonel Festing writes—"Surgeon-Major Rowe, who acted in more capacities than those of his own profession, rendered valuable assistance on all occasions. Surgeon M'Dermott, R.N., was most indefatigable in giving help to those in need." Captain Fremantle says—"I had appointed Dr. Francis H. Moore, Staff Surgeon Second Class of this ship, to be in medical charge of the expedition, and his suggestions to me proved most valuable, while, although technically a non-combatant, he did not shrink from being well to the front and under fire, ready to attend to those who were wounded." Certainly if ever promotion was fairly earned it is earned by such services on the West Coast of Africa. With regard to the health of the marines and sailors, Captain Fremantle writes—"Every precaution that could suggest itself to Dr. Moore or myself was taken to preserve the health of the men engaged. They had quinine served out going and returning; and the sick-list of the squadron has not been increased in consequence of the expedition."

Our correspondent at Wimbledon writes—"This has been hitherto the healthiest meeting of all. The hospital has been empty for some days."

THE SANITARY STATE OF WAKEFIELD.

"The hour has now arrived (says the *Wakefield and West Riding Herald* of the 12th inst.) when we must open our eyes to the 'incontrovertible logic of facts,' and emphatically demand that the attention of the officers of our Local Board of Health be directed to a matter of the most vital importance to us in a sanitary point of view. Complaints have reached us from various quarters of the borough relative to nuisances existing by reason of large fever-engendering accumulations; and to our own knowledge this is but one of many similar instances which might be given. No less than three persons have been prostrated by fever owing to the unsanitary condition of the adjacent middens, ashpits, and pigstyes. Two months since the inspector complained, and threatened to take action; but day after day and week after week has since brought larger accumulations, with viler odours than ever; and the question is very pertinently asked, 'Where has he been and what doing during the interval?' There are scores of such plague-spots in the borough; therefore we urge the powers that be to immediate precautionary measures."

TESTIMONIAL TO SIR WILLIAM FERGUSSON, BART.

We are sure that the following circular now being sent to the numerous friends and admirers of this distinguished and most popular surgeon will receive the response it unquestionably deserves. The portrait will be presented to the Royal College of Surgeons:—

"It has been proposed by numerous friends and admirers of Sir William Fergusson to open a subscription-list, with the view of having his portrait painted by an artist of eminence. The portrait will, with Sir William's sanction, be offered to the Council of the Royal College of Surgeons, in the hope that it may be retained in that institution as a permanent record of one whose valuable contributions to surgical science and whose social character render him peculiarly worthy of so distinguished an honour. Subscriptions will be received by Surgeon-Major Logie, of the Royal Horse Guards, Regent's-park Barracks, and Charles Moss, Esq., of 6, New Cavendish-street."

DIFFERENCES IN MEDICAL OPINION AND THEIR RESULTS.

A serious mortality having occurred from an outbreak of measles, which appeared in May last among the pauper children at the Workhouse at Walton-on-the-Hill, Derbyshire, the guardians determined that an investigation should be held for the purpose, if possible, of ascertaining the cause. The following evidence was given before the visiting committee of inquiry into the subject, and offers an instance of the awkward position in which medical practitioners are sometimes placed. We are unacquainted with the reasons which led Dr. Macrae to adopt his line of conduct; but it seems to us a matter of regret that any apparent difference of opinion between himself and his colleague was not avoided.

"Dr. Hughes was the only medical witness examined, it being stated that Dr. Macrae, although asked to attend, had refused to do so unless he was paid two guineas, which was declined. Dr. Hughes explained the mode of treatment he had adopted, which was to direct the children to be kept warm, with, however, thorough ventilation in the ward; and he insisted upon the use of cold water as a beverage for the children. Being asked by the Committee whether this method was approved and pursued by his deputy, he said he had every reason to believe that it was, because he did not find that Dr. Macrae had made any alteration on the 'page' of any of the patients. It was ascertained, however, from the nurse who had charge of the ward, and from several of the mothers who were in attendance on their own children, that, although Dr. Macrae did not absolutely change the mode of treatment adopted by Dr. Hughes, he had been heard to state that he would not prescribe cold drinks for the children. The mothers of the children in the ward had a great objection to the use of cold water, and they admitted that they did not follow that part of the instructions given by Dr. Hughes. As to the ventilation of the ward, the statements of the nurses showed that the windows were sometimes ordered to be closed by Dr. Macrae, and that Dr. Hughes generally directed them to be opened; so that the treatment of one came to be spoken of as

'cold' and the other as 'warm.' The Committee recorded their opinion as follows:—'That, after a most careful inquiry into the prevalence of measles, and the deaths arising therefrom, at the Walton Workhouse, Dr. Hughes, Mr. Goode, and several of the nurses having been examined in reference thereto, the Committee have come to the conclusion that the treatment as prescribed by Dr. Hughes was, in his opinion, the best under the circumstances; that Dr. Hughes be requested to nominate another duly qualified medical practitioner in the stead of Dr. Macrae, he having objected to attend this meeting unless a fee of two guineas was paid to him; and that nurse Pickering has been very remiss in not seeing the orders of the medical officer properly carried out. The Committee also find that the treatment for measles, as pursued by Dr. Hughes and Dr. Macrae, is entirely opposite in its nature, and that it would have been well had they consulted each other previous to adopting the methods they did.'"

SELF-SUPPORTING DISPENSARIES.

A MEETING of the medical practitioners of Salford was held on the 7th inst. in the board-room of the Salford and Pendleton Hospital, to discuss the provident system of medical relief. There were present Mr. John Boutflower, F.R.C.S., Messrs. Stocks, Ingle, Haywood, Andrew Boutflower, Somers, White, Orchard, Bradbury, Pinder, Davies, Hamilton, and Nathaniel Shelmerdine. Dr. Crompton, Honorary Physician to the Hospital, presided. A paper was read advocating the establishment of provident dispensaries as the simplest, and on the whole most successful, system of remedying the present wholesale abuse of hospital charity, preserving the independence of the working classes, and affording them, their wives and children, prompt and sufficient medical assistance in time of sickness. An animated discussion followed the reading of the paper, in which the widely divergent views entertained by the profession on this subject were exhibited. Finally, the following resolution was put to the meeting:—

"That, in the opinion of this meeting, it is desirable to call into existence some such institution as is supposed by a provident dispensary, whereby hospital abuse may be remedied and the independence of the working classes supported; and that if in any way such an institution could be combined with the existing out and home patient department of the hospital it would be likely to be more successful."

This was negatived by a majority of six to four, the chairman and a few others abstaining from voting. A cordial vote of thanks was passed for the valuable paper just read, and the meeting separated, after a discussion of over two hours.

INSANITY IN ENGLAND AND WALES.

THE Twenty-seventh Annual Report of the Commissioners in Lunacy, just issued, shows that the total number of lunatics, idiots, and persons of unsound mind in England and Wales registered on January 1 last was 60,296, being an increase of 1856 upon that of January 1, 1872. These numbers do not include 188 lunatics so found by inquisition residing in charge of their committees elsewhere than in asylums, hospitals, and licensed houses. The total of 60,296 registered on January 1 last consists of 7023 private patients and 53,273 paupers—the increase during the year having been among the former 381, and among the latter 1275, total 1656. The increase of the year 1871 upon that of 1870 was 1885, represented by 188 additional private patients and 1697 paupers.

A NEGLIGENT SANITARY OFFICER.

THE Hackney District Board of Works last week resolved, on the report of their Sanitary Committee, to dismiss one of their sanitary inspectors for neglect of duty in failing to see certain orders issued by the Board carried out on several sanitary improvements. The inspector had reported nuisances abated without visiting the premises; and the Medical Officer of Health subsequently discovered that the necessary works for that purpose had not in some instances even been commenced. The result of such a dereliction of duty on the part of a sanitary officer might be of a very serious nature, especially if an outbreak of epidemic disease occurred in the district. We commend the Board for their promptitude in adopting the recommendation of the Sanitary Committee to discharge the officer capable of such neglect of duty.

DUBLIN SANITARY ASSOCIATION.—THE THREATENED APPROACH OF CHOLERA.

WE understand that on Thursday, the 10th inst., an influential deputation, composed of members of the Association, and including some of the leading medical men of Dublin, waited upon the Local Government Board for Ireland, to press their views with regard to the preventive measures likely to arrest the progress of an epidemic of cholera, and to bring under the notice of the Board the present unsatisfactory state of Dublin as regards sanitary arrangements. The deputation was most courteously received, and a distinct pledge was given that their representations would meet with the earliest and most attentive consideration. That the Local Government Board is fully aware of the exigency of the crisis, and is anxious to carry out the powers entrusted to them, appears from an order published in last week's *Dublin Gazette* relative to the preventive measures to be put in force by the boards of guardians, and in seaports threatened with the disease from the navigation.

MR. ERASMUS WILSON, F.R.S.

THE friends of Mr. Erasmus Wilson propose to place his portrait in the library of Epsom College on the occasion of opening the new master's house in September next. This new house is the gift of Mr. Wilson. Dr. Jonson, of South Eaton-place, S.W., and Dr. Carr, of Blackheath, S.E., are the joint treasurers to the fund now being raised, subscriptions to which, not exceeding £1 1s., may be sent to them.

HEALTH OF THE PUNJAUB.

THE Sanitary Commissioner's return of deaths in the Punjaub for the week ending May 17 last states that the small-pox pestilence at Delhi continues to extend its ravages. The total number of deaths has risen from 152 to 191, and the deaths registered under the head of small-pox from thirty-six to fifty-four. The small-pox mortality is almost entirely confined to children; only one adult died from the disease. The adult population, being protected by a previous attack, which has for the most part left them scarred, disfigured, and partially or in many cases totally blind, are very rarely attacked a second time. The Delhi Municipality keep up a large staff of vaccinators, but the native members afford them no assistance in overcoming the prejudices of the native population against vaccination, and the result is that the great mass of the children population are unprotected. Rewári, Bhewáni, Firozpúr, Jalándhar suburbs, Amritsar, Kusúr, Síálkot, Pasrúr, and Jelálpúr are also suffering severely from the pestilence. The total small-pox deaths registered in the districts from which returns have been received were 1520, as compared with 1395 in the previous week. There were only three deaths registered from cholera—two in Lahore and one in Firozpúr.

HEALTH OF SCOTLAND.

DURING the month of June, 1873, there were registered in the eight principal towns of Scotland the deaths of 2448 persons, of whom 1201 were males and 1427 females. Allowing for increase of population, this number is 36 under the average June mortality of the last ten years. A comparison of the deaths registered in the eight towns shows that during June the annual rate of mortality was 22 per 1000

persons in Aberdeen and in Leith, 23 in Edinburgh and in Dundee, 24 in Perth, 27 in Greenock, 29 in Glasgow, and 30 in Paisley. Of the 2448 deaths, 1064, or 43 per cent., were of children under five years of age. In Perth 26 per cent. of the persons who died were under 5 years of age; in Paisley, 28; in Aberdeen, 32; in Leith, 34; in Edinburgh and in Dundee, 38; in Greenock, 46; and in Glasgow, 51 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 483 persons, thus constituting 19·7 per cent. of the mortality of the eight towns. This rate was exceeded in Glasgow from the prevalence of measles; while in Perth the only deaths tabulated in this class of diseases were 2 from diarrhœa.

HEALTH IN HALIFAX.

The death-rate in Halifax is at the present time much lower than it has been for several years, and the Borough Hospital at Stony Royal is quite empty.

FROM ABROAD.—OSSIFICATION OF MUSCLES—SUPPURATION OF MUSCLES—MEDICINE AND PHARMACY IN THE FRENCH ARMY.

At a recent meeting of the Vienna Medical Society, Professor Podratsky related a remarkable case of "Myositis Ossificans" which had come under his care. It occurred in the person of a soldier, in whom, in consequence of violent gymnastic exercises, an ossification of the lowest portion of the brachialis muscle was produced. The ossification took place with great rapidity, having been preceded by myositis. After about eight days' gymnastic exercises (consisting of those termed *Armwelle*) there was observed at the insertion of the brachialis internus of the right arm a very hard and somewhat painful tumour. The case was closely observed by the reporter from its commencement. At first the swelling was very elastic, and, although decidedly belonging to the brachialis, it was adherent to the humerus. The tendon of the biceps ran clearly over the muscle, and the elbow was contracted to a right angle, extension being impossible. A large needle could at first be by some force thrust into the tumour, giving the feeling of passing through cartilage, but without causing any pain to the patient. The swelling remained in this condition for about three weeks, at the end of which time forcible extension was made under chloroform. The resistance was considerable, but gave way with a plainly audible crushing sound. The tendon had apparently separated from the muscle, and the arm was kept for some days upon a splint in the extended position. The movements of the elbow-joint were thenceforward more free, but the brachialis muscle became harder, and at last bony in the proper sense of the word. At the time of the report even the strongest needle, under the employment of very great force, would not enter the tumour, which was about the size of an egg, and presented all the characters of complete ossification.

Cases similar to this have been observed in soldiers as a consequence of their exercises; and in 1864 Professor Pitha brought before the Society an exactly similar case affecting the same muscle, and also brought on by gymnastic exercises. Professor Volkmann also, in his article on "The Diseases of the Organs of Locomotion," in Pitha and Billroth's "Handbuch der Chirurgie," relates an analogous case, which is illustrated by a woodcut.

While upon the subject of affections of the muscles we may refer to an interesting paper by M. Poncet, relating (*Gazette des Hôpitaux*, Nos. 53 and 54) two cases of suppuration of muscle occurring in the practice of M. Ollier at the Hôtel-Dieu de Lyon. He observes that the cases of rupture of muscles, whether of the abdomen or of the thigh, which are brought to the hospital generally soon do very well when they are complete or considerable, as the patient is at once compelled to remain in a state of complete repose. When, however, only more or less of the fibres are ruptured, so that movement, although painful, is still possible, inflammatory action may be readily set up, and a lesion, insignificant in itself at first, may be followed by even fatal consequences. An example of this occurred in M. Ollier's service in the person of a patient who entered the hospital long after the occurrence of a partial rupture of the rectus femoris. An acute abscess extended from the iliac spine to the middle of the thigh, the patient only having ceased working a few days before. The abscess was opened, and, hospital gangrene prevailing in the hospital at the time, the man was carried off in a few days.

Although rupture of muscular fibre is the common cause of suppurating myositis, M. Ollier admits that this may occasionally arise from cold, and especially in rheumatism. Ordinarily any inflammatory action that may exist in the cellular tissue surrounding the muscular fibres terminates in rapid resolution. Occasionally, however, suppuration is produced; and a distinction is to be observed as to the manner in which this occurs. Thus, the superficial muscular fibres may alone be affected (peri-myositis or peri-muscular phlegmon), and the pus forming, not at the expense of the envelope of each muscular fibre, but at that of their common sheath, the muscle does not undergo any deep-seated alterations. But the muscle may in other cases become infiltrated with pus throughout its entire substance. At the bedside it is not always easy to separate these two forms of myositis. It is, in fact, rare for the inflammatory action to be limited to the muscle or to the cellular sheath, although the one or the other of these is more especially affected.

These remarks are illustrated by two cases. The first was an example of suppurative inflammation of the sub-aponeurotic cellular tissue of the sterno-cleido-mastoideus, attended by some symptoms resembling those of a true myositis. In less than two months after discharge of pus by means of the aspirator, however, the muscle had reacquired all its normal suppleness, and the movements of the head and neck were as well performed as before. The second case was an example of suppuration supervening upon rupture of the biceps. The abscess was opened, and cicatrisation ensued. Six years after the accident the biceps was found still diminished in size, and only capable of imperfect contraction. In the first case the abscess had been formed at the expense of the cellular sheath and of the cellulo-adipose tissue which separates the two portions of the sterno-mastoideus; while in the second case the loss of muscular substance produced at the seat of rupture was replaced by fibroid tissue, and the contractile power of the organ proportionately enfeebled.

Last week Professor Broca read a report to the Académie de Médecine which is of considerable interest. It seems that in the French army, besides the doctors, there are the pharmaciens, who occupy posts of much the same dignity and emolument; and as both doctors and pharmaciens are immediately under the control of the sub-intendants of the army, and independent of each other, they sometimes come into collision. However, it has been repeatedly represented to successive governments that great advantage would be derived from the subordination of the pharmacien to the medical element, as is the case in other Continental armies. The present War Minister, in view of the reorganisation of the army, which is imminent, resolved to elicit the opinions of the Academy of Medicine upon this knotty point; and accordingly the Academy appointed a committee to consider and report upon it. This consisted of three surgeons, MM. Larrey, Legouest, and Broca, two of whom have been Directors-General of the Army in time of war; three physicians, MM. Depaul, Devergie, and Gubler; and three pharma-

ciens, M.M. Poggiale, Gobley, and Bussy. During the first four meetings of the Committee the present condition of the respective services in the Medical Department were minutely inquired into, both oral and documentary evidence having been received in abundance; but on the fifth the three pharmacien members withdrew, declaring that from the questions put and explanations elicited by the other members they foresaw that an impartial decision would not be come to. This policy of withdrawing from contests when they fear to be left in the minority, which seems such a favourite with Continental politicians, and is so inexplicable to ourselves, was persisted in, and the remaining six members held the other two meetings without their colleagues, and the resolutions they arrived at were unanimous. Professor Broca, in his report, enters into the history of the present organisation of the medical and pharmaceutical services, which, it seems, dates from a dictatorial decree in 1852, replacing the system by which these two services were united in 1836. One of the questions now submitted to the Committee was whether such union or "fusion" should be revived; but to this they opposed a decided negative, under the belief that the practice of military pharmacy would then fall into the hands of doctors very imperfectly informed on the subject, and who had probably failed in other branches of the profession; while pharmacy, ceasing to be pursued as an independent subject of attention, the series of distinguished pharmaciens who have issued from the central pharmacies and the laboratories of the great military hospitals would be brought to a close. Here M. Dumas, the celebrated chemist, demanded to be heard before the Committee, and, with that forcible eloquence of which he is an acknowledged master, dwelt upon the necessity of maintaining an institution in the army that had furnished so many remarkable men to French chemistry, and the utility of which has become even greater than heretofore, in consequence of civil chemistry being led away more and more by specialities, to the abandonment of purely scientific research. The military pharmacien has not only to concern himself with mere pharmacy and the dispensing of medicines, but is constantly engaged with chemical examinations of substances submitted to him, requiring extended and deep chemical knowledge. Anyone, indeed, who is acquainted with the official publication, "Recueil de Chirurgie, Médecine et Pharmacie Militaires," must be well aware of the value of the contributions by the pharmaciens on all subjects relating to the health of the army.

Having disposed of this point, the Committee had to consider whether they would recommend a subordination of the pharmaciens to the doctors, or leave matters as they are. Here the Committee, and especially the military members, perceived that the question really merges into that vital one of emancipating the French medical service from the control of the Intendance, which has hitherto been, and is still, its curse. The interests of the public and of the soldiers, they observe, should dominate over questions of mere professional rivalry; and as long as the Intendance has the power of playing one of these services against the other, no united action will be possible. The independence of the two services is now complete, and each has the same grades of rank—the only difference being that the number of doctors is about eight times larger than that of the pharmaciens. The pharmacien executes the medical prescriptions of the doctor, but receives no orders from him, nor is the signature of the doctor, however high in rank, of any worth, unless countersigned by the Intendance. Bad enough this in time of peace; and during war, even, when the Intendants cannot be found doctors have no power of action without them! The Committee insists that this state of things calls for instant reform, and that the medical service should be at once rendered autonomic under the responsibility of a director chosen from its own body, and accountable only to the commanding officer, and it regards the subordination of the pharmaceutical and administrative elements as a necessary consequence. It can see no degradation in such subordination, but only a necessary step for rendering the medical service at all times operative. France is well-nigh the only country in which the administrative element (often aided by the pharmaceutical) is allowed to ride rough-shod over the medical. The Committee, therefore, in reply to the Minister of War, proposes—1. That the system of fusion of military medicine and of pharmacy should be rejected as prejudicial to the interests of the army. 2. The present organisation of the medical service does not respond to the wants and interests of the army. It is necessary that this service should be placed under the direction of a competent head taken from its own ranks. 3. The autonomy of the medical service implies, as a logical consequence, the subordination of pharmacy to medicine in the army.

PARLIAMENTARY.—MEDICAL OFFICERS IN THE ARMY.

In the House of Lords,

Earl De la Warr rose to move that a humble address be presented to her Majesty directing her attention to the present position of the medical officers of the army who served on the West Coast of Africa between 1859 and 1867 as regards rank and pay. According to a Royal Warrant, dated October, 1858, the medical regulations of the army with respect to service on the East Coast of Africa were shown to contain the following proviso:—"Each medical officer volunteering for the West Coast of Africa will be required to serve there continuously for a period of twelve months; every such year of service on the Coast to count as two years for promotion and retirement." The noble earl said that on the faith of this Warrant many medical officers volunteered for service in this unhealthy climate, believing, as one of them wrote, "that the double service would count towards the rank of Surgeon-Major." After some time, however, another Warrant was issued, stating, as before, that each year of such service should be allowed to reckon double for promotion and retirement, adding, however, these words, "but shall not so reckon towards increased pay"; and another later Warrant added, "or qualify for the rank of Surgeon-Major." Neither of these qualifications appeared in the first Warrant, under which seventy-six medical officers had volunteered their services upon the West Coast. Of those gentlemen a large number had died, others were invalided, others had retired from the service, and there now remained about thirty, whose case was, as he submitted, a hard one. It might be objected on the part of men of older standing that these thirty medical officers should not be promoted over their heads. It was still harder, however, that the thirty should have served for seven years under the impression that their service would count as double, and should then be told that it would count neither for pay nor promotion. The noble Earl was quite content to leave this subject in the hands of her Majesty's Government with the assurance that it would receive a fair consideration. The Marquis of Lansdowne replied that promotion was transfer from one grade to another. A Surgeon becoming a Surgeon-Major was not so transferred. He contended that the officers referred to had no real grievance, but that they had received all to which they were entitled. The motion was withdrawn.

MEDICAL ACT AMENDMENT (UNIVERSITY OF LONDON) BILL.

A Bill to Amend the Medical Act so far as relates to the University of London.

Whereas by the Medical Act (hereinafter called the principal Act), and Acts amending the same, every person becoming possessed of any one or more of the qualifications mentioned in the said Acts is to be entitled to be registered under the principal Act, and one of such qualifications is that of Doctor, or Bachelor, or Licentiate of Medicine, or Master of Surgery in any university of the United Kingdom.

And whereas by the principal Act it is further provided, that any two or more of the colleges and bodies in the Medical Acts in that behalf mentioned may, with the sanction and

under the directions of the General Council, unite and co-operate in conducting the examinations required for qualifications to be registered under the principal Act.

And whereas the University of London is one of such bodies, but doubts are entertained whether it is able to take advantage of the hereinbefore recited provisions of the principal Act unless it receives further powers from Parliament; and accordingly it is expedient to amend the Medical Acts so far as relates to the said University.

Be it enacted by the Queen's most excellent majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons in this present Parliament assembled, and by the authority of the same, as follows:

1. If, in pursuance of the principal Act, the University of London unites or co-operates with any of the colleges or bodies in that behalf mentioned in the Medical Acts in conducting the examinations required for qualifications to be registered under the principal Act, then, notwithstanding anything in any statute or charter contained, it shall be lawful for the chancellor, vice-chancellor, and fellows for the time being of the said University to prescribe, by a by-law under the common seal of the said University, that no person shall become a Doctor, or Bachelor, or Licentiate of Medicine, or Master in Surgery of the said University unless (in addition to passing such examination, if any, and complying with such other conditions, if any, as may be prescribed by any by-laws in force for the time being made in pursuance of any charter of the said University) he shall have passed such examination for qualification to be registered under the Medical Act, and complied with such conditions relating thereto as may be agreed upon between the said University and the college or body, colleges or bodies with whom the said University may be united or co-operating as aforesaid.

Provided, that no by-law made in pursuance of this Act shall be of any force unless it has the assent of one of her Majesty's Principal Secretaries of State, and that it shall be lawful for one of such Secretaries of State at any subsequent time, if he shall think fit, to revoke such assent.

2. This Act may be cited for all purposes as the Medical Act (University of London), 1873, and shall be construed as one with the Medical Acts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following is the report from the Court of Examiners of the number of candidates who have presented themselves for the primary and pass examinations for the diploma of Member of the College during the collegiate year 1872-73, showing the numbers who have passed and who have been rejected from each medical school during that period, and will be read with considerable interest by both metropolitan and provincial teachers:—

Primary Examinations.

Medical Schools.	Totals.	Number passed.	Number rejected.	Percentage of rejections.

At the written portion of the primary or Anatomical and Physiological examination on Saturday last, 113 candidates offered themselves, to whom the following questions were submitted. They were required, as usual, to answer four out of the six:—1. Describe the course and relations of the right subclavian artery; and state the difference which exists between it and the left. 2. Describe the relations of the stomach when empty and when distended, its bloodvessels, its nerves, and the structure of its mucous membrane. 3. Describe the dissection necessary to display a side view of the muscles of the tongue, and the structures cut through in carrying it out. 4. Describe the ciliary body of the human eye, its situation, connexions, and structure, and the dissection necessary to expose it. 5. Describe the ligaments of the knee-joint; their several attachments, together with the inter-articular cartilages, and their uses. 6. Describe the structure of a mature Graafian vesicle, the mode in which the ovum enters the Fallopian tube, and how it finally becomes attached to the uterus.

At the primary examination, which was brought to a close on the 17th inst., out of the 113 candidates examined 56 were referred to their anatomical and physiological studies for three months. There were 22 rejected on the first day out of 38

examined, 23 out of 39 examined on the second day, and 11 out of 36 examined on the third and last day.

For the pass or Surgical and Pathological examination, which commenced this day (Friday), there were 176 candidates.

NOTES ON MADRAS AS A WINTER RESIDENCE.

No. III.

Opium-eating: Districts of England in which it Prevails; Moral Character of the English Opium-eater; Enormous Consumption of Opium in the East; the Revenue therefrom; Opium-smoking in Madras; How it is Done: A Chinaman's Defence of Opium *versus* Grog.

Amongst the sights which I have been able to see here, is opium-smoking in the genuine Oriental fashion. By way of introduction, may I say a few words on opium-eating in England?

To begin with, one must make a distinction between the use of opium as a medicine, and as a luxury or food. The line is not a very level one always, and there are many cases difficult to allot to one side or the other, but we may say broadly that whoever uses opium for the relief of pain, or to procure sleep, uses it as a medicine, even though it be used habitually. On the other hand, whoever uses it merely for exhilaration of mind, or for the enhancement of bodily comfort, uses it as a luxury. The lines between food, stimulants, or luxuries, and medicines, are often purely arbitrary, but still there are cases which can be clearly referred to one of these classes, though others are of a mixed kind. The great English opium-eater—De Quincey—began the use of it as a remedy for neuralgia; just so, women who are incautiously recommended to take wine or brandy as a medicine for debility, may continue it as a luxury; and the use and misuse have generally some meeting-point.

Now, opium-eating is practised—as a luxury—in England; and I believe that this, if carefully studied, will be found to give the key to the whole question in the East. In England opium-eating is a trifle; in the East it is a matter of imperial policy,—but the conditions which give rise to it in one place and the other are alike.

Opium-eating is not to be found in London. Of course amongst the three millions and three-quarters there are to be found some persons here and there who take it as a luxury, though by far the greater number of those who take it in anything like quantity do so for some old neuralgia or rheumatic malady, and began under medical advice. Neither is it to be found over the agricultural or manufacturing districts, save in the most scattered and casual way. The genuine opium-eating districts are the ague and fen districts of Norfolk and Lincolnshire. There it is not casual, accidental, or rare, but popular, habitual, and common. Anyone who visits such a town as Louth or Wisbeach, and strolls about the streets on a Saturday evening, watching the country people as they do their marketing, may soon satisfy himself that the crowds in the chemists' shops come for opium; and they have a peculiar way of getting it. They go in, lay down their money, and receive the opium pills in exchange without saying a word. For instance, I was at Wisbeach one evening in August, 1871; went into a chemist's shop; laid a penny on the counter. The chemist said—"The best?" I nodded. He gave me a pill-box and took up the penny; and so the purchase was completed without my having uttered a syllable. You offer money, and get opium as a matter of course. This may show how familiar the custom is. By-the-bye, there is an excellent museum at Wisbeach, well worthy of a visit.

In these districts it is taken by people of all classes, but especially by the poor and miserable, and by those who in other districts would seek comfort from gin or beer. But there is this remarkable characteristic about the opium-eaters. They are probably dirty, slovenly, and lazy, lying and sanctimonious, begging of the clergy and district visitors, but they are not uproarious, and don't swear. There are none of the deeds of brutal violence that are inspired by beer, and none of the foul language. Where others say "damn," they say "bless;" and, in fact, you may almost know an opium-eater by his use of the word "blessed." "Law, mum," said an old woman, "what a beautiful dog of yourn, and what a blessed tail he've got!" "Our Tom have been stealing, and deserve to be hanged, he dew, bless him!" Such are the moral effects of opium when used as a luxury in England: a state of dreamy comfort and a forgetfulness of aches and pains of mind and body—a state in which people dream of virtue, and goodness, and piety, and do nothing. The districts in which it is popular show the cause: the agueish, chilly, neuralgic maladies of the district, for which opium is a remedy, and which create a kind of constitutional peculiarity that tolerates opium. So that some persons who begin to take it as a medicine continue it as a comfort, and others follow their example, and take it without the original excuse. Question an opium-eater, and he or she will most likely deny the habit point-blank: if they confess it, they plead the *comfort* it gives.

Now let me turn the terrestrial globe one-fourth of its circumference, and come to tropical India, where I am at present domiciled. The newspapers are full of jubilation at the remission of various taxes and at the prosperous state of the revenue.

There is a surplus of one million and a half of receipts over expenditure for the year ending March, 1873; but, says Sir Richard Temple, the "surplus of the year is mainly attributable to gain in opium." For, in truth, the manufacture and sale of opium is a gigantic and most profitable monopoly in the hands of Government. People who sell their own opium deserve to pay a heavy tax, which amounted in this year to £2,614,700, whilst there was an extraordinary rise in the selling price and decrease in quantity, and consequently in the sums paid for Bengal opium. One remarkable feature is the steady increase of the opium revenue, and the way in which it overtops the estimate formed of it. The Minister had calculated on receiving seven millions and three-quarters—the actual receipts were eight millions and two-thirds. "Within four years," says Sir R. Temple, "we have received from this source net £3,894,140 in excess of the Budget estimates. Year by year the opium estimate has received the approval of the Secretary of State, as being prudent and in accordance with the known facts of the time; the actual receipts, however, have proved larger than the anticipation. This, too, happened during a period when some authorities seem to consider the Indian opium trade as threatened with serious competition from the increasing culture of the indigenous drug in China, and even from the produce of other countries; when the Indian opium harvests have been considerably below the average, and when the area under poppy cultivation has not materially increased. Indeed, the fiscal facts point to the conclusion that the demand in China for the Indian drug is firmly sustained. Doubtless the ability of China to pay a good price for the opium is maintained by the growing wealth and rising trade of that country."

From these remarks may be gathered the enormous and increasing use of opium in these tropical regions of the East. In Madras, whence I date my letter, we are on the mere outskirts of the opium-consuming districts, which, I am told, begin at Masulipatam and stretch northwards along the coast to Calcutta. Still, Madras gives some opportunities for witnessing the use of it, and I gladly availed myself of an invitation to accompany Inspector-General B—— (a man of truly encyclopædic knowledge and experience in all that concerns the languages, customs, and ethnology of India) on a visit to one of the establishments where opium-smoking is carried on.

Opium-smoking is generally carried on at public shops, because people have no convenience at home, and are generally of the humbler classes; so one need not wonder that the shop we visit is of a humble character. Moreover, wives do not allow smoking at home. In one of the second-rate streets of Black Town, Madras, we stop at the house of Mr. J. Hussam, livery-stable-keeper, whose card announces that he has "neat coaches and fleet horses for hire either by the day or month"; "also boots and shoes"; for the fact is that Mr. Hussam is a practical man, and carries on the business of shoemaker in the "pyal" or verandah in front of his house. He seems to use part of his premises for carriages and horses, and devotes two rooms on the principal floor to the accommodation of opium-smokers. Mine host and his family are Chinamen; quiet, plain-spoken, practical people, who showed us all the paraphernalia of their trade without any hesitation. They buy the crude opium in mass; then dissolve, and strain, and evaporate until they have reduced it to the consistence of a thick syrup, of a rather fragrant smell, and free from the rankness of crude opium. I suppose they do what the Pharmacopœia

orders in the preparation of "extractum opii purificatum." This is weighed out into portions, which are put into little cardboard trays, and are sold to the customers at a half-anna a piece, equal to three farthings of our money. Our host, a hale old fellow of sixty-five, told us that he had been a smoker for thirty-five years; his daughter's husband had also smoked many years; and these two gave us an exhibition of the way in which the thing is carried on. Let me say that the house and its belongings were, *mutatis mutandis*, like those of a respectable English tradesman. The people were well dressed, like English people, were it not for the men's earrings and hair plaited and coiled round the head; they are Roman Catholic Christians, but keep a corner for a tablet containing certain sacred precepts in Chinese, before which a stick of incense is burned every day.

Well, the person who smokes opium must, first of all, have a comfortable place to lie down in. This is a *sine quâ non*. Next, he must be provided with a small lamp. Possibly three or four people lie around one lamp, their heads towards it and their legs outside. The pipe is a thing difficult to explain,—it is generally of bamboo, the size of a flute, and at its further end it has a projecting piece of metal, like a pegtop, with a hole in its middle leading into the cavity of the bamboo. Besides these the smoker must be provided with a thing like an iron probe or packing needle. Then he begins operations by scraping up the opium on the end of the probe, holding it in the flame of the lamp, where it frizzles and hardens; then he moulds the hardened opium around the little hole in the metal pegtop projection of the pipe, and lastly sets the opium for an instant on fire in the lamp, and inhales some of the smoke. After one or two whiffs (if he is a poor man smoking with a party from a pipe in common) he passes it on, and so it goes round until all the opium is consumed. Considering the dilution of the opium, and the frizzling it undergoes in the lamp, and the quantity of smoke that escapes, I am quite unable to form any idea of the quantity actually inhaled. Our host and his son-in-law each took a pipe before us; the effect of which was a little suffusion and glistening of the eyes, but no acceleration of pulse. We were now refreshed with genuine Chinese tea, and next conducted into the public smoking-room, which was crowded, because many of the smokers from the other shops, hearing that a visit was to be paid by the Inspector-General, came to this one in the hope of being treated by the visitors, and in this respect they were not disappointed. The room was full of men, lying on slightly raised sofas by twos and threes round each lamp. They seemed simply sleepy and quiet, with heavy eyes; just like people of the same rank of life—carters, cabmen, labourers, and mechanics—in an English tap-room, but without the *tapage*, and riot, and bad language.

When we had satisfied our curiosity, we entered with our intelligent host into the moral and political side of the question. Surely these people, we said, are pursuing a very dangerous pleasure; they will go on and lose their health and faculties, and become idiots and spectres. "Sir," said our host, "if people choose to do without anything of an intoxicating sort, why not? But we know they all do take something: the Englishman, he takes his rum and beer and tobacco; the Chinaman and Mussulman, they smoke opium. Why do they choose opium? Why, a young man goes into hospital sick with fever, and comes out very bad and weak, not able to eat; then a friend says, 'Why do you not smoke?' So he takes a pipe, and feels better and stronger directly. Opium does not take away the appetite—on the contrary, it makes a man wish to eat plenty of rice, and especially plantains. A man has cold and rheumatism, and cannot do his work, and smoking cures him; or he is very tired, and fit for nothing, until a few whiffs make him feel quite strong and happy. Then he goes on and uses it as a comfort, and advises all his friends to do so too; and so the practice is a growing one. There is a Chinese opium shop in the East-end of London. You may say what you please against it, and no doubt many people use too much. But here I have smoked for thirty-five years, and my son-in-law for fifteen; and do we look like sots or intemperates? I like my pipe in the morning after breakfast, and again in the evening after business, and it gives me strength and spirits; I take enough, and have no wish to take more. 'Tis with opium as with cigars: a prudent man will spend a half-anna or more, as he can afford it, and as his habit leads him. But even if the habit be a bad one, it is better than drinking grog, for many reasons. First of all, women never smoke opium. Then, people who smoke don't smell of it, as they do after grog. Then see the difference—a man takes opium, and remains his own master; but grog *takes him!* and masters him, and makes him talk nonsense and fight uproariously; whilst the very essence of opium-smoking is quietness. The smoker must lie down, and can't talk, and does not want to fight,—he is fit for his work or to go home to his wife and family; and you can't always say this for the grog-drinker."

So far my Chinese philosopher. Being a mere student of human nature in a strange place, I do not venture to add any comment, save that however much opium-smoking, when once introduced, may spread by example and moral contagion, I believe, from all I hear, that the hot-beds of the habit are to be found in the swampy, marshy, fever-stricken districts, where a broiling sun by day is succeeded by chill dews at night, and ague and lassitude infest the population. So that whoever wants to put down the use of opium as a luxury must drain land, improve the diet of the people, and make quinine cheap. The cinchona plantations will give the antidote if any antidote there be. I was talking the other day with a most intelligent native servant, who had been some time ago up the coast in a very opium-smoking district. I asked him if there was fever there. "O lord yes, master; there is a burning sun, and when it rains the drops are as big as your fist; the country is all jungle; and European gentlemen soon get to be like frogs—all head, and swelled belly, and no limbs."

PROFESSOR HOLMES'S LECTURES AT THE COLLEGE OF SURGEONS.

Abstract of Lecture III.

The occurrence of spontaneous aneurism of the vertebral artery in the neck has not as yet been noticed, but traumatic aneurisms of this artery are not so very infrequent, and there are already records of eleven cases in which the carotid artery has been tied,—in four for wound and in seven for traumatic aneurism of the vertebral.

It is worth while to see what were the leading features of these cases, and how such an error could in future be avoided. For undoubtedly the ligation of the carotid in a case of vertebral aneurism must be fraught with double mischief: in the first place it aggravates the disease by throwing the strain of the anastomosing circulation on the vertebral; and in the second place, if the circulation in the wounded vertebral artery is interrupted before the operation of the ligature of the carotid, the stoppage of the blood supply to the brain through the carotid is rendered doubly perilous to the nutrition of that organ.

The Professor referred to a table of the cases of wounds and of traumatic aneurisms of the vertebral artery in which the carotid had been tied by mistake; and he made special reference to the one most fully reported, and which best illustrates the diagnosis. It is a case of traumatic aneurism of the vertebral artery recorded by Lücke in the eighth volume of Langenbeck's *Archives*, in which compression on the carotid diminished, but did not quite stop, the pulsation. As the symptoms persisted after the ligature of the carotid, the aneurism was injected with perchloride of iron. It burst and was laid open, and the bleeding vessel commanded by pressure. The patient died, and it was found that the vertebral artery was wounded between the atlas and occipital bone.

In commenting on this case, Lücke remarks on the error into which he was led by the fact that compression on the carotid checked the aneurismal pulsation. He explains this by supposing that compression on the carotid acted simultaneously on the vertebral, and he points out that this may easily happen if the vertebral enters the foramen of a higher vertebra than usual. Other writers have, however, observed the possibility of checking the pulsation of vertebral aneurism by pressure applied in the same way as for aneurism of the carotid, even in the normal relations of the vertebral artery. Chassaignac, writing on digital compression of the vertebral artery in the "Des Opérations Chirurgicales," says:—"As the vertebral near its origin lies immediately behind the common carotid, between it and the spinal column, the simultaneous closure of both arteries is inevitable when the pressure is made on the carotid low down, and it is an error to think that very powerful compression is required for this

purpose." He then refers to an experiment devised by M. Fraeys, of Ghent, which illustrates the fact that water injected into the aorta will cease to flow from the vertebral if light pressure be made upon the common carotid of the same side in the space extending between two and three inches above the clavicle; and he says—"If pressure is made with the same force on the common carotid above the 'carotid tubercle'—*i.e.*, the anterior tubercle of the transverse process of the sixth cervical vertebra—the space below that tubercle being left free, the jet from the vertebral artery will continue, while that from the internal carotid wholly ceases." He proceeds to show that the tubercle in question is much higher than is generally supposed, being always from two to three inches above the upper border of the clavicle. The bearing of this fact on the diagnosis between carotid and vertebral aneurism is obvious. The surgeon must, therefore, not conclude that the aneurism affects one of the carotids or some branch of the external carotid until he has seen that pressure stops the pulsation when applied at a higher level than the carotid tubercle, or when applied to the carotid in such a way as to isolate it from the other structures, as M. Rouge did. A traumatic aneurism whose pulsations are unaffected by compression so applied must be regarded and treated as vertebral.

The ligature of the carotid for a wound of the vertebral not followed by aneurism in which the injury was assumed to be of the carotid or one of its branches, is a course still more to be regretted. There are in all regions grave objections to the ligature of a trunk vessel for the wound of a branch if any other course be open; but to tie the carotid artery for a wound of the vertebral has a direct effect in promoting bleeding from the wounded vessel, and the operation is certainly unjustifiable when any doubt exists on this point. However dangerous and difficult the operation may be which is necessary to expose the wounded artery, it is the only one admissible, and if the surgeon thinks it undesirable to hazard its performance he should at any rate not complicate the case further by tying the carotid.

Lücke comments at great length on the treatment which should be adopted, allowing that the diagnosis of vertebral aneurism has been established. The ligature of the vertebral artery at the root of the neck is a difficult and formidable operation, nor is there any probability that it would check the circulation through the upper portion of the vessel so near its inosculation with its fellow. He argues, therefore, conclusively against any such attempt; and still more is the attempt to tie the subclavian above the origin of the vertebral to be reprobated. But the course which he followed—viz., of repeated injections of perchloride of iron—is not at all to be recommended; for in order that this mode of cure should have any chance of success, it seems necessary that the artery should be commanded both above and below the tumour.

The only case which can be referred to of alleged cure of an aneurism of the vertebral artery is one reported by a surgeon named Möbius, in 1827. The swelling, which increased to the size of four and a half inches by three and a quarter inches, was found suddenly to have become cold, quite hard, and pulseless, after the prolonged application of ice and snow, —the patient having obstinately refused to submit to any operation. The tumour, which was of traumatic origin, and caused by a stab over the lower right half of the occipital bone, finally disappeared, and the patient was alive at the time of the report of his case two years afterwards. The cure was produced in all probability by the mouth of the sac becoming obliterated by the accidental detachment of a portion of the clot. Bearing this case in mind, we ought to hesitate before proceeding to any extreme measures in traumatic aneurism of the vertebral artery. Professor Holmes does not see what operation can be practised on such a tumour with any hope of success, except that modification of the method of Antylus proposed by Mr. Syme. The effect of compression applied over the lower part of the carotid ought to be carefully noticed, and if this stops or greatly reduces the pulsation of the tumour, there seems no reason why it should not produce a cure, if the patient can tolerate it.

The conclusions, then, to which present experience points on this subject of vertebral aneurism may be thus summed up:—

1. A traumatic aneurism may be taken to be vertebral when it is situated in the course of that vessel, and when its pulsations are not commanded by compression of the lower part of the common carotid.

2. When a traumatic aneurism is situated as above, and its pulsations are commanded, however completely, by pressure on the common carotid low in the neck, it ought not to be treated as carotid or as affecting a branch of the carotid unless it is clearly proved that its pulsations are stopped by pressure applied above the level at which the vertebral ceases to be compressible—*i.e.*, above Chassaignac's "carotid tubercle."

3. An aneurism diagnosed as vertebral may be treated by compression (gradual or rapid, as the case demands) of the root of the vertebral artery in the neck if this is found feasible.

4. If indirect compression will not stop the pulsation, or if it cannot be borne, the tumour should be subjected to direct compression and refrigeration, to which internal remedies may be added, and possibly the subcutaneous injection of ergotine may be of use.

5. If these means fail and the tumour appears likely to burst, or if it have burst, the sac should be opened with all due precaution and an attempt made to tie or plug the wounded artery.

6. A wound known or suspected to be of the vertebral artery should be treated either by direct pressure or by ligature of the vessel in the wound.

In order to complete the subject of aneurisms of the head and neck, it remains to speak of intracranial aneurism (by which is here meant aneurisms not within the cranium, but within the membranes of the brain) and aneurism of the intracarotid or its branches in the orbit or cavernous sinus.

With regard to intracranial aneurism, we know nothing at present of its diagnosis, so that no treatment can as yet be directed especially to it. And looking at the very free intercommunication of the four large cranial trunks, it would seem unlikely that surgical measures directed to any one of them would do much towards the consolidation of an aneurism. Nor would the consolidation render the patient secure from cerebral symptoms. Yet the question occurs whether the trial may not be worth making, even allowing the prospect of success to be but small, if only the diagnosis could be established. Professor Holmes then referred in detail to two cases—one by Mr. Coe, of Bristol; the other by Professor R. W. Smith—and then went on to observe that, although there is some possibility that a few cases of intracranial aneurism (meaning, thereby, not "within the skullcap," but "within the membranes of the brain") may become subjects of surgical treatment, our information on the subject is at present very limited, and surgical treatment is almost untried.

Of orbital aneurism, on the contrary, we have ample experience, and the surgical treatment of the disease has certainly not been wanting in activity. The most various opinions have been expressed with regard to the real nature of these aneurisms—or rather of these pulsating tumours, since some of them have not proved to be aneurismal. It is well known that Mr. Travers, who was the first to treat the disease successfully, described it without hesitation as aneurism by anastomosis; and that in this opinion he was followed by all succeeding writers, until Mr. Busk took occasion to expose the numerous points of difference which exist between intra-orbital aneurisms and the undoubted instances of aneurism by anastomosis. He regarded these tumours as true aneurisms of the ophthalmic artery, in which view he was followed by Mr. Curling and Mr. Nunneley. Yet this explanation cannot universally be maintained in the face of the well-known case under Mr. Bowman's care, in which, after death, no disease whatever was found in the arterial system, although the cavernous sinus was filled with coagula extending into the neighbouring sinus and the ophthalmic vein. Accordingly, Mr. Nunneley, in his second paper, states his opinion that "in several of these cases there has not existed any aneurism at all, and in the great majority where there has been aneurism, it has been within the cranium and not in the orbit." And he explained the protrusion of the eye and the pulsation to pressure exercised on the veins of the orbit by an intracranial aneurism, the pulsation of which was transmitted to the fluid in the enlarged veins and so to the eyeball. Mr. Erichsen goes further, and suggests that in some cases there may be no vascular disease at all, but that "some derangement of the vaso-motive influence of the sympathetic may really occasion the symptoms of increased vascular activity that are so characteristic of this singular disease."

Cases of the spontaneous subsidence of this disease as recorded by Erichsen, Collard, and France were mentioned. In all of these there was complete recovery from the symptoms of the disease. Other cases of so-called orbital aneurism, in which the symptoms have been proved to depend on arterio-venous communication in the cavernous sinus, were described, especially four cases by Dr. Delens.

ABSTRACT OF LECTURES ON THE

VARIETIES IN THE MUSCLES OF MAN.

By Prof. HUMPHRY, M.D., F.R.S., of Cambridge.

Lecture III.(a)

In the lower limb the muscular irregularities are fewer than in the upper limb, owing partly to the less complex disposition of muscles in the limb, and to the absence, in consequence of the fixity of the pelvic girdle, of muscles, the homologues of which in the upper limb are the seat of many varieties. The sartorius is the most erratic of those passing from the pelvis, and it is the most variable in lower animals. The biceps by its occasional connexions with the gluteus and extension to the sacrum and the crista of the ilium, harks back, as it were, to its primitive relations with these parts.(b) The adductors may be variously segmented. The semitendinosus, semimembranosus, and popliteus do not vary much.

The irregularities in the calf muscle are on the side of excess rather than of deficiency; although that muscle is in man more complicated than in any other animal. They consist chiefly in the presence of additional heads to the gastrocnemius, or in extensions of the origin of that muscle and of the solcus. The plantaris is sometimes absent or abnormally connected with adjacent parts above or below.

In the deep flexor muscles the most interesting varieties are in connexion with the accessorius, which is a remnant of the primitive wide attachment of the simple unsegmented flexor mass in the Urodelans to the bones of the leg, the tarsus, and the metatarsus. Accordingly, extensions of it, or derivatives from or adjuncts to it, are often found spreading up the leg along the fibula or widely connected with the tarsus. Below, it is sometimes more largely united with the flexor digitorum than usual, or it joins the flexor hallucis or the lumbricales, or it gives off one of the flexor tendons of the toes. The varieties in the flexors of the toes consist chiefly in the closer union of the flexor digitorum and the flexor hallucis, as is the case in lower animals, and in the partial absence of the flexor brevis, or the blending of it with the flexor longus, which more particularly happens with regard to the division to the little toe.

On the dorsal aspect of the limb the quadriceps is but little liable to varieties. The portion of the tibialis anticus attached to the metatarsal bone is sometimes separate, and, further, is sometimes subdivided, one portion passing to the first phalanx, thus resembling the disposition of the extensor tendons to the pollex. Sometimes the tibialis anticus extends to the plantar fascia; or it ranges upon the dorsum of the foot, as in the hippopotamus. The peroneus longus seldom varies; though sometimes attached to other metatarsals in addition to the first, it rarely or never fails to reach the first. The other peronei often show their imperfect segmentation from the extensor digitorum by spreading upon the toes. Particularly is this the case with the peroneus tertius, the complete separation of which and its devotion exclusively to the tarsus is a human feature and is related to the mode in which the forepart of the sole is planted fully upon the ground in man. The extensor digitorum sometimes shows a persistence of connexion with the metatarsal bones, with the extensor hallucis, and with the extensor brevis, which are reminders of the primitive oneness of the extensor mass, and which are evidences of imperfect segmentation of it. No instance had presented itself, however, of that extension to the forepart of the femur which is so frequent in other Mammals.

The varieties in the small muscles of the foot and hand were also discussed.

In indicating the relation between utility and variability, and showing that that which is the most useful has on the whole the greatest stability, the Professor did not express any view as to the connexion between the two, or wish to prejudge the great questions associated with this subject and with the allied problem—how that which is most fitted for its purpose in each animal and each part comes to be present. Other questions were alluded to: whether, for instance, the variety in muscles which are of least importance, on the one hand, and in those which are peculiar to man, on the other, is an indication that those muscles are in process of being fixed in, or expunged from, the economy; also whether varieties are more or less frequent in the more advanced and more civilised members of the human family than in others. At present there is not sufficient evidence to furnish an affirmative answer to any of these questions, or to establish the hereditary transmission of muscular varieties which must be regarded as probable. The nerve-supply to the supernumerary muscles, in the few instances in which it has been described, seems to corroborate the view "that nerve-course is somewhat too arbitrary or too much regulated by convenience in each instance for us to be able to rely upon the disposition of the nerves as sure guides to the discernment, in difficult cases, of the homological relations of muscles and other structures."(c)

MR. MUNDELLA'S FACTORY BILL.

(*Communicated.*)

In June last we brought under notice the main provisions of the Bill introduced by Mr. Mundella to shorten the hours of labour in factories, and also presented an abstract of the report of the Commissioners (Dr. Bridges and Mr. Holmes) charged to inquire into the health of the workers in textile factories, and the influence of their occupation upon it. Now, it has happened that Mr. Mundella's propositions have not received the suffrages of a large proportion of those individuals—both masters and workpeople—in whose behalf they were professedly put forward, and the Bill, which has reached a second reading in the House of Commons, may be reckoned among the failures of the session. Unluckily for its success, the Government give it no help, but rather oppose it as an uncalled for attempt at legislation.

The Home Secretary has signified his opinion that the necessity for the measure has not been demonstrated; and we have now in our hands a reply to the Commissioners' report by the Association of Employers of Factory Labour in the Textile Districts, in which it must be admitted that many of the arguments to be advanced in favour of Mr. Mundella's scheme are disposed of as erroneous and inconclusive. At the same time great credit must be given to Messrs. Bridges and Holmes for collecting much valuable information, and for indicating some direction in which amelioration of the conditions of factory labour may be effected. The manufacturers indeed recognise, in their critical report on the Commissioners' statements, that two important facts are established—viz., "That disadvantages attend the employment of married women in factories, and that one of the consequences of such employment is an excess of infant mortality over that in districts where married women are not employed." It is impossible to over-estimate the importance of such an acknowledgment, which at least admits the imperative necessity for some remedy. But Messrs. Bridges and Holmes lacked time for a thorough and efficient inquiry, and may be reasonably supposed to have no special knowledge relative to the processes and conditions of factory work. The result is that their inferences and conclusions generally, when tested by the evidence they themselves adduce, and also by the special or technical knowledge of the manufacturers, cannot be sustained. To quote the words of their critics, their "summaries do not flow naturally from their allegations;" their statistics are faulty and inefficient; their statistical comparisons are for the most part foreign to the inquiry; and their conclusions, even were the facts as alleged, are illogical and inconsequent, and, "if accepted, the legislation they suggest would provide no remedy, nor scarcely even an alleviation of the evils of which they complain."

The "Observations of the Employers" are replete with particulars in support of these general charges against the value and accuracy of the opinions and representations advanced by the Commissioners. Such particulars cannot be reproduced here, but we may present in abstract some of the defects and errors as pointed out.

The conclusions as to the increased strain upon operatives by modern machinery as compared with that of some years since, are asserted to be erroneous, and the mistake to be owing chiefly to the want of special knowledge of the matter on the part of Messrs. Bridges and Holmes. On the contrary, the improvements effected in machinery are represented to be in favour of the workers. As to the alleged unhealthiness of

certain processes, it is shown that of 450,000 persons 300,000 are employed in departments of manufacture pronounced by the Commissioners themselves to have no debilitating tendency; and also that with regard to the branches of labour alleged to be debilitating, these are, according to the showing of the Commissioners, not so much so in themselves as in consequence of aggravation by imperfect sanitary arrangements. "And further, we inquire (write the manufacturers), if the high temperature and the dust are (as represented) the causes of the debilitating tendency, which would be more efficacious in promoting the health of the workers—working one hour less daily in such an atmosphere, or its purification?"

The high rate of mortality in the textile districts is another matter commented on in the report as if unquestionable, but the manufacturers have been at considerable pains to show, by an appeal to the returns of the Registrar-General (which are assumed to establish the fact adverted to), that the death-rate of textile towns is really less than that of other large towns where no like manufacturing processes are carried on. In this statistical conflict we would not entirely endorse the figures quoted on either side, so delusive are crude statistics without a complete acquaintance with all the circumstances affecting populations; but we hold that the employers sufficiently make out that their towns are not so black as they are painted in regard to their bills of mortality.

The deterioration of the factory children in physique is a point the Commissioners endeavoured to establish, but the plan of measurement adopted, particularly in connexion with the girls, is fraught with error, and the results arrived at almost unimportant. The smaller development of the children is not demonstrated to be connected with their labour as a direct result. With reference to the general recommendation of the Commissioners, that it is desirable to mitigate the evils of manufacture, especially of a bad atmosphere so often involved in it, by working one hour less per day in it, the manufacturers justly urge that, were the reduction to nine hours a day sanctioned, every argument now advanced by Messrs. Bridges and Holmes would still be of the same force as at present in advocating further reduction of working time to eight or to seven, or to any other number of hours desired, inasmuch as the shortening of working time leaves untouched the sanitary evils complained of.

Hence the Commissioners are much more on the right tack when observing that "some of the evils admit of entire removal, and *all* probably of mitigation, were sanitary inspection of factories rendered more efficient than in the present state of the law it is;" and, in commenting on this sensible reflection, the manufacturers prudently suggest "that the proper course is *at once* to make sanitary inspection efficient . . . . and not in the *meantime* to pass a law which, if passed, will be permanent, and will operate as a heavy export duty upon productions supplying £120,000,000 out of the £220,000,000 of our exports."

We must not fail to remark that the medical testimony called for by the Commissioners in the districts visited does not seem entirely to bear out their views respecting the unhealthiness of factory labour, and that there is no demand on the part of the majority of the working population for a reduction of the hours of work. The impression will obtrude itself that the honourable member who has made this Nine Hour Bill his pet object is the victim of an enthusiastic sentimental philanthropy, and of specious representations, or rather misrepresentations, hatched by the self-constituted protectors of the working classes who prefer the part of paid agitators to their lawful calling. These men have met with too much encouragement and countenance from those in power, and have been allowed to sap to no mean extent the foundations of this country's prosperity, and it now behoves all who wish well to their country to resist such further efforts as may be made to cripple the manufacturing industry of the nation.

AT a meeting of the President and Council of the Royal College of Surgeons in Ireland held on the 3rd inst., the following resolution was adopted unanimously:—"That the Honorary Fellowship of the College be conferred on the Rev. Samuel Haughton, Fellow of Trinity College, Dublin, in acknowledgment of his contributions to various branches of scientific knowledge, more especially to that of scientific anatomy."

REVIEWS.

On the Operative Surgery of the Foot and Ankle-joint. By HENRY HANCOCK, President of the Royal College of Surgeons of England; Consulting Surgeon to Charing-cross Hospital. London: J. and A. Churchill. Pp. 476.

WHEN in 1865 Mr. Hancock was made Professor of Surgery to the Royal College of Surgeons, he undertook a course of lectures on the anatomy and surgery of the foot, part of which were at the time published in a somewhat incomplete form. These he now publishes, carefully revised and perfected. Mr. Hancock has long been held an authority on this subject, and undoubtedly the present publication only tends to confirm that opinion. The lectures are ten in number. The first merely deals with the anatomy of the foot as far as bones and ligaments are concerned. The second begins the operative surgery of the foot, and deals with perforating ulcer of the foot, and what Mr. Hancock calls tubercular disease of the foot,—not, however, tubercular in the ordinary sense of the word, but rather, we fancy, the disease now called fungus-foot. Lecture three treats of Syme's amputation, an operation much to the mind of Mr. Hancock; whilst that which succeeds deals with the various modifications of that operation, including Pirogoff's. The fifth lecture is devoted to the subastragaloid amputation of the foot, also known as Lignerolles' operation. Lecture six is on excision of the astragalus; seven on excision of the ankle-joint; eight also dealing with the same and compound dislocation of the ankle-joint. The ninth lecture deals with Chopart's operation; and the tenth with resection of the os calcis. After this comes a valuable appendix and a useful index. It will thus be seen that the subject is not a limited one; and Mr. Hancock does full justice to it.

The first chapter, as already said, is purely anatomical; but Mr. Hancock takes care to make this the basis of the later portions of his work. In the second chapter the part relating to perforating ulcer is exceedingly interesting, and to Mr. Hancock is mainly due the merit of making this curious malady known to the British medical profession. Some interesting cases of it are here recorded.

If there is one thing more than another which distinguishes Mr. Hancock's surgery, it is conservatism in the highest sense of the term. He is never tired of reiterating the sound maxim, "Save all you can," and in so doing he is careful to insist on the practicability of safely cutting through bones which many have dreaded to touch, and of opening joints which many have considered dangerous in the extreme to meddle with. He is also jealous for the honour of British surgeons, and rebukes the attempts which have been made to wrest their well-merited honours from them; though in this respect he is eminently fair, and strives to do equal justice to all.

The labour of collecting the statistics of the results of various operations must have been exceedingly great; but they will be duly valued by those who want to estimate aright the risks of various operations. Some of the operations here recorded are extremely ingenious, but none more so than that proposed by Mr. Hancock himself, which is well illustrated on page 213—it is, in fact, a kind of combination of the beauties of Pirogoff's and Lignerolles' operations. Equally ingenious is his modification of Chopart's operation.

Perhaps one of the most interesting chapters in the book is that relating to excision of the astragalus, and it is illustrated by an excellent drawing of a section of a foot from which the astragalus had been removed some time before death (which resulted from totally different causes) by Mr. Canton. This drawing, like the others in the book, is by Mr. Bellamy, and is exceedingly well done.

We should say that the volume is enriched by a great variety of cases, most of them original, and contributed by various gentlemen throughout the country. These are of course of very various degrees of merit, but they at all events serve to show the general esteem shown by the profession for the late President of the College. It would be invidious to select any as better than their neighbours, but we may refer to some by Mr. Samuel Hey, of Leeds, partly on account of the eminence of that gentleman as a surgeon, and partly because so little of his doings have been published. It would be quite impossible in this short notice to do full justice to such a volume; indeed, this would be hard to do in any notice, for it is chiefly as a book of reference that Mr. Hancock's

book will be used. The facts are too numerous to be grasped, but the spirit is excellent: that we have already tried to express, and, it is needless to say, with the highest approbation.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 27.

Dr. C. J. B. WILLIAMS, F.R.S., President, in the Chair.

Dr. EDWARD HEADLAM GREENHOW related the particulars of a case of Abdominal Aneurism successfully treated by Proximal Pressure of the Aorta. In the year 1864 Dr. William Murray, of Newcastle-on-Tyne, communicated to the Royal Medical and Chirurgical Society a "Case of Abdominal Aneurism cured by Proximal Pressure upon the Abdominal Aorta." The patient remained well for six years, and then died of a second aneurism. It was found that the remains of the original aneurism consisted merely of a fibrous mass, and that complete collateral circulation had been established by the enlargement of vessels both on the outside and inside of the abdominal cavity. Last year a similar case, cured by the same means, was communicated to the Society by Dr. Moxon and Mr. Durham, of Guy's Hospital. These are the only two such cases which have as yet been fully recorded; and the author trusted that the report of a third case would not be considered superfluous, more especially as in this latter some of the results of the compression of the aorta appeared to have an interest apart from that belonging to the cure of the aneurism. Christopher F., aged 28, warder in the House of Correction at Kendal, was admitted into the Middlesex Hospital, under Dr. Greenhow's care, on May 20, 1872. He was a strong-looking man, and his health had been good until December, 1868, when he was on board H.M.S. *Princess Charlotte* as an able-bodied seaman. Whilst drawing water from alongside he suddenly felt something give way in his abdomen. Was soon after invalided, and on his return home he obtained employment as warder. In December, 1871, he again began to suffer and lose strength. On admission, he complained of pain in the abdomen and loins, shooting downwards to the groins and thighs. A somewhat globular pulsating tumour, about the size of a large orange, was found in the abdomen, immediately above the umbilicus. It extended more to the right than to the left of the median line, and beat forcibly with an expanding lateral as well as with a forward impulse. Firm pressure over the aorta above the tumour, when the patient was sitting up, stopped the pulsation for the time being. The medical staff of the hospital having agreed with the author as to the nature of the tumour and the means to be attempted for its cure, Mr. Hulke undertook to apply the tourniquet. May 25: Chloroform having been administered, Lister's tourniquet was screwed down between the tumour and the xiphoid cartilage until pulsation ceased both in the tumour itself and in the femoral arteries. On account of vomiting the pressure was withdrawn after three-quarters of an hour. The impulse remained as before, but the tumour felt rather more solid. 27th: When the patient was thoroughly under the influence of chloroform, Mr. Hulke applied the tourniquet with the same effect as before, and with two brief intermissions the pressure was maintained during four hours. After some time there appeared marked lividity of the lower extremities, which, as well as the lower half of the abdomen became quite cold. Temperature taken between the toes was 90°. Sphygmographic tracings of the radial pulse showed increased arterial tension. The breathing became very shallow and gasping. Pulse from 100 to 120, respiration from 44 to 56 per minute. The removal of the pressure was immediately followed by the subsidence of all these symytoms. The pulsation in the tumour was decreased, the forward impulse being much less forcible and the lateral expansion omly slight. For several days the patient suffered much from vomiting, the vomit containing altered blood, and from pain, numbness and coldness in the lower extremities, more particularly in the right limb, which gradually disappeared as the circulation became re-established. The impulse in the aneurism very greatly decreased, until on June 10 it could scarcely be felt, and the patient was allowed to sit up for a short time. June 25: The pulsation in the tumour having decidedly increased again in force during the previous week, the tourniquet was once more applied, so as thoroughly to compress the aorta, and the pressure was maintained for three hours almost continuously. The pulse and breathing showed the same characters as during the former operation, and there was the same coldness of the lower extremities and of the right more than the left foot. When the tourniquet was removed there was forward pulsation of the tumour, but no lateral expansion, and the tumour felt firmer and more solid. During several days the vomiting and coldness of the extremities continued as before. The urine was albuminous for two days. The impulse in the aneurism continued to diminish until July 1, when it could not be seen, and scarcely felt. On July 14 the patient was well enough to be discharged home to Kendal. September 20: In accordance with Dr. Greenhow's request, the man returned to show himself. No pulsation was found in the seat of the aneurism, nor was there any distinct tumour remaining; but above the umbilicus, to the right of the median line, was an undefined somewhat movable hardness. No pulsation could be detected in the aorta from an inch above the umbilicus downwards, nor in the femoral, popliteal, or anterior tibial arteries. Mr. Noble, of Kendal, who sent the patient to the hospital, wrote to Dr. Greenhow quite recently to say that the man was in perfect health. It would appear certain from this case, taken in conjunction with Dr. Moxon's and Mr. Durham's, that the process of cure by coagulation of blood in the sac of the aneurism is not necessarily a rapid process, as it was in Dr. Murray's case, but may last during many days, and sometimes even for weeks. The direct effects of the pressure upon the pulse and respiration were very remarkable, and not less so the secondary effects of the disturbed circulation on the stomach and kidneys, producing the hæmatemesis and albuminuria which followed the operations. The occurrence of such symptoms would seem to suggest that the intense arterial distension caused by the treatment might be attended by serious danger to persons suffering from any kind of organic disease, especially degenerative disease of the arteries.

Dr. MURRAY (of Newcastle) said that the plan pursued by Dr. Greenhow and Dr. Moxon was in accordance with his views, and confirmed them. In the cases he had seen when coagulation once set in it proceeded very rapidly, and was complete. He referred as an example to a case of iliac aneurism under Dr. Heath, of Newcastle. The case had not yet been fully reported, but pressure was maintained for ten hours with no result; the pulsation was as free as before; the tourniquet was re-applied for twenty minutes, and at the end of that time the tumour was quite solid, and never pulsated again. In other cases (about six) the coagulation was within an hour; in his own case after three hours. He felt convinced that the coagulation occurred rapidly in those cases, and a long period, as fourteen days, was not needed to complete the operation.

The PRESIDENT thought that the rapidity of coagulation would differ in different individuals; also, that the tendency of chloroform to produce liquidity of the blood should be considered. It was probable that some other anæsthetic might be employed with greater advantage.

Mr. HOLMES did not think that the operation was free from danger; in some cases it had been followed by death. Mechanical lesions of the gravest kind were often produced. He did not think the treatment should be employed in all cases. If an aneurism was rapidly enlarging it might be resorted to; but it was beyond justifiable surgery to do so if milder means would do. There was distinct evidence of injury from the violent pressure on veins. In three cases death had occurred. Then the prolonged application of chloroform was in itself a source of great danger. He thought a surgeon ought to consider if abdominal aneurism could not be cured by milder means. Low diet and rest often ameliorated. In other cases it was amenable to slow pressure, as by a pad or finger for a portion of the day, and without the danger attending more forcible pressure. The latter was more efficient as well as more dangerous. Though the three successful cases had been reported, yet there were others which had been unsuccessful. As to the coagulation of the blood, he thought there were two ways in which it might occur—firstly, gradually, as shown in Mr. Durham's and Dr. Moxon's case, in one month; secondly, by the impaction of a clot in the artery, as in Dr. Murray's case.

Mr. HENRY LEE said that it was stated in the paper that the urine was albuminous, and it was explained as due to increased pressure on the vessels of the kidney. This he could not understand, as the pressure was not applied below the origin of the renal arteries.

Dr. Greenhow said that, with regard to Dr. Murray's remark on slow coagulation, he could not see where there had been any failure in the management of the case tending to produce this. The pulse was quite stopped in the femorals on the application of the tourniquet, and continued so as long as the pressure was maintained. He was not aware of unsuccessful cases treated in this way; as he had stated in the paper, he thought such treatment would be very dangerous in persons suffering from organic disease. He thought the danger in treating abdominal or any aneurism below the aorta by means of Lister's tourniquet arose from shutting off the flow of blood to the lower half of the body. The tension in the arteries of the upper half of the body was extreme. He thought the hæmatemesis was due to the hyperæmia or over-tension of the arteries, not the veins, of the stomach; and that the albumen in the urine was due to the same cause. The man recovered from these in a few days.

Dr. George Johnson read a paper "On the Etiology of Albuminuria as deduced from an Analysis of 200 consecutive Cases." About ten years since the author had made a tabular analysis of nearly 300 cases of albuminuria. In each case special inquiry had been made as to the probable exciting cause of the malady, and in the tabular statement of the main points in the history of these cases one column is set apart for the etiology of the disease. Some recent discussion on the influence of alcohol in exciting diseases of the kidney had led him to refer to his analysis of cases for evidence bearing upon this question; nine-tenths of the cases analysed belonging to the class of hospital or dispensary patients. Taking 200 consecutive cases, it is shown that the various etiological influences, single and in combination, come under no fewer than thirty-three heads. It is also shown that scarlet fever, intemperance, cold, wet, and gout—these influences, either single or combined, account for 120 cases out of 200, or 60 per cent. Thus, albuminuria was probably the result of scarlet fever in 24 out of 200 cases, or 12 per cent.; of intemperance in 28, or 14 per cent.; of intemperance and gout in 12, or 6 per cent.; of intemperance and cold in 12, or 6 per cent.; of gout in 8, or 4 per cent.; of cold and wet in 23, or 11·5 per cent.; of cold in 13, or 6·5 per cent. It is shown that intemperance, either alone or combined with other influences, was the probable cause of albuminuria in 58 out of 200 cases, or 29 per cent. Of these 58 cases, in 28 intemperance was believed to be the sole cause; in 12 intemperance with gout, in 12 with cold, in 4 with syphilis, and in two with lead. Cold, either alone or combined with other influences, was the exciting cause of albuminuria in 25 per cent. of the cases. In 6·5 per cent. cold alone is believed to have been the cause of albuminuria, in 11·5 per cent. cold and wet, in 6 per cent. cold and intemperance, and in 1 per cent. cold and fatigue. It appears, then, that albuminuria was associated with scarlet fever in 12 per cent. out of 200 cases, with exposure to cold and wet in 25 per cent., and with intemperance in 29 per cent. The following table shows the proportion per cent. of deaths, recoveries, and of persistent albuminuria in cases resulting from—(1) scarlet fever, (2) exposure to cold and wet, (3) habits of intemperance.

	Scarlet Fever.	Cold and Wet.	Intemperance.
Deaths..	45·83	.. 27·5	.. 67·23
Recoveries	50·	.. 38·88	.. 10·36
Persistent albuminuria	4·16	.. 33·33	.. 22·41

Of the 58 intemperate patients, 11 were women, and 47 were men. In 5 cases out of the 47 men the occupation had not been recorded. Of the 42 men whose occupations had been noted, 5 were waiters. The remaining 37 intemperate men had no fewer than thirty different occupations, not one of them connected with the manufacture, sale, or distribution of alcoholic liquors. Evidently, then, it is not right to assume that men in the class of hospital patients who are not engaged in the liquor trade, and not notorious drunkards, may be placed in a "non-alcoholic" class. The excess of Bright's disease amongst males, as compared with females, is explained by the fact that as a rule men are more intemperate and more exposed to cold and wet than women. Amongst the cases analysed, 76 per cent. were males, and 24 per cent. females. Out of the 58 cases associated with intemperance, 83 per cent. were males; and of the 36 resulting from cold and wet, 77 per cent. were males. In addition to the causes of albuminuria before referred to, the following influences appear to have been causative, the figures showing the proportion per cent. in a total of 200 cases:—Typhus fever, 4; typhoid fever, 1; erysipelas, 1; pyæmia, 1; measles, 1; rheumatic fever, 1; purpura, ·1; cholera, ·5; hooping-cough, ·5; diabetes, ·5; syphilis, 3; phthisis, 2; venereal excesses, 5; poverty and hard work, 2·5; emphysema and bronchitis, 3·5; morbus cordis, 3·5; scrofulous disease of bones or joints, 2·5; scrofulous abscess, ·5; pneumonia, ·5; lead, 1; tropical climate, ·5; hydrophobia, ·5; mental anxiety, 1·5; pregnancy, 2·5. The result of the author's later experience would be to add to this long list of causes of albuminuria, particular reference being made to diphtheria, relapsing fever, malarious fevers, yellow fever, and to certain forms of dyspepsia, either with or without an excessive consumption of alcohol or of tobacco, as causative of albuminuria and degeneration of the kidney.

Dr. Dickinson said much caution was necessary in tracing albuminuria to drink. Both albuminuria and the use of alcohol were so common in this country, that it was inevitable that a considerable proportion of those so suffering might be, unless drink was a sure preventive, charged with intemperance. This would happen with any disease which affected adults; with a parasitic affection, for instance, like scabies, a large number of the sufferers could undoubtedly be convicted of alcoholic excess. Any such tabulations as those just given, compiled with the object of tracing renal disease to drink, must be received with much hesitation. The figures implied no more than that of a certain number of persons so many could be accused of the liberal use of alcohol. Looking at the statistical details, it would be seen that intemperance was assigned as a cause in 29 per cent. (more than one-fourth of all the cases)—an incredible proportion, considering how many women and children must belong to the number. According to that, intemperance was a more common cause of albuminuria than scarlatina, cold, or any other cause. Other causes had obviously been underrated; phthisis was credited with only 2 per cent., syphilis with 3 per cent. The cases of lardaceous disease, so common in hospital practice, amounted altogether, so far as could be judged by the statement, to only 8 per cent. Diseases of the heart, frequently as such disturbances made the urine albuminous (and the paper dealt only with alteration of the secretion), caused albuminuria only in 3 per cent. Lead was credited with only 1 per cent.—a startling conclusion, for lead was the most injurious of all foreign bodies as a cause of renal disease. It was the most common cause of granular degeneration of the kidneys. Of forty-five men, hospital patients, taken without selection save that they all died with granular degeneration, ten were workers with lead. Then, on the reverse side, of workers with lead dying of all causes, accident or disease, during seven years, more than a half had granular kidneys. This connexion was well known to those who had to do with hospital patients, and yet was represented by only 1 per cent. in the tables. Thus other causes appeared to have been dwarfed so as to give greater prominence to alcohol. Then Dr. Johnson had examined 200 cases, and had found the cause in every instance. A great number of these must have been granular degeneration, the result of hereditary, climatic, senile, or other obscure influences. He had examined cases, and could come to no conclusion as to the cause in more than a half. Again, if alcohol had this overbearing influence, then all over the world renal disease ought to be more or less common; but this was not found to be so; it varied according to climatic influences. From the army returns we could tell the amount of renal disease in our garrisons throughout the world; and albuminuria did not depend so much on alcohol as on climate. It was a disease of temperate climates, and those chiefly where the temperature was most variable. Not temperance but temperature gave immunity. Again, renal disease should preponderate in those cases where there was a peculiar access to alcohol; but it was not found to do so. In a paper he had read before the Society he had endeavoured to prove this. Dr. Johnson had taken exception to his headings of alcoholic and non-alcoholic with reference to the two classes, as though he had inferred that the use of liquor was all on one side. He had only wished to show that there was a sufficient excess of liquor on one side to influence the pathology. If this were denied, he would like to ask why potmen, draymen, etc., died in great numbers between thirty and forty years of age? why they suffered as they did from disease of the nervous system? why their serous inflammations suppurated? why their wounds refused to heal? and, above all, why they had cirrhosis of the liver nearly three times as often as the class with which they were compared? The fact must be evident to everyone that those persons who drank more than others suffered more from it, and might be fairly used to supply some information as to its consequences. The comparison was not so neat as one between drunkards and teetotalers. He did not use that, not

being able to get at it. In conclusion, he thought it clear that alcoholic drinks caused a red enlargement of the kidney, and had a certain effect in bringing on granular degeneration—a change analogous to cirrhosis of the liver; but the effect of drink in this respect was more marked upon the liver. Alcohol sometimes, but rarely, set up acute tubal nephritis. It had no power to cause lardaceous disease. The effect of alcohol upon the kidneys had been very much exaggerated, and never on more insufficient evidence than in the paper just read.

Mr. Henry Lee did not think the discussion should be altogether on the side of the physicians. Surgeons also saw something of albuminuria, and that independently of disease of the kidney, as from congestion of the urinary organs albumen in urine resulted. He remembered a case some years ago of a patient who was supposed to have disease of the kidney. A consultation was held, and the man was sent to India to die of chronic albuminuria. He returned after a time, and died of apoplexy. There was no disease of the kidney, but an intussusception of the ureter; the albumen was persistent. Then albumen was often met with from inflammation of organs. With regard to alcohol, he thought many things might do quite as much harm as the balsams, turpentine, and such ingredients which are found in gin, etc.

Mr. Callender said he would like to ask Dr. Johnson about the prevalence of albuminuria among Mussulmans. It was said to be exceedingly rare. He thought this might have some bearing on the question, as they were by practice teetotalers.

Sir William Gull said he was astonished that the Society should be discussing the causes of albuminuria; he looked upon it as a sign of retrogression. He was quite surprised to hear albuminuria talked about as though it could be settled by statistics. Dr. Johnson said he had ascertained the cause in 200 cases. What Dr. Dickinson had said was fully the case; in two cases out of five the cause could not be found. It was frequent in boys above puberty, but it was not found out because it was not looked for. But in weak, delicate patients the urine might be loaded with albumen; what was the cause he could not say. Then, again, in men over fifty-five, in the disease he had brought forward, "arterio-capillary fibrosis," the causes could not be made out; he believed it was due to changes in the vessels quite apart from the kidney, and not from alcohol, cold, etc. Then cold was said to be a cause; but who had not had a cold? And because a man got a cold did he get albuminuria? He thought such statements too vague. We ought to consider the forms of the kidney disease, the state of the urine, and such-like; for although albumen was present in the urine, yet, as long as the salts of the urine were secreted, health was maintained. This must be thought of; the causes were not known, and were often very remote.

Dr. George Johnson, in reply, said that Dr. Dickinson thought the greater part of the paper was directed against him; it was against what he thought was the necessary conclusion from Dr. Dickinson's paper. Briefly, Dr. Dickinson did this: he took the post-mortem records for thirty years, and divided them into those who had traded in, or had to do with liquor, and those who had not. These were not general patients, but those who had died in hospital. Intemperance was said to be more among the first than the latter, who were not in the liquor trade. But among hospital patients intemperance was very common; nearly three-fourths were intemperate, and their diseases were dependent upon that. So he did not think it was sufficient to take the post-mortem examination, but the habits of each patient should be inquired into, and not assumed that men not in the liquor trade had not had access to alcohol. Then Dr. Dickinson was astonished at the small number of cases from heart disase. The two were often associated, but heart disease was more often the consequence than the cause of Bright's disease; the renal disease the primary, and the heart disease the secondary. So with regard to lead: many men had been exposed to it; but painters were often drinkers, so he attributed to alcohol what Dr. Dickinson said was due to lead. It was hasty to assume that every plumber who got kidney disease got it through lead, and not through alcohol. Sir William Gull was astonished that albuminuria should be discussed there to-night; he had only brought forward the exciting causes, so as to afford trustworthy results. Then he was surprised that the cause had been discovered in so many cases; he had only taken 200 cases in which a cause could be found, and had omitted the others. As to the cause of albuminuria in the young subjects of whom Sir William Gull spoke, it could be often traced back to scarlet fever or measles. Sir William Gull thought cold could not be a cause of albuminuria. But why not, if it caused pneumonia? On this point Dr. Dickinson and Sir William Gull were opposed to each other; for Dr. Dickinson maintained that cold had much more to do with the causation of the disease than alcohol.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, June 4.

E. J. Tilt, M.D., President, in the Chair.

Thomas E. Jones, M.R.C.S., Wrexham, and James Stewart, M.D., Whitby, were elected fellows of the Society.

The President said: It is my painful duty, gentlemen, to inform you of the sudden death of Dr. Tyler Smith, which occurred last Monday. You are all of you well acquainted with his earnest devotion to the interests of this Society, and you will fully realise the loss it has sustained. Some time hence I shall have to tell you what he did for science and for us; I have only now to add that your Council has decided that we should at once give expression to our heartfelt sympathy for the widow and the relatives of our deceased founder, and I therefore call on Dr. Barnes to read the resolution he has been asked to move.

Dr. Barnes said the Society would be anxious to record in the most emphatic manner possible its sense of the loss they and obstetric science have sustained by the death of Dr. Tyler Smith. He would not obtrude any reflections upon his conspicuous merit as an author and practitioner; he would simply refer to the deep debt which the Society owed to him for its foundation, for his constant work in scientific memoirs, in debate, and in the administration of its affairs. His conduct towards the Society had throughout been directed by the single object of promoting its welfare. Thus, at its foundation he had postponed his own pre-eminent claim to be the first president, in order to secure for it at starting the prestige of Dr. Rigby's popularity and reputation. Not only had he done this, but he had strenuously promoted the re-election of Dr. Rigby for a third year. He concluded by moving the following resolution:—"That the Obstetrical Society of London having learned with deep regret the death of Dr. Tyler Smith, its founder, hereby records its sense of the loss this event has occasioned to this Society, to science and to humanity, and respectfully expresses its heartfelt sympathy with his widow and family in their affliction."

Dr. Madge seconded the resolution, and after speaking in very high terms of Dr. Tyler Smith's abilities and attainments, he mentioned some personal experiences and recollections as instances of the tact and firmness, combined with much kindness and consideration for the feelings of others, with which Dr. Tyler Smith when president was accustomed to preside over the meetings of this Society.

After passing this resolution, the Society, desirous to show in the most emphatic manner its respect for the memory of its founder, postponed its ordinary business and adjourned.

OBITUARY.

JAMES MILL, L.R.C.S. Edin.

By the death of Mr. James Mill, of Thurso, Caithness, we have lost one of our most devoted practitioners of Medicine. He studied at the University of Edinburgh, and when only nineteen became a Licentiate of the Royal College of Surgeons of that city. During his period of study he was apprenticed to Dr. Goodsir, of Anstruther (father of the late Professor Goodsir, of Edinburgh), who always regarded the late Mr. Mill as a brother. In 1827 he went to Wick, where for twenty years he practised his profession with great success. In 1848 he received a requisition from the inhabitants of Thurso to become their medical man, with which he complied; and for the last twenty-five years he has worked among them with an ardour and zeal seldom equalled and rarely excelled. He was Surgeon to the Halkirk Poorhouse, as also to three neighbouring parishes. His district extended over upwards of seventy miles, and whether by day or night, whatever the distance, he was always ready to go at the call of the suffering, and thus rendered himself, in every sense of the words, "the beloved physician." Not only did he devote himself to his practice, but his spare time was given to advance the interests of the town in which

he lived. He was elected chief magistrate in 1852. He retired from this office in 1860, but in 1865 he was re-elected, and for some years he acted as Sheriff-depute, which duty he always discharged with a liberal spirit and a desire for the good of his fellow-men. Last year the public showed their appreciation of his services by presenting him with a handsome carriage, timepiece, and silver tea-service. For the last six months his health has been failing; serious gastric symptoms evidenced themselves, and in spite of all the kind endeavours of his brother-practitioners both in Edinburgh and Thurso, he sank on the 27th ult., deeply regretted by everyone who had the honour of his acquaintance, and mourned as a friend and brother by those who had the privilege of his medical services. He was honoured by receiving a public funeral, the largest ever seen in Caithness, the coffin being borne shoulder-high by the rifle volunteers of Thurso, to whom the deceased was Surgeon.

MORITZ HEINRICH ROMBERG.

This distinguished Berlin professor was born at Meiningen in 1795, but at his father's death (in early childhood) came with his mother to Berlin, and received his education in the Gymnasia and University of that city. He received his doctor's degree in 1817, and in 1820 received an appointment as physician to the poor, which he held during twenty-five years. In 1830 he first commenced, as *privat-docens*, the academical career which proved so beneficial to the university. He was made extraordinary professor in 1838, and in 1840 became the director of the University Polyclinic, which he raised to so universal a reputation. He received an ordinary professorship in 1845, and continued to fulfil its duties with pride and honour until his death, except when impeded by gout, to which he became subject after his sixtieth year. The jubilee of the fiftieth year of his doctorate, held in 1867, was a most memorable event, calling forth as it did manifestations of honour and affection from former pupils and fellow-professors from all parts of Germany, and even beyond its limits. A few years before his death symptoms of disease of the heart manifested themselves, but did not prevent his fulfilling his duties until eleven weeks before his death, which took place on June 16, in the 77th year of his age.

It was, Dr. Waldenburg observes in a highly appreciative obituary notice in the Berlin *Wochenschrift*, in the province of the pathology of the nervous system that Romberg's celebrity was attained, founding it on the "epoch-making" discoveries of Charles Bell and John Müller in neuro-physiology. As the creator of this his name will always live in the annals of Medicine, and his "Lehrbuch der Nervenkrankheiten" is a classic monument of German medical science, which, as a source of instruction, is inexhaustible. Earnest intellectual work excites in others similar activity; and the various other provinces of knowledge will under the same discipline not long remain in the background, if the pulsations of a reinvigorated life have begun to manifest themselves. In this way the impulse of Romberg's creation excited productive emulation in other branches of practical medicine, constantly calling new productions into existence; and if a justifiable pride may be felt at the present position of German medical science—which during the first third of the present century was so incomplete and powerless, all of importance being derived from abroad,—it should never be forgotten that, before all, this is due to those men who first came forward, Romberg the most vigorous among them, with good original work.

EDMOND WATERS, L.R.C.P. Edin., etc.

We regret to record the death of this gentleman, which resulted from an accident. After making a call at a neighbouring village on Monday last, he was about to remount his horse, and had placed his hand upon the saddle for that purpose, when the animal suddenly started up, throwing the unfortunate gentleman to the ground with such violence that he died the next morning. Dr. Waters filled several public appointments. He was educated at University College.

SURGEON W. P. PALIOLOGUS

Died at Isleworth on the 5th inst. He was on the half-pay list. He entered the army September 1, 1854; became surgeon October 20, 1869, and retired upon half-pay April 13, 1872. He served with the 34th Regiment in the Indian campaign of 1857 and 1858, including the actions of November 26, 27, and 28, 1857, at Cawnpore, siege and capture of Lucknow, and relief of Azinghur; medal with clasp.

MEDICAL NEWS.

King and Queen's College of Physicians in Ireland.—At examination meetings of the College held on Tuesday, Wednesday, and Thursday, July 8, 9, and 10, the licence to practise Medicine was granted to—

Atkin, Nicholas Edward.
Brereton, Joshua George.
Crowe, John Wainwright.
Keelan, Peter.
Loughnan, Michael.
M'Ganu, James.
Richardson, Henry Anthony Wills.

The Midwifery diploma was granted to—

Atkin, Nicholas Edward.
Crowe, John Wainwright.
Keelan, Peter.
Loughnan, Michael.
Richardson, Henry Anthony Wills.

It is proposed to elect three Fellows of the King and Queen's College of Physicians on St. Luke's-day, October 18. Five candidates have entered the lists to compete for the three fellowships—namely, Drs. Hawtrey Benson, Robert Cryan, George F. Duffey, Thomas More Madden, and J. W. Moore.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in Anatomy and Physiology, at a meeting of the Court of Examiners on the 15th inst., and when eligible will be admitted to the pass examination, viz.:—

Alsop, Thomas O. F., student of the Edinburgh School.
Clippingdale, Samuel D., of the London Hospital.
Cornilliac, John J. P., of the Dublin School.
Davies, Francis Thomas, of the Glasgow School.
Evans, Thomas D. F., of the Edinburgh School.
Howe, Lucien, of the New York School.
Jackson, George H., of the Liverpool School.
Job, John, of the London Hospital.
Mackenzie, John, of the Bristol School.
Martin, John H., of the Edinburgh School.
Morshead, Ernest G. A., of University College.
Needham, Joseph, of the London Hospital.
Rygate, Brougham R., of the London Hospital.
Smyth, John, of the Belfast School.
Stone, Herbert Stanley, of the Edinburgh School.
Wright, Newton W., of the Manchester School.

The following passed on the 16th inst., viz.:—

Ayres, James Wm., student of the Charing-cross and Guy's Hospitals.
Fox, Thomas C., of the University College.
Greenwood, Charles, of the University College.
Griffith, Thomas N., of the University College.
Harvey, Thomas P., of the London Hospital.
Hunter, Christian B., of the University College.
Jones, John D., of the University College.
Kesteven, Leighton, of St. Bartholomew's Hospital.
Moore, Charles A., of St. Bartholomew's Hospital.
Norman, Walter, of the Birmingham School.
Orchard, Thomas N., of the Aberdeen School.
Pearson, Alfred W., of the Birmingham School.
Sankey, Herbert R. O., of the University College.
Taunton, William W., of the University College.
Thompson, Harold, of St. Bartholomew's Hospital.
Tweedale, James T., of the Manchester School.

The following passed on the 17th inst., viz.:—

Barlow, Thomas C., student of Guy's Hospital.
Barrow, Lancelot A., of St. Bartholomew's Hospital.
Bass, Charles W., of University College.
Bernays, Herbert L., of St. Thomas's Hospital.
Brenchley, Algernon D., of Guy's Hospital.
Coates, William H., of Guy's Hospital.
Coley, Frederic C., of Guy's Hospital.
Collins, Floyd, of University College.
Gardner, Arthur J., of the Leeds School.
Gibbons, Robert A., of the Edinburgh School.
Jones, Charles A., of St. Bartholomew's Hospital.
Lacy, A. G., of Guy's Hospital.
Lequesne, Edwin J., of St. Bartholomew's Hospital.
Lilley, George H., of University College.
Maples, Reginald, of St. Thomas's Hospital.
Miskelly, William J., of the Liverpool School.
Norman, John Edward, of the Aberdeen School.
Palmer, Francis C., of the Bristol School.
Parkinson, George W., of St. Bartholomew's Hospital.
Pearce, Herbert D., of St. Bartholomew's Hospital.
Routh, Alfred C., of Guy's Hospital.
Sykes, John F. J., of Guy's Hospital.
Thomas, John H., of University College.
Traill, Mark W., of University College.
Watteville, Armand de, Baron, of the University College.

Apothecaries' Hall.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a Certificate to practise, on Thursday, July 10:

Hudson, John, Horsforth, Leeds.

The following gentlemen also on the same day passed their primary professional examination:—

Cree, William Edward, Middlesex Hospital.
Davies, Elijah Knox, Middlesex Hospital.
Dry, Herbert Bernard, Guy's Hospital.
Newton, Edward Shackfield, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALEXANDER, JOHN, L.R.C.P. Edin., L.R.C.S. Edin., L.M.—Medical Officer to the Parish of Watten, Golspie, N.B.

AROLES, FRANK, M.R.C.P., M.R.C.S.—Medical Officer to the Schools at Leytonstone.

BRICKWELL, BENJAMIN ARTHUR, M.R.C.S., L.S.A.—Medical Officer of Health for the Rural Sanitary District, Amersham, Bucks.

CORBY, HENRY, A.B., M.D., M.C. Queen's Univ. Ire., L.A.H.I.—Resident Surgeon at the North Charitable Infirmary, Cork.

HAMILTON, A. MACLEOD S., M.D., M.R.C.S. Eng.—Assistant Medical Officer to the Workhouse, Brownlow-hill, Liverpool, *vice* Armand Bernard, L.R.C.S. Edin. M.B. Dub. Univ.

LAVER, ARTHUR H., M.R.C.S., L.S.A.—House-Surgeon at Sheffield General Infirmary, *vice* Mr. Arthur Hallam, resigned.

MACDONALD, JOHN, M.B. Glasg., C.M.—Parochial Medical Officer to Drymen and West of Stirlingshire.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—The undermentioned officers have been promoted to the rank of Staff-Surgeon of the second class in her Majesty's Fleet, with seniority of the 7th inst. Henry Ricard, William Edward Dillon, George Mair, M.D., John Stephen Dobbyn, John Mulvany, John Lambert. Thomas A. O'Donnell, Surgeon to the *Rattlesnake*, additional for disposal. Septimus Evans, Surgeon, to the *Royal Adelaide*; Henry Beaumont, Surgeon, to the *Beacon;* John Mackie, Surgeon, to the *Ariel;* William A. O'Connor, M.D., Surgeon, to the *Cambridge*. S. Fisher, Staff Surgeon, second class, to the *Rattlesnake;* John T. W. Bremner, Staff Surgeon, to the *Duncan*, additional for services at Deal; Samuel S. D. Wells, Staff Surgeon, to Haulbowline Hospital; James N. Dick, Staff Surgeon, to the *Lord Warden*.

WAR OFFICE.—Army Hospital Corps: Apothecary to the Forces Ferdinand Fernande, to be Captain of Orderlies. Medical Department: Surgeon Edward Thomas Palmer is placed upon temporary half-pay.

BIRTHS.

CLOTHIER.—On July 9, at 7, Ridgmont-terrace, Highgate, the wife of H. Clothier, M.D. Lond., of a son.

LONGMORE.—On July 8, at Woolston, the wife of Surgeon-General T. Longmore, C.B., of a son.

PEARCE.—On July 7, at the Manor House, Brixton-rise, S.W., the wife of Chaning Pearce, M.B., M.R.C.S., L.S.A., of a daughter (Amelia Stancomb).

ROBERTS.—On July 10, at Eastbourne, the wife of Bransby Roberts, L.K.Q.C.P., M.R.C.S. Eng., L.S.A., of a daughter.

MARRIAGES.

AUSTIN—VINE.—On July 9, at St. Martin's-in-the-Fields, John Edward Austin, eldest son of James Austin, Esq., of Glastonbury Abbey, Somersetshire, to Ada Harriet, third daughter of George J. Vine, M.D., of 3, Henrietta-street, Covent-garden, W.C.

BLACKWOOD—DAVEY.—On June 10, at St. James's Church, Lahore, India, Captain and Bt.-Major G. F. Blackwood, Royal Horse Artillery, to Madeline Grantham, daughter of J. G. Davey, M.D., Northwoods, Gloucester.

CASSIDY—ANGUS.—On July 8, at the parish church, Sandhurst, Berks, David M. Cassidy, M.D., Broadmoor, to Helen, elder daughter of the late James Angus, Esq., of Inverkeithing, Fife.

FENTON—MACKAY.—On July 9, at St. George's Church, Kensington, Frank John, eldest son of John Fenton, M.D., to Anne Julia, third daughter of the late Hugh Mackay, Esq., of Liverpool and Quebec.

HINGSTON—HINGSTON.—On July 8, at St. Andrew's Church, Plymouth, George, son of Alfred Hingston, Esq., to Clara Gertrude, daughter of the late Charles Hingstou, M.D., of Seven Trees, Plymouth.

ROBERTS—THORNDIKE.—On July 3, at St. Simon's, Southsea, Warden H. E. W. Roberts, Assistant-Paymaster R.N. (Retired List), eldest son of the late John Isbell Warden Roberts, Surgeon R.N., to Diana E., youngest daughter of the late Lieut. Charles Alexander Thorndike, R.N.

ROMF-FIRTH.—On July 10, at the parish church, Stone, James Romf, Esq., of Stone, to Ellen, youngest daughter of the late John Firth, M.R.C.S. Eng., L.S.A., of Macclesfield.

SMART—BRYANT.—On July 15, at St. James's, Paddingtou, R. Lynn Smart, Lieutenant R.N., H.M.S. *Excellent*, son of the Rev. Prebendary Smart, rector of Burghfield, to Caroline Wentworth, youngest daughter of Walter Bryant, M.R.C.P. Edin., F.R.C.S. Eng., L.S.A., of 23A, Sussex-square, Hyde-park, W., and Highwoods, Burghfield, Berks.

DEATHS.

BRAMLEY, EMILY JANE, wife of Lawrence Bramley, F.R.C.S. Eng., L.S.A., Halifax, on July 9.

BROUGHAM, CHARLOTTE, widow of Stephen Brougham, M.R.C.S. Eng., L.S.A., at Falmouth, on July 12, aged 71.

HAMMOND, JANE, wife of George Hammond, M.R.C.S. Eng., L.S.A., Irthlingborough, Northamptonshire, and relict of George Fletcher, Esq., surgeon, Croydon, Surrey, at the residence of her brother, W. G. Marshall, F.R.C.S. Eng., L.S.A., Colney Hatch, on July 11.

LASSETTER, RICHARD, M.R.C.S. Eng., L.S.A., at Bramshall, near Uttoxeter, on July 13, aged 67.

MARTIN, EMMELINE HARRIET, only daughter of the late Charles Martin, of Twickenham, Middlesex, aud niece of the late Thomas Martin, Esq., Solicitor, Havant, Hants, at Havant.

PRIDHAM, THOMAS LAWRENCE, M.R.C.S. Eng., L.S.A., J.P., late Coroner for the Borough of Bideford, at his residence, Hyefield, Bideford, North Devon, on July 11, aged 70.

TODD, ARMSTRONG, M.B.T.C.D., youngest son of the late Charles H. Todd, Esq., Professor of Surgery, R.C.S.I., on June 3.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM, BOROUGH OF.—Surgeon to the Borough Prison. Applications, with testimonials, to Messrs. Gem and Hebbert, Magistrates' Clerk's Office, Moor-street, Birmingham, on or before July 21.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Candidates must be legally qualified. Applications, with testimonials, to the House Governor and Secretary, on or before July 26.

BOURNEMOUTH DISPENSARY.—Resident Surgeon. Candidates must b duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

BRADFORD INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to W. C. Woodcock, Secretary, 65, Market-street, Bradford, on or before August 4.

CHARING-CROSS HOSPITAL.—Assistant-Physician. Candidates must possess a degree from one of the Universities recognised by the General Medical Council, and be Fellows of the Royal College of Physicians of London. Applications, with testimonials, to Henry Woolcott, Esq., Secretary, on or before July 22.

CHESTER, TARPORLEY, &c.—Medical Officer of Health. Candidates must be legally qualified medical practitioners, and registered under the Medical Act of 1858. Applications, with testimonials, to Mr. Walker, Town Clerk, Chester, on or before July 24.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to John Binks, Esq., Hon. Sec., Wakefield, on or before July 21.

DERBY COUNTY ASYLUM.—Assistant Medical Officer. Candidates must be duly qualified in Medicine and Surgery. Applications, with testimonials, to John Barber, County Lunatic Asylum, Mickleover, Derby.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Applications, with testimonials, to the Secretary, 4, Victoria-street, Derby.

KING'S COLLEGE, LONDON.—Chair of Anatomy. Applications, with testimonials, to the Council.

KNIGHTON UNION.—Medical Officer for the Llanbister District. Candidates must be legally qualified medical practitioners. Applications, with testimonials, to Edward Hooper Deacon, Clerk to the Guardians, Knighton, Radnorshire, before August 2.

LEICESTER INFIRMARY AND FEVER HOUSE.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, 24, Friar-lane, Leicester, on or before August 4.

LONDON TEMPERANCE HOSPITAL.—Visiting Physician and Visiting Surgeon. Candidates must be total abstainers. Applications, with testimonials, to Chairman of Managers, London Temperance Hospital, 112, Gower-street, W.C.

NORTH BIERLEY UNION.—Medical Officer of Health. Applications, with testimonials, to W. Lancaster, Esq., Solicitor, Bradford, Yorkshire, on or before August 4.

NORTH STAFFORDSHIRE INFIRMARY, HARTSHILL, STOKE-UPON-TRENT.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before July 23.

NORWICH DISPENSARY.—Resident Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Treasurer, R. Chambers, Esq., Catton House, Norwich.

NORTHUMBERLAND CO. LUNATIC ASYLUM, MORPETH.—Assistant Medical Officer. Candidates must be unmarried, and duly qualified and registered. Applications, with testimonials, to Mr. Wilson, Medical Superintendent, on or before July 19.

PENRITH UNION AND LOCAL BOARD OF HEALTH.—Medical Officer of Health. Candidates must be legally qualified medical practitioners aud registered under the Medical Act of 1858. Applications, with testimonials, to W. B. Arnison, Clerk to the Rural Sanitary Authority, Penrith, on or before July 19.

SAFFRON WALDEN AND DUNMOW UNIONS.—Medical Officer of Health. Candidates must be legally qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to Wm. Thurgood, Clerk to the Rural Sanitary Authority, Saffron Walden, on or before July 19.

SEAMEN'S HOSPITAL, GREENWICH.—Visiting Surgeon. Candidates must be F.R.C.S. Eng. Applications, with testimonials, to Kemball Cook, House-Governor and Secretary, on or before July 21.

STRATFORD-UPON-AVON, ALCESTER, AND EVESHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to J. C. Warden, Esq., 11, Guildford-street, Stratford-upon-Avon, on or before July 19.

THIRSK UNION.—Medical Officer. Candidates must be legally qualified medical practitioners and registered under the Medical Act of 1858. Applications, with testimonials, to C. McC. Swarbreck, Clerk, on or before July 24.

WANDSWORTH AND CLAPHAM UNION.—Resident Medical Officer for the Workhouse and Infirmary. Candidates must be duly qualified. Applications, with testimonials, to John Sanders, Clerk to the Guardians, New Wandsworth, on or before July 26.

WOBURN UNION, BEDFORDSHIRE.—Medical Officer for the Aspley Guise District. Candidates must possess both a medical and surgical qualification, and be registered under the Medical Act of 1858. Applications, with testimonials, to the Clerk to the Board of Guardians, Woburn, on or before July 31.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Physician's Assistant. Candidates must be graduates in Medicine of a British University, or be possessed of such medical qualifications as are satisfactory to the Medical Committee. Applications, with testimonials, to the Chairman of the Medical Committee, on or before August 9.

WREXHAM INFIRMARY AND DISPENSARY.—House-Surgeon. For particulars, apply to Mr. J. G. Buckton, Secretary, 9, High-street, Wrexham.

MR. R. H. LLOYD, Resident Medical Officer of Princes-road Workhouse, Lambeth, has resigned.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bideford Union.—The Bideford District is vacant; salary £30 per annum. Also the Workhouse; salary £25 per annum.

Manchester Township.—Mr. J. Westmorland has resigned the Cathedral District; salary 170 per annum.

Neath Union.—Mr. F. M. Russell has resigned the Eastern District; population 14,628; salary £45 per annum.

Norwich Union.—Mr. Wm. Summerhayes has resigned the Third District; population 10,262; salary £75 per annum.

Oswestry Incorporation.—The Llansilin District is vacant; area 18,173; population 3120; salary £52 per annum.

Woburn Union.—Mr. Thos. E. Trew has resigned the Aspley Guise District; area 7406; population 3334; salary £70 per annum.

APPOINTMENTS.

Dudley Union.—Thos. F. Higgs, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Dudley North District.

Goole Union.—Thos. H. Wagstaffe, M.R.C.S. Eng., L.S.A., to the Swineflect District.

Headington Union.—Thos. E. Blick, M.R.C.S. Eng., L.S.A., to the Otmoor District.

Hunslet Union.—Joseph M. Nicholson, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Workhouse.

Leeds Borough.—Mr. Thos. Fairley, F.C.S., as Analyst.

Liverpool Parish.—Armaud Beruard, M.D. Dub., L.R.C.S. Edin., to the Seventh District.

Lunesdale Union.—Wm. Wyllie, M.D., C.M. Univ. Glasg., to the Third and Fourth Districts.

Manchester Township.—John Williams, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Schools at Swinton; and Joseph Westmorland, M.R.C.S. Eng., L.S.A., to the St. Michael's District.

Portsea Island Union.—George Turner, L.R.C.P. Lond., M.R.C.S. Eng., as Analyst for the Borough of Portsmouth.

Preston Union.—Lawrence W. Spencer, M.R.C.S. Eng., L.R.C.P. Edin., to the Longton District.

Shipston-on-Stour Union.—Charles Wm. Morris, M.R.C.S. Eng., L.S.A., to the Campden and Mickleton District.

SUPERANNUATION ALLOWANCE.

Bath Union.—Mr. Wm. Hitchins, late Medical Officer for the Sixth District, has been granted a superannuation allowance of £26 13s. 4d. per annum, after fourteen years' service.

We are requested to announce that Mr. Lane's lecture on Tertiary Syphilis—unavoidably postponed on July 9—will be given at St. Mary's Medical School on Wednesday next, July 23, at 3 p.m.

The excellent health enjoyed by the troops on the march to Khiva the *Russian Invalide* attributes greatly to the substitution of tea for brandy as a regular beverage.

Cholera.—The telegram reports that the cases of cholera at Vienna are very few, and we may add that visitors there know nothing of it until they see the foreign papers.

Sensible Guardians.—Mr. Ward, a guardian, gave notice at the meeting of the Wakefield Board of Guardians, last week, that at their next meeting he should move that the Board refuse to prosecute any person or persons for neglecting to have their child vaccinated. This notice was received with laughter.

Insanitation in China.—There are cities in the North (says Mr. Harvey, of the China Inland Mission) where only one side of the main street can be used at once,—the other forming the receptacle for filth of all kinds, which in the hot summer sun bakes hard, when it is walked upon and becomes the walkable part of the road; whilst the other side is used by the neighbours along the respective streets to receive all conceivable filth for the next twelve months.

Royal College of Surgeons.—From the annual report of the receipts and expenditure at the above institution, which was submitted to the Council at its meeting on Thursday, it appears that in the year, from Midsummer-day, 1872, to Midsummer-day, 1873, the total receipts amounted to £13,311 16s. 5d., derived principally from fees paid for the diplomas of Fellow, Member, Licentiate in Midwifery, and Licentiate in Dental Surgery, which produced £10,713 7s.; rent of chambers and dividends on stock, £2061 1s. 6d.; elections to the Fellowship, Council, and Court of Examiners, £231. The expenditure amounted to £12,276 6s. 2d., or a balance of £1035 10s. 3d. in favour of the College. The largest amount in the disbursements was in fees paid to the Council, Courts of Examiners, and expenses incidental to the examinations—viz., £5067 8s. 4d.; followed by salaries and wages in the three departments of college, museum, and library—viz., £3314 16s. 9d.; for pensions, £353 12s.; taxes, rates, and stamps (exclusive of postage), £1034 1s.; lectures and oration, £265 11s. The following is a summary of receipts—viz., the College income, £13,021 0s. 3d.; trust funds, £290 16s. 2d.—total, £13,311 16s. 5d. The summary of disbursements for College purposes, £12,092 16s. 1d.; for trust funds, £183 10s. 1d., being a total of £12,276 6s. 2d.

NOTES, QUERIES, AND REPLIES.

He that questionetly much shall learn much.—*Bacon.*

John Forster, Esq., Mount Barker, New Zealand.—Letter with enclosure received.

Edwin T. F.—The third number of *Public Health*—article, "Hospital Reform."

Ralph.—The *Examiner*, July 12—"Spiritual Séances."

G. V. C.—Mr. Darwin has been rejected by 26 against 6 votes as Corresponding Member of the French Academy of Sciences.

M. C. S.—Dr. J. Simms, of New York, has been delivering a course of lectures on "Physiognomy and Physiology" in Edinburgh during the past fortnight.

Arts Examination.—The result of the recent preliminary examination for the diplomas of Fellowship and Membership of the Royal College of Surgeons has just been communicated to the numerous candidates.

F.R.C.S.—Mr. John Marshall will go out of office in July next, but of course will be re-elected. He occupies the chair vacated by Mr. Charles Hawkins, whose turn it would have been. Mr. J. F. South is the last surviving life-member of the Council.

Students, Br. Museum.—A small school manual of Comparative Anatomy and Zoology, by Dr. C. Carter Blake, of the Westminster Hospital School, will shortly be published. The preface will, it is said, be by Professor Owen, F.R.S.

Orion.—The mortality of the troops serving in the United Kingdom in 1871, by the statistical report just published, shows the deaths were 8·62. This is considerably less than the average of the last ten years (1861-70), which was 9·45. The mortality was lower than in 1870 at all the groups of stations, excepting the manufacturing towns and among the men detached from their corps.

A Ratepayer.—The Metropolitan Board of Works have directed their Works and General Purposes Committee to inquire and report to the Board what, if any, steps have been taken by the water companies to carry out the Metropolis Water Act, 1871, and the regulations of the Board of Trade under that Act.

The late Mr. Streeter.—We have received a letter from Mr. William Streeter referring to the obituary notice of his brother in our last issue. That notice he states contains "two inaccuracies." We give the corrections in his own words:—"He was born in Frith-street, Soho, and not in Drury-lane, where he never resided until about the years 1825 or 1826. He was not buried at 'Thornton's Heath,' but at Sanderstead, a rural, quiet little village about three miles south-east of Croydon."

Professional Examinations.—The following unpublished letter from Sir Astley Paston Cooper will, no doubt, be read with some interest at the present time; it is addressed to William Lynn, Esq., President of the Royal College of Surgeons, who filled that position in 1825-26,—the letter, which is undated, must therefore have been written at that time:—

"My dear Sir,—As I lecture this evening at eight o'clock, I cannot possibly attend the meeting at the College.

"My suggestions for the improvement of the examinations would be—

"1st. That each person should attend two evenings, and that the first evening he should be examined in Anatomy, and the second in Surgery.

"2nd. That each examiner should examine an individual applicant for examination instead of two persons as at present.

"3rd. That the person who examines in Anatomy should not examine the same individual in Surgery. I am, yours very truly,

"Astley Cooper.

"P.S.—If I can I will see you at nine o'clock."

Sir Astley Cooper was twice elected President of the College—viz., in 1827, and again in 1836.

Mr. Greenslade's Fracture Apparatus.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I have read Mr. Greenslade's letter in your issue of July 12, correcting errors which he thinks I am "evidently labouring under" respecting the above-named apparatus. The only error I may have committed is in thinking the space between the hinged side-splints unalterable, and this error is pardonable, considering the point is not mentioned in the description of the apparatus in your issue of May 31. I thought these side-splints were simply hinged to the back-splint, after the fashion of certain fracture-boxes of a former century. I now presume the hinges are made to traverse across the back-splint. With fixed hinges, the *free edges* of the side-splints could be made to lean towards each other when treating a small limb, but this would be objectionable on account of the pressure which would be exerted on the limb from before backwards. However, as I have intimated in my former communication, I do not consider hinged side-splints possess any "peculiar advantage" over unattached splints, and that even supposing the employment of hinges to be advantageous, the idea is an old one. That perforated metal splints are superior to wood splints in cases of compound fracture, or where moisture is applied to the limb, is very evident, but I am not aware we are indebted to Mr. Greenslade for these appliances, which have existed many years. I have occasionally used metal side-splints, and any surgeon, when using my apparatus, may do likewise; but it would be wrong to term such use one of the advantages offered. This is not a matter of mechanical construction. Mr. Greenslade speaks of *his* "suspending bar." Considering the above-named apparatus has only been introduced four years, and that a similar bar formed a part of my suspender in 1864 (a description of which appeared in the *Lancet* of February 24, 1866), this contrivance, also, can scarcely be termed a novelty. The few improvements I made a year or two afterwards

in my apparatus may be seen at the International Exhibition. As regards the power of the patient "to shift sideways"—or rather, I presume, to lie diagonally across the bed—whilst his leg is suspended in any narrow two-sided framework, fashioned like Salter's leg-sling, it must be very limited, and to do this he must first draw himself up in the bed so as to get the trucks near the upper end of the truck-rail, and he need then be careful not to slide down in the bed whilst in that position. As to adduction or abduction of the limb in an apparatus of this kind, or shifting the body sideways, there is no provision for such movements; a lateral swinging motion is all that can be obtained.

In sending this communication, which will be my last in this matter, I beg to remind you that in my first letter I avoided criticising the fracture apparatus reported on in your issue of May 31, having written simply in defence of my own invention. The subsequent correspondence arose out of your editorial note of the 21st ult. I am happy to say my suspender has been the means of saving limbs which were considered beyond the pale of treatment, and that it has met with the approval of some of the most celebrated surgeons of the day, one of them—Mr. Haynes Walton—having paid me a high compliment by describing it at a meeting of the Medical Society of London as "one of the best appliances of modern surgery." I have now great pleasure in adding the favourable testimony of your correspondent, Mr. George Greenslade.

I am, &c.,

Plymouth, July 12. HENRY GREENWAY.

COMMUNICATIONS have been received from—

Dr. PEACOCK; Dr. HANDFIELD JONES; Mr. E. LUND; Mr. J. CHATTO; Dr. CHEADLE; Mr. TEALE; Mr. BLOCKADER; Mr. T. C. WHITE; Mr. W. STREETER; Mr. GREENWAY; Dr. IRVING DE LISLE; Dr. ROYLE; Mr. D. ALEXANDER; Mr. LAVER; Mr. B. H. HERBERT; Dr. BAKEWELL.

BOOKS RECEIVED—

On the Influence of Digitalis on the Weak Heart of Typhus Fever, by Dr. Grimshaw—Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques, vol. xvii.—Leishman's System of Midwifery—Pettenkofer on the Air in relation to Clothing, Dwelling, and Soil, translated by Hess—A Treatise on Pneumatic Aspiration, by Dr. Dieulafoy—Jagielski on Marienbad Spa—Physiological Action of Light, by Dewar and M'Kendrick—Life and Mind, by Robert Lewins, M.D.—Watson's New Operation for Anchylosis of the Elbow-Joint resulting from Fracture.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Nature—Pharmaceutical Journal—American Journal of Obstetrics, vol. vi., No. 1—Gazette Médicale—Gazette des Hôpitaux—L'Union Médicale—Le Progrès Médicale—The Colonial Standard and Jamaica Despatch—Le Mouvement Médical—La Tribune Médicale—La France Médicale—Journal of the Scottish Meteorological Society—Guy's Hospital Gazette—Gazette Hebdomadaire—Manchester Guardian, July 9 and 11—Chemist and Druggist—Canada Lancet—Bulletin Thérapeutique—Western Lancet—Medical Notes and Queries—Masonic Magazine—Grant College Students' Journal—Preston Herald—Medical Press and Circular—Allgemeine Wiener Medizinische Zeitung.

APPOINTMENTS FOR THE WEEK.

July 19. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

21. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

22. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

23. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

24. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

25. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Annual General Meeting: Election of Officers and President's Address.

VITAL STATISTICS OF LONDON.

Week ending Saturday, July 12, 1873.

BIRTHS.

Births of Boys, 1142; Girls, 1075; Total, 2217.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·79 in. The highest was 29·98 in. on Wednesday morning, and the lowest 29·57 in. at the end of the week.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE ON TWO CASES OF ACUTE PHTHISIS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

W. R., aged 22, worker at coachmaking, admitted August 6 1869 [2227]. Felt quite well yesterday morning; about 6 p.m. was taken with spitting of a little blood; soon after this he began to retch and vomit blood: he brought up half a pint, he thinks, at once. He turned faint, but did not become insensible. Before this he had been spitting a little blood with cough for a week. During the seventeen hours after his admission he spat up very little. Pulse (on 7th) 90, soft, regular. Good resonance and good full breathing in both fronts; expiration much prolonged at right upper front. In left back there are some dry sounds at upper part; at base some obscure crepitation. In right back at lower two-thirds the vesicular breath-sound is very weak, the air enters imperfectly, and on a deep inspiration high-pitched tube-sound is heard. At upper third of back the breathing is more free. No dulness in either back. Heart's sounds quite normal. Bowels open. Temperature 98·8°; respiration 30. No indigestion. All his family very healthy. Plumbi acetet. gr. ij., opii gr. ss., in pil. ter die. Ice, 2 lbs. Broth.

August 8.—Was much the same. Had only spat up several bloody coagula while I was in the ward; but soon after (3.30 p.m.) he was taken with severe dyspnœa, without much cough. He was dry-cupped, and had some ice, and it ceased in about fifteen minutes. He did not sleep much in the night.

9th.—This morning he was pretty quiet: said he was pretty comfortable; but about 1.30 a very severe paroxysm of dyspnœa came on, for which he was cupped to about four ounces with much relief. Before the cupping was performed he was quite cyanotic. I saw him before the cupping was concluded, and found the pulse 158, sharp. He had expectorated several ramifying coagula, evidently moulded in the bronchi. He complained of being unable to get his breath, from a sense of oppression at the right front. There was dulness at the left posterior base, and some way higher up. The breathing almost everywhere was weak and imperfect. The heart's sounds were not clear, but without distinct bruit; its action was struggling. Respiration 56. Pulv. ipecacuanhæ gr. xxx. was administered in three doses, and vomiting was produced. Shortly after he became better. His pulse was about 120; respiration 44.

10th.—Night not good—much cough. Has brought up a good deal more blood in black lumps. His breathing, he says, is a great deal easier. Dulness at lower half or more of both backs, and breath-sound very weak, but scarce any râle. In the fronts the breath-sound is fairly free—better in the right than in the left. Has taken his food to-day better than he has yet. The ramifying casts brought up yesterday consisted to a great extent of decolorised fibrine, of healthy appearance, containing but few corpuscles, some fibrils. He has begun ext. ergotæ liquid. ℥ j. 3tis horis. Ordered to repeat the ipecacuan until vomiting is produced.

11th.—Faints away on very slight exertion; has done so several times since last evening. Gets very dark in the face at times. At 4 a.m. had another attack of dyspnœa, which lasted two hours. Breathes now with difficulty. No sleep. Face flushed; lips of good colour. Pulse 102, jerky, not apparently weak; temperature 103°; respiration 44. Ergot omitted. Acidi gallici gr. xv., glycerinæ ℥ j., aquæ ℥ j., o. ½ horâ.

12th.—Pulse 102, of fair force; temperature 103°. Has brought up but little more blood. The sputa are reddish and watery, with lumps of blood coagulum as before, and with a greenish tinge. Some syncope now and then. Has had no paroxysm of dyspnœa. Has port wine—four ounces.

13th.—Pulse 100, of good force; temperature 102·2°. No syncope; has spit up much less blood.

14th.—Pulse 102, compressible, jerky; temperature 102·9°. Resonance in both backs impaired; breathing weak, very deficient, attended with sonorous and half-moist râles; eyes bright; sputa more mucous; urine clear, high-coloured, sp. gr. 1024, gives a notable dark precipitate with liq. ferri murias. He is nervous and restless; does not like to be alone.

15th.—Loses himself, and wanders at times; feels giddy. Sputa dark-stained, more mucous. Temperature 103·3°; pulse 100, small and weak. Reptr. mist. 2dis horis.

18th.—Pulse 105—hand feels cooler; temperature 103·3°; respiration 33. Sputa scanty, mucous, with some dark-green masses; urine clear, sp. gr. 1023, strikes an inky black with liq. ferri murias. Still rambles at night. Two or three suspicious spots, like typhoid flecks, on chest.

19th.—Wandering decidedly to-day. Pulse 107, soft; temperature 103·3°. Asks for more food—fish.

20th.—Loud, clear breathing below right clavicle; below left abundant expiratory moist râles. In both backs there is heard a great deal of moist râle. Quin. disulph. gr. v., acid. q. s., aquæ ℥ j., 4tis horis. Temperature 103°.

23rd.—Pulse 108; respiration 36; temperature 101·5°. Sputa scanty, yellowish. Tongue inclined to be dry.

26th.—Expectorates ordinary muco-pus. Temperature 103·3°; pulse 146; respiration 48. Urine of natural appearance, not albuminous. Bowels rather loose.

28th.—Patient died.

Autopsy.—A large cavity at left apex; the greater part of left lung occupied with masses of greyish-whity solid tubercle, and with separate tubercles. The vast majority of the masses and tubercles showed no traces of softening. In the right lung there were numerous tubercles, but they were not aggregated into masses as in the left, and there was no cavity. The process was evidently much less advanced. Lower lobe of right lung was of dark purple colour, containing very much blood and some tubercle. Lower lobe of left was filled with tubercle, but was not so dark and hyperæmic as that of the right lung. A small tubercle from a part where there were but few, showed a limited deposit blocking up the air-cells. This consisted of abundant finely granular matter with nuclear corpuscles, most of them spherical and small, not bigger than a red blood-globule; some larger and more or less fusiform. The adjacent air-cells exhibited their homogeneous membrane distinctly, beneath which were numerous corpuscles not unlike those of the tubercle. The masses of tubercle taken from a part where the process was most advanced were evidently not made up simply of aggregated spherical tubercles, but were formations of very various shape and size, consisting, however, of quite the same material as the smaller isolated tubercles. This material did not contain any large granular cells, and seemed to be very different from inflammatory exudation. Heart unusually pale, thin, and flabby; weight 9 oz. Small intestines much inflamed with greatly enlarged mesenteric glands. Kidneys normal; left weighed 6½ oz., right 5½ oz. Left was much paler than right.

The above case may be fairly reckoned one of galloping phthisis. The man was fairly well at the beginning of August, and was dead before the end of the month. He seems to have had no hereditary tendency to the malady, but I do not think this point was sufficiently inquired into. If none of his family had suffered from chest disease, they might have from strumous joint disease, or other similar. His first symptom was hæmoptysis, which, beginning gradually, came on after some days with great severity, and well-nigh killed him outright. No definite cause can be assigned for it, but it is worth notice that there was great tendency to syncope, much more than the mere loss of blood can account for. At the post-mortem the heart was found unusually pale, thin, and flabby. It seems as if the cause which produced leakage of the small vessels produced weakness of the heart also. The hæmorrhage persisted, in spite of a fair trial of acetate of lead, ipecacuanha emetics, cupping, and full doses of ergot; but yielded, or at any rate ceased, under the administration of gallic acid *à haute dose*. The system was well saturated with the drug, for not only were the sputa rendered dark green by it, but the urine was turned to dilute ink when muriate of iron was added to it. The temperature on admission was nearly normal, but before the hæmorrhage had ceased it had risen to 103°, about which figure it remained to the close. Why did it rise? The hæmorrhage would not raise it, but have the contrary effect. The presence of tubercle masses not undergoing softening does not seem a very likely cause. Was it, then, the irritation produced by blood which had been effused or drawn into the air-cells? This is recognised as a cause of inflammation by Niemeyer, Baümler, and Weber, as it had been by physicians before the time of Laennec. Weber, however, objects to Niemeyer's statement as going too far when he says that most cases of hæmoptysis are followed by more or less violent irritation of the lungs and pleura. He tells us that five out of nine

cases of more or less severe hæmoptysis, which he watched carefully during at least ten days after the occurrence of the bleeding, presented no rise of temperature or other sign of pleuro-pneumonia (*Clin. Soc. Trans.*, ii., p. 153). I do not deny the possibility of the hæmorrhage exciting inflammation and fever, but I think there is much need for us to be on our guard against *post hoc propter hoc* conclusions when we find the supposed cause so often not followed by the expected effect. Not only in such instances as Dr. Weber has noticed is pneumonia often awanting, but in cases of pulmonary apoplexy from cardiac disease this seems still oftener the case. Moreover, I should feel great difficulty in admitting that the cheesy masses, which were so large and numerous in this instance, had resulted in so short a time from changes in extravasated blood, or in exudation produced thereby. They were certainly very unlike ordinary inflammatory products. Again, if we look at our other case, we find a very considerable amount of broncho-pneumonia existing without any hæmoptysis, and with a much smaller amount of tubercle. What caused the fever in this instance is not easy to say,—at any rate, not hæmoptysis; but whatever the unknown cause may have been, it seems no unreasonable assumption that it may have been the efficient fever motor in the first case also. It may be noted that two or three spots resembling those of typhoid were observed on the chest, though of course much stress cannot be laid on this single observation. Death evidently occurred from asthenia, as in low fever. Quinine given in full doses lowered the temperature 1·5° F., but had no beneficial influence otherwise. The autopsy showed the existence of muco-enteritc, with an abundant formation of cheesy tubercle in the lungs. This certainly appeared to be primary.

Case 2.—J. H., aged 28, admitted October 8, 1871. Was in good health up to two weeks ago; caught a cold, had shivering, and became feverish and thirsty, with a troublesome cough. At the end of a week he got worse, and had to go to bed. He has lately lost his wife, and had some young children left on his hands; in fact, has suffered mental distress. He is lying on his back towards his left side; his face is rather dusky; his aspect dull and heavy, like that of a man in fever; no eruption. Temperature 99·4°; respirations 40; pulse 84. Breathing abdominal; some dulness in both subclavicular regions; moist râles are heard here and throughout both fronts, indicating the presence of mucus in the smaller and medium-sized bronchi; the vesicular sound is much impaired —nearly lost. Both backs are dullish, the right rather the most, and moist râles are heard all through both. Tongue dry and coated. His temperature on the 10th was 105·4°; pulse 136; respirations 48; both radials compressed by 300 grammes. On the 11th the temperature was 105°. 12th: Face very dusky, lips tumid and bluish, and no expectoration; râles as before; lies down completely; temperature 103·6°. 13th: Pulse 123; left radial compressed by 192 grammes; respirations 39; temperature 103·6°. Tongue very dry; auscultatory signs much the same. Died at 9 p.m. of 15th. Was very dusky all day, and drowsy, but quite sensible. Temperature 104°; pulse 144; respirations 44, and laboured last day of life. The treatment employed was stimulant, brandy being given in doses increased to eight ounces daily.

Post-mortem.—Lungs highly congested and extensively consolidated, their upper and posterior parts presenting much the appearance of red hepatisation. The cut surface presented a multitude of little elevations, which were hardly to be pronounced tubercles off-hand, though one bystander immediately recognised them as such. In thin sections prepared for the microscope minute semi-pellucid whitish spots were seen, surrounded by congestion, but apparently devoid of vessels themselves. In one of these the deposit appeared as soft, pinky, granulous, and amorphous matter, quite devoid of corpuscles. After hardening portions of the lungs in chromic acid solution, I made a careful examination, and obtained distinct proof both by the naked eye and microscope of the presence of numerous minute tubercles. They consisted of a granulous basis matter, embedding feebly formed corpuscles. The tubercle masses were of various size, and evidently infiltrated the tissue, usually blocking up the air-cells. The bloodvessels were all full, even most of the minuter except the capillaries. The bronchial glands were not enlarged. The heart, spleen, liver, kidneys, and intestines were normal. The mesenteric glands were enlarged; two or three of them were as large as a walnut or nut, others about the size of a pea. The cut surface of the larger showed a whity, dense, opaque substance, much more consistent than that of cheesy masses, and rather resembling scirrho-encephaloid. The largest presented some small spots of caseous matter. Microscopically the enlarged glands exhibited only the normal structure of lymphatic glands—*i.e.*, nuclear corpuscles, embedded in a fibrous stroma, and canals, traversing the parenchyma, apparently without definite walls.

Remarks.—The course of this case was very rapid; death occurred in three weeks after the setting in of acute symptoms. Before this time he seems to have been healthy, and I presume was so structurally, with the exception of his mesenteric glands. These underwent chronic change, apparently primary, which marks him, to my thinking, as the subject of a strumous diathesis. The small spots of caseous substance in some of the glands will no doubt be regarded by some as the source of the infectious matter which produced the general malady and the miliary deposit, but I cannot assent to this view while cheesy masses are so often met with unattended by symptoms of infection. I quite agree, however, with the view held by Buhl, so far that I think the disorder in acute tuberculosis is the result of some infective material having entered the blood, though it seems very difficult to form an opinion as to what it really is. The great similarity, however, of the resulting condition to that existing in enteric fever suggests that it may be a miasm closely related, though not identical, with that which produces typhoid. I have long been inclined to think that enteric fever is by no means so specific and well-defined a malady as it has been commonly held; and though I do not mean to intimate my complete acceptance of Dr. J. Harley's views—viz., "that enteric fever and all its attendant phenomena may occasionally become a part of almost any other more general inflammatory condition, specific or simple,"—I think that they have really a foundation of truth.(a) In one respect the two cases I have related contrast strongly—viz., in the amount of tubercle discovered on dissection. In W. R. it was very large; in J. H. very small. Yet both cases ran a rapid course; the temperature in both was barely morbid at the time of admission, and rose afterwards. In W. R. the physical signs on first examination by no means indicated the existence of any large amount of tuberculous deposit in the upper parts of the lungs. If any connexion subsists between the abundant formation of tubercle and the profuse hæmoptysis, the cause may be found in this—viz., that hæmorrhage implies a loss of the natural retentive power of the vessels, which, though checked by the astringent so as to prevent the escape of the red corpuscles, still persisted for the phthinoplasms (as Dr. C. J. Williams calls them—the degenerate leucocytes), which therefore emigrated readily and produced the tubercle. It would be needful, however, to show a frequent correspondence of this kind to substantiate the hypothesis. At any rate, we may remember that acute tuberculosis may occur in either of these forms—viz., with copious or scanty production of tubercle, though some, I suppose, would not regard W. R.'s case as tuberculosis at all, but what they call "cheesy pneumonia." From this view I must dissent.

Much stress has been laid upon the fact that tubercular growths, and those disseminated, can be produced in rodents, especially in guineapigs, by the irritation of a mere seton, without any inoculation at all. The notion of tubercle as a specific growth is considered to have been well-nigh overthrown by these observations. Dr. Bastian, however, entertains doubts whether it be safe to conclude from what occurs in guineapigs that the same occurs in man; and I share his dubitation—especially for this reason: that in man similar irritations are constantly being produced without such effects ensuing. Think of the common impetigo pustules, the whitlows, the abscesses, the suppurations connected with diseased bone, the empyemas, and many like conditions, where common pus is generated and retained for a longer or shorter time, and might most easily infect the system if *per se* it were capable of giving rise to tuberculous formations. Yet surely we have no reason to think that such lesions have any power to set up acute or chronic tuberculosis in an otherwise sound and not predisposed system. Fistula in ano is believed by no mean authorities to have a preventive influence on the development of phthisis. The late Dr. Seymour mentioned an instance to me where six out of seven children of a family had died of this disease, the survivor having a fistula in ano. Schönlein in his "Vorträge" says—"So long as the latter is present the chest affection remains quiescent; but now comes in a surgeon delighting in operations,—he operates, and cures the fistula: this is at first a

(a) *Vide Med.-Chir. Proc.*, vol. vii., p. 18.

matter of rejoicing and congratulation, but three or four weeks after the chest affection starts afresh, pulmonary phthisis developes itself with great rapidity, and the patient succumbs." Whether fistula in ano has this preventive power or not, it can scarcely be held that it produces phthisis, and therefore may well be added to the list above given. The following passage from a paper by Dr. Goodhart (*Edinburgh Medical Journal*, October, 1871) is also very apposite to this topic; I had quite forgotten it until some days after writing the above I lighted on it again:—"But if it be the fact that caseous and suppurating deposits are liable to set up a tuberculosis, we shall find, it may be said, in surgical wards a large amount of such disease. Is this so? Several hospital surgeons have told me that it is not so very common, and this opinion is borne out by post-mortem records; for of 147 cases of joint disease with prolonged suppuration inspected at Guy's Hospital during the last seven years, I find only thirty-three, or less than a fourth, were affected with tubercle." Also, as to the constant dependence of miliary tubercle on pre-existing cheesy deposits, Goodhart finds among 166 cases of tuberculosis in the post-mortem records at Guy's Hospital for 1868-69, that eighty, or nearly half, have no mention of any suppuration or cheesy glands, or anything of the kind. Among my notes I find mention of a male dying with disease of supra-renal capsules; these organs contained a whity deposit partly firm, partly softened and disintegrating; no miliary tubercles anywhere. Such instances I take it are common. This evidence seems to me quite sufficient to outweigh that derived from experiments on rodents, and therefore this objection—the gravest yet made to the specific quality of tuberculous phthisis—falls to the ground.

As to the anatomical diagnosis of tubercle, which has been thought by some so very uncertain, I believe in the vast majority of cases it presents no serious difficulty. A firm, roundish, well-defined mass of the size of a small shot, made up of ill-developed nuclear corpuscles closely crowded together and blended with a varying amount of granular and fatty matter, represents to me a tubercle. The distinction between this and the inflammatory exudation-cells — much larger and often nucleated,—which are frequently very abundant in the adjacent air-cells, is as marked as can be. Even in cases of grey hepatisation, where the exudation product consists solely of much smaller corpuscles, like those of pus, there can be little difficulty in perceiving the difference between this diffused product and a tubercle mass. The action of acetic acid on the two kinds of corpuscles would separate them sufficiently. Moreover tubercle, however small, is always infiltrated, while inflammatory products occupy the alveoli. I hold with Dr. Wilson Fox and Dr. Moxon that there is no histological distinction between yellow caseous tubercle and the grey granulation. The larger masses have the same structure as the smaller, only that they are more prone to contain the *débris* of tissues and of inflammatory products. If now we add that tubercle is devoid of vessels and tends speedily—in consequence probably—to decay, we have a list of diagnostic features which are quite sufficient, I believe, when well marked, to enable us to recognise it with great certainty. Certainly it cannot be confounded with ordinary acute inflammatory exudation; certainly not with any kind of cancer, with amyloid deposit, hydatids, fibroids, sarcomata, or myxomata. As to lymphatic overgrowths in the liver of leucocythæmatic subjects, they are so rare, in comparison with tubercle, that we need not shudder at the confusion likely to ensue from including them, even if the state of the blood did not at once distinguish the one pathema from the other. But I do not think we ought to conceive of tubercle as always of a typical kind, and I am quite disposed to believe that there are various grades which approximate to common fibroid induration material on the one hand, and on the other to grey hepatisation, or to a state where the consolidating material consists of small pyoid corpuscles instead of large nucleated cells. That grey hepatisation may occur primarily from acute inflammation the following case shows, and that it may occur similarly from chronic inflammation I have little doubt, when the system is under the sway of the tuberculous diathesis. It is of such cases, I believe, that Dr. Bennett writes—"Discussion has taken place as to whether such cases should be denominated chronic pneumonia or phthisis. In my opinion there is no difference between them. The exudation of the pneumonia degenerating, and not being absorbed, is transformed into tubercle, causing softening, ulceration, and destruction of the lung, in exactly the same way as if phthisis had been developed from tubercle at the commencement." The only point I question in the above passage is that the exudation is transformed into tubercle, although this quite corresponds with Laennec's statement as to the conversion of grey and jelly-like tuberculous infiltrations into yellow tuberculous matter. I should prefer to say that the exudation was transformed into matter behaving like tubercle, though perhaps not presenting the same histological features. But this is a small matter, and I think Dr. Bennett comes much nearer the truth than sundry German-worshippers when he says—"Transferring or limiting the term tubercle to the accidental granule, and calling the general and essential morbid product chronic inflammation or adenoid growth, constitutes no real advance in pathology. What we have from the first maintained is that we have to do with a *tubercular exudation*, which differs from an inflammatory and cancerous exudation in its low vital energy and diminished power of transformation into cell-forms, and that this is the essential ment of phthisis pulmonalis." (b)

The case of grey hepatisation above alluded to is as follows:

E. W., about mid-age, a hard-drinking man, discharged from his work for misconduct, threw himself into the canal. He was got out alive, but died in forty-eight hours from the effects of the immersion. A very large part of both lungs was in a state of grey hepatisation, sinking in water, and of a very faint pinky-grey colour. Examination with the microscope showed the air-cells more or less filled and blocked up with corpuscles, which were remarkably uniform in size and appearance, and were essentially the same as pus or mucus globules. There were no glomeruli, no large nucleated celloid particles; the membrane of the air-cells was normal. There was scarce any trace of blood. The point which I wish to lay stress upon is, that the hepatisation must have been grey—puriform—from the first. And so I think, in a predisposed state of system, and with a process of slower course, the consolidation might have been of tuberculous quality from the first. Such a condition would correspond to Rokitansky's description of infiltrated tubercle, "which arises (he says) from a more or less extensive croupous pneumonia, whose products . . . become variously discoloured and converted into yellow tubercle instead of being absorbed or dissolving into pus."

Next as to the process by which the tubercle or cheesy mass is produced. Rindfleisch ("Patholog. Histol.," ii., p. 30) regards the grey granulations as broncho-pneumonic foci, whose walls are infiltrated with cells and pass uninterruptedly into the catarrhal infiltration of the surrounding alveoli. Following Virchow, he traces many cases of phthisical destruction of the lungs to a primary catarrhal affection of the mucous membrane of the bronchi, especially of those which ramify in the upper lobes. "This catarrh is characterised partly by its singular obstinacy and tendency to recur, partly by the never-failing enlargement of the retro-bronchial glands." Here it seems to be admitted that there is something special about the catarrh: it affects the upper regions of the lungs, while ordinary catarrh affects the lower; it is singularly obstinate, and is attended constantly with scrofulous enlargement in the related lymphatic glands. These are very material distinctions. Niemeyer, on the other hand, confidently asserts that every form of pneumonia may, under certain conditions, terminate in cheesy infiltration; and there is no form of pneumonia of which cheesy degeneration is the constant and only result. He thinks that the creation of a tubercular or cheesy pneumonia from the beginning of a special kind is quite a mistake, and threatens us with fresh confusion. In common acute pneumonia, however, he admits this termination is rare; in chronic catarrhal it forms almost the rule. This latter disease, he says, is one of the very commonest,—a statement which seems to me sufficiently startling, and utterly opposed to my own experience. In fact, I know of no such morbid state unassociated with tuberculous or cheesy deposit, except those conditions of induration of the lung of inflammatory origin, so well described by Dr. Addison. These, according to his account, may occur quite unassociated with any tubercle, may give rise to cavities, and produce a very exact symptomatic picture of phthisis. He says if he were to give an expressive name to tubercular phthisis it would be scrofulous pneumonia. He distinguishes pneumonic phthisis, tuberculo-pneumonic phthisis, and tubercular phthisis. In the first the disorganisation of the lung results from mere inflammation and its consequences; in the second, which is very common, although tubercles are present, the really efficient

(b) Reynolds's "Syst. of Med.," vol. iii., p. 553.

cause of the phthisical mischief is pulmonary inflammation; the third is characterised by a preponderance of asthenic compound tubercles—*i.e.*, of cheesy masses much more prone to disintegration than the grey. Dr. Addison closes one of his essays with the proposition that "inflammation constitutes the great instrument of destruction in every form of phthisis." He was by no means regardless of the influence of the state of the system on the results of inflammation, and uses the terms "strumous" and "scrofulous" to designate that in which the symptoms evoked are those of pulmonary phthisis. To return now to Niemeyer, who evidently has trod in Addison's footsteps. True, tubercles, according to Niemeyer, in the majority of cases are secondary formations, originating in some unknown way in the action of cheesy morbid products on the organism, these products being situated in the lungs or elsewhere. Buhl holds the same view, and considers that the etiology of acute miliary tuberculosis is to be explained by the theory of infection, the infectious matter being derived from pre-existing cheesy centres. He admits, however, that they may be developed independently of such centres as the result of a primary tubercular inflammation. Buhl further admits the existence of a constitutional predisposition as lying at the root of tuberculosis as well as of desquamative pneumonia. Dr. Hughes Bennett, while fully admitting in some cases the influence of lung inflammation, holds, as a general conclusion, that the great cause of tubercle is weakness of constitution, or diminished vital power, however produced. Dr. Moxon believes that all phthisis is tuberculous—he does not know active phthisis without tubercle. He thinks it contradictory to the certain evidence of facts to say, with Niemeyer, that the early stage of phthisis is catarrhal pneumonia. He holds it certain that the initial stage of chronic phthisis is not a diffused disease, such as catarrhal pneumonia is. Instead of this it is a small circumscribed patch. However early phthisis is seen, there are the tubercles; nay, the more early chronic phthisis is seen, the more purely tuberculous it is. However phthisis first begins, it does not attain one inch in extent before it has tubercles present in it. In one instance under my own care, the limitation of the morbid process at the outset was very marked, though subsequently it became much more extensive, and ended fatally in about ten months. The pulmonary expansion was very full and free everywhere, and free from râle except in the right apex, where, especially posteriorly, there were distinct and rather small crepitations.

To bring this discussion to a close, I would say that it seems to me as reasonable to ascribe phthisis with its tubercles, cheesy masses, or infiltrations to ordinary non-specific inflammation, as it would be to ascribe syphilis or gout with their lesions, or psoriasis, or lupus, to the same cause. In all these pathemata there is inflammation; but there is something more, and that something is all-important to a true pathology.

The chief points in debate may be comprehended in the answers to the following questions:—(1.) Is inflammation *per se* an adequate faction of phthisis, or must it be inflammation occurring in a peculiar state of system and giving rise to a peculiar product? (2.) Can tubercles or cheesy masses be formed without any pre-existing inflammation? (3.) Is the deposit of tubercle essential to constitute the condition termed phthisis? (4.) Can a diffuse induration consolidating a lung be regarded as the equivalent of tubercle, capable of undergoing the same changes, and of affecting the system in the same way? To the first, I reply that without a special state of system inflammation does not produce phthisis, but that in a predisposed system it may precipitate it very greatly. To the second, that in very many instances, perhaps the majority, tubercles are deposited without any pre-existing inflammation as the result of deterioration of the health. To the third, that, as a rule, tubercles, large or small, are essential to the production of phthisis. To the fourth, that in comparatively rare cases a diffuse induration may act as the equivalent of tubercle. These indurations may mostly be distinguished by the following features:—They are more apt to be one-sided, to involve the lower parts of the lungs, to be attended with a lower temperature, to be more chronic, and to affect the general system less injuriously than tuberculous formations.

If the answers returned to the above queries had little or no bearing on practice, we should not need to attach so much importance to them. But you will see immediately that this is not the case. The practical outcome of Niemeyer's views is very apparent in his directions for the treatment of ordinary phthisis (*vide* pp. 65, 66, "Lectures on Phthisis," Syd. Soc. Translation). "Let any one (he says) make the experiment of having patients with the supposed signs of a commencing pulmonary tuberculosis strictly confined to their beds for a time, forbidding them all unnecessary talking and coughing, covering their chests with poultices, ordering a local abstraction of blood by leeches, or cupping on the first appearance and on every recurrence of pleuritic pains, and he will soon satisfy himself that many a patient gets well who would formerly have been assumed to be the subject of tuberculosis, and therefore incurable (*vide* p. 65). . . . The treatment just alluded to (he continues) must also be urgently recommended for the exacerbations which occur in the course of a chronic pulmonary consumption with symptoms of more intense pyrexia. . . . We can prove (says Niemeyer) by a great number of recorded cases how great even in such conditions is the influence of a treatment which takes into account the inflammatory nature of the lung disease. In the clinique at Tübingen, which principally gets its patients from the population of the neighbouring villages, it is common for phthisical patient to be during several years repeatedly admitted for a short time. In these cases it is of quite frequent occurrence that in the few weeks during which they stay in the hospital and are treated in the above manner, the fever, the debility, and the emaciation which on their admission have often reached such a degree that the worst might have been anticipated, completely disappear, and that the patients themselves ask to be discharged in order to return to their occupations."

My experience of the effects of hospital residence on phthisical patients is sadly unlike Niemeyer's. Real improvement is quite the exception; deterioration rather the rule. Commend me, if I had phthisis, not to Niemeyer's treatment of lying in bed with leeches or poultices on my chest, but to Sydenhem's, of daily riding on horseback, which he says is all in all—"Do this and you may neglect the rules of diet, and deprive yourself of no sort of meat or drink." Dr. Bennett has known several young men on large sheep-farms in Australia cure their tuberculous lungs by eating fat mutton and galloping about on horseback. He says—"It is now twenty-five years ago since I became convinced of the injury of shutting up patients in their rooms during winter and regulating the temperature, as was formerly the custom. A young man with cavities in his lungs, who had borne confinement in this way tolerably well for a winter, found it so irksome on a second trial that on one occasion he went out and walked to the top of Arthur's Seat. Instead of being worse, he ate his dinner that day with appetite, all his symptoms were moderated, and under the combined influence of pure air and exercise he ultimately worked out a perfect cure, and is now alive and in good health." Dr. Stokes's case of recovery under a prolonged course of duck-shooting, involving frequent wading in water, is to the same purpose. No doubt there is risk of exasperating pulmonary inflammation by exposing phthisical patients to chill, damp air, but they will not escape catarrhs (influenzal) by any amount of confinement to warm rooms, and they certainly suffer injury by breathing deteriorated air. On the whole, as it has been well said, there is more danger in staying in the house than in going out.

Death of Dr. Berend.—Geh. Sanitsrath Dr. Berend died on June 25 at Berlin, in which city he had practised with great success as a surgeon during forty years. Formerly an assistant of Dieffenbach, and then surgeon to the Jews Hospital, he became famous in operative surgery. He is best known abroad, however, for his famous Orthopædic Institution which he founded thirty-three years ago, and continued to direct with great success, patients resorting to it from all parts, his great aim being not to separate orthopædics from the general practice of surgery. He founded, also, the Berlin "Gesellschaft für Heilkunde."—*Berliner Wochenschrift*, June 30.

Quinine in Pertussis.—Dr. Dawson strongly recommends the employment of quinine. For children under three years of age he gives from five to eight grains to the ounce of water, and for older children ten to twelve grains. Of the mixture, not less than a teaspoonful should be given every hour, or, at longest, every second hour during the day, and when the cough comes on during the night. Nothing should be given for five or six minutes (after when some sugar or orange may be given) to destroy the taste, or wash out the mouth. It should be continued to be given although the first doses may be vomited.—*New York Medical Record*, June 16. [American children must surely be more tractable than the British infant, to admit of this nauseous mixture being given so frequently.]

ORIGINAL COMMUNICATIONS.

ON

A CASE OF MYDRIASIS, WITH PARALYSIS OF THE ACCOMMODATION.

By C. S. JEAFFRESON,
Surgeon to the Eye Infirmary, Newcastle-upon-Tyne.

Cases of uncomplicated mydriasis and paralysis of the accommodation are sufficiently rare in ophthalmic practice to be worthy of placing on record, and I trust the details of the present one may be interesting to the profession.

W. S., aged 30, captain of a small vessel, complained of confusion of sight, especially when looking at close objects. Imagining himself bilious, he applied to a medical man, who, noticing the dilated condition of one of his pupils, sent him to me. When he presented himself a careful examination was made, with the following result:—

The pupil of the right eye was dilated to about 3‴ in diameter; it was perfectly immovable to any stimulant of light; that of the left eye was active, and varied from 2½‴ in partial obscurity to a little less than 1‴ in bright diffused sunlight. The patient was most anxious about his condition, for close-to his vision was most defective $=\frac{1}{xx}$, nor could he see well at a distance $=\frac{20}{xl}$. This circumstance led me to suspect the presence of hypermetropia, and an examination of the sound eye proved that it suffered from Hm $\frac{1}{30}$. The accommodation of this eye being paralysed by atropine, I found that its total hypermetropia or Ht $=\frac{1}{24}$. Inferring that the refraction of both eyes would be similar, I now placed a $+\frac{1}{24}$ before the diseased eye, when the sight became at once normally acute for distance, or $=\frac{20}{xx}$. A $+\frac{1}{10}$ was now placed before the eye, and it was found that at 11½ inches he could read No. 1 perfectly; thus the absence of amblyopia and the presence of hypermetropia was conclusively diagnosed.

The cause of the mydriasis and paralysed accommodation was not very evident in this case. The patient was a healthy-looking man in the prime of life, was at sea when first attacked, and had suffered from no rheumatic or other constitutional affection. It is true that four years ago he had had a small sore upon the penis, but this had not been followed by any one symptom of constitutional syphilis, and its specific nature was doubtful. Latterly he had suffered from occasional attacks of epistaxis, indicating congestion of the great nerve-centres, and to this cause alone I considered the attack referable. Inwardly an aperient tonic was administered three times a day; locally the use of the Calabarised discs.

The characteristic effects of the bean were very rapidly produced, and on the first application the following notes were taken:—

At 10 a.m. on June 20 a Calabar disc was introduced into the eye. The pupil then measured 3‴, and . . . . . V = $\frac{20}{xl}$

At 10.15 the pupil measured 2½‴ . . . V = $\frac{20}{xxx}$

At 10.30 the whole of the hypermetropia was neutralised. The pupil measured a little less than 2‴ . . . . . V = $\frac{20}{xx}$

At 10.45 the pupil had not varied perceptibly . V = $\frac{2}{vi}$

At 11 o'clock the pupil had apparently somewhat suddenly contracted, and was a little less than 1‴ in diameter . . . . . V = $\frac{2}{ii}$

At 11.15 no change was noted in the pupil . V = $\frac{9''}{i}$

In one hour and one quarter, then, the height of the action of the bean was observed, the near point being brought to within 9″ of the eye. From this time the effects of the bean began rapidly to subside, and at 2.30 p.m. of the same day its effects had entirely passed off, and the eye had resumed its condition of paralysis, the pupil, however, remaining somewhat smaller than previously.

For a week the patient was directed to place a disc into the eye every morning, and at the end of this time I again repeated my experiments. On this occasion, though I found the acuity of vision the same, the patient readily reading No. 1 with a $+\frac{1}{10}$ at 11½″, yet the influence of the bean upon the accommodation had much deteriorated. The discs now produced only sufficient accommodative power to enable the patient to read 3½ at 18″, and it required a much stronger solution to bring the near point to within 9″ of the eye. I regret to say my patient's occupation prevented his remaining sufficiently long with me to enable me to make further experiments or watch the result of treatment; but I wish to call attention specially to the gradual failure of the characteristic effects of Calabar bean after its prolonged use,—a circumstance I have observed on more than one occasion.

CASE OF TRUE SYCOSIS.

By GEORGE GASKOIN,
Surgeon to the British Hospital for Diseases of the Skin.

A. P., aged 21, clerk. He presented himself with an eruption principally in the region of the beard. The patient believes that he has received infection from his sister, who has ringworm of the scalp. I bade him bring the girl with him, and found that she had patches of denudation with uneven scars, and some few ulcers. In her the disease seemed to be wearing itself out; in the brother it is recent: it displays much virulence, and an inclination to disseminate itself with rapidity from detached foci. The chin, the lower lip, sub-mental region, whiskers, eyebrows, and cheeks are successively invaded. There are spots upon the forehead, and patches which approach the pole of the neck, resembling those on the beard—discharging surfaces which are round as a shilling, and somewhat projecting. The disease, in fact, is not different from ordinary ringworm as seen on the scalp or pubes. Partly to economise the time of the patient, temporarily dismissed from his employ, and partly to indulge my fancy in the study of the complaint, I undertook the treatment by epilation. The roots of the hairs were white with trichophyton.

The cure lasted five weeks with use of the ordinary parasiticides. This, then, is the true sycosis,—the "barber's itch" of colonial life. So much do we read of it; what we see of it is comparatively little. In its course and its behaviour, can anything be more unlike the sycosis of our daily experience? Call it eczema, impetigo, or acne sycociforme, there would be many a case to one of this. The proportion would be far greater than exists in the young between eczema capitis and ringworm.

As affecting the beard, these non-parasitic eruptions are about the most tedious and obstinate that are seen. There are rich men in London who can never get rid of them, proceeding as they commonly do from some hereditary taint. But even where local causation is in fault they are beyond measure tedious.

I have now under my care a German engineer, of tolerable health, but phthisical aspect, who has a defined spot of impetigo sycociforme on the right whisker: it lies between aching teeth on the lower jaw and an ear that troubles him with chronic inflammation; and this single spot, no larger than a shilling, has been with him off and on for thirteen years. It is altogether another thing from the invasion of parasites, which, indeed, have no special preference for the strong-bearded adult. Indeed, it is not in such that we are accustomed to look for ringworm on the scalp.

What shall we conclude, then, of the modern teaching, which leans so strongly in the direction of parasitic disease? The practitioner will expect to find it always in sycosis, and he will find it but seldom. What are we to say of the instruction of Dr. Hardy, that talented expositor of the French dermatology? Has he not sinned immensely against proportion, or was there not rather a plague of trichophyton at Paris in the days when he wrote his book, as at Rome in the days of Pliny? French writers, indeed, have suggested fluctuations that are considerable in this complaint. In London there would appear to be a great declension or extreme mitigation of parasitic disease. The averages of Glasgow, Paris, and Vienna concern us not at all, further than as they may suggest to us Rochefoucauld's maxim, which is too unamiable to be repeated.

Since I am upon the subject, I cannot omit a question that was put to me by a patient's father one evening, Whether

animals could take the ringworm? He stated that since his boy had been kept away from school, where he took the complaint of a schoolfellow, they had observed both the dog and the cat to part with hair. Both of them had been fondled by his son. *Valeat quantum.*

It would serve to show that these interesting animals expose themselves to risk in their intercourse with mankind, and especially with educated man.

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, &c., &c.

THE subject of snake-poisoning is one of considerable interest to the inhabitants of those countries in which venomous snakes abound, and also of occasional great anxiety to the medical practitioner who may be called upon, always suddenly, to treat a bitten person. From the English reader, moreover, it deserves attention, as affording unmistakable evidence of direct inoculation or infection, and presenting a series of results directly flowing therefrom. In this respect it is as interesting to the pathologist as is syphilis or small-pox, and to the toxicologist as is prussic acid or any other rapidly fatal poison. It is the duty, therefore, of everyone who enters into this peculiar field of research, and who may not regard it in so hopeless a light as his fellow-workers, to present his facts as to him incontrovertible—that is to say, that where his own observations are detailed, they should have been, whenever possible, thoroughly repeated, and, when practicable, verified by others. This is the spirit in which I have always worked, and it is requisite it should be here stated, for I have had during the last few years some ardent admirers and quite as bitter opponents. I have kept myself as clear as possible from both parties, striving to remain uncontaminated by praise or blame, and keeping my mind intently fixed on the physiological and pathological questions involved. How far I may have succeeded in this difficult but necessary task it is for others to judge.

The accident of snake-poisoning is one very embarrassing to the practitioner. In a large number of instances the reptile is not seen, or glides away so rapidly that the person bitten is unable to tell the sort or species of snake it may have been. Then the patient has very frequently been drenched with brandy and ammonia, so that it becomes perplexing to say how far the comatose symptoms may be due to alcohol or to venom. Again, the usual suddenness of the thing, the consternation it frequently gives rise to, and the insidious action of the poison, perplex the practitioner to a degree little understood by people not on the spot. Some of the bystanders are for giving more brandy; others for walking the patient about; others for tying him behind a horse and cart, and trotting him about till he recovers or dies; others for beating it out of him with good sticks. More recently, however, the injection of ammonia into the veins has been resorted to, and we cannot at all wonder that this mode of treatment has also added to the anxiety of those adopting it; for previously to my experiments it had never been thought possible to throw ten or twenty minims of the strongest liquor ammoniæ into a man's veins without killing him on the spot. This treatment, then, has always been resorted to under circumstances of anxiety and doubt, and with more fear than there was occasion for, since we now know we may repeat this quantity many times during the progress of a bad case. Had it fallen to my lot, or to that of any one medical man, to have treated all the cases recorded in this communication, the value of the treatment would have been more easily arrived at, but I have myself only seen one of the cases here recorded,—the remainder have occurred miles away; but I have been most careful to ascertain, by correspondence or personally, the facts of importance: and before proceeding further, tender my thanks to the various practitioners and others for the full details they have forwarded to me. I have spared no trouble in seeking information from them, nor have they, I am pleased to say, in giving it to me.

And first, of the snakes of Victoria. If we exclude the two species of blind snakes (typhlops preissii and typhlops bicolor), there are only two which are not venomous—viz., morelia variegata (carpet snake) and dipsas fusca (brown tree snake); whereas there are nine venomous species, viz.:—

Hoplocephalus curtus—Tiger snake.
Hoplocephalus superbus—Copper-head.
Hoplocephalus flagellum—Little whip snake.
Hoplocephalus coronoides—Whip snake.
Diemenia superciliaris—Brown snake.
Diemenia reticulata—Grey snake.
Pseudechys porphyriacus—Black snake.
Vermicella annulata—Ring snake.
Acanthophis antarticus—Death adder.

Of these the most common in Victoria, and those to which the bites are chiefly due, are probably in the following order:—Hoplocephalus curtus; Diemenia superciliaris; Pseudechys porphyriacus; Hoplocephalus superbus.

In some districts these species literally swarm. In the settled parts a snake is only rarely seen; in others they may be occasionally met with basking in the garden, coiled up in the nursery, or somewhere about the bedroom.

Hoplocephalus curtus: Very common and very deadly; will occasionally attack. It is an extremely vicious species, and is that with which I am most familiar. About four feet and a few inches is its average length as met with here; it is said by Mr. Gerard Krefft(a) to attain to six feet.

Diemenia superciliaris: A more sluggish snake; common, and extremely venomous. Length from four to six feet.

Pseudechys porphyriacus: Very common in swampy districts; its bite is very fatal. Length five to six feet.

Hoplocephalus superbus: May attain according to Krefft a length of from five to six feet. The same author considers it to be of a "highly venomous nature." By experiment I have ascertained that it is so.

The probabilities are, therefore, that when a person finds himself bitten by a snake in Victoria, and sees two minute punctures about a quarter of an inch apart, the snake is venomous, and his case should be attended to at once. Not that it is necessarily to be fatal, for such an idea would certainly add to the mischief.

Viewing these snakes anatomically, no one would doubt, from the presence of tubular poison fangs, ducts, glands for the secretion of the venom, and powerful striking and ejecting muscles, of their affinity to the celebrated cobra di capella of the East Indies. I know of no more graceful sight than that which is exhibited by our tiger snake when curving and pirouetting about with dilated neck and flashing eyes under excitement. It has its exact parallel in the behaviour of the cobra under similar circumstances.

There has been a very great tendency to underrate the potency of the poison of our snakes. It may be that in the southern parts of Australia, as Victoria, owing to the greater coolness of the climate, the bites of our snakes are less serious than the bites of venomous snakes in the hotter parts of India. And we should expect it to be so,—for there is no animal more invigorated by heat or depressed by cold than a snake. The sensitiveness of these creatures to heat is well seen by their immediately arousing from the torpid condition when subjected to a moderate rise of temperature; and when, as I have frequently seen, the sun's heat is condensed with a burning-glass upon any portion of a snake's body it cannot endure the condensed rays for an instant, but flies about the cage, and, if the experiment is repeated a few times, the reptile is driven into a state of apparent mad excitement. We find also that when we have had a succession of hot days, as during the past summer, accidents from snakes are far more numerous; the creatures are, in fact, more active, and, as a consequence, when they bite, eject more poison than in colder weather. But in the tropical parts of Australia I should fear the bites of snakes as much as I should fear similar accidents in Bengal. Moreover, the effects of increased temperature have probably an injurious influence upon the bitten animal. All chemical and vital processes follow on faster in hot climates than in cold. Exhaustion is sooner induced, the progress of fevers is more rapid; and as in tropical countries no twilight, or little, intervenes between day and night, so there is frequently little interval between life and death. But if we leave out of consideration all the accessory circumstances and modifying influences of snake-poisoning, we shall have reason to believe that there is little difference in the power of the poison itself, whether taken from an Australian, Indian, or American snake; for the death of a dog follows as rapidly after the bite of an Australian snake as after the bite of a cobra; the symptoms

(a) "The Snakes of Australia," by Gerard Krefft, F.L.S., C.M.Z.S., etc.

preceding death are alike, and the post-mortem appearances identical.

That death follows as rapidly after the bite of hoplocephalus curtus as after that of cobra di capella I infer from the following data :—

Deputy-Inspector-General Dr. J. Macbeth records the deaths of twenty-nine dogs which had been bitten by cobras, and to which no remedy had been applied. The average time between the bite and death in these cases is three hours and twenty-three minutes; the shortest eleven minutes. I find that two hours and fifteen minutes is the average time between the bite of hoplocephalus curtus and the death in nineteen dogs, the shortest interval being seven minutes. The cobra kills fowls, according to the same authority, in about eighteen minutes. I have preserved no notes as to the time required by our snakes to kill birds, but my memory enables me to say that it is quite as short. In the case, however, of puppies a few weeks old, three died from the bite of the hoplocephalus curtus in eight minutes; a fourth lingered on one hour and a half.

(*To be continued.*)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

BIRMINGHAM GENERAL HOSPITAL.

MALIGNANT TUMOUR FROM THE BONES AT THE BASE OF THE CRANIUM, SUCCESSIVELY DESTROYING THE SEVERAL OCULAR NERVES: THE PROGRESS MARKED BY PARALYSIS OF THE MUSCLES OF THE GLOBE, AND BY HORIZONTAL LOSS OF VISION.

(Under the care of Dr. RUSSELL.)

J. J., AGED 36, was admitted on June 13, when he presented the following symptoms :—Ptosis of the right eye nearly complete. Right eyeball nearly immovable, from paralysis of all the recti muscles alike, the cornea occupying the median line. The pupil acted sluggishly in consonance with that of the opposite eye. He could only distinguish No. 16 Jaeger with the right eye. The left eye was natural in every particular, and the function of all the other cerebral nerves was performed in a normal manner. The patient complained of a considerable amount of pain diffused over the entire right side of the head. He appeared in perfect health, and very robust. There was entire absence of any other nervous symptom. The pain in the head began five weeks before admission, and had been continuous ever since; it was worse at night; the muscular apparatus of the eye became affected soon after.

At this time the eye was examined by Mr. Priestley Smith, the House-Surgeon of the Eye Hospital, and the optic disc appeared healthy.

The diagnosis made at first was that there were probably two separate foci of disease, affecting the third and sixth nerve; and on this account, with the confirmation derived from the man's previous history, a syphilitic hypothesis was adopted in explanation of the symptoms, and a corresponding treatment was prescribed.

On July 9 the condition of the right eye remaining unchanged, our clinical assistant, Mr. Blake, drew my attention to the circumstance that voluntary movement was extinguished in the *left* external rectus, though the muscle retained power to antagonise the opposing muscle. The patient now complained that vision in the right eye had declined still further. On July 16 Mr. Priestley Smith made a careful examination of the condition of the eyes, and he then discovered horizontal hemiopia in the right eye, vision being absolutely lost in the half of the retina above the equator, whilst with the lower half the man could distinguish No. 10 Jaeger. With the left eye he continued to read No. 1. The veins of the disc were engorged, and the arteries were very fine, but no difference was observable between the upper and lower halves of the disc. The margin of the disc was not quite clear. Subsequently, the conjunctiva of the left eye was noticed to be much injected, and there was considerable secretion of mucus from it. The correctness of the original diagnosis was of course rendered more than questionable by the larger extension now attained by the disease; and the presence of a tumour—probably maglignant—which involved several of the nerves at the base, was now accepted as the more probable supposition.

On August 3 vision was completely extinguished in the whole of the right eye, both upper and lower half, even as tested by the reflector of the ophthalmoscope. The veins of the disc Mr. Smith found distended, and the arteries lessened in size. With the left eye the patient still read No. 1; the veins, however, were large, and the arteries small; there was also obscurity at its edge, chiefly on the inner side. The left palpebral conjunctiva continued very vascular, and secreted mucus. The pain in the right side of the head was still present at times.

I now left town, and am indebted to Mr. Blake and Mr. Priestley Smith for further reports. On August 14 no change had taken place in either fundus, the sole abnormal appearance being engorgement of the veins and slight diminution in the size of the arteries, with lessened clearness of the edge of the disc; but now vision was nearly destroyed in the left eye also, the only sensitive portion being the lower and outer quarter of the retina. A discharge of very fetid sero-sanguinolent fluid was taking place from the right nostril. The man was sallow and emaciated, had become very dull, and slept all day, and his intellect was manifestly enfeebled. Early in September he was incoherent. Both eyes were closed; he tried ineffectually to raise the lids with his fingers. The discharge from the nostril was copious and offensive. I found him on my return semi-comatose on September 14, and he died on the 20th.

There was some increase of sub-arachnoid fluid. A soft, spongy, undefined mass of considerable size lay in the middle line at the base of the brain, occupying a space a little in advance of the pons to somewhat in front of the optic commissure; it had much the aspect of blood entangled in loose cellular tissue, and blood oozed from it in considerable quantity, though none had been effused during life. The mass had hardly invaded the cerebral tissue, but had entirely destroyed the body of the sphenoid bone and a portion of the ethmoid, thus laying open the nasal cavity. The optic commissure itself, and each optic nerve also, were completely divided transversely. The optic nerve on the right side (the side on which vision had been injured for the longest period) was only half the diameter of that on the left side; its sheath was much thickened.

All the cerebral nerves passing to the orbit were involved in the tissue of the tumour. An irregular cavity, presumably the result of softening, lay in the right optic thalamus. No vessel at the base was obstructed, though the circle of Willis was covered by the mass. All the other organs of the body, the lymphatic glands included, were healthy.

The mass consisted mainly of vessels having very thin walls, and of cells 1-800 inch in diameter, most of them circular; a considerable number, however, were oblong, and not a few candate.

LARGE SARCOMATOUS TUMOUR SPRINGING FROM THE DURA MATER IN THE TEMPORAL REGION—OPTIC NEURITIS—ALMOST SUDDEN DEATH.

(Under the care of Dr. RUSSELL.)

J. W., aged 24, married, applied at the Eye Hospital on account of blindness. Mr. Priestley Smith, the House-Surgeon, sent him to me with the following ophthalmoscopic report :—Loss of vision complete. Extreme neuro-retinitis in both eyes. Right disc completely invisible—even its position not clearly distinguishable; position of the left disc indicated by short portions of retinal vessels which were visible near their point of convergence. Region around the disc in each eye occupied by large irregular patches of hæmorrhage, some recent, others undergoing absorption. Only very small portions of retinal vessels are here and there visible. Besides the loss of vision, the patient was considerably deaf with each ear.

During the three days he passed in the Hospital he is described by the nurse as being "mindless." He did unmeaning things, would not be quiet in bed, and repeated the same thing many times over. There was no paralysis, but it was a curious thing that he always insisted upon standing whilst he ate. His power of swallowing seemed somewhat impaired. Of the food, some regurgitated, and some was swallowed with a sudden effort; this, however, was not constantly the case. Of liquids, a part ran out of his mouth. A prominent symptom at the patient's admission was incessant desire to pass urine, even two or three times an hour. The day of his entrance the urine was densely loaded with amorphous phosphates, but on the day before his death it was quite clear; it was free from albumen.

On the third day of his residence in the Hospital he was suddenly taken with weakness in the right arm and leg, but he was able, nevertheless, to stand whilst taking his tea. During the night he is reported to have become very hot; beads of perspiration stood on his brow, and he complained much of his head. By midnight he was speechless, and the power of the right hand was quite lost. He had no convulsions, though he frothed during the day following. He died in the evening.

The patient was a remarkably healthy-looking man of regular habits. He did not admit the duration of his illness beyond three months, though he had had headache for two months previously. Three months before his death he was seized with shivering, and for several subsequent weeks he was liable to frequent shivers, with a sensation of cold. During the same period he vomited frequently, directly after taking his food. Impairment of vision dates from the same time (three months), and deafness seems also to have been contemporary. He had not had any fits.

On post-mortem examination, a large ovoid sarcomatous tumour weighing six ounces and a half was found in the right parietal region; it evidently sprang from the dura mater, with which it was perfectly incorporated in the temporal region. It originated in a small dense nucleus the size of a small walnut growing from the fibrous membrane, and presenting closely set fibres radiating from the surface of attachment; around this nucleus the main tumour was collected, soft in tissue, but exhibiting delicate fibres radiating through its substance from the nucleus. At the posterior extremity the tissue was intermixed with effused blood. The tumour had considerably indented a part of the middle lobe of the brain, but had chiefly compressed the posterior lobe. It appeared to have contracted organic connexion with the convolutions of a part of that lobe, as on being removed it drew away with itself a considerable tract of grey matter. The lateral ventricles were very capacious, but did not contain much fluid. There was no evidence of pressure having been exerted upon the parts at the base, and the deafness was unexplained. The auditory apparatus was healthy. By great carelessness I forgot the vessels at the base of the brain, and therefore the final attack was not accounted for: presumably it was occasioned by obstruction in the middle cerebral artery. The microscopic characters of the tumour differed from those usual in round-cell sarcoma, in the presence of strands of fibres derived as outgrowths from the dura mater, which gave to the sections much of the appearance of the loculi of carcinoma.

BRISTOL GENERAL HOSPITAL.

CASE OF POISONING BY VITRIOL—DEATH.

(Under the care of Dr. BURDER.)

[Reported by Mr. J. Howell Thomas.]

J. H., aged 34, was admitted June 19. Patient was brought to the Hospital at 9.15 p.m., with the history that he had just swallowed some oil of vitriol.

State on Admission.—Patient was quite insensible; pulse weak and feeble; stertor; extremities cold. He had vomited once on his way to the Hospital; lips were white, but there were no marks of the acid on his face. The tube of a stomach-pump was cautiously introduced, as he could not be got to swallow anything, and some solution of magnesia was injected. It was then withdrawn. The patient then vomited a quantity of black-looking fluid, consisting of blood, mucus, and epithelium, which had a strongly acid reaction. He then sufficiently rallied to be able to swallow some of the solution and also some olive oil. Enema of brandy ʒij. was also administered. He now spoke, and mentioned his name; these were the only words he uttered whilst in the Hospital. He continued to vomit similar fluid to the above at intervals until he died at 5.45 a.m. on June 20, having lived eight hours and a half since admission. It was ascertained that he must have taken at least two ounces of the strong oil of vitriol.

Autopsy (thirty-two hours after death).—Rigor mortis well marked; body emaciated; lips white and dry; front teeth blackened, but none of them were loose; the tongue and roof of the mouth were dry, shrivelled, and of a brownish-black colour; the epiglottis was shrivelled slightly, and of a dirty brown colour. On opening the larynx, the cords were seen to be covered with a brown glutinous liquid. The trachea was inflamed, and covered with the same liquid. Similar appearances were found in the bronchi, even into their divisions in the lungs. The lining membrane of the œsophagus was black and very much charred. On opening the stomach, some black glutinous liquid escaped. The wall of the stomach presented similar appearances to the œsophagus, only in a greater degree, the charring being more marked. There was one large perforation at the commencement of the greater curvature at the cardiac end of the stomach; there were several very thin spots on the wall, but no other distinct perforation; the contents of the stomach had escaped through this perforation into the abdominal cavity. The pylorus was contracted. The appearances in the duodenum were similar to those in the stomach and œsophagus. There were also two perforations—one about two inches from the pylorus, and the other about three inches further on. In the jejunum the charring was not so marked—it had the colour of dirty white paint; it had not gone further than the jejunum. The peritoneum was black at the upper part of the abdominal cavity. The under surface of the left lobe of the liver was also blackened. Brain: Convolutions were small. Some serous fluid in the lateral ventricles. The basilar artery was atheromatous, otherwise there was nothing to be remarked about it. The right pleura was strongly adherent to the chest-wall. Right lung: There was some yellow cheesy infiltration in the upper lobe; two cavities in the apex; the lower lobes were simply pneumonic. Left lung: Some amount of collapse in the lower lobe. Heart: Weight, 12½ ozs.; left ventricle contracted,—there was one small clot in it; right ventricle,—several clots in it, but it was not full. Liver: Weight, 3 lbs. 1½ oz.; substance fatty. Spleen: Weight, 6½ oz. Kidneys: Weight of both, 17½ ozs.; capsule very adherent; surface granular; ureters slightly dilated. There was a stricture in the urethra.

LEEDS GENERAL INFIRMARY.

TWO CASES OF AMPUTATION AT THE HIP-JOINT.

(Under the care of Mr. PRIDGIN TEALE.)

[Reported by Mr. A. F. McGill, formerly Resident Medical Officer.]

Case 1.—Rapid Development of Malignant Disease of the Femur following an Injury—Amputation at the Hip-joint—Recovery.

In the *British Medical Journal* for July 23, 1870, Mr. Teale reported a case very much like the present, in which the patient was admitted into the Infirmary with a swollen knee resulting from a blow on the joint a fortnight previously. The swelling proved to be cancerous, and amputation was performed a few months later at the hip-joint, on January 9, 1869. The boy recovered rapidly from the operation, but died eight weeks after from rapidly developed cancer of the lung.

Ann O., aged 15, a weaver, residing at Kilpenhill, was admitted on January 17, 1873.

Previous History.—Fourteen weeks before admission, while running, she fell on her hands and knees. At the time she was apparently none the worse for the tumble. Four weeks after the fall, and ten weeks before admission, the right knee began to swell, and gave her constant pain of a burning, cutting character. She continued work for a fortnight, and then, two months before admission, sought medical advice. Various liniments and iodine paint were applied, but notwithstanding the treatment the knee gradually increased in size, the pain became worse—preventing sleep,—and the skin over the tumour became red and inflamed. She lost her appetite, and her general health began to suffer.

Present Condition.—The patient is a thin, anæmic girl, with a hectic flush and an anxious countenance. She complains of cutting pain in the right knee and leg, but states that this is not so severe as it was a week before her admission. The right knee, leg, and thigh are much swollen, as the following comparison between the two sides will show:—Circumference of right thigh, 17 inches; left, 12 inches. Circumference of right knee, 23 inches; left, 13 inches. Circumference of right leg, 16 inches; left, 10 inches. The tumour has an elastic, semi-fluctuating character, the skin over it being very tense and shining, and of a mottled livid-red colour. The right leg and foot are œdematous, and the glands in the groin are slightly thickened. The various organs in the body are apparently healthy.

January 22.—She has suffered much and slept but little since her admission. The circumference of the tumour has increased an inch in the last five days.

23rd.—After consultation it was determined to amputate at the hip-joint.

Operation.—The patient having been placed under ether, and the femoral artery secured by digital pressure as it passes over the pubes, Mr. Teale marked out by incision through the skin a long anterior flap. He next transfixed the muscles in front of the femur, bringing the knife out through the skin incision, and, having secured the large vessels, opened the capsule of the joint. The operation was completed by making a short anterior flap by cutting from without inwards. The after-progress of the case was most satisfactory. The relief from pain was immediate, and the general health rapidly improved. The greater part of the wound healed by the first intention, but a sinus on the outer side leading to the acetabulum remained open. On March 2 she got up for the first time. Shortly after the unhealed sinus became unhealthy and phagedænic; she had to return to bed for a month, and then was well enough to be made an out-patient. In the end of June she returned to the Hospital, having fallen off in health, and symptoms of thoracic mischief (prebably cancerous) having developed themselves.

Case 2.—Amputation at the Hip-joint, after Excision of the Hip, accompanied by Fracture, and followed by Necrosis of the Shaft of the Femur—Rapid Recovery.

George H., aged 16, was admitted on November 10, 1871.

Previous History.—Shortly before Christmas, 1870, he became lame, had violent pain in the right knee and hip, and was soon unable to walk. He went to bed, and stayed there till June, 1871. By that time he was somewhat improved; the pain was less, and he could walk on crutches. This he did daily. He could not, however, put his foot to the ground, and he suffered considerable pain when he flexed his thigh in sitting down. A week before admission he noticed a swelling near the hip, and this it was that caused him to apply to the Infirmary.

Present Condition.—Besides the usual symptoms of hip disease, there is below the great trochanter a fluctuating swelling the size of an orange. The various organs are apparently healthy.

November 18.—The swelling below the trochanter is opened, and some ounces of pus are evacuated.

December 28.—There has been much suppuration for the last six weeks, and the patient is evidently losing ground; it is therefore determined to excise the head of the bone.

Operation.—Mr. Teale first made a semicircular incision over the neck of the bone, and dissected down to the joint. An attempt was then made to rotate the head of the bone out of the socket, when unfortunately the femur was broken about the middle. The head and neck of the bone, and the great trochanter—the latter very much thickened and softened—were removed piecemeal by means of the gouge and sequestrum forceps. After removal to bed a weight was applied to the limb.

The after-progress of the case was most unsatisfactory. Periostitis of the whole of the shaft of the femur supervened, and on January 20 a large abscess containing about sixteen ounces of pus, communicating with the fracture, was opened. From this date the discharge of pus was very great, and it was thought probable that the patient would sink. In spite of his rapid pulse, and of his exhausted and wasted condition, Mr. Teale (on July, 18, 1872) amputated at the hip-joint, after the manner described in Case 1. The operation, owing to the previous excision, was easily performed, and little blood was lost. On August 11 (twenty-two days after the amputation) the wound was nearly healed, and on August 18 he went home convalescent. He is now a stout, healthy lad.

Remarks.—Control of the Femoral Artery.—In these cases the femoral artery was controlled without difficulty by digital pressure near Poupart's ligament. In the case previously reported the circulation was commanded most perfectly by Lister's abdominal clamp, but Mr. Teale refrained from using it because of the sickness and epigastric tenderness which followed its employment. He thinks that the pressure on the abdominal viscera, and perhaps on the sympathetic nerves and ganglia, may be injurious. *The Form of Flap.*—The form of flap proved to be remarkably convenient. By the preliminary incision through the skin the exact amount required would be secured, long enough and broad enough up to its extremity to cover easily and amply the transfixed muscular portion of the flap—a condition which cannot be secured by simple transfixion of muscle and skin at one cut. The larger flap, being long and ample anteriorly, fell naturally over the front of the stump, and lay without tension or drag in the position required, the union of the flaps being in the position most favourable for the drainage of fluids. When a long posterior flap is made, it is liable by its own weight to fall away from its fellow, even when it may have united by first intention, and when aided to the utmost by care in dressing—a care which in these cases of the long anterior flap is superfluous.

SATURDAY, JULY 26, 1873.

THE REWARD OF SCIENCE.

The recent refusal of the Treasury to increase the very inadequate stipends of the scientific staff at the British Museum is pretty conclusive evidence of the value set upon science by the average Englishman of the present day. It will scarcely do to assert that it is part of the ordinary cheese-paring policy pursued by Mr. Lowe and his colleagues, for unless the present Government believed that they would be supported by a considerable part of the public, they would not have ventured to refuse a request presented with the sanction and support of some of the first men in science and literature in the United Kingdom. The fact is, that although the present degree of prosperity of the country is primarily the fruit of the labours of its scientific workers—although science is belauded everywhere with an amount of lip-service which would be satisfactory if it were real,—there is no walk in life so likely to lead to disappointment and penury as the pursuit of science for its own sake, and there is no kind of labour for which the ordinary Anglo-Saxon Philistine is so unwilling to pay as the labour of scientific men.

Mr. Lowe has lately been explaining before a Commission of Inquiry the reasons on which a high rate of payment of clerks in the Treasury has been fixed. These offices compete in attraction with College Fellowships, and they are intended to be filled by men who in a public school have acquired the peculiar "freemasonry" which the education there given is supposed to confer. We are not of those who would depreciate public school education, or the power of "holding your own" which it gives; but at least the special education of a first-rate zoologist, botanist, or archæologist (and none else would be likely to get an appointment in one of the departments of zoology, botany, or archæology in the British Museum) should be held to represent as valuable a qualification as

the classics and mathematics possessed by a sixth-form boy. Why the latter should be bribed to serve in the public service by £250 a year to begin with, which is gradnally increased to £1200 or more, whilst the scientific man begins at £90, and rarely rises to £600, it is hard to understand except on the principle that Englishmen do not value science as they value the sum total of conventionalities which go to constitute the "freemasonry" discoursed of by Mr. Lowe. To come again to the scientific professions, we find that their present rate of remuneration is fast falling behind that of the commercial and bnsiness classes. Successful merchants or stockbrokers would be dissatisfied with the earnings of the foremost physicians and surgeons, and these wonld not bear comparison with the receipts of great brewers, ironmasters, or contractors. The physician's fee of one guinea is the same as it was in Radcliffe's time, althongh it does not represent mnch more than one-third of the valne. In addition to this, the amount of gratuitous work imperatively demanded by the public from the medical profession is enormously increased.

A statement by Sir Dominic Corrigan has lately gone the ronnd of the papers, to the effect that in Dnblin the ordinary medical income would average from £800 to £1000 a year, and the higher ones would monnt up to £5000. Irish estimates of fortnnes are proverbially often mistaken; but, accepting this as a trne statement, we wonld observe that the incomes of our Hibernian brethren are at least as good as those of medical men on this side the Channel, but that they are very small in comparison with the value set by a former generation on medical services. The medical practitioners of the last century, with far less of scientific training, with far less of expensive education, died and left large fortunes to their families. Such occurrences are at least rare in the present day.

For this state of things it is difficult to find a remedy. By some it may be asserted that the remnneration of the scientific professions is in the hands of those professions themselves, and that the doctors have only to take a lesson from trade unionists to bring abont a better state of things. Bnt Medicine has never yet been degraded into a trade by its professors, and we trnst it never will be. The remedy, we believe, is to be found in the dissemination amongst the pnblic of jnster views of the value of medical services, and especially by urging on the Government the duty of remnnerating scientific workers properly. A revised scale of pay for the Poor-law medical officer would tend to increase the remuneration of all medical men. Again, we think that medical men who have attained the highest round of the ladder of success shonld, in justice to their younger or less fortnnate brethren, distinctly refnse a class of practice which is not highly remunerative. Were the physicians and surgeons who now enjoy the cream of London practice to refnse any fee of less amount than two guineas, the income of the profession throughout England would be at least donbled in the conrse of twenty years.

RESPONSIBILITY IN OBSTETRIC PRACTICE.

At a recent inquest in the East of London the jury were asked to decide more than one question of some difficulty and delicacy. We shall not mention any names, as these are not essential to the objects we have in view. Moreover, as the only newspaper report which has reached ns is very imperfect in a medical point of view, and we have not the whole of the depositions before ns, it wonld probably be doing an injustice to some of the parties concerned were we on snch materials to fonnd an *ex cathedrâ* judgment of the whole case. But facts which are so far undisputed, especially if read in the light of another recent award by a jury of £300 damages against a medical practitioner for alleged malpraxis by an assistant in an obstetric case, warrant us in drawing attention to some points which are of interest to the whole profession. The present case presented two or three complications which we wish to clear away as non-essentials before we proceed to put the real question at issue. Thus the alleged fact that the principal, or defendant, possessed no diploma, is, we are informed, counterbalanced to a certain extent by his being registered under the Medical Act as being in practice before 1815. And further, it must be remembered that the law has forborne to affix any penalties to the mere practice of either medicine, surgery, or obstetrics by undiploma'd practitioners. As long as the practitioner makes no false pretences, the old maxim of *caveat emptor* must, in the present state of our jurisprudence, be considered applicable. Nor does it much matter whether, as alleged on the one side, the assistant, who happened to be also the son of the principal, had no qualification at all; or, as we have been since informed, that he had passed one or two primary examinations—notably those on anatomy and physiology at the Royal College of Surgeons. The fact that he was deaf, althongh it might account for some misunderstandings, mattered little, since it is not averred that he was deficient in other senses, such as sight. And again, his having attended 500 or 1000 cases of labour before this, and the deceased herself on two previons occasions, although it may very properly have weighed with the coroner and the jury, is non-essential to us, since this particnlar case might as well have happened at the ontset of his career. If any personal questions originated the inquiry or embittered its proceedings, we set them aside as uninteresting and unimportant to the bulk of the profession, and proceed at once to the relation of so much of the story as is necessary to understanding the important questions which arise out of it. It appears, then, from the evidence before us, that on June 12 last a multipara, who had been attended by the assistant in question on two previous occasions (he acting all the while on behalf of his father, who is said to be a registered practitioner, but laid aside from illness), sent again for this assistant, whom we will call Mr. A. No. 2, to attend her in labour. The summons was urgent, and his brother, whom we will call Mr. A. No. 3, attended for him, and was there until both a living child and a placenta of some sort came into the world. At this point, however, Mr. A. No. 2, first sent for, arrives, and takes charge of the case. Mr. A. No. 3 retires, and we need take no further notice of him, since it appears that Mr. A. No. 2 then assumed the responsibility of the case. It is admitted that he examined the placenta, and reapplied the usual binder; but there is a conflict of opinion on the perfect state or the reverse of the after-birth. The only nurse who was present was the patient's mother, and although she stontly affirmed on oath that she always thonght that only a part of the after-birth came away, she kept these views to herself till some sixteen or seventeen days had elapsed, and she had been shown what purported to be a portion of placenta by two other medical men, whom we will call Messrs. B. and C. But we are anticipating, so far, our story. This same witness (nurse and mother in one) also declared that there occurred some two or three distinct floodings, the first on the third day, and the rest between that and the ninth or tenth day. Mr. A. No. 2 confirmed her evidence as to the first flooding, but declared on oath that although he made inquiry he never heard of floodings No. 2 and No. 3. It is, however, only fair to the mother to say that her evidence was corroborated by the hnsband and others, as well as by the snbsequent medical evidence. As partially exculpating Mr. A. No. 2, we may consider the fact of his deafness, and this further consideration, that no one (not even the deceased herself) appears to have attached much importance to the hæmorrhage; and the poor woman paid, and it is said dismissed, Mr. A. No. 2, and moved, or was moved, into another room, and sat on a couch, in the company of several friends; this was about the tenth day.

But here comes the peculiarity of the case: there was an interval of a whole week, during which she does not appear to have been seen by any medical man, but during the whole of which she appears to have flooded more or less, and at the last to such an extent that even her somewhat lethargic friends grew alarmed, and, by the landlady's advice, called in Mr. B. He comes, and finds the patient blanched, bleeding, and collapsed. He introduces his hand, withdraws what he and Mr. C., his partner, who now arrives, call a portion of placenta, and otherwise attends to the case, by giving stimulants and support, in spite of which the woman dies at the end of six days; and at a post-mortem examination it seems clear, as far as we can judge from the evidence, that she died from loss of blood. It is alleged that Messrs. B. and C. made but a hasty examination of the so-called placenta, and that it might have been a blood-clot, or one of those supplemental placentæ which are sometimes, though not very commonly, met with. But all this is beside our object, and it is probable that the local jury, in dividing the blame between the poor woman's guardians and her actual attendant, and using the same words, "an error of judgment," were not far wrong in their own judgment of the case. Our own view is that the friends were far too eager to get her up, and that her medical attendant was too willing to believe everything was going on well without personally satisfying himself that it was so. The medico-legal bearings of the case appear to us to be these: —First,—How far could Mr. A. No. 1, who never appeared on the scene at all, although he appears on the Register and on a door-plate, be considered responsible for the acts of his assistants, Messrs. A. Nos. 2 and 3? Secondly,—Whoever may be considered the responsible medical attendant, not in this case, but in any other which may arise, can he fairly be held responsible for the *finale* of a case which he has ceased attending by the consent of the legal guardians of the patient, and it may be of the patient herself—when, as was somewhat crudely stated, he has been paid off,—and no further steps are taken by any one *quoad* medical assistance until a whole week of valuable time has been lost? Thirdly and lastly,—As this patient did not die till July 6, twenty-four days after her confinement, and as in the interim what the witnesses called an operation—viz., the introduction of the hand into the vagina, and more or less completely into the uterine cavity—had taken place, could her death be fairly charged at the door of her first medical attendant, he having ceased to attend her by general consent of all the parties concerned? We think the common sense of the jury has fairly answered the whole of these questions, because, the evidence tending to show that the engagement to attend the deceased was a direct bargain between herself and the assistant Mr. A. No. 2, they very properly ignored the existence of Mr. A. No. 1 altogether. How far they were right in law is another matter; but there was nothing in fact to show that any of the parties knew Mr. A. No. 1 at all. Secondly, whatever may be the local customs as to nine days or a month, or any other term, we hold that the original medical attendant must be held responsible, to the best of his skill and judgment, to do all that in him lies to secure the return of the woman who has been confined to as perfect a state of health as possible; and no woman can be safe as long as flooding is going on, or her pulse remains at or about 100, and her temperature on an elevated plane. But this responsibility, of course, involves the co-operation of the patient if in a state of sanity, and at all events of her friends; and this appears to have been wanting in this case. Thirdly and lastly,—the careful introduction of the hand into the uterine cavity, however dangerous in certain points of views, and however cautiously it ought to be undertaken, is no doubt less dangerous than the risks of hæmorrhage, and, provided it were indubitable that placenta or even large quantities of clot were left behind, the consultant should undoubtedly be held guiltless for endeavouring to substitute a lesser risk for a greater, and the first attendant must be held in a certain sense responsible. The medical evidence on both sides in this case, as it has been reported to us, was sadly defective. There were no certain data on either side of the condition of the patient or of the uterus on any given date. The description of the post-mortem appearances was vague, and in some matters self-contradictory; and none of the witnesses appeared to feel sufficiently the true bearings of the case. We do not insist upon the desirability of preserving in spirit or some other way the *corpus delicti* of so-called placenta, since the medical witnesses asserted that the inquiry was none of theirs; but it would certainly seem to us that the case would have been far more satisfactory to everyone if the post-mortem examination had been made by a disinterested person.

THE PHYSIOLOGY OF MENSTRUATION.

It is probably the general belief among physiologists and the profession in general that during menstruation one or more ova reach the uterus, and there either become attached to the surface of the mucous membrane or disappear, according as fecundation has occurred or not. If an embryo is developed from the ovum it will correspond with the menstruation immediately preceding—or, in other words, pregnancy will date from the menstruation which last occurred. Dr. Kundrat, of Vienna (Rokitansky's senior assistant), has just published an account of certain researches of his upon the anatomical condition of the uterine mucous membrane before, during, and after menstruation, which throws very grave doubts upon the correctness of this belief (*Medizinische Jahrbücher*, 1873, vol. ii., p. 135. Kundrat's investigations are all the more worthy of attention that they were of a purely anatomical nature. He examined the mucous membrane of the human uterus in the intervals of menstruation, immediately before the hæmorrhage, during the hæmorrhage, and again after it had ceased, and the results which he obtained are certainly in favour of the considerable modifications which he would introduce into the physiology of ovulation and menstruation as presently received. The mucous membrane of the human uterus in the "state of rest" has certain peculiarities, as pointed out by the author. There is no submucous tissue, and the mucosa comes into immediate union with the muscular layer. Its matrix is peculiarly rich in round or spindle-shaped cells. The glands, which it is known to possess in great numbers, are lined, like the free mucous surface, with ciliated epithelium. This condition is markedly altered at the monthly period of uterine activity. The mucous membrane is swollen, thick, loose, and almost diffluent, covered with a whitish or bloody mucus, finely injected at spots, and in many cases uniformly coloured of a deep red. A microscopical examination reveals increased abundance of the cellular matrix, especially at the surface, with great elongation and dilatation of the glands. So far there is nothing specially original in the description given by Kundrat, but new and important facts remain to be enumerated. He discovered in the first place, that the condition of uterus just described probably precedes the occurrence of the discharge of the ovum and—what is perhaps more striking—the menstrual flow by "several days." The author considers that this observation goes far to prove that the uterus is prepared for the reception of the ovum a certain time before the rupture of the Graäfian vesicle. Again, while the rough characters remain as described during the menstrual flow, with the addition of the oozing from the surface, and for a short time after it has ceased, careful examination reveals a very remarkable change in the microscopic appearances. The cells

of the stroma and the vessels, as well as of the epithelium of the glands and surface, are dull in appearance and filled with fat granules. The question occurs, What is the relation of the hæmorrhage to this fatty degeneration of the cells and vessels? Kundrat replies by stating his belief that the hæmorrhage does not cause the fatty change, but is caused by it. He refers to the fatty change which is known to occur at the end of pregnancy, and would consider the two phenomena homologous. He also points out the improbability of the cause of the flow being found in congestion, as this occurs so frequently without hæmorrhage. One fact he has ascertained is that the fatty change is most abundant at the surface of the mucosa, where the bleeding takes place. The anatomical sequence of events, therefore, according to Kundrat, at the monthly period of uterine activity is—swelling of the mucosa, fatty change in the cells and vessels, vascular rupture, and hæmorrhage. With the blood much altered epithelium is thrown off, but not the whole mucosa, as some believe. It is a short time after the cessation of the menses before the mucous membrane has returned to its "condition of rest."

In inquiring now into the physiological relations of the three processes—the swelling of the mucosa, the discharge of the ovum, and the flow of menstrual blood—Kundrat insists strongly upon the ascertained chronology of the events. The first mentioned of the three is the first in order of time, and it is almost certainly the preparation for the reception of the ovum. It is much more improbable that the uterus during the menstrual flow is in a condition suitable for this function—with a retrogressive process going on in the mucosa, its vessels ruptured, and its surface discharging blood. It is even more improbable that the mucosa in this state of degeneration will on the descent of an ovum take on a totally opposite process, and become highly developed. The type of the impregnated uterus is seen in the active uterus when the mucosa is swollen and menstruation has not yet commenced. If the bleeding does commence, it is a sign that the ovum has perished, and that the mucosa is returning to its state of rest. Thus we arrive at the highly important conclusion that a developing ovum, or growing embryo, belongs not to a menstrual period just past, but to one just prevented by fecundation. Löwenhorst has already expressed this opinion from a consideration of the clinical aspects of menstruation, and we believe that the method of calculating the duration of pregnancy suggested by the new facts is not altogether a new one among the gynæcologists and practitioners of this country.

THE ESTIMATION OF UREA IN URINE.

Few problems in practical medicine are at once so difficult and so desirable as a ready and accurate method of ascertaining the amount of urea in the urine passed by patients suffering from various diseases, such as diabetes, Bright's disease, gout, and others which will at once occur to the minds of our readers. The method of Liebig, though sufficiently accurate, is far too tedious and difficult to become popular, and Dr. John Davy's method, by the use of hypochlorite of soda, is hardly accurate enough. The substitution of a solution of hypobromite of soda or of baryta, as proposed by Knop and applied by Hüfner, is a considerable improvement on Dr. Davy's method, and is sufficiently rapid to be of clinical use. The *Gazette Hebdomadaire* of May 30 last contains a modification of this by M. Esbach, which gives results rapidly, and, although wanting in absolute accuracy, is one of the best we have seen for ward-work and also for private practice. M. Esbach uses a ureometer, or glass tube, closed at one end, 38 centimètres long (=15 inches nearly), with a cubic capacity of 28 cubic centimètres (rather less than one fluid ounce) graduated into tenths of cubic centimètres (1 cubic centimètre=15·44 grains nearly). He pours in 6 cubic centimètres of the bromated solution (made by mixing 130 parts of distilled water, 50 of liquor sodæ, and 2 of bromine, all by measure), and then adds pure water up to 10·4 cubic centimètres (rather more than one-third of the tube). To this he adds one cubic centimètre (15·44 grains nearly) of the urine, which should be filtered and freed from albumen. The thumb is placed over the top of the tube, the whole shaken briskly, and then plunged into a basin of water with the mouth of the tube downwards. The volume of gas is then read off, deduction being made, of course, for the air previously in the tube. The remainder is the volume of nitrogen evolved from the urine decomposed, and an easy calculation (on the same principles as Davy's method—viz., that every twenty-eight of nitrogen equal sixty of urea) will give the quantity of urea in the sample; and the daily excretion by the urine if the quantity passed per diem of the latter can be ascertained. In this method glycocoll, leucine, amido-benzoic acid, taurine, acetamide, ethylamine, aniline, conicine, and nicotine do not interfere, as they do not give up their nitrogen. Oxamide, however, is entirely decomposed; uric acid and creatine partially so; also guanine and caffeine slightly; and albuminous compounds are slowly split up.

We are glad to see that M. Boymond, the greatest living authority on urea, and author of the well-known monogram on the subject,(a) gives this method by the hypobromite his approval. He has recently published a note on the estimation of urea in the July number of the *Annales de Chimie et de Physique*, 1871, p. 351, from which we extract the following account of a less rapid, but more accurate, method founded by him on Millon's process. He says that the action of nitrous acid on urea has long been known. According to Gerhardt, Wurtz, Hoppe-Seyler, and others, the result was formulated thus—$C^2H^4N^2O^2+2NO^3=4HO+4N+2CO_2$. But Prevost and Dumas, in making analyses of urea with oxide of copper, have established the fact that urea, in splitting up, furnishes equal volumes of nitrogen and carbonic acid; or, according to Berthelot, the equation is as follows:—$C^2H^4N^2O^2+6O=4HO+2N+2CO_2$. The same thing takes place in Davy's process. [We may parenthetically remind M. Boymond that it was Dr. *John* Davy, not Sir Humphry, who invented the hypochlorite process for urea.] There is also a formation of ammonia; and the true reaction of nitrous acid on urea is most probably represented by the formula—$C^2H^4N^2O^2+NO_3=HO+NH^3+2N+2CO_2$; or $C^2H^4N^2O^2+NO_5HO+NO_3=HO+NH^3NO^5HO+2N+2CO_2$.

Liebig, Neubauer, and many others admit the formation of ammonia. If we express the preceding formulæ in words, the result is, that when nitrous acid reacts on urea, water, ammonia, and equal volumes of nitrogen and carbonic acid are evolved:

$$C_2H_4N_2O_2=2N+2CO_2$$
$$\overbrace{\qquad}^{60} = \overbrace{\qquad}^{28\quad 44\ =\ 72}$$

—or 60 grains of urea produce 72 grains of nitrogen and carbonic acid, or 100 grains represent 120 grains of gases. We can thus calculate the amount of urea by the loss of weight, if we take care to drive off the gases. For the purpose of doing so in urine, the apparatuses of Geissler and Alvergniat are used by M. Boymond. These weigh from 45 to 50 grammes when empty; when full (as used by him), they weigh from 80 to 90 grammes. 0·20 grammes of urea ought to produce a loss of weight of 0·240 grammes. In operating on urea dried at 100° C. (212° Fahr.), these figures were often obtained, and at other times very close approximations, such as 0·235, 0·238, 0·242, 0·244, etc. In the originals the apparatus used is figured, and an exact description of the *modus operandi* is given, which space compels us to omit. The actual reagent employed is a modified Millon's solution, made by

(a) "De l'Urée, Physiologie, Chimie, dosage." Par M. Boymond. Paris: MM. J. B. Baillière et fils. 1872. Pp. 167.

dissolving 125 grammes of mercury in 170 grammes of pure concentrated nitric acid, in the cold, or with gentle heat, and then adding an equal bulk of distilled water. The gases evolved are passed through a mixture of pure strong sulphuric acid and sulphate of iron, to absorb the water, and binoxide of nitrogen. The difference between the weighings or loss of weight serves to calculate the urea, x; since 120 of gas=100 of urea.

Now $\frac{120}{100}=\frac{P}{x}$; $x=\frac{P\times100}{120}$ or $x=\frac{P\times5}{6}$; or we may take as sufficiently accurate the co-efficient 0·8333; thus $x=P\times0{\cdot}8333$. According to Millon neither uric, hippuric, acetic, oxalic, lactic, nor butyric acids, albumen, diabetic sugar, nor biliary matters have any sensible effect in the result. To this list Bunsen adds milk, blood, muscular fibre, fat, saliva, nasal mucus, and phosphate of ammonia; and M. Boymond states that the same may be remarked of creatin, creatinin, xanthin, hypoxanthin, guanine, leucine, and tyrosine. It will thus be seen that none of the ordinary ingredients of urine are likely to interfere much with the result. It is true that ammonia salts would be decomposed, but our object as physicians is generally to find the total excretion of nitrogen by the kidneys; and in order to obviate the evolution of carbonic acid from ammoniacal urine, we can add tartaric acid, and warm gently, after filtering.

THE WEEK.

TOPICS OF THE DAY.

The results of the first Hospital Sunday in London are now before the world, and it cannot be asserted that the success of the movement has been startling. The total sum raised was £27,403 0s. 11d.—an amount £8000 short of the annual expenditure of one hospital—the London—alone. The tone of the speakers at the Mansion-house on Wednesday was generally apologetic. They promised better things next year, when the clergy and ministers of different congregations would have had time to prepare their flocks for the effort. But, whatever gain may be promised by this consideration, it cannot be denied that the novelty of the movement will have gone, and there is just the chance that people may come to regard it as an annual tax, to be met with grudging decorum. There is also the danger we have already pointed out—that persons may excuse themselves from subscribing in the ordinary way to medical charities, on the ground that they have already contributed to the hospital collection in church or chapel.

However, we will not prophesy even the partial failure of a movement which has undoubtedly been commenced and carried into effect with the best and most philanthropic intention. The distribution of the money seems in the main to have been founded upon a principle which we believe to be a good one—that of encouraging and supporting the institutions which provide in-door maintenance and relief for the sick rather than giving money to be expended on the far more doubtful benefit of furnishing medicine indiscriminately to out-patients. The Mansion-house Council have apportioned £24,571 13s. 4d. to hospitals, £967 18s. 4d. to dispensaries, and £881 13s. 4d. to other institutions, making a total of £26,421 5s.—the surplus having been chiefly expended in printing and other necessary expenses. Of the £24,571 voted to the hospitals, eight of the large hospitals take £15,966, as follows:—The London, £3833; St. George's, £2875; the Middlesex, £2300; University College, St. Mary's, King's College, and Westminster, each £1500; and Charing-cross, £958. Of the £8605 remaining, the City of London Hospital for Diseases of the Chest has obtained about £1000, and the remainder is divided amongst the fifty-four smaller hospitals, most of which are special, but a few—such as the Great Northern—are general. The Council have made their awards on a consideration of the income and expenditure of the charity, and, as we have said, the principle of supporting in-door rather than indiscriminate out-patient relief has been kept steadily in view. In proportion to the number of beds, St. George's and the Middlesex have obtained the greatest award—St. George's Hospital being one in which limits are placed on the number of out-patients. St. Bartholomew's, Guy's, and St. Thomas's, already amply endowed, receive no part of the fund. Of course, as may be supposed, the distribution of the fund has met with great disapproval from the representatives of the dispensaries and the supporters of the indiscriminate out-patient system. But the truth was told the meeting on Wednesday by Sir Anthony de Rothschild and Sir Charles Trevelyan,—the former of whom denounced the practice of distributing medicine gratuitously and without investigation, and stated it was found in the Jewish Dispensary at the West-end that "the medicine given annually was more than sufficient to supply the whole population of Whitechapel." If indeed, as Sir Charles Trevelyan believes, the effect of the movement will be "to prevent or give a powerful check to the great abuse of large numbers of persons availing themselves of those charitable institutions who were in no way entitled to do so," it will be difficult to over-estimate its benefits, both to the public and to the profession of medicine. The same speaker continued—"That was the real cause why medical institutions were more constantly in pecuniary embarrassment than any other. It was a great public evil that the medical profession should not receive the due reward of its pains; above all, the tendency of admitting all comers, without question and without payment, had a most mischievous influence in accustoming our people to pauper or dependent habits. Whatever the Council might have done this year, the administrative influence it would be able to exercise would be ten times more beneficial in the end."

The Medical Act Amendment (University of London) Bill has passed the Commons, and has been read a second time in the House of Lords. The Committee on the Bill in the Upper House was fixed for Thursday, July 24.

Dr. Curnow, a distinguished student of King's College and graduate of the University of London, has been elected to fill the Anatomy chair at King's College, vacant by the death of Professor Partridge.

A new extinct Struthious bird from Australia is described by Professor Owen in the newly issued part of the *Transactions of the Zoological Society*. The name proposed by the Professor for the extinct bird is *Dromornis Australis*.

MR. LE GROS CLARK.

It is always a subject of regret when a medical school loses the services of a teacher who has been connected with it for a lifetime, and while rising to the foremost rank in his profession has identified himself with his school; but there is no more honourable termination to such a connexion than that which we have to record this week. Mr. Le Gros Clark retires from the office of Senior Surgeon to St. Thomas's Hospital and Lecturer on Surgery in the Medical School, and he leaves with the regret of his colleagues and of the students, but with their warmest feelings of affection and esteem. There are few who have deserved this more thoroughly, for few have devoted themselves so unselfishly to their duties, and few again have commanded so much personal respect. It is not the lot of many to be endowed with the strength of will and moral fearlessness in addition to the wisdom, courtesy, and commanding appearance which we look for among the heroes of a past age; but we may learn a lesson from those who do possess them, and particularly when they are leaving their togas to another generation. Mr. Le Gros Clark entered early upon hospital work. He was apprenticed in 1827 to Mr. Travers,

and while an apprentice was selected to fill the office of Demonstrator of Anatomy at St. Thomas's. He became Assistant-Surgeon in 1843, upon the death of Mr. Tyrrell, and remained in this office ten years, during which time he gave the lectures on Anatomy single-handed. It was early in his career that the views of Marshall Hall were promulgated, and met with so much opposition; but Mr. Clark strongly supported Marshall Hall, and was one of the first, if not *the* first, of English authors who accepted the then heterodox views enunciated by that gentlemen. He was appointed Surgeon in 1853, and for many years delivered the entire course of lectures on the Principles and Practice of Surgery. In this he was joined, during the last few years by the late Mr. Solly, and recently by Mr. Sydney Jones. We understand that Mr. MacCormac will succeed Mr. Le Gros Clark, both as Surgeon and as co-lecturer on Surgery; and the School of St. Thomas's may be congratulated upon finding so able a successor, though until recently an entire stranger to it. Mr. Clark gave his farewell lecture on Thursday week. The largeness of the attendance and the attention with which his words were listened to were the best evidences of the affection and respect in which he is held. May he long live to enjoy the rewards of an honourable and useful life!

THE CHOLERA.

Cholera still continues to spread, but slowly. Since our last notice it has extended somewhat in East Prussia and on the Danube, but it presents none of those indications of rapid advance we have been accustomed to see in former epidemics, especially the great historical ones whose history is now sufficiently well known. In these the disease seemed to break out in isolated patches all over the country, apparently defying all attempts to account for its spread, though that is now known to be almost invariably along the lines of human communication and intercourse. From Vienna the latest accounts we have are only up to the 9th inst. In the week ending on that date upwards of 4000 cases of various forms of disease were treated in the military and civil hospitals. Among these were sixty cases of vomiting and purging (*Brechdurchfall*), but, as seen in the full report given by the *Times*, most of the cholera cases have occurred in hotels and among strangers. Vienna is at no time a savoury city, and its hotels are singularly deficient in sanitary arrangements. Moreover, it is in these we should expect to find the first indications of infection, as in these most likely will be found strangers from already infected districts. The name of cholera does not yet figure in the Viennese returns.

THE ASHANTEE WAR.

Notwithstanding the assurances conveyed in Parliament last week by Lord Kimberley, to the effect that the medical stores sent out from this country to meet the exigencies of the Ashantee war had not been lost in the two mail-steamers so unfortunately wrecked on the West Coast of Africa, we are very happy to be able to state that a further supply of those medicines most likely to be required was prepared and shipped by the packet of the 17th inst. The Medical Department at home would appear to be determined that no blame shall attach to it on the score of short-sightedness or want of forethought; and, without anticipating the worst, we much fear that the supplies now forwarded will be urgently required at Cape Coast Castle.

The last despatches received conclusively prove that, as everybody anticipated, the invading savages possessed but a scant chance of success when encountered by disciplined men; but we think the assumption that they will be chary of attacking us again after this last defeat, somewhat premature: the King of Ashantee has marched too far, and gained too many advantages over the tribes under our protection, to be convinced by one minor reverse; and the critical position of the handful of men opposed to him is doubtless well known to his sable majesty. If our rulers wish to put an end to the irritation arising from this petty annoyance, and prevent the recurrence of an outbreak which will cost us some money and many lives, they would do well to collect a force sufficient to break up the Ashantee power for good and all. Up to the present time we have only "scotched the snake, not killed it"; and if on the present occasion the authorities rest content with merely beating back the impudent invasion of our territory, without teaching a lesson the recollection of which will for years be fresh in the Ashantee mind, they may depend that so soon as our troops and vessels have left the Coast the same annoyances will recommence. Whatever course it may be considered the wisest to take, one thing is certain,—we must, in such a climate, be prepared for a considerable loss of life by disease. At the best of times the Coast is peculiarly fatal to Europeans, and by the last accounts, from a variety of causes, it would appear now to be at its very worst; therefore it will not be surprising if we find that for every soldier struck down in battle we have twenty rendered *hors de combat* by sickness. With this knowledge in our possession, it is reassuring to find that the Director-General of the Army Medical Department has taken every precaution which experience suggests to provide a supply of those remedies most likely to be urgently needed; and we can only hope that a short but decisive campaign will settle the present difficulty for ever, and save a multitude of those lives which will be sacrificed if we are likely to be engaged in a feeble and protracted struggle in such a pestilent spot.

DEATHS ON RAILWAYS.

A statement having recently been published as to the number of persons killed annually on the railways of the United Kingdom, and doubt having been expressed as to the accuracy of the figures which were given, we have, through the courtesy of the Secretary of the Board of Trade, obtained the official returns for the last five years. This information is of great public as well as of professional interest, and the numbers certainly support the representations of those who are endeavouring to obtain Parliamentary interference for the preservation of life and limb in railway travelling. The numbers, of course, throw no light as to the percentage of lives shortened by injuries received in railway travelling:—

Number of Passengers, Servants of the Companies, and other Persons Killed and Injured, and of Suicides, upon the Railways of the United Kingdom in each of the Years 1867, 1868, 1869, 1870, *and* 1871.

Year.	Passengers.		Servants of the Companies.		Suicides.	Other Persons.		Total.	
	Killed.	Injured.	Killed.	Injured.		Killed.	Injured.	Killed.	Injured.
1867 . .	36	697	105	90	6	62	8	209	795
1868 . .	62	525	83	65	8	59	10	212	600
1869 . .	39	1060	151	148	12	119	24	321	1232
1870 . .	90	1094	115	129	15	66	16	286	1239
1871 . .	57	896	*213	*323	16	118	42	404	1261

* The great increase of these numbers is to be attributed to the fact that previous to the passing of the Regulation of Railways Act, 1871, many railway companies did not make returns of accidents to their servants.

HEALTH IN THE LEAVESDEN SCHOOLS.

Dr. Rudyard, Medical Officer of the Leavesden Asylum, reported to the St. Pancras Board of Guardians, last week, that there was an almost entire absence of skin diseases at the schools. Ninety of the children were now ready to be returned to the schools quite cured.

PROVIDENT DISPENSARIES.

A MEETING of medical practitioners of Manchester and the neighbourhood was held at the Town Hall, Manchester, on the 18th instant, at which the following resolutions were passed. The meeting was largely attended. Mr. R. T. Hunt presided:—

Proposed by Dr. Noble, and seconded by Dr. Reed:

"That, in the opinion of this meeting, the institution of provident dispensaries, as hitherto proposed, is not calculated to remedy admitted evils, while the scheme would hardly be consistent either with the due interests or the proper dignity of the medical profession."

Proposed by Dr. Armstrong, seconded by Mr. J. Platt:

"That the formation of medical provident dispensaries, as now in operation, would tend to bring the great majority of the working classes of this country, their wives and families, under one vast system of medical and surgical relief; would enter into unfair competition with, and be ruinous to the best interests of, the great majority of the medical men of this country; would create a system which is even more liable to be abused, and that on a larger scale then the present generally admitted abused hospital charities are; and in addition to this, it is most likely they would cause a large falling off in the subscriptions to the present medical charities."

Proposed by Mr. Frank Holmes, and seconded by Mr. Henry W. Toyne:

"That as regards the medical profession the necessity for these 'provident dispensaries' does not exist, since by the poor-laws the really poor are provided with skilled medical and surgical relief free. The establishment of these dispensaries will bring them into competition with the existing friendly and other societies (originated and managed by the working classes) for relief in sickness and distress; and considering that it has been the invariable rule of the medical profession to charge the working classes according to their means, and to accept from them payment of their accounts by instalments, when necessary, this meeting is therefore opposed to the establishment of these dispensaries."

Proposed by Mr. Henry Winterbottom, seconded by Dr. John Watson:

"That the undermentioned gentlemen be elected from this meeting to form a committee of the general profession to watch any scheme which may be proposed, and, if necessary, report to any future meeting of the profession to be called for that purpose; and that this committee consist of Dr. Royle, Dr. Armstrong, Dr. John Roberts, Mr. F. H. Walmsley, Mr. W. Walls, Mr. Chas. Holmes, and Mr. Joseph Westmorland, with power to add to their number."

The meeting terminated after a vote of thanks had been passed to the Chairman for the able manner in which he had conducted the proceedings, which was proposed by Dr. Royle, and seconded by Dr. Armstrong.

This question is surrounded with much difficulty, and it is only by the full and free discussion of it that a just conclusion respecting it can be arrived at. It is well that meetings of the profession like the one in Manchester should be held in the various large towns throughout the country to discuss the subject.

PUBLIC ANALYSTS.

THE rumour gains ground (says the *English Mechanic and World of Science* of the 18th inst.) that some of the analysts appointed under the Adulteration Act are, to say the least, not fully competent. Bakers and others have been convicted of adulterating bread and flour with alum, while protesting their innocence. If an analyst says he finds alum in a loaf when both flour dealer and baker know they did not put any in, it will not be long before the confidence of the public in the ability of the chemical expert will be seriously shaken. It has been suggested to purposely adulterate loaves and samples of flour with known quantities of alum, and thus practically test the skill of responsible officers who should be above the shadow of a suspicion as far as the accuracy of their analysis is concerned. No doubt great care should be taken in the analysing of food for the detection of adulteration. Although mistakes may sometimes be made, and differences of opinion arise—consequences common to almost everything in life,—still we should be sorry to indulge a belief that our public analysts, as a body, are not above the shadow of a suspicion as far as the accuracy of their analyses is concerned. Great good has already been attained by the enforcement of this important Act.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

THE following changes have been effected in this School:—Dr. Basham and Mr. Holthouse have been appointed special Lecturers on Clinical Medicine and Surgery; Mr. Pearse and Mr. Cowell have been elected to the chairs of Surgery and Practical Surgery; and Mr. Davy has succeeded to that of Anatomy. Dr. Potter takes charge of the class of Forensic Medicine and Hygiene, Dr. Dupré the Toxicology; and Dr. Allchin gives the lectures on Pathology and Morbid Anatomy. In addition to the present special courses, Mr. Bond has been appointed to deliver a short course of lectures on Diseases of the Skin. Two entrance scholarships, and an exhibition in Anatomy and Elementary Physiology for first year's men, have been founded. Mr. Cowell is the new Dean of the School, and will deliver the introductory address on October 1.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE Directors of the Society held their usual Quarterly Court on July 9. The chair was taken by the President, Dr. Burrows. A legacy of £1000 from Miss Brackenbury was announced. There were two fresh applications from widows for assistance. Fifty-six widows and twenty-eight children applied for a continuation of their grants, and a sum of £1260 10s. was voted to be distributed according to the wants of the applicants. The expenses of the quarter amounted to £61 12s. 3d. The meeting heard with regret of the death of the late treasurer, Dr. Hamilton Roe, and directed a letter of condolence to be written to Mrs. Roe. It was resolved that Dr. Quain should be recommended for election as treasurer at the next general meeting.

MEETING OF POOR-LAW MEDICAL OFFICERS OF ENGLAND AND WALES.

IT is proposed to hold a meeting of Poor-law Medical Officers of England and Wales on Thursday, August 7, at 3.30 p.m., in one of the lecture-rooms of King's College, in connexion with the approaching annual meeting of the British Medical Association, under the auspices of the Poor-law Medical Officers' Association, and under the presidency of Dr. Lush, M.P., the President of that Association. The attendance of Poor-law Medical Officers is invited, to discuss the objects at which the Association should aim, and the best mode of furthering the same in the next Parliament.

DIFFERENCES OF OPINION.

A MR. GIBSON was summoned at the Glasgow Police-court some time ago for selling adulterated butter. Dr. Thorpe, the city analyst, gave evidence for the prosecution. Dr. Wallace, another chemical professor, gave evidence to the contrary for the defendant. Ultimately samples of the butter were sent to professors of chemistry in Edinburgh and Glasgow University. Last week their reports were laid before the Glasgow Police Board. They totally disagreed with the city analyst. A member of the Board said Mr. Gibson had been greatly injured by the prosecution, and that the public would have no faith in any decision in the police-courts in prosecutions for adulteration.

DEATH FROM CHLOROFORM AT SIR P. DUN'S HOSPITAL, DUBLIN—ACTION FOR DAMAGES AGAINST THE OPERATING SURGEONS.

At the Co. Wicklow Summer Assizes an action was commenced on Tuesday last, June 22, in the issue of which every member of the medical profession should feel a deep and even a personal interest. On February 12, 1873, a tradesman named Joseph Lamb was admitted to Sir P. Dun's Hospital shortly after an accident in which two of his toes had been broken by a flagstone falling upon them. Next morning it was considered necessary to amputate one of the injured toes, and accordingly Dr. John Barton, House-Surgeon to the Hospital, administered chloroform to the patient in the presence of Dr. Edward H. Bennett, surgeon on duty, and the operator on the occasion. The patient's pulse was felt, but no searching examination of the heart or lungs was made. All requisite caution appears to have been used in the administration of the anæsthetic, but in about five minutes from the inhalation of the first whiff the pulse and respiration ceased suddenly, and the man was dead. An action has been brought by the widow of the deceased for negligent administration of chloroform, resulting in loss of life, and damages are laid at £1000. The defence is a denial of the negligence, and also an assertion that death did not result from the chloroform. The case is still at hearing. *Pendente lite*, we shall at present refrain from making any special comments upon this particular case, but it appears to us that the bringing of such an action against a most able surgeon, whose acknowledged abilities have placed him in the position of colleague of such men as Professor Robert W. Smith, Mr. Butcher, and Professor Benjamin George MacDowel, is a proceeding calculated seriously to imperil the independence of the profession. The action is really one for want of skill in the treatment of an ordinary surgical injury, and involves the principle of liability of an attending physician or surgeon should his treatment of a given case unfortunately prove not successful.

Since writing the above a telegram has reached us stating that the jury found for the defendant before even counsel for the plaintiff was heard.

HOSPITALS FOR EPIDEMIC DISEASES.

Mr. Stansfeld stated in the House of Commons on Monday, in reply to an inquiry on the subject, that nine acres of land adjoining the New Cross-road at Hatcham had been bought by the Metropolitan Asylums Board for the purpose of erecting temporary hospitals in the event of small-pox or any epidemic fever again occurring in the metropolis. With reference to the opposition of the inhabitants of the district against the erection of another small-pox hospital at Hatcham, Mr. Stansfeld said it was necessary that such sites should be conveniently contiguous to the population which might use the hospitals, and sufficiently isolated to prevent the spread of the disease, and this site had been favourably reported on by one of the inspectors of the Local Government Board.

SIR CHARLES WHEATSTONE.

The vacancy caused by the death of Baron Liebig, as Foreign Associate of the French Academy of Sciences, has been filled by the election—almost unanimous, the voting being 43 out of 45—of Sir Charles Wheatstone. Sir Charles was for many years previously corresponding member of the Academy, but the honour now conferred upon him is the highest which the Academy can confer upon a foreigner.

YELLOW FEVER IN AFRICA.

The correspondent at Bonny, Bight of Biafra, writing to the *Liverpool Courier* under date of June 12, says that yellow fever was raging there with dreadful intensity. Young and old—whether acclimatised or unseasoned—all are prostrated by the scourge. The rainy season, now overdue, has not yet set in, and until it does there will be no abatement in the present sickly term. The death-rate has been awful, nearly three-fourths of the regular residents being dead. One firm alone lost eighteen out of twenty-three men. In all cases the course of the disease is rapid and virulent.

FOOD ADULTERATION IN PADDINGTON.

Dr. Hardwicke reported to the Paddington Vestry, last week, that during the past three months he had analysed about twenty articles of food, consisting of bread, milk, tea, and mustard. Alum was found in most of the samples of bread, and in two cases he advised a prosecution. The milk was very bad; scarcely any of the tea was pure leaf; and the mustard was not pure in any one instance. The Vestry decided that the delinquents should be prosecuted.

STUDENTS AT BERLIN UNIVERSITY.

According to the *Allgemeine Zeitung*, the number of matriculated students at the University of Berlin in the winter session of 1871-72 was 2603; in the summer of 1872, 1990; in the winter of 1872-73, 1918; and in the present summer only 1590. A continuous decline is therefore going on in the number of students.

FROM ABROAD.—ACTION FOR NULLITY OF MARRIAGE IN FRANCE—THE MORTALITY OF BERLIN IN 1872.

The *Gazette des Hôpitaux*, July 5, 8, and 10, has published the judgments in a recent suit for "nullity of marriage," a brief abstract of which will prove of interest as illustrative of the modes of procedure adopted in such cases in France.

In December, 1866, M. Darbousse, a landed proprietor, aged 23, married Justine Jumas, aged 25, and after cohabiting with her for more than two years, applied to the civil tribunal of Alas for a decree annulling the marriage, on the plea that his wife possessed none of the organs essential to a woman. The wife replied that however this might be the plaintiff must put up with it, as the code declares that a demand for nullity cannot be made after six months' cohabitation. The plea was overruled, and the plaintiff heard. He declared that his wife possessed neither breasts, womb, ovary, or vagina; that her pelvis was as small as that of a man, and that although twenty-seven years of age she had neither menstruated nor perceived any periodical lumbar or abdominal pains. This somewhat specific statement was derived from some statements which a midwife had spread about after having examined the defendant. The Court, not having much confidence in these, ordered her to be officially examined by the head midwife of the Montpellier Maternité. With her was to be conjoined Dr. Fabre, of Alas, who was not to examine the person himself, but to confer with the midwife both before and after she had done so, and then report for the information of the Court—a rather derogatory procedure on the part of a doctor of medicine in relation to a midwife! However, no examination or report was ever made, for Justine Jumas energetically refused submitting to these experts, and appealed to the Court at Nîmes.

When the case came on there, Darbousse had fortified his position by the production of the opinion of Dr. Legrand du Saulle, the well-known medical jurisconsult, who espoused his cause with almost indignant enthusiasm. What had to be decided, he said, was whether the defendant was a woman, a man, or of no sex at all. That a person could not be a woman who had never menstruated and was unprovided with breasts or any of the female external or internal organs of generation was plain enough. Without a clearer account than had yet been given he could not say that the person was not a man,

but the strong probability was that it was of no sex at all. "Brought up as a girl, it has assumed and maintained the vain appearance of one, exhibiting the timidity, gentleness, piety, and temper of such. Does not habit become a second nature? Wretched being, capriciously cast out of the normal channel, condemned to the isolation of a fatal celibacy, it can only take its place amongst the monsters! A blameless victim of a freak of nature, and married by mistake, this being should not condemn its conjoint to the indefinite horror of a union so cruelly unjust." However, the "wretched being" being possessed of considerable power of resistance, brings its expert into court—Dr. Carcassonene, of Nîmes,—to whom it had submitted itself for an examination. He rejects Dr. Legrand's theoretical stigma, and rehabilitates the defendant in her feminine characteristics, although he admits that these are somewhat limited. She has, he declares, a mons veneris, labia, clitoris, and meatus urinarius, but there is no vagina, or this is imperforate, so that copulation is impossible. This evidence seems to have determined the Court that it was really dealing with a woman, and it nonsuited Darbousse—the admitted fact of absence or imperforation of the vagina notwithstanding.

However, the cause did not stop here, for on some legal point, apart from the facts, the Cour de Cassation annulled the judgment, and ordered a new trial before the Court of Appeal at Montpellier. Darbousse reinforced himself with the opinions of two important personages—Professor Tardieu and M. Courty, of Montpellier. It is evident that "doctors differ" just as strongly on one side of the Channel as on the other. We have seen one witness declaring the defendant to be possessed of no sex at all, and another that she was a woman, but of faulty construction; and now we have so high an authority as Professor Tardieu stating that the Court was really dealing with a man. M. Courty could not confirm this view, but, while he admitted that there were some external appearances of the female sex, there was every reason to believe that the organs indispensable for characterising a woman were either absent or rudimentary. The person in question should be ranked amongst those beings which, properly speaking, have no sex at all, and to whom marriage with either sex should be prohibited. The Court rejected the appeal of the defendant against her being examined by experts, and referred the cause back again to the original tribunal at Alas. The President having summed up all the facts of the case and animadverted upon the refusal of the defendant to submit to examination, annulled the marriage, with costs. The litigation has been going on during the last four years.

Geh. Med.-Rath. Dr. E. Müller has just issued his report on the mortality of Berlin during 1872. During that year there were 35,723 births and 28,191 deaths. Comparing these with the census taken in December, 1871 (828,406 inhabitants), there was therefore 1 birth for every 23 inhabitants and 1 death for every 29, or 43 births and 34 deaths per 1000. Although the mortality is considerably less than it was during 1871, yet it still continues large in proportion to that of former years. This has, however, for the last ten years, and especially for 1872, been caused by the increase of the number of births. One birth for 23 inhabitants is a proportion that has never before been reached, this having varied during the last five decennial periods from 1 for 30 inhabitants to 1 birth for 25.

Of the 35,723 *births*, 18,320 were male and 17,403 female. Of these, 4993 were illegitimate—viz., 2529 male and 2464 female. There were 410 twin and 6 triplet births. The *marriages* in 1872 amounted to 11,234, being 2989 more than in 1871.

As in every other year, the maximum number of deaths took place during the summer months, this being due especially to the number of children carried off by diarrhœa and cholera. The proportion of deaths in different quarters of the town, which is always proportionate to the number of births in such quarters, varies so much as from 15·7 to 54·9 per 1000 inhabitants. The *ages* at which the deaths took place were as follows:—During the first year, the deaths were 399 per 1000; from one to ten years, 180; from ten to twenty years, 31; from twenty to thirty years, 83; from thirty to forty years, 81; from forty to fifty years, 64; from fifty to sixty years, 55; from sixty to seventy years, 50; from seventy to eighty years, 36; from eighty to ninety years, 12; from ninety to a hundred years, $\frac{1}{9}$th.

The number of infants *born dead* was 1570, or 5·5 per cent. of the entire deaths, the proportion in 1871 having been only 3·9 per cent. Still, the increase is only apparent, for while in 1871 the born-dead were 4·3 per cent. of the entire births, in 1872 they were 4·4 per cent. As is always the case, the male born-dead far outnumber the female—viz., 911 to 659. The proportion of illegitimate children born dead is far greater than of the legitimate, mounting up to 7·4 per cent. The death-rate from debility after birth is 6·9 per cent. in illegitimate, and only 3·4 in legitimate children.

Suicides.—These were 200 in number; 144 taking place in men, 54 in women, and 2 in boys. Among the females 61 per cent. of them were committed between the ages of twenty and thirty, while among the men only 28 per cent. were committed at those ages. Two boys, aged respectively ten and fifteen, were the youngest, and the oldest was a man more than eighty years old. The following were the modes of procedure:—Hanging in 68 men, 15 women, and 1 boy—84; shooting in 40 men and 1 woman—41; drowning in 24 men, 15 women, and 1 boy—40; poisoning in 9 men and 21 women—30; opening bloodvessels in 1 man and 2 women—3; and jumping from a window in 2 men. The various forms of accidents gave rise to 265 deaths; and the bodies of 38 dead new-born infants were found.

Of the causes of death, *variola*, which during the latter part of 1870, the whole of 1871, and the earlier part of 1872 had prevailed epidemically, in the second portion of this last year only occurred sporadically. The total number of deaths for the year was 1100—551 being males and 549 females. The greatest number of deaths occurred during the earliest years before vaccination had been performed, and the fewest in the later years of childhood up to the twentieth year. From *scarlatina* 309 deaths are recorded (154 in males and 155 in females), the greatest number taking place between the third and fourth year. From *measles* (186—males 97, females 89) most died during their first year. *Pertussis* caused 168 deaths (75 in males and 93 in females), which occurred especially during the first two years. The number of cases of *gastro-nervous* and *typhus fever* was large (1195—males 568, females 627), being 421 more than in 1871. The ages between twenty and thirty were those in which most cases occurred, the month of October being especially fatal. *Diarrhœa*, *cholera*, and *dysentery* only caused death in thirteen adults; but the deaths from these affections in children were very numerous—viz., 3705 (males 1933, and females 1772)—the greatest number occurring in July. From *inflammation of the brain* (1070—males 568, females 502), children during the two first years of life were also the chief victims. From *croup and diphtheria* there died 888 (males 461, females 427), almost all in early childhood. *Inflammation of the air-passages* caused 595 deaths (298 males, 297 females), most of them occurring during the first and next during the second year. *Inflammation of the lungs and pleura* caused 1206 deaths (703 males and 503 females), the greatly preponderating number being in childhood, and then after the twentieth year. Among the deaths from organic diseases there is nothing to distinguish them from other years, except the fact that the number of deaths from *pulmonary tuberculosis* is con-

siderably less than that of the preceding year; they amounted in 1872 to 3218 (males 1899, females 1319).

Notwithstanding that the proportionate mortality of the year is, upon the whole, more favourable, yet the infantile mortality still continues excessively high, although this is in a great measure due to the increased number of births; but the prevalence of diarrhœa, cholera, and emaciation of children, and the time of year at which these deaths principally occur, show that improper or defective nutrition of infants at the early periods of their lives is the chief cause of such mortality. The influence of illegitimacy is shown by the fact that while, including the born-dead, there is upon the total mortality a death-rate of 45 per cent. of children under fifteen years of age, this is raised to 59 per cent. for illegitimate children.

PROFESSOR HOLMES'S LECTURES AT THE COLLEGE OF SURGEONS.

Abstract of Lecture IV.

Continuing the subject of orbital aneurism, and especially that of arterio-venous aneurism in the cavernous sinus, Mr. Holmes remarked that the cases he had been able to refer to proved beyond any possibility of doubt that a wound or fracture may cause rupture of the internal carotid artery within the cavernous sinus, and that this rupture may be followed by the formation of an arterio-venous aneurism, with consecutive dilatation of the ophthalmic veiu; and that this affection is accompanied by all the symptoms usually attributed to orbital aneurism. It is in the highest degree probable, if not certain, that a similar rupture may take place spontaneously. Such cases as one from St. George's Hospital, described in Lecture I., show that a small crack may form in the carotid artery as the result of atheroma, and this may occur as easily in the curve of the internal carotid within the sinus as elsewhere.

The symptoms of many of the published cases certainly appear to lend probability to Dr. Delens' conjecture of their arterio-venous nature, and this explanation readily accounts for the great enlargement of the veins which is frequently present in orbital aneurism; but, on the other hand, we must admit that Dr. Delens' explanation appears to be refuted by indubitable evidence. Thus, in Mr. Nunneley's report of the post-mortem examiuation of his second case, he speaks of the tumour as a circumscribed aneurism of the root of the ophthalmic artery. Mr. Bowman's case, reported by Mr. Hulke, is another in which post-mortem examination excludes the idea of any rupture of the carotid artery. Dr. Delens suggests that in this instance, as in some others to which he refers, some minute fissure may have escaped observation; but this, Mr. Hulke asserts, was not the fact; and in another similar case reported by M. Aubry, Dr. Delens himself is fain to admit that no lesion could possibly have existed in the internal carotid artery, since this vessel was successfully injected so as to fill the ophthalmic artery without auy of the injection penetrating into the cavernous sinus.

Common aneurisms situated on the ophthalmic artery and on the internal carotid, both within the cavernous sinus and at its termination in the circle of Willis, have often been recorded, and Professor Holmes has himself described, and preserved in the Museum of St. George's Hospital, an aneurism of the interual carotid in the cavernous sinus, where there is certainly no communication with the venous system. The Museum of the College of Surgeons contains two specimens of a similar nature, showing the internal carotid artery on either side affected by aneurism in the sella turcica.

To sum up, then, our present knowledge of these tumours. Travers' original assumption that orbital aneurism is usually anastomotic has been conclusively refuted. Aneurism by anastomosis sometimes affects the vessels of the orbit, but the symptoms are quite different from those of the disease now in question. It has been also proved beyond denial that some of these aneurisms are of the arterio-venous form, and it is probable that a great number of the successful cases on record were so. But it is equally impossible to deny that in others the aneurism has been of the ordinary circumscribed form. Finally, it is not clear how we can avoid admitting that in some instances the usual aneurismal symptoms have been produced by the pressure of enlarged and consolidated veins upon the arteries of the orbit. The character of the bruit is the main point in the diagnosis of the arterial from the arterio-venous form. A clear, intermittent, blowing murmur can hardly proceed from an arterio-venous communication, which has, on the contrary, a soft, continuous murmur interrupted by the intermittent arterial whiz, and this latter is exaggerated occasionally, according to Dr. Delens, into a piping or whining sound. The difference in the bruit may suffice, then, in some well-marked cases to exclude the idea of ordinary arterial aneurism.

But the more important question is, whether it is possible to recognise those cases in which no arterial disease whatever exists, and this is much more difficult. There are at least two carefully recorded cases in which all the symptoms of orbital aneurism were present—viz., Bowman's case, recorded by Hulke, and Aubry's case; and on reading over these one does not find one symptom absent which is usually taken as decisive of the pressure of aneurism. In both there were pulsation and bruit, exophthalmos, and the dilatation of the venous system of the orbit. Another case, in which the post-mortem evidence of arterial lesion was at any rate very unsatifactory, was under Mr. Berkeley Hill's care. Neither Dr. Ringer nor Mr. Hill could satisfy themselves of the existence of any aneurism.

Mere coagulation of blood in the cavernous sinus without dilatation of the veins of the orbit will not cause the symptoms of orbital aneurism, as Knapp's cases of thrombosis of the cavernous sinus show; nor will mere dilatation of the orbit unaccompanied by coagula in the sinuses. It is possible that we may hereafter learn the diagnosis of these affections, and the more so since the attention of surgeons has been forcibly called to the subject, not only in this country, but in America by Dr. Morton, and in France by MM. Demarquay and Delens; but at present all that we can say is, that the symptoms of orbital aneurism are in some cases exactly imitated by cases in which only the venous system is affected. But this fact, though only a negative one, forms obviously a very powerful motive for caution in undertaking operative treatment.

Another and a very curious feature in these pulsating tumours of the orbit is the occasional transference of the symptoms from one side to the other. Velpeau has made the following remarks in connexion with this subject:—"We have had two patients affected with erectile tumours of the orbit. One of these persons had a tumour in both orbits. He ascribed the origin of these tumours to a blow on the nape of the neck. I hardly see what connexion there could have been between the blow and the existence of the tumours. However this may be, the curious point about this patient was that the compression of the right carotid caused the immediate cessation of the pulsation in the tumour of the left orbit, and that of the left carotid stopped the pulsation in the right orbit. This phenomenon appears inexplicable to me. I tied the right carotid— the left tumour subsided; that on the right side diminished a little, but soon appeared as large as before the ligature, and presented the some characters. I proposed to the patient the ligature of the left carotid, but he would net consent, and left the hospital having obtained no other benefit than what resulted from the ligature of the right carotid. I saw the patient again a short time ago. The erectile tumour on the left side was perfectly cured, but continued to grow on the right. The thing is hardly explicable, for the carotid has no anastomoses which could account for such a phenomenon."

Mr. Busk and Mr. Curling long ago solved Velpeau's first difficulty—viz., how to account for aneurism, which he called "erectile tumour," in the orbit following on a blow on the head or nape—by referring it to a fracture of the base of the skull traversing the ophthalmic or internal carotid artery; and a case of M. Nélaton's is an interesting anatomical proof of the correctness of their opinion; so that at the present day we are not much surprised to find the disease so often commences after injury. But the transference of the disease from one side to the other—the fact that the pulsation in one orbit is controlled by pressure on the other carotid—is far less easily accounted for. Dr. Delens has invented an ingenious hypothesis to explain this curious fact. He supposes that the right internal carotid was divided inside the cavernous sinus so as to be severed into two parts; that the sinus became

obstructed by coagula separating its posterior from its anterior portions; that the blood-stream from the right internal carotid, thus barred from finding a passage into the right orbit, made its way through the anastomosing sinuses (circular and transverse) into the left cavernous sinus, producing the usual symptoms of arterio-venous communication there, while the anastomoses between the left and right arteries brought back the blood into the anterior part of the right cavernous sinus, and thus occasioned the symptoms of arterio-venous aneurism in the right orbit. This idea is certainly in harmony with many of the facts of the case: it explains why the disease was less marked on the left side than on the right, since the anastomoses of the sinuses are less direct and less dilatable than those of the arteries; why the symptoms in the left orbit were under the direct control of the circulation in the right artery and *vice versâ*. But to Professor Holmes this hypothesis is a little too elaborate, and he is not sure that all the symptoms may not depend on the mere fact of the clot having extended from the sinus of one side to that of the other through the circular and transverse sinuses.

There are other cases besides Velpeau's in which the crossing of the symptoms has been noticed. Such cases harmonise with the general conclusion to be drawn from published records of the more ordinary cases of orbital aneurism, so far as to show that many of the phenomena of the so-called "aneurism" must be due, not to any arterial disease, but to some lesion or some unnatural condition of the venous channel of the cavernous sinus, which unnatural condition has in the instances last quoted extended to the opposite side from that on which it originated.

This examination of the pathology and of the various theories which have been adopted as to the nature of this remarkable disease is a necessary prelude to the consideration of its surgical treatment. If we admit that the symptoms may be caused by coagula in the sinus pressing upon the artery without any disease of the latter, surely we ought to do all in our power to avoid so serious an operation as the ligature of the common carotid. If we admit, with Mr. Erichsen, that the disease may probably enough disappear spontaneously, the same conclusion is irresistible.

If we agree in Dr. Delens' teaching, that a very large proportion of these cases are arterio-venous, we know that the ligature of the vascular trunk at a distance from the opening in the artery is a very uncertain remedy in arterio-venous aneurisms. We know also from the experience of arterio-venous communications in the neck and elsewhere that this injury does not necessarily involve any fatal symptoms. After attaining a certain extent many such cases have remained stationary for an indefinite period. If even we could adopt the old idea, that the tumour was due to a cirsoid dilatation of the arteries of the orbit, we know how nugatory the ligature of the trunk vessel usually proves in that disease.

Finally, if we adopt the opinion of Mr. Busk, Mr. Curling, and Mr. Nunneley—which is the prevalent opinion at present,—that these tumours are of the nature of true aneurisms of the ophthalmic or internal carotid, we should reasonably expect success by milder methods than the ligature in a tumour so small as this must be, and in a disease the symptoms of which are confessedly due more to dilatation of the veins than to arterial lesion. The records of practice speak plainly to the same effect.

It is quite true that by statistics the operation of tying the carotid for orbital aneurism is made to appear a very successful operation, but this method of viewing the subject can hardly be employed either for or against the treatment until we know the natural progress of the disease, and the results of other kinds of treatment. As to the natural progress of the disease, though certain cases prove that there is no occasion for hurry, and that a natural cure is not impossible, the same cannot be affirmed generally. If the exophthalmos is rapidly increasing, the loss of motion of the eyeball advancing so as to threaten disintegration of the nerves traversing the cavernous sinus, and the loss of sight testifying to pressure on or stretching of the optic nerve, no good surgeon would probably refrain from active treatment. But then compression of the artery, either digital or instrumental, undoubtedly deserves trial before a patient is exposed to the danger to life which the ligature of the carotid involves. Cases of successful compression of the carotid in this affection have been recorded by Gioppi and Scaramazza, and of direct compression by C. Freeman.

Another method which has been practised twice in three cases, and twice at least with success, and which deserves renewed trial, is the injection of coagulating fluid into the tumour. These cases afford much encouragement for the repetition of the practice in appropriate cases—*i.e.*, cases in which the venous tumour is large, fully developed, and growing, and where the compression of the carotid has failed after a full trial. The other local measure which has been tried is electro-puncture; of this only two instances are on record, in one of which it failed, and in the other it proved fatal.

The recorded experience of milder modes of treatment justifies the conclusion that the ligature of the carotid should never be used in so-called orbital aneurisms until after a patient trial of the less dangerous measures. But when these have failed, and the disease is advancing, we are justified in employing the ligature, and that, too, although on the one hand the disease has not been observed to run on to a fatal termination, while several patients have recovered spontaneously, and on the other, the ligature of the carotid has by no means universally exercised a curative effect.

Some surgeons, as Demarquay, prefer the ligature of the internal to that of the common carotid, but there seems no good reason for this preference, nor is there any objection to tying the external along with the common carotid.

In connexion with carotid aneurism, and especially in connexion with orbital aneurism, it is worth while to mention cases of arterio-venous communication in the neck between the carotid arteries and the veins lying in contiguity with them or in their neighbourhood. We shall find—a fact which is not very easy of explanation—that the existence of a traumatic arterio-venous aneurism in the neck is very often harmless, and, as far as published cases enable us to judge, does not usually prove fatal if left alone.

As regards the surgical treatment, it is useless and improper to interfere in those cases of arterio-venous aneurisms in the neck where there are no dangerous symptoms; but in others the gradual advance of the symptoms points strongly to the necessity for some interference, if possible, before it is too late to save the patient's intellect or life. In these instances, if the foreign body which caused the wound is lodged, an incision must be made down upon the tumour, the circulation being controlled below, and if possible above also, the tumour opened, the foreign body removed, and the artery and vein tied. Where there is no evident lodgment of the foreign body it is possible that the combination of direct with indirect pressure might be successfully employed which Vanzetti has introduced in the treatment of varicose aneurism of the brachial artery. If the venous thrill and murmur could be suppressed by direct pressure on the tumour it would be a proof that the venous orifice was controlled, and in that case simultaneous compression of the lower part of the artery might be trusted to complete the cure.

THERAPEUTIC MEMORANDA.

Butter-Milk in Typhoid Fever.

Sir,—Although it may be thought by some of your readers that the evidence in favour of a new or modified treatment, obtained by the observation of only two cases in which it has been exhibited, is insufficient to bring it before the notice of the profession, yet the immunity from this class of disease that we enjoy in Guernsey is so great that it may be years before I have the opportunity of again treating enterica. A gentleman who has enjoyed a large and varied practice here for upwards of thirty years, and on whose word and skill in diagnosis I can confidently rely, informed me that although he was parish surgeon for ten years before our town was drained, and fever necessarily more prevalent than now, he did not think he had treated more than fifty cases of typhoid fever.

The first case that I have to record was in an anæmic girl aged 17. The diarrhœa was severe when I first saw her—from twelve to fifteen stools a day, their character being typical of the disease; there was also considerable tympanites, the belly being tense and greatly swollen. I placed the patient on milk. This decreased the number of stools to four or five per diem, but the tympanites remained unchecked, and resisted all the usual forms of treatment.

On the sixth day of my attendance, and the sixteenth of the disease, the patient requested to be allowed to take butter-milk, as she thought sweet milk increased her thirst. On reflecting that butter-milk contained all the protein matter of the milk, and that that was the most important in cases of

fever, which always involve a great loss of nitrogen, I gave my consent.

The beneficial effect of the change was most marked. On arriving the next day I found that the tympanites had quite disappeared, and the belly was soft and fallen; the patient expressed herself as feeling "much better." The number of the stools was reduced from this time to one, and sometimes —very rarely—two per diem; the temperature and the pulse remained unchanged.

The patient made a good recovery, and was far less emaciated when the disease had run its course than would be expected in a delicate girl. The convalescence was shorter than usual.

The other patient was a young woman, aged 22, who had lately married; she generally enjoyed good health. I placed her on butter-milk diet from the first, but as she did not like it unless it was fresh, I allowed her to take sweet milk during two days in the week, when she was unable to obtain fresh butter-milk. The change to sweet milk always increased the number of stools, which on the butter-milk days rarely exceeded one, but on the sweet milk days the patient passed her motions five and six times a day. In this case, as in the other, the convalescence was short, and the patient made a good and quick recovery.

I account for the stools being reduced so considerably in number by a change from sweet milk to butter-milk from the fact that from the latter the fatty matters have been removed; and it is well known all oleaginous substances have a somewhat purgative action. The shortness of the convalescence I am inclined to attribute to the lessening of the number of the stools, thereby removing one of the many depressing causes that manifest themselves in this disease, rather than to any increase in the amount of nutriment obtained from the use of butter-milk. The mild acidity, also, of the butter-milk renders it most grateful to thirsty fever patients: this is one great point in favour of its recommendation. I am, &c.,

Frederick Irving de Lisle, L.R.C.P.,
Medical Officer of the St. Peter Port Hospital, Guernsey.

REVIEWS.

Memoir of Sir James Y. Simpson, Bart., M.D., D.C.L. Oxon., etc., etc. By J. Duns, D.D., F.R.S.E., Professor of Natural Science, New College, Edinburgh. Edinburgh: Edmonston and Douglas. 1873. Pp. 544.

The life of Sir James Young Simpson, however unskilled the relator, could not be degraded to the level of ordinary biography. Whether viewed as a history of effort crowned by success romantic in its completeness, or regarded in its bearing upon the relief of human suffering and its influence on the healing art, or dissected as a study of character of a man of remarkable intellectual ability and activity, excelling qualities of heart and head, yet displaying sufficient of the foibles of our common nature in his mental composition to raise the interest of close kinship in more ordinary mortals,—however contemplated, a life of Simpson if only it were a plain unvarnished tale of what he did and said and thought,—of his struggles, his work, his success—could not but constitute a narrative of surpassing interest. Dr. Duns' memoir is such a narrative. It is moreover a well-written and well-arranged book, creditable in its literary workmanship, and not the less interesting to members of Simpson's profession inasmuch as it is a non-medical retrospect of his life and character.

The fact that the biographer is not a physician is throughout patent. The book is in many respects a better book on this account; in some perhaps the reverse. We think that there are certain passages in the life which a medical admirer of Simpson would probably not have handed down. Such are the stories of some of his squabbles with professional brethren, and the evidence of some pardonable weaknesses which his remarkable success brought to light and excused. But then on the other hand we have a truer, fuller picture—a more faithful delineation of the man, his contemporaries, and his surroundings—a life-history painted with an admiration and a fidelity worthy of a countryman of Boswell.

James Young Simpson was the son of David Simpson, a small baker at Bathgate, in Linlithgowshire, who at the time of his birth was in struggling circumstances. Both his father and mother, however, were persons of excellent character, with a good share of intelligence. Simpson's mother especially seems to have been a woman of great energy. Dr. Duns relates that "when James was born the household circumstances were at the worst. The small cash-book in which the shop drawings for the day were marked bears this entry—'7th June, 1811. Drawn 8s. and 3d.' Hoping that things might mend and take a turn for the better, David Simpson had carefully concealed the true state of affairs from his wife; but a crisis seemed at hand, and he was forced to acquaint her with their condition. She had previously given her undivided attention to the care of her children, leaving business matters wholly to her husband; but now she took prompt steps to help him. Means were found to meet a pressing debt of £100, credit was restored, and under her wise and energetic management business speedily began to prosper. The lowest entry in the cash-book was on the day of James's birth. Up to that event matters had been steadily getting worse. With his appearance sunshine broke in upon the household."

An entry in the visiting-book of Dr. Dawson, the local practitioner, proves that the celebrated accoucheur was himself ushered into the world with little aid from art, and that the modest fee paid to the doctor on the occasion was half a guinea. Simpson lost his excellent mother when he was a child of nine years; but to the last he cherished her memory. Amongst the many incidents related which endear Simpson to the reader of his biography we may quote the following:—"But he had homelier memories of his mother. When in the height of his fame I heard a lady tell him of an industrial school for girls which she had set up in a village near Bathgate. 'And what does your schoolmistress teach the girls?' he asked. 'Some fancy work,' was the answer, 'and plenty of plain sewing and darning.' Shortly after he said to me, 'Do you know, the mention of "darning" a little ago recalls a very very old and precious memory? One day, when a child, I came into the house with a big hole in the heel of my stocking, and my mother sat me on her knee, darned the stocking, and, as she drew it on, said—"My Jamie, when your mother's away, you will mind that she was a grand darner." I remember the words as if they had been spoken yesterday. I would like to give a prize to the best "darner" in the school.'"

Although his birth was sufficiently unpretending, he, like all Scotchmen, had a pedigree. He was on his mother's side related in some distant degree with the Clelands of that ilk. A Cleland had married the grandfather of William Wallace, and the Clelands had fought at Flodden. The name of Simpson, however, is destined to outlive that of Cleland.

We must pass over the account of Simpson's childhood; "a rosy bairn wi' laughin' mou' and dimpled cheeks" when he went to the parish school at four years old, and afterwards took round his father's rolls—his boyhood early showing signs of a bent for natural history and an interest in local antiquities—and his entrance at the University of Edinburgh at the age of fourteen. In his second session he obtained a Stewart Bursary of the value of £10, tenable for three years. He joined his friend John Reid, also a Bathgate bairn, who afterwards became Professor of Anatomy at St. Andrews, and they lived with Dr. Macarthur, who had formerly been assistant in the Bathgate parish school. Simpson during his first years at the University studied classics, mathematics, and moral philosophy. Macarthur had graduated in Medicine, and seems to have exercised great influence over Simpson and Reid. His mode of training was heroic. "When they had been a short time with him, he said to Mr. Simpson's brother, Alexander, 'I can now do with four hours' sleep, John Reid can do with six, but I have not been able to break in James yet.'" Simpson did not make a remarkable figure in the classical and mathematical schools, but it is evident that he worked steadily, and that he lived with an economy and self-denial rarely to be found amongst lads except north of the Tweed. As a medical student Liston was one of his favourite teachers. His notes of Liston's lectures are free from queries, these signs of dissent or doubt being not unfrequent in the notes taken in other classes. Simpson's sensibilities, however, like those of many another young medical student, were sorely tried by what he witnessed in the operating theatre. Dr. Duns relates that "after seeing the terrible agony of a poor Highland woman under amputation of the breast, he left the class-room and went straight to the Parliament House to seek work as a writer's clerk; but, on second thoughts, he returned to the study of Medicine, asking 'Can anything be done to make operations less painful?'"

Simpson passed the Edinburgh College of Surgeons at nineteen years of age. He went home to his brother in Bathgate, who throughout his early struggles behaved to him with true

fraternal kindness, and spent his time in assisting the local practitioner, and in botanising amongst his native hills. About this time he tried to get an appointment as surgeon to a ship, but this scheme not succeeding, he returned to Edinburgh, and became assistant to Dr. Gairdner in dispensary work, and also re-entered at the College. He proceeded to graduate in the University, and after unsuccessfully applying for the situation of parish doctor at Inverskip, he became assistant to Professor John Thomson (who had been attracted to him by the ability displayed in his graduation thesis) at a salary of £50 a year. From that time he made Edinburgh his home, and commenced the career which left his name a household word in every country in the civilised world. It was by Thomson's advice that Simpson applied himself to the study of midwifery, and resolved to become a teacher in that department. One of his earliest papers which attracted attention was that on "Diseases of the Placenta." He worked late and early, became President of the Royal Physical Society of Edinburgh, and began to form a museum. In 1835 he visited London and Paris in company with Professor Douglas Maclagan. His diary during the tour forms one of the most interesting chapters in the early part of the memoir. He goes to the London University and sees Carswell in his museum, notes that Liston is treating cases of iritis without mercury, "and none of them go wrong." They go with Dr. Lee to the Royal Society, where they see Bostock, Paris, Brande, Stanley, Earle, Owen, and Clift, with the last-mentioned of whom they take tea in the library-hall. At Guy's they go round the wards with Mr. Bransby Cooper, who "appears to be a great mercurialist and promoter of the business of the apothecary." Tyrrell and MacMurdo at the Moorfields Eye Dispensary show a wonderful degree of the *visus eruditus*. One evening they are taken by Spence, the entomologist, to a meeting of the Linnæan Society, when the President, the Duke of Somerset, goes to sleep during the reading of the paper, and has to be woke by the Secretary. In Paris they see Lisfranc (a French reprint of Liston), Louis, and Andral in their cliniques at La Pitié, and they go off to Charenton to see Esquirol, and are struck at the degree to which coercive treatment is discarded. Then they visit Namur and Liege, where they see Professor Fohman, who is the victim of *tremblement metallique*—from having worked for years in making mercurial preparations. Home once more in Edinburgh, Simpson is elected Senior President of the Royal Medical Society, his colleagues being Dr. Martin Barry —"one of the manliest of Quakers and most endearing of men,"—Dr. J. H. Pollexfen, and Dr. John Reid. He soon after became a Fellow of the Royal College of Physicians, and an extra-academical lecturer. At this time he got up to write papers at two or three o'clock in the morning, and was beginning to get practice. He had formed an attachment to a young lady, Miss Grindlay, whom he soon afterwards married, and was pushing his fortunes with marvellous pluck and energy. In 1839 the Midwifery chair became vacant by the resignation of Professor Hamilton. Simpson became a candidate, and, as it is well known, was opposed by Dr. Evory Kennedy, who was especially backed by Syme and the other leading professors of the University; but Simpson was elected by a majority of one. From that time his success was uninterrupted.

We have so lately reviewed the volumes of Sir James Simpson's collected medical works, and the facts in connexion with his great discovery of the anæsthetic properties of chloroform, and his other labours on the subjects of acupressure, hospitalism, etc., are so fresh in the minds of the profession, that we feel we may not unfairly leave our readers the pleasurable task of following Sir James Simpson's career, after he obtained the Professorship in the University, in Dr. Duns' pleasant pages. Simpson's letters—written with childlike simplicity to the members of his family, for whom he always cherished the warmest affection—show him in all his amiable qualities, not above displaying some tincture of honest pride at the success which had placed the baker's bairn at the tables of the noblest in the land, but always good, kind, and genial. With regard to the clouds which so frequently floated over the medical horizon, it is only fair to the memory of Simpson to say that he was never the one to raise the tempest,—although, as those who knew him will well remember, he was perfectly capable of taking his own part. Another generation, knowing the high class of men to which Simpson, Syme, and their colleagues belonged, may well wonder at the squabbles which so frequently ruffled the calm of the learned society of Edinburgh. But we are bound to add that Simpson seems never to have been the aggressor.

We have not in this notice referred to the religious character of the latter part of this volume. Such subjects, we think, are not best suited for discussion in our pages. It is enough to say that Sir James Simpson passed from this life as he had lived—a firm believer in the religion and a humble follower of Him who, since His sojourn upon earth, has been known amongst men as the Great Physician.

"Sir James Simpson's death is a grievous loss to the nation: it is truly a national concern." Such was the just tribute paid by the present Prime Minister to the physician whose life we have reviewed.

The Causation of Sleep. A Physiological Essay. By James Cappie, M.D. Edinburgh: J. Thin. Pp. 76.

This short essay is divided into two portions. In the first the author deals with the causation of sleep entirely from his own point of view; in the second he is more controversial. Briefly, his views are these:—By pressure the functions of the brain can be arrested, as in sleep. Pressure is possible by alteration in the size of the cerebral vessels, especially the veins. During functional activity the capillary circulation of the brain is most active, consequently the cubic contents of the capillaries at their greatest variation in one part of the cranial cavity cause variation in another, the cubic space being a constant quantity. When the brain rests, therefore, and its circulation grows languid, the space left vacant by decreased capillary flow must be filled somehow, and Dr. Cappie thinks this is done by increased fulness of the cerebral veins; but increased fulness of the cerebral veins implies pressure on the cerebral surface—a condition incompatible with mental exertion,—and so sleep follows. Such is Dr. Cappie's argument, stated, we hope, fairly, if boldly; but the boldness of the statement we fear only tends to show that it is hardly tenable. We do not say it is wrong; we do not attempt to disprove it; but, in Scotch fashion, we are entitled to return a verdict of "not proven." However, Dr. Cappie's essay is ingenious and interesting, and well worthy of perusal.

The Physical Basis of Mental Life: A Popular Essay. By R. R. Noel. London: Longmans. Pp. 74.

This is an essay on phrenology of a kind superior to those we commonly encounter, yet, as usual, delusive. Broadly speaking, everyone is agreed that the brain is the organ of thought, and that, very roughly indeed, the size of the head may be taken as an index of mental power,—still more roughly, perhaps, that the shape indicates certain mental characteristics; but no mapping out of the brain, still less of the head, into organs of special function is possible. By careful and enlightened study much has been done, but much more remains to be done. We are not of those who deny that Gall and Spurzheim did good service; but their writings were also very mischievous, and the bad continues to predominate over the good.

Notes on the Pharmacopœial Preparations. Specially Arranged for the Use of Students Preparing for Examination. By W. Handsell Griffiths, Ph.D., L.R.C.S.E., Librarian Royal College of Surgeons of Ireland, etc. London: Baillière, Tindall, and Cox. Pp. 110.

This is an attempt to deal with the Pharmacopœia from a purely pharmaceutical point of view. Neither the substances whence the preparations are derived nor the uses or actions of these preparations are considered. But as an attempt to introduce the student of medicine to subjects which are hardly technical as regards his art, the notes are fairly successful. Much information is condensed within these pages, and in the limited fashion already indicated they are worthy of every praise. We have noted one or two small inaccuracies, but they are not of great importance.

The Retford Board of Guardians, who had previously postponed the appointment of a medical officer of health for six months, have again postponed doing so for three months, on the score, principally, of the unsatisfactory state of local taxation. During the discussion several guardians said the Public Health Act was unnecessary in rural districts.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

Paris, July 14.

Hospitalism in Paris—Gangrene—Typhus and Typhoid—Enlargement of the School of Medicine—The Shah in Paris.

The insanitary condition of the Paris hospitals is proverbial, but just now as the weather gets warmer they are simply intolerable. The wards, which are always overcrowded, stink to such a degree that an English physician on a visit to Paris observed to me that he always felt squeamish in walking through them, and that the smell from them reminded him more of a dead-house than a place intended for living people. This applies particularly to the surgical wards, where the air is more contaminated, not only from the emanations of the body, but from open suppurating wounds, ulcers, abscesses, etc. Add to these the dejections of bedridden patients in different stages of putrefaction, the poultices and other dressings undergoing decomposition, and your readers may form an idea whether the chances of recovery are in favour of the inmates. No wonder, then, that erysipelas, hospital gangrene, and kindred affections should be almost endemic in the Paris hospitals. As for pyæmia and septicæmia, these are so common that the physicians and surgeons almost look upon them as natural consequences; whether they have the power to remedy such a state of things I am not prepared to say, but the facts remain, and have done so since the existence of these hospitals. In conversation with some of the hospital staff on the subject, I have always had the same traditional reply from all: that they were powerless in the matter; that they were there to treat the patients, and had nothing to do with the internal administration of the hospital. But surely the "administration" do not prevent the opening of the doors and windows to renew the foul air of the wards, nor do they stint the patients of what may be necessary or conducive to their recovery; and yet it is a well-known fact that proper ventilation and good nursing are the great desiderata, and the absence of these constitutes the principal cause of the frightful mortality in the Paris hospitals. This is so true that most surgeons in performing the simplest operation are always in dread of the case turning out a bad one, and there are times when they will hardly venture to open a small abscess, much less perform an amputation. I have a case fresh in my mind, where, some years ago, a man was admitted into one of the modern or model hospitals with a bit of glass under the skin just below the elbow, which was there lodged for several years. This did not much incommode him, but he nevertheless was anxious to have it removed. The glass was cut out, and the patient, being in good health, did not wish to remain in the hospital, but the surgeon persuaded him to do so to watch the case. In a week after the operation (an incision about half an inch), inflammation and suppuration having set in, large incisions were made to relieve the tension and give vent to the pus. In another week the arm sloughed and looked gangrenous, and amputation was performed to save the patient's life; but, alas! in another week he was no more, as he died from purulent infection. This case is a fair sample of what occurs almost every day in all the hospitals in Paris, and which I might multiply *ad infinitum*. But while on the subject of hospitalism, I shall take the opportunity of giving one or two examples more of its pernicious influence on the sick which also came under my own observation. A woman, aged about fifty, was lately admitted into M. Richet's ward in the Hôtel-Dieu with contraction of the right leg, and as there was no confirmed anchylosis nor appreciable disease of the knee-joint, M. Richet performed tenotomy, and, having afterwards forcibly extended the limb, put it up in splints to keep it in that position. Soon, however, mortification set in, amputation above the knee was performed, and the patient was carried off in less than six weeks from the first operation. M. Richet's explanation as to the cause of the accident that had supervened was very plausible, which was that the internal coat of the femoral artery was most probably ruptured, which gave rise to embolism, and thus, preventing the due supply of blood, caused the death of the limb. This, however, was not borne out by the post-mortem, but, with all deference to the learned Professor, I should attribute the accident to the unhealthy state of the ward, blood-contamination, and the consequent debilitated condition of the patient. In the same Professor's ward may be seen to this day a lad, aged 18, who was admitted on March 1 last with gangrene of both his feet, with which he was affected under the following circumstances:—A cook by profession, he was going home late at night, when he was waylaid by three or four men, who attacked him with the intention of robbing him. He was then left almost senseless on the ground, where he lay till the break of day, when he was picked up by a police agent and conveyed to the hospital with his feet in a gangrenous condition. They went on from bad to worse, and the process of separation was all but achieved, when, on April 27, M. Richet completed the spontaneous amputation just above the ankle. In three days after the operation both the stumps were affected with hospital gangrene, which was arrested by the application of lemon-juice, followed some time after by a pure solution of the perchloride of iron. The patient was going on well, healthy granulations had sprung up, and the stumps were nearly healed, but he is now affected with erysipelas of the face, which, of course, is a serious complication.

But if the surgeons and physicians are powerless in the matter, they can surely protest against the overcrowding, or do as some surgeons do—send the patients to their own homes as soon as circumstances permit, or have them removed to tents or wooden huts. No amputation or suppurating cases ought, in my opinion, be left in the wards in summer unless the patients have a cubic space of at least 1200 feet, whereas in reality in many of the hospitals they have scarcely 800 cubic feet; and in one ward of the Hôtel-Dieu the cubic space allotted to each patient is only 500! but when the bed-curtains are taken into account the cubic space falls far short of this amount.

As there were several cases of gangrene in the wards, M. Richet took occasion to give a lecture on the subject, and, after having gone through the etiology of the affection, he said that alcoholism was one of its most prolific causes; but, without attempting to deny the pernicious influence of alcohol on the system, I think that this substance as a potent agent in the pathogeny of disease is much abused. One has only to turn to the British hospitals, whose inmates are for the most part of the same class that are admitted into the Paris hospitals, and are accustomed to stronger drinks than the French, and he will learn that such affections as hospital gangrene, erysipelas, and pyæmia are far less common in the former than in the latter hospitals. The cause must therefore be sought elsewhere. As to the question of amputation of gangrenous limbs, M. Richet adheres to the old rule of waiting till the line of demarcation is formed, as, if done before, the chances are that the disease will continue its course and ultimately kill the patient. Out of eight cases of traumatic or surgical gangrene in which he had amputated *before* the limitation of the disease he had five deaths; in eleven cases *after*, only one death occurred.

The discussion at the Academy of Medicine as to the identity or non-identity of typhus and typhoid fever, in which Briquet, Bouchardat, Fauvel, and Chauffard were the principal speakers, was considered as having been closed when M. Briquet, who looks upon these affections as identical, differing only in degree (the absence of intestinal lesions in typhus being a fortuitous circumstance), reiterated his arguments. M. Chauffard, who with Bouchardat and Fauvel is for their non-identity (M. Chauffard differing from these latter Academicians only as to their etiology), replied in the following terms:—"There may be certain analogies or affinities between the two affections; but analogy is not identity. They are perfectly distinct from each other; and if pathological anatomy has any real value, the post-mortem appearances rather disprove than confirm their identity." He concluded by adding that the doctrine of the identity of typhus and typhoid fever is a superannuated one, and cannot be any longer entertained by those who would keep pace with the progress of science.

The reconstruction—or rather the enlargement—of the Paris School of Medicine is all but decided upon; for, whatever may be the political opinions of Ministers of Public Instruction who have succeeded each other for a series of years, all have been unanimous as to the insufficiency of the building to meet the requirements of scientific research, and of the increasing number of the students, who now muster

about 4000 in different stages of their curriculum. M. Batbie, the present Minister of Public Instruction, not only promises, but means earnestly to have these defects removed as soon as possible; and if the plan of the architect be carried out he will deserve great credit, as the space and material with which the alterations are to be effected had already tried the capacity of other architects, who had to give it up as impracticable. It is estimated that the School with its dependencies will cost nearly 4,000,000 fr.; and in order to prevent any inconvenience to students and professors, the work will be effected piecemeal, and will not be completed before the next five years. But Ministers propose and Governments dispose; and whether the present Government or any succeeding one will give effect to the growing wants of the Faculty is another question. Here, as in Great Britain and elsewhere, the interests of the medical profession are but of secondary importance to the powers that be. There is no lack of examples of the disfavour in which the profession is generally held; we need only refer to the recent decision of the French National Assembly on the proposition of M. Naquet for the amelioration of the present state of medical education in France, which was thrown out by a great majority. The present School of Medicine, which is situated in the Quartier Latin, stands on the site of the old College de Bourgogne, and is only about a century old, and those of your readers who have visited the building will remember the splendid amphitheatre from which have issued some of the most eminent men of the medical world. It is capable of holding 1400 students at a time, and when the place is full it is really an imposing sight. This part of the building is well adapted for its purpose; its acoustic arrangements are almost perfect, and the seats go up in gradation. It is lighted by a skylight, and contains a large painting by Matout, representing Ambrose Paré practising for the first time the ligature of an artery after amputation. The lectures here are gratuitous and open to the public, and every facility is afforded even to foreigners for attendance on them.

The Shah of Persia is, of course, the lion of the day in Paris, as indeed he is of all Europe for the present. Fêtes, reviews, and sight-seeing are the order of the day, and notwithstanding the intense heat the review on Thursday last was a great success, not only as a magnificent military display, but as a proof of the powers of endurance of the French soldiers; for out of about 62,000 of all ranks that were under arms for nearly the whole day there were only twenty-five men who fell out and had to be taken to the ambulance tents erected for the purpose. The crowd of spectators was also dense. Owing to this cause, coupled with the intensity of the heat, several persons fainted. There were only a few cases of insolation, far less indeed than might have been expected under the circumstances. The *fête de nuit* and the pyrotechnic display got up last night for the Shah are beyond description. The whole of the Champs Elysées to the Trocadero was in a blaze, but the enjoyment of the sight was marred by a strong wind and a slight shower, which, however, were otherwise welcomed, as owing to the myriads of lights and the density of the crowd the atmosphere was stifling; but I have not heard of any accidents. The whole was concluded hard upon midnight by a magnificent *retraite aux flambeaux*, the torches, Bengal lanterns, and the national and Persian flags being borne by regiments of soldiers headed by their own bands, told off for the occasion. The Shah is very active in visiting the different monuments and public buildings of this great city, not even disdaining the Christian places of worship; but the hospitals do not seem to have any great attraction for him, as I have not heard of his having as yet visited any since his arrival among us. Should, however, the Shah have any intention of doing so, it is to be hoped that timely notice will be given in order that the wards may be thoroughly disinfected before the arrival of the august visitor. The following anecdote *àpropos* of the visit to Notre-Dame is related of the Persian sovereign:—Among the sacred objects that were exhibited to him the chalices seemed to have most attracted his notice. In being told of the office of these vessels, the Shah, through his interpreter, asked the canon present whether Christ permitted the use of wine, to which the priest replied, He not only permitted it but used it Himself. The Shah then inquired whether Christ had always made use of wine, to which the reply was in the affirmative, the priest adding that if Christ permitted the use of wine He condemned the abuse of it; that it was Mahomet who unreservedly forbade the use of it. So you see the teetotalers may claim for their patron the head of the Mussulman faith.

GENERAL CORRESPONDENCE.

WATER SUPPLY TO MARITZBURG.

Letter from Surgeon-Major Black.

[To the Editor of the Medical Times and Gazette.]

Sir,—In reference to the subject of the connexion between the production of typhoid fever and the nature of the water supply of towns abroad, I may adduce the instance of Maritzburg, the capital city of Natal, with its garrison of Fort Napier. Here a healthy station to all appearance, in a very salubrious climate, is converted into one of very doubtful sanitary reputation, both amongst the civilian and the military populations, owing to the prevalence of typhoid fever more or less constantly every year.

This city lies in an upland country, on a sloping ridge, open to all aspects but the north, with ample means of drainage down each side to the streams below, and is fully exposed to the ozoniferous sea breezes from the south-east.

Fort Napier, where the troops are stationed, is still better located—on the top of a hill, at the western end of the town, open to every breeze and view all round. Both town and fort lie on the horizontal strata of the lacustrine sandstone, which, being fully jointed, allows perfect permeation of rainfall through its cracks, and therefore the sites are dry.

Now, the inhabitants of Maritzburg and the troops at Fort Napier have been generally subject to typhoid fever prevailing more extensively at one time than another, according to the nature of the season. All sorts of conjectures floated about for some time as to the cause. At one time it was thought to be the heat, at another the fruit, and so on, till experience has eventually drawn attention to the defective nature of the plan of its water supply.

Graham Town, of English origin, the next city of any size on the southern coast of Africa, has its water carried for its inhabitants by pipes from reservoirs in the neighbouring hills, and is reported to be a very healthy station. Maritzburg, on the other hand, was planned by the Dutch originally, and they adopted the open sluit or channel system for their waterworks, which suited them both for irrigation and house purposes.

These sluits or open ditches came down from a valley between the Town Hill and the Twent Kop Hill where the head springs are, and through fields under cultivation and pasturage, where manure is extensively used and also deposited by the cattle. The sluit supplying Fort Napier runs on a higher level than that for the town, but passes through the same sort of arable land and meadow, which has a gradual slope down at right angles to the watercourses.

Now, when rains take place, as they do in the summer chiefly, they come down like tropical showers with thunderstorms, and therefore the waters run rapidly off all sloping grounds, washing light and loose material down with them. What tends to render the whole matter more insalubrious is that these sluits are simply dug as channels in the earth, and are not lined by brickwork or masonry, which would prevent soakage into the earth and permit them to be properly cleaned out. In consequence, therefore, the sewage matters of these meadows all get washed into the two sluits above named, and supply the inhabitants and troops with excellent solutions of manure. When parts of these ditches are required to be cleaned out occasionally to remove obstructions, the detritus deposited in them is found as black and offensive as that out of any horsepond in a farmyard.

Though this glaring sanitary defect has been often pointed out by professional men, yet, as far as I am aware, no new system of waterworks has been constructed on the European plan of reservoirs and pipes and cisterns.

These sluits on arrival at the town are divided and subdivided down the sides of the different streets, and run past the doors of the houses and gates of the gardens, and are therefore further liable to be contaminated by the washings of ordure and filth from the traffic. When the servant then dips her pail into this water-sluit for a domestic supply opposite her master's door towards the lower end of the town, it may be easily conceived what a disgusting solution it must be.

It may also be conjectured what must be the nature of the subaqueous deposition going on in the ditch daily, and that there is therefore a well-grounded fear of cleansing them all out, in case of stirring up a foul source of disease. This sluit system has been gradually eliminated by the English

colonists from other large towns in South Africa designed by the original Dutch settlers, and it is surprising it has been allowed to remain so long in the capital of Natal. In the meantime, all the water used for drinking and culinary purposes imperatively requires the constant use of filtration as the only available preventive at present against the sewage poison entering the blood of the inhabitants and producing the fever recorded in civil and military Blue Books.

Extracts from Army Medical Reports.

1859, p. 98.—Fevers of the continued type have been thrice as prevalent at Natal as on the Eastern frontier.

1860, p. 86.—In January and February the admissions for continued fevers in Natal were much above the average.

1868, p. 101.—The corps which furnished the highest proportion of cases (of continued fevers) was the 20th Regiment in Natal.

1867, p. 96.—The former 99th Regiment was quartered in the early part of the year at Natal, where fever is stated to be endemic in January and February (in the summer).

1865, p. 79.—The 11th Regiment, at Fort Napier, furnished the highest number of cases, etc., of continued fever.

I am, &c., W. T. Black, Surgeon-Major.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, May 27.

Dr. C. J. B. Williams, F.R.S., President, in the Chair.

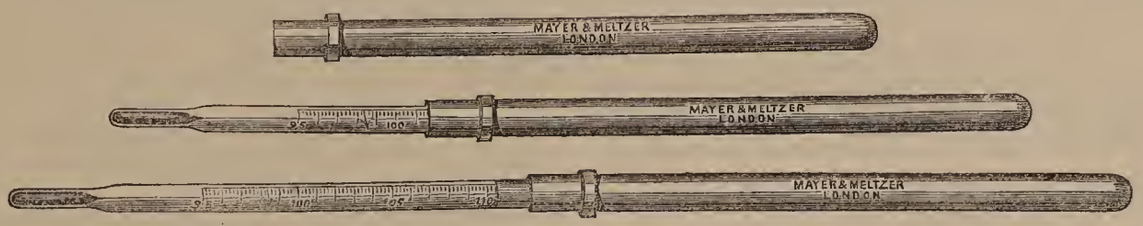
Dr. Wilson Fox read a paper entitled "Analysis of Observations on the Temperature, Pulse, and Respiration in Phthisis and Acute Tuberculisation of the Lungs." In this paper the author gives an account of an analysis of the morning and evening observations on the temperature, pulse, and respiration of eighty cases of phthisis made at University College Hospital. The cases are divided by him into five classes—viz., (1) acute tuberculosis; (2) acute tubercular phthisis; (3) chronic phthisis; (4) cases with high temperatures not ending fatally; (5) cases with comparatively low temperatures not ending fatally. The phenomena relating to temperature are considered under the following heads:—1. The maximum and minimum temperatures. 2. The maxima of the morning and evening. 3. The mean temperatures of the morning and evening. 4. The exacerbations and remissions occurring from evening to morning and from morning to evening. 5. Circumstances influencing the degree of pyrexia. In the cases analysed by the author the highest temperatures were most frequently attained in acute tuberculosis, but temperatures exceeding 104° were found in all classes except in the cases categorised as "low temperatures not ending fatally." The highest temperatures were, as a rule, met with in the fatal cases, but in chronic phthisis the temperatures are lower than in other classes, with the exception of the last named. In chronic phthisis high degrees of pyrexia (exceeding 102°) are for the most part due to pneumonic complications. The mean temperatures of the cases not ending fatally fell considerably below those of the other classes, owing to a gradual fall in temperature being observed in many during their stay in hospital. The mean morning temperature may fall within normal limits in certain cases in all classes. This, however, is due in some instances to the extent of the remissions which occur from evening to morning, and which may reach subnormal degrees. Such low averages of the morning temperature are, however, more common in chronic than in acute phthisis. Averages of the evening temperatures not exceeding 99° were only met with by the author in cases of chronic phthisis and the class of low temperatures not ending fatally; he, however, alludes to the fact that these have been recorded by other observers in cases of acute tuberculosis. They are in some cases due to a large proportion of the remissions taking place from morning to evening. The maximum temperature is usually attained in the evening, but by no means invariably. In 10 per cent. of the cases the maximum temperature of the morning and evening observations was equal. In 23 per cent. of the cases the maximum morning temperature observed was higher than the maximum evening, and in 15 per cent. the means of the morning temperatures were higher than those of the evening. High morning temperatures were more common in the class of acute phthisis than in any of the others. Exacerbations from evening to morning occurred with greater or less frequency in 90 per cent., and remissions from morning to evening in 92 per cent. of 75 cases examined; and these variations were pretty evenly distributed through all classes of cases, being, however, least common in the cases of acute tuberculosis analysed. A morning temperature higher than that of the evening may be found also when the temperature does not exceed normal limits. In a few cases the morning temperature may, throughout nearly the whole series of observations, be found to be higher than that of the evening. Usually, however, these variations occur irregularly throughout the course of the cases. As the author's analysis is founded solely on morning and evening observations, he thinks it probable, from some cases which he has observed where the temperature has been more frequently recorded, that the apparent remissions from morning to evening may be interrupted by a midday exacerbation; but nevertheless, in a fair proportion an actual rise takes place from the evening to the ensuing morning. Equality also between the evening and morning is sometimes maintained, though rarely during long periods. It may, however, extend over thirty-six or forty-eight hours. It may exist both for febrile and for non-febrile temperatures; and, as regards individual mornings and evenings, may form a large proportion of the observations in any given case. Such approximative equality between the mornings and evenings is usually associated with high pyrexia and with severe forms of the disease. The order of the remissions and exacerbations is thus frequently interrupted by the conditions now described, when the usual course of exacerbations from morning to evening and of remissions from evening to morning is inverted or neutralised. Severe exacerbations are, however, commonly attended with equally great remissions; the maxima of each of those observed being an exacerbation from morning to evening of 8·8°, and a remission from evening to morning of 8·4° Fahr. The remissions and exacerbations do not, however, precisely correspond: 10 per cent. had remissions, and 8·4 per cent. had exacerbations exceeding 5° Fahr. The larger exacerbations and remissions are nearly equally distributed among the fatal cases and among those not fatal, but presenting in some part of their course high temperatures. The author, from an analysis of the remissions and exacerbations observed, considers that Prof. Niemeyer's statement that acute tuberculosis is distinguished by continuity of high temperature is not borne out by facts; for a greater proportion of large remissions and exacerbations is observed in the highly pyrexial cases of this class than in any others. Although the morning temperature is not unfrequently higher than that of the evening, yet the exacerbations from evening to morning, and the remissions from morning to evening, are usually less great than those following the converse order. In some cases, however, they are greater. Severe exacerbations are sometimes traceable to extension of the disease, sometimes to intercurrent inflammations, but neither of these conditions is always discoverable. Great remissions are most commonly due to exhaustion, and are an unfavourable symptom. Sweating is perhaps not the cause, but the consequence, of the remission. It may exist when the temperature is high, and remissions may take place without its appearance. Hæmoptysis has no necessary connexion with any peculiarity of temperature. Lardaceous disease has no necessary connexion with any peculiarities of fever. The fever of phthisis is most closely allied to suppurative fever. The observations on the pulse in relation to the temperature and respiration are analysed in respect of the quickest and slowest pulses observed in the morning and evening of each case, and also of the means of all the observations on the pulse as compared with the mean temperature and the mean number of respirations. The author on these points comes to the following conclusions:—1. That the pulse stands, in respect of rapidity, in the majority of cases, in tolerably definite relations to the intensity of the disease and to the severity of the fever, but that a rapid pulse and a high temperature are not always simultaneously present. 2. That the morning pulse is commonly more rapid than that of the evening, thus confirming Dr. Edward Smith's observation on this point. Exceptions, however, were not uncommon, and the rule chiefly applies to the quickest pulses observed; for in the slowest pulses, and also in the means of the pulses in each case, the reverse condition appears to prevail in the periods during which these observations were taken (9 to 11 a.m. and 8 to 10 p.m.) The respirations are also accelerated, but their frequency bears no proportion to the intensity of fever in the averages of the cases; but this correspondence may be occasionally

observed. The relation of the respiration to the pulse is, in respect of frequency, more constant than that to the temperature, but quick respiration may be associated with a slow pulse; or, more commonly, the pulse may be rapid when the respiration is very little accelerated, and the rise of the pulse is commonly greater than that of the respiration. In the more rapid pulses, and also in the means of the pulse and respiration, the ratio of respiration 1, pulse 3 to 4, is commonly maintained; but in the slower pulses the most common proportion is respiration 1, pulse 2 to 3, and occasionally the respiration may be more rapid than the pulse. The pulse-respiration ratio is but little influenced by the temperature; but, as the pulse is commonly slower when the temperature is low, a high ratio of the respiration to the pulse is sometimes found under these circumstances. Great variations, however, exist in individual cases in the relation both of the pulse and respiration to the temperature on different days. Either the pulse or the respiration may be singly accelerated or not both when the temperature falls or rises, or any one of the three may fall while the others rise in frequency or degree of temperature. The absence of correspondence between the rate of respiration and the degree of temperature is probably due to the variations in the amount of respiratory surface remaining as compared with the requirements of the system. Severe pyrexia may, however, be excited by a comparatively small area of disease in the lungs. Pyrexia, however, *per se*, tends, as noticed by Traube, to increase the frequency of respiration.

NEW INVENTIONS.

THE UNIVERSITY POCKET CLINICAL THERMOMETER.

This little instrument consists of the usual pocket clinical thermometer, enclosed in an outer case, to the end of which it is attached firmly by a clip. This admits of opening to fix a new tube in case of breakage. By a simple screw arrangement the thermometer can be projected from the case or returned to it at will, while the clip fastening enables any person in case of loss or breakage to fix a new tube without the trouble, uncertainty, and annoyance of cement. An octagonal collar on the case prevents it rolling. The arrangement is patented, and can be applied to caustic-holders, or any instrument requiring easy and expeditious elongating or retracting. It is invented and manufactured by Mayer and Meltzer, 59, Great Portland-street, London.



MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 21st inst., viz.:

Atkins, Francis Thomas, L.K. & Q.C.P. Ire., Plumstead, Kent, student of Guy's Hospital.
Barrow, Frederick, L.S.A., Holloway, of King's College.
Bennett, William Henry, Chilmark, near Salisbury, of St. George's Hospital.
Berry, William, L.R.C.P. & S. Edin., Wigan, of the Glasgow School.
Brodribb, Charles Aikin, L.S.A., Newton-road, W., of St. Mary's Hospital.
Cash, Alfred Midgley, M.B. Edin., Edinburgh, of the Edinburgh School.
Clarke, George Mouat Keith, L.S.A., Gerrard-street, Soho, of the Charing-cross Hospital.
Counsellar, William Parkinson, L.K. & Q.C.P. Ire., Whalley, Lancashire, of the Manchester School.
Daniel, James, L.K. & Q.C.P. Ire., Harpurhey, Lancashire, of the Manchester School.
Dobson, Joseph, L.S.A., Leeds, of the Leeds School.
English, Thomas Johnston, L.S.A., Fulham-road, of St. George's Hospital.
Gunn, Robert Marcus, M.B. Edin., Sackville-street, of the Edinburgh School.
Hallett, Henry Arthur, M.B. Aberd., Banchory, of the Aberdeen School.
Jelley, Richard, L.S.A., Elton, Northamptonshire, of the University College.
Jennings, William Oscar, L.S.A., Bedford-row, of Guy's Hospital.
Joynes, Francis James, L.S.A., Chipping Norton, of King's College.
Kitcheu, Charles Frederick Hewick, L.R.C.P. Lond., Manchester, of the Manchester School.
Lee, Edmund, L.R.C.P. Edin., of the Manchester School.
Leftwich, Ralph Winnington, M.B. Aberd., Holloway, of St. Bartholomew's Hospital.
McKay, Henry Kellock, L.S.A., New Kent-road, of Guy's Hospital.
Martin, Richard Johnson, L.S.A., Atherton, near Manchester, of the Manchester School.
Mears, Robert, L.R.C.P. Edin., Atherstone, Warwickshire, of the Edinburgh School.
Packman, Augustus Tenasserim Vance, L.S.A., Sheffield, of the Sheffield School.
Penny, William Lowry, M.B. Cantab., Bridgefield, Lancashire, of the Middlesex Hospital.
Williams, Trevor William Wynn, L.S.A., Montagu-square, of St. Bartholomew's Hospital.
Young, Ralph, L.M. Durham, Bishop Auckland, of the Newcastle School.

Admitted Members on the 22nd inst., viz.:—

Archer, Edmond Lewis, L.S.A., Highgate, student of St. Bartholomew's Hospital.
Balding, Mortimer, M.B. Cantab., Barkway, near Royston, of the Middlesex Hospital.
Bindley, Philip Henry, Birmingham, of University College.
Booth, Philip Lancashire, Manchester, of the Manchester School.
Burn, George Wilson, L.S.A., Fleet-street, of St. Bartholomew's Hospital.
Craven, Robert Musgrave, Southport, of the Liverpool and Edinburgh Schools.
Eales, Henry, Yealmpton, Devon, of University College.
Fenn, Charles Draper, L.S.A., Newmarket, of Guy's Hospital.
Gould, Alfred Pearce, Norwich, of University College.
Hutchings, Arthur Carey, Alderbury, near Salisbury, of King's College.
Kershaw, Alfred, Bolton, Lancashire, of the Manchester School.
Kershaw, Robert, Hampstead, of the London Hospital.
Parkinson, Richard Thomas, Manchester, of the Manchester School.
Paul, Frank Thomas, Pentney, Norfolk, of Guy's Hospital.
Reckless, Alfred, Sheffield, of the Sheffield School.
Skerritt, Edward Markham, Wokingham, of University College.
Smith, James, Newcastle, of the Newcastle School.
Stansfield, George Sutcliffe, Bacup, Lancashire, of the Manchester School.
Stericker, William, L.S.A., Bromptou, Yorkshire, of Guy's Hospital.
Wear, Arthur Taylor, Newcastle, of the Newcastle School.
Wilson, John Smith, Aberdeen, of the Aberdeen School.

Admitted Members on the 23rd inst., viz.:—

Baly, William, Exeter, student of St. Bartholomew's Hospital.
Cassan, Theodore, Lewisham, of King's College.
Greenwood, John William, Preston, Lancashire, of St. Thomas's Hospital.
Harricks, John Hugh, Liverpool, of the Liverpool School.
Hewetson, Henry Bendelack, Leeds, of the Leeds School.
Howe, Lucien, M.D. New York, Louisville, Kentucky.
Jennings, John Downes, Tamworth, of the Birmingham School.
Johnson, Cottingham Greaves, L.S.A., Rectory-grove, Clapham, of St. Thomas's Hospital.
Keer, George Edwardes, L.S.A., Wickham Market, Suffolk, of Guy's Hospital.
Messiter, Matthew Ardun, Repton, near Burton-on-Trent, of the Birmingham School.
Page, Herbert Markant, Birmingham, of the Birmingham School.
Pickles, John Jagger, Shelf, near Halifax, of the Leeds School.
Riding, Edwin, Liverpool, of the Liverpool School.
Sparrow, William Christopher, Dublin, of the Dublin School.
Torbock, William Hall, M.D. Philad., Darlington, of University College.
Vawdrey, Theophilus Glascott, St. Austell, of University College.
Verdon, Henry Walter, Eccles, near Manchester, of St. Thomas's Hospital.
Wherry, George Edward, Bourne, Lincolnshire, of St. Thomas's Hospital.
Wilson, Samuel, L.S.A., South Shields, of the Newcastle School.
Wilsou, William Teasdale, L.M. Dur., Newcastle, of the Newcastle School.
Wreford, Samuel, Exeter, of the London Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, July 17:

Burn, George Wilson, Fleet-street, E.C.
Hooper, Alfred, Burton-on-Trent.
Joseph, George William, Liverpool.
Pilkiuton, William Binns, University College.

The following gentlemen also on the same day passed their primary professional examination:—

Burtonshaw, Thomas, London Hospital.
Henbeck, Frederick Emanuel, St. Mary's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRUCE, WILLIAM, M.D., L.R.C.S. Eng., J.P.—Parochial Medical Officer for Reay, Caithness.

CASS, HENRY, M.R.C.S.—Attending Medical Officer at the Provident Medical Institution and Lying-in Charity, 20, Pimlico-road, S.W., *vice* Dr. O'Neil.

CAVAFY, JOHN, M.D., M.R.C.P.—Physician to the Victoria Hospital for Children, Gough House, Queen's-road, Chelsea.

CLARKE, LOCKHART, M.D., F.R.S., M.R.C.P.—Consulting Physician to the Provident Medical Institution and Lying-in Charity, 20, Pimlico-road, S.W., *vice* Dr. C. J. B. Aldis, deceased.

DIXON, JOHN, M.B., L.R.C.P. Edin., C.M.—House-Surgeon at the London Temperance Hospital, Gower-street, W.C.

EDMUNDS, JAMES, M.D., L.R.C.P. Edin., M.R.C.S. Eng., L.S.A.—Visiting Physician to the London Temperance Hospital, Gower-street, W.C.

GRACE, HENRY, L.R.C.P. Lond., M.R.C.S. Eng., L.M., L.S.A.—Medical Officer of Health for the St. George's Urban Sanitary District, Bristol.

LYNES, EDWARD, M.D.—Certifying Factory Surgeon for the City of Coventry, *vice* Edmond Waters, L.R.C.P. Edin., deceased.

MOORE, SAMUEL W., L.R.C.P. Edin., L.R.C.S., L.S.A., F.C.S.—Visiting Surgeon to the London Temperance Hospital, Gower-street, W.C.

PLETTS, JOHN MENHAM, M.R.C.S.—House-Surgeon at the Royal Isle of Wight Infirmary, Ryde.

RIDGE, JOHN JAMES, M.D., M.B., B.A., and B. Sc. Lond., L.R.C.P. Lond., M.R.C.S. Eng.—Visiting Physician to the London Temperance Hospital, Gower-street, W.C.

NAVAL APPOINTMENTS.

ADMIRALTY.—Thomas L. Bickford, Staff Surgeon, 2nd class, to the *Royal Adelaide* for temporary service; H. A. Close, Staff Surgeon, 2nd class to the *Duke of Wellington;* John B. Nicoll, Staff Surgeon, 2nd class, to the *Pembroke;* John P. Courtenay, Staff Surgeon, 2nd class, to the *Nankin.*

BIRTHS.

EVANS.—On July 15, at The Cottage, Drumcree, Westmeath, the wife of Usher W. Evans, M.D., Deputy Inspector-General, of a son.

HOOD.—On July 19, at Bletchingley, the wife of D. W. C. Hood, M.B., L.R.C.P. Lond., L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., of a daughter.

HOLLIS.—On July 18, at 13, New Cavendish-street, W., the wife of W. Ainslie Hollis, M.D., of a son.

IMAGE.—On July 20, at Westgate-street, Bury St. Edmunds, the wife of Francis E. Image, M.A., M.B., L.R.C.P., L.R.C.S., M.R.C.S. Eng., of a son.

MCDONALD.—On April 28, at Hamilton, Tasmania, the wife of Wallis McDonald, M.R.C.S., L.R.C.P. Edin., of a daughter.

PURVIS.—On July 19, at Royal-hill, Greenwich, the wife of John Prior Purvis, M.R.C.S., of a son.

WORKMAN.—On July 17, at 1, Clarendon-terrace, Teignmouth, South Devon, the wife of C. J. Workman, M.D., of a son.

MARRIAGES.

HUGHES—WOODFORDE.—On July 15, at the Church of St. Mary Magdalene, St. Leonard's-on-Sea, the Rev. Geoffrey Hughes, fourth surviving son of the Rev. Henry Hughes, of All Saints, Gordon-square, to Gertrude Mary Cardew, second daughter of Francis Henry Woodforde, M.D., of Amberd House, near Taunton, Somerset.

NEWSTEAD—POPE.—On July 17, at the Church of St. Mary Magdalene, Stoke Bishop, James Newstead, M.R.C.S. Eng., to Louisa Anne, younger daughter of George Pope, Esq., of Stoke Lodge, near Bristol.

RUSSELL—LANE.—On July 17, at Christ Church, Clifton, Bristol, Philip Cecil Crampton, youngest son of the late Christopher Russell, M.D., of Enniskerry, Ireland, to Lucilla Mary Elizabeth, only daughter of the late Odiane Coates Lane, Esq., of Clifton.

STEPHENSON—HORWOOD.—On July 16, at the parish church, Esher, Heathfield Harman, son of the late Charles Thomas Stephenson, M.D., of Esher, to Maria Willbee, eldest daughter of John Horwood, Esq., of Esher.

DEATHS.

PIRRIE, JOHN MILLAR, A.B., M.B., M.D. Dub., L.R.C.S.I., of Belfast, at the residence of his brother, Washington Pirrie, Esq., 139, Cumberland-terrace, Upper Parliament-street, Liverpool, on July 16, aged 48.

RALFE, MARY HOWARD, wife of Charles Henry Ralfe, M.A., M.B., at 26, Queen Anne-street, Cavendish-square, on July 18.

SHILLINGFORD, RICHARD SHORTLAND, eldest son of Isaac Shortland Shillingford, M.R.C.S. Eng., L.S.A., 124, Hill-street, Peckham, S.E., on July 20, in his 18th year.

SIMPSON, VIOLET JULIA, only child of Thornton G. Simpson, L.R.C.P. Edin., L.M., L.S.A., at Fairlie House, King Edward's-road, South Hackney, on July 16, aged five months and a fortnight.

WRIGHT, ALEXANDER BRYAN, only child of Dr. D. Wright, Residency Surgeon, at Katmansoe, Nepaul, on June 17, aged 18 months.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to the Medical Committee, Children's Hospital, Steelhouse-lane, on or before August 4.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Candidates must be legally qualified. Applications, with testimonials, to the House Governor and Secretary, on or before July 26.

BOURNEMOUTH DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

BRADFORD INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to W. C. Woodcock, Secretary, 65, Market-street, Bradford, on or before August 4.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

COVENTRY PROVIDENT DISPENSARY.—Surgeon. Candidates must be M.R.C.S. of London, Dublin, Edinburgh, or Glasgow, and possess a licence from one of the Royal Colleges of Physicians, or from the Society of Apothecaries. Applications, with testimonials, to the Honorary Secretary, on or before August 2.

DERBY COUNTY ASYLUM.—Assistant Medical Officer. Candidates must be duly qualified in Medicine and Surgery. Applications, with testimonials, to John Barber, County Lunatic Asylum, Mickleover, Derby.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Applications, with testimonials, to the Secretary, 4, Victoria-street, Derby.

KING'S COLLEGE, LONDON.—Chair of Anatomy. Applications, with testimonials, to the Council.

KNIGHTON UNION.—Medical Officer for the Llanbister District. Candidates must be legally qualified medical practitioners. Applications, with testimonials, to Edward Hooper Deacon, Clerk to the Guardians, Knighton, Radnorshire, before August 2.

LEICESTER INFIRMARY AND FEVER HOUSE.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, 24, Friar-lane, Leicester, on or before August 4.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Demonstrator of Anatomy. Applications, with testimonials, to R. Harrison, Registrar (of whom particulars may be obtained), before August 13.

LOYAL UNITED BRETHREN BENEFIT SOCIETY.—Surgeon and Apothecary. Candidates must be M.R.C.S.E. Applications, with testimonials, to the Secretary, Mr. S. Emmanuel, 24, High Holborn, W.C., on or before August 4.

NORTH BIERLEY UNION.—Medical Officer of Health. Applications, with testimonials, to W. Lancaster, Esq., Solicitor, Bradford, Yorkshire, on or before August 4.

NORTH RIDING INFIRMARY, MIDDLESBRO'-ON-TEES. — House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom, and possess a medical qualification recognised by the Medical Council. Applications, with testimonials, to the Secretary, on or before July 30.

SUFFOLK GENERAL HOSPITAL, BURY ST. EDMUNDS.—Physician and Surgeon. Candidates for either appointment must send testimonials to the Committee on or before July 29.

WANDSWORTH AND CLAPHAM UNION.—Resident Medical Officer for the Workhouse and Infirmary. Candidates must be duly qualified. Applications, with testimonials, to John Sanders, Clerk to the Guardians, New Wandsworth, on or before July 26.

WOBURN UNION, BEDFORDSHIRE.—Medical Officer for the Aspley Guise District. Candidates must possess both a medical and surgical qualification, and be registered under the Medical Act of 1858. Applications, with testimonials, to the Clerk to the Board of Guardians, Woburn, on or before July 31.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Physician's Assistant. Candidates must be graduates in Medicine of a British University, or be possessed of such medical qualifications as are satisfactory to the Medical Committee. Applications, with testimonials, to the Chairman of the Medical Committee, on or before August 9.

WREXHAM INFIRMARY AND DISPENSARY.—House-Surgeon. For particulars, apply to Mr. J. G. Buckton, Secretary, 9, High-street, Wrexham.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bakewell Union.—Mr. Wm. Cantrell has resigned the Cromford District; area 2662; population 2895; salary £15 per annum.

Martley Union.—Mr. Samuel Lloyd has resigned the Leigh District; area 11,266; population 4703; salary £85 per annum.

Pocklington Union.—Mr. John E. L. Macdonald has resigned the Second Pocklington District; area 25,555; population 2500; salary £20 per annum; —the Bishop Wilson District; area 21,580; population 2478; salary £28 per annum;—and the Workhouse; salary £20 per annum.

APPOINTMENTS.

Abingdon Borough.—Mr. Wm. F. Donkin as Analyst.

Bethnal-green Parish.—Frank Argles, L.R.C.P. Edin., M.R.C.S. Eng., to the Schools at Leytonstone.

Bideford Union.—Joseph R. Dowman, M.R.C.S. Eng., L.S.A., to the Hartland District.

Buckingham Union.—John Cheesman, M.D. St. And., M.R.C.S. Eng., L.S.A., to the First District; and Robt. De'Ath, M.R.C.S. Eng., L.S.A., to the Second District and the Workhouse.

Maidstone Union.—John Walter Bury, L.R.C.P. Edin., M.R.C.S. Eng., to the Sixth District.

Whittlesey United Parishes.—Charles N. Elliott, M.B. and M.C. Dub., to the Southern District and the Workhouse.

Wisbeach Union.—David C. Nicholl, M.R.C.S. Eng., L.R.C.P. Edin., to the Seventh District; and George Mason, M.R.C.S. Eng., L.S.A., to the Ninth District.

Worksop Union.—Christopher Fleming, L.R.C.S. Ire., L.K. & Q.C.P. Ire., to the Harthill District.

SEVERAL deaths from sunstroke have occurred in Constantinople since the present hot weather has set in.

THE EARL AND COUNTESS OF DUDLEY have consented to open the new Birmingham and Midland Counties Middle Class Idiot Asylum, recently erected at Knowle, on August 30.

THE HUNTERIAN MUSEUM—His Imperial Highness the Grand Duke Cesarewitch, accompanied by Colonel Tecsdale, paid an unexpected visit to the Royal College of Surgeons on Tuesday last, the 22nd instant, where he was received by Messrs. Trimmer and Stone, and conducted over the whole of the museums, library and examination rooms, and, after remaining two hours, took his departure, expressing the great pleasure he had derived from the visit.

WE have just received from Messrs. Barraud and Jerrard two admirable photographic portraits of the late Bishop of Winchester, which were taken on the day before his death. Those who wish the last portrait of the Bishop, who was the subject of universal admiration and esteem amongst all classes, will no doubt hasten to obtain one of these photographs.

DISEASE AMONGST INDIAN SOLDIERS.—It is reported from Bombay that sickness is so prevalent in the 40th Regiment that 100 men are away at the hills and eighty in the hospitals.

FOUNDERS' DAY AT EPSOM COLLEGE, JULY 17.—An unusual and melancholy interest attaches to this anniversary by the presence of the late Bishop of Winchester, who took part in the ceremonials of the day, presiding during the speeches, and previously in the chapel, confirming upwards of thirty of the boys. All present during the chapel services, which, it is believed, were the last engaged in by the Bishop, were particularly impressed by his more than ordinary solemn admonitions. His words, pregnant with holy aspirations and suggestive of the beginning of a new life in Christ, fell from his lips and rich-toned voice with an accent never to be forgotten! He strongly urged the necessity of resisting impurity, and of beginning from this moment the new life. Truly, they were words worthy of being spoken by one (as he proved to be) on the verge of another world. The Council were represented by Drs. Jonson, Carr, and Hogg, and Messrs. F. Hird and Bransby Powys. The general company included Rev. Dr. Hessey, Professor Key, Dr. Webster, of Dulwich, and Dr. Price, of Deptford, in addition to a large gathering of ladies. The Carmen Gratulatorium Latinum was well pronounced in the new style by Mr. Bannister, and all the speeches were well received. The day was a great success, and augurs well for the future of the Medical College.

EXAMINATIONS.—The following were the questions in writing submitted, on Friday last, to the candidates who are now going through the oral portion of their examinations for the diploma of Membership of the Royal College of Surgeons of England, viz.:—1. Under what circumstances may blood be passed by the urethra? By what signs would you distinguish its probable source? State the treatment which you would adopt. 2. What is carbuncle? State in what conditions of the general health this disease usually occurs. Describe its course from its commencement to its termination in a favourable case. 3. Describe, in the order in which they appear, the parts met with in a dissection from the skin to the peritoneum, of that region of the abdominal wall which is bounded, below by Poupart's ligament, and above by a horizontal line drawn from the anterior superior spine of the ilium to the median line. 4. How does dislocation of the head of the humerus into the axilla usually occur? What are the chief signs upon which you would rely to distinguish this injury from others in the same region? 5. In what cases, and under what circumstances, may tracheotomy be required? Describe the operation, and point out the difficulties and dangers that may arise in the course of it. 6. What fluctuating or fluid swellings may present themselves in the popliteal space? Describe their characteristics; and state briefly the treatment appropriate in each. The following were the questions on the Principles and Practice of Medicine at the written examination on Saturday last, viz.:—1. A person suddenly becomes more or less unconscious, and falls down, and on recovery is found to have lost the use of the left arm and leg. What are the conditions on which the seizure may depend, and the other symptoms which the patient may present? 2. What are the different kinds of worms which infest the human body? where are they chiefly found? and how do they probably gain access to the system? Mention the chief remedies which may be employed for their expulsion or destruction, and the doses and modes in which they should be given. 3. Mention the chief preparations of mercury and opium contained in the British Pharmacopœia; state the uses to which they are applied, and the doses in which they should be given.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Howard Smith, M.D.—If you have a qualification from a good university you can be examined on this side; but you can obtain a qualification only by examination.

L. D. S.—Liston's "Elements of Surgery," second edition, page 786.

E. I.—1. No. 2. Next week.

Iota.—The Hygienic Tract Society has been started: its object is to print and distribute tracts and leaflets on sanitary subjects, written by qualified men.

M.D.—According to the evidence given before the Civil Service (in Ireland) Inquiry Commission, just issued, the incomes of successful medical practitioners in Ireland vary from £800 to £1000 a year, and sometimes, but rarely, reach £5000.

A. N. O.—"Foods," by Edward Smith, M.D., vol. i. This volume gives an account of the chemical elements of food and drink and their effects on the health.

Wickland.—See Lectures on the Bones and Joints, delivered before the College of Surgeons, by James Wilson, 1820.

Gregory, W.—Albayn Hyll, a physician of the sixteenth century, studied at Oxford, and afterwards took a doctor's degree on the Continent. He died in London in 1559. Some call him a native of Wales, others of Scotland.

Spes.—Lord Houghton has accepted the office of President of the Social Science Congress, to be held at Norwich on October 1.

An Australian Correspondent says that "there is too much cramming nowadays among students, and anatomy is not sufficiently attended to. You are sending out far worse surgeons than they were twenty years ago. I feel astonished at some of the men that come out, calling themselves Fellows of the College; I sometimes think what had been crammed into their brains had been washed out on the voyage!"

THE "PRÆDIUM RUSTICUM" OF JAMES VANIER, S.J.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Do your readers know the "Prædium Rusticum" of Jacobus Vanierius, a didactic poem on country life, published in the last century? It is full of the quaintest advice and shrewdest axioms. To me the estimate it gives of the value of medical advice is quite charming. What it says of manure is Liebig anticipated; and the judgment on wine is perfect wisdom.

I send six extracts to amuse your readers, and have subjoined a translation done by one of my sons, an Oxford man, in English hexameters. I like to see a little flavour of "humanities" in the *Medical Times and Gazette*.

I am, &c., VALETUDINARIAN.

Jacobi Vanierii, Soc. Jes., "Prædium Rusticum." Ed. Nov. Abrincæ Numatianæ, 1782.

I.

Elige vicinos magnis aut urbibus, agros
Aut grandi pago, vel (quò ratis ambulet) amni;
Ditat enim villam facilis vectura; colendo
Nec desunt operæ ruri, nec agrestibus armis
Artifices, nec prompta tuis obsonia mensis.
Nec medicus, tibi qui subitis in casibus ægro
Præsentem nisi prestet opem, solantia, saltem
Verba ferat; sic urbe tamen distabit ab alta
Fundus, ut hospitio non infestere perenni.—Lib. i., p. 7.

Sudoribus omnia vendunt
Di superi, et magno stant optima quæque labore.—Lib. ix.

III.

In nitro vis omnis humi est, multaque gravitem
Fertilitate, sales signis absumit, amica
Restituas ope; quæ ruris mihi summa colendi est.—Lib. vi.

IV.

Mucor si qua fides amenti lumina vitro.—Lib. vi.

V.

Sed nulla est hausto potior medicina Lyæo.—Lib. vi.

VI.

Sinæra ruentem
Vina fovunt stomachum; pellentes corpore morbos
Et fraudes animis et edaces pectore curas
Fœdaque vaniloquis abigunt mendacia linguis
Et retegunt mentes dubia sub fronte latentes,
Illinire vetant ora, refert frons vitreus uudam.—Lib. xi.

[Translation.]

Hard by some city large, or near to some prosperous hamlet,
Choose thee thy site, or else by some stream which is open for traders;
So shall thy house be enriched, being easy of access. For tillage
Thus neither tools will be wanting, nor yet for the implements workers;
Thus due supplies of provisions thou'lt have close at hand for thy tables;
Thus, too, a leech thou can'st have, who (if by some sudden misfortune
Sickness should seize thee), e'en if he no remedy present can think on,
Words full of comfort at least may pronounce. But see that thy villa
Stand just so far from the walls of the city that thou, by thy neighbours
Coming too oft, undisturbed may'st remain.
The climate should be mild, and breezes soft
Should blow more oft than gales. The fertile land

Should slope a little toward the show'ry west.
Let neither vales too deep encumber it,
Nor mountains rough, nor stagnant poisonous lakes.
A hill that faces north is vext with storms,
And corn that grows on flats is spoilt by rain.
A house that's hid in valleys deep both lacks
The light of heaven and rots with stagnant damp;
And frequent fogs, in watery clouds condensed,
Destroy the crops of grain and blooming grapes.
A meagre yield of fruit,
With stunted shoots and little sap, will show
If fault lies in the soil; but of unhealthy climes,
The cause of wasting sickness, tokens sure
Are these: But few old men are seen; the lip
Is thin and bloodless; sight grows dim, and breath
Grows short; the sufferer's mind is also dulled.
With healthy climate water should combine—
'Tis best when from a beetling rock it falls;
If not, then such as easy fills thy wells;
Or choose a cistern. Worst is that which creeps
With sluggish stream along the silent fields;
If mixt with marshy reeds it stagnant lies,
One draught will poison those, who thus must die.
The ground gives stores for walls; the grove gives trees
Unbought for roofs and carpentry; green boughs
And timber fit to hew it also gives,
With which to burn thy tiles and lime; the sand
Is either dug, or from the neighbouring stream
Is brought in carts. These things do thou provide
Before the springing walls begin to rise.
The oxen strong through winter's rest draw stones;
Let many a plane in neighbouring glades lie low,
And oaks of fearful weight by axes felled,
And fir trees, lasting long when kept well dry.

COMMUNICATIONS have been received from—

Dr. Eustace Smith; Mr. A. F. McGill; Dr. Russell; Dr. C. Handfield Jones; Mr. J. Chatto; Dr. Aveling; Mr. G. Gaskoin; Mr. Scoones; Mr. Vulpy; Mr. Blackett; Mr. J. H. METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·737 in.
Mean temperature	59·4°
Highest point of thermometer	75·6°
Lowest point of thermometer	46·4°
Mean dew-point temperature	52·7°
General direction of wind	S.W.
Whole amount of rain in the week	1·21 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, July 19, 1873, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1873.*	Persons to an Acre. (1873.)	Births Registered during the week ending July 19.	Deaths Registered during the week ending July 19.	Temperature of Air (Fahr.) Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values.	Temp. of Air (Cent.) Weekly Mean of Mean Daily Values.	Rain Fall. In Inches.	In Centimetres.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·74 in. The highest was 30·02 in. on Saturday at noon, and the lowest 29·21 in. Sunday, the 13th inst.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture V.—Endo- and Myo-carditis.

Endocarditis, like pericarditis, is very rarely an idiopathic affection, but occurs during the progress of the same diseases with which pericarditis is connected. It is the most frequently seen in connexion with rheumatism, and, so far as my own observations apply, is about as frequent as pericarditis in that affection. I have met with it in 16·7 per cent. of the cases treated, or in one case out of 5·9. I have also remarked that it is especially apt to occur in cases of severe rheumatism, while pericarditis more usually arises in the slighter cases. The general symptoms by which its presence is indicated are yet more indecisive than those of pericarditis. There may be some uneasiness at the region of the heart, or even decided pain; the action of the heart may be quickened and irritable, and the breathing may be laboured and rapid; but all these symptoms are often absent or very slightly marked, and do not generally exist to a marked degree unless the endocarditis has been some time in existence, and has led to serious interference with the functions of the heart. Generally, however, the temperature becomes more or less elevated so soon as the cardiac disease sets in. The diagnosis of endocarditis could not, however, be effected by the general symptoms alone, and must be deduced from the physical signs. These consist of a soft blowing murmur, heard with the systole of the heart towards the base or apex, according as to whether the valves affected are the aortic or mitral. In the former case, the murmur, which is due to thickening or the presence of vegetations on the valves, is most distinctly heard at the base, and is propagated in the course of the aorta or up the right side of the sternum. In the latter, the mitral valve is thickened or its surface the seat of fibrinous exudations, and the murmur is heard at the apex and is transmitted towards the left axilla. If the mitral valve be simply thickened, or the fibrinous deposits be situated on the auricular side of the valve, the murmur should, as I shall have again occasion to remark, precede the systole; but the sound heard seems to be generally systolic, and must therefore be supposed to be due either to the slow closure of the valves or to their being imperfectly adjusted, so as to admit of regurgitation. If the disease go on, the valves may be softened, and may break down and become incompetent, and thus there may be a diastolic regurgitant sound at the base or a systolic at the apex.

The diagnosis of an endocarditic murmur is not generally attended with much difficulty—the only errors which could be committed would be to mistake it for an exocardial murmur, or for one dependent on anæmia. The deeper seat of the affections of the endocardium is generally very obvious, though occasionally a valvular murmur, and a murmur dependent on lymph in the pericardium which is becoming organised, are very similar in character. The former murmur is, however, also propagated in the course of the circulation, while the exocardial is limited to the pericardial space. The anæmic murmurs and the blowing valvular murmurs are also often very much alike, but the former would almost certainly be also heard in the pulmonary artery and in the arteries of the neck, and might probably be attended by a venous murmur in the neck; and these circumstances would form very distinguishing peculiarities. The greatest difficulty sometimes occurs in distinguishing these murmurs when (as not unfrequently occurs) an anæmic murmur becomes superadded to one dependent on an organic cause, towards the end of an attack of rheumatism.

I have refrained from speaking of the prognosis in cases of peri- and endo-carditis; for the two affections are so closely allied that it is difficult to speak of the prognosis of each separately. When either form arises in the course of advanced renal disease or in pyæmia, it must be regarded as of very serious import, for such affections almost always prove rapidly fatal. Rheumatic peri- and endo-carditis are, however, if unconnected with old disease of the heart or other complication, rarely a source of immediate danger, and are in a large proportion of cases recovered from, though with more or less damage to the heart, which may entail serious results at a more distant period. The probability of the entire removal of all the signs of cardiac disease, when it arises during the progress of rheumatic fever, depends very much on the time after the commencement of the symptoms at which the patient came under treatment, and especially on the particular form which the disease assumes,—pericarditis being certainly a more curable form of disease than endocarditis. Thus, of the cases referred to in the last report, seven uncomplicated cases of pericarditis were all entirely cured, though in two some increased dulness on percussion remained. On the other hand, in seven cases of combined peri- and endo-carditis the cure was complete in only two cases, and in five there remained some signs at the time of discharge. One case in which there was endocarditis only was cured. The general inference is that when a case of rheumatic fever is complicated by simple pericarditis the local disease will probably be recovered from without leaving behind it any obvious defect in the heart. When, on the contrary, there is endocarditis, either alone or with pericarditis, and especially if the local disease is fully established before the patient comes under treatment, there is great risk that some marked defect in the heart will remain. Such injury in a large proportion of cases probably lays the foundation of future cardiac disease, but the immediate danger to life is not very serious. Thus, of seventy-one cases of recent rheumatic heart affection—pericarditic and endocarditic—only three proved fatal at the time, and in all three there was pericarditis, with pre-existing disease of the heart and other serious complications. I have, however, reason to believe that the physical signs do ultimately disappear in some of the cases in which they remain at the time of the discharge of the patient from the hospital; and the frequency with which the white or milk spots on the surface of the pericardium and adhesions between the vessels at the base are found in persons who die from causes entirely independent of the heart, is confirmatory of the view that in many cases an entire and permanent cure is effected. When the adhesions between the two surfaces of the pericardium are general or occupy a large portion of the heart, the movement of the organ must be seriously interfered with, and hypertrophy of the heart seems an almost necessary result.

If pericarditis prove fatal, it may be by the organ becoming compressed by the accumulating effusion; and in cases of endocarditis only, or where peri- and endo-carditis co-exist, by the destruction of the valves, by thrombosis of the cavities and orifices producing obstruction, or by embolism of the smaller vessels of the brain or other organs or of the extremities, and by the implication of the pleuræ, lungs, and kidneys in the disease.

The morbid appearances in cases of pericarditis consist in the presence of lymph of harder or softer consistence on the surfaces of the attached and reflected pericardium, and of a yellowish serous or sero-purulent fluid in the cavity. The solid exudation generally has a peculiar velvety or honeycombed appearance, and occasionally it has a deep bloody colour. Sometimes, and especially in cases of pyæmia, there is distinct pus in the cavity, and the amount of effusion may be very large—I have seen upwards of two pints. When the patient dies at a later period, the liquid effusion may have been wholly absorbed, and the pericardium may be covered by distinct layers of solid and firmly adherent membrane. When the pericarditis is connected with tuberculosis, there may be either liquid effusion in the cavity or the surfaces may be adherent, and in some cases of chronic pericarditis connected with this cause the deposits between the two surfaces of membrane may be very thick—fully half an inch,—and the inner layers may have a peculiar yellowish colour and a friable cheesy character much resembling the so-called tuberculous infiltration.

In cases of fatal endocarditis there is at first only opacity and thickening of the endocardium, with the exudation of lymph on the surface of the membrane or beneath it; the fibrine of the blood also becomes deposited on the roughened surface, forming vegetations in larger or smaller masses. In this way the valves become sources of obstruction to the flow of blood from or into the ventricle; they may also be softened so as to break down under the pressure of the blood, and so allow of regurgitation. In the aortic valves the thickening may either involve the edges or the portion of the fold which is exposed when the segments come in contact, and in either case when the thickened tissue contracts the valves become small and their sacs shallow, so as ultimately

to be incompetent. The folds of the mitral valve may also become united together, or the attached fold may be adherent to the walls of the ventricle, and so great obstruction may be caused; or the chordæ tendineæ may give way, and the valves may fall back so as to allow of regurgitation.

Myocarditis.

Myocarditis is probably always seen in connexion with inflammation of the investing or lining membrane of the heart or of the two combined, and seems especially prone to occur when these affections arise in persons of dissolute and intemperate habits. In severe cases of peri- and endo-carditis some affection of the subjacent muscular structure not unfrequently occurs; the muscle has a peculiar yellow colour, and is softened so as to be very friable. Occasionally these changes involve a large portion of the substance of the heart. This is especially the case at the apex when the pericardium is affected, and at the base when the aortic valves and endocardium are diseased. If during the first or acute stage the muscular substance beneath the endocardium be much involved, it may break down under the pressure of the blood, and an aneurismal tumour may result—constituting the false consecutive aneurism of Breschet or the acute aneurism of Rokitansky. If, on the other hand, the condition be partially recovered from, the muscular substance may become atrophied and be replaced by fibroid or fibro-cartilaginous tissue, which being, as explained by Cruveilhier, less resistant than the natural structure, may become dilated and form a true aneurismal sac, according to Reynaud, or the chronic aneurism of Rokitansky. In some cases the inflammation of the muscular substance runs on to suppuration, so that the tissue becomes infiltrated with pus, or, the matter being circumscribed, a true abscess is formed. Of the latter condition a small number of cases are on record. I have myself seen one such case, which occurred in the Edinburgh Infirmary in the practice of Dr. Craigie, and has been described by that gentleman. In that instance the abscess occupied the septum of the auricles, and was bilocular, each portion being sufficiently large to have lodged a cob-nut. One portion of the abscess had opened into the origin of the aorta, and another was on the point of bursting into the cavity of the pericardium. The disease coexisted with pericarditis, and with extensive recent disease of the aortic valves. The subject of the affection was a female aged 35, of irregular habits, who had suffered from rheumatic pains for some weeks, and in whom the right knee was swollen and tender. While in the hospital she was in a state of great agitation and alarm, but was intelligent when spoken to. She had occasional attacks of dyspnœa, but at other times was able to lie down on the back or on either side. No notes were taken of the case during life, and, indeed, the existence of heart disease was not suspected, her excited condition being ascribed to her habits of intemperance. There are not, indeed, any means by which inflammation of the muscular structures of the heart could be diagnosed during life—though the cases have generally, as in the instance just referred to, been characterised by hurried and tumultuous action of the heart, feeble and irregular pulse, urgent difficulty of breathing, and great distress and agitation of mind, and sometimes delirium with rapid prostration of strength.

It only remains for me to speak of the treatment I have been in the practice of adopting in cases of inflammatory affections of the peri- and endo-cardium. When the disease is developed in a person previously in good health, and commences with active symptoms, leeches may be applied over the region of the heart, or the patient may be cupped. Cases of this kind are, however, comparatively rare; and generally, in those which we so often meet with in the course of rheumatic fever, such active measures do not seem to be needed, while in many cases depending on other causes they would be inapplicable from the state of the patient. In rheumatic peri- and endo-carditis I do not generally make any material change in the remedies which the patient is taking. I usually, indeed, order the region of the heart to be blistered, and, regarding the occurrence of the internal disease as an indication that it is desirable to arrest the rheumatic symptoms as soon as possible, I very freely blister the affected joints, directing warm poultices to be persistently applied over all the blistered surfaces. With this treatment calomel or grey powder with Dover's powder is cautiously given. If under this course the disease be not arrested, and the effusion in the pericardium ensues, I usually give small doses of iodide of potassium. During the treatment suitable nourishing food must be allowed, and when the patient's strength begins to give way, stimulants—wine or brandy—must be cautiously exhibited. There are, indeed, no forms of disease in which, when had recourse to at the proper period, a greater amount of benefit is derived from the use of stimulants.

After the attack has passed off it is of the greatest importance that perfect rest should be enjoined, and the patient be retained in the recumbent position for a long time. It is impossible, also, to be too particular in impressing on the patient and his friends the necessity for his long refraining from any active exertion and avoiding all excitement of mind. Neglect of these precautions might keep up an irritable state of the heart, and lay the foundation of subsequent disease. The greatest care must also be observed by suitable clothing and other means to protect the patient from cold, for if he should have another attack of rheumatism, there is the greatest risk that the heart would again be involved.

COMMENTARIES ON DISEASES IN CHILDREN.

By EUSTACE SMITH, M.D. Lond.,

Physician to His Majesty the King of the Belgians,
Physician to the East London Hospital for Children,
Assistant-Physician to the Victoria-park Hospital for Diseases of the Chest.

IV.—Pleurisy.

(*Continued from page* 61.)

Empyema causes great interference with the nutrition of the patient. The child wastes more and more, becoming daily thinner, paler, and weaker. His appetite is lost, he is restless and irritable, and sleeps badly at night. The circulation is feeble; the fingers become clubbed at the extremities; and the hands and feet are often cold, although the general temperature of the body is slightly raised towards the evening, and the child perspires profusely in the night. There is often much tenderness of the affected side, and the child shows great distress when a physical examination of the chest is made.

If no operation is performed for the evacuation of the purulent fluid, this may become gradually absorbed, and the child may eventually recover. In other cases the fluid points at some part of the chest; a swelling appears at one of the interspaces, becomes red, and after a few days bursts, and the fluid slowly drains away. When this takes place the child may recover, the opening closing after several weeks; or the perforation may remain open, and the child die, worn out by long-continued suppuration. Instead of opening externally, a perforation may take place into a bronchial tube, and the fluid be evacuated in the form of profuse expectoration. These cases also often end fatally. In a third class of cases the presence of purulent fluid in the pleura seems to be a determining cause of a general formation of tubercle, and the patient dies from acute tuberculosis.

In the following instance spontaneous perforation of the fluid took place through the wall of the chest, and the recovery was surprisingly complete:—

Anne B., aged 6, a thin child, rather small for her age, very pale and weakly-looking, had been suffering, it was said, from "low fever" for a considerable time. Her illness had begun in the middle of February with fever and cough, and she had ever since been getting paler and thinner, although the fever had in a great measure subsided. Her cough was still troublesome, but was loose, and gave her no pain.

When seen on June 4 she complained of pain in the left hypochondrium, and this part was said to swell at times. On examination the left side of the chest was seen to be almost motionless in respiration. There was no fulness at the seat of pain, but that spot seemed tender on pressure. The whole left back was completely dull from apex to base, with increased resistance. The breathing was loud and almost cavernous over the whole dull area, and the vocal vibration was annulled except at the supra-spinous fossa, while the resonance of the voice was everywhere increased. In front of the same side percussion was dull and the breathing blowing, although weaker than at the back. The heart was displaced slightly to the right.

A few days afterwards a swelling the size of a hen's egg formed in the left nipple-line, the centre of which was over the eighth interspace. This was very tender to the touch, and

fluctuated freely. As the mother objected to any operative procedure, she was directed to apply a succession of hot linseed-meal poultices. In the course of the week a second swelling appeared higher up on the same side, just below the nipple. This also fluctuated. The superficial veins of that side, both of the chest and belly, were very well marked. The skin over the abscesses became very red and tense, and on July 3 the lower one burst, and discharged a considerable quantity of thin purulent fluid. After this the upper swelling subsided without opening. The child seemed at once very much relieved; her appetite, which had been quite lost, returned; her spirits improved, and she began at once to regain flesh.

On July 26 the following note was taken:—Looking much fatter and stronger; runs about, and her spirits are good; eats heartily. Cough loose, and very troublesome at night. Perspires very much, especially when in bed. The abscess is still discharging, and about an ounce of thin watery fluid comes away from it in the day. There is much flattening under the left clavicle, and the left front of chest does not move in inspiration; laterally, however, the intercostal spaces sink in a little in inspiration, and the ribs move slightly. Spine curved laterally, with convexity to right. Shoulder and lower angle of scapula on the left side rather depressed. Percussion is dull all over left half of chest—both front and back. In front no respiration is heard at all, but over the whole left back it is loud and blowing. Vocal resonance there is slightly stronger than natural.

After this report the child was not seen again until the following February, six months afterwards. The improvement then was very remarkable. The abscess had continued to discharge for six weeks. It had then closed, and the child had been ever since constantly improving. She now coughed very little, and only in the morning or after exertion, and then sometimes expectorated a little thick yellow phlegm. She was fat, and looked strong and healthy.

On examination of the chest some slight retraction was seen at the lower part of the left side, but the deformity was scarcely noticeable; the left shoulder was not depressed, the spine was straight, and the nipples were on the same level. The apex of the heart beat one inch below the nipple in the nipple line. No dulness was found at any part of the left side, and the respiration was generally healthy, although towards the upper part of the left back it was rather loud and slightly blowing. Vocal vibration was felt faintly as far as the extreme base.

This case affords a very good illustration of the extraordinary readjusting power possessed by childhood. The left lung had been exposed for a considerable time to great pressure from the effused fluid, but it had notwithstanding been able, on the removal of this fluid, again to expand, and to do this so effectually as almost entirely to remedy the deformity at first noticed, and which threatened at one time to become permanent.

The retention of purulent fluid in the chest-cavity is always attended with considerable risk, for not only is the general nutrition of the child seriously affected while such fluid remains, but there is also a direct danger that its presence may lead to the development of general tuberculosis, as in the following case:—

Charles B., a little boy, aged 2 years and 9 months, sixteen teeth, was admitted into the East London Children's Hospital on September 17.

Little information could be gained as to the history of his attack. The mother could only say that he had been healthy two or three months previously; that he had then begun suddenly to cough and to lose flesh, and that during the last month his bowels had been relaxed five or six times a day, causing him to waste very rapidly.

State on Admission.—Child greatly emaciated; eyes hollow; cheek-bones project; complexion rather earthy; head square-shaped; fontanelle size of a shilling, depressed; veins of forehead full. Abdomen rather swollen, and feels hot to hand; abdominal veins full; no enlarged glands felt in belly on deep pressure; spleen and liver appear to be of normal size. Ends of long bones not large; fingers slightly clubbed. Tongue clean and red. Stools yellow, slimy, and offensive. Has a frequent cough. Temperature in rectum 100·6°; pulse 130; respiration 40.

Physical Signs.—Very little respiratory movement comparatively on right side. Intercostal spaces not bulged, and can be seen to sink in to a slight extent on that side at the lower front; but on the left side they sink in deeply at each inspiration. Heart's apex beats on the left side in the fifth interspace in nipple-line. The chest measurement at the level of the nipple is on the right side $8\frac{7}{8}$ inches, and on the left $8\frac{5}{8}$ inches. No vocal fremitus felt either side. Percussion dull all over right side, back and front. Behind, the dulness is complete, with extreme sense of resistance. In front, the dulness is more tubular, especially under the clavicle, and does not reach quite to the middle line. Still, the percussion-note at the right edge of sternum is not quite resonant. Respiration all over right lung is loud and bronchial, with intense resonance of voice and cry. Between the scapulæ the breathing is cavernous. Here and there dry rhonchi are heard, but there is no friction or crepitation. The left lung is apparently healthy.

A lead and opium mixture was ordered to check the diarrhœa, and ten drops of brandy every three hours. For his diet, bread and milk. The diarrhœa ceased at once, and the child's appetite began to improve. He continued still very thirsty, and the temperature remained high, varying from 100° to 102°—generally one degree of difference between the morning and evening temperature.

September 24.—Child seems weaker. The bowels act twice a day; motions not offensive. Physical signs as before. The right side seems tender, and the pressure of the stethoscope causes pain. Cough loose and rather frequent; if the child coughs violently all the veins swell up, even down to the wrists; jugular veins then much distended. Temperature in evening 102·4°; pulse 120; respiration 30. He was ordered ol. morrhuæ ʒ ss. ter die, with a mixture containing tinct. ferri perchlor. Some meat and broth on alternate days were added to his diet.

On October 4 the respiration on the right side in front was covered by a grating rhonchus, and at nipple a coarse crepitation was heard. These, however, had disappeared by October 9. On this date the two sides of the chest were measured with cyrtometer, when at the nipple level the right side was found to measure $8\frac{7}{8}$ inches, the left $9\frac{1}{8}$ inches. The temperature remained high at night, varying from 101° to 103°, or even 104°, and sinking to 100° in the morning; pulse 130 to 140; respiration 44 to 48.

22nd.—Child wasting more and more. Physical signs much the same on right side. Over lower part of right front fine bubbling is heard at the end of a deep inspiration. On the left side percussion is rather dull in the supra-spinous fossa, and generally over the left back is too high-pitched. Respiration in supra-spinous fossa is bronchial; below, harsh, with a little dry rhonchus. Over left front respiration is harsh, with a little sonorous rhonchus. Temperature in evening 104°; pulse 120; respiration 48.

On October 25 the child had an attack of diarrhœa. The temperature then fell to 100° in the evening, and remained low till October 29, when the thermometer again marked 104° in the rectum.

On November 5 the percussion signs were unaltered, but under the right clavicle the loud bronchial respiration was accompanied by a large metallic bubbling rhonchus, which was also heard downwards as far as the extreme base. At the nipple the breathing was blowing, almost tubular. The same bubbling rhonchus was heard also in the right infra-axillary region and at the back, but posteriorly the bubbles were smaller and less metallic. After a violent cough the rhonchus partially disappeared at the front and side. On the left side some fine crepitant râles were heard at the end of inspiration. Temperature in the morning 102°; pulse 130; respiration 44°. In the evening, temperature 103°; pulse 132; respiration 56. On the previous evening (November 4) the temperature had been as high as 105°.

From November 5 to November 19 the temperature continued exceedingly high in the evening, the thermometer marking 104 to 105°, and on one occasion (November 15) 106° in the rectum. There was always a great fall towards the morning, and the heat of the body was almost uniformly 99° at 10 a.m. There was usually a difference of about twenty beats between the morning and evening pulse, and the respiration was also always higher at night, ranging at that time from 42 to 60. The subsidence of the fever in the morning was always accompanied by a marked change in the behaviour of the child. In the morning he would sit up in bed and play with his toys, eat a hearty breakfast, and sometimes cry out for cake. In the evening he lay with flushed face and parched lips, completely indifferent to all that passed around.

On November 18 the bubbling rhonchus was universal on

the right side, and at the left back the breathing was harsh and was accompanied by a rhonchus coarser than before, and mixed here and there with a finer crepitation.

On November 20 patches of dulness were discovered at the left back, and there was greater resistance to the finger; the breathing on that side was bronchial, and everywhere it was accompanied by a coarse bubbling rhonchus as on the right side. On this date the temperature suddenly became lowered; in the evening it reached no higher than 99·2°. On the following morning it was 97°, and fell in the evening to 95·2°. A few hours afterwards the child died. The temperatures were taken throughout the case in the rectum, and with great care.

Autopsy.—Body extremely emaciated. Right lung almost entirely adherent to chest wall; the adhesions with difficulty broken down, especially at apex, where they are so firm that the lung is torn in bringing it away. A little purulent fluid—about one ounce—is found in right pleura at the base. Right lung smaller than left, tough, and firm. Scattered through the substance, and forming nodules projecting on the surface under the pleura, are yellowish-white non-friable tubercular masses, varying in size from a pin's head to a pea. These have not the granular appearance of cheesy masses, and do not appear to be softening. With them are more pellucid small bodies, evidently grey granulations. In many places, where the tubereles are collected closely together, the intermediate lung tissue is the seat of quite recent broncho-pneumonia. Left lung not condensed, but presents the same masses. It was firmly adherent to the pericardium, which could not be detached from it. The same masses are found in the spleen, which is thickly studded with them. They are also present, although to a less amount, in the kidneys, and on the upper surface of the liver are some grey granulations. There are no tubereles in the meninges.

The diagnosis in this case was not difficult. The complete dulness over the whole of the right half of the chest, both at the back and at the front, combined with the extreme sense of resistance; the breathing, which was everywhere loud and piercingly bronchial; the intense bronchophonic resonance of the voice and cry; the absence of liquid rhonchus or crepitation,—these signs occurring, without any contraction of the side, at so late a period of the disease (for the child had been ill two or three months at the time of his admission) could only be the result of pleurisy. Inflammation seldom affects the whole of a lung from apex to base, and pneumonic consolidation, if extensive, does not long remain indolent. Small pneumonic deposits may remain unchanged in children for many months, and may eventually be removed; but large deposits soon begin to give evidence either of commencing absorption or of degeneration and decay, leading to destructive disease of the lung in which they are situated. Again, the sense of resistance to the finger on percussion is very much greater when fluid is present, or in the case of a lung solidified by pressure, than where the consolidation is owing to pneumonia; and this alone is a very important element in the diagnosis. The heart, again, was slightly displaced to the left, and the apex was found to beat in the fifth interspace in the nipple-line. It had been probably pushed farther to the left, but was being drawn back into its normal position as the effused fluid became gradually absorbed.

The dulness in the right front did not reach quite to the middle line, but this would not contra-indicate the presence of even a considerable effusion; for the fluid might be prevented by adhesion from touching the mediastinum. At the time of admission there was probably little fluid left in the diseased pleura, for the intercostal spaces on the affected side were not prominent, and were even seen to sink in slightly at each inspiration.

In the after progress of the case the continued wasting, the high evening temperature, combined with the occurrence of dry and crepitating rhonchi on the diseased side, and eventually in the opposite lung, made it evident that tubercular formation was taking place. The variations in the temperature are worthy of notice, for the difference between the heat of the body in the morning and in the evening was more marked than the ordinary course of a case of pulmonary tuberculosis would lead us to expect.

The pleurisy was here evidently the primary disease, occurring, as it did, suddenly, while the child was in his ordinary health; and the tubercle was a secondary formation. In many cases, however, tuberculosis is the primary disorder, and itself gives rise to a secondary pleurisy. The pleurisy is then generally of the fibrinous variety, a plastic exudation being thrown out, which is seldom attended by liquid effusion, and gives rise to but few symptoms, pain in the side being as a rule the only thing complained of.

The ordinary serous pleurisy is always accompanied by a certain amount of fibrinous exudation, and when this is extensive it may lead to secondary results after the fluid which was first thrown out has become reabsorbed. These cases form a special variety of basic lung disease, to which, as occurring in the adult, attention has been directed by Dr. Andrew Clark. The pathological alteration consists in an excessive formation in the base of the lung of fibroid tissue, which causes a loss of elasticity of the part, so that it no longer contracts and expands as in health. If present to an extreme degree, the part attacked shrinks, the bronchial tubes become dilated, and the heart may be drawn towards the affected side. At first, however, there is no contraction of the base of the chest, and this contraction may even be absent throughout if great dilatation of the bronchial tubes be present.

The following case furnishes a good illustration of the early stage of this condition before the occurrence of contraction:—

Martha B., aged 8 years, a thin but not unhealthy-looking girl, was admitted as an out-patient under my care at the Victoria-park Hospital in February, 1873. She had been out of health for twelve months. Her illness began in January, 1872, with cough and pains about the body. At first she was an out-patient at the London Hospital; but after three months she ceased to attend, although she still coughed a great deal, and was losing flesh. Ever since, she had continued to cough, and had slowly wasted. In the autumn the child passed some weeks in Suffolk, and seemed to derive benefit from the change.

When I first saw her on February 6 the cough was said not to be very frequent, and to be dry. Her appetite was good, the bowels regular, and she slept well at night. Skin quite cool, and not rough or dry to the touch. The right shoulder and angle of scapula were on rather a lower level than the left; and there was a slight curvature of the spine, with concavity to the right. The right nipple was, however, rather higher than the left. The edge of the liver could just be felt below the false ribs. The chest expanded pretty well superiorly, and equally on both sides; laterally the chest was rather flattened at each base, and the movement was limited,—the right base not expanding at all. The intercostal spaces were well marked inferiorly at each side—perhaps more so at the right than the left,—and they certainly sank in more at the right side during a deep inspiration. The heart's apex beat close to the left nipple, just below it on the inner side.

The chest measured, at a point one inch below the nipple-level, on the right side 11 inches, on the left $10\frac{7}{8}$ inches. At the level of ensiform cartilage the right side measured $10\frac{7}{8}$ inches, the left $10\frac{5}{8}$ inches.

Vocal fremitus was stronger on the right side than on the left, from above downwards as far as the nipple in front and the angle of the scapula behind. Below these points it could not be detected on the right side, although on the left it could be felt faintly as far as the extreme base. On the right side percussion was resonant from the apex as far as one finger's-breadth below the nipple in front, and the angle of the scapula behind. Below these points it was completely dull, with considerable sense of resistance. The change, however, from clearness to dulness was not abrupt; at the upper level of the dulness the percussion-note had a tubular quality all round the right side from front to back. There was no change in the percussion-note on change of position. Over the dull area the respiration was everywhere very weak, but distinctly bronchial, without friction or rhonchus of any kind, and the vocal resonance was completely annulled. Elsewhere in the same lung, and also in the left lung, respiration was loud and healthy.

After a few days the cough became looser, and the child expectorated a little phlegm. In the morning the cough was rather prolonged, and on one occasion after coughing for some time she brought up some frothy phlegm with retching efforts.

On February 28 the girl was transferred as an in-patient to the East London Children's Hospital, and there, in order to be able positively to exclude the presence of fluid, I requested my colleague Mr. Reeves to make an exploratory puncture into the right base with a fine trocar. This was accordingly done, but no fluid was found.

This case was a very interesting one, and simulated very closely a pleurisy of the right base; but there were certain distinguishing points to be taken into consideration. In the

first place, the intercostal spaces on the right—the diseased—side were as well marked as at the corresponding part of the left side, and during inspiration sank in, if anything, rather more deeply. Then, the transition from dulness to resonance was not abrupt; at the upper limit of the dull area a tubular note was found. If fluid be present this is seldom the case, the change from a dull to a clear note being then usually immediate and complete. Again, no alteration of the percussion-note was found on change of position, the dulness still persisting when the child was made to stoop forwards so as to bring the back into a horizontal line. This sign was one of very great importance, for although in an early stage of pleurisy it is not uncommon to find that changes in position produce no corresponding change in the physical signs, yet later on in the disease, after absorption has begun, it is comparatively rare to find the physical signs absolutely unaffected by position, as in this case. Lastly, the exploratory puncture made by my friend Mr. Reeves furnished a complete proof of the absence of fluid; the canula penetrated to a sufficient depth to insure the escape of fluid had any been present.

The child was last seen in the month of May, 1873. She was then fat and looked very well, but still coughed occasionally. On examination of the chest the physical signs were found to be unaltered.

The case was no doubt one of fibroid induration of the base of the right lung, without contraction, consequent upon an attack of pleurisy. The prolonged fit of coughing which is mentioned as having occurred on one morning, ending in retching efforts and the expectoration of frothy phlegm, is characteristic of this condition, and is due to the loss of elasticity of the smaller bronchial tubes. If these are much dilated, the secretion usually accumulates in them and putrefies, so that the expectoration is very offensive. In such cases a faint fine bubbling is often heard at the seat of disease.

(To be continued.)

ORIGINAL COMMUNICATIONS.

OPERA CLINICA.

ON ARTIFICIAL RESPIRATION AFTER THE OPERATION OF TRACHEOTOMY.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

At the conclusion of a lecture published in the *Medical Times and Gazette* on December 4, 1869, in which was described the double-acting elastic hand-bellows I have invented for artificial respiration, I took occasion to point out that in various cases of acute disease—such as cases of bronchial spasm or of failure of respiratory power,—when death is at hand, the practice of artificial respiration, by the bellows, might prove of service. The following clinical history, briefly told, illustrates forcibly the truth of this proposition:—

A child, aged 4 years and 4 months, was under the care of my friend and neighbour Dr. Neale. She had shown for ten days some obscure symptoms, varying in intensity, of irritation of the throat, with intermittent pyrexia. On Sunday, the 20th of last month (July), on his morning visit, Dr. Neale found the child breathing heavily, and again feverish. On examining the throat, he discovered a diphtheritic patch on each tonsil; he detected also a croup-like respiration. A little later in the day I was called to meet Dr. Neale in consultation. We agreed as to diagnosis and treatment, and all progressed well until Tuesday morning, the 22nd, at three o'clock. At that time the symptoms changed, food and medicine were refused, and in a few hours the respiration was embarrassed from obstruction in the larynx. Severe paroxysms of spasmodic breathing also occurred at frequent intervals.. An emetic gave great temporary relief; but the symptoms afterwards increased, and at 2 p.m. were so urgent that the question of the performance of tracheotomy came under consideration. At half-past six, at a consultation between Dr. Neale, Mr. Christopher Heath, and myself, the operation was determined upon as a necessity. I administered methylene bichloride, which acted promptly and effectively, and Mr. Heath operated.

Recovery from the anæsthesia was rapid, and the little patient soon began to breathe freely through the tracheal tube. Dr. Neale having to leave, I undertook to remain until his return. About an hour after the operation the child was suddenly seized with an attack of severe spasmodic breathing, followed by the escape of tenacious frothy mucus through the tracheal tube. I cleaned the tube freely, and drew up the mucus through the tube, but the paroxysm continued; the features became livid; there was a sharp convulsion; the natural respiration ceased; the pulse ceased; and, to all appearance, there was death. At this moment, affixing an inner tracheal tube to the double-acting bellows, I thrust the inner into the outer tracheal tube, and commenced steadily to keep up artificial respiration. I confess I had no great expectation of useful results; but to my relief, after sustaining the artificial respiration for a period of three minutes, the patient recommenced to breathe independently, and by the time Dr. Neale, who had been sent for, returned—about ten minutes,—she was quite conscious, warm, and breathing freely. We watched alternately through the night, and the night was passed comfortably. Food was freely taken, sleep was natural, the pulse was firm and regular, never exceeding 120, while the respiration, though at times quick (36 per minute), was not laboured. At 8 a.m. on Wednesday, the 23rd, Mr. Lovell and Mr. J. E. Neale being now in attendance, a paroxysm of very severe dyspnœa and spasm recurred, but was quickly relieved by the use of the bellows, and on Dr. Neale's arrival, later in the day, the recovery was so complete that the child was playing at "catch ball" with a sponge. She progressed favourably until 8 p.m. of this day, the 23rd, when from a sleep of about twenty minutes she awoke with another violent paroxysm of the dyspnœa. *In extremis*, Dr. Neale again set up the artificial respiration, and in two minutes the natural respiration was restored. After this there was natural action of the kidneys, and milk was freely taken: At 9 p.m. another extreme attack of the dyspnœa supervened, relieved in the same manner after the use of artificial respiration for five minutes.

At 9.30 I rejoined Dr. Neale, and we found now, for the first time, moist crepitation from exudation or condensation of fluid in the upper surfaces of both lungs. Relief in removal of some of this fluid was afforded by a device of Dr. Neale's of making a Higgins syringe act as an aspirator, and there followed a period of gentle and hopeful breathing. But at 10.30, on the occurrence of another of the extreme paroxysms of dyspnœa, the respiration ceased altogether, the pulse ceased, the countenance assumed the lividity of death, and death, indeed, once more appeared complete. The tracheal tube was removed, the tube of the bellows was inserted into the tracheal opening, artificial respiration was established, and after an interval, as far as we could measure, of five to six minutes, the natural respiration was restored.

From this time, unhappily, the pulmonary lesion increased; the obstruction to the breathing passed from a local to a general condition; the bronchial passages became closed from accumulation of fluid; and absolute death, without return of asphyxia and without a struggle, occurred at 1.30 of the 24th.

To have to record the ultimate fact of death in this case, after such restoration from apparent death, is indeed a painful duty. Yet the one particular process for restoration—artificial respiration—is thereby, in no degree, lessened of its value. It gave a renewal of thirty hours of life, during which if we had known more respecting the removal of those fatal conditions which so commonly commence in the extreme or peripheral parts of the pulmonary organs, we might have made the temporary safety complete and permanent. Step by step, and with that agony of experience which ever attends the highest efforts of the human mind, we shall attain one day even to this perfection. We shall acquire a still more perfect method of maintaining artificial respiration; we shall learn to introduce, with good effect, other gases and vapours with the common air; we shall regulate pressure on the pulmonary surface; we shall sustain, by some simple means, the muscular force; and we shall supply to muscle the stimulus it has lost from the exhausted nerve. In a word, we shall hold mastery of conditions in the presence of which the sick person cannot die. This, the *summum bonum* of medical science and art, may be afar off; but he is no physician who does not live for it, and the history I have written above demonstrates that one of the most important steps towards it is laid for our advancement.

CASES OF PNEUMONIA, WITH CLINICAL REMARKS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

Case 1.—*Physical Signs but little developed.*

C. P., AGED 9, admitted May 5, was taken ill on the 3rd with shivering and vomiting, having been quite well the evening before. On the 4th he was feverish and thirsty, and during the night was semi-delirious, calling out in his sleep. Has a considerable eruption of herpes labialis, which appeared this morning. Temperature 104°; pulse 120, small and weak. Heart's sounds normal. The left lung was acting well, except quite at the base posteriorly, where the resonance and breathing were slightly impaired. In the right front there was some dulness (comparative), and some harsh breath-sound, with (at times) prolonged and harsh expiration. At the posterior base there was also dulness, or rather impaired resonance, and harsh breathing. He was ordered an aperient, as the bowels were confined—Pot. bicarb. ʒ ss., tinct. cinchon. ʒ ss., aq. ℥j., 4tis horis; chloral gr. x., liq. opii sed. ♏v., aq. ℥j. o.n.

May 6.—Both lower backs notably dull in their lower thirds, but the breathing is quite audible and pretty full, and there are no râles. The child was cheerful and placid. Temperature 103°; pulse 112.

7th.—Less dulness in both lower backs; breathing heard fairly well, though rather harsh. Temperature 103°; pulse 120. Urine, which the day before had been very thick with lithates, was now clear and light-coloured.

8th.—More resonance and better breathing at both lower backs. Temperature 100°; pulse 100. Was very weak this morning. Tinct. cinchon. ʒ ss. quater die, wine ℥ij.

9th.—Seems much better. Temperature 98·6°; pulse 108. Breathing quite good in both backs and fronts.

The temperature on the 10th was 97·16°, and the same on the 12th, when good full clear breathing was heard at both lower backs. The herpes presented an abundance of thick scabs. After this he convalesced steadily, with the exception of a few days during which he seemed to have a slight attack of measles, and left the hospital well.

When I saw this boy's herpes labialis, and heard of his high temperature, I could not but think of pneumonia, and was surprised not to find more positive signs of its existence. I expected that they would be present next day, but they were not, nor did they ever appear in a well-marked manner. The dulness and weak breathing at the lower backs, which scarcely lasted more than two or three days, were occasioned, I believe, by some fluid effusion in the pleuræ. The absence of bronchial breathing and of râles affords pretty good evidence that there was little intra-pulmonary affection. It is possible that hepatisation did take place, but too deep-seated and limited to produce evident physical signs. This, however, does not seem very probable. I am much disposed to regard the case as an exceptional one in respect of the local disorder being slightly developed, while the general was well marked and severe. About the same time I saw in consultation a girl, aged 6, who had been ailing some days, but was taken with so severe a fit the day before my visit that she was thought for a time to be dead. She was very feverish and thirsty when I first saw her—temperature 104°; pulse 150; wandered occasionally, so that she did not know her mother always, but in the intervals was rational. There were no lung signs, except a slight impairment of resonance and rather increased expiratory sound in the right lower back. No typhoid spots; no herpes. There was a good deal of doubt as to the nature of the case, but after some time the usual physical signs of pneumonia became well marked, and the disease ran its usual course. Now, if the local lesion be a-wanting, or nearly so, as in the first case, or if it be posterior in time to the general disorder, as in the second case, it seems quite certain that it cannot be regarded as its cause. In other words, the inflammation of pneumonia is not the cause of the fever, which must therefore be regarded as primary. I have often made the remark that pneumonia by its abrupt mode of termination approximated much more to typhus than to true inflammation. The same held true in these cases of its commencement. If, then, pneumonia, as we see it nowadays, is a fever and not an inflammation, it is clear that the object of treatment must rationally be, not to arrest it, but to conduct it to a safe termination. This view is very generally acted on, and is strongly supported by Dr. Bennett's experience, who makes it his aim to conserve the patient's strength. There is, however, no inconsistency in our using various means for the mitigation of special symptoms.

Case 2.—*Ergot employed.*

J. D., aged 21, messenger, admitted May 19. Health generally good. Was taken ill on 16th, about noon, with pains in chest and back, but has had no shivering. He brought up, by coughing, much blood on the 16th, and has continued to do so till now; has brought up, he thinks, a pint. A little herpes at left corner of mouth. Temperature 104°; pulse 96, pausing completely now and then; respiration 47; cheeks flushed. Good resonance in both fronts. Breath-sound harsh and rather weak under left clavicle, normal in third space; below right clavicle the breathing is also weak and harsh, and attended with prolonged expiration. Good resonance and breathing in all right back and upper third of left; in lower half, or more, of left there is marked dulness, bronchial breathing, and bronchophony. He has had pain in left side, but has not much now. Lies down flat. Slept very badly last night. Had only some dry cough before this illness; did not spit anything; had not lost flesh. He is of spare make, and his chest is narrow. His family, he states, is healthy; no phthisis among brothers and sisters. Spoon diet, milk; turpentine stupe to backs. Liq. ergotæ ʒ j., mist. ammon. acet. ℥j., quater die.

May 20.—Sputa mucous, mixed with red blood. Temperature 102·9°; pulse 102; respiration 48. A well-developed tracing taken with 28 grammes pressure, not with 56. Beef-tea, two eggs. Pil. hyd. e. coloc.

21st.—Sputa still much blood-stained. Pulse 86; temperature 100·7°; respiration 33.

22nd.—Temperature 98·6°; pulse 78, distinct; respiration 44. Sputa almost quite free from blood, quantity less; appetite better; left lower back decidedly more resonant; bronchial breathing ceased; some vesicular sound heard.

23rd.—Temperature 97·9°.

24th.—Temperature 97·9°; pulse 66; respiration 34. Scarce any sputa; what there is is only clear mucus. Ate fish to-day, and enjoyed it. Fairly good breathing in lower left back. Liq. ferri muriatis ♏xx., spt. chlorof. ♏xv., aq. ℥j., ter die.

27th.—Doing well; tracing taken with pressure of 84 grammes shows a normal form. He is up and about. Some time after went out. The breathing below both clavicles remaining somewhat weak and harsh.

In this case defervescence was complete by the seventh day, and, what is remarkable, resolution was somewhat advanced. The administration of ergot was suggested by the rather copious hæmoptysis, and it seemed to be beneficial in checking the hæmorrhage; but whether it had any effect in promoting the defervescence and resolution remains uncertain. It seems, however, a rational procedure to give such a drug with the view of checking local hyperæmia. The weakened condition of the heart on the fifth day of the disease was very markedly shown by the low pressure necessary to be employed before a proper tracing could be obtained. On the twelfth day a threefold greater pressure was requisite, the patient being convalescent. It is noteworthy that, though the upper parts of the lungs were in all probability the seat of tuberculous deposit, yet the pneumonia avoided those parts, and kept to its usual locality at the base.

Case 3.—*Delirium Ferox—Opium and Chloral used freely.*

J. G., aged 28, admitted March 25, 1873. Ill a month with a bad cold; went out on 21st, got cold again, and pain in right side came on. Has slight cough and tinged expectoration. Temperature 104°; pulse 153, weak; tongue pretty natural; respiration 36; urine red, turbid with flocculi, contains albumen in some quantity. Is rational now, but says he was light-headed last night. Lower half of right back dull. Some breathing in upper right back; in lower two-thirds no normal breathing, but marked bronchial and bronchophony. Left back resonant; breathing pretty good in most of this region, except at base, where it is weak; no râles. Left upper front more resonant than right, and breathing more natural. Is a very large, broad-chested man; face pale; manner rather excitable. Spoon diet: beef-tea, milk. Pot. bicarb. ʒ j., m. e. ℥j., 4tis horis, opii. gr.j. ter die.

March 26.—Pulse 105, small, weak; temperature 103·3°; respiration 36; sputa watery and tinged; urine pale, clearer, contains no chloride, is albuminous. Some moist râle in lower left back. Pupils of medium size. Two eggs, brandy ℥iv.

27th.—Was rather troublesome in night; but this morning got out of bed, upset the nurses, and forced his way downstairs

into the street. Is now talking in an excited, rambling way. Tongue rather dry in middle; pulse 120, very weak; temperature 102·2°; face pale; pupils quite of medium size. Liq. opii sed. ℥x., subcutan.; chloral gr. xx., p.r.n. Brandy ʒviij. Omittur mist. alkalin.

28th.—Pulse 102, larger; temperature 102·2°. Has had six doses of chloral since yesterday at 2 p.m.; has been much quieter. First sound of heart weak; tongue dry along a median stripe; takes food well; bowels open three times in night.

29th.—Pulse 90, quieter, very weak; temperature 98·9°; tongue moister. Not delirious, but restless; face pallid; a little tinged expectoration. Reptr. pil. o.n.

31st.—Pulse 84, exceedingly weak; temperature 98·6°. Dulness still in right lower back; there is a good deal of large mucous râle, and also well-marked fine crepitation. In left lower back breathing is weak, and there is a good deal of half-dry small tube-râle. He convalesced steadily after this, and went out on April 20.

The danger in this instance was not at all from apnœa depending on extensive blocking up of the air-cells, but from asthenia resulting partly from the morbific agency, and partly from the exhausting delirium. To calm the latter, opium first, and afterwards opium and chloral, were given freely; and to sustain the strength, nourishment and brandy. These remedies proved efficacious. There can be little doubt that the delirium would have produced before long fatal prostration had it not been checked, and that its arrest was mainly due to the calmatives. The pneumonia probably began on the 21st, and defervescence ensued on the ninth day.

Case 4.—*Continuous Delirium—Fatal Issue from Asthenia.*

J. H., aged 32, inspector of police, died February 24, 1873. Was taken ill on the 20th with rigors, which lasted for three-quarters of an hour on getting up in the morning; he had also vomiting for about half an hour. Went back to bed again, and got slightly warm. Lost appetite, and became thirsty. Pain came on in left hypochondrium and over left lower ribs. Is very delirious at night, and seems now on the verge of delirium; does not always answer pertinently. Pulse 112, small and weak; temperature 102·9°. Tongue red, dry, and coated, except at edges; expectoration like white of egg, sometimes yellow. Both fronts resonant, and breathing there is pretty good. Right back fairly resonant; air enters the lung in this region fairly well, but at base some small crepitation is heard, and distant tubular breathing—probably communicated from left. In left back there is breathing in the upper third, but in the lower two-thirds there is dulness and marked tubular breathing with bronchophony. No typhoid spots. Continuous poultices to left back. Ammon. carb. gr. v., tinct. cinchon. ʒj., dec. cinchon. ʒj., 4tis horis; brandy ʒvj.; pulv. Doveri gr. x. o.n. Simple diet, milk, beef-tea, eggs.

25th.—Was very delirious in night towards the morning. Is now, at 2 p.m., only half-conscious. Pulse 138, weak; respiration 36; temperature 103·3°.

26th.—Has been removed to a separate ward; seems not to have been so delirious as the night before. Looks very ill. Pulse over 120; temperature 103·6°; respiration 38. Has had since yesterday twelve ounces of brandy.

27th.—Pulse very weak, cannot be felt for subsultus; temperature 104·7°. Is very delirious now, but not noisy; was quiet in night, only rambling. Fumbles much with bedclothes. Takes plenty of milk and brandy. Died next day.

This was a case which impressed me a good deal. Here was a well-conditioned, respectable man, in the prime of life, free, I believe, from renal disease, taken with one-sided pneumonia and dying on the ninth day of exhaustion. I have usually considered that such a case under reasonably good care ought certainly to recover. But here treatment availed nothing. The temperature rose progressively day by day, the delirium persisted, and the patient died of exhaustion in spite of all efforts to sustain him. I do not think the stimulants were improper: the state of the heart and general system called for them. But I suspect I ought to have used calmatives more freely. Subcutaneous opiates or chloral should have been employed to calm the delirium, and if this could have been accomplished the result might have been better. Continuous active delirium—not mere rambling—is a very evil sign, and under it I am sure the vital power runs down very rapidly. Here opium and other like drugs may be of immense use by conserving force. This they seem to have accomplished in

CASE OF EXTRA-UTERINE FŒTATION.

By LAWSON TAIT, F.R.C.S.,

Surgeon to the Birmingham Hospital for Women and Lying-in Charity, Consulting Surgeon to the West Bromwich Hospital.

On July 16, 1872, I was asked by Dr. Call Weddell, of Bloomsbury, to see in consultation with him Mrs. T., aged 32, who had been suffering for some time from anomalous and perplexing symptoms. She had had one child, nine years previous to the above date, and for some months had been under the impression that she was again pregnant. For some days before I saw her she had been suffering from feverish symptoms, and her condition had evidently become very critical. A crescentiform tumour occupied the pelvis and iliac fossa, giving no special indication of its nature from above, save that at one spot less than half an inch in diameter, and situated about an inch below the umbilicus, there was a distinct bruit, which was much intensified when the pressure of the stethoscope was increased. Vaginal examination revealed a tumour behind the uterus, occupying the whole available space, immovable, and with a peculiar boggy feeling to the touch. The uterus was open, four inches in internal measurement, and presenting very much the characters as if a miscarriage at the third or fourth month had recently occurred. It was movable over the front of the tumour to a limited extent, the fundus being anteverted and readily felt over the pubis. On examination by the rectum I felt what I believed to be the knee of a child and the edge of the placenta. The total absence of any history which could lead us to believe that we had to deal with a case of pelvic hæmatocele, confirmed me in the belief that it was a case of extra-uterine gestation.

On July 17 the condition of the patient was manifestly much worse, and admitted of no further delay. We therefore placed her under chloroform, and I passed the needle of an aspirator into the retro-uterine tumour and evacuated a few ounces of fluid, which was undoubtedly liquor amnii. The diagnosis being thus placed beyond doubt, I followed the needle with a knife, and came at once on the knee of a fœtus. I enlarged the incision, and had no difficulty in delivering a fœtus of about the eighth month, which had evidently been dead for some time. As soon as the child was born I passed my hand through the aperture and searched for the placenta, which I found situated in front. I also found that the cyst had been ruptured above, and that some intestine was extruded into the sac. There was no difficulty in removing the placenta, and no hæmorrhage seemed to result from its separation. It weighed when put together nearly three pounds, and was very hard and fleshy. The patient rallied from the chloroform, but sank in a few hours.

I am indebted to Drs. Sawyer and Weddell for notes of the post-mortem examination.

There was a considerable amount of clotted blood among the coils of the intestine. The uterus was enlarged and displaced, being carried so much to the left that its right margin corresponded to the middle line, and so much forward that its fundus projected over the symphysis pubis. The cyst was large enough to contain two clenched fists, and was situated between the uterus and vagina in front, and the rectum and sacrum behind, the greater portion of it being to the right of the middle line. The cyst was extensively ruptured inferiorly, and the small intestines freely protruded into its cavity.

The lessons derived from this case and its failure are three—first, that we should not delay interference after the child has come to the term or after it is dead; second, vaginotomy should invariably give place to abdominal section as being more scientific and less risky; and third, that the placenta should not be interfered with, but should be left to separate. I have profited by these lessons, and have since been able to operate on a case successfully.

Birmingham.

New Sydenham Society.—The annual meeting of the New Sydenham Society will be held in King's College on Friday morning, August 8, at 9 a.m.

The salary of Mr. George Borlase Childs, Surgeon to the City Police force, has been increased from £500 to £600 a year.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

BIRMINGHAM GENERAL HOSPITAL.

FINAL ISSUE OF EXTREME CURVATURE OF THE SPINE IN MECHANICAL INTERFERENCE WITH RESPIRATION — DIMINUTIVE LUNGS — EXAGGERATED ORTHOPNŒA—QUESTION OF PERICARDIAL EFFUSION.

(Under the care of Dr. RUSSELL.)

THE following case exhibits a vivid picture of the ultimate result of extreme contraction of the chest through spinal deformity, in impeding the respiratory function until the impediment becomes inconsistent with life. The obstacle opposed to the necessary growth of the lungs, by the unfavourable condition in which these organs were placed, is distinctly announced by their small size, as discovered after death. It seemed matter of surprise that life had been prolonged through twenty-two years under such unfavourable circumstances, for although the patient was much emaciated, his growth was not greatly stunted otherwise than by the change in the direction of the spine. Probably the chest attack to which the patient referred the beginning of his troubles was responsible for producing the general adhesion of both lungs, which would then occasion further lessening of their capacity, if not also atrophy, by exposing them still further to suffer from the pressure of the heart. To the same date may perhaps be referred the change in the mitral valve, which must have constituted a grave addition to the pulmonary troubles; and, moreover, the valvular incompetence must have combined with the pulmonary insufficiency to lessen the chest-space in an ever increasing ratio, by adding to the size of the heart through increase in the size of the right ventricle. But the chief interest to myself lay in the question of the existence of pericardial effusion, which was brought in a very urgent manner under our notice by the gravity of the patient's symptoms; and in the solution which the question received at the post-mortem. It might have been supposed that in this case physical examination would have furnished a satisfactory reply, but it was not so. I may just notice in passing that about the time to which the present case refers we had two or three similar cases in the Hospital. In one of these I was called upon, in the absence of a colleague, to decide on the propriety of venesection in consequence of sudden and urgent dyspnœa with cyanosis. The operation was attended with complete but temporary relief. The man died with effusion in the chest and in the pericardium. Like my patient, he had albuminuria. In another case of my own the pericardium was not uncovered by the lung, and there was not much orthopnœa. The young woman had a trifling attack of bronchitis, which much increased her trouble. She left cured of the bronchitis, but soon returned with the renal symptoms, which she had previously presented, much increased, and of these she died, the chest symptoms remaining quite subordinate.

C. D., aged 22, was admitted in a state of pitiable distress from dyspnœa, the result of extreme spinal deformity. Not only could he not lie down, but he was unable to endure even the erect posture. During the first six days of his residence in hospital, he passed the whole time, day and night, half dressed, standing by his bed and leaning forwards with his arms resting on the pillow, raising himself with a weary air when addressed. For six weeks he had been compelled either to lie on his belly or to relieve himself by a change of posture on his elbows and knees, and both elbows and knees were severely excoriated from friction. An attempt to place him on his back, even for a moment, occasioned such alarming dyspnœa and so much increase of lividity that we were compelled to conduct such examination as was possible by placing ourselves flat on the bed, the patient bending over us. He narrated his history in short broken sentences, bending over the interrogator, who lay beneath him on the bed. The face was leaden; the lips and nose deeply cyanosed; the hands and feet and even the legs were livid, and at times even purple; the ends of the fingers were expanded, but not clubbed; the pupils were of medium size and contractile. Throughout the patient was remarkably intelligent, and was easily roused from his sleepy condition. There was considerable anasarca of the lower extremities, and some effusion in the abdomen. The upper extremities were much attenuated. The urine was densely albuminous; specific gravity 1030; the first two days alkaline, and acid on the fourth. Respiration was at times rapid—from 32 to 44,—entirely diaphragmatic, the chest walls being immovable.

The ultimate cause of the patient's distressing condition was extreme antero-posterior curvature of the spine, dating from early childhood, and consequent crowding and immobility of the ribs, with great contraction of the chest. The neck was sunk between the shoulders, the tips of the scapulæ were only two inches and a half from the pelvis, and the distance between the spine of the scapulæ and the iliac crest was but six inches and a half. The largest circumference of the chest, measured over the projecting vertebræ and the prominent tip of the sternum, was thirty-three inches.

The patient dated his trouble chiefly from a chest attack twelve months ago. During three weeks he never lay down, but passed his time stretched across a table, and at night knelt on a sofa, the elbows resting on the raised end. He has never since been able to stand fully erect, and œdema of the legs, which formed at that time, has continued ever since. At first, after his recovery, he was carried to his work, which merely involved sitting at a desk. He could not stay in the house, he said, from dread of the monotony of his life; but for this change he would have gone melancholy mad; but this resource soon failed him, and the last six months he has been at home entirely. He has employed himself in reading, and when tired of reading could do nothing but think. He has hardly been properly in bed during the whole of this period; if he tried to sleep in bed his night was so wretched that for some time he feared to repeat the experiment. His food gave him great uneasiness, "blowing him up"; for two hours after eating the pressure on his stomach was dreadful. He also described extreme weakness of his legs, which appeared almost to amount to paralysis.

The exaggerated orthopnœa, which was so prominent a symptom, and was evidently hurrying the case to a fatal termination, of course suggested at once the probability of pericardial effusion—a probability greatly strengthened by the large space of the chest occupied by the heart's dulness, which covered a space of five inches in vertical height and six inches transversely at the base, extending from the right edge of the sternum. It would have appeared not very difficult with so large a space of dulness to determine whether the dulness were occasioned by effusion into the pericardium or by uncovering of the heart by the lung; but, perhaps in great part from the peculiar condition of the patient, a very careful consideration of the case with reference to the question of puncturing the pericardium left the subject still in uncertainty. The cardiac sounds were clear over the dull space, and a mitral bruit was discovered; but, on the other hand, there was singular absence of impulse (probably from the impure condition of the blood in the coronaries), and on this account, as well as from the intolerance of the patient, the effect of variation of position could not be satisfactorily tested. Subsequently, however, the question was postponed in consequence of unhoped-for relief being afforded by tapping the abdomen, which was found to contain an unexpectedly large quantity of fluid, amounting to seventy ounces. The relief was remarkable. The pulse, which had become very feeble, rose at once, and the lividity greatly lessened. The patient was at once able to lie on his back. Unfortunately the puncture produced peritonitis, rapidly aggravated by a dose of castor oil indiscreetly given by an attendant at the earnest request of the patient, and he died on the third day after paracentesis.

On post-mortem examination the pericardium was found to be completely uncovered by lung, but did not contain fluid. The heart was large (ten ounces), owing to hypertrophy and dilatation of the right ventricle; the main cusp of the mitral valve was contracted. The lungs were quite concealed by the heart, and were, besides, universally adherent to the costal pleura; they were of very small size, the left lung weighing only five ounces and a half, the right nine ounces. The liver weighed twenty-four ounces. The two kidneys weighed eight ounces and a half; their cortex was anæmic; the lobular markings were indistinct; the capsule stripped readily.

It should be added that the temperature in the axilla was between 99° and 100° during the first two days; on the third

and fourth it was steady at 98°; on the evening before death with the peritonitis it registered 99°.

CLINICAL LECTURE
ON TWO CASES OF DEATH AFTER HOLT'S OPERATION.

By R. W. TIBBITS, M.B., M.R.C.S.,
Surgeon to the Bristol Royal Infirmary, Lecturer on Surgery at the Bristol Medical School.

GENTLEMEN,—Those of you who take an interest in the treatment of stricture of the urethra are certain to read Mr. Barnard Holt's very interesting work upon this subject. You will see that he sums up the great advantages to be derived from his method of forcible dilatation or rupture in the proposition—"that the process is facile, speedy, prompt in its effects, and free from every danger—immediate or remote." I am afraid that the two cases I intend to bring under your notice this morning must throw considerable doubt upon the absolute correctness of the latter part of this proposition, or at least show that this rule is not without an exception.

The first case was that of a healthy-looking sailor, aged 25, who was admitted into No. 11 ward on February 21. Five years ago he had been laid up with a sharp attack of gonorrhœa, and since then had suffered from a gradually increasing stricture. Several unsuccessful attempts had been made by medical men to pass instruments into his bladder; after each attempt he had shivered and felt unwell for one or two days. He was kept in bed for three days, the bowels freely opened with castor oil, and on the evening of February 24 a full dose of Dover's powder was administered.

February 25.—Holt's instrument was easily passed, and the stricture—a slight one—split with the largest-sized dilator. Afterwards No. 11 catheter was introduced into the bladder.

26th.—Patient seemed perfectly well. Had not shivered after the operation, and passed his urine in a full stream, with slight pain.

27th.—Still going on well. No. 10 catheter passed easily, causing little pain.

28th.—Twenty-two hours after the passing of No. 10 catheter, and seventy hours after the operation, he was suddenly seized with a severe rigor, which lasted for two hours. He then perspired freely. Countenance extremely anxious-looking. Complained of much pain in his head and back. No tenderness in the perineum or over the abdomen. No albumen or pus in the urine. Nothing to be detected with the stethoscope. Pulse 120; temperature 101·6°.

March 1.—Complained of feeling very ill. No recurrence of the rigor. No pain anywhere. Tongue dry and brown. Morning: Pulse 136; temperature 105°. Evening: Pulse 128; temperature 103·6°.

2nd.—Evidently much worse. Complained of no pain or tenderness anywhere. Urine scanty, but free from albumen. Nothing to be detected with the stethoscope. Morning: Pulse 136; temperature 104·2°. Evening: Pulse 116; temperature 104°.

3rd.—Perspiring freely. Could not be roused sufficiently to understand the questions asked him. Extremities congested. A dark purple petechial-looking rash had appeared over the whole of the body, especially on the chest, where it was very thickly distributed. Tongue dry and brown. Pulse 160; temperature 104·5°.

From this time he gradually passed into a state of coma, and died on the following night at a quarter-past one o'clock, the temperature rising to 107·6° fifteen minutes before death.

Post-mortem Examination (thirty hours after death).—Lungs congested posteriorly; extreme staining of inside of heart and bloodvessels; liver healthy; spleen enlarged, and broke down into a pulp when cut; kidneys presented numerous hæmorrhagic spots, varying in size between a pin's head and a small pea,—many of these showed signs of softening in their centre; bladder healthy, walls rather hypertrophied. Around the seat of stricture, at the junction of the spongy and membranous portions of the urethra, there was a slight extravasation of blood; the mucous membrane over this part was perfectly smooth—there was no apparent rupture of it. The prostatic veins were considerably obstructed, and one of them was blocked with a firm clot for about an inch and a half.

This, gentlemen, is one case. Let me now briefly read you the notes of the second one, which appeared in our post-mortem room yesterday, and which you have all had an opportunity of observing:—

D. S., aged 46, a muscular Irishman, was admitted into No. 9 ward on December 13. He told us that he had only noticed that his urine came in a small stream during the last two years; that on several occasions he had had small-sized instruments passed, and that once or twice he had shivered after their passage, but this was not the rule.

December 14.—A No. 5 sound was attempted to be passed, but only for a short time, as the stricture bled at the slightest touch of the instrument.

15th.—Had suffered no inconvenience from the attempted passage of the sound. Ordered ten grains of Dover's powder at night and half an ounce of castor oil the next morning.

16th.—Holt's instrument was passed with little difficulty through a stricture in the membranous part of the urethra, which was split with the largest-sized dilator; one or two drops of blood following the operation. Ordered thirty minims of tr. opii and two ounces of brandy to be taken in hot water. In the evening he passed his water freely with little pain.

17th.—4 a.m.: Whilst at the closet was seized with a severe rigor, which lasted for about two hours. 9 a.m.: Temperature 102·2°; pulse 120. Ordered brandy and an opiate draught. 12 noon: Temperature 102°; pulse 130, weak; extremities cold and congested. Ordered five grains of carbonate of ammonia every two hours. 2 p.m.: Pulse weaker. Ordered three ounces of brandy in hot water. 5 p.m.: In much the same condition. Brandy to be repeated. 9 p.m.: Temperature 100·2°; pulse 130. Brandy and ammonia to be continued; hot-water bottles to be applied to extremities.

18th.—9 a.m.: Temperature 100°; pulse uncountable. To continue brandy. 2 p.m.: Temperature 101·2°; pulse imperceptible at wrist; extremities mottled purple. Has passed no water during the last twenty-four hours; bladder not distended. Patient perfectly sensible, but restless. Ammonia to be discontinued; half an ounce of brandy every fifteen minutes; to be dry-cupped over loins and to have hot fomentation of infusion of digitalis applied over the abdomen.

From this time his condition changed but little. He passed a small quantity of water at about 6 p.m., and remained sensible to within a short period of his death, which occurred at 3 a.m. on the following morning—sixty-two hours after the operation, and forty-eight after the first rigor.

Post-mortem Examination (ten hours after death).—Moderately firm old pleuritic adhesions on both sides of the chest; lungs healthy, but congested at bases; heart and its valves healthy—a small quantity of clot and fluid blood in each cavity,—no clot in the pulmonary artery; intestines and peritoneum healthy; liver to some extent congested, otherwise perfectly healthy; spleen healthy; kidneys healthy, not even congested. The bladder contained about six ounces of urine; walls slightly hypertrophied; mucous membrane healthy, and not congested, except for a patch about the size of sixpence at the posterior part of the neck of the bladder; the tissues under this were also congested for the depth of about the eighth of an inch. The urethra was slightly congested along its whole tract, and at the juncture of the spongy and membranous portions there was a patch of deep congestion, showing the seat of the stricture. There was slight extravasation of blood into the tissues around this for the depth of about the eighth of an inch. The mucous membrane over this point, examined under the microscope with a two-inch lense, showed no sign of rupture.

It has seldom been my duty to draw your attention to cases of so painful an interest as the two I have just related. Those of you who saw the first patient will recollect what a fine healthy-looking man he was. You will also remember that in the operation-room I mentioned that it was the slightest case of stricture that I had ever performed forcible dilatation upon. It may be said that in this instance the passage of the catheter on the second day after the operation was the cause of the mischief; but then the subsequent passing of a catheter follows as a necessity upon this method of treatment. In the second case no such question can arise. This man, with all the organs of his body healthy, died in sixty-two hours from the undoubted effects of the operation.

There was a certain amount of resemblance between these two cases. In each the first symptom was a severe rigor, coming on many hours after the operation, and in each there was the same dusky congested appearance of the extremities.

Very little either was there to be detected during life, and still less in the post-mortem examinations; for I look upon it as probable that the deep-red condition of the inside of the heart and large vessels in the first case was due to a considerable extent to the effects of decomposition. But the hæmorrhagic spots in the kidneys of the first patient were exactly similar in appearance to that which you sometimes see in well-marked pyæmia. Moreover, during life the symptoms and appearance of these patients closely resembled what we see in the worst cases of septicæmia following after other operations or injuries which sometimes, but fortunately very rarely, occur in the wards of our Infirmary. Therefore I should put down the cause of death in both instances to blood-poisoning.

The practical lesson I wish you to learn is, that in performing any operation upon the urethra you cannot be too careful. When the patient's history points to the stricture being a bad one, or more especially should he habitually have suffered from rigors after the passing or attempted passing of an instrument, let me urge upon you the advisability of insisting upon at least twenty-four hours' complete rest before you attempt to do anything. It has always been my rule to do this; and for two reasons—firstly, you will find it much easier to pass an instrument through a bad stricture if your patient has been kept quiet for some time; secondly, I believe that previous rest often obviates the occurrence of subsequent unpleasant symptoms, for I have more than once found that patients who had always suffered inconvenience from the passage of an instrument would stand considerable manipulation with impunity, previous rest having been insisted upon. At any rate, should mischief result, you will have the satisfaction of knowing that all rational means had been taken to prevent it. Holt's operation is one you have seen me perform moderately frequently, but never without having kept the patient in bed for at least forty-eight hours.

Mr. Holt claims for his operation that cases of stricture treated by this method show less tendency to contract than after any other plan of treatment. My experience relates only to strictures situated in the neighbourhood of the membranous part of the urethra; but it is decidedly in favour of this assertion. At the same time, as a rule, unless a full-sized instrument is afterwards passed with tolerable regularity, you are running your patient to unnecessary risk; for to a certainty will the diseased tissues again contract.

There is one more point of very special interest that these cases help to demonstrate. I mean what actually occurs when you rapidly force the dilator through the stricture. Mr. Holt advances the proposition that the diseased submucous tissue is alone split, and that the mucous membrane is simply dilated. This is a matter of considerable importance, because, with any considerable wound of the mucous membrane of the urethra, there would be a risk of infiltration of urine being the result, though I believe this risk would be slight. We particularly examined both these cases, with the view of obtaining information on this point, and undoubtedly they go towards proving the correctness of Mr. Holt's supposition; but we must bear in mind that during the time these patients lived after the operation a certain amount of rupture might have healed. Still, they certainly seem to prove that, at any rate when the stricture is not a bad one, the injury, if any, that is done to the mucous membrane is of the slightest.

With these two cases before us, it may perhaps suggest itself to the minds of some of you to ask—Why continue to perform the operation? You cannot learn too early that cases of stricture, as a class, are some of the most troublesome and difficult that you will have to deal with, and also that no method of treatment is perfectly free from danger, for death has more than once resulted from the simple passing of a catheter. There are also persons who will not submit to the tedious treatment by gradual dilatation. Specially have I found this amongst the lower classes, with whom time is of importance. These people will remain under treatment till the stricture is partially relieved, and then cease to attend, to come back again in a few months' time worse than ever. But even under these circumstances you would not be justified in performing Holt's operation, if the risk to life from it is considerable, unless the advantages to be derived from it are far more considerable. But what is the increased amount of risk? Sir H. Thompson, in his lectures on "Diseases of the Urinary Organs," lays no stress upon this point, neither is it referred to by many of our best surgical authorities. Moreover, the results published by Mr. Holt are extremely favourable; therefore, we have a right to assume that the cases we have this morning considered are very exceptional. My experience of the advantages of the operation in successful cases is decidedly satisfactory; but unless the patient afterwards submits to the periodical passing of a full-sized instrument, the stricture will again to a certainty contract, and the operation will have been useless.

In treating all ordinary cases of stricture let me advise you, as a rule, to adopt first of all the simplest method at your disposal, and fairly try the plan of gradual dilatation, reserving Holt's operation for the more severe cases, or for those patients who will not submit to lengthened treatment. Remember, also, that there are certain persons whose constitutions resent any interference with their urethra, and who will tell you that they nearly always suffer from a rigor after any attempt to pass a catheter. It will behove you in such cases to be especially careful.

SATURDAY, AUGUST 2, 1873.

THE BRITISH MEDICAL ASSOCIATION.

The coming meeting of the British Medical Association in London may be regarded from different points of view. Socially, it will be without doubt a very pleasant reunion. Town and country will shake hands, and the good offices of the former, we are certain, will be lavished to welcome the latter. The *fêtes* and *conversaziones* will be very largely attended, and the *salons*, we may safely prophesy, very hot. There will be an enormous consumption of ice and claret cup, and there will be plenty of opportunities for estimating the progress which the present generation of English cooks are making in their art under the direction of South Kensington. Then, again, there will be many special attractions, to borrow a phrase from the theatrical managers, which have been cunningly devised to give *éclat* to the present gathering. The meeting will be commenced with a religious service in the central temple of the national church—one of the grandest cathedrals of Christendom (if only the capitular authorities would push on its repairs a little). The Association is to be entertained by a most deservedly popular Lord Mayor, who, having wound up the accounts of a great benevolent movement for the patients, is now most willing to show the high estimation in which he holds the doctors. They will be

received in the institution consecrated by the genius of Hunter and of every venerable name in British surgery on one evening, and on the next they will meet within the walls of a college which has influenced the teaching of modern medicine at least as much as any school in the three kingdoms, whilst their ordinary meetings take place daily in another, the boast of which is to prove by experiment that modern science may be the handmaid of the Christian faith. Regarded in its social aspect, therefore, there can be no doubt that the meeting of the British Medical Association in 1873 has all the elements of a great success. The weather is charming, the death-rate low, the country healthy, and the means of transit at everyone's command. Never was a holiday planned under more propitious circumstances.

Then, again, we are promised addresses by men whose reputations are of the highest in their respective spheres. It is perhaps a pity that these orations are to be delivered in the morning, when many London men are obliged to be in their consulting-rooms. But if they were to be delivered at midnight the names of Parkes, Quain, and Burdon-Sanderson would be sure to attract audiences. We hear that this year, as far as is practicable, discussions are to take the place of papers of varying merit. This we think, if it can be done, is a right step, although there is a danger that discussion may degenerate into mere oratory, as with our Gallican neighbours.

If we were in a mood to criticise the British Medical Association, we should at least have no fault to find with its social organisation or its annual choice of members of the profession to fill its chairs. The Association, however, has its weak side as well as its strong one. It is a body of large numbers and large income. In these respects it is undoubtedly a great success. But powerful bodies with large annual receipts have responsibilities which they ought not to evade. It is a question often asked—Is the influence of the British Medical Association in forwarding the progress of Medical Science in any degree comparable with the influence in favour of General Science exerted by the British Association or by the Royal Society? We fear this can scarcely be answered in the affirmative. A society possesing a revenue of five or six thousands a year might in the course of four or five years find the means for clearing up a large number of medical and surgical problems of the highest importance, not merely to the medical profession, but to the world at large. It is not our wish to criticise the mode in which this body expends its income, but we should be the first to welcome any sign that the British Medical Association were a society looking beyond the mere popularity of the day—an Association bent upon influencing for good, in any permanent degree, the great art of healing.

THE PROVIDENT SCHEME IN MANCHESTER.

It is said that what Illinois thinks one year the American Union will think the next; and somewhat similar claims have been set up for Manchester as regards this country. Certainly, the politicians of these parts show little hesitation in grasping and dealing with the most difficult problems, though there may be two opinions as to the value of the solutions afforded by them. At all events, when an attempt is made to revolutionise the whole system of medical charity in a city of the size of Manchester, which is the medical centre of one of the most populous districts in England, it behoves us to inquire very carefully into the merit of the proposals. Meeting after meeting has been held—one, we are sorry to see, with closed doors: for no good comes of secrecy in such cases,—and still there is difference of opinion where there should be unanimity; but unanimity, we fear, in the present instance is hopeless; and it is certain that the minority, on whichever side, will endeavour to carry out their own views, despite of opposition or indifference on the part of their opponents. Our views on the subject have long been well known, and we are heartily glad to find that they have so far prevailed as to seriously modify all propositions now made for the institution of provident dispensaries, and have, indeed, been made the platform of the Medico-Ethical Association of Manchester; but the whole thing has been so grievously misunderstood that we are constrained once more to enter into a discussion of the whole subject on its merits.

Hospitals, it is often triumphantly said, are special characteristics of the Christian era; their object is the relief of suffering humanity. Founded and supported by the rich for the benefit of the poor and needy, there is but one claim which can be admitted as absolute on behalf of those seeking relief in them—that is, suffering. We take it that the fundamental principle of all our general hospitals is this—that no one really ill shall be turned away from their doors without at least temporary relief. It was found that the appointments to such hospitals constituted great advantages in the race of life, as schools were soon established along with most of our large hospitals, and lucrative practice was the prize of most of their officers. But then hospitals were close boroughs—their appointments were not open to the profession at large; and so some disappointed men began to found an opposition to them—dispensaries,— in many instances at least not for the sake of Christian charity, but for their own interests. Special hospitals have been, too often, a later development of the same principle.

In course of time there have grown up certain other institutions connected with hospitals, but which are not of their essence—out-patient departments,—and these now mainly occupy the ground formerly occupied by the dispensaries, so that the two as it were compete in their attractions for patients. These out-patient departments are exceedingly valuable if properly worked: they constitute an excellent means of selecting the patients to be admitted with most advantage to themselves and others; and they form an admirable school for training students in a class of cases they should never see in the wards. For the dispensaries there is nowadays no such *raison d'être* save in certain localities. Both dispensaries and out-patient departments have, moreover, it is well known, had pauperising influences; and it has been proposed to stop this by inducing men when well to lay up a provision for illness by a small weekly payment. An institution on this principle is called a Provident Dispensary. We have again and again pointed out the faults of provident dispensaries as usually worked. They have attempted to combine what should be distinctly kept apart—charity and independence. Charity is charity, and independence is independence; but this provident system is neither one thing nor the other. These institutions have been unjust in many instances to medical men, by enabling one or two who work the dispensary to make a large income, whilst their neighbours starve; for the class of men who fill these posts are not physicians or surgeons who act as consultants only, such as traditionally is the hospital caste, but gentlemen in ordinary general practice. Again, it is useless for a man to lay by money to pay a doctor when he is ill if he cannot also obtain the food necessary for himself and family. Some sick allowance ought clearly to be included in the provision, as in the club system. Now, it is proposed to extend the benefits of the provident system to large masses of the community who, among other advantages obtained by strikes, now seek cheap physic. But surely to extend anything like charity mixed with independence to such will hardly do them good. They like being independent, it is said. Well, let them! They can belong to a club or call in a medical practitioner and pay him; their wages are quite good enough. If it is the policy of the profession to screw the last farthing out of a poor man's pocket who wants to go to a hospital, it cannot be the same policy to take part fees from those who can pay whole.

We are heartily glad that the Manchester Medico-Ethical Association have in the main adopted these views when recommending the adoption of the provident system throughout the city. Their principles are these—that provident sick societies should be entirely self-supporting; that every qualified medical man should have the option of attaching himself to some one society; and that no medical officer should delegate his duties to an unqualified assistant. Such principles are perfectly sound, but they have nothing to do with charity; that is left as before. Undoubtedly every effort should be made to exclude improper persons from obtaining relief at hospitals and dispensaries; but a small payment will only aggravate, not alleviate, the mischief.

THE DEATH FROM CHLOROFORM IN SIR P. DUN'S HOSPITAL, DUBLIN.

Our readers were, no doubt, much pleased to find that in the trial, *in re* Lamb *v.* Barton and Bennett, the jury had no difficulty in returning a verdict for the defendants. We may be allowed to congratulate these gentlemen on their triumphant acquittal from a charge which (as one of their counsel, Mr. Gibson, Q.C., described it) "was calculated to blast their reputation and ruin their prospects."

Now that the trial is over, we desire briefly to draw attention to a few points of special interest in the evidence given on both sides. In the first place, it will be observed, from a consideration of the arguments of counsel for the plaintiff, that an endeavour was made to establish two things—first, that there had been negligence on the part of the defendants in not making a thorough examination of the heart and lungs before the administration of chloroform, and in delegating to a student the duty of watching the behaviour of the pulse under the influence of the anæsthetic; secondly, that the use of chloroform as an anæsthetic was now almost exploded, and that American and Continental authorities were almost unanimous in condemning its employment. We cannot help thinking that both these plans of attack broke down completely and at once. The patient was a stalwart man, six feet two inches in height, of immense muscular development, and with a full, steady pulse at 70—he himself had stated that he had not suffered from any serious illness. The chest was fully exposed during the administration of chloroform, and so the respiration could be accurately watched by Dr. Barton, the Resident Surgeon of the Hospital; while an experienced and intelligent student kept his finger on the pulse unceasingly. But this was not all, for another student, Mr. Forsythe, who in evidence stated that he had seen chloroform given several hundred times, had control of the femoral artery of the injured limb, and was thus in a position to judge of the state of the patient's circulation. As a matter of fact, three persons were throughout watching the patient uninterruptedly, and all three cried out simultaneously when the respiration altered and the arterial pulsation began to flag. Great stress, however, was laid upon the fact that it was a student who watched the pulse. If we wished, we might with fairness rebut this charge by an admission that we are all students; and, indeed, a physician or surgeon who is not ready to admit, even after an experience of a quarter or even a half-century, that he is still a student, has failed to view our calling in its true light. But, apart from this, it was merely to support a legal argument that it was attempted to draw a broad distinction between an advanced student and a qualified medical practitioner, especially as the former had had ample opportunities and had made good use of them.

The endeavour to taboo chloroform appears to have been far from successful, and the statements made by counsel as to its disuse in America were at once sweeping and extremely inaccurate. Indeed, we should not have thought it necessary to allude to these statements at all were it not that some of the skilled medical witnesses for the defence, when cross-examined as to their accuracy, seemed to acquiesce in their correctness to some extent, even with respect to the late American war. Now, we have before us at the present moment Circular No. 6 of the Surgeon-General's Office, War Department, Washington, November 1, 1865; and at page 87 of this official document we read as follows:—"There have been consulted, in regard to the employment of anæsthetics, the reports of 23,260 surgical operations performed on the field or in general hospitals. Chloroform was used in 60 per cent. of these operations, ether in 30 per cent., and in 10 per cent. of the cases a mixture of the two was administered. At the general hospitals the greater safety of ether as an anæsthetic was commonly conceded. It was often employed, and no fatal accident from its use has been reported. In the field operations chloroform was almost exclusively used. The returns indicate that it was administered in not less than 80,000 cases. In seven instances fatal results have been ascribed with apparent fairness to its use." It may be mentioned that in at least three of these seven fatal cases death occurred suddenly, as in Dr. Bennett's case, and post-mortem examination failed to indicate the cause of death. In the Franco-German war, again, chloroform appears to have been very generally used. On the whole, the plaintiff's side, in attempting to prove too much as to the shortcomings of chloroform, failed to prove anything at all.

Here we would willingly have brought these comments to a close, but that a strong feeling of duty compels us to criticise—we trust in no unkind or partial spirit—some of the medical evidence on behalf of the plaintiff. Dr. Austin Meldon's description of the physiological effects of chloroform seems to have been much more suited to a class-room than to a court of law. But, even passing this over in silence, we would ask Dr. Meldon candidly whether the four stages in the administration of chloroform, and their increasing degrees of danger, described by him with such graphic minuteness, can be so accurately isolated as he would lead his audience to suppose? Indeed, in the case of Lamb, that unhappy man appears to have died at the end of what Dr. Meldon terms the first stage, or "stage of excitement." We cannot help thinking that this "protesting too much" is a habit in a medical witness which cannot be too strongly deprecated.

With a statement of another medical witness, also, we feel disposed to quarrel. The gentleman in question laid stress upon the fact that the patient Lamb had suffered from "functional derangement of the heart," and that therefore he was not a fit subject for chloroform. We should be sorry to say that these words, "functional derangement of the heart," were used in an *ad captandum* sense to impress, and possibly influence, the jury. But at the best they were dangerous words, and for two reasons: first, because they were capable of misinterpretation by the non-medical world; and secondly, because the gentleman who used them stated on cross-examination that "Lamb had no organic disease of the heart, no valvular disease, no fatty degeneration." Why had these latter words to be dragged from him, while the former ones, of at least doubtful interpretation, flowed glibly from his lips? If the patient had functional derangement of the heart, would this have been a valid reason for withholding the chloroform? We believe this to be at least an open question.

THE WEEK.

TOPICS OF THE DAY.

The social characteristics of the meetings of the British Medical Association are generally in the ascendant, and the days devoted to excursions are usually among those marked with a white stone when the meeting is over.

One year these excursions were so numerous and interesting that sectional work was well-nigh forgotten; it is even said that on one occasion no papers were forthcoming—even the secretaries had gone holiday-making. This year the excursion arranged to Woolwich Arsenal for Friday after the sectional work is over, and those for Saturday, promise to be of unusual interest. The Arsenal will then be in full work, and arrangements have been made so that some of the special processes shall be seen in actual operation. On Saturday one excursion of great promise is that to Windsor and Clevedon—the river seat of the Marquis of Westminster, and one of the most lovely spots on the loveliest river in England. The Queen has been graciously pleased to throw open all but the strictly private apartments in Windsor Castle for that day, and the Princess Christian has induced her husband, the Ranger of Windsor Park, to send a buck from her Majesty's herd to regale the visitors. Eating and drinking are important matters on such days, and by the kindness of a gentleman who is unable to do in town what he would like to do for visitors, a luncheon will be provided at Windsor free of cost to all who make up the party, and in the evening a dinner will be provided at Maidenhead at a cost which is comparatively trifling. The excursionists will leave by one of the ordinary trains from Paddington about nine, will first visit Windsor Castle, and thence by ordinary train to Taplow. Shallops will be in readiness to convey the party up the river to Clevedon Woods, whence they will return in the same fashion, and after dinner, which will take place in a fine marquee, the party will return about 9.30 by a special train to Paddington.

For those who are unable to start so early an excursion to another portion of the river has been planned. Excursionists will proceed by the loop line from Waterloo to Teddington for Bushey Park. For this party Dr. Langdon Down has been kind enough to offer every hospitality. He will meet them in the park with light refreshments; and for those who care for such things, her Majesty's laundry-shed will be open for inspection. Hampton Court and its picture-galleries, to say nothing of the gardens, are exceedingly well worthy of a visit. Thence the party may proceed by boats or otherwise to Kingston to visit Dr. Langdon Down's interesting asylum, where that gentleman will hospitably entertain them; after which the party may return, some by way of Richmond, others by the South-Western, the station of which is close to Dr. Langdon Down's place.

Unfortunately to both these excursions the number must be limited—the Windsor and Clevedon excursion can only accommodate 150, that to Hampton Court 100—and to neither can ladies be admitted. Fortunately there are no such restrictions in the excursion to Brighton. The London and Brighton Railway Company have consented to take all members at a reduced rate, and arrangements have been make for a *table d'hôte* dinner at the Grand Hotel. For those who want a sniff of sea and a look at the grand aquarium, this excursion will offer unusual facilities. The aquarium, library, and museum will all be open to members free of charge, and are well worthy of a visit.

During the week Lambeth Palace will, by the kindness of the Archbishop of Canterbury, be open for inspection. Its library contains some matchless treasures. Equally interesting, but in a totally different way, are Stafford House and Grosvenor House, both of which will be open to members. Of the evening festivities we can hardly here speak—a reception by the Lord Mayor, a *conversazione* at the College of Surgeons, a public dinner in the grand hall of Lincoln's-inn, and the *conversazione* given by the Professors and Council of University College, will amply fill the time of those who seek such things. The Museum of the Association, too, will be full of interest; among other things there will be collected for the first time the most perfect series of electrical apparatus for medical purposes which has been exhibited in this country. Altogether the attractions are something sensational, and the meeting can hardly fail to be a success.

We have recently had to note the appointment of a lady physician to the Children's Hospital at Bristol. We now have to record the resignation of the whole of the male medical staff.

Sir D. Wedderburn has come forward as the champion of the women-doctors. He gave notice in the House of Commons on Tuesday that early next session he should move for leave to introduce a Bill to empower the Universities of Scotland to admit women to the medical curriculum and grant them degrees. It is said that a great effort is being made to obtain medical education for them at the University of St. Andrews.

CHOLERA.

We have this week been startled by the report that cholera had crossed the sea, and had broken out in Sweden and Helsingborg, a port opposite Elsinore in the Sound, and not far from Copenhagen. Hardly had we mastered this piece of intelligence and its full meaning when we were still more startled at hearing that a fatal case of Asiatic cholera had occurred in London. Two cases occurred on the 28th inst.; one of them has already died; but the subjects were emigrants, and the disease imported. They were members of a band of emigrants from various parts of Denmark and Sweden, who sailed from Copenhagen on the 22nd for Kiel; from Kiel they crossed by rail to Hamburg, and thence came to London, where they landed at Blackwall, on their way to New Zealand. As far as we know, neither Kiel nor Hamburg are as yet infected, but Copenhagen, as we have seen, if not already attacked, is at all events near infected spots; but during the whole time occupied in the journey from Copenhagen no case of illness occurred among the party. The first patient seized was a man aged 45, who was very bad, but has not died. The second was a girl aged 12; she speedily sank. Other members of the party have suffered from diarrhœa, but there has been no further outbreak of the cholera. Prompt steps were taken by the gentleman in charge, Mr. Holt, to put himself in communication with the Privy Council authorities; and along with Dr. Buchanan, Mr. Liddle, and Mr. Harry Leach, the newly appointed medical officer for the port of London, an attempt was made to collect all the suspected into one group, where they might be the more easily controlled. Other means were also employed to avert the danger of spreading. They were authoritatively forbidden to go on board any ship or otherwise risk the spread of the contagion. All this is the more necessary as the cholera news which reach us from abroad are far from reassuring. The latest official reports announce that at Königsberg, in Prussia, up to the middle of July there had occurred scattered cases in the town and various parts of the province. Still worse were the tidings from Warsaw; there, from May 30 to July 11, had occurred in the city 298 cases with 103 deaths, whilst the disease was present in all parts of the kingdom of Poland. From the Roumanian territory we learn that in Jassy two deaths had occurred up to July 14. In Rutschuk, up to July 10 the town was free, but the disease was present in the neighbouring villages; whilst in Shumla, from July 5 to July 7 inclusive, 143 cases occurred. From July 12 to July 16, 22 deaths occurred in Galatz, whilst in Crajova and neighbourhood a good deal of cholera was about up to the middle of July. In Silistria and Widdin scattered cases. In Bulgaria (Sofia) cholera broke out early in July (?), and is extending over neighbouring districts. Turning now to Hungary, we find that in Pesth, from July 1 to 8, 70 cases and 46 deaths occurred; from July 9 to 15, 190 cases and 80

deaths, thus showing a tendency to increase; whilst throughout the whole of Hungary the disease was widely prevalent. In Italy cholera continues to prevail in the province of Treveso; thus, from July 1 to 6, 20 new cases occurred, and 10 deaths, 16 remaining under treatment on July 6. In the province of Venice from July 1 to 6 there were 3 new cases and 23 deaths, 35 remaining under treatment. In Trieste 2 scattered cases had occurred. Thus we see that for this year cholera has assumed epidemic proportions all over Central Europe. We ourselves have had the disease imported to our shores. It is high time to provide for dealing with the disease promptly and rigorously where that has not been already done.

THE NEW MEDICAL WARRANT.

Mr. Cardwell, in reply to an inquiry in the House of Commons on Monday last from Mr. D. Dalrymple, whether he had considered the representations made to him by its Parliamentary Bills Committee and other bodies on behalf of the army medical officers affected by the recent Army Medical Warrant, stated that the subject had received a good deal of consideration in the department, but as yet he had been quite unable to submit to the Treasury any modification of the Warrant. There should be no unnecessary delay in the matter. But our brethren must bear the reproach of Shylock: "Sufferance is the badge of all our tribe."

WIMBLEDON CAMP.

The recent meeting has been one of the most successful in a sanitary point of view that have ever been held. The daily rate of sickness, according to the senior medical officer's report, amounted to no more than 1·5 per 1000, and scarcely more than half a dozen cases required to be seen oftener than once or twice. The cool weather and persistent breezes which prevailed no doubt had a great deal to do with this result; but the strict cleanliness and total suppression of nuisances which are enforced in the camp must be credited with a large share of it. The dry earth system is carried out on a very large scale—sufficiently large to provide not only for the 3000 who sleep in camp, but for the 10,000 or 20,000 who spend part of the day there,—and gives complete satisfaction. Staff-Surgeon Temple, V.C., of Woolwich Arsenal, and Dr. Mayo, Fellow of New College, Oxford, of the Inns of Court Corps, have for several years past divided the medical work between them. We see by the *Army List* that the former meritorious officer, whose distinguished services in New Zealand have not prevented him from remaining an Assistant-Surgeon for nearly fifteen years, is now fifth on the list for promotion; we trust that although the length of time that has elapsed since the New Zealand war has naturally produced many changes among those who preside over the department, those services will not be forgotten at this juncture. The intensely hot days which immediately followed the meeting forced strongly on the attention of the remaining inhabitants of the camp the total absence of shade on the common. The consequence of this is that the peaty and sandy soil becomes baked, and gives out again the whole of the heat that it receives, producing a climate which the old soldiers compare to Ceylon or India. A body of important local personages called "conservators" was established some time ago to improve and protect the common, but it does not appear that they have taken any steps whatever to remedy this great defect. Not a single tree has been planted. That trees will grow there is sufficiently shown by the presence of a few poplars round "The Cottage" which affords a temporary residence to the public-spirited Chairman of Council of the National Rifle Association, the Earl of Ducie, and his family, during the meeting. To plant a few thousands of quickly-growing trees would be a mode of deserving the gratitude of the frequenters of the common which we respectfully commend to the notice of the conservators. Sunburnt faces have a wholesome look, which excites the envy of the pale prisoner of the desk or counter; but the process need not be carried so far as to remove the entire cuticle of the nose and cheeks. It is fortunate that the great rise in temperature did not take place during the meeting; for a place where men are driven into the glare of the sunshine, in order to escape the stifling heat of the tents, can scarcely be confidently recommended as a health-resort.

DOES WINE IMPAIR DIGESTION?

We suppose no practical physician doubts that large quantities of wine, or of any other alcoholic beverage of equal or greater strength, not only retard, but impair digestion. The well-known experiments of Dr. Beaumont went to prove that even small quantities had an effect similar in kind, if not in degree. Now we have a paper in the *Pharmaceutical Journal* by Mr. Charles Symes, Ph.D., detailing the results of experiments with different pepsines, from different firms, prepared by different processes; and he gives two experiments in which wine was used as the solvent of good pepsines. In both cases less than 50 per cent. of the albuminous material employed was digested; whilst some of the dried pepsines supposed to be equivalent in strength dissolved 76, 97·5, and 98·5 per cent. of the same egg-albumen. These experiments will greatly delight the nephalists, but the problem we have to solve in practice is less simple than the artificial digestion of hard-boiled eggs. We have to deal with men and women whose bodily and mental powers are more or less exhausted by hard work, preceding illness, or some other method of exhaustion; and it can scarcely be seriously denied that many of them can take and digest, *with* a stimulant, what they could neither eat nor digest without one. But the fact that wine, *per se*, tends to retard, if not prevent, the digestion of certain kinds of food, must, we presume, be taken as pretty fairly established, without resting on these experiments of Mr. Symes. His paper is, however, deserving of perusal on other grounds, as he shows that there is a great difference between the solvent powers of pepsines prepared by different makers and by different methods.

REPORT ON SLAUGHTER-HOUSES AND OFFENSIVE TRADES.

The Select Committee appointed "to consider the operation of clauses 55 and 56 of Act 7 and 8 Vict., c. 84, and the best means of making provision concerning the offensive or noxious businesses therein specified," published their report on Monday last. It states that if it is the wish of Parliament to banish the trades of fellmongers, slaughterers, tallow-melters, boilers of various kinds, etc., from the metropolis, or from any portion of it, the change should be made directly by clear legislation, and should not be made indirectly by the strict enforcement of these sections of the Act of 1844, which in the more thickly covered districts of the metropolis would involve so large a cost as to be practically prohibitory. In regard to the trade of slaughterers of cattle and sheep—the most important of the enumerated trades,—the Committee have come to the conclusion in the first place that the 55th section of the Act of 1844 should be repealed. They are, however, of opinion that it would be desirable, so far as possible without interfering with the trade or subjecting those who carry it on to expense or inconvenience, to diminish, or rather to accelerate the diminution of, the number of these private slaughter-houses. With this object the Committee recommend that additional private slaughter-houses, varying in size, should be constructed, and other conveniences given at the Copenhagen-fields market, and other markets if established, so as to induce butchers to slaughter animals on the spot, and not drive them through the

streets to their own premises. The Committee also recommend that no additional private slaughter-houses should be established in the central part of the metropolis except under special circumstances, and not then except with the consent of some such authority as the Metropolitan Board of Works or the Courts of Quarter Session. To meet the decrease that must be continually going on of private slaughter-houses attached to butchers' shops, they desire to encourage the substitution of private slaughter-houses belonging to the individual butchers in suitable localities in the vicinity of public markets; and the Committee wish to draw a clear distinction between private slaughter-houses so attached to markets and public slaughter-houses possessed by the market authority. After insisting upon the necessity for a strict and constant supervision of all public and private slaughter-houses, the Committee observe with respect to all businesses that may be called noxious, whether enumerated in the Act of 1844 or not mentioned in it, that they should not be actually banished from the metropolis unless a case of nuisance can be established against them, but that they should all be subjected to stringent rules and frequent inspection, and the sections of the Act of 1844 concerning the enumerated trades should be repealed. It will be seen by the above report that the question is one of the utmost difficulty. In the main we agree with it, as it deals with the subject in a practical manner.

HEALTHY DWELLINGS.

The report of the Improved Industrial Dwellings Company, just issued, for the half-year to June 30 last, states that the number of dwellings erected and in course of erection is 1517, which will accommodate about 7500 persons. The report congratulates the members on the complete success of the Company during its ten years' existence, and shows that a great improvement in the moral and physical condition of the tenants has been effected. The death-rate in 1872 was only 15·8 per 1000 in the buildings, compared with 21 in the metropolis, the average death-rate during the eight years' occupation having been 16 per 1000, against 24 in the metropolis.

PRECAUTIONS AGAINST CHOLERA.

Quarantine regulations have just been adopted by the Dover Local Board, in conjunction with the Collector of Customs for that port, in consequence of the appearance of cholera upon the Continent. All vessels from suspected ports bound for Dover are not to come into the harbour until they have been examined by the medical officer and released from quarantine. A series of regulations are given in Tuesdays evening's *Gazette*, applicable to Scotland, as to the examination of vessels which may be infected with cholera or choleraic diarrhœa on arrival within the limits of any port in the country, and for preventing the spread of the disease.

COFFEE AND MILK ADULTERATION.

Out of thirty-eight samples of coffee submitted to Dr. Muter, Analyst to the Wandsworth District Board of Works, by the inspector, he found twenty-one adulterated and seventeen pure; and out of forty-two samples of milk only six were described as "good," the rest as "skimmed," "skimmed and watered," and twelve of the samples were watered with proportions of water varying from 11 to 27 per cent. In one of the samples he says that the milk had either been skimmed from the top of the can, or had had cream added purposely to deceive the analyst, but without success.

SANITARY SUPERVISION.

Now that the meetings of our metropolitan vestries and local boards are beginning to be adjourned for the usual summer recess, we trust that proper provision is being made for strict sanitary supervision in their several districts during the period of these adjournments. Any want of care in this respect would not only involve a charge of neglect of a very important duty, but it might lead to consequences highly dangerous and disastrous to the public health.

THE COLLEGE CONVERSAZIONE.

We are requested to state that at the reception by the President, Vice-Presidents, and Council of the Royal College of Surgeons, on Wednesday, the 6th inst., admission can only be obtained by tickets, procurable at the College any day up to five o'clock on the evening of Tuesday. As the museum will no doubt be the principal object of attraction, ladies for obvious reasons cannot be admitted.

FROM ABROAD.—INJECTION OF IODINE DURING ACUTE INFLAMMATION—REPORT ON DIEULAFOY'S ASPIRATOR IN AFFECTIONS OF THE KNEE.

Dr. Menzel, Senior Surgeon to the Trieste Civil Hospital, has published an article in the *Gazetta Medica Lombardia* of July 19 on "The Injection of Iodine into Tissues the seat of Acute Inflammation." He observes that while during the last ten years various articles have been injected into the substance of tissues affected with different forms of chronic disease, he is not aware of any instances in which such practice has been pursued during the existence of acute inflammation. Repugnance has been felt to injecting tissues the seat of acute phlogosis with substances possessing more or less power of inducing inflammatory action. His object in the present paper is to show that such practice may nevertheless be attended with great benefit; and although he certainly is able to adduce but very slight evidence in favour of this view, we may as well lay it before our readers. During last spring diphtheria prevailed severely in Trieste, defying the various remedies employed, such as cauterisation, the chlorate and permanganate of potash, carbolic acid, quinine, etc. Most of the children brought to the hospital were already affected with excessive bilateral tumefaction of the cervical glands, the lymphadenitis pursuing a rapid course in diphtheria, and inducing a far greater amount of swelling than is observed in ordinary catarrhal tonsillitis. In the author's opinion the frequent inefficiency of caustics arises from the circumstance that the morbific agent has been transported from the parts accessible to their action (as the tonsils, velum, etc.) to the glands of the neck, and thence into the circulation. Under such circumstances the caustics will only act by limiting the local gangrene; and, although the tonsils may be freed, the ganglionary intumescence and the general symptoms persist, and the patients succumb. The question arose whether the "parenchymatous injection" of iodine might not arrest the local destructive process, and at the same time, by its absorption, exert a favourable effect on the progress of the disease. The first case in which it was tried seemed to realise the most sanguine expectations. A girl, aged 6, when brought in had been ill two days, and the tonsils were so swollen as to be in intimate contact with each other. The removal of the white membrane which covered them exposed an ulcerated surface. Beneath the angle of the jaw on each side were two or three glands the size of walnuts, of an elastic consistency, and very tender to the touch. Each tonsil, by means of a Pravaz syringe, was injected with four drops of Lugol's solution. Next day the tonsils were found reduced to their normal dimensions, and the glandular swellings were hardly perceptible. In other cases the iodine was injected in part into the tonsil and in part into the arch of the palate and the velum, and was repeated daily until the tonsils were reduced. Of seven children so treated three recovered; and although two died, and the other two, not being heard of again, probably also died, yet, as the

epidemic was a very severe one, even this amount of success is not to be despised. Dr. Menzel, however, admits that he has not brought much material forward, but he observes that the means is quite innocuous, and is productive of no local inconvenience.

At a meeting of the Paris Society of Surgery, which took place in May, but which has only just been reported (*Gazette des Hôpitaux*, July 15), M. Desprès read a report on a memoir submitted by M. Dieulafoy on the application of his aspirator for the evacuation of effusions into the knee-joint. This memoir is founded on twenty-two cases in which capillary punctures, followed by aspiration, have been performed sixty-five times for the discharge of sero-sanguinolent or purulent collections, none of these operations having been followed by any accident. M. Dieulafoy classes his cases according to the duration of the treatment—1. Hydarthroses which are cured by from one to three aspirations occupying from three to eight days; they are chiefly traumatic. 2. Acute hydarthroses, *à frigore* or rheumatismal, in which there are leucocytes contained in the serous liquid, and which require from four to six aspirations during a week or fortnight. 3. Old hydarthroses and some of those of a rheumatic character, which recur with such remarkable facility that sometimes two aspirations are required in one day. They are generally cured in the third week. Compression of the knee is employed after the puncture. One peculiarity that is met with in all these cases is that so small a relative quantity of liquid has been drawn from the knee by aspiration. This has been a mean of 60 grammes only in traumatic hydarthrosis, 70 grammes in rheumatic hydarthrosis, and 40 grammes in hydarthrosis with sero-purulent liquid. The frequency and rapidity with which the liquid reaccumulated in rheumatic hydarthrosis is also remarkable, showing that in these cases aspiration exerted no curative effect until the cause which maintained the fluid in the joint had ceased to exist. In one-half of the traumatic hydarthroses, also, two reproductions of fluid followed its removal.

The question arises whether these punctures effect a cure more completely or more rapidly than the means ordinarily in use. One is apt to become enthusiastic about remedies we have found successful, and to exaggerate the gravity of the diseases for which we have employed them. This has evidently been the case with M. Dieulafoy in regard to hydarthroses. Indeed, M. Desprès is of opinion that the prognosis of this affection has been regarded too seriously in French works on surgery, and appeals to his own recollections and those of his auditory for numerous instances which have readily yielded to remedies. He cites the last six cases that came under his care at the Cochin, four of traumatic and two of rheumatic hydarthrosis, and none of them selected. These recovered as readily as those treated by M. Dieulafoy. Without denying that there are cases in which aspiration may be usefully employed, the reporter believes that it cannot be recommended as a general mode of treatment. He concludes as follows:—1. That in hydarthroses of a traumatic origin the usual methods cure the disease as well and as quickly as aspiration. 2. That in those of a rheumatic nature the punctures have no effect, as these, if performed early, require repetition, and only, in fact, effect a cure after twenty-five or thirty days—*i.e.*, the time required for the cessation of the irritation in the synovial membrane, which is the true cause of the evil. 3. In blenorrhagic arthritis the punctures have no superiority over revulsives. 4. In chronic hydarthrosis which has remained stationary more than two months, as in three cases related by M. Dieulafoy, aspiration has exerted an evident curative action. This is only in harmony with the experience of former surgeons, such as Bonnet, Velpeau, Boinet, etc., who in obstinate chronic hydarthrosis have derived advantage from puncturing the joints and injecting iodine. For this purpose the excellent apparatus of M. Dieulafoy is well adapted. 5. In effusion of blood within the joints these evacuatory punctures are entirely contra-indicated.

M. Blot entirely agreed with the reporter. He thinks that the use of these aspiratory punctures should not be encouraged for articular effusions, believing that a penetrating wound of the knee, however small, is not exempt from danger. M. Verneuil does not employ the apparatus. In some cases of acute dropsy of the joint relief is obtained by puncture, but the effusion and the pain with it soon return. Compression and immobilisation of the joint will relieve the pain as well as puncture. M. Demarquay observed that at the present time there was a complete rage for these aspiratory punctures, and, strange to say, it is surgeons who have to set their face against them, while physicians are employing them on all manner of occasions. In simple hydarthrosis of the knee there is very little pain, so that there can be no occasion for making a puncture. In acute effusions he cannot imagine how evacuation of the fluid can be thought of, and he entirely endorses the conclusions of the reporter, not being able to accept these aspiratory punctures as a good practice. M. Dolbeau observed that to such an extent had the passion for articular punctures gone that the examiners at the Faculty often had to oppose the theses written upon the subject. It had even been carried so far as to propose aspiration for effusion of blood consequent on fracture of the patella. For his part he could only join his colleagues in opposing this practice. M. Panas has never made these punctures in the knee, and has only had recourse to them in the treatment of cold abscesses. Even here they are not quite inoffensive, as the orifice may remain fistulous and keep up a communication with the air. M. Marjolin agreed with the reporter in his adverse conclusions, but believed that some reserve should be made with respect to hydatid cysts. M. Duplay believed that the reporter's opinions against aspiration should be expressed still stronger; for while the procedure is neither more efficacious nor more speedy than other measures, it is more dangerous. He referred to two cases of suppuration of the tunica vaginalis (one occuring to M. Dieulafoy himself) which followed several aspiratory punctures. M. Sée also regarded aspiration as dangerous in acute hydarthrosis, and of no especial benefit in chronic cases. He has employed it in a blenorrhagic hydarthrosis without any result. M. Labbé has performed aspiration upon the knee-joint both for effusions of serosity and effusions of blood, and he has never witnessed the slightest accident. The adverse opinion of so many of his colleagues has much touched him, but he recalls to them the practice of Jarjavay; while he has himself punctured articular effusions with a lancet with good results. M. Tillaux has punctured a great number of chronic and traumatic hydarthroses without having ever observed an accident; and in the latter of these affections he believes that puncturing diminishes the duration of treatment. M. Dubrueil observed that Jarjavay punctured the joint not with a trocar but a lancet; and during many years M. Voillemier treated in the same manner fracture of the patella with bloody effusion, without meeting with any accident. M. Desprès replied that in a procedure possessed of so little efficacy as that of M. Dieulafoy's, even rare accidents ought entirely to proscribe its employment.

PARLIAMENTARY.—ARMY MEDICAL OFFICERS.

In the House of Commons, on Monday, Mr. Cardwell informed Mr. D. Dalrymple that the department had given a great deal of consideration to the representations of the Parliamentary Bills Committee of the British Medical Association and other bodies, on behalf of the army medical officers affected by the recent Warrant, but had been unable as yet to recommend any modification of the Warrant.

CLINICAL REMINISCENCES.—No. I.

By PEYTON BLAKISTON, M.A., M.D., F.R.C.P., F.R.S.

[To the Editor of the Medical Times and Gazette.]

SIR,—A short time ago you told me you were of opinion that some clinical remarks on subjects not embraced in my previous works would be acceptable to the readers of the *Medical Times and Gazette*, particularly if illustrated by cases that had fallen under my observation during the last half-century. In accordance with your suggestion, I send these pages, with no hope of adding a single grain to the stock of medical knowledge, but simply with that of furnishing a small link in the chain which connects the workers of the present day with those of the past age. In one respect the endeavour to bring to memory facts that have taken place during this period of time has been a painful one, for it has brought up vividly those fellow-students, fellow-workers, and colleagues who have passed from amongst us, and of whom not more than one or two remain: some taken in their youth or their prime, others after having filled up the full measure of their days. In another respect, however, the memory of the past has afforded much pleasure, for I have recognised the good clinical and physiological work that has been done by earnest, truthful men, and can feel well assured that the amount of sound medical knowledge has been greatly increased by it, and that medical practice has been placed on a much firmer basis than that on which it stood fifty years ago.

It is probable that among the cases here recorded more will be found to indicate failure than success in the discovery and treatment of disease; but they shall be given, nevertheless, in the full belief that a *past failure*, carefully observed and faithfully recorded, may become the means of promoting a *future success*. I am, &c.,

55, Victoria-street, S.W. PEYTON BLAKISTON.

CEREBRAL AFFECTIONS.

During the period in which I was engaged in the study of medicine, and attending hospital practice, I witnessed several instances in which the appearances discovered in the brain after death were very different from those which were supposed to have been indicated by the symptoms which occurred during lifetime. Consequently, from the commencement of my own practice, I was very cautious in giving a decided opinion as to the nature and seat of diseases occurring within the cranium, etc. I had not long been Physician to the Birmingham General Hospital before a case occurred which proved the necessity for such caution:—A female, aged 29, was admitted as a patient with complete hemiplegia and amaurosis. The symptoms were said to have existed about ten days, but whether they came on suddenly or not I cannot now remember. The pupils were of opinion that disease of the brain would be discovered in that portion of it wherein the nerves belonging to the affected parts met, but, to their great astonishment, I declined committing myself to any such diagnosis, simply telling them that I would not venture to pronounce any opinion as to the nature and seat of the mischief, but, as the patient was evidently sinking, they would probably ere long be able to discover them.

Six hours were spent in the examination of the body, but not a trace of disease was discoverable in any part of it. This was more than thirty years ago, when the microscope had not been brought into full use, and it was not employed in this case, otherwise it is possible the result might have been different.

Again, in two cases of aggravated hysteria, death ensued apparently from effusion on the brain. In one case a red speck was seen in the choroid plexus about the size of a pin's head, and in the other there were a few drops of fluid in the ventricles more than usual—nothing more.

A gentleman, aged 48, suffered greatly from violent paroxysms of pain in the head. His father and grandfather had both committed suicide. The notes of this case having been mislaid, I cannot recall all the symptoms, but I think there was at times some unsteadiness in walking. At any rate, I gave it as my opinion that there was organic disease of the brain, the nature of which was unknown to me, but I believed it to be seated in the lower and back part of the skull. He then consulted a physician of some position in London, who pronounced the case to be one of tic-douloureux, and had the courtesy to laugh me to scorn for having treated it as disease of the brain. He prescribed large doses of morphia, and for a short time the pain was diminished, and the patient went to his country seat. On a violent paroxysm of pain returning, the same physician was sent for; he still maintained that the disease was tic-douloureux, and that the patient would certainly recover. The next morning he vomited violently, and soon after died. An abscess was discovered in the cerebellum, which had burst into the spinal cavity.

Cases of albuminous dropsy often terminate in coma; but here I have generally found much serous effusion in the ventricles. When, however, a similar termination has taken place in diabetes, I have failed in some cases to find any abnormal appearance in the brain.

It is by no means uncommon to hear a positive diagnosis given in chronic affections of the brain, more especially that of softening; but both in the hospitals of Paris and of this country I have seen the same symptoms occur in cases of softening, induration, and arterial degeneration.

It will then, I think, be allowed by practical men who have been much occupied in comparing the lesions found after death with the symptoms evinced during life, that, as regards cerebral affections, we still "see through a glass darkly," and that a man in many cases will best show his knowledge of his profession by golden silence rather than by giving a positive diagnosis.

Even when there is no doubt of serious injury or death having resulted from external violence, it is often difficult, on account of the arched form of the cranial bones, to ascertain the exact nature of the injury. In one instance, however, I was enabled to swear in court that a death had been caused by a blow immediately behind the ear, but whether the blow was given by a weapon or a missile, or from the skull coming in strong contact with a projecting body, of course I could not say. A boy died from the effects of inflammation of the dura mater near the right ear extending inwards. On examining the body, not only were the effects of such inflammation visible, but on closely regarding the petrous process it was found to be cracked across its middle portion, the crack not extending to the neighbouring sphenoid bone. It was clear, therefore, that the blow which produced it must have been on its long axis, which pointed just behind the ear. It was in evidence that a brick had been thrown at him, and had struck him behind the ear, and the evidence was thus confirmed by the post-mortem examination.

Errors in prognosis are by no means unfrequent in cerebral affections—most unexpected results taking place. I have myself seen several cases of recovery from an apparently hopeless state after apoplectic attacks. A lady about 60 years of age was struck with apoplexy, after having had two or three previous attacks, which had left her partially paralysed on one side. She was totally unconscious. A physician and a surgeon from London met me in consultation on the case, and we all agreed, from the state of prostration in which she was, that she would probably not live twenty-four hours. However, enemata of beef-tea and brandy were frequently administered, and in seventy hours she gradually revived, and lived twelve months longer, with increased loss of power. She then had another attack, but died before a medical man could reach her. Much the same occurred in a gentlemen aged 64, but he revived much sooner.

A very eminent architect, a short, fat little man, died in the thirteenth attack of apoplexy. An empty cyst was found, about the size of a pigeon's egg, communicating with one of the ventricles. He had once passed some blood per anum, but had never complained of pain in the abdomen, which was loaded with fat, and was never examined to my knowledge. The liver was found to contain a large number of cancerous tubera,—one of the size of a small melon. His nephew, one of the most distinguished pathologists of the day, could hardly credit this until I sent him a drawing with the exact measurement of some of the tubera.

I have usually in such cases placed some calomel on the back of the tongue, with or without a drop of croton oil. One short and stout lady frequently had attacks, on which occasion about twenty or thirty grains of calomel were placed on the tongue. She rapidly came round. In her case, although the flushed state of the countenance would seem to have indicated venesection, it was never employed, as the circulation was found to be much depressed. Her maid was cautioned to mention the treatment to any medical man who might be called to her. She went a journey, although advised to remain quiet; was

seized with one of her attacks at an inn; a medical man was sent for,—he bled her, and she died in six hours.

On the other hand, a lady, very large and stout—weighing, in fact, nineteen stone,—had a very spongy state of the uterus, from which she had frequent enormous discharges of blood. Being a great feeder, in a few days she would make up this loss. When this ceased she had violent rushing of blood to the head; and if venesection was not promptly employed she became almost black and her breathing stertorous. She removed to London, and when she had another attack venesection was not practised, and she died at once. Whilst on this subject I may mention the case of a lady, aged 75, of extremely temperate habits, who had a slight apoplectic attack, which left her with loss of power of one arm. When seen she was on very low diet, and was becoming rapidly weaker and weaker. She was placed on a more generous diet; never had another attack; and has recently died at the age of 96.

On several occasions I have met with cases in which some cerebral disease was indicated, but have never had an opportunity of ascertaining its nature by a post-mortem examination. Noises in the head, dizziness, and occasional impaired vision and hearing, have been the first symptoms observed by the patients—generally persons advanced in age,—succeeded by unsteadiness of gait and staggering to such an extent as to require the assistance of one or two persons in walking. In all cases most marked benefit resulted from the application of an open blister behind one or both ears. One case was that of a lady aged 72, and occurred about twenty-two years since. She recovered the power of walking with very little assistance, and when I last heard of her (about ten years ago) she was alive. Two other ladies are still living—one 84, and the other about 64—the first symptom of the disease having occurred about fifteen years since. Whenever an attempt has been made to dry up the blisters, the old symptoms have reappeared; so that a raw surface has been always kept up, although in general of a size not exceeding that of a threepenny-piece. In all these cases I had reason to believe there existed an atheromatous condition of the arteries.

Three cases have come under my notice in which inflammation, acute or chronic, of a portion of the brain has subsided after destroying vision—in two cases of both eyes, and the other of one. In the latter case—a mechanical engineer of great talent, who had over-taxed his powers—the attack was so severe as totally to disqualify him from following his business; but after the loss of vision of one eye his health improved very much, and his intellect was undisturbed. In four or five years afterwards cerebral disease—probably softening—set in and destroyed his life.

In a second case—that of a gentleman aged 72—violent inflammation set in behind one eye, which became glaucomatous, the attack not yielding to treatment; and whilst under the influence of mercury the second eye was attacked, and total blindness ensued. After that his health was gradually restored, his intelligence remaining perfect, and he died some years afterwards of old age. No post-mortem examination was made. The third case was that of a medical man of very active habits. The attack commenced about twenty-seven years ago, was of a chronic character from the onset, and terminated in total loss of vision. That the brain was the subject of disease was evident from the fact that the ophthalmic nerves had lost their power, and he was not able to direct the eyeball and to bring the eyes into focus. He is still alive, and has enjoyed very good health ever since he became blind.

A striking instance occurred about thirty years ago in the Birmingham General Hospital, showing the manner in which cerebral irritation was produced by injury to a distant part of the body, and how it was removed by remedies applied to the injured part. A lad, aged 16, was admitted, the flesh of whose thigh and leg had been fearfully lacerated and almost torn from the bone by a waggon-wheel. Severe convulsive fits came on, and were fast wearing out his strength. I was requested by Mr. Hodgson to meet him and Mr. Jukes in consultation on the case. I suggested immediate amputation so that the extensive lacerated portion might be removed, and a simple incised wound substituted for it, which was much less likely to cause cerebral irritation. It was objected that there was no case on record in which amputation had been performed during convulsions; but on the score that he was certain to die if he remained longer in his present state, they agreed to perform the operation. The convulsions then gradually ceased, and the boy made a complete recovery.

Having frequently observed the best effects produced in cerebral inflammation by mercurial purging, soon after joining the staff of the Birmingham General Hospital I persuaded some of my surgical colleagues to sanction the application of calomel in large quantities to the back of the tongue in all cases of supposed cerebral concussion; and although I cannot now refer to statistics, I well remember that the mortality in such cases was much diminished, the mercurial action being thus made to forestall the inflammation likely to occur from the injury received.

Now, although the cases here slightly sketched can in no way add to our knowledge of the pathology or diagnosis of disease, yet they are sufficient to prove the necessity of extreme caution in pronouncing a diagnosis or prognosis in certain cases of cerebral affections,—and thus to prevent the occurrence of mistakes, injurious to the medical attendants, and distressing to the friends of the patient.

PROFESSOR HOLMES'S LECTURES AT THE COLLEGE OF SURGEONS.

Abstract of Lecture V.

Aneurism in the axilla is not perhaps quite so rare as in the neck—a result probably of the comparative frequency of wounds and injuries of this region. But the connexion of the artery with the capsule of the shoulder-joint is by no means so direct as is that of the popliteal with the capsule of the knee. Consequently the sprains and injuries so common in the neighbourhood of the shoulder less often affect the axillary than those of the knee do the popliteal artery. In speaking of axillary aneurism, Professor Holmes adopted the same plan of treatment as with carotid aneurism—*i.e.*, he first referred to the preparations in the museum of the College, and then showed some diagrams of those forms of this aneurism which he considered characteristic, and which illustrated his view of its surgical treatment. Thus a preparation (No. 1694) was produced as a typical example of the normal relations of the disease, showing the close connexion of the sac with the nerves of the plexus and the great branches which leave the artery close to the sac. This preparation showed likewise the curability of the disease even under unfavourable conditions: extensive disease of the heart existed, yet the aneurism is compactly filled with laminated coagula. The second preparation produced (No. 1695) showed the enormous size to which this aneurism grows. The whole axilla was filled, and there was a large sausage-shaped pouch running down the arm, and due no doubt to a partial rupture at some previous period. In this case the artery was originally tied with two ligatures by Mr. Liston, and the case is reported and figured in the *Edinburgh Medical and Surgical Journal* for 1827. Three other preparations exist in the museum (No. 1696 and Nos. 1694 A and B); these illustrate the tendency of axillary aneurisms to occur as popliteal aneurism pretty often does, on both sides of the body. Such preparations as these, which constitute the whole series of axillary aneurisms contained in the museum of the College, are characteristic and valuable because they demonstrate most of the debatable points in the surgical treatment of this disease.

Professor Holmes commenced the discussion of the surgical treatment of these aneurisms by exhibiting four diagrams which illustrate forms of this disease curable by different surgical proceedings. In such a case as Liston's (No. 1695), already referred to—where the enormous tumour extends into the subscapular fossa, the sac has given way at one point, and the walls of the great sac are incorporated with the muscles of the axilla, having the axillary plexus of nerves and the axillary vein lost in its substance—there is practically no hope of saving life by the Hunterian method. Cure by compression is out of the question. The operation recommended by Mr. Syme could not have been performed, for though the upper end of the artery might by possibility have been tied, the lower end of the vessel seems to have been separated by an interval of many inches instead of being close to the upper, as Mr. Syme leads us to expect, and could not have been found. The size and shape of the sac, too, would have rendered its obliteration by a process of suppuration fatal to the patient.

There would besides have been the risk of bleeding from arteries opening into the tumour.

For such cases as these no remedy remains except amputation at the shoulder-joint. After the subclavian artery had been secured, the limb might have been amputated and the remains of the sac could then have been easily cleared out of the subscapular fossa—a desperate operation, it is true, but one from which recovery would not have been hopeless. The tied end of the vessel would have been far less likely to be the seat of secondary hæmorrhage after the removal of all the parts below it than when tied in its continuity. In such cases as this, then, no minor operation holds out any hope of benefit. If the surgeon is not prepared to adopt the extreme and most hazardous measure of removing the limb, he should allow his patient to die a natural death. On the other hand, the cases most probably amenable to the ligature of the subclavian are like one produced from Guy's Hospital, in which the tumour is of large size, and the artery has a free entrance and exit at either end of a sausage-shaped sac; a great branch arises from the artery just as it enters and two others just as it leaves the sac, and the brachial plexus of nerves envelopes the tumour on all sides. Compression would probably have failed, not so much on account of the size of the tumour as on account of the free anastomoses by which the circulation would have been constantly carried on. The relations of the sac would have made an attempt to lay it open, as Mr. Syme proposed, exceedingly hazardous, and in all probability fatal from lesion of the nerves, from the necessary ligature of the collaterals and from the too probable injury to the vein. But there seems a very fair prospect that the arrest of the main stream of blood by ligature of the subclavian might have been sufficient to effect a cure. In many such recorded cases, though the aneurism has retained some pulsation for a time—in consequence, no doubt, of the large branches opening into it,—yet coagulation has gradually advanced and has finally been completed. Another of Mr. Liston's preparations, preserved in the museum of University College, affords an illustration of the kind of case in which it is not impossible that an enterprising surgeon might carry out the operation described by Mr. Syme, although not without much risk of injury from the proximity and the uncertain position of the vein and nerves. It is a specimen in which there is that relation between the vessel and the sac which Mr. Syme described as universal, but which Mr. Holmes has shown to be exceptional. The last illustration is a diagramatical representation following closely on the model of Mr. Gay's preparation (No. 1694A), it is intended to show the usual conditions or relations of an elongated or fusiform aneurism in the axilla, and if compared with a preparation of axillary aneurism seven years after it was cured by compression, it will be found to correspond in all essential particulars with the state of things there shown. The conditions here represented render it desirable to avoid if it be possible the ligature of the subclavian artery; both because the situation of the ligature must always be dangerously near the aneurism, and the possibility of curing these moderate-sized aneurisms in the axilla by compression can be amply proved by cases.

Hitherto—in this country, at least—the treatment of axillary aneurisms has been almost uniform; nearly every case having been treated by the ligature of the third part of the subclavian artery. We have had very little experience of the compression, or indeed of any other of the substitutes for the Hunterian ligature.

Mr. Erichsen, in writing only last year, thus sums up—and Professor Holmes thinks very fairly—the views of surgeons on this subject:—"Digital compression might be advantageously used, but compression by instruments on the cardiac side can seldom be made applicable to aneurisms in this situation, inasmuch as the pressure that is brought to bear upon the subclavian must necessarily at the same time influence the greater part of the brachial plexus of nerves to such an extent as to be unendurable to the patient. Yet it is not impracticable, and means might be devised to overcome this difficulty. Ligature of the artery is still the surgeon's chief resource in the treatment of these cases."

Daily experience, however, proves how very dangerous a resource ligature of the subclavian is in axillary aneurism. The earlier statistical tables of Norris and Porter show that nearly half of the cases in which the subclavian artery has been tied in its third portion for aneurism have died, and the more recent researches of Koch go to prove the same. Out of ninety-four cases where this artery has been tied for aneurism in the axilla not extending above the first rib, and, therefore, permitting the ligature of the subclavian in its third part, fifty-one have recovered and forty-three have died. Thus, almost as many cases of axillary aneurism which have been operated on by ligature of the subclavian have died from the operation as have survived; and there can be but little doubt that a good many of those who have survived the operation have not survived very long.

The dangers of the operation on the subclavian artery for axillary aneurism increase, as those of ligature of the common carotid for carotid aneurisms do, the nearer the ligature has to be laid to the aneurismal sac; and several of the preparations on the table prove that in these cases the ligature is often in contact with the aneurism. Besides the risk of inflammation and suppuration under these circumstances, there is (as proved by a case of Sir W. Fergusson's) another danger; for the sac, even though not wounded in the operation, may give way from the loss of support due to the proximity of the wound to its tissue.

The Professor produced several preparations from different museums which showed how frequently the operation proves fatal from other causes (pyæmia, plugging of great veins from inflammation going on around them, hæmorrhage from diseased arteries, etc.), even when all is going on well with the aneurismal sac and its contents; and, lastly, he drew attention to the fact that hidden dangers beset the path of the operator, even in cases which present no apparent risk beyond the common. Thus, in one of the preparations from the Irish College of Surgeons there was seen a diverticulum from the aneurismal sac the existence of which was not suspected during life, but which (as Professor Porter says in his account of the case) must necessarily have been wounded had any attempt been made to tie the artery as it passes over the first rib. Thus, by statistics, histories of cases, and preparations, the danger of ligature of the subclavian are sufficiently illustrated. Still these dangers are no argument against the employment of the ligature if no safer means of treatment exist. But as there are cases of the most unpromising character which have been successfully treated without resort to so dangerous an operation, we must inquire under what conditions it is possible to treat axillary aneurisms without operation; and when, on the contrary, we should feel justified in exposing a patient to all the dangers of the Hunterian or Anel's ligature; and, further, in what cases it may be justifiable to cut into the axilla and seek for the two ends of the artery, or to remove the limb altogether. Allusion must also be made to modes of treatment which are applied directly to the tumour itself—viz., manipulation, galvano-puncture, and coagulating injection.

Notwithstanding the admitted fatality of Hunter's or Anel's operation on the subclavian, English surgeons have not as yet made any very serious attempts to treat aneurisms of this kind by milder methods. Fischer, in an elaborate paper, has collected all the published cases which he could find, in which digital compression had been used with or without success in the treatment of various forms of aneurism.

The number of cases of axillary aneurism he alludes to which have been so treated are only two, and the compression was in both cases unsuccessful.

Compression of the subclavian artery in axillary aneurism is as old as the time of Desault, whose attempt is related in Broca's work. The patient did not give the treatment a fair chance: being frightened, he left the hospital and placed himself under Ferraud, at the Hôtel-Dieu, who, mistaking the aneurism for an abscess, opened it, and the patient died at once of hæmorrhage. Another unsuccessful trial of pressure in this form of aneurism is also referred to by Broca, who, however, gives it as his opinion that axillary aneurism is not suitable for compression at all.

It may be doubted whether digital pressure is so applicable in this form of aneurism as instrumental, or that combination of the two which consists in the application of manual pressure by means of some pad such as that designed by Mr. Coles; for the artery lies at so great a depth that the fingers soon get weary, and the pressure is liable to become unsteady, being both uncertain in its direction and also varying in its force—*i.e.*, both insufficient and painful.

Out of ten cases of axillary aneurism—contained in the table alluded to in the first lecture, of 337 cases surgically treated in our British hospitals—three of them were submitted to compression: in one with perfect success. In a second case the patient was at the extreme age of 78 years, and died during his stay in hospital apparently from natural decay;

only direct pressure by pad and bandage was used. In the third case pressure was tried, but could not be borne by the patient; then an attempt was made to tie the subclavian, but by mistake the posterior scapular artery, which was unusually large and came off from the third part of the subclavian, was taken up instead. The patient died two days afterwards. The first of these cases is of much interest, as being the only one in which the cure of axillary aneurism by compression has been effected in one of our large metropolitan hospitals. It occurred last year at Guy's Hospital, under Mr. Cooper Forster's care, and is published in the *Guy's Hospital Reports* for 1873.

A case which was recently under the care of Professor Rizzoli, of Bologna, proves that an axillary aneurism—even of the most formidable kind—accompanied with degeneration of the subclavian artery to such a degree as must have precluded the prospect of successful ligature of that vessel—may nevertheless be cured by pressure. Rizzoli terminates his account of this case by saying—"I hope the cure of this case by compression may help to moderate the impatience of those surgeons who, discouraged by the first unsuccessful trials of compression, with reprehensible haste resort too quickly to the ligature of great arteries, exposing their patients thereby to the grave dangers which frequently follow on such operations, however skilfully performed, and even after the most approved method of operating." Rizzoli also refers to two other cases—one related by Ciniselli, to which brief reference is made in the New Sydenham Society's Biennial Retrospect for 1867 and 1868, and of which a full account is to be found in "Bulletins delle Scienze Mediche di Bologna"; and the other is a case of Dutoit's.

These cases are of great value, as showing that there are instances of every kind of axillary aneurism which are amenable to the cure by compression. Rizzoli's case was depending upon spontaneous disease of the artery; Ciniselli's, a distinctly traumatic aneurism, the artery being almost certainly healthy; Dutoit's, of that mixed or uncertain kind occurring after an accident, but in which it is always a matter of doubt whether the artery will not be found more or less diseased; Cooper Forster's was somewhat of the same nature—*i.e.*, one in which the cause of the disease is uncertain, but its rapid increase renders it most probable that the artery is extensively diseased.

These cases prove further that the cure may be effected either by digital or instrumental pressure. They show the feasibility in many cases of digital pressure, and also that it may be borne for a considerable period without producing unbearable pain or any loss of function from injury to nerves.

The facility with which the subclavian artery can be compressed, and the ease with which it can be separated from the nerves of the brachial plexus, so as to be compressed without much pain, vary very much in different persons. In some, where the artery rises high in the neck, there is no difficulty in stopping the pulse with moderate pressure of a single finger, and the patient will not complain of much inconvenience when this is done. In others the pressure has to be directed almost under the clavicle; too great force is required to be efficiently maintained for any length of time, and this gives so much pain as to induce the patient speedily to beg for its cessation.

Then arises the question, If pressure on the subclavian be too painful to be endured without an anæsthetic, cannot it be successfully employed under anæsthesia? Professor Holmes can see no objection to the use of total compression under chloroform in the case of the subclavian artery, except the difficulty of making a proper instrument. It is true there may be some risk of contusing the nerves of the brachial plexus by prolonged pressure; but this risk is so trifling in a disease so dangerous as axillary aneurism, and is so very small in comparison with the dangers of the ligature, that it seems quite justifiable to make the attempt. It must be left to future experience to decide in how large a proportion of cases success may be hoped for, and whether the attempt is worth persevering in. But the complete success obtained in Mr. C. Forster's case is a most powerful encouragement to renew it.

Mr. Harry Leach, M.R.C.P.L., has been appointed Medical Officer of Health for the Port of London until March 25 next, at a salary of £400 per annum.

MEGRIM, OR SICK-HEADACHE.(a)

There is no more distressing malady during the time it lasts than sick-headache, but, on the principle that all's well that ends well, the poor sufferer meets with little more sympathy than the possessor of a toothache. Its investigation has consequently been too much neglected in this country; but recently two treatises—one a most formidable-looking one—have been given to the public, whose fault it now will be if they lack information when so much is offered.

In truth, the history of sick-headache has been sadly neglected. It is too common a malady to excite much interest, and yet we have monographs on it by such distinguished men as the Astronomer Royal, Dubois-Reymond, Lebert, Sir John Herschel, Wheatstone, and others, who have all suffered from it to a greater or less extent. We might divide sick-headache into more than one variety. First, there is the curious form described by Airy and Herschel, where there is loss of sight over a certain area of the field of vision; or a certain mistiness over the whole of it; or where there is a semblance of a fortified city as far as the jagged outline is concerned, sometimes coruscating with various colours and sometimes plain. Again, there is the more common form, where, after a slight mistiness of vision, not unfrequently absent, the headache comes on intensely; and a third, where difficulty of expression and numbness of some part, generally unilateral, precede the development of the headache.

The phenomena of sick-headache are only too well known. Coming on with or without this misty vision—sometimes early in the morning, sometimes later in the day,—the pain gradually increases until hardly bearable. Yawning and sickness early make their appearance, but vomiting is not an invariable phenomenon. The patient is for the time being utterly incapacitated for business or any active occupation. The only thing is to be as quiet as possible. Noise is an abomination; every beat of the heart even seems to be both heard and felt on the affected side. Now, as a rule, the sick-headache is distinctly one-sided sooner or later, but it may begin by affecting the whole forehead, gradually concentrating its violence on one spot in the temple or sometimes in one eye—which throbs as if it would burst; it is tender on pressure, but deep pressure gives relief. In other cases the pain begins at one point, and spreads all over the head; but on the whole the former is more commonly the course of development. If the nausea goes on to vomiting, first food (if any has been taken) is brought up; afterwards bile. In some the vomiting, though intensely painful—every heave seeming as if it would burst the head,—gives relief; but in others this is not the case. There seems to be only one real mode of securing rest—that is by sleep; and curiously enough, though the pain is so great, this is not so difficult. After some hours' sleep, very likely restless, the patient wakes shaky and debilitated, but free from pain. The stomach is still in a ticklish condition, but there is no absolute nausea, and a little walk and a cup of strong tea help to restore the patient to his normal state. Many and various are the causes which lead to such attacks. Excitement or reaction from excitement may pave the way; anything else will do to set it up. We well remember the case of a young lad brought up in the country to whom a visit to the market town was something to be looked forward to. On the mother's side such headaches were hereditary, and to him the excitement of such visit was invariably the origin of a splitting headache. All the way to town the headache kept off, and so it would during business, but as this invariably on his part culminated in a visit to the docks to see the shipping, there the headache invariably began—the smell of tar seemingly the direct cause. Even now, at the interval of many years, the smell of tar will often set up headache of the same kind, but different in certain respects. Then the pain affected the whole forehead, now it only affects one side and one eye, and on this side the first grey hairs appeared. In the lad's case the return journey was hardly bearable; every step seemed to add to the pain until home was reached, and then bed was the only refuge. All this was accompanied by intense nausea and disagreeable belchings, but vomiting was very rare save something

(a) "On Megrim, Sick-Headache, and some Allied Disorders: a Contribution to the Pathology of Nerve-Storms." By Edward Liveing, M.D. Cantab., formerly Physician to King's College Hospital, etc. London: J. and A. Churchill. Pp. 512.

"On Nervous or Sick-Headache: its Varieties and Treatment." By P. W. Latham, F.R.C.S., Physician to Addenbrooke's Hospital, Deputy for the Downing Professor of Medicine, etc. Cambridge: Deighton, Bell, and Co. Pp. 71.

unwholesome had been eaten, and then it gave no relief, though sleep did.

In the volumes before us the pathology of this curious state is considered. The old idea was that such headaches were the result of "foulness of the stomach," and truly they are often accompanied by clammy mouth, and some amount of oral catarrh, but undoubtedly they are of nervous origin. The popular theory as to their causation seems to be that they depend on disordered innervation of a limited area of the sympathetic. First comes on a period of contraction of vessels due to vaso-motor irritation, with mistiness of vision, etc. Sometimes the first indications come from the vagus, with yawning, nausea, and the like. In either case the end seems the same—paralysis of the vaso-motor system over a certain area, and hence fulness of vessels, with throbbing pulsation, redness, and pain. Hence, too, the slightest increase of vascular pressure by lowering the head, movement of any kind, still more by vomiting, will increase the pain. Its nervous origin is likewise indicated by the remedies which are most useful—these are sleep and stimulants; but there seem to be only two kinds of stimulants of especial use. True, in some cases alcohol does good, but these are not the majority; in most it does harm. Strong black or green tea, strong black coffee, guarana—all of which seem to act in exactly the same fashion,—are the remedies most generally useful; ammonia in the form of aromatic spirit in good full doses is also very good; but the most useful remedy we have seen, though rarely mentioned, is smelling salts or any other form of ammonia taken by inhalation through the nose. Fortunately this can be easily combined with the former, and by dint of them a man who otherwise would be hopelessly incapacitated from business may be enabled to conduct it in comparative comfort.

We can cordially commend Dr. Liveing's and Dr. Latham's books. The former is a bulky treatise, and deals with many other neuroses besides this. Dr. Latham's is a smaller and less pretending work, but contains much sound sense on the subject.

REVIEWS.

Outlines of Physiological Chemistry, including the Qualitative and Quantitative Analysis of the Tissues, Fluids, and Excretory Products. By Charles Henry Ralfe, M.A., M.B., late Scholar of Granville and Caius College, M.R.C.P. London: Lewis. Pp. 231.

Dr. Ralfe has undertaken a task of no ordinary difficulty. The subject of physiological chemistry is very far from easy—many points are altogether unsolved; indeed, the whole of this department of biology even now is but in its infancy,—but Dr. Ralfe's is an honest attempt to give a sketch of the subject such as may be useful to students and practitioners. It is because Dr. Ralfe's work is so entirely unambitious that we are the more ready to award it this meed of praise, for in it we could pick a good many faults; but, taking the whole circumstances of the case into consideration, we are inclined to overlook these when we might find them in greater abundance in works of more pretension and less accuracy. The earlier portion of the volume is devoted to that somewhat dreary subject, the organic and inorganic constituents of the human body. Dr. Ralfe, in dealing with these, has adopted the new notation, which will be a comfort to recent students, if not to those of older date, for whom the conflicting notations now in use are somewhat trying. This part we shall lightly pass over with a query as to the value of the graphic mode of showing the composition of some of the more complex substances. At all events, Dr. Ralfe has not adopted it,—whether to the advantage or disadvantage of the student is not easy to say, though we incline to the latter belief.

It is, however, where chemistry and physiology come most nearly in contact that Dr. Ralfe chiefly fails to come up to the accuracy so necessary to the student. Turning, for instance, to saliva and the action of nerves on the submaxillary gland, he fails to separate the effects of stimulating the sympathetic from those of the chorda tympani, although they are as different as may be; he contrasts the saliva formed by stimulation with that of paralysis only. So again as regards pepsine, he tells us that it is best prepared by macerating the mucous membrane of the stomach of a recently killed animal with phosphoric acid until completely dissolved; but this process implies the presence of peptones. In point of fact, it is a question whether perfectly pure pepsine has ever yet been obtained.

Fault-finding is, however, an ungrateful task, and so we rather turn with pleasure to the marked good qualities of the book. Chief among these we would note the processes for estimating quantitatively such fluids as urine and the like. They are terse and clear, perhaps all the more so within certain limits that the book is highly condensed. In his preface Dr. Ralfe says that most of the work described in his pages has been carried out in Mr. Heaton's laboratory at Charing-cross Hospital. This is in itself a great guarantee for care and accuracy, and decidedly adds a stamp to Dr. Ralfe's book which is of the greatest value. We are, at all events, in a position to say that no better guide to physiological chemistry, practical and theoretical, is now available for the English-reading student.

Posological Tables. By W. Handsel Griffiths, Ph.D., etc. Second edition. Dublin: Fanning and Co.

This is a valuable sheet of information, both as regards students and practitioners. It is a classification of the doses of official substances. At a glance the student may ascertain these doses, and thus afford an aid to the memory of immense importance to him. To practitioners, apothecaries, and dispensers it is valuable as a work of reference. The tables should be framed and hung in the study of every pupil, and in the dispensary of everyone who has to prepare medicine.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, July 2.

E. J. Tilt, M.D., President, in the Chair.

The following gentlemen were elected Fellows of the Society:—James Henry Bennet, M.D.; Francis Davison, L.R.C.P., Armagh; Simon Fitch, M.D., Portland, Maine; Robert Henry Moon, F.R.C.S., Norwood; and Richard Wilkins, Madras.

Dr. Heywood Smith exhibited a Fœtus with a Diaphragmatic Hernia. It was a male and a fifth child. Of these five children the first only lived an hour, the three next were born dead, and this only lived three-quarters of an hour. On opening it the liver was found fairly normal; a prolongation posteriorly passing upward was embedded in the diaphragm. The stomach was lying nearly perpendicularly. There was only a short portion of small intestine, and about the lower half of the large. On opening the thorax all the rest of the intestines were seen occupying its left side. The heart was placed centrally, taking up the space of the right lung, while the left lung was rendered even smaller by the large space taken up by the intestines, which were found to have passed upwards through an opening in the left posterior aspect of the diaphragm just large enough to admit the tip of the little finger. To the right of this was seen the spleen dipping into and filling a sort of pocket at the posterior margin of the diaphragm.

Dr. Squire exhibited an Earthenware Bed-Pan, modelled by Phillips, of Oxford-street, on the design of a nurse, to allow free ablution; also a Linen Breast-Supporter, invented by the same nurse, and found to be very useful.

Dr. Heywood Smith did not know whether Dr. Squire was aware that there was a bed-bath, made by Maddox, in University-street, which was exceedingly convenient, and much lighter than the pan now exhibited.

Dr. Protheroe Smith exhibited his Pneumatic Indiarubber Plug for facilitating the introduction of cylindrical specula. It forms a soft elastic cushion in the end of the speculum, and renders the introduction of it painless to the patient.

Dr. Aveling showed a drawing demonstrating what he considers to be the Best Mode of Opening the Vein so as to enable the operator to pass a tube into it with ease in Transfusion. He stated that he had transfused blood a second time by the immediate method, and that this plan of opening the vein was the result of his further experience. He seizes the exposed vein with a pair of fine forceps, and incises it so as to form a V-shaped flap. Although the opening thus made may become obscured by blood, it is still readily to be found by using the forceps as a director, and passing the tube down it into the vein.

Dr. Savage (Birmingham) remarked that in a case of transfusion which had occurred in his practice he had used Dr. Aveling's syringe. He found no difficulty in opening the vein nor in inserting the nozzle. He exposed the vein by transfixing the skin, and then passed a probe under it. It seemed to him that nothing could be simpler or more successful than using Dr. Aveling's syringe.

Dr. Aveling thought it unnecessary to pass a probe under the vein, and that the less the vein was disturbed the better.

The President congratulated the Society on the readmission of Dr. Henry Bennet, the importance of whose scientific work could be best estimated by the very different character of the books on the diseases of women published before and after 1845, when Dr. Bennet published his little work "On Inflammation, Ulceration, and Induration of the Cervix." In that work he taught the profession of this country the two great lessons he had learnt in the Paris Hospitals—1. That diseases of the womb must be studied like other diseases, by every available mode of investigation. 2. That the treatment of diseases of the womb should be to a great extent surgical. These views have been adopted by all the eminent men who have written in English on diseases of women since 1845, and a school of gynæcology had sprung up which he called English, comprising American, Scotch, and Irish authors, and which he believed to be richer and more varied than that of any other country. Dr. Henry Bennet was the founder of this school, and it was a matter of congratulation for the Obstetrical Society that his unexpected recovery again enabled him to take an active part in its labours.

Mr. George Roper read a case of Hypertrophic Elongation of the Cervix Uteri at the Full Term of Pregnancy. E. C., aged 22, a primipara, was taken in labour on the morning of November 3. The next day the membranes ruptured naturally, and the pains became strong and frequent. The cervix uteri protruded from the vulva to the extent of about three inches; it was in circumference about the size of an ordinary adult male wrist, the portions without and within the vagina measuring about four inches in length. The canal of the cervix would just admit the forefinger, but no presentation could be felt. The canal was too long to allow the finger to pass up to the uterine end. The structure of the cervix had a firm, hard, and gristly condition, and there seemed to be no probability of its expansion under natural efforts of the uterus. Dr. Barnes saw her when she had been in labour thirty-six hours, and slight expansion had taken place; the pains were not violent, and there were no symptoms of exhaustion. Further delay was advised, but should further expansion not take place free incision of the lower part of the cervix was recommended. After waiting four hours, seven incisions in the os externum were made, the tissue cutting with a gristly sensation. After the operation a gradual dilatation took place, occupying sixteen hours, at the end of which time the patient was delivered by forceps. The duration of the labour was fifty-two hours. The child was alive, and the mother made a good recovery. The author believed such a case as this was not amenable to treatment by means of water- or air-bags. Two months after delivery the uterus was found fairly involuted, and the cervix slightly larger or longer than usual. The portion which had been elongated hung down into the vagina like a shrivelled skin. This was removed, and she has since had several children after easy labours.

Dr. Brunton thought that in this case great benefit might have arisen from putting the patient in the knee-elbow position. He had met with a similar case, and had found this method of treatment successful, the prolapsed uterus passing into its natural position, and labour terminating in a short time.

The President wished to know what was the effect of pregnancy in preternatural elongation of the cervix—whether the result of the puerperal tissue-transmutations was to shorten it in a manner analogous to that softening of the hard cervix which he had repeatedly seen to follow pregnancy.

Dr. Barnes said that these cases were sometimes cured by labour and sometimes not. Dilatation would occasionally answer as a mode of treatment, but incisions were now and then necessary. He had seen a case in which the protruded cervix formed such a large mass as to be mistaken by the midwife for the whole uterus; and he believed that this mistake had often been made.

Dr. Playfair said that with regard to incisions it was right to remember that in such cases as that now related and in cases of rigid cervix they were very different things. In the latter the cervix was stretched and thin, and the incisions would be merely linear; in the former each cut would be the entire length of the hypertrophied cervix (in this case nearly four inches), and the risk of septic absorption would be of course materially increased. He did not make these remarks to criticise the practice adopted, as he believed it was the only means of overcoming a very formidable difficulty.

Dr. Madge said it was generally supposed that laceration of the cervix uteri during labour, without any ill consequences following, was a common occurrence. That being the case, there was not so much fear in making incisions in the cervix when rigid and unyielding.

Dr. Protheroe Smith could confirm the remarks of Dr. Barnes, having for many years been in the habit of incising the cervix when it formed an obstacle to the progress of labour; and in no case had he found the wound to extend beyond his incision. He had seen a case in which an unyielding cervix had been completely torn from the body of the uterus. He advocated the plan of cutting only laterally to avoid wounding the peritoneum, and of using the douche freely afterwards to prevent absorption of putrid lochia.

Dr. R. Eardley-Wilmot read a paper "On the Fillet or Loop as an Obstetric Aid, with especial reference to a New Modification of the Instrument." The author pointed out that the fillet was an instrument of great antiquity, but that it had fallen into disuse; that it was treated in our text-books either with silent contempt or unqualified condemnation. In spite of this he believed the fillet to be a useful instrument. It may be used in cases where slight or great force is required, and as a general rule in any case where the head is clear of the os uteri. It is lighter, more portable, and can be used more easily than the forceps, and it does not frighten the patient. If desirable it can even be used without the patient's knowledge. He had employed it in twenty-five cases: all the children had been born alive, and in only one was there slight rupture of the perineum. The fillet in its old form he believed to be difficult of introduction and adjustment, and liable to injure the child. Dr. Westmacott had improved it by rendering the instrument capable of being easily removed, one end of the loop being made so that it can be detached from the handle. But the difficulty of adjusting still remained. This the author overcomes by having the handle of the fillet divided longitudinally, so as to leave one end of the whalebone loop attached to each section of the haft. The two portions are separable at pleasure, or united when compressed, by steel pins projecting from one half of the handle and perforating the other. The instrument may be introduced as usual; let one half of the handle then be taken in each hand, and by a gentle sawing movement in the direction required, and by pressure on each limb alternately, the loop is readily brought into its due position.

Dr. Westmacott said that four years ago he had shown the Society his fillet with the improvement of being able to remove the end of the whalebone loop from the handle. The idea struck him then of dividing the handle; but, wishing to keep the instrument as simple as possible, he had abandoned it. He had since added a strong indiarubber ring, which slides up and down the loop, to make it more portable, and to compress the head of the child. He objected to the author's plan of applying the loop over the chin, as it might slip towards the neck and strangle the child. He usually applied it over the eyebrows or nose, and he had seen no other bad result than a slight mark, which disappeared in a few days. He thought the loop of the instrument now exhibited too thin. Its sharp edges might scratch the skin, or twist, or split. He had used his own fillet sixty or seventy times, and with favourable results in almost every case.

Dr. Aveling thought that obstetrical writers very properly omitted any lengthened description of the fillet. Compared with the forceps, it was an unscientific instrument. Its liability to slip had been observed long ago, and Levret, to prevent this accident, added a third branch. This same modification had been a short time since reinvented by Dr. Sheraton, and, he was sorry to say, also patented. If the fillet were hooked over the chin, as recommended by Dr. Eardley-Wilmot, there was a chance of its slipping round the neck and producing strangulation; and if over the nose or brow, as advised by Dr. Westmacott, it might injure the former or slip off the latter. The instrument might answer where slight traction was required, but he would be sorry to have to rely upon it where largeness of the fœtal head and rigidity of the maternal passages demanded the exercise of much force.

Dr. Playfair believed that the reason why the fillet did not sink into well-merited oblivion was the appearance of sim-

plicity about it, and the fact that it could be used without the knowledge of the patient—this latter being, in his opinion, one strong reason why it should not be used. But the truth was, as Dr. Aveling had remarked, that the fillet was essentially an unscientific instrument. If it were applied when the head was high in the pelvis, traction over the face would necessarily produce extension of the chin before the time of that change had arrived. Another strong objection to the fillet was, that it drew attention from the forceps—an instrument perfect in its adaptation to the natural mechanism of labour.

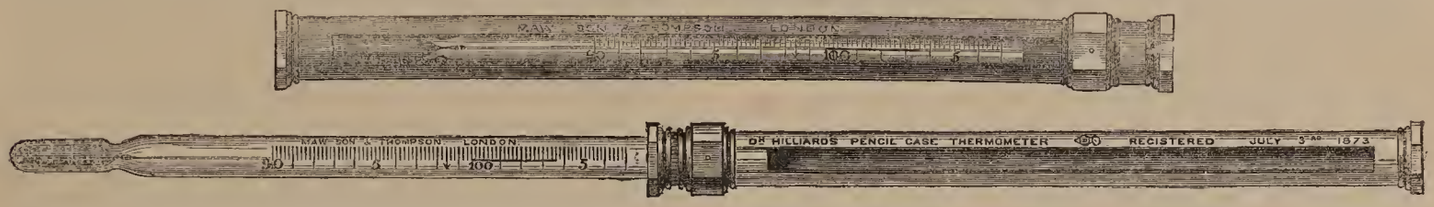
Dr. Eardley-Wilmot found his own fillet much more easy to use than Dr. Westmacott's. He did not think there was fear of strangling the child or of the loop slipping; nor did he think the fillet an unscientific instrument, or likely to interfere with the natural course of labour. He never intended to place it in competition with the forceps as a means of delivery in difficult labour.

Dr. E. H. M. Sell read a case of Complete Uterus Bicornis, the Septum extending into the one Common Cervix, with Pregnancy of the Right Horn. This case occurred at the General Hospital of Vienna, and the diagnosis was made out by Professor C. Braun while the patient was under chloroform. Owing to the narrowness of the pelvis, delivery was very difficult, and the child had to be extracted by turning. The conjugate diameter of the pelvis measured only two inches and a half. The placenta had also to be removed by the hand, as the uterus was powerless. On the sixteenth day after delivery the patient left the Hospital, well.

NEW INVENTIONS.

DR. HILLIARD'S PENCIL-CASE POCKET CLINICAL THERMOMETERS.

The accompanying engravings will explain the simple but very ingenious mechanism by which Dr. R. Harvey Hilliard, of Upper Holloway, secures three desirable objects at one and the same time, by applying the familiar principle of the pocket pencil-case, with sliding ring, to clinical thermometers. These three objects are—1, portability; 2, protection; 3, protraction. As regards portability, they are of course as easily carried about as an ordinary pencil-case is, in the waistcoat-pocket. The thermometer is thereby protected, both in carriage and in use, because even in the axilla it is not necessary that more than the bulb should be protruded, as the index can be read afterwards. We understand that Dr. Hilliard has registered a still further protection in the shape of an inner jacket, on which the scale can be engraved, thus doing away with all danger of file-marks on the stem, and still further obviating the risk of breakage. It will be seen that the ends and the sliding ring are octagonal, so that it will not roll off the table. As regards the last object, protraction, it is obvious that the length is almost instantaneously doubled whenever desired. We understand that by simply warming the varnish in the cheap instruments, or by unscrewing the button in the more expensive ones, the instrument can be taken to pieces for the sake of cleaning both tube and case.



OBITUARY.

JOHN WYNNE, M.R.C.S.,

After a short illness, died at his residence in Oswestry, on the 4th inst., in the sixty-third year of his age. He pursued his medical studies at St. Bartholomew's Hospital, London, and Richmond Hospital, Dublin. Mr. Wynne had been in practice in Oswestry for about thirty years. He was medical officer under the Incorporation for the parishes of Llansilin, Sclattyn, and Sychlyn, and one of the surgeons to the Oswestry Dispensary and the Cottage Hospital. His services to the two latter were rendered gratuitously from their commencement. He had been for years surgeon to the Lodge, Glyn, and other friendly societies. His remains were interred in the family vault at Selattyn.

MEDICAL NEWS.

Royal Colleges of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their first professional examination during the July sittings of the examiners:—

Beatty, Thomas Carlyle, Seaham.
Douglas, Thomas, Northumberland.
Forrester, James Stevenson, Edinburgh.
Walker, George Abraham, Darlington.
Walsh, Thomas, Limerick.
Willacy, Charles, St. Michael's.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—

Ashworth, Handel, Lancashire.
Atkins, George Purcell, Cork.
Bohrendt, Maximilian Raphael Julius, Prussia.
Court, Adam Smith, Barrow-on-Humber.
Davies, David Llewellyn, Glamorganshire.
Hughes, Robert Jaffray, Birkenhead.
James, William Mawer, Jersey.
Leslie, Louis Gordon, Hampshire.
Martin, John, county Down.
Mathews, James Snodgrass, county Londonderry.
Piggott, Edward Alfred, London.
Rundle, George Edward, Hampshire.
Spowart, Thomas, Fifeshire.
Stewart, James, Canada.
Welch, William John Joseph, Staffordshire.
Whitla, William, Monaghan.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 24th inst., viz.:

Batterbury, George Henry, Haverstock-hill, student of King's College.
Beresford, William Hugh, Westbourne-park-road, of St. Mary's Hospital.
Boodle, Robert Maxwell, Highbury, of St. Bartholomew's Hospital.
Burgess, Edward John, Brentwood, Essex, of St. Bartholomew's Hospital.
Davies, John, Kington, Hereford, of the Westminster Hospital.
Davies, Lewis, Llandyssil, Cardigan, of Guy's Hospital.
Ellis, Herbert Mackay, Chudleigh, Devon, of St. George's Hospital.
Fox, Charles Allen, Stoke Newington, of the London Hospital.
Hartley, Charles, Stocking Pelham, Herts, of the Charing-cross Hospital.
Hughes, Richard David, Aberystwith, of Guy's Hospital.
Jackson, Henry, L.S.A., Great Torrington, North Devon, of the Middlesex Hospital.
Keetley, Charles Robert Bell, L.R.C.P. Lond., Cleethorpe, Great Grimsby, of St. Bartholomew's Hospital.
Lyons, Alfred De Courcy, Wednesbury, Staffordshire, of St. George's Hospital.
Mackinlay, James Egan Harrison, Kensington, of St. George's Hospital.
Manser, Robert, L.S.A., Chatham, of Guy's Hospital.
Mills, Joseph, Andover, of St. Bartholomew's Hospital.
Nicholls, Henry Alfred Alford, M.B. Aberd., Kingsland-road, of St. Bartholomew's Hospital.
Sherwood, Arthur Paul, Reading, of St. George's Hospital.
Sprod, John, Adelaide, South Australia, of the Bristol School.
Strugnell, Frederick William, Kilburn, of St. Bartholomew's Hospital.
Tucker, Robert Goldsworthy, Shrewsbury, of St. Bartholomew's Hospital.

Admitted Members on the 25th inst., viz.:—

Carline, William Arthur, Lincoln, student of King's College.
Cheese, Frederick, Newport, Mon., of St. Bartholomew's Hospital.
Chitwood, L.R.C.P. Edin., Waltham Abbey, Essex, of St. Bartholomew's Hospital.
Cousins, Dennis Wood Deane, Witheridge, North Devon, of St. Bartholomew's Hospital.
Davis, Harry, L.S.A., Callington, Cornwall, of University College.
Davis, Edwin Harry, Dorchester, of St. Thomas's Hospital.
Hicks, Edward John William, George-street, Hanover-square, of Guy's Hospital.
Jones, Charles Griffith, Cardigan, South Wales, of St. Bartholomew's Hospital.
Jones, James Thomas, Tredegar, Mon., of St. Thomas's Hospital.
Keates, William Cooper, Peckham-rye, of St. Thomas's Hospital.
Kingsford, Percival, L.S.A., Sunbury-on-Thames, of Guy's Hospital.
Leonard, John, Sheffield, of the Charing-cross Hospital.
Mahon, Edward Elphinstone, Aspley Guise, Beds, of St. Mary's Hospital.
Paley, James Hewitt, Honduras-terrace, E., of Guy's Hospital.
Palmer, Frederick John Morton, L.R.C.P. Edin. and L.S.A., Old Kent-road, of Guy's Hospital.
Stephens, Augustus Edward Richard, Chatham, of the Charing-cross Hospital.
Sturge, William Allen, Bristol, of University College.

Taylor, Christopher Musgrave, Wrawby, Lincolnshire, of St. Thomas's Hospital.
Whittingham, George William, Rutland-street, of University College.

Admitted Members on the 26th inst., viz.:—

Adams, James, M.B. Aberd., Kingsbridge, Devon, student of St. Bartholomew's Hospital.
Bevan, John Paul, New Cross, of Guy's Hospital.
Cattell-Jones, Thomas, Dalston, of Guy's Hospital.
Cursetjee Framjee Khory, M.D. Grant College, Bombay, of the Bombay School.
Gabb, James Edward, Dowdeswell, Gloucestershire, of St. Bartholomew's Hospital.
Gaunt, John Penn, Alvechurch, Worcestershire, of the Birmingham School.
Hills, Thomas Hyde, Maidstone, of St. George's Hospital.
Holden, Lonsdale Andrew, Durham, of St. Bartholomew's Hospital.
Humphreys, Robert William, Carnarvon, of Bartholomew's Hospital.
Johnson, Francis, Brigg, Lincolnshire, of the London Hospital.
Rustamjee Cowasjee Badhurjee, M.D. Grant College, Bombay, of the Bombay School.
Satchell, Walter Alfred, Kensington, of St. Mary's and Charing-cross Hospitals.
Woodforde, Alfred Pownell, Clevedon, Somerset, of St. Bartholomew's Hospital.

Of the 175 candidates examined, 53 having failed to acquit themselves to the satisfaction of the examiners, either in Surgery or Medicine, or both, were referred to their professional studies. The Court of Examiners will not meet again till November. Those candidates not examined in Medicine possessed the following medical degrees:—M.B. Cantab., 2; L.R.C.P. Lond., 1; L.R.C.P. Edin., 2; L.R.C.P. & S. Edin., 1; L.R.C.P. Edin. and L.S.A., 1; M.B. Aberd., 4; M.B. Edin., 2; L.S.A., 25; L.K. & Q.C.P. Ire., 4; L.M. Durham, 2; M.D. Philad., 1; and M.D. New York, 2.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examination during the July sittings of the examiners:—

Crawford, John Liston, Girvan.
Grant, James, Caithness.

The following gentlemen passed their final examination, and were admitted Licentiates of the College:—

Brown, John, Melrose.
Greene, John Joseph, Dublin.
Maxwell, Theodore, Barnsley.
M'Naughtan, John, Perth.
Whittington, Thomas Price, Glamorgan.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, July 24:

Chaple, Charles, Burdett-road, E.
Deakin, Chas. Washington Shirley, Kingstone Grange, Hereford.
Drake, Arthur John, Kingsclere, Bucks.
Eskell, Maurice Clifford, Grosvenor-street, Grosvenor-square, W.

The following gentlemen also on the same day passed their primary professional examination:—

Barnes, James John Fredk., Westminster Hospital.
Beaumont, William Marden, Middlesex Hospital.
Romano, Fredk. Wm. Richard, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ASHBY, ALFRED, M.B. Lond., F.R.C.S.—Medical Officer of Health for the Rural Sanitary Districts of the Grantham, Newark, and Sleaford Unions, and the Grantham, Little Gowerby, Newark-upon-Trent, Sleaford, and Ruskington Urban Sanitary Districts.

CURTIS, ALBERT, M.R.C.S. Eng., L.S.A.—Medical Officer of Health for Staines.

DAVIES, WILLIAM, M.R.C.S., L.S.A.—Assistant Medical Officer to the Northumberland County Lunatic Asylum.

GREALY, JOHN, L.R.C.P., L.R.C.S. Edin.—Medical Officer for the Spiddal District of Galway Union.

MORGAN, GEORGE, M.R.C.S.E.—House-Surgeon to the London Hospital.

MORGAN, WM. LEWIS, L.R.C.P. Lond., M.R.C.S. Eng.—House-Surgeon to the London Hospital.

PIERCE, FREDERICK MORRISH, M.D., L.R.C.P. Lond.—Physician to the Hulme Dispensary, Manchester.

RHIND, SAMUEL, L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer of Health for the Joint Districts of Tormoham and St. Mary's Church, Torquay.

WEBB, WILLIAM, M.D., F.R.C.S. Eng.—Certifying Surgeon for the Factories at Wirksworth, Matlock Bath, Cromford, Lea, and Bonsall, in the county of Derby, *vice* William Cantrell, F.R.C.S., resigned.

NAVAL APPOINTMENTS.

ADMIRALTY.—Patrick Keelan, Staff Surgeon, additional to the *Asia;* Septimus Terry, Staff Surgeon to the *Duke of Wellington;* Dr. Alexander Turnbull, Staff Surgeon to the *Cambridge;* E. C. Thompson, Staff Surgeon to the *Lord Warden;* Septimus Sexton, Surgeon to the *Jackal.* Bradley Gregory, Staff Surgeon to the *Spiteful;* John M. Hunter, M.D., Staff Surgeon to the *President;* John Nihills, Staff Surgeon to the *Serapia;* Seaton Wade, Staff Surgeon to the *Crocodile;* Cecil Drake, Surgeon to the *Narcissus;* Robert A. Bernal, M.D., Surgeon to the *Spiteful.*

BIRTHS.

GARRETT-ANDERSON.—On July 28, at 20, Upper Berkeley-street, Portman-square, Mrs. Garrett-Anderson, M.D., of a daughter.

HARLEY.—On June 24, at Saffron Walden, the wife of Edward Harley, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., of a daughter.

JACOB.—On July 24, at 79, Harcourt-street, Dublin, the wife of Archibald Hamilton Jacob, M.D., F.R.C.S.I., of a daughter.

ORANGE.—On July 27, at Broadmoor, Wokingham, Berks, the wife of Wm. Orange, M.D., of a daughter.

MARRIAGES.

DIXON—FORSTER.—On July 29, after banns, at Bisham Church, near Marlow, Stephen Brown Dixon, Esq., of Pewsey, Wilts, to Emily, eldest daughter of J. Cooper Forster, F.R.C.S. Eng., M.B. Lond., of 29, Upper Grosvenor-street, W.

DREW—THOMPSON.—On July 23, at Christ Church, Brondesbury, Walter Henry Drew, M.D., of 72, Gower-street, Bedford-square, to Edith Emma (Woodie), second daughter of William Thompson, Esq., The Avenue, Brondesbury.

FINNY—WATSON.—On July 24, at St. Matthias Church, John Magee Finny, M.B., of Lower Baggot-street, to Agnes Anne, youngest daughter of William Watson, Esq., of 25, Fitzwilliam-place, Dublin.

GREAM—GOOCH.—On July 28, at St. George's, Hanover-square, George T. Gream, M.D., F.R.C.P. Lond., L.K.Q.C.P. Dub., of 2, Upper Brook-street, Grosvenor-square, and Frogmore Lodge, Herts, to Lady Gooch, widow of the late Sir Edward Sherlock Gooch, Bart., of Benacre, Suffolk, and daughter of R. A. Hankey Hirst, Esq., of the Down Grange, Hants.

HALL—WILLIAMS.—On July 22, at the parish church, Blore, Staffordshire, James Thomas Hall, M.R.C.S., L.R.C.S., of Alton, to Mary Jane, younger daughter of Wm. Williams, Esq., Solicitor, Caton House, Calton.

KENNEDY—ABERCROMBIE.—On July 22, at Christ Church, Cheltenham, George O'Brien Kennedy, Esq., of York-street, Dublin, to Clara, eldest daughter of John Abercrombie, M.D., of Suffolk-square, Cheltenham.

LUND—CLARKE.—On July 24, at St. John's Church, Hackney, Edwin, third son of the late John Richard Lund, Esq., of 41, Cornhill, and Manor-park, Lee, Kent, to Charlotte Emily (Emmie), second daughter of Benjamin Clarke, F.R.C.S., of Upper Clapton, Middlesex.

TRENCH—SOWTON.—On July 24, at St. John's, Notting-hill, William Power Banbury Trench, eldest son of the late John Power Trench, M.D., Staff Surgeon, to Elizabeth Marianne Pennington (Bessie), eldest daughter of the late Wm. March Sowton, Esq., of the Inner Temple, barrister-at-law.

WHEELER—PRICE.—On July 23, at Holy Trinity Church, Margate, the Very Rev. Thomas Wheeler, co-Dean of Bocking, and Rector of Hadleigh, Suffolk, to Matilda Lydia, eldest surviving daughter of the late David Price, M.D., J.P., of Margate.

DEATHS.

BRIDGE, ALEXANDER, M.R.C.P. Lond., F.R.C.S. Eng., L.S.A., at 7, Argyle-place, on July 23, aged 59.

CARTER, MARY ANNE TROUGHTON, widow of the late William Francis Carter, M.D., R.N., at the residence of her son-in-law, J. A. Warwick, Esq., 22, Lorn-road, Brixton, S.W., on July 23, in her 70th year.

CHANDLER, ANNE COOPER, wife of Thomas Chandler, M.R.C.S. Eng., L.S.A., at 10, King-street, Finsbury-square, E.C., on July 29.

FULLER, HUGH PITTER, M.R.C.S. Eng., L.S.A., at his residence, Bramerton House, Abbey-road, N.W., on July 29, in his 61st year.

SHILLITOE, ERNEST BUXTON, eldest son of Buxton Shillitoe, F.R.C.S. Eng., at Birch Mount, Sydenham Hill, on July 4, aged 17.

SINCLAIR, DONALD, M.D. Edin., M.R.C.S. Eng., youngest brother of the late Sir John Sinclair, Bart., of Barrock, N.B., at 1, Lyndhust-road, Peckham, on July 23, in his 59th year.

WARD, WILLIAM, M.D., F.R.C.S. Eng., L.S.A., of Huntingdon, on July 22, in his 74th year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to the Medical Committee, Children's Hospital, Steelhouse-lane, on or before August 4.

BOURNEMOUTH DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

BRADFORD INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to W. C. Woodcock, Secretary, 65, Market-street, Bradford, on or before August 4.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

COVENTRY PROVIDENT DISPENSARY.—Surgeon. Candidates must be M.R.C.S. of London, Dublin, Edinburgh, or Glasgow, and possess a licence from one of the Royal Colleges of Physicians, or from the Society of Apothecaries. Applications, with testimonials, to the Honorary Secretary, on or before August 2.

DERBY COUNTY ASYLUM.—Assistant Medical Officer. Candidates must be duly qualified in Medicine and Surgery. Applications, with testimonials, to John Barber, County Lunatic Asylum, Mickleover, Derby.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Applications, with testimonials, to the Secretary, 4, Victoria-street, Derby.

ESSEX AND COLCHESTER HOSPITAL.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Committee, on or before August 21.

KNIGHTON UNION.—Medical Officer for the Llanbister District. Candidates must be legally qualified medical practitioners. Applications, with testimonials, to Edward Hooper Deacou, Clerk to the Guardians, Knighton, Radnorshire, before August 2.

LEICESTER INFIRMARY AND FEVER HOUSE.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, 24, Friar-lane, Leicester, on or before August 4.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Demonstrator of Anatomy. Applications, with testimonials, to R. Harrison, Registrar (of whom particulars may be obtained), before August 13.

LOYAL UNITED BRETHREN BENEFIT SOCIETY.—Surgeon and Apothecary. Candidates must be M.R.C.S.E. Applications, with testimonials, to the Secretary, Mr. S. Emmanuel, 24, High Holborn, W.C., on or before August 4.

NORTH BIERLEY UNION.—Medical Officer of Health. Applications, with testimonials, to W. Lancaster, Esq., Solicitor, Bradford, Yorkshire, on or before August 4.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Junior House-Surgeon. Candidates must be Graduates in Medicine of one of the Universities, or Members or Licentiates of one of the Colleges of Surgeons of the United Kingdom, and duly registered. Applications, with testimonials, to the Secretary, on or before August 6.

ROYAL SOUTH HANTS INFIRMARY, SOUTHAMPTON.—House-Surgeon. Candidates must be M.R.C.S. and L.S.A. Applications, with testimonials, to the Assistant-Secretary, on or before August 16.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Physician's Assistant. Candidates must be graduates in Medicine of a British University, or be possessed of such medical qualifications as are satisfactory to the Medical Committee. Applications, with testimonials, to the Chairman of the Medical Committee, on or before August 9.

WREXHAM INFIRMARY AND DISPENSARY.—House-Surgeon. For particulars, apply to Mr. J. G. Buckton, Secretary, 9, High-street, Wrexham.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Bridgwater Union.—Mr. Antey has resigned the Middlezoy District. Area 6997; population 2317; salary £36 per annum.

APPOINTMENTS.

Barnsley Union.—William Ritchie, Queen's University, Ireland, M.R.C.S. Eng., to the Hoyland Nether District.

Boston Union.—James A. Storey, L.R.C.P. Edin., L.R.C.S.I., to the Sutterton District.

Cardigan Union.—James M. Phillips, M.D., M.R.C.S.E., L.S.A., to the Second District.

Chelmsford Union.—Ebenezer Shedd, L.R.C.S., L.S.A., to the Second District.

Falmouth Union.—Newton Greenwood, M.R.C.S.E., L.S.A., to the Penryn District.

Guildford Union.—Joseph H. Sutcliff, M.R.C.S.E., L.S.A., to the Horsley District.

Kingsbridge Union.—Frederick Howard Clarke, L.R.C.S., L.S.A., to the Seventh District.

Liverpool Parish.—Alexander M. S. Hamilton, M.D., M.R.C.S.E., to the Brownlow-hill Workhouse.

St. Saviour's Union.—Alfred Matcham, M.R.C.S., L.R.C.P.E., L.S.A., to the First District.

Spilsby Union.—Richard Lauphier, M.B.T.C.D., L.R.C.S.I., to the Alford District.

West Derby Union.—Alexander Dunbar, M.B., C.M. Edin., to the Workhouse.

QUEKETT MICROSCOPICAL CLUB.—The eighth annual general meeting was held on Friday evening last, July 25, at University College, Gower-street, Dr. Braithwaite F.L.S., F.R.M.S., President, in the chair. The report of the committee for the past year was read, and testified to the continued prosperity of the Club, which now numbers 570 members. The president delivered the annual address, in the course of which he noticed the progress of microscopical investigation in botany and zoology. The ballot then took place for the election of officers. Dr. Braithwaite was re-elected president. Dr. Matthews, Messrs. B. T. Lowne, T. W. Burr, and C. F. White vice-presidents; and Messrs. Bywater, Crisp, Hailes, Hind, Waller, and T. C. White were elected to fill the six vacancies on the committee. Mr. J. E. Jugpen succeeded Mr. T. C. White, who retires from the office of honorary secretary owing to increase of his professional duties, after four years of unremitting and valuable service. The proceedings terminated with the usual *conversazione*.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

H. C. C.—Consult your medical attendant.

A Father.—The Naval and Indian Medical Services are both in want of qualified practitioners.

M.R.C.S.—The new Naval Hospital was established on shore, at Hong-Kong, on May 29. The hill on which the establishment stands has in compliment to the commander-in-chief been called Mount Shadwell. The old Melville Hospital ship will now probably be broken up.

Inquirer.—The Scandinavian Congress of Naturalists held its meeting at Copenhagen at the beginning of last month.

Epidemic.—At the Stockwell Small-pox Hospital in the years 1871 and 1872 there were 4747 cases of small-pox under treatment, and the average death-rate was 17·8 per cent.

A Member.—Write at once to the Secretary of the College, when you will obtain a ticket of admission to the *conversazione*, to which Members of the College and also of the Association are invited.

A Tutor.—The list of those who passed at the recent preliminary examination in Arts, etc., for the diplomas of Fellowship and Membership of the College of Surgeons is too long for publication at the present moment in the *Medical Times and Gazette*.

S. S. P.—It is distinctly stipulated in the 27th section of the Vaccination Act of 1867, 30 and 31 Vict., cap. 84, that the guardians on receipt of the registrar's half-yearly list of defaulters "*shall* make inquiry into the circumstances of the cases contained in the said list, and if they find that the provisions of the Act have been neglected, *shall* cause proceedings to be taken against the persons in default." Thus a duty is imposed upon guardians which they cannot disregard without infringing an important direction of the Act.

C. N. S.—Dr. Andrew Marshall built a dissecting-room and opened an anatomical school in Thavies Inn, to which his reputation attracted a large number of pupils.

Senex.—William Barrett, an eminent surgeon, of Bristol, died at Higham, in Somersetshire, September 15, 1789. He was the author of the "History and Antiquities of the City of Bristol."

CASE OF AORTIC OBSTRUCTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I send a few notes of a case of obstruction of the aortic valves which perhaps you may think worthy of insertion in your next number.

W. B., aged about 57, had come under my care in March, 1872, for gout. He had at this time considerable enlargement of the liver, and a well-marked, though not very loud, systolic bruit heard only at the base of the heart, and traceable for some distance up the course of the aorta. He had been a constant dram-drinker, frequently consuming a pint and a half of whisky in the twenty-four hours. Under treatment the gout disappeared, and he recovered sufficiently to go to the seaside in July for change of air.

He came back in August, and on the 12th of that month I was sent for again, and found him suffering from severe præcordial oppression, considerable œdema of the lower extremities, and total loss of sleep. His tongue was foul, and his lips congested. The base of both lungs dull on percussion, and without any respiratory murmur. Pulse 75, soft and round. Liver still enlarged. Systolic bruit at base of heart unchanged. Cough troublesome.

Under small doses of pil. hydrarg. with pulv. Doveri and night draughts of henbane, Indian hemp, and Hoffman's ether (afterwards changed for bromidi potassii, chloral hydrate, āā gr. xij., in a draught at bedtime), he improved, and for a month did well; but on September 18 he was attacked with violent vomiting, with a feeling of fulness in right side. Pulse 72, hard and full. Vomiting allayed by a blister to epigastric region. The præcordial oppression and want of sleep then returned, and the pulse became most variable—from 65 to 75—sometimes hard and jerking, sometimes soft and intermittent.

On the 26th vomiting returned with constipation. Breathing laboured. Pulse 80, intermittent and compressible. At this time the area of hepatic dulness was not at all enlarged. Vomiting checked by ice dipped in brandy, and allowed to dissolve on tongue.

29th.—Severe attack of angina pectoris. Pulse 120, feeble and intermittent. Orthopnœa. Heart thumping violently; bruit as before. The œdema of extremities at this time had returned considerably.

October 4.—Another tremendous attack of vomiting, with cold clammy sweats. Ice dipped in brandy with iced brandy-and-water and iced beef-tea gave relief when creasote, hydrocyanic acid, sinapisms to the epigastrium, *et hoc genus omne*, had failed.

18th.—Almost sleepless at night, and when sleep comes it is attended with horrible dreams. Eyes suffused; manner wild. Complains of a feeling of oppression in the left side, extending from the head to the knee. Frequent attacks of faintness, accompanied by cold sweats. Œdema at a standstill.

23rd.—Visible pulsation of carotids, never observed before. Bruit unchanged in character, and heard over exactly the same area as before. Patient beginning to rave at night.

30th.—Suppression of urine, which yielded to sinapisms over kidneys. Delirium at night much increased. Mind wanders at times through the day. Patient becoming violent and unmanageable. Insisted on going to Dublin, and actually got his way, having thrown down a man-servant who tried to prevent his leaving the house.

November 15.—Returned from Dublin. The œdema of extremities is now very great; face, scrotum, and prepuce also œdematous. From the size of the two latter the penis is completely hidden. Some ascites also present. Bruit unchanged. Urine free from albumen. Very irritable, and at times dangerous.

At this time I tried the following mixture:—℞. Liq. hydrarg. perchlor. B.P. ʒj., tinct. scillæ, tinct. digitalis, āā ʒij., spt. juniper, spt. chloroform, āā ʒiv., decoct. cinchon. ad ℥xij. Sig.: a tablespoonful thrice daily.

21st.—Albumen present in urine for first time. Anasarca less. Pulse 120, jerky and feeble.

22nd.—No albumen present in urine. Mind terribly astray.

28th.—Anasarca much less. Patient very sleepy. Pulse 100, very weak. Urine high-coloured, acid reaction, scanty, sp. gr. ·024; no bile present, but heat and nitric acid threw down a deposit of albumen to the extent of one-fourth fluid in test-tube.

29th.—Coffee-ground vomit and suppression of urine.

30th.—Died quietly in a comatose state.

The circumstances in this case to which I wish to call attention are—first, the apparently trivial nature of the bruit which marked disease of so severe a nature; secondly, that the bruit never became intensified or altered from first to last. The third point to which I wish to call attention is the various ways in which the heart disease was masked, as it

were, by the very symptoms which it produced. There was congestion of the back of both lungs; and as the systolic bruit was audible only over the base of the heart, and for about two inches up the course of the aorta, it might very possibly have been overlooked, and the case treated as one of simple congestion with gout. The next set of symptoms which developed themselves were gastric—violent vomiting, etc.; next in order came more distinctive cardiac symptoms—fainting fits, cold sweats, horrible dreams, orthopnœa, angina pectoris; then came the mental alienation—due, I presume, to an insufficient supply of arterial blood to the brain; and, lastly, the immediate heralds of death's approach were the appearance of albumen in the urine, showing that the tired kidneys could no longer perform the extra work cast upon them, and the coffee-ground vomiting, probably caused by blood oozing through the coats of the gastric vessels for want of the ordinary means of escape checked by the valvular obstruction.

As to remedies I need say little. Minute doses of mercury seemed to give most relief to the heart symptoms, and to increase the effect of diuretics in causing absorption of the anasarca. The angina and fainting fits seemed most under the control of equal parts of spt. ammon. arom., Hoffman's ether, and spt. chloroform—a teaspoonful in cold water for a dose. The vomiting could only be checked by ice and brandy; and as for the want of sleep, opium and morphia in various forms, Indian hemp, lupuline, henbane, chloral hydrate, bromides of potassium and ammonium were all tried, and all found equally unavailing. I am, &c.,

Armagh, Ireland. A. Leslie Mease, M.B.

APPOINTMENTS FOR THE WEEK.

August 2. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

4. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

5. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

6. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

7. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

8. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

EXPECTED OPERATIONS.

London Hospital.—The following Operations will be performed on Thursday next, at two o'clock:—

By Mr. Hutchinson—Lithotomy, and other operations.

VITAL STATISTICS OF LONDON.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·87 in. The highest was 30·03 in. on Monday morning last, and the lowest 29·73 in. at 9 a.m. on Wednesday.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

SUPPLEMENT

TO THE

Medical Times and Gazette.

No. 1205. LONDON, SATURDAY, AUGUST 2, 1873. Vol. II. 1873.

A COMPANION FOR VISITORS

TO THE

MEETING OF THE BRITISH MEDICAL ASSOCIATION,

LONDON, AUGUST, 1873:

BEING A DESCRIPTIVE CATALOGUE OF PLACES OF MEDICAL INTEREST IN THE METROPOLIS.

The meeting of the British Medical Association in London will without doubt bring together a large number of medical practitioners from the provinces, who have had of late years but little actual acquaintance with the places and sights of interest in this great city. It has therefore seemed probable that to many of our readers a short descriptive catalogue of the principal institutions and places of scientific, general, and especially of medical interest in the metropolis might be a real boon. We therefore offer them this Supplement to our journal, not as an exhaustive account of all worth seeing—for this would fill a large Murray or Baedeker, and would detain our guests as many weeks as the Association meeting will number days,—but as a help to spend their spare hours during their absence from the sections with amusement and profit.

We may divide London into the five principal divisions—the City, the West-end, the East-end, the North, and the South. In each of these the medical visitor will find a number of places of interest. Some of the chief of these we shall now indicate. We will begin with the City proper.

THE CITY.

Starting from King's College, the City—the oldest part of London—may be reached by the Strand or by the new Thames Embankment. In the City, besides the time-honoured attractions of St. Paul's and the Tower, which the medical visitor should see, if he has not done so in the days of his boyhood, we would point out as institutions especially worth a visit the following:—

ST. BARTHOLOMEW'S HOSPITAL.

This magnificent Hospital, by far the oldest in London, is so replete with interest that only comparatively few of its attractions can be noticed here. Entering by the west gate from Giltspur-street, the visitor will find before him the gardens with the large blocks of buildings containing the wards. Of these we can only say that they will amply repay a visit. On the west side of the Hospital are the College buildings. The museum is large and excellent, and is decorated with busts of Hunter, Freke, Pott, Lawrence, etc. The visitor should on no account neglect to ask for the handsome new laboratory for practical chemistry. Towards the south side of the Hospital will be found the dispensary, where the application of steam in practical pharmacy and the arrangements for supplying hundreds of patients daily with medicine are very wonderful. At the north-east corner are the casualty out-patients' rooms, where a single physician may *see* over 200 patients of a morning.

St. Bartholomew's also possesses much of æsthetic interest. By the kindness of the authorities the grand staircase and the various halls will be thrown open for the inspection of members of the Association. The walls of the grand staircase are splendidly decorated, being chiefly occupied by two magnificent paintings by Hogarth of "The Good Samaritan" and "Christ at the Pool of Bethesda." The great hall at the top of the staircase is of splendid proportions and elaborate finish. It contains several excellent pictures—as St. Bartholomew, by Carducci; Henry VIII., unknown; and portraits of William F. White, Esq., by Knight; Sir G. Carroll, Sir W. Pritchard, and Alderman Lucas. There are also a plaster bust of Harvey; a marble bust of Abernethy, by Sievier; and a painted window given by the son of Alderman Barber. In the Prince's Room, beside the hall, are some fine water colours. Returning downstairs, the visitor will find on the right the committee-room, with several very interesting portraits in oil—Henry VIII., probably by Janssen or Holbein; Percival Pott, by Reynolds (extremely fine); Abernethy, by Sir Thomas Lawrence; Sir William Lawrence, by Pickersgill; Dr. Baly, by Knight; Dr. Burrows, by Knight; Dr. Radcliffe, by Kneller; John Vincent, by Eddis; and Colston and Sir N. Rainton, by doubtful artists. The portrait of Sir James Paget, by Millais, is not yet hung. On the north side of the Hospital is the Church of St. Bartholomew the Less, which ought to be seen. The tower at the right of the entrance is all that remains of the original priory of the same name. The fine alabaster pulpit is by Phyffers, of Belgium. Above the church-gate (1702) are two figures of cripples and a statue of Henry VIII. A few yards to the right of this gate, beyond the out-patients' entrance, is to be seen in the wall a tablet to the memory of several martyrs burned near the spot at the time of the Reformation.

The medical officers at St. Bartholomew's visit the Hospital at 1.30 p.m.:—Dr. Black on Monday, Tuesday, and Thursday; Dr. Harris on Tuesday, Thursday, and Saturday; Dr. Andrew on Monday, Tuesday, Thursday, Friday, and Saturday; Dr. Southey on Monday, Wednesday, Thursday, and Saturday. The surgeons—Mr. Holden, Mr. Savory, Mr. Callender, and Mr. Thomas Smith—attend almost daily. The physician-accoucheur, Dr. Greenhalgh, attends on Thursday at 1.30 p.m. and Saturday at 9 a.m. The ophthalmic surgeons attend—Mr. Power on Tuesday and Thursday, Mr. Vernon on Thursday and Saturday. Operations on Wednesday and Saturday at 1.30 p.m.; ophthalmic operations on Tuesday at 1.30 p.m. Post-mortem examinations at 1 p.m. and 2.30 p.m.

BARBER-SURGEONS' HALL.

In the old *Barber-Surgeons' Hall*, Monkwell-street, near the Hospital, is Holbein's celebrated picture of Henry VIII. presenting the charter to the company at the time of the union of the surgeons and barbers in 1540, Mr. Thomas Vicay kneeling to receive the charter. Among the other figures are those of Sir John Chambre in a furred gown, and the famous Dr. Butts, introduced by Shakespeare in "Henry VIII."

THE GUILDHALL MUSEUM AND LIBRARY.

The new building for the Library and Museum of the Corporation of the City of London has a special interest for members of the medical profession, inasmuch as one of our *confrères*, Dr. Sedgwick Saunders, has taken a very active part in promoting its erection. The new building is in general accordance with the Gothic of the old Guildhall, and its windows and fittings are of remarkable beauty. The Museum contains some most interesting specimens of Roman London, and the Library possesses MSS. of great antiquarian interest. The Guildhall, which is approached by King-street, Cheapside, is a grand specimen of Gothic civic architecture. It was restored in 1865.

APOTHECARIES' HALL, BLACKFRIARS.

Many of our visitors may like to see "the Hall" once more, and to inspect some of the curious and valuable pictures which it contains. The Hall, which is situated in Water-lane,

Blackfriars, has been but little altered since the Great Fire of London, and is a very good specimen of Stuart domestic urban architecture. It contains an unique portrait of James the First of England and Sixth of Scotland (which we cannot help thinking Sir Walter Scott must have seen before he wrote "The Fortunes of Nigel"), and many other portraits of interest, especially a fine one of the late Professor Brande, and one of Mr. Wheeler, formerly Lecturer on Botany at St. Bartholomew's.

The stranger should also, before leaving the City, see the Bank of England, the Mansion House, and Royal Exchange. Returning to King's College along Fleet-street, the Temple with its ancient church and modern library—its memories of Johnson and Dickens, and the grave of Goldsmith—is well worth a visit.

In Somerset House are the meeting-rooms of the Society of Antiquaries and the Astronomical Society. The former possesses a very remarkable collection of English historical portraits and a good library.

Admission to the rooms of most of the learned societies may be obtained from the Fellows or Members.

THE EAST-END.

For those whose curiosity or love of investigation will lead them to the East-end of the metropolis, there are several institutions worthy of the attention of the country or foreign medical man. If he selects to go by underground railway to Moorgate-street, there is the Ophthalmic Hospital, Blomfield-street, Moorfields, within three minutes' walk. After this has been visited, a green omnibus to Mile-end will within fifteen minutes convey the visitor to the London Hospital. From the London Hospital the distance to the City of London Hospital for Diseases of the Chest, Victoria-park, is within a walk or cab-drive of a mile and a half, and from Victoria-park Hospital the distance to the Bethnal-green Museum is very slight indeed. Any of these places are easily accessible from any central or west part of London by omnibus as well as cab. To Bethnal-green omnibuses pass every ten or fifteen minutes along Grosvenor-place, Piccadilly, Long Acre, and Cheapside. To the London Hospital any Mile-end 'bus will pass close by the building. Victoria-park may be reached by omnibus or rail from the City.

THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS,

founded in the year 1804, owes its origin and success as a school for ophthalmic surgery to John Cunningham Saunders, who first adapted the operation for cataract to the condition of infancy. It is the earliest, in order of time, of institutions of this kind, now so general in this and other countries. It is situated in Blomfield-street, E.C., close to Broad-street Station, and within three minutes' walk of Moorgate-street Station; it is also within six or seven minutes' walk of the Bank of England. Some of the Surgeons attend every morning from nine till about twelve o'clock—thus, Mr. Bowman, Mr. Critchett, and Mr. Lawson attend on Tuesdays and Fridays; Mr. Hulke and Mr. Wordsworth on Wednesdays and Saturdays; Mr. Hutchinson and Mr. Streatfeild on Mondays and Thursdays. There are operations upon the eye most days at about eleven o'clock.

Any of the resident staff will be happy to show strangers over the wards and other parts of the building upon the presentation of their visiting cards, and the curator of the museum or his deputy will accompany any visitor through the small museum connected with this Hospital.

In this museum, which has not long existed, are already contained very complete sets of pathological specimens of eyes lost after pyæmia, syphilis (acquired and inherited), fevers, measles, small-pox, injuries and operations; others illustrative of the ravages of diseases of different tissues of the eye; and a numerous assortment of coloured drawings of ophthalmoscopic and naked-eye views of diseased eyes.

THE LONDON HOSPITAL.

The school buildings of this Hospital are very compact, and the museum contains several excellent anatomical specimens, and some admirable coloured portraits of skin diseases lent by Mr. Hutchinson, as well as some of pathological conditions of many of the viscera by Dr. Sutton. It is worth while to call to the minds of intending visitors to the London Hospital that it enjoys the credit of having, in 1785, set the first example of a complete medical school, in connexion with a hospital, upon the model of the medical faculty of an university; and in 1792, besides courses of lectures on the then usual subjects of medical education, a course of lectures on clinical medicine was at that time given in the school. The present medical college was inaugurated in 1854, and enlarged in 1867. Previously the school buildings—the expense of erecting which devolved to a great extent upon one of the officers of the period, Sir W. Blizard—stood at the east end of the Hospital.

In the Hospital will be found ophthalmic, venereal, and clinical wards—these latter being essentially similar to those at Guy's Hospital, in which cases are set aside for the more accurate and painstaking observation and instruction. The days and hours of attendance in the wards of the physicians and surgeons are the following:—Dr. Davies at 8.30 a.m. on Tuesdays and Fridays; Dr. Andrew Clark at 1.30 p.m. on Mondays and Thursdays; Dr. J. S. Ramskill and Mr. Couper at 1.30 p.m. on Wednesdays and Saturdays; Dr. Langdon Down and Mr. Maunder at 1.30 p.m. on Tuesdays and Fridays; Mr. Hutchinson at 2 p.m. on Mondays and Thursdays; Mr. Rivington at 1 p.m. on Mondays and Thursdays. The obstetric wards are visited by Dr. Head at 1.30 p.m. on Tuesdays and Fridays. The regular operating day is Wednesday at 2 p.m.

VICTORIA-PARK AND THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

This picturesque and capacious park serves as a huge lung for the inhabitants of Spitalfields and Bethnal-green. The first cost of its formation was covered by the purchase-money received from the Duke of Sutherland for the Crown lease of York House, St. James's. A very handsome granite Gothic drinking-fountain was erected in the park, at a cost of £5000, by Baroness Burdett Coutts.

The Hospital was established in 1848, and the new building at the Victoria-park was opened in 1855. The Hospital contains accommodation at present for 120 patients, in wards of two, four, six, eight, and twelve beds, each so as to afford opportunities for the proper classification of the cases. There is a good day-room for convalescents and excellent corridors in which patients take exercise.

Recently a new wing has been added, which, when furnished, will allow the number of beds to be increased to 164. The Hospital is always open to visitors.

BETHNAL-GREEN MUSEUM

is open daily, except on Sundays. On Monday, Tuesday, and Saturday admission is free from 10 a.m. to 10 p.m.; on Wednesday, Thursday, and Friday, admission 6d., from 10 a.m. to 6 p.m. As we have said, the distance from Victoria-park and the London Hospital to the Bethnal-green branch of the South Kensington Museum is not great. It is situated close to the Mile-end Station (one mile from Shoreditch on the Great Eastern Railway), near the junction of the Hackney and Cambridge-heath Roads, one mile and three-quarters from the Bank of England, and two miles from the General Post-office. Omnibuses run in all directions to and from most parts of London.

The oblong open space upon which it is situated was bought as a gift to the poor in the reign of James I. The building is to a very considerable extent constructed of the iron columns, floors, and fittings of the old iron buildings of South Kensington Museum; but brick walls and a slate roof give the East London building more dignity of appearance and greater permanency than the old "Brompton boilers" possessed. In front of the principal entrance has been erected that well-known fountain of majolica, made by Messrs. Minton, which formed a principal ornament of the International Exhibition of 1862, and which was afterwards placed in the Horticultural Gardens. The interior arrangements of the building consist of a large hall, around which runs a double gallery—the lower one raised some feet above the level of the hall, and of moderate height; the upper gallery reaching to the roof, and obtaining, in consequence, an upper light very favourable to the exhibition of the beautiful pictures and other works of art here collected. At the beginning of the year 1872, when the building was sufficiently advanced for the reception of objects, two important collections, formerly exhibited in the South Kensington Museum, were transferred to the Bethnal-green branch—viz., the *Animal Products Collection* and the *Food Collection*. These, with an important series of examples of *Economic Entomology*, now occupy the whole of the space on the ground-floor under the galleries, and, forming as they do no inconsiderable contribution towards a complete trade museum, will

no doubt prove of great and abiding interest and educational value to the inhabitants of the East-end of the metropolis.

The food collection consists of specimens of breads, wines and spirits, the substances used for adulterating foods, the strange objects considered as delicacies by other nations (such as sharks' fins, sea-slugs, and edible birds'-nests), the different kinds of tobacco, and the variable kinds of edible and non-edible fungi.

The portion of the ground-floor *not* under the galleries, and the upper galleries of the Museum, are for the present occupied by pictures and other art treasures, lent by Sir Richard Wallace, who has placed at the disposal of the authorities of the Museum the chief treasures of the long celebrated, though rarely seen, Hertford collection of art objects. These treasures, collected by the late Marquis of Hertford, K.G., during a period of thirty years, have hitherto been almost unknown to the English public, and, in fact, a large portion of them was specially brought over from Paris by Sir R. Wallace just previous to the opening of the Museum. The paintings in oil and water-colours, the porcelain—especially the Sèvres—the majolica ware, and the bronzes are all very fine and particularly worth seeing. As, however, Sir R. Wallace intends to remove everything he has lent on view when his mansion in Manchester-square is finished, it is probable that all these gems and valuables will not remain up to Christmas next. Unquestionably, however, the pictures will form the greatest attraction to visitors—gentlemen as well as ladies. And well they may do, for probably there is not a finer collection of paintings to be seen at the present time in England. They are arranged in the Museum according to their schools—English, Dutch, Flemish, Italian and Spanish, and French. Here are to be seen in perfection the works of Bonington, Canaletto, Claude, Cuyp, Decamps, Greuze, Micris, Murillo, Pater, Rembrandt, Reynolds, Rubens, Turner, Vandernecr, Vandevelde, Vandyck, Velasquez, Vernet, Watteau, Wernix (Jan), Wouvermans (Peter and Philip), and a host of other well-known great artists.

Let all who can take the opportunity while it lasts of seeing this splendid collection of works of art.

GERMAN HOSPITAL, DALSTON, E.

This Hospital, which contains 100 beds, is situated close to London, and can be reached by omnibus from the Bank, or by the North London line of railway. It has been opened since 1845, and is for the reception of poor natives of Germany and others speaking the German language, and English in all cases of accidents. It is in a healthy and pleasant locality, but at the same time in the vicinity of that crowded portion of the East-end of London where most of the poor Germans reside. All the medical officers, the matron, nurses, and servants are German. Some of the physicians make their visits daily, either in the early morning or at two o'clock in the afternoon. The surgeons visit on Wednesdays and Thursdays at about three o'clock.

For the relief of out-patients there are three German Dispensaries in connexion with the Hospital—one in the East and one in the West-end of London, and the third at Dalston, in the front wing of the house. There is also a sanitarium in the Hospital, which offers accommodation to German patients not belonging to the lower classes who, being unmarried or away from their families, desire to have hospital attendance in a room by themselves on payment of a moderate sum.

GREENWICH.

NAVAL COLLEGE, NAVAL SCHOOL, SEAMEN'S HOSPITAL.

Many of our guests will no doubt be tempted by the fame of the dinners at the "Ship" to refresh themselves by a trip by steamboat or railway to the "green Greenwich" which "greets the growing god of day," and where "warbling whitebait win their welcome way." Let those of them to whom the place is new go a little earlier than the hour for dinner, and take a look over the Naval College, picture gallery, the Naval School on the opposite side of the road to the College, and last, but not least, the Seamen's Hospital.

The Naval College—for such, we believe, the "Royal Hospital for Seamen at Greenwich" is now and in the future to be called—is situated on the southern bank of the Thames, and for its architectural beauty is not excelled. The fabric comprises four distinct piles, and the terrace fronting it extends 1182 feet in a straight line east and west. The Painted Hall or Naval Gallery, designed by Sir C. Wren for a large dining-hall, was for a long while used as a refectory for the pensioners, until the number of pensioners had so increased that a different arrangement became necessary. It was then retained as a depository for objects of national interest, and in 1823 it was prepared for the reception of naval pictures. His Majesty King George IV. presented a valuable series of portraits from the galleries of Windsor Castle and Hampton Court, besides paintings from his Majesty's private collections at St. James's Palace and Carlton House.

Here are colossal statues of Nelson, Howe, Duncan, St. Vincent, and others; and a monument to the memory of Franklin by Westmacott. The ceiling, which is beautifully painted in compartments, is the great feature of this gallery. This celebrated work was executed by Sir James Thornhill during a period of nineteen years, and is graphically described by Sir R. Steel in "The Lover," which was written at the period when the work was just completed. The Hall is open every day to visitors.

The Greenwich Hospital School occupies a long range of buildings on the south side of the College, the centre building of which was completed by Inigo Jones: three extensive wings have been subsequently added to it. The school consists of 800 boys between the ages of ten and fourteen years, with the exception of eighty who constitute the "Nautical Division," and who are allowed to remain one year longer. Adjoining the easternmost wing of the school buildings is a very compact and admirably arranged observatory, fitted with mural circle, transit instruments, clocks, and equatorial and other telescopes, for the use of the senior boys of the Nautical Division. Between the centre building and the road separating the school from the Royal Hospital or Naval College, is a handsome model of the deck and upper works of a corvette of 500 tons completely rigged, and with sails bent, wherewith the senior boys are exercised in reefing and furling, etc. This model ship is also supplied with small pieces of brass ordnance, in exercising which a number of the boys acquire a knowledge of gunnery. The school broke up, and most of the boys left for their holidays, on Saturday, July 26; but strangers are permitted to go over the school buildings any day except Sunday, by making application by card to the Captain in residence, who will then give orders for an official to accompany the visitors and explain the different parts of the establishment.

The Seamen's Hospital.—The Seamen's Hospital Society owes its origin to the Committee of 1817-18, appointed to manage a fund for the temporary relief of distressed seamen. In 1821, at a meeting of this same Committee, it was determined to establish a floating hospital on the Thames for the use of sick and diseased seamen only, to be supported by voluntary subscriptions and managed by a committee. The *Grampus* (a fifty-gun ship), moored off Greenwich, was used as the first hospital; but the *Grampus* being too small to satisfy the growing demands of applicants, the Government in the year 1830 exchanged her for the *Dreadnought* (104-gun ship) which was fitted up by the Society for the purposes of the hospital in 1831. In 1857 this vessel having become very unhealthy, was replaced by H.M.S. *Caledonia* (120-gun ship), and her name was altered to *Dreadnought*. Each ship in succession was moored in the most central and eligible situation that could be found in the Thames off Greenwich, but of late years the position of the *Dreadnought* became injuriously affected by the increasing number of iron ship-building yards, the incessant noise from which was very detrimental to the patients. As the act of incorporation of this Society empowered the Committee to build a hospital on shore if thought desirable at any time, it was decided that the floating establishment should be given up. Soon after this decision of the Committee, the Royal Hospital at Greenwich became emptied of its former tenants, and the Lords Commissioners of the Admiralty in the year 1870 granted the Society a lease of ninety-nine years of the infirmary of Greenwich Hospital in lieu of the loan of the ship. This building is entirely separate from the main edifice of Greenwich Hospital or Naval College, and was built for the same kind of work as that carried on by this Society. It affords room for 300 patients, and consists of eighty-eight wards, the majority of which contain but three beds. The Hospital comprises a large quadrangular building, the east and west sides of which are occupied by patients and are two storeys in height; and an adjoining building, which has ground-floor wards only, and is well adapted for casualties. The wards are situated on both sides of a corridor which runs down the centre of every floor. The kitchen and bath-rooms are situated in the centre of the

quadrangle, so that each wing might form a distinct hospital. There is also some ground around the buildings in which the convalescent patients take exercise, and thus in this respect the Hospital possesses a great advantage over the *Dreadnought*.

A visit to this compact and excellent Hospital will well repay the medical man. There are interesting cases to be seen in the wards, and the internal arrangements are well worthy of notice. The resident medical attendants make their rounds in the morning before mid-day, but there is always someone at hand who would be happy to show visitors over the buildings at other times during the day. There is, too, in connexion with this Hospital the nucleus of an anatomical and pathological museum. A great many specimens of skulls of different races of mankind, which even the Committee of Management of the Hunterian Museum might be glad to possess, occupy one large case in the room given up for the purposes of a museum.

Our visitors will now return to King's College. Before starting on a fresh expedition they may, however, wish to know something of the College where the meetings of the Association are taking place.

KING'S COLLEGE AND HOSPITAL.

But little need be said about these buildings for the information of visitors to the British Association meeting, because as the College building is to be the great centre and place of meeting, all the features of these institutions will be brought before the attention of the members of the Association who are present at the London conferences.

It will be sufficient to remark, therefore, that the College is situated between the thoroughfares of the Strand and the Thames Embankment, close to the Temple Station on the Metropolitan District Railway, by which easy access can be obtained from the more distant parts of London and the suburbs. The building includes a house for the principal, rooms for a limited number of matriculated students, a chapel, the general class-rooms for the College and School, museums, libraries, laboratories, anatomical rooms, and workshops. The Hospital connected with the medical department is situated in Portugal-street, Lincoln's-inn-fields.

The Chapel is undergoing restoration in accordance with original designs by Sir Gilbert Scott. The expense of finishing the work and of completeing the organ satisfactorily will amount to £2000. It occurs to us that now would be a very appropriate time for obtaining from the beneficently inclined considerable aid in this undertaking. No doubt when the need is put before the gentlemen attending the Association, the actual and personal acquaintance with it will be sufficient to induce many to contribute. However, even in its present very incomplete state the work has more than realised the hopes and expectations of the Committee of the Restoration Fund. When completed the chapel will, we think, present one of the most artistic and interesting interiors in London.

The Museums.—Her Majesty the Queen having conferred on King's College the valuable collection of mechanical models and philosophical instruments formed by his Majesty King George III., a suitable room has been fitted up for its reception. Extensive additions have been since made to this Museum by the Council and private individuals. This Museum, under the charge of the Professors of Natural Philosophy, Chemistry, and Manufacturing Art, is perhaps unequalled by any other of its kind in London. There are also—(1) a museum of minerals and geological specimens, and of chemical productions both natural and artificial; (2) museums of human and comparative anatomy and of materia medica and botany, in the medical department, under the charge of the curator, Dr. Kelly.

The Libraries are medical and general, quite distinct from each other, and under the charge of separate librarians.

The Hospital, which is situated in what was once a most populous district between Holborn and the Strand, is well adapted for, and furnished with every means of, practical instruction. The hall, staircase, and landings are capacious and lofty, and the operating theatre is undoubtedly one of the best—if not actually the best—in London.

The physicians and surgeons, some of whom attend every day, make their visits as under:—Dr. Johnson, Monday and Thursday, at 2 p.m.; Dr. Beale, Tuesday and Saturday, at 2 p.m.; Dr. Garrod, Wednesday and Friday, at 2 p.m.; Dr. Playfair, Tuesday, Thursday, and Saturday, at 1.30 p.m.; Dr. Duffin, Wednesday and Saturday, at 1 p.m.; Professor Sir W. Fergusson, Bart., Tuesday, Thursday, and Saturday, at 1.30 p.m.; Professor Wood, Monday, Wednesday, and Friday, at 1.30 p.m.; Professor Cartwright, Tuesday and Friday, at 10 a.m.; Professor Wells, Tuesday, Thursday, and Saturday, at 1 p.m.; Mr. Smith, Monday, Wednesday, and Friday, at 1 p.m.

THE NORTH.

THE ROYAL COLLEGE OF SURGEONS, IN LINCOLN'S-INN-FIELDS.

We feel it is unnecessary for us to say one word with regard to the surpassing interest and value of the scientific and literary treasures which are stored in the Hunterian museum and library. These will be open on Wednesday evening to the members of the Association. The College also possesses a fine collection of portraits of distinguished surgeons. The gem of the collection is, of course, the well-known portrait of Hunter, by Reynolds. Besides these are portraits or busts of nearly every surgical celebrity since the time of Percival Pott, and earlier.

THE SOANE MUSEUM.

Exactly opposite the College of Surgeons, on the north side of Lincoln's-inn-fields, is the Soane Museum, which the lover of the beautiful and the curious should not fail to visit. It is open on Wednesday only from 10 a.m. to 4 p.m. by card, which may be obtained at the door. No fee.

The Museum contains several famous pictures, especially Hogarth's two series of "The Rake's Progress" and "The Election," several landscapes by Canaletto, and a sea-piece by Turner. Among the numerous pieces of sculpture is a nymph by Westmacott. There are also a host of curious antiquities—especially an Egyptian sarcophagus of alabaster,—objects of art of the middle ages and of the Renaissance, miniatures, manuscripts, and curiosities of all kinds. One of the most wonderful sights in the place is the manner in which everything is arranged. A number of very valuable books and manuscripts may be seen by express permission of the keeper: among them the most interesting are the first four editions in folio of the works of Shakespeare and the manuscript of Tasso's "Jerusalem Delivered."

Leaving Lincoln's inn-fields by one of the narrow exits on its north side, we reach Holborn. On the north of Holborn is Bloomsbury—classical to the readers of most of our English humourists, from Fielding to Thackeray. But the point of attraction in Bloomsbury is undoubtedly

THE BRITISH MUSEUM,

which will be open daily during the week to members of the Association. We will not attempt to describe, even shortly, the treasures of the British Museum. Every department is represented on a magnificent scale. On entering the building, the visitor should discover from the official guide-book the locality of the departments he is anxious to inspect, and make his way to them at once. He cannot hope to do much more than walk through the most of the rooms at a single visit. The Natural History Department will interest many of the members, and we would especially refer to the magnificent specimen of the gorilla (upper floor, mammalia saloon, case 11), and to the fossils in the northern gallery. We believe there is also a very extensive osteological collection, which may be seen under special circumstances. According to the present arrangements, parties will be formed amongst the members of the Association on the afternoons of Friday and Saturday, August 8 and 9, to visit the British Museum, when objects of special interest will be shown. Names to be given in not later than noon on Wednesday.

Separated from the British Museum by the length of Gower-street are

UNIVERSITY COLLEGE AND HOSPITAL.

Those who attend the *soirée* at University College on Friday evening, August 8, will no doubt have an opportunity of seeing the libraries, the museums, the Flaxman gallery, the Marmor Homericum, and Mr. Cave Thomas's large cartoon. The libraries contain between 60,000 and 70,000 volumes, and upwards of 15,000 pamphlets. They are divided into general and medical, and consist of the Bentham, the Morrison Chinese, the Ricardo, Graves, Sharpey, and many other collections. The museums consist of collections of—(1) philosophical apparatus; (2) geology and mineralogy, greatly added to by the late Sir R. I. Murchison; (3) anatomy, commenced by the purchase of Sir Charles Bell's series of specimens; (4) comparative anatomy, which contains the large and valuable private collection of Professor R. E. Grant. The works of the late John Flaxman,

the first professor of sculpture in the Royal Academy, adorn the hall under the dome of the College, the adjacent apartments, and the staircase. These consist principally of the casts in plaster from the original clay models of groups of figures, statues, and compositions, in alto- and basso-relievo, among which are many of the great artist's noblest productions. They were in his studio at the time of his decease, when they became the property of his executrix and adopted daughter, Miss Maria Denman, who presented them to University College as a free gift. There are, besides, between four hundred and five hundred drawings by Flaxman. The public are admitted by tickets to the gallery on Saturdays during the months of May, June, July, and August, from 10 to 4, but persons properly introduced to the Secretary may obtain admission at any time throughout the year, between 11 a.m. and 4 p.m. The published works of the late Mr. Flaxman may be seen in the College library.

The Marmor Homericum, a mural decoration depicting Homer singing to the Greeks of Delos, was designed and executed by Baron H. de Triqueti. This, situate in the south cloister of the College, was purchased and placed here at the expense of the late Mr. Grote. It consists of eleven pieces arranged as a central composition, borders and angles; composed of pieces of different marbles inlaid and engraved. Its execution is by processes previously unknown. The colouring is given by the incrustation of cements which have the same hardness, adherence, and durability as the marble itself. It is not affected by atmospheric influences—so often fatal to fresco painting,—and it was therefore supposed by its originator as likely to take the place of fresco mural decorations.

The antique studio in the Fine Arts School contains a large collection of models and casts adapted for the purposes of instruction: among them are the Apollo Belvedere from the studio of Flaxman, and a fine cast of the Laocoon presented by the late Sir Matthew White Ridley, Bart.

The *Hospital* is on the opposite side of Gower-street to that on which the College is situated. It contains about 120 beds, and some excellent new and improved bath-room accommodation. The nursing is conducted by ladies of the St. Margaret-street Home. The days and hours at which the surgeons and physicians attend are the following:—

Physicians.—Sir W. Jenner, 1.15 Monday, Wednesday, and Friday; Dr. Russell Reynolds, 2.30 Tuesday, Thursday, and Saturday; Dr. W. Fox, 1.30 Tuesday, Thursday, and Saturday; Dr. Ringer, 1 Tuesday, Thursday, and Saturday; Dr. Bastian, 1.30 Monday and Thursday; Dr. Graily Hewitt, 1.30 Monday and Thursday; Dr. Tilbury Fox, 1.30 Tuesday and Saturday.

Surgeons.—Mr. J. E. Erichsen, 2 Monday, Wednesday, and Friday; Mr. J. Marshall, 2 Tuesday, Thursday, and Saturday; Sir H. Thompson, 1.30 Tuesday and Friday; Mr. B. Hill, 1.30 Monday and Thursday; Mr. C. Heath, 1.30 Tuesday and Friday; Dr. Wharton Jones, 2 Monday, Wednesday, and Friday; Dr. Ibbetson, 10.30 on Wednesday.

Crossing Tottenham-court-road, and proceeding down Goodge-street, we reach

THE MIDDLESEX HOSPITAL.

This Hospital has existed since 1745. It contains 305 beds, and has attached to it a very complete set of school buildings and a museum of over 5000 specimens. Thanks to the kindness of Mr. T. Hyde Hills, the museum possesses a most complete set of materia medica specimens, consisting of upwards of 600 drugs. Besides medical and surgical wards and special wards for diseases of women and venereal cases, there is in connexion with this Hospital a separate charity which is one of much value in itself, and is believed to be unique throughout the world. In the year 1792 Samuel Whitbread, Esq., fitted up and endowed a ward for *patients afflicted with cancer*. Since his death this Cancer Fund has been augmented by Mrs. A. M. Stafford, and Sir Joseph De Courcy Laffan. In consequence of these endowments three wards—Whitbread, Stafford, and Laffan,—are appropriated exclusively to females suffering from cancer, and in addition several male patients afflicted with the same disease are accommodated in Handel ward. Here the victims of this hopeless malady find a permanent refuge, and remain until "relieved by art or released by death."

The existence of this charity affords to those interested in the study of the ravages of cancer unparalleled opportunities of witnessing the disease in all stages of its course, from the earliest beginnings to the termination.

The museum contains many valuable preparations formerly the property of Sir C. Bell, Dr. Sweatman, Mr. Langstaff, and other eminent anatomists and pathologists. Here is to be seen the brain of Cuvier, and a model of the largest arm and forearm on record, taken from an athlete who was at one time a patient in the Hospital. The medical and surgical staff attend as follows:—

Hours of Hospital Visits, etc.—In-patients are visited by Drs. H. Thompson and Greenhow at 1 p.m. on Tuesdays, Thursdays, and Saturdays; Dr. R. Liveing at 1.30 p.m. on Mondays, Wednesdays, and Fridays; Dr. J. H. Davis at 1.30 p.m. on Tuesdays and Fridays; Mr. De Morgan at 1 p.m. on Mondays and Fridays; Mr. Nunn at 1 p.m. on Tuesdays and Fridays; Mr. Hulke at 1 p.m. on Mondays and Thursdays; Mr. Lawson at 1 p.m. on Thursdays and Saturdays; Operations at 1 p.m. on Wednesday. Out-patients: Diseases of the Skin are seen by Dr. Liveing at 4 p.m. on Thursdays; Cancer cases by Mr. Morris at 1.30 p.m. on Thursdays; Diseases of the Throat by Dr. John Murray at 4 p.m. on Tuesdays; Diseases of the Ear by Mr. Andrew Clark at 1 p.m. on Mondays; Diseases of the Eye by Mr. Hulke at 8.30 a.m. on Tuesdays and Fridays; Dental cases by Messrs. Tomes and Turner, at 9 a.m. each day. Surgical operations are performed on Wednesdays at 10 o'clock.

From Bloomsbury the Regent's-park, with the Zoological and Botanic Gardens, are easily reached.

THE ZOOLOGICAL GARDENS

are open daily from nine till sunset. Entrance 1s.; on Monday 6d.; on Sunday by Fellow's ticket. On Saturday afternoon there is a band. The visitor to the Zoo' should remember that the carnivora are fed at 4, the pelicans at 2.30, the otters at 3, and the birds of prey at 3.30 p.m. The seals are fed about four o'clock, and the process should be seen if possible.

THE BOTANIC GARDENS,

Regent's-park, may be visited by means of a Fellow's order daily, except Wednesday. The gardens are large, and both skilfully and tastefully laid out; the wild flowers are arranged according to their natural orders. The conservatory contains many fine tropical and other plants.

THE SOUTH SIDE.

GUY'S HOSPITAL.

The situation of this institution close to London-bridge Railway Station, the modes of access, and its merits as a leading hospital and medical school of London, are probably well known to all our readers. It may be, however, that the great beauties of the museum connected with it are not so familiar to those who have not been educated at Guy's; and those who have an inclination to do so, and are able to give up the time, we can strongly recommend to make a journey hither, to see the admirable and unsurpassed wax models of human normal anatomy and of skin diseases, the work of that excellent artist Mr. Towne. The models of anatomy include all regions of the human frame, and are remarkable alike for their accuracy and their completeness in the minutest details of the subjects represented. The models of the brain are especially noteworthy, and consist of thirty which exhibit sections through various parts of the organ, and thirty-nine illustrating its development from the earliest fœtal condition and the arrangement of the cerebral convolutions in the principal varieties of the human race. The organs of special senses, more particularly the ear, are also fully illustrated.

The numerous and very beautiful wax models of the diseases of the skin are wonderful for their exactness and for the lifelike manner in which the part of the body is placed before the observer. Typical specimens represent the ordinary diseases, while there are several models of the less common conditions, such as glanders, vitiligoidea, and leprosy. There are also numerous wax models of the viscera in various morbid states, as well as a complete series (in the comparative anatomy section) exhibiting the changes in the egg during incubation, and another beautiful series of the brains of vertebrata, showing the gradual development of the lobes and convolutions up to the human type.

By separating the departments of anatomy and comparative anatomy from the other sections of this very fine museum, and transferring them to the long gallery in the new building, he old museum has been set free for the better display of the preparations and models which form the pathological department, and the old model-room has been converted into a large class-room for the classes of histological and other studies.

The Hospital contains accommodation for 715 patients. The surgical beds and operating theatre occupy the whole of the old building. The ophthalmic wards, the obstetric, most of the general medical cases, and the out-patients' rooms, are in the new building. The physicians and surgeons are in daily attendance at 1.30 o'clock—Dr. Habershon on Tuesdays and Thursdays, Dr. Wilks on Mondays, Thursdays, and Saturdays, Dr. Pavy on Mondays, Wednesdays, and Fridays, and Dr. Moxon on Mondays and Thursdays. Mr. Birkett and Mr. Foster make their regular rounds on Mondays and Thursdays, Mr. Bryant on Mondays and Wednesdays, and Mr. Durham on Wednesdays and Saturdays. The obstetric wards are visited by Dr. Hicks and Dr. Phillips on Wednesdays at 1.30, and Mr. Bader performs operations on the eye on Tuesdays at 1.30. The regular days for operations in general surgery are Tuesdays and Fridays at 1.30.

THE EVELINA HOSPITAL FOR SICK CHILDREN

is situated in Southwark-bridge-road, and but a short distance from Guy's Hospital. It was founded in the year 1869 by the Baron Ferdinand de Rothschild, who for some time had maintained thirty beds at his own cost, and in January, 1871, gave up to the public at large the rest of the accommodation, making a total of 100 beds. Boys are admitted between the ages of two and ten, and girls between the ages of two and twelve years. There are twelve wards well lighted and ventilated, one of which is appropriated expressly to cases of hooping-cough (a distinguishing feature of this Hospital), and another to Jewish children. Though no cases of fever are admissible, a separate building is provided for such cases of an infectious nature as may originate in the hospital building itself.

ST. SAVIOUR'S, SOUTHWARK.

The visitor to Guy's Hospital who is interested in architecture or archæology will do well, if the places are unknown to him, to give a passing notice to St. Saviour's Church and the Talbot Inn. St. Saviour's Church, Southwark, situated in the low ground by Southwark Market, and near the Bridge House Hotel, was first erected into a parish church by Henry VIII. in 1540. After Westminster Abbey, St. Saviour's contains the finest specimens of early English in London. Nothing, however, remains of the nave of the original church; only the choir and the Lady Chapel have been saved. The nave was taken down in 1840 without sufficient cause, much to the disgrace of the parish, and the present unsightly structure built. In the reign of Mary the Lady Chapel of St. Saviour's was used during the Marian persecution by Bishop Gardiner (1555) as a court for the trial of heretics. There are several monuments of mark in the choir and Lady Chapel; and it was in this church that Edmund Shakespeare, "player" (the poet's youngest brother), John Fletcher (Beaumont's associate), and Phillip Massinger (the dramatic poet), were buried.

Near by is the site of the Bishop of Winchester's former palace, close to which stood the Globe Theatre, in which Shakespeare acted.

A little further up the Borough from London-bridge than Guy's Hospital, and on the same side, stands the Talbot Inn—the "Tabard" of Chaucer's "Canterbury Tales"—the starting-place of Chaucer's Canterbury Pilgrims. This building has lately been brought before the notice of readers of the *Times* by letters protesting against its threatened destruction.

No. 119, High-street, Borough, occupies the site of the Marshalsea, where many of the martyrs in Queen Mary's reign were imprisoned for their religion.

ST. THOMAS'S HOSPITAL, ALBERT-EMBANKMENT, WESTMINSTER-BRIDGE, S.E.

This building, being the newest of its kind in London, will be an object of inspection for many—externally, on account of its style of architecture, and internally because it contains all the latest improvements, or supposed improvements, both in hospital and school departments. We have been informed that special arrangements have been made to show visitors belonging to the British Medical Association over the Hospital and its school-buildings on Wednesday and Thursday, August 6 and 7, from 3 to 5 p.m. In addition, visitors will, of course, be received and welcomed by the surgeons and physicians to accompany them in their morning visits. These visits are as follows:—Mondays and Thursdays, 9 a.m., Dr. Murchison; Tuesdays and Fridays, 9 a.m., Dr. Peacock; Wednesdays and Saturdays, 9.30 a.m., Dr. Bristow and Dr. Clapton. The surgeons' visits are also made daily at 9 a.m. or 9.30 a.m., but we do not specify on which days each attends, as just now the surgeons are undergoing a change, owing to the resignation of Mr. Le Gros Clark, and the days of visits are not as yet definitely fixed. The operations take place on Wednesdays at 1.30 o'clock. The mode of ventilating the wards and the lifts are worth the attention of those interested in hospital buildings. The museum offers a wide field of observation in normal and morbid anatomy.

The site of this Hospital and the ways of access to it are far too well known to require a notice at our hands for the guidance of visitors.

BETHLEM HOSPITAL, ST. GEORGE'S-FIELDS.

This hospital for the insane is certainly well worthy of a visit. Originally founded in 1246 as a priory of canons in Bishopsgate Without by Simon Fitzmary, one of the sheriffs of London, it was afterwards given by Henry VIII. to the City of London, when it was first used as a hospital for lunatics. Subsequently (1675) Fitzmary's Hospital was removed to Moorfields, where it remained till 1812, the date of the erection of the present building. It may be reached by train from Ludgate-hill or Victoria to the Borough-road Station, or by omnibuses from Westminster, Waterloo, and Blackfriars-bridges, as well as by all other 'buses going to the obelisk in St. George's-circus, at the bottom of Blackfriars-road.

The hour at which the physicians attend in the wards is eleven o'clock every morning, and the best hours for medical visitors will be between eleven and two o'clock, when they can accompany one of the physicians—Dr. Williams or Dr. Savage—on his round.

SCHOOL FOR THE INDIGENT BLIND.

Standing close to Bethlem Hospital, being one of the buildings immediately in St. George's-circus, is the School for the Indigent Blind. This building was instituted in 1799 for the education—religious, general, and industrial—of those who, not in *extreme* indigence, cannot "distinguish colours or more than light from darkness; are not under the age of ten nor above twenty years of age; are not deficient in intellect or physical power; are in good health, and not married; are able to wash and dress without assistance; and are not subject to fits or scrofula, or any disorder which may be prejudicial to the other pupils of the School."

LAMBETH PALACE.

The Palace of the Archbishop of Canterbury—situated on the south side of the Thames, opposite the Houses of Parliament, and close to the Lambeth boat-pier—can be visited at any time, by making an application in writing to do so; but just now special permission has been granted to gentlemen attending the British Medical Association meeting to look over the buildings. The library is open on Mondays, Wednesdays, and Fridays from ten to three; it contains over 25,000 volumes, and amongst them one of its greatest curiosities is a MS. of Lord Rivers' translation of "The Dictes and Sayings of the Philosophers," containing an illumination of the introduction of Caxton by the Earl to Edward IV. The chapel, the oldest part of the Palace, built in the early English style, with lancet windows and a crypt, and the Lollards' Tower at the west end of the chapel (in which, by the way, it is now ascertained that the Lollards were *not* imprisoned) are the chief features about this venerable and celebrated building. His Grace the Archbishop of Canterbury has lately offered to the Council of King's College the use of the Lollards' Tower as a hall for resident theological students. This offer, however, the Council felt compelled to decline, because of the large outlay it would have necessitated.

THE BROWN INSTITUTION,

founded in pursuance of the will of the late Thomas Brown, for the study and cure of the diseases of animals useful to man, deserves a visit from all interested (as who is not?) in comparative pathology. It includes two departments—the sanatory and the pathological. The former of these is a hospital for animals, where as many as twenty to thirty or more sick horses, dogs, etc., may be seen under treatment of a morning (nine to eleven o'clock). The second department is represented by the laboratory, where experimental researches in pathology are prosecuted by pupil-subscribers, working under the superintendence of Professor Burdon-Sanderson. Any member of the profession is admitted to view the Institution on presenting his card. The buildings are situated in the

Wandsworth-road, close to the Nine Elms goods depôt of the South-Western Railway. It may be reached either by rail or by river. It is five minutes' walk from Vauxhall Station, to which the visitor will book from Waterloo-bridge (trains at intervals of a few minutes), or from Charing-cross (South-Eastern) Station, changing at Waterloo Junction. The penny river steamboat is a more pleasant means of conveyance to the Nine Elms pier, where the stranger should ask to be directed to Wandsworth-road.

Returning now to King's College, we may proceed to point out some of the places of interest in its immediate neighbourhood and to the West.

THE WEST-END.

CHARING-CROSS HOSPITAL

stands close to the West Strand, at the junction of that street with King William-street and Agar-street. It is a modern building, in a single large block, containing 150 beds. The visiting hour of the staff is 1.30 p.m., and the days of attendance of the various physicians and surgeons as follows:—Dr. Headland on Monday, Wednesday, and Friday, Dr. Pollock on Tuesday, Thursday, and Saturday, Dr. Silver on Tuesday, Thursday, and Friday, Mr. Canton on Tuesday and Friday, Mr. Hird on Monday and Thursday, and Mr. Barwell on Wednesday and Saturday. Dr. Watt Black (Physician-Accoucheur) attends on Monday, Wednesday, and Friday; Dr. Sparks (for diseases of the skin) on Tuesday and Saturday, at 1 p.m. Post-mortem examinations at 2.30 p.m.; operations on Saturday at 2 p.m.

THE NATIONAL GALLERY

is fast becoming one of the most important collections of pictures in Europe. Amongst its latest additions is the celebrated Peel Collection, which contains some of the most delightful specimens of Dutch and Flemish art extant. We would recommend all lovers of the fine arts who have not seen these pictures to pay them a visit. The Gallery is open to the public on Mondays, Tuesdays, Wednesdays, and Saturdays.

THE ROYAL COLLEGE OF PHYSICIANS.

A little farther west, on the opposite side of the road, stands the Royal College of Physicians, in Pall-mall East. To medical men a visit to the College will prove of great interest. There is a magnificent collection of portraits of medical worthies from the time of Henry VIII. to our own—Linacre, Sydenham, Harvey, Mead, and many more. The library is also well worth seeing. The almost priceless Caxton, which a few years ago was found on a forgotten shelf in the library, is now shown under a glass case.

From Charing-cross our visitors had better proceed down Whitehall to Westminster, and, if they have not already seen them, spend an hour or two in the chapels and nave of the glorious Abbey, and compare the modern Gothic of the Houses of Parliament with its ancient prototype. On his way he may visit

THE ROYAL UNITED SERVICE INSTITUTION MUSEUM,

in Whitehall-yard, almost directly opposite the Horse-guards. It is open daily (except Friday) from eleven to five. Admission by ticket from a subscriber. It contains a curious collection of objects belonging to the various arts and applied sciences—chiefly relating to the army and navy—such as arms of all kinds, models of vessels, medals, natural history specimens, books, and objects of ethnological and archæological interest. There are to be seen here the swords of Cromwell and Nelson, some of the Franklin relics, some *souvenirs* of Captain Cook, models of the battles of Trafalgar and Waterloo, the skeleton of one of Napoleon's horses, etc.

THE EAST INDIA MUSEUM

deserves a visit from those who are interested in the history and products of the East. It is open daily (except Thursdays) free. The visitor should apply at the south-west entrance in the large court of the India House. In seven rooms are exposed specimens of the various products of India—minerals, plants, cloth, embroidery, arms, jewellery, etc., etc. There is a large collection of the Indian materia medica, including the varieties of opium. In the last room may be seen the collection from Yarkand and Kashgar, in Eastern Turkestan, by the brave and unfortunate Shaw: it is a most miscellaneous one, of garments, arms, domestic and personal requisites, natural history specimens, etc.

WESTMINSTER HOSPITAL

stands opposite the north-west corner of Westminster Abbey. It is built in the Tudor style of architecture, and contains about 200 beds. It is interesting as having been the first Hospital in the metropolis to be built and supported by public voluntary contributions. Chiselden became a surgeon to the Westminster Hospital in 1726, and his portrait hangs in the board-room along with those of Carlisle, Guthrie, White, etc.

The medical officers attend at one or half-past one o'clock on the following days:—Dr. Basham, Monday, Tuesday, and Thursday; Dr. Fincham, Monday, Wednesday, and Saturday; Dr. Anstie, Monday, Tuesday, and Friday; Mr. Holthouse, Monday, Tuesday, and Friday; Mr. Pearse, Monday, Wednesday, and Saturday; and Mr. Cowell on Monday, Thursday, and Friday. Operations on Tuesdays at 2 p.m. Post-mortem examinations at 2 p.m.

Returning then to Charing-cross, and proceeding down Piccadilly.

THE UNIVERSITY OF LONDON.

The University of London is a handsome new structure standing back to back with the Royal Academy buildings in Burlington-gardens, Piccadilly. The front is both imposing and fine, and is adorned with numerous statues of the most famous philosophers and men of science of all ages. The interior of the building, we are able to state, may be visited by the members of the Association during the end of the meeting-week. Within the walls little is to be seen beyond examination-rooms, but even these are interesting in the completeness of their arrangements. The largest hall contains the library of the late Mr. Grote, bequeathed by him to the University. In the senate-room, at the top of the staircase, is a fine portrait of Mr. Grote by Millais.

When at the University of London the visitor should look at Burlington House, where the Royal, Linnæan, and other scientific societies have rooms. The Royal Academy buildings also are well worth seeing.

THE MUSEUM OF PRACTICAL GEOLOGY, JERMYN-STREET, ST. JAMES'S.

is open gratuitously to the public on Mondays and Saturdays, from 10 a.m. till 10 p.m., and on the other days of the week (except Friday) from 10 a.m. till 4 p.m., during the months of November, December, January, and February, and until 5 p.m. during the remainder of the year, with the exception of one month of vacation, from August 10 to September 10. This museum is intended for the exhibition of the rocks, minerals, and organic remains illustrating the maps and sections of the geological survey of the United Kingdom; also to exemplify the applications of the mineral productions of these islands to purposes of use and ornament. The collection divides itself into two principal groups—First, the *Natural Materials*—geological and mineralogical. Those interested in granites, serpentines, marbles, and minerals will find here much to occupy them. Secondly, the *Artificial Productions*, including a vast collection of pottery, porcelain, ancient and modern glass, and mosaics. Further, there are to be seen—(1) the mechanical appliances which are used in working the raw materials; (2) historical specimens which have been added for the comparison of the productions of other ages and countries with modern manufactures; and (3) foreign and colonial minerals imported in their natural state. There are besides other objects of a miscellaneous character which cannot be brought within any of the above groups, such as geological and mining models. The Palæontological collections are of great value to the searcher for mineral treasures.

This Museum is not sufficiently known to the general public, yet it abounds in objects of the highest interest, and its importance as illustrating the mineral productions of the country, and as showing their commercial value, is unspeakably great. Lecture-theatres and laboratories are attached, in which a large number of students are yearly instructed in analytical and agricultural chemistry, metallurgy, mining, and mineralogy, and the analysis of minerals, rocks, and soils.

This institution, which is now under the Department of Woods and Forests, was started in Craig's-court in 1837, and was removed in 1845 to the present building, erected by Mr. J. Pennethorne. The new Museum was opened by the Prince Consort in 1851, and has done a great deal towards the promotion of knowledge serviceable both to the agricultural and mining interests of this country. It is well worth a visit, and from its very central situation, and the free access which is permitted, no doubt many of our guests during the next

week will avail themselves of the opportunity of inspecting the treasures here contained.

ST. GEORGE'S HOSPITAL, HYDE PARK-CORNER, is a place of great interest to surgeons as the Hospital of Hunter and Brodie. There is nothing very remarkable about the building. The medical school, and especially the museum, is worthy of a visit. The board-room, where John Hunter died, contains a portrait and bust of Hunter, and a portrait of the Rev. Mr. Clarke by Callcott.

The medical officers visit the Hospital as follows:—On Monday and Friday, Dr. Fuller, Dr. Wadham, Mr. Prescott Hewett, and Mr. Holmes; on Tuesday and Saturday, Dr. Ogle, Dr. Barclay, Mr. Lee, and Mr. Pollock. The ophthalmic surgeon, Mr. Brudenell Carter, operates on Wednesdays at 1.15 p.m. Operations on Thursdays at 1 p.m. Post-mortem examinations daily at 2 p.m.

THE SOUTH KENSINGTON MUSEUM is certainly the most interesting collection of its kind in London, combining the scientific and æsthetic elements in a pleasing and quite remarkable manner. The departments include—paintings, sculpture, decorative furniture, porcelain, jewellery and other works in the precious metals, musical instruments, the food collection, and the educational collection. The Museum is open daily, either free or by payment of sixpence. At the gate the visitor should ask for a ticket to the National Portrait Gallery.

It is impossible here to do more than refer to the chief objects of interest; the visitor should possess himself at once of a catalogue and adopt the following plan:—

From the principal entrance (in Brompton-road) he will turn to the right and enter the South Court. Here is the Loan Collection of works of art in the precious metals, maiolica, clocks, etc., decorative furniture, wood carving, and a fine collection of musical instruments. In the Oriental Court to the right are works of art from India, China, Japan, and Persia. Passing on to the North Court and Cloister the visitor will find reproductions and models of famous sculptures, and should not fail to inspect several after Michael Angelo, including his "David." In this court are the Abyssinian spoils. Towards the west the court leads into the corridor in front of the refreshment-rooms, where there are a number of statues in marble, and original models by Campbell, Baily, MacDowell, Rauch, Thorwaldsen, and Marochetti. At the west end of the corridor, and on the right hand side, will be found the door leading into the north-west and north cloisters, containing small objects in bronze, copper, and iron; and furniture, carved and inlaid, of the middle ages. At the end of this cloister is the staircase to the Fine Art Gallery, where many of our finest national pictures are to be seen. Here we will tell the visitor to pass through the rooms in the order in which they are numbered, and with this advice leave him to himself. After inspecting the first ten rooms he will find himself in the large Raphael room, surrounded by the cartoons of which the country is so proud. Thereafter he should visit in succession the four rooms containing the Sheepshanks collection, the water colour gallery, the Prince Consort's gallery of treasures of art of the middle ages, and the ceramic gallery. Keeping to the left he will find himself at the staircase by which he ascended, and reaching once more the west end of the corridor he should enter the rooms containing the food collection. To the right he will find the educational collection of school books, designs and models for instruction in the fine arts, botanical, geological, and mineralogical specimens, and chemical and optical apparatus, etc.

THE NATIONAL PORTRAIT GALLERY should be visited after the South Kensington Museum. It stands on the opposite side of Exhibition-road, close to the International Exhibition building. The collection comprises 295 portraits and busts—many of great value from an artistic point of view—of kings, queens, statesmen, warriors, philosophers, artists, and members of our own profession. Among the painters and sculptors of the works are Janssen, Reynolds, Romney, Pickersgill, Kneller, Lawrence, Wilkie, Phillips, Woolman, Gibson, and Marochetti.

GARDENS OF THE HORTICULTURAL SOCIETY. The visitor to the International Exhibition should not fail to visit the gardens of the Horticultural Society, in which the Exhibition stands. Admission 6d.; on Saturdays 1s., and afternoon (band of the Guards) 2s. 6d.

INTERNATIONAL EXHIBITION. At the Exhibition of this year the fine arts represented are—paintings of all kinds; sculpture, carving, and the allied arts; engraving and photography; works of art by officers in the army and navy; lace and tapestries exhibited for their designs; reproductions of ancient works of art, etc. The chief manufactures to be seen are—silk fabrics; steel cutlery, surgical instruments, etc.; carriages; foods, including the various forms of drinks and tobacco; food-machinery; and the science and art of cooking.

The most interesting class professionally is that of surgical instruments and appliances (Class X., in the Royal Albert Hall, West Theatre.—"Official Catalogue," page 142). All kinds of instruments are here exhibited to interest the surgeon, obstetrician, chloroformist, oculist, orthopædist, dentist, aurist, and physiologist. Specially to be mentioned are the collection of instruments for lithotomy, etc., exhibited by the President of the Association, Sir W. Fergusson; the collection from the College of Surgeons; the selection from Liston's collection from University College; the case of ancient surgical instruments from the College of Physicians; and Dr. P. Chamberlen's case of obstetrical instruments, exhibited by the Royal Medical and Chirurgical Society. There is also a good collection of antique instruments from various countries.

The class of foods is abundantly represented (East and West Quadrants). The numerous specimens of adulteration of nearly every article of common consumption will be found very interesting (West Quadrant.—"Official Catalogue," No. 4328). There is a good collection of wines, spirits, beers, and tobaccos, and the processes of tobacco and pipe manufacture may be watched by the visitor.

The machinery in motion is this year almost confined to the preparation of Foods (East and West Galleries.—"Official Catalogue," pages 183 *et seq.*). Among the processes most worth inspection are the manufacture of maccaroni, mustard, and confectionery, and the bottling of soda-water.

The large collection of carriages will interest many visitors (East Arcade, South Corridor, French Court, etc.—"Official Catalogue," page 146).

Many of the pictures are exceedingly fine, especially the foreign. The sixteen pictures of Meissonier alone are worthy of a visit to Kensington (West Gallery, Room VI., screens.—"Official Catalogue," page 10). Every lover of the fine arts will carefully study the pictures of Phillip and Creswick—the first of the series of annual collections of the works of deceased British artists (East Galleries, Rooms XVI. and XVII.—"Official Catalogue," page 45).

Before leaving this neighbourhood, the visitor will of course see the interior of the Albert Hall, and the Albert Memorial on the opposite side of the road.

THE HOSPITAL FOR CONSUMPTION, BROMPTON. At the International Exhibition the visitor is about ten minutes' walk from the Hospital for Consumption; at the South Kensington Museum about five minutes' walk.

The Hospital contains about 200 beds, and has a very large out-patient department. The medical officers attend daily. There are at present several very interesting cases of aortic aneurism in the wards. The ventilation in the new parts of the building is worth inspection. The Hospital possesses several pictures by Opie.

ST. MARY'S HOSPITAL, PADDINGTON, contains about 200 beds. The medical officers attend at the Hospital as follows:—The physicians at 1.15 p.m.—Dr. Handfield Jones (out of town) on Monday and Thursday, Dr. Sieveking on Tuesday and Friday, Dr. Broadbent on Wednesday and Saturday; the surgeons at 1.5 p.m.—Mr. Spencer Smith on Monday and Thursday, Mr. Haynes Walton on Wednesday and Saturday, Mr. Lane on Tuesday and Friday. Dr. Meadows (Physician-Accoucheur) on Tuesday and Friday, at 9.30 a.m.; Mr. H. Walton (Ophthalmic Surgeon) on Monday and Thursday, at 1.30 p.m.; Mr. P. Allen (Aural Surgeon) on Tuesday and Friday, at 2 p.m. Post-mortem examinations at 2 p.m.; operations on Wednesday at 1.15 p.m.

St. Mary's Hospital may be reached by the Metropolitan or District Railways to Paddington, Praed-street Station, or Edgware-road Station; or by Bayswater omnibus from Oxford-street, Holborn, and the City to the corner of Praed-street.

London: Printed by PARDON and SON, of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and Published by J. & A. CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—August 2, 1873.

ORIGINAL LECTURES.

LECTURES ON THE DIAGNOSIS OF TUMOURS OF THE BRAIN.(a)

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,
Physician to the London Hospital, and to the Hospital for the Epileptic and Paralysed.

Lecture I.

As we have always some cases of intracranial tumour in the Hospital, I make an opportunity of speaking at length on the diagnosis of this form of cerebral disease. I must, however, speak not only of tumours ordinarily so-called—such as gliomata—but of syphilitic growths (so-called syphilitic "deposits"), of cerebral abscess, and, indeed, of many kinds of adventitious products. I speak, in short, of what I have in the lecture on optic neuritis (see this journal, August 26, 1871, *et seq.*) called "foreign bodies" and "coarse disease." However different the several foreign bodies mentioned may be among themselves, many of their doings are just the same. Each of them may, and usually does, produce severe headache, urgent vomiting, and double optic neuritis. Putting this in another way, I would say that it frequently happens that you can easily decide that a patient has an adventitious product of *some* kind within the cranium, when you cannot tell of *what* kind it is. Let us consider a particular difficulty. The symptoms of a cerebral abscess are so like those of a cerebral tumour that the diagnosis betwixt the two is admittedly most difficult. I think it is altogether impossible *from the symptoms which the tumour or abscess provokes;* you are obliged to rely for diagnosis on the presence or absence of disease of some part of the cranial wall—mostly of the petrous bone. No one fails to inquire for discharge from the ear when his patient suffers severe pain in the head or has any acute cerebral symptoms. If you find symptoms showing that there is an adventitious product of some sort, and then discover that there is offensive discharge from the ear, you may infer, having excluded meningitis, that the adventitious product is an abscess. Occasionally, although rarely, even the evidence of aural disease is deceptive; there is sometimes found in association with it, not abscess, but "scrofulous tumour," which, however, I think probably depends on aural disease.

There is one other thing which I must mention in this connexion most prominently. It is, that syphilis may produce an intracranial tumour, which, when established, can next cause just the same sort of symptoms as the common kind of non-syphilitic tumours—gliomata—do. It is of extreme importance to bear this fact in mind. It is one way of putting the statement that syphilis mostly produces nervous symptoms by a very indirect process. In particular illustration of this statement, I here mention that optic neuritis from a syphilitic mass does not differ from the optic neuritis produced by a glioma. To state the same thing epigramatically, "optic neuritis from syphilitic disease of the brain is not syphilitic optic neuritis." This kind of distinction may seem simple enough when it is thus put definitely with regard to a particular symptom; but it is often ignored. It applies to most syphilitic nervous symptoms, and very strikingly to the three kinds of Syphilitic Hemiplegia I so often speak to you about.(b)

I make the above preliminary remarks because I particularly wish you to think methodically about cases. It is true that severe headache, vomiting, optic neuritis, etc., are "symptoms of cerebral tumour"; but unfortunately they are also symptoms of cerebral abscess, of syphilitic growths, etc.

So our first step in diagnosis is to find out that there is an "adventitious product" of *some* kind—of any kind,—or, as it is occasionally put, that there is "organic disease." But, of course, we have to investigate further in order to find the position of the adventitious product: this is the second step. Next we have to discover the *particular* nature of the adventitious product: this is the third step. We classify the symptoms according to these three diagnostic steps.

Class 1. *Symptoms which show that the Patient has an Adventitious Product of some kind "within his Cranium."*(c)—The chief of these are Headache, Vomiting, and Double Optic Neuritis. Emaciation also occurs not unfrequently during some *part* of the course of a case of adventitious product. Sometimes there is an acute illness—a rapid development of symptoms—in which the pulse and respiration are altered.(d) I have now only to mention these "vital" symptoms. It is during this illness that the patient becomes thin. When the headache, vomiting, and other symptoms are over, the patient may become fat, the reason for which is in part no doubt that, being blind or defective in sight, he leads a life of enforced idleness.

Now, these symptoms—the severe headache, the urgent vomiting, and the double optic neuritis(e) are the most characteristic of them all—are almost certain proof of the existence of an adventitious product inside the head. But do not forget that they are of no value as evidence of the position of that adventitious product nor of its *particular* nature; they only tell you that there is one of *some* kind.

Before I pass on to enumerate the symptoms of Class 2, I will, at the inconvenience of a lengthy digression, advert to a common misapprehension as to the *kind* of value in diagnosis which double optic neuritis, with or without amaurosis, has. It may at first glance seem that optic neuritis (since a *cranial nerve* is affected) belongs to the same group of symptoms as does paralysis of the third nerve—that it should be considered as a localising symptom among others in Class 2. But it is *not* a localising symptom: its diagnostic value is, I repeat, as to the *nature* of intracranial disease only; it points to "coarse" disease—to a "lump," to speak in a common way. This is another thing which it is exceedingly important for you to bear in mind. It would look superficially clear, but would be really barbarous, to place amaurosis from optic neuritis in the same category as palsies of cranial nerves. There can be no sort of doubt that amaurosis from optic neuritis belongs to the same group of symptoms as do vomiting and headache. This is as important clinically as it is pathologically. To those who had not investigated many cases of nervous disease it would seem far "simpler" to place vomiting, not with optic neuritis, but with symptoms referable to the digestive system. To show that my conclusions are not hastily arrived at, I quote from an old paper. In the *Royal London Ophthalmic Hospital Reports*, vol. iv., part 4, p. 408 (1865), I say—"It is a very great mistake to suppose that this form of amaurosis [there may be no amaurosis with or even *after* optic neuritis] necessarily indicates disease primarily involving the Optic Nervous System. . . . From this form of amaurosis alone (optic neuritis or its sequela of atrophy) I could no more diagnose the position of disease within the head than I could from the purposeless vomiting." To make this clearer by contrast, let me remark that such an "eye symptom" as hemiopia is localising, for it is one which must depend on disease of some *part* in particular.(f) To put the two symptoms (amaurosis from optic neuritis and hemiopia) together would be to make a superficial arrangement, not a simple one; it would be as bad as putting gonorrhœa and primary syphilis together.

Here it may be conveniently mentioned that deafness *is* a localising symptom, provided we can ascertain that it is of nervous origin, and also, of course, that it came on at the same time as—belongs to the same group as—the other symptoms of the case. It points to disease actually involving the nervous system of hearing. Amaurosis from optic neuritis

(a) I delivered a lecture on this subject about a year ago. Cases of intracranial tumour have been spoken of at length in several other lectures delivered at the Hospital before and since. The above in its present shape is, indeed, like others to follow it, a compilation from notes of several lectures, and is therefore more systematic than clinical. I have not hesitated to add the results of my most recent experience, nor to intercalate remarks on collateral topics. As texts for this lecture and others to follow it, eight cases of cerebral tumour have been recorded in the "Hospital Reports" of this journal, the first of them on November 16, 1872. That series will be continued.

(b) See this journal, May 23, 1868, p. 552.

(c) I use this clumsy sounding expression advisedly; for, so far as the signs mentioned go, the tumour might not be of a nervous organ; it might grow from the base of the skull, not actually growing into any division of the encephalon, although it would squeeze some part of it.

(d) I use the very general expression "altered" because they are variously altered. Such alterations occur in cases of cerebral hæmorrhage and in most cases of severe lesion of the cerebrum or cerebellum.

(e) Of course, strictly speaking, optic neuritis is not a symptom in the same sense as headache is; it is a pathological condition. As I have repeatedly insisted, there may be no symptom—no defect of sight attached to this pathological condition.

(f) And probably double optic atrophy coming on slowly, and not preceded by neuritis, should (if there were such other symptoms as palsies of cranial nerves, headache, etc., to show that the atrophy was not spinal) be considered as a localising symptom.

does not necessarily, nor even commonly, point to disease (g) involving the optic nervous system. The two symptoms are not different only in the very obvious sense that two different senses are affected, but in the far more important way that one is dependent on a change *secondary* to a tumour, the other on involvement of the auditory nerve by pressure of the tumour, direct or transmitted. Deafness *does* therefore belong to the same category as paralysis of the third nerve.

To the best of my belief, deafness never occurs by any process from tumour or any other sort of disease of the cerebrum or cerebellum.

The diagnostic value of loss of smell is probably as varied as is that of loss of sight. Of loss of taste I have nothing to say beyond what will come later on under the head of palsy of the fifth nerve, except to remark that loss or defect of taste is often supposed to be present when really there is only loss of smell.

The symptoms in Class 1 may be referred to as "non-localising," because they do not help us at all in the diagnosis of position. They may be called "general," because they result from disease of any part, or of numerous parts, of the encephalon. Indeed, vomiting can occur from disease of widely separated and most different parts of the body—from renal calculi, hepatic abscess, labyrinthine disease, etc.

Class 2. *Symptoms which Localise.*—These are palsies of cranial nerves, anatomical(h) varieties of hemiplegia, affections of speech and articulation, mental symptoms, *certain* convulsive seizures, reeling gait, etc.

It is important to remember that these symptoms *by themselves* enable you to do nothing more than localise. Strictly, they are not symptoms of cerebral tumour: they are symptoms of position of lesion of any kind; they are of no value whatever in deciding whether there is an adventitious product or not; they are localising only. They may be called Special nervous symptoms.

Class 3. *Symptoms and Conditions which help to show the Particular Nature of the Adventitious Product.*—We will suppose you have correctly determined that there is one. These are age, history, or presence of external signs of syphilis, discharge from ear or nose, history or signs of blows on the head, symptoms of phthisis, etc. There are also some empirical rules.

There are certain symptoms and conditions which one does not know in which class to put. For example, enlargement of the head is a localising symptom when it occurs with reeling gait (in that association it points indirectly to disease of the cerebellum); it is partly evidence of the nature of disease when it occurs with hemiplegia, for it then points to a *voluminous* adventitious product. Some intracranial tumours diagnose themselves by coming through the cranial wall into the mouth or out at the vertex.

The above threefold arrangement of symptoms is, I think, of value. It is very important to avoid mixing symptoms which have fundamentally different significance. To think of the symptoms of cerebral tumour in such an incoherent sequence as "pain in the head," "hemiplegia," "optic neuritis," "noises in the ear," "giddiness," etc., is to think very unmethodically. It may be convenient *in taking notes of a case* of hemiplegia to put down "that the patient's tongue is much furred *and* turns to the right;" but in thinking of his case, the two facts belong to altogether separate series. The investigator who thinks of symptons in this way is probably one who has no real method: it will be found, I believe, that his method (improperly so-called) is only an elaborate *arrangement* founded on superficial resemblances. In an argument on a case of cerebral tumour, to put in the same general category such symptoms as amaurosis from optic neuritis and deafness, or to think of the vomiting as a symptom of disorder of the digestive system, is to put together symptoms, not on such a kind of method as the botanist adopts in *classifying* plants, but on the kind of plan on which a gardener *arranges* them. It is true that the gardener's *arrangement* is better than the botanist's *classification* for *some purposes*. Similarly, certain arrangements of symptoms are better than natural classifications for some purposes—note-taking, for instance; but they are of very slender value in investigating difficult cases, or in finding out new things. A true classification should be also a means of investigation. The grouping of symptoms I have suggested does not pretend to be strictly methodical; our knowledge of cerebral symptoms is not sufficiently deep to permit of full method. It is, however, I trust, something more than a mere arrangement. Yet there are certain remarks to be made against the threefold classification.

Pain in the head is of some value in localising, *if it be persistently one-sided.* Again, hemiplegia, which we have called a localising symptom, is also very strong evidence of the *nature* of internal disease—that it is tumour—*if the palsy comes on very slowly*, the parts affected getting a little weaker day by day. Strictly, it is not the palsy, but its very slow onset, which points to tumour. Again, I have never seen entire loss of speech from any sort of adventitious product; so that loss of speech would negative tumour, abscess, etc. Disease of the ear is of some value in localising, because cerebral abscess therewith associated is usually found in a lateral lobe of the cerebellum or in the middle lobe of the cerebrum. However, the three lines of investigation are largely distinct. Let me give you an example of the steps in diagnosis which corresponds to them:—

First Step.—A young, healthy-built man, who is getting thinner, comes to you for severe pain in the head and urgent vomiting, and you discover double optic neuritis, although, perhaps, his sight is good. You conclude that this man has an adventitious product of some kind within his cranium.

The second step is to find in *what* part of the encephalon the adventitious product is. But he may have no localising symptoms; he may have only the symptoms above mentioned. *This is very often so.* Then, you cannot possibly tell in what part the adventitious product lies. Be sure of this, and don't guess; you may easily deceive yourselves. Since there is, we are supposing, *no* paralysis, etc., you may be almost certain that the adventitious product is *not* of the motor tract, and that it is, therefore, either in the mass of the cerebrum or cerebellum, for extensive disease in either of these parts need not produce obvious paralysis. But if you can get so far as this, you cannot get any further. If, then, because you have seen a case "exactly like it," in which there was discovered an adventitious product in the cerebrum or cerebellum, as the case may be, you venture on a diagnosis—if you say, for instance, "It is in the cerebellum,"—you may by chance be right, for there is only one other place in which it is likely to be. In reality, you cannot decide by the evidence supplied by all the symptoms I have mentioned in Class 1. For fear of misunderstanding, I remark that I do not mean to say that there are no differences in the sequence and grouping of symptoms of the *first* class in cases of disease of the cerebrum and cerebellum, but only that, so far as I have learned, no one is yet able to declare what these differences are.

Second Step.—Now, we will suppose that there *is* a localising symptom. Let us suppose that the patient comes again; he has had since the first visit a convulsive seizure *affecting the left side of his body.* The arm and leg of this side may have been paralysed for a short time after the fit. (The last is not essential, nor is loss of consciousness nor tongue biting. It is the one-sidedness of the convulsion which is diagnostic of position.)

You may then with confidence make the second step in diagnosis—you can localise. *You may be sure* that the adventitious product is of, or affects, the surface of the right side of the brain.

The Third Step.—Of what pathological nature is the adventitious product just localised? This is the most difficult part of our task: there may be no evidence, or there may be negative evidence only. There is no discharge from the ear, no history of a blow, no sign of syphilis, etc., and then you say that the adventitious product is most probably a non-syphilitic new growth. If there be a history of a blow, followed by a puffy tumour, you may diagnose abscess. If there be signs of syphilis in the patient's body, you say it is probably syphiloma. If there be phthisis, you infer that there is a mass of tubercle. So far in mere illustration.

I would earnestly beg of you to keep the three lines of investigation distinct, *even in cases where the diagnosis is very easy.*

(g) Of course, as the expression "optic neuritis" implies, there are pathological changes in the optic nerves, but primary disease is meant; the neuritis is the secondary result of disease at a distance from the nerve.

(h) By "anatomical varieties" of hemiplegia I mean one-sided palsies depending on lesions of lateral halves of different levels of the encephalic divisions of the sensori-motor tract. For example, palsy of the third nerve on the right, with palsy of the face, arm, and leg on the left, is an anatomical variety of hemiplegia; it depends on disease of the right crus cerebri; and so on for levels above and below this point.

THE HUNTERIAN MUSEUM.—A vacancy has been occasioned in the Board of Trustees by the lamented decease of the Bishop of Winchester.

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Resident Medical Officer to the London Fever Hospital.

No. IX.

(*With Photo-lithographic Plates.*)

On Aneurism: Precautions in Application; Direct Effect of the Sac on the Pulse-wave—Aneurism of Brachial—Axillary—Innominate, pure—Innominate and Aorta—Effect of Chloroform.

The present communication and the one following it will be devoted to the aid afforded by the sphygmograph in the diagnosis and treatment of some of the more common forms of aneurism. The fallacies attending its use in these cases are very numerous. Here, more especially, the instrument in the hands of an unpractised and careless observer is certain to lead to error. No one should attempt to use it who cannot readily obtain exactly similar tracings from the two radials of a healthy person. The results obtained from it, even under the most favourable circumstances, are sometimes disappointing; but the extreme value of the information it occasionally yields, on which alone diagnoses may be arrived at, unobtainable by all other means, will well repay any trouble that may be spent over it.

To insure a reliable result it is necessary that the greatest care be taken in the application of the instrument:—

1. Guard against all causes of transient excitement, especially as regards the instrument. Put the patient quite at ease by letting him see it applied to others, or by taking one or two preliminary tracings of himself.

2. Place the patient in as comfortable a position as possible, and let the position of each arm be the same when either radial is under examination.

3. Take care that the sphygmograph is applied to exactly corresponding parts of each radial, and that the pressure employed is similar.

4. Never be content with a single application of the instrument; apply it at least twice to each wrist, and do not accept the tracings so obtained unless they exactly coincide. Where the pulse in the two radials is found to differ the precautions taken must be redoubled, and it will be well to apply the instrument again on some other occasion to make sure that a similar result is obtained.

If besides these rules those previously laid down for discovering the most perfect tracing to be obtained from an artery be borne in mind, the sphygmograph will often prove an important aid to diagnosis.

But supposing all these sources of error to have been guarded against, the tracings of the two radials may be found to differ, although no aneurism is present. The more common causes for inequality in the radial pulse are the following:—

1. An abnormal distribution of arteries in the arm, such as a large median, or an alteration in the course of the radial. Some abnormalities about the aorta will produce it. The writer has seen a congenital contraction of the aorta, just below the junction of the ductus arteriosus, produce an inequality in the radials which gave rise to a suspicion of aneurism.

2. An old fracture or injury of the arm may have interfered with the flow of blood down the radial.

3. Paralysis of the arm, by interfering with the vaso-motor nerves and with the return of the venous blood, may alter the character of the pulse on that side.

4. A tumour external to the artery, either intrathoracic or extrathoracic, may impede the flow of blood down it.

5. Endarteritis, by partially blocking up the artery in some part of its course, may diminish the pulse-wave.

The first three causes may be discovered by an examination of the limb; the last two have characteristics which will be referred to hereafter.

When comparing the tracings of either radial the following points of difference must be looked for:—First, is there any difference in percussion—*i.e.*, is one upstroke more sloping or shorter than the other, or the apex less pointed? Second, is the tidal wave equally high and sustained in each? Thirdly, is the dicrotic wave equally developed? A difference may exist in one or all of these points. If it exist in the tidal wave alone it need not, and probably will not, be due to aneurism: it is the loss of percussion and dicrotism that is the most characteristic of this disease.

In order that the immediate effect of an aneurism on the pulse-wave may be demonstrated under conditions free from any complication, two cases have been selected, and placed first on the plate, where the aneurismal sac occurs directly in the course of the radial, or rather in that of the artery of which it is a continuation. From the characteristics of these tracings it may be gathered what indications are to be expected, though in a less marked degree, in cases where the aneurism is more remote, and the diagnosis of which may be more difficult.

Figs. 1 and 2, Pl. vii., represent the tracings obtained of the radials of A. B., a woman, aged 69, admitted into Guy's Hospital November 14, 1870, under the care of the late Mr. Poland. She had an aneurismal tumour which extended above and below the elbow of the right arm. It appeared after a fall a fortnight previous to her admission, and was rapidly increasing. The aneurism was considered by Mr. Poland to be one of the brachial artery just above its point of bifurcation. Fig. 1, obtained from her left radial—that unaffected—demonstrates well the highly atheromatous condition of her arteries. This is indicated by the well-marked percussion-wave, the peculiarly sustained tidal (which terminates by an almost vertical descent, instead of the more gradual one produced by the contraction of the elastic coat of a healthy artery), the small dicrotic wave, and the succeeding almost horizontal line, occurring during the diastolic portion of the tracing, instead of the gradual collapse produced by the continued contraction of the normal elastic coat. In this condition we see how the contraction of the heart, which becomes therefore necessarily hypertrophied, is the only motor power in the arterial system—the aid of the elastic coat, which plays so important a part in the mechanism of the circulation of a healthy person, being entirely lost.

Fig. 2, representing the pulse-wave in her right radial, shows most markedly the effect produced by the presence of the aneurismal sac: all the three waves entering into the composition of the normal pulse are affected—two of them, the percussion and dicrotic, are totally annihilated; the third, or tidal, is diminished in volume and prolonged. The shock produced by the contraction of the ventricle that gives rise to the percussion-wave is lost in the aneurismal sac, which breaks the continuity of the column of blood of a certain tension that is required for transmitting a rapidly moving wave or vibration such as this. In a like manner the smaller and less marked dicrotic wave is also lost in the sac, which is dilated by and entirely absorbs it. It may here be remarked that the disappearance of the dicrotic wave, which occurs in this and other aneurismal tracings, gives evidence of the proximal origin of this wave, and disagrees with the theory of its distal origin maintained by Dr. Sanderson. The tidal wave, however, being of much greater volume than the other two, passes on beyond the sac, though retarded and diminished in size, the sac having been first filled, and by its interposition having altered the character of the tidal wave entirely.

The tracings represented in Figs. 3 and 4, Pl. vii., were obtained from H. S., a man aged 36, admitted into Guy's on February 9, 1872, under Mr. Cooper Forster. It will be unnecessary to enter into the details of this and other cases, which by the kindness of the physicians and surgeons of Guy's Hospital have been used to illustrate these papers; suffice it to say that the patient suffered from a large aneurism of the right axillary artery, which was cured by compression of the subclavian. The tracing of the pulse in the left radial (Fig. 3, Pl. vii.) has no especial characteristics beyond an indication of a large heart, while that of the right (Fig. 4, Pl. vii.) is a typical aneurismal pulse, and presents the same characteristics as the corresponding pulse in the preceding case. From this tracing it will be seen how greatly an aneurism situated directly in the course of an artery going to the upper extremity, and which does not implicate the aorta, affects the pulse of the side on which it is situate. In those rare cases of suspected aneurism of the subclavian or axillary arteries where the diagnosis in uncertain, the sphygmograph often proves extremely useful: such a case I have met with while writing this paper, but unfortunately too late to insert the tracings in the plate. A patient has been admitted into Guy's Hospital, under the care of Mr. Cooper Forster, with a pulsating tumour, corresponding in appearance and position to one produced by an aneurism of the left subclavian; indeed, it was

considered such by many. Without any particulars of the case being known or an examination made, tracings were obtained of either radial, and from the very slight difference in the pulse-wave of either side, the presence of an aneurismal sac arising from the subclavian was denied. The only difference that could be detected in the two pulses was that the left pulse required one ounce less pressure than the right, and that the percussion-wave was diminished on this side. This opinion was arrived at before any examination or diagnosis had been made by Mr. Forster, and coincided with that subsequently formed by him. The pulsation may be considered due possibly to a dilatation of the subclavian throughout its entire course.

The next two tracings (Figs. 5 and 6, Pl. vii.) are from a case of the highest possible interest, and one in which the value of the sphygmograph was pre-eminently illustrated J. B., a man aged 36, was admitted into Guy's, under the care of Dr. Habershon, November 15, 1871. He appeared to be suffering from an aneurism of the innominate, but whether the aorta was implicated or no could not be determined by physical signs; there was, however, no reason to doubt but that, following the general rule, it was. After an examination by the sphygmograph, it was stated that the opening between the aorta and innominate was extremely small, and that the former vessel was not involved. The case was, moreover, recommended as one suitable for ligature of the innominate, but, owing to an attack of bronchitis, this was out of the question at the time, and a day or two afterwards the patient died during an attack of dyspnœa.

The post-mortem revealed an aneurism of the innominate, about the size of an orange; there was half an inch of innominate between the aneurism and the aorta, the size of the opening between the two vessels being about that of a sixpence. Both the right carotid and subclavian arteries arose from the back of the tumour. The tracing obtained from the left radial (Fig. 5, Pl. vii.) does not possess any characteristic features, while that of the right (Fig. 6, Pl. vii.) is strikingly aneurismal. It exhibits a complete loss of percussion, the upstroke being sloping and the summit rounded; the tidal wave is not much if at all diminished, while the dicrotic wave is almost absorbed. It will be noticed that the pressure employed on this side (*i.e.*, seven ounces) is much greater than that on the left (*i.e.*, four ounces); but it is not to this that the difference is due,—the lighter pressure was previously tried on this side, but the tracing was found to be most perfectly developed with the higher. The question will naturally be asked, On what ground was the small opening between the vessels diagnosed? It was for this reason:—Aneurisms of the innominate, when the aorta is also involved, affects the pulse of the right side very slightly, if at all, and often no difference can be detected in the two radials; for, the innominate being connected with the aorta by a large opening, the whole sac virtually forms part of a dilated aorta, from which the innominate rises as usual: and this occurs before either of the large arteries take their origin from the aorta, and is not enough to produce a characteristic tracing on either side, or if it affects one it will often affect both. In cases of innominate aneurism this therefore forms a gauge of the amount to which the aorta is involved: the less it is implicated, the greater is the difference in the radial pulses.

The following case is a more obscure one, the diagnosis not having been verified:—T. H., a man aged 33, was admitted under Dr. Wilks on April 22, 1873. The position of the pulsating tumour rather indicated an aneurism of the arch than of the innominate, for it had caused the absorption of the first and second costal cartilages; but the constant pain, so great as to preclude the use of the right arm and shoulder, indicated pressure on the brachial plexus, and this could hardly have been caused by an aneurism of the ascending arch. The man was removed to a naval hospital, so that the termination is not known. The tracings (Figs. 7 and 8, Pl. vii.) show a very considerable difference in the pulse on either side. In Fig. 7, taken from the left side, there appears to be some diminution of the percussion-wave, and a tendency to rounding of the summits; while in Fig. 8, obtained from the right radial of the same individual, the tidal wave is much diminished, the percussion-wave is altogether absent—the upstroke being sloping and the summit rounded,—and the pulse is decidedly aneurismal. This occurring on the right side, while the left is not equally affected, evidences that the aneurism must interfere very considerably with the passage of blood down the innominate, even if that vessel be not solely involved. It is unfortunate that the result is not known, for the tracings are of great interest.

The next case is one chosen to demonstrate the fact that the presence of a large innominate aneurism, when the aorta is implicated, may produce no appreciable result on the pulse of the right side:—J. S., a man aged 33, was admitted under Mr. Bryant suffering from aneurism of the innominate involving the aorta. The tumour had existed for more than eighteen months. Mr. Bryant applied a ligature to the subclavian artery, and the man left the hospital much improved. the tumour being harder and the pulsation less. Figs. 9 and 10. Pl. vii., were obtained from his left and right radials respectively. The tracings present exactly the same characters, and no sufficient difference on which to base a diagnosis can be detected.

After ligature of an artery the establishment of a collateral circulation can be discovered by the sphygmograph before it can be detected by the finger. In this case, after ligature of the subclavian, by feeling for the cord of the contracted and almost empty artery, and applying the instrument, a tracing (Fig. 11, Pl. vii.) was obtained ten days after the operation, before any perceptible pulsation could be detected—indeed, if it had been attempted, a tracing might have been obtained previous to this, as much smaller waves than those in the plate have been traced after ligation of an artery. Seven days after this, when the pulsation could be distinctly felt, the tracing represented by Fig. 12, Pl. vii., was obtained.

The case illustrated by Figs. 13 and 14, Pl. vii., is another instance of an aneurism of the innominate implicating the aorta in which the pulse on either side does not materially differ. J. J., aged 55, was admitted into Guy's on April 3, 1872, under Mr. Cooper Forster. He gives a history of pain at root of neck for three years, and a tumour has been noticed for three months. Fifteen months ago he had been attacked during sleep by paralysis of his left arm and leg. His symptoms arising from the aneurism becoming more severe, he was admitted for operative interference. He died on the eighth day, after compression of the right carotid under chloroform; and at the post-mortem examination an aneurism was found which involved the whole of the innominate, part of the aorta, and about one inch of the carotid. The opening from the aortic into the innominate part of the aneurism was about the size of half-a-crown. If the tracings of the two radials be compared, it will be noticed that on the right side percussion is a good deal diminished; the upstroke, if carefully examined, will be found to be rather more sloping, while the sharp hook at the summit has almost entirely disappeared. The tidal wave, however, is not diminished; while the dicrotic, being more easily absorbed by the sac, is much more affected. There is, however, not sufficient sphygmographic evidence, either in this case or in the one preceding it, upon which to found a diagnosis of innominate aneurism. It is necessary to remember, therefore, that although the pulse tracings may be exactly equal, an aneurism may be nevertheless present, but that under these circumstances the aorta is almost certain to be involved.

While discussing aneurisms of the innominate and large vessels, it will be well to notice what indications the pulse gives that assist in the selection of a method of operative procedure. The distinction it affords as to whether the aneurism implicates the aorta or not, and is accordingly more or less remediable, has already been pointed out.

There yet remains an extremely important point to be noticed—namely, the effect of the prolonged administration of chloroform during the operation of compression of an artery. This appears to affect patients very differently, and to vary chiefly with the condition of their hearts and arteries—conditions which, in the presence of an aneurism, are of the gravest moment.

This important point does not seem to have been clearly recognised, yet sometimes the life of a patient may be imperilled by it; and the thought suggests itself, that a few cases must have occurred where this knowledge might have determined the choice of operation. Fig. 15, Pl. vii., represents the pulse of the same man as Fig. 3, Pl. vii., while under chloroform during the compression of his subclavian. When this tracing was obtained, he had been under the influence for some hours, and a most marked and extraordinary change had occurred in the pulse—it had increased to an enormous size; the heart was acting far more powerfully than was usually the case: for not only is there the great increase in size of the tracing to be considered, but also the fact that five ounces of

pressure had now to be employed, while two ounces was all that was previously required. The dangers to which the patient is exposed are evident:—1. Apoplexy, which will be found to occur in the following case. 2. Formation of another aneurism if the arteries are generally atheromatous or otherwise diseased, as by syphilitic arteritis. 3. If the pressure were distal instead of proximal, rupture of the aneurismal sac might probably ensue. 4. Retroflexion of an aortic valve may be induced, or, in case of previous cardiac disease existing, this may be increased. This latter probably occurred in the present instance. Previous to the operation, the heart's apex was found to be displaced outwards, and the organ appeared hypertrophied. A systolic and very faint diastolic bruit had been heard at the base and down the sternum. This under chloroform increased in intensity, while at one time the dicrotic wave in the tracing almost disappeared. After the operation the diastolic murmur appeared slightly louder than before, and although his cardiac symptoms did not increase, and the aneurism was cured, still one can imagine that a very different result might have been produced.

In the case of J. J., above referred to, a more serious consequence is exemplified. This man, it will be remembered, had, fifteen months previously, been attacked by hemiplegia. While under chloroform for compression of his right carotid, he was attacked by apoplexy. He lived after this, though without returning to consciousness, for eight days. At the post-mortem capillary hæmorrhages were found in the cortical substance of both hemispheres of the brain. His heart was hypertrophied and his arteries atheromatous. Fig. 16, Pl. vii., represents his pulse after being under chloroform for some hours, while Fig. 13, Pl. vii., was obtained previous to the operation. The pulse-wave is very much increased in size by the chloroform; but what is more important, the heart is acting so powerfully as to require a much greater pressure to develope the tracing. An ounce and a half was previously sufficient for the purpose; now it requires five ounces. The natural effect of this violent action of the heart in a subject peculiarly liable to such a result, and who indeed had already suffered in a similar manner, was to rupture the delicate cerebral vessels, and produce hæmorrhage.

Both these cases, where the heart was stimulated to such excessive action by the administration of chloroform, are similar, in that both had hypertrophied hearts and bad arteries. In other cases where the aneurism has been due to localised arterial disease, and has not been accompanied by cardiac hypertrophy and general atheroma, I have not found the same effect produced. The pulse is then but little altered in its character; it generally becomes a little fuller and harder, but not to such an extent as to deserve attention. Figs. 11 and 13, Pl. viii., in the case of T. D., are instances of this. The indication afforded, therefore, appears to be this:—In cases of aneurism occurring in patients whose hearts are hypertrophied and arteries generally atheromatous, it is better either to compress without chloroform, or else to apply a ligature if possible, rather than submit them to a prolonged administration of the anæsthetic.

(To be continued.)

List of Naval Medical Candidates who were successful at the competitive examinations held at London in February, and at Netley in August, 1873, after having passed through a course at the Army Medical School, Netley, and who will receive commissions as Surgeons in Her Majesty's Navy:—

	Names.	Studied at	Number of Marks.(a)

SATURDAY, AUGUST 9, 1873.

THE ADDRESSES AT THE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Like time and tide, the periodical press waits for no one, but with pitiless persistence and inexorable punctuality demands its pabulum. "Copy" must be forthcoming at the fixed normal time, come what will: "*ruat cœlum*," but feed the printer's devil. And so it happens that we must set to work for the instruction and edification of our readers just when the meeting of the British Medical Association is in full—play, we had very nearly said, but perhaps the expression might be misapprehended; "full swing" hardly sounds dignified enough for such an occasion; we may be permitted, perhaps, to say—just when the meeting is at the very top of the spring-tide of business and pleasure. Every hour of the working day is given up to addresses-in-chief, addresses in the sections, papers, and discussions, or to medico-ethico-political meetings; and in the evenings and far into the nights every minute is absorbed by public or private hospitalities; while all the hours—of business and of pleasure alike—are brightened and gilded by the formation of new and the refreshing of old friendships. Under such circumstances no one can expect that our editorial calmness and judgment can remain so uninfluenced that we can coldly criticise the quality of the work being done. We do not even pretend to attempt to do so, but we feel that we must, even this week, say a few words on some of the addresses that have been given.

The President's Address demands, of course, the place of honour in our notice; but we do not propose to say much about it, except to commend it to the consideration of our readers. The annual presidency of such a body as the British Medical Association must always be looked upon as a high honour, and especially so when the Association meets in London; but we confess that we think the necessity of giving an opening address to the Association must be felt by the President to be a heavy burden. Whether he be physician or surgeon, his own familiar field of practice is handed over to some other eminent man, who has to give an address in medicine or surgery, and so the lines of thought and work

most familiar to the President are of necessity almost closed to him. He of course acknowledges the honour conferred on him by his elevation to the presidential chair, and modestly magnifies his office and underrates his own merits; he utters some words of warm welcome to the Association on the part of the profession in the city in which it meets, and of the branch of the locality; he gracefully acknowledges the hospitalities and courtesies, civic, civilian, and professional, proffered it; and he dilates, more or less, on the past achievements of the Association, and on its future greatness and glory. But all this will not serve to make an "address," and the President has to cast about for some topic that will most probably not be dealt with in any of the other addresses.

The President for this year, Sir William Fergusson, took "Water Supply" for his subject, and boldly advocated quantity *versus* quality as the great desideratum. At least that will, we think, be the general impression made by his address; as he appears to argue that by far too much stir is made about the purity of the water supply compared with its copiousness. He says, "I fancy that the pure chemist is too often taken for one of us; I fear that many of us affect too much the airs of the pure chemist"; and towards the close of his address he says, "I cannot but again express my opinion that we, in our professional capacity, may err grievously in making trivial and questionable objections to the quality of water, when there seems a fair prospect of getting that which is most desirable for man's use—a full, ever-flowing quantity which might give a perpetual current, day and night, well-nigh fresh from the dew of heaven." We suspect that many of his arguments and illustrations are very open to hostile criticism, and that his plan for an ever-flowing supply of "nature-distilled, nature-filtered" water, by the formation of artificial lakes, will hardly be generally accepted as a practicable solution of the water-supply question. But we imagine that all he really wished to urge was that we should have water free from organic impurities for drinking, and a plentiful supply of soft rather than hard water for domestic purposes. He concluded his address with a happy allusion to the motto of the College that has courteously placed its buildings at the service of the Association—"We have begun our work this morning holily, under the dome of St. Paul's, let us conduct it wisely, and thus fulfil the well-chosen motto of King's College, within whose walls we are met—'*Sanete et sapienter.*'"

No words from us are needed to secure full and attentive consideration for Professor Parkes's able and interesting Address in Medicine. Recalling the medical practice of his student days, "now not very far from forty years ago," and thinking over the progress that has been made in the diagnosis, the cure, and the prevention of diseases, he, for our instruction, passes "in brief review the principal points in practical medicine which have seemed of most influence" during his medical life; and the retrospect with which he presents us is highly interesting and encouraging. Foremost in the list of discoveries and gains he places "Richard Bright's recognition of albuminuria, and Laennec's application of the ear to discover the normal and abnormal actions of the heart and lungs"; and he points out how wonderfully great were the advances thus made, and how marvellously little of error and incompleteness there was in the work of these men; and how, while Bright's work was inevitably less complete than Laennec's, yet it included "wonderfully little error of commission." "While Laennec," the Professor observes, "in his discussion on tubercle, wished to give a complete and exhaustive account, which he could not really do, and desired to bring everything into the narrow circle of a definition, which really left half out, Bright kept to his facts. What he saw he stated, and, as far as the facts warranted, he interpreted; but he went no further; and in this he showed a more philosophical mind even than the illustrious discoverer of auscultation."

Then Professor Parkes notices the discovery of embolism and thrombosis as, to his mind, "one of the most important practical advances in the last thirty years," and he seizes the occasion to pay a graceful compliment to Virchow: "Among all the discoveries in pathology which have been made by the surpassing genius of Virchow (and he has touched pathology at all points, and never without adorning it), there is none more valuable than the recognition of embolism."

The immense advances made in the knowledge of the entozoic diseases of man, and of the mode of access and the transformations of the entozoa, are then noted, as also is the recognition of diseases owing to cryptogamic plants, and "the researches which seem to trace so many affections, in part or wholly, to the influence of the bacteroid bodies which at present we must call plants"; and the Professor ventures to predict "that in this direction practical medicine is about to make another step, and that as there is 'a disinfecting surgery,' so also there will have to be 'a disinfecting medicine.'" We cannot attempt to follow Professor Parkes through all the subjects he handles so well, but we would especially direct attention to his able notice of the changes that have been made in the doctrine of inflammation, in our views of the pathology of phthisis pulmonalis and of tubercle, and of the advances made in our knowledge and understanding of the specific febrile diseases. In speaking of the latest dissertations and discussions on phthisis and tubercle, he well observes that "it would be rash to assert how we now stand in this matter"; but we think that he not unfairly sums up the results when he states, "it seems to me that the late able discussions in this country and in Germany tend more to the idea that the tubercular character is the consequence merely of an anatomical condition, and that the greater or less amount of lymphoid tissue in the lungs, and the fact of its involvement, will account for the peculiarity of form," and again, "the tendency of the inquiry seems to me to indicate that we must look to the anatomical condition of the bodily tissues, and especially to the abundance or special condition of the lymphatics in the lungs or throughout the body, to explain the hereditary nature of tubercle in certain cases, and also to account for those instances of general tuberculosis which formed the basis on which Bayle built up his hypothesis of phthisis." It is satisfactory to observe that Dr. Parkes, while fully acknowledging the labours of our brethren in Germany, France, and elsewhere abroad, does not forget to fully acknowledge also the labours of his brethren at home, but is careful to note that not a few of the points most insisted on in the pathology of the day had been taught in England years ago, though so disregarded, ill-appreciated, or forgotten that they have been rediscovered by foreign workers. It is highly satisfactory, also, and encouraging to find that a man of Professor Parkes's full learning and ripe experience is no sceptic as to the real advances made in the knowledge of practical medicine and in the art of curing disease. He believes his review "chronicles an immense forward movement in practical medicine," that it shows "that few subjects can boast more original investigations, and that, in spite of great difficulties, and oftentimes of great differences of opinion, the general knowledge of practical medicine has advanced continuously, and has advanced greatly." He has found his retrospective view cheering and hope-giving, and is able to feel "that we have played no unworthy part in the great drama [of the last forty years], and that among the restless activity of modern times, and the growth of newly-born sciences, an old art has not stood still, but with ever increasing power is still, as it always has been, a very present help in time of need."

Of the Address in Surgery, by Professor John Wood, of King's College, we can say but a very few words this week. Its character is that of the "practical" address; indeed, we

should best point to its value and interest were we to call it a clinical address on some important subjects in surgery; and we think that its author would appreciate and accept the compliment we pay him in thus valuing his work. The main subjects dwelt on are pyæmia, septicæmia, and erysipelas, in connexion with the antiseptic system of dressing wounds, the radical cure of rupture, and the treatment by plastic surgery of ectopia vesicæ, epispadias, and other cases of deficient development or of loss by injury. On all these subjects Professor Wood speaks with the authority of a master, and illustrates them from his own large experience. But we hope to return next week to the consideration of his valuable lecture.

THE PROPAGATION OF CHOLERA.

The discussion on cholera in the Section of Public Medicine at the meeting of the British Medical Association was seasonably opened and competently maintained, and we find with satisfaction that the results of it are on the whole reassuring. Four weeks ago, in writing upon the question of the propagation of cholera, we directed attention to two disquieting circumstances. The first of these was characterised as nothing less than alarming: it was the fact that the sanitary authorities of the Russian Government, headed by Dr. Pelikau, have arrived at the conclusion that cholera is endemic in Russia, and that the disease as it is seen at the present moment there and elsewhere on the Continent deserves the name, not of Asiatic or Indian, but of European or Russian cholera. To this view the opinion of no less an authority than J. Netten Radcliffe, representing the Medical Department of the Privy Council, is distinctly opposed. If the experience of our cholera authorities in England and India, as well as of the laborious students of the disease on the Continent, was of any value, there was *primâ facie* everything in favour of the Russian opinion being a mistaken one, and of the cholera visitation of 1869 representing a wave of the disease which had arisen in India. The fact that the contrary opinion is startling shows this, and there is still more powerful evidence. In 1867 Dr. Murray, the Inspector-General of Hospitals, watched cholera arise and pass through the north-west corner of India, and he foretold that the wave which had thus begun to roll would spread over Persia and Europe. As we now know, he was no false prophet: in 1869 cholera raged in Persia and Russia. Pelikau and the Russian Government urge, as we have seen, that this and other more recent visitations were but the outbursts of the smouldering embers of their predecessors; but in the evidence which they adduce in support of their views there are several flaws of sufficient magnitude to nullify the importance of their conclusions. The first, and perhaps the chief of these, is their entire disregard in their calculations of the presence of cholera in North-Western India and especially in Persia. We have seen that it was in India shortly before, and in Persia it was both extensive and severe. There is no doubt that in 1869 the Russian authorities at Kiev were prosecuting the treatment of cholera as a local disease, oblivious to the existence of the plague in Persia, and to the free communication between their much-frequented city and their Oriental neighbours. Even granting that the 1866 epidemic had lingered on till 1869—and this is the second weak point in the Russian evidence—there is nothing to show that a fresh wave from India and Persia did not add its weight to its declining predecessor. On the contrary, Dr. Murray's observations and logical conclusions, and the presence of cholera in Persia, convert the probability almost into a certainty that such a fresh visitation did occur.

The second circumstance, which we may now regard with more composure, is one which refers to the propagation of cholera, not from country to country and nation to nation, but from man to man. In the article to which we alluded above, we entered at some length into Pettenkofer's views, and took occasion to remark that their effect is disturbing and may possibly prove pernicious. Pettenkofer's rejection both of direct and indirect contagion in the propagation of cholera reduces us to a condition of almost helpless ignorance, and stultifies many of the sanitary measures which we congratulate ourselves on having completed. It is for this reason that we feel relieved in learning that such men as Murray and Parkes still stoutly maintain that cholera is propagated by drinking-water, and by this medium chiefly. If the poison of cholera reaches the body mainly by drinking-water, we have it in a palpable form, and can deal with it accordingly. If, on the other hand, it were a miasm, as Pettenkofer would have us believe, not communicable by water or by direct contagion, we should have to do with a poison which we cannot grasp, but which, like that of ague, has such a peculiar local disposition as completely to elude us. It was interesting to hear several of the provincial speakers in this section expressing in emphatic language their belief in the communicability of cholera by direct contagion especially. At the same time, few, if any of them, refused to water in some degree or other the power of acting as a medium for the conveyance of the disease.

THE WEEK.

TOPICS OF THE DAY.

We are sorry to state that a number of cases of typhoid fever have occurred in the parish of Marylebone, and suspicion has been directed to the milk supply of the inhabitants of the districts which have been chiefly attacked. In reference to this matter we have received the following letter from Dr. Whitmore, the Medical Officer of Health to the district. As the matter is of vital importance to the population of the northern part of the West-end, we trust that any of our readers who may meet with cases of typhoid in that neighbourhood will not fail to institute the inquiries Dr. Whitmore suggests, and will communicate to him the results:—

"Department of Medical Officer of Health,
"Court House, St. Marylebone, W.
"August 6.

"Sir,—It has come to my knowledge that many cases of typhoid fever have recently occurred in this and neighbouring parishes amongst families who are supplied with milk from the same source. I shall feel under great obligation to any of your medical readers who may at the present time be treating the disease, or have recently done so, in this or the neighbouring parishes, to inform me with the least possible delay of the source from which in these instances the supply of milk to the family has been obtained.

"The great importance to the health of the community of the matter which my official position calls upon me to investigate, is my apology for asking your valuable assistance.

"I am, Sir, your obedient servant,
"J. Whitmore, M.D.,
"Medical Officer of Health for the Parish of St. Marylebone."

During the Session of Parliament which has just concluded, the only Bill affecting directly the medical profession which has passed both Houses and received the Royal assent, is the short Bill which we published in a recent number, giving the University of London the power to unite and co-operate with any two or more of the Colleges and bodies mentioned in the Medical Act of 1858 in conducting examinations. In future, then, if the conjoint examination be established in England, it will be lawful for the University to prescribe that no person shall become a Doctor, or Bachelor, or Licentiate of Medicine, or Master in Surgery, unless (in addition to passing such examinations as shall be prescribed by the University) "he shall have passed such examination for qualification to be registered under the Medical Act, and complied with such conditions relating thereto, as may be agreed upon between the said University and the College or body,

Colleges or bodies, with whom the said University may be united or co-operating as aforesaid." Another paragraph provides, as our readers know, that the assent of one of her Majesty's Principal Secretaries of State is necessary to give force to the arrangement between the University and the co-operating bodies, and also that one of such Secretaries of State may, at any subsequent time, if he shall think fit, revoke his assent—a provision which does not increase our belief in the stability of the whole scheme.

We are sorry to state on undoubted authority that there have been cases of cholera at Hamburg. No more cases have occurred on board the *Rhin*, and arrangements have been carried into effect for removing from quarantine the healthy emigrants.

In the House of Commons, on Monday, the order for the second reading of the Factory Acts Amendment Bill was discharged.

The *Times* has recently published, in its outer sheet, a long letter from Mrs. Garrett Anderson, M.D., in which the writer, after reviewing the condition of the medical profession, the conservative instincts of the Colleges, the "trades unionism" of country medical men, and the general benighted condition on the subject of female medical education of doctors who are fathers of daughters as well as of sons, recommends the aspiring damsels who wish to practise physic to give up England and Scotland as a bad job, and to go to Paris, where they can get a degree. "*Solvitur ambulando*" is the motto she would have them adopt. Of course, foreign degrees are not registrable, but this she seems to think is of little consequence, and after all it will only be for a time. When women get the franchise, one of the first things they would hope to obtain "would be the throwing open to them of the benefits of the Scotch universities." It will be seen that Mrs. Anderson still advocates a common medical education for men and women.

RECRUITING AND THE BRITISH ARMY.

We recently commented on the subject of recruiting for the army upon the occasion of a debate which took place in the House of Lords on this matter, and we pointed out that from the returns which had been furnished it was abundantly evident that, as regarded stamina and physique, our army could not be said to be on a satisfactory footing. An incident which is reported to have occurred at the Autumn Manœuvres now taking place on Dartmoor will amply explain our meaning. One of the battalions of the 9th Foot was brought by rail to within seven miles of its appointed camping-ground; it should have been met on its arrival at the station by certain commissariat waggons of the Control Department, in order that breakfast might be served out to the men. No waggons, however, appeared, and after waiting for some time the order was given to march for the camping-ground. The morning was certainly warm, and the troops fasting, but such a scene as was presented by this regiment *en route* could scarcely be considered reassuring by the most ardent admirer of the powers that be. The men began to fall out almost as soon as the column moved. They are represented to have been for the most part youths, apparently perfectly unable to make head against the weather on empty stomachs; and the corps would appear to have finally reached its camping-ground with about half the number which filled its ranks at starting. Such a state of things is matter for grave consideration, and the question which naturally arises is, What would have been the result in actual warfare if this is to be taken as a sample of a march undertaken in time of peace? It may be argued that the men were exhausted for want of food; but supplies are not always at hand in time of war, and we think all our generals will agree that the British army should be composed of soldiers who could make a march, such as this regiment was asked to do, under almost any difficulties. The Franco-Prussian war exhibited instances of enormous marches undertaken by the Germans. The advance on Paris after the battle and capitulation of Sedan was spoken of in terms of wonder by military men, on account of the rapid and continuous work which the men were called upon to get through, yet the stragglers were utterly inconsiderable. Now, we cannot for one instant allow that the stamina of our countrymen is inferior to that of the Germans; but the class of recruits obtained under the present short-service system is not up to our lowest standard. We have abolished pensions, and removed at least one inducement for men to remain in the army, and after six years' service we lose the growing youths at the very time that they have, thanks to regular feeding and good training, developed into stalwart, healthy men.

The service is not so popular as it should be. The recruiting returns show that the numbers obtained during the past year were far below what was required, hence the qualifications are reduced as regards height and chest measurement; and that army, which should be second to none for physique and stamina (when the health and hardiness of the inhabitants of these islands is taken into consideration), affords in one of its sections the example which we have now quoted.

We are assuredly a supine people, even where our greatest interests are concerned; and if at some future day, with dissatisfied officers (military and medical), weak and incompetent men, and an inefficient Control system, we meet with some huge disaster, we may possibly apply a sweeping and vigorous system of reform to the administration of our army affairs, and perhaps regain our former state of efficiency; but nothing short of such a calamity would appear to have the slightest power in arousing our rulers to a sense of the decadence of our country in a military point of view.

THE ROYAL COLLEGE OF PHYSICIANS.

The following are the names of the Members of the Royal College of Physicians of London who were elected to the Fellowship on July 31, 1873:—William Wilson, M.D. Gott., Florence; Henry Moon, M.D. St. And., Brighton; Francis Cornelius Webb, M.D. Edin., Woburn-place; Alfred Hall, M.D. Edin., Brighton; Sigismund Sutro, M.D. Munich, Finsbury-square; John Cameron, M.D. Glasg., Liverpool; Sir Joseph Ritchie Lyon Dickson, M.D. Malta, Teheran, Persia; Robert Elliot, M.D. Edin., Carlisle; Charles Coates, M.D. Aberd., Bath; Alfred Meadows, M.D. Lond., George-street, Hanover-square; Thomas Beath Christie, M.D. St. And., Royal India Asylum, Ealing; Alfred Baynard Duffin, M.D. Edin., Devonshire-street; Christopher Mercer Durrant, M.D. Ipswich; William White Williams, M.D. St. And., Cheltenham; John Beddoe, M.D. Edin., Clifton; William Coverdale Beaty Eatwell, M.D. Glasg., Oriental Club, Hanover-square; Peter Eade, M.D. Lond., Norwich; George Hare Philipson, M.D. Cantab., Newcastle-on-Tyne; Balthazar Walter Foster, M.D. Erlang., Birmingham; Thomas Tillyer Whipham, M.B. Oxon., Green-street; Thomas Buzzard, M.D. Lond., Grosvenor-street; Richard Douglas Powell, M.D., Henrietta-street; Joseph Frank Payne, M.B. Oxon., Savile-row.

EDINBURGH UNIVERSITY CLUB.

The "Capping-day" dinner of the Edinburgh University Club was held at St. James's Hall Restaurant, London, on the 1st inst.; Sir John Rose Cormack, of Paris, M.D., F.R.S.E., presided. After the usual loyal toasts, the Chairman proposed the "University of Edinburgh and the hundred gentlemen who had a few hours previously been created Bachelors and Doctors of Medicine." In the course of his remarks he read a telegram, which he had just received from Edinburgh,

announcing the number of new graduates and the names of the medallists. In continuation he said—

"In ancient days, when the University of Paris proudly and truly called herself the instructress of nations, we read that her sons counted themselves as one family, and were bound together in the closest bonds of brotherhood. When crusading bands of rival nations met in distrust on the plains of Palestine, distrust ceased on their finding that they had an equal claim to an Alma Mater on the distant Seine. "Nos fuimus simul in Garlandiâ"—we were fellow-students in the University of Paris. These magic words dispelled national antipathies, and inaugurated enthusiastic solidarity and brotherhood. Is it not with exactly similar feelings in our hearts, and with almost the same words on our lips, that we have this evening taken our seats around this social board, saying, 'You and I, and all of us, are Edinburgh men'? (Cheers.) The telegram that we have just received carries us back in memory to the old scenes of study and amusement, when life was young, and to some particular August 1, it may be many many years ago—a long past cappiug-day. Prosperity, then, to the University of Edinburgh, and may God speed the hundred graduates who have this day received their diploma."

The Chairman then proposed the toast of the evening, "The Edinburgh University Club." Dr. Sieveking proposed "The Health of the Chairman," who he said was an honour to the club, to his profession, and, as the Queen had signified, to his country, by her having conferred upon him the honour of knighthood. The Chairman, in his reply, gave some graphic sketches of incidents in which he had taken part during several of the battles around Paris during the German siege, and in Paris during the terrible days of the Commune. He stated that during the thirty or forty hours of the battle of the Faubourg St. Honoré he had received no less than sixty-four cases of gunshot and shell wounds into Sir Richard Wallace's Ambulance Anglaise. He concluded his interesting sketches by saying that those who had gone through such scenes felt perhaps more intensely than others the blessing of belonging to a nation as yet a long, long way from communistic contamination. Dr. Whitely proposed the health of Lady Cormack, whom he knew well was a true wife, a worthy helpmate of her courageous husband, and, as he had heard from many sources, she had proved an invaluable fellow-worker with her husband in the trying times of the two sieges. The Chairman, in returning thanks, said that without his wife's support he did not think that he could have emerged a living man from the ordeal. The entire want of news for months of absent loved ones, the long famine of food and fuel, and the personal danger to which he was often exposed, tried her sorely.

LUNATICS AND ALLEGED LUNATICS.

A special committee reported to a meeting of the Islington Board of Guardians held last week the result of their visit to the Hanwell and Colney Hatch Lunatic Asylums. It was stated that some of the patients were not really insane, and a Mr. Cafflin said many persons were sent to lunatic asylums in consequence of the pecuniary inducement offered to boards of guardians, as when they were kept in workhouses the allowance from the Metropolitan Common Poor Fund was 5d. a day, but when they were sent to asylums the allowance was 12s. a week. With whatever sincerity—and we do not doubt it—Mr. Cafflin made his statement, we cannot believe it to be correct. The regulations respecting the custody of lunatics in our public asylums are, if carried out efficiently, competent to prevent such a gross outrage upon humanity. We believe that these regulations are so carried out. But, whether this be the fact or not, Mr. Cafflin's statement demands a searching inquiry, and we feel confident that the Commissioners in Lunacy will take steps to test Mr. Cafflin's accuracy. Whatever abuses in times past may have existed with respect to the custody of "lunatics," either in private or public asylums, we are convinced at the present time they do not prevail. The public mind, however, is extremely sensitive on this question, and its sensitiveness is kept at a maximum by the stimulus administered by writers of fiction. Nothing is more difficult in some cases than to determine whether a person be really of unsound mind. That this question should be left to the judgment of laymen would be a great mistake. The worst and most dangerous of lunatics are those whose real mental condition is at times only to be discovered by the searching investigation of experts. If a mistake be occasionally made, it should certainly be promptly rectified. There is no class of unfortunate members of society more "hedged in" by legal protection than persons of unsound mind, whether as regards their custody or the protection of their property.

ALLEGED DEFECT IN THE ADULTERATION ACT.

Dr. Tidy, the analyst for the parish of Islington, stated to the Vestry meeting last week that in performing the duties devolving upon him under the Adulteration of Food Act he had thought it better to commence with the common food of common people—bread and milk. Of the former he had analysed twenty samples, and out of these sixteen did not contain any alum at all, and the other four such a small quantity that he did not think it advisable to recommend a prosecution in either case. He intended to proceed with the analysis of other articles of food; but with regard to spirits and beer, he thought they were not included in the Act, and that the duty of analysing these drinks belonged to the Excise officers, who had power at any time to enter publicans' cellars and take samples. He knew it was a legal question, but until it was decided he did not feel called upon to analyse beer or spirits. He did not think it would be well to push the Act to its extremity. The Act must be sadly deficient if Dr. Tidy is right in his opinion. There are no articles consumed by the public that probably are more adulterated than spirits, wine, and beer. Dr. Tidy, from his large experience, is entitled to be heard with respect on the subject. On such an important point, however, it is of the last importance that no "legal" doubts should exist.

A WORTHY TESTIMONIAL TO A GOOD MAN.

In the decline of Athens, when it became the fashion of erecting statues to "deserving citizens," it was said, somewhat ironically, that it was easier in that renowned city to find a statue than a man. What with monuments and other marks of esteem to persons who have done public service, however small or great, England may at no far distant period be open to the charge that these marks of approbation have been too indiscriminately given. An exception to this practice is therefore worthy of being recorded. Such an exception is that which we have the pleasure of recording with respect to Dr. Chadwick, of Southport. A bronze statue of Dr. Samuel Taylor Chadwick, of Southport, has been erected at Bolton. Dr. Chadwick formerly practised in Bolton, and a few years ago made a gift to the town of £20,000 for erecting a model dwelling and orphanage. Twenty-five houses have been built, and the rents—£725 per annum—are to be appropriated for the support of the orphanage, which will accommodate eighty girls. In commemoration of these gifts of Dr. Chadwick the statue has been erected by the inhabitants. The statue itself is an admirable likeness of Dr. Chadwick. The sculptor is Mr. C. B. Birch.

AN EXCEPTIONAL OCCURRENCE.

At an inquest held last week by Dr. Hardwicke on the body of George Pearce, aged 40, a commercial traveller, who was taken ill in the Wandsworth-road, a Mr. Hayward, a witness, stated that he procured a cab and took him to St. Thomas's

Hospital, where he was refused admission, the beds, as was alleged, being full. Mr. Hayward then went to the Westminster and subsequently to the Charing-cross Hospitals; at both of these admission was refused on the same grounds. The deceased was then taken to the police-station at Bow-street, and Mr. S. Mills, the divisional surgeon of police, finding the deceased very ill, sent him in a cab to the workhouse, where he died four hours after admission. A verdict of "Died from natural causes" was found, the jury appending the following to their verdict:—"We, the undersigned jurymen empannelled and sworn touching the death of George Pearce, think it highly reprehensible on the part of the officials of so large a hospital as St. Thomas's to have no beds available for the receipt of such patients as the deceased, who was brought in a cab to the hospital in a dying state by one Henry Hayward, on the evening of the 26th inst., and we consider that the other two hospitals' officials are also to be blamed in the matter. And we regret that we cannot properly reward Mr. Hayward for his good feeling and kindness towards the deceased."

PULMONARY CONSUMPTION IN TASMANIA.

After thirty years of observation (says a medical practitioner at the antipodes in a communication to the Royal Society of Van Diemen's Land), I find that in Tasmania the death-rate from consumption and other diseases of the respiratory organs is less than half that of England.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION,

London, 1873.

The meeting of the British Medical Association has undoubtedly been a great social success. There has been a vast influx of medical population to the metropolis, and we may hope that the health of the country will not proportionately suffer. We can congratulate our country *confrères* on the excellent appearance they have presented—a set of more healthy, hearty, happy-looking gentlemen it would be difficult to meet. The lecture-rooms, sections, and especially the *conversaziones* have been very largely attended, and everything has hitherto gone off most pleasantly and smoothly. The reception at the Mansion House on Tuesday evening, attended by between two and three thousand people, worthily inaugurated the festal part of the proceedings. The Lord Mayor, Sir Sidney Waterlow, received his guests with all possible kindness, and provided for their amusement an excellent concert of vocal and instrumental music, which would have been more highly appreciated, we think, had there been less conversation. But there was much to be said in excuse for the talkers, for many of them had not met for many years, and recollections of old friendship are apt to make people forget that they ought to listen even to Mattei's playing or Madame Albani's singing. The scene at the Mansion House was a very brilliant one, and it was of course heightened by the magnificence of the apartments and decorations. The suites of apartments were fitted with every kind of attraction calculated to please the most different tastes, objects of science and art being presented in agreeable combination. Pictures, sculpture, photographs, etc., were relieved by microscopes, spectroscopes, and electrical apparatus. The number of visitors being so large (it is said 1400 gentlemen and 900 ladies were present), the scene was both animated and gay, and the well-dressed crowd was occasionally very dense in the refreshment-rooms and the Egyptian-hall. Notwithstanding this, the reception was pleasant in the extreme, and the expression of enjoyment general and hearty. It was an early hour before the last of the guests took their departure.

A number of distinguished medical *savans* from the Continent have honoured the Association with their presence. Amongst them are Professor Virchow, Drs. Cornil, Krishaber, Lazarewitch, Professor Spiegelberg, Baron Langenbeck, Drs. Chauveau, Ollier, Gueneau De Mussy (of the Hôtel-Dieu), and Oscar Liebreich.

The Annual Museum of the Association is an exhibition of specimens of normal and morbid anatomy, drugs and articles of diet, recent medical and scientific literature, and professional instruments of every description. Too high praise cannot be bestowed on the Museum Committee, and especially on Messrs. Waren Tay and Francis Fowke, the honorary secretaries, and Dr. Kelly, the honorary curator. The labours of these gentlemen must have been almost superhuman to have produced such a complete catalogue and such a magnificent display of objects within a limited time.

The department of pathology is illustrated by specimens, casts, drawings, and photographs, and the combination of form and colour has been so artistically made that the whole has a most pleasing and interesting aspect. The objects are arranged according to the various systems, and in addition there are special departments for the exhibition of specimens of lymph-adenoma, diseases of the supra-renal capsules, morphœa, visceral syphilis, and leucocythæmia. Many of the objects are of historical interest, as the six specimens of diseased kidneys originally described by Dr. Bright; of the viscera in lymph-adenoma from cases which occurred in the practice of Hodgkin himself; and of diseased supra-renal capsules from Addison's own patients. We cannot go more into detail in this place; suffice it to say that all the specimens are of interest. There is a valuable selection of casts of skin diseases from Guy's Hospital. Among the drugs are preparations of eucalyptus globulus and guarana. Among the instruments, physiological and electrical apparatus are well represented. Ordinary surgical appliances are of course in great abundance, as well as instruments for all the specialities.

The serious business of the meeting commenced on Tuesday afternoon, with the farewell address of Mr. Baker, F.R.C.S., of Birmingham, and the installation of the new President, Sir William Fergusson, Bart., F.R.S., who on taking the chair was loudly cheered. He proceeded to deliver

THE PRESIDENT'S ADDRESS.

Sir William Fergusson said that on assuming that position he naturally felt impelled to express the very high sense he entertained of the great honour conferred upon him. Looking back to the long list of distinguished men who had preceded him in that position—distinguished alike by their high social qualities and eminent professional reputation—the honour of being selected to hold this chair was such as might be thought to fill to overflowing the cup of ambition upon which any member of the Profession might have set his mind. It had happened to him to have received a share of honours far beyond his humble merits, and far beyond what the wildest dreams of youth and early years could have anticipated. For these he was dutifully grateful, and for that crowning distinction which placed him for a time at the head of the largest association of medical men ever voluntarily banded together for the general good of the profession, he said with a heart full of emotion that he was thankful, far beyond the command of words to express, for this indication of their appreciation of his personal or professional merits, to hold the foremost place among them. He referred at length to the character of the addresses given in former times by the President of the year, and he pointed out that while at one time the "address" was a review of the year, at another stage of the Association's existence the orator of the year was deemed a sort of Hippocrates, a Galen, or a Celsus, who should display an amount of concentrated knowledge such as might be expected in a well-appointed University. This seemed, he said, to be followed by a feeling that this extensive range was something which overtaxed the best men, and what had before been prescribed for one man was looked for from more; hence arose the custom of separate addresses on Medicine, Surgery, Physiology, and other subjects, irrespective of what might be expected of the President. He referred them to the President's address last year, and said Mr. Baker left the ordinary beaten path, and, like some of his predecessors, adroitly seized on a subject which possessed, for the time, an interest even more exciting than ordinary professional subjects. The town of Birmingham and its surroundings, the topography of the district, its great factories, its

deep mines, out of which so much of the wealth of England had been developed, were themes which proved most attractive, and every one present felt that he was listening to a story of England's greatness, described by one whose lifelong residence in the district, and whose talents and acquirements qualified him in a high degree for the duty he undertook. Conjecturing what he (Sir William) might say on this occasion, he naturally, from the local example of last year, thought what a subject he had before him were he to take London and its environs. With a history well-nigh as old as our knowledge of the island of Great Britain, with a progressive aggregation of humanity larger than the world had ever seen, there were materials for hundreds of addresses, and it might be allowed that the valley of the Thames, however beautiful as regards its surface, or interesting as the largest and most populous in our island, lacked much of that special interest which engrossed the attention and occupied the labours of modern men in reference to the mineral products from underground. There was nothing in the London clay, nothing in the geology of the valley of the Thames which could compare in interest with under-surface matters in other parts of the country. There were, however, certain features connected with the valley of the Thames which seemed worthy of special attention; and questions might fairly be raised as to the hygienic condition of the locality. He supposed there could be little doubt that those who planted London as a post or capital looked to the ground on which the Tower stood as a good commanding position on the estuary of the Thames, and that little was thought then of the teeming millions of subsequent inhabitants who would populate the town and valley above. At that date there must have seemed a world of waters sufficient for all after years; the question of drainage would then be little thought of. In primitive times, springs, river-sides, and shallow wells were the chief immediate sources of water supply. As years rolled on where population increased, these resources were found deficient, and additional ones, in a higher style of engineering, were required. He was more impressed regarding the civilisation of the Romans, by what they had left indicative of their efforts to give supplies of water when required for health and comfort, than by any other features now extant. The great conduits which testified to the engineering skill of the time, as also to the expenditure incurred in regard to this necessity of life, and the remains of their baths, were ample proofs to this effect. To many it might seem strange that he should refer specially to such a subject on this occasion. It might be thought to pertain chiefly to water companies, engineers, and ratepayers; but, in reality, it pertains to the public at large, to public hygiene, and in the latter respect peculiarly to this profession; and for such reasons he knew of no section of what is now often called State Medicine more interesting than that of water supply "where men do congregate." It was right and fitting, in his opinion, that at a meeting such as this some special reference should be made to the subject. Next to the treatment of disease and accident, it stood foremost in professional minds, for water was as much a question of food as any other dietetic material that can be named. Our supplies of vegetables, of fish, of animal material, came possibly second in importance to this necessary of life. Mother Earth herself took nourishment from her own direct produce—effete vegetation, from the decay of fish, and the *débris* of animal life; but all these would count for nothing if she were deprived of water-nourishment. Rational physiology might be called the philosophy of life, and the profession, claiming physiology as one of the highest departments, might claim, as the most skilled conservators of public health, that their opinions regarding water supply should hold due influence over the public mind. It was to the honour of this and all other similar meetings that almost every paper in the sections was devoted to the amelioration, the mitigation, the suppression of disease. In law, man dealt with what man had done or chose to do. In diseases, the profession dealt with causes and courses which, in general terms, might be said were far beyond the ken of man; they came in contact or into collision with nature in varied aspects and phases which the wise thinker in the profession would hardly venture to explain. It was at this point, perhaps, that the profession had from time to time broken down by attempting too much. Who among them knew what miasm was? What sense was there in the idea that it might be averted or obstructed by coverings or nets, driven away by fires, or frightened off by artillery? Yet all such theories had obtained more or less favour in the profession, even in the nineteenth century. Who among them could positively, in reasonable terms, define the physical condition of miasm as it once prevailed in the fens and swamps of Lincolnshire, or possibly even now lingered, if it did not dwell, in horrid perfection, on the banks of the Niger? It was to be hoped that the profession might in time be able to appreciate the palpable physical qualities of the great enemy in this shape. They had learnt empirically in time how to knock him on the head by force of quinine, but he was as impalpable now in these days of dengue as in the time of Hippocrates. But to return to common palpable matters irrespective of rivers of biblical, classical, or strategical interest, there were few to compare with Father Thames. The wealth carried on his surface below London-bridge well-nigh defied calculation. Besides the large share of what might be called our domestic wealth, the argosies of every country in the world were welcome to his waters. There laid the true greatness of the Thames. There seemed no exaction that man could ask from such a father which had not been granted; yet it was most worthy of consideration how far those who had lived and now survived on his banks had dealt fairly with the great stream. The Thames, in his lower course, was one of the greatest highways of commerce ever known to man. In his upper reaches he had been one of the best or worst abused streams that the world had known. He had been at once called to be one of the essentials of life to the inhabitants on his banks, and the cloaca of human aggregation. His streams had been run shallow, and his clear waters had been dimmed by the filthiest pollutions, until the sense of man had, in a manner, revolted at the work. The river thus abused was, in the days of Henry VIII., declared by Parliamentary document the finest salmon stream in his Majesty's dominions. This polluted upper stream was a large source of the water supply of the south and west of London. In many respects a "water question" was one of the most interesting in social life. It was as great now as when Moses struck the rock;. water was an absolute necessary of life. Many of what were called comforts and luxuries might be absolutely dispensed with; but, without water, both vegetable and animal life would cease. Here, as in many other public and national questions, there was great diversity of opinion. The sources of supply, the quantity, quality, and expenses thereof, formed separate heads, of which various classes of the community took special notice. The quantity and quality were the features in which, perhaps, the professiou were most interested. The public at large probably looked upon the sources and expenses as the most important features; but even here the profession, as ordinary citizens, were as much interested as were their fellows. In regard to quantity and quality, all seemed to agree that there should be the largest and best imaginable of both; no stinted time supply, but a continuous run of the finest. It seemed, however, next to an impossibility to have such in that locality. The Thames could not afford a sufficient supply unless his main stream were nearly run dry; nor did it seem possible, under the circumstances, to render the purity of that quantity such as should satisfy all. Filtering in great tanks on the river-side, in cisterns or vases in houses, scarcely seemed to accomplish this; and he was tempted to say that possibly a fault lay on the side of the profession that they expected too much for themselves, and led the public to expect too much, on the score of what might be considered quality and purity. Moreover, they differed largely among themselves in regard to these points. As educated chemists, in reference to animal life and nourishment, they talked and wrote learnedly about elements. The purest water might be defined as that which held least saline, animal, vegetable, or earthy material. The physician thought so highly of this feature that in a fluid dose of medicine he ordered the bulk of the potion of distilled water; yet in that water he probably congregated an amount of saline, animal, or vegetable material which no natural spring or unpolluted stream could be compared with. He sent his patients hundreds or thousands of miles to partake of waters where the converse of purity was generally the chief feature of the fluid. (A laugh.) But this, it would be said, was in accordance with the science of combinations and a just appreciation of the efficacy of salines, especially those compounded by nature in the bowels of the earth. He did not object to those impregnated waters as curative agents in certain forms of disease; he did not quarrel with the physician when he ordered distilled waters as the purest fluid for his compound—but in either instance that physician could not fancy that his patient was about to drink pure water—it might

be admitted that he had no such idea, yet the same man insisted stoutly on the necessity for unexceptionably pure water for ordinary drinks. This "Adam's wine" might be filtered, boiled, distilled, yet certain so-called impurities would hold their place or speedily reappear. Vegetable matter, animal matter, earthy or saline matter, were the bugbear of those who wanted pure water for man. Even the presence of a few fleas, to use a familiar expression, dead or alive, in a great natural basin of water, has been held as an influential objection to a scheme offering a double supply. He then supposed a pint of absolutely pure water given to the meal of the "pet of the day," the "working man," a model teetotaler who had taken a vow against alcohol and all fermented liquors, and asked his hearers to trace the frugal meal—say water and bread—as far as their physiological imagination could, down the intestinal canal and into the blood, and fancy from their knowledge the affluents thereon. Could "pure water" be recognised beyond the teeth in this downward course? Mucus, saliva, tonsillary secretions, mucus again, and gastric juice, and pancreatic, and biliary, all joined the ingredients of the simple meal. But suppose that the working man indulged in the luxury of a bit of beef or mutton, with some of the usual adjuncts—potatoes, turnips, greens, cabbages, peas, or beans—what was the fate of the pint of pure water which was deemed the grand feature of this excellent fare? Here vegetable and animal matter were joined with pure water to an extent a thousand times beyond the imagination of the pure water theorist, and the bread and water system was simplicity itself compared with this. He supposed other cases in different classes of society, and he asked, as to the grouse and venison eaters, supposing them to be "pure water" men, what became of the water as soon as it was swallowed? What about the pleasing adjuncts to these delicious articles of food, and what (to those who were always referring to salts in waters) about the common salt which was consumed in quantities so palpably larger than those pointed out by the chemist in so-called saline waters? What could medical men say of the refinement in diet of the savage who preferred animal food in a putrid state to that recently killed, and uses such surface water, or any other kind, as chance might put in his way? He fancied that the pure chemist was often taken for a medical man, and he feared that many of the profession affected too much the airs of the pure chemist, too frequently jumbled up chemistry and physiology, so that the characters of each seemed to suffer. He asked if they were not in reality too fastidious about "pure water." While the public—no doubt considerably influenced by the opinion of the doctors—haggled over this feature, the more important of ample supply, for all the purposes of man, was overlooked. Although water for drink was essential to existence, how small in proportion was that, compared with the requirements for sanitary purposes otherwise, such as cleaning, washing, in arts and manufactures. For man's stomach, the requisite quantity of wholesome water was so small that the trouble and cost of purifying by filtering and otherwise would be as nothing compared with the advantage of having what might be called a superabundance. If that superabundance was what the simple housewife called soft, the water desideratum would be fulfilled. He had heard on the best authority that in Glasgow alone, with a population of nearly half a million, where a large and wise expenditure had been incurred, there had been a saving of something like £40,000 a year in soap, owing to the softness of the water from a natural reservoir, which doubtless was formed by the watershed of the district in which it laid. The good folks of Glasgow tapped the side of one of the most beautiful and classical of Scottish lochs, and brought the water through conduits some forty miles long to place it at public disposal. The loch was none the worse, and the benefit to the citizens of the second city in the kingdom was perhaps incalculable. It seemed almost by instinct that, in the humblest of our cottages, and in most of our moderate unpretending dwelling-houses, there was a desire to have a supply of rain-water. The pump or the nearest open well or spring might be resorted to for water to drink, but the small quantity that can be caught from a stone, tile, or slate roof was eagerly sought by the judicious housewife. The quality of this water suits domestic purposes better than the brightest from well or pump. Largely though this little luxury was indulged in—for the water-butt abounded in every district—it was curious how this sort of instinct had been neglected by many who have catered for the supply of water on a large scale. There were many who approved the project of increasing the supplies of Manchester, Birmingham, and other midland towns, including London, from the natural lakes of Cumberland and Westmoreland. But might not something be done, less stupendous, yet equally effective? Natural lakes of sufficient bulk were not to be found in many districts, but might not artificial ones be constructed, which would largely supplement our present water supplies? In most of the upland districts in this country there were spaces, hollows, ravines, and valleys, where—as much of the surface is otherwise worthless—the water might be dammed up, and lake above lake might be made to appear on the landscape. This was no new proposal, and it had been acted upon in countries of ancient historical date, whose civilisation was never equal to that we now boast of, and the custom prevailed to a considerable extent in this island. Look to the rainfall of a season in this country, and consider how much, or how little, of this gift from heaven was actually used by man. Of all the necessaries of life this was the one which came upon us in this island most bountifully, and yet how much it was neglected. Instead of letting the floods damage our best alluvial soils, destroy vegetable and animal life, endanger man himself, and finally flow uninterruptedly to the sea, might not much of this flood be impounded on our watersheds, and there form small and large reservoirs and lakes, which would be ample supplies of the best water at every season of the year, and even keep in fair volume some of those primitive streams which doubtless were the attraction of those who originally settled on their banks? It was distressing to see, in some of our large towns, to what condition these once fair streams had been reduced; the water was taken off above until the bed of the river had been dried, and then let on again in every imaginable degree of pollution. Under such circumstances, the water thus taken from the stream might be supplemented by the upper stores, or, better still, these stores might be relied upon for most of the requirements of large communities. He had seen several severe droughts in this country, and had occasionally wondered what might be the result to animal life—man and beast—if the general distress should continue a few days or weeks longer. This involved a great hygienic question; and, interested as they were in it professionally, taught as all were in the virtues of water—home-distilled, nature-distilled, home-filtered, nature-filtered,—looking to the value of water to man as regards his internal and external bodily wants, he did not know any point of hygiene of more interest. Fish, sheep, and cattle can be brought in reasonable quantity—hundreds, it may be—in conserved condition, thousands of miles, but water could not be fetched such distances in sufficient quantity at reasonable terms. And here he could not but again express his opinion that in their professional capacity medical men might err grievously in making trivial and questionable objections to the quality of water when there seemed a fair prospect of getting that which was most desirable for man's use, a full, ever-flowing quantity which might give a perpetual current day and night, well-nigh fresh from the dew of heaven. He then touched upon the programme set before the meeting, and, referring to the gathering under the dome of St. Paul's, said the meeting had begun holily, and let them conduct it wisely, and they would then fulfil the well-chosen motto of the College within whose walls they were met—"*Sancte et sapienter.*"

The great event of Wednesday was the delivery of the Address in Medicine by Professor E. Parkes, F.R.S., of Netley. We need not say that Professor Parkes's most able address was listened to with the greatest interest and attention by a closely crowded audience.

ADDRESS IN MEDICINE,

By E. A. Parkes, M.D., F.R.S.,

Professor of Hygiene, Army Medical School; Emeritus Professor of Clinical Medicine in University College.

When the Council of the Association did me the honour of asking me to deliver the Address in Medicine, my thoughts naturally turned to the progress in the art of recognising, curing, and preventing diseases which has taken place during the period over which my personal knowledge extends. I began to try and recall the medical practice of my student days, now not very far from forty years ago, and to think over the chief changes which have since occurred. I found the retrospect interesting; and, in the hope that it may prove so to others, I shall endeavour to pass in brief review the

principal points in practical medicine which have seemed of most influence during my medical life.

When I commenced attending hospital practice thirty-seven years ago, the two great discoveries of the first quarter of this century—viz., Richard Bright's recognition of albuminuria, and Laennec's application of the ear to discover the normal and abnormal actions of the heart and lungs—had hardly made their complete impression on medical practice. The urine, indeed, was tested in every hospital, and the stethoscope was taught in every school; but we were still able to see something of the old practice, and to observe how great a change had been produced. By a little effort a student of the present day may imagine what a light the discovery of renal and of auscultatory signs threw upon the chaotic practice of earlier times. Without a recognition of the state of the kidneys, diagnosis was often little better than guesswork, and in many cases was impossible. Diseases such as some dropsies and uræmic nervous conditions ran their course without their nature being in any way detected. There were still some old practitioners who did not use the stethoscope, and were obliged to rely on very uncertain indications when judging of heart or lung diseases. But everywhere these two grand advances were being diligently pushed on, and their extraordinary importance for the whole human race was recognised. Our everyday work became defined; indecision, the most harassing of our troubles, was replaced by certainty; symptoms thought to be identical were suddenly separated; what had been deemed important was seen to be useless; what seemed insignificant was shown to be full of meaning.

Nor has any advance since that time equalled these two great steps. To Laennec's work, indeed, as far as it concerns the interpretation of auscultatory phenomena, little has been added. The completeness of his investigation is nothing short of marvellous. Let anyone go over the diagnosis of the diseases of the thoracic organs in the ante-Laennec period, and then read his wonderful treatise—then let him look through the almost countless works since—and he will see how much was done, how little was left undone, by the great Frenchman. He never went wrong, except when he left the interpretation of what he heard, and attempted details of morbid anatomy, for which the time had not yet come. And, if Bright's great work was not so complete, this was inevitable from the very nature of the case. He was not merely investigating the meaning of sounds which a special instrument made audible; he was dealing with the most intricate changes within the body. It was impossible he should round off and make clear the signs of the several kidney-degenerations whose nature was not even suspected; yet all he did do was perfect. It is wonderful how little error of commission there is in Bright's essays. While Laennec, in his discussion on tubercle, wished to give a complete and exhaustive account, which he could not really do, and desired to bring everything into the narrow circle of a definition, which really left half out, Bright kept to his facts. What he saw he stated, and, as far as the facts warranted, he interpreted; but he went no farther; and in this he showed a more philosophical mind even than the illustrious discoverer of auscultation.

These two great discoveries stand high above all that has followed, nor is it likely that equal advances will be made in this century. Laennec's work has been somewhat enlarged, and here and there corrected. Bright's albuminuria, like a newly discovered country, has been separated into provinces, surveyed, classified, and enumerated. The work is not yet ended, but I presume we see now its limits more or less distinctly, and can foresee the time when, for practical purposes, it may be considered to be thoroughly known.

The value of the discoveries which have since chiefly influenced practical medicine will be estimated differently by different persons. To my mind, one of the most important practical advances in the last thirty years is the discovery of embolism and thrombosis. The immediate effect on diagnosis was considerable. To be able to separate a class of apoplexy from other apoplectic cases, to recognise blockage of the pulmonary, the ophthalmic, and other arteries, was a great gain; but the indirect consequence of the doctrine of embolism—the recognition of the effect of minute capillary blockage, and of the transference of cells which are arrested in other parts and give rise to growths there—has a still more important bearing. In the same way the doctrine of thrombosis—of so-called spontaneous clotting and arrest of circulation, and the mixed cases of embolism and thrombosis—has most important practical consequences, which are gradually becoming clear. In 1845 Virchow first got the hint for his great discovery of embolism, which he subsequently fully elucidated in his essays published in 1846 and 1848. Among all the discoveries in pathology which have been made by the surpassing genius of Virchow (and he has touched pathology at all points, and never without adorning it) there is none more valuable than the recognition of embolism.

Another advance which appears to me to have greatly influenced practical medicine, is of a very different order. The entozoic diseases of men have long been known; but the mode of access and the transformations of the entozoa have been only made out within twenty-five years. How marvellous they are—what light is thrown upon obscure diseases by the tracing of the embryo or ova through its different stages and hosts to its maturity in its last resting-place—I need not say The labours of Van Beneden, Küchenmeister, Leuckart, our own Cobbold, and many others, have given us a degree of certainty about these animals and the diseases they cause which was quite unlooked for thirty years ago. We now understand, and can therefore prevent if we please, not merely the common entozoic diseases, such as tapeworms, round worms, and the like, but we see how to deal with such wide-spread maladies as the indigenous liver-disease of Iceland, which has been traced to an echinococcus; as the chlorosis of Egypt, caused by the dochmius duodenalis; as the fatal trichina disease which has doubtless been until now confounded with the specific fevers; and as the Bilharzia affection of Natal. The importance of recognising these diseases, of bringing them out of the domain of mystery into the light of common day, and of thus freeing the class they were mixed up with from a heterogeneous element which made investigation very difficult, is too obvious to need comment.

The latest contribution to our knowledge of entozoa is by no means the least curious. That a nematoid worm shall live in the blood of a man—shall multiply there, or, at any rate, somewhere in the system—shall be in such numbers that there must be many thousands at once in the body, is wonderful; but passing wonder is the fact that these thousands of active, living, feeding worms seem to do little injury. Their discoverer, Dr. Timothy Lewis, of the Army Medical Service, has given evidence which proves that some of the persons infested with them must have had these worms for years, and yet not only live, but pursue their avocations, and are in the possession of fairly good health. How is it these thousands of worms do not cause blockage and obstruction? Why do they not take the nutriment the body ought to have? What becomes of them when they die and decay, for they must do so? Where do they decay? and in what way is the structure of the bloodvessels and other parts through which they pass influenced by their passage? What a number of singular points arise, for which further investigation must find an answer! The discovery shows us, at any rate, that the entozoic diseases are not yet exhausted, and that many things must still lie over for those who have eyes to see and energy to use their eyes.

The recognition, again, of the diseases (chiefly of the skin) which are owing to cryptogamic plants, has had important bearings on practice; it leads at once, as in the case of the discovery of the itch insect in the last century, not only to the adoption of a local treatment of a special kind, but to the recognition of the method of spread and to the means of prevention. At present, the recognised diseases from the implantation and growth of plants have been chiefly those of the surface, or of what may be called the external passages, such as the throat, stomach, or bronchi, which are in communication with the air. But what shall we say of the researches of the last three or four years, which seem to trace so many affections, in part or wholly, to the influence of the bacteroid bodies which at present we must call plants? Without venturing to decide what relationship the class of plants which, for convenience, are massed together as schizomycetes, have to the specific and infectious diseases, or to putrefaction, it seems clear that a profound study of them must be fraught with deep consequences to practical medicine. We are now certain that penetrating from without by the surface of wounds, or more rarely by the intestinal surface, these minute cells, whose numbers are to be reckoned as untold millions, pass into spaces or bloodvessels (on the walls of which they colonise and live), or enter living cells, it may be wandered white blood cells, and get carried to distant parts of the body, or grow in and block vessels and cause a sort of embolism, or adhere to and grow on the valves of the heart, and may, in one way or another, cause

various diseases and complications, and in some cases originate a disease which is mortal within a few days' time. Without exaggerating the frequency or the importance of these "mykoses," we can yet feel sure that in this direction practical medicine is about to make another step, and that, as there is "a disinfecting surgery," so also there will have to be a "disinfecting medicine."

In a class by itself, for the recognised cause of the disease cannot at present be referred to any plant, though it resembles perhaps no common animal cell, must be placed the small cell which, by its extraordinary powers of growth and attraction of food, causes the painful and obstinate sores known in India and Syria by so many names. The Delhi or Damascus sore, the Aleppo evil, and other names have been applied to a disease which is spread all over the East, affecting men and dogs, and which, though not fatal, is yet in the highest degree harassing and discomfiting. The discovery of the cause and its cure we owe to Dr. Fleming, of the Army Medical Service, and it is a good instance of the great use of the microscope in the hands of a competent man. Dr. Fleming found as a constant element in these rodent ulcers a small cell: its nature is quite doubtful; no kind of plant can be developed from it, and it is presumably of animal origin; it contains nuclei, and grows marvellously fast, though whether by cleavage or budding or exosmotic transit, so to speak, of small cells through its wall, has not been made out. By pressing on and absorbing the nutrition of the skin, it soon destroys portions of the surface, and forms most unsightly and painful ulcers. That this cell is the cause has been proved by repeated inoculations. It is very tenacious of life and resistant to chemical agents, hence the uselessness of the common plans of local treatment which have been so repeatedly tried without effect. The only cure is at once to destroy the cells with potassa fusa. In a few days a sore which has been open and extending for months is cured as by magic. The cure is infallible, and if this plan of Dr. Fleming is carried out, he will have the merit of having at once obliterated a disease which has been a plague for hundreds of years, and neither spared the great Aurungzebe in his hall of paradise nor the meanest pariah who was no more than useless dust beneath his feet.

The discoveries I have now referred to—*i.e.*, embolism and the entozoic and microphytic diseases—exert at once a great influence, not only on diagnosis but on treatment and prognosis. But to some the changes in the general doctrines of pathology in the last forty years will appear, perhaps, even more interesting. During this time we have learnt partly to know the great class of degenerations with its two divisions—viz., degenerations which are simply the result of age (*i.e.*, of the loss of the peculiar formative force, which first builds up, then maintains, and then finally dies out and leaves behind it a tissue worn out, effete, and useless); and degenerations which are the slow result of some excessively slight, but constant, failure in nutrition. Fibroid, fatty, and atheromatous changes, and wastings especially of muscular fibres, but also of gland-cells and mucous membranes and nerves, come in to complicate the acuter maladies, and largely to increase their mortality. It must be confessed that while they will account oftentimes for failures of treatment, the chance of degenerations being present in middle-aged patients is a source of great embarrassment in prognosis. Except when attacking the kidneys and the muscular tissue, they are diagnosed with great difficulty, and slow degenerations of the alimentary mucous membrane or of the nervous system are among the most puzzling of maladies. In the means of detecting the presence and estimating the amount of these degenerations, we have still much to learn, and no greater benefit could be conferred on the human race than a perfect analysis of their causes and a recognition of how they may be avoided.

The great subject of inflammation, which underlies so much of pathology, has suffered many changes, and yet the views held by some observers thirty years ago at the outset of microscopic research were to a large extent correct.

Thirty years ago the doctrine of the Vienna school, based partly on the teaching of Rokitansky, though never, I think, accepted as a whole by that great master, was dominant in Germany and in France. Everything was dyscrasia, and the belief that a profound alteration of the fluids, and especially of the blood, underlies most morbid changes, for a long time governed a large school of pathologists.

In this country it never obtained great weight, though it certainly tended to modify our ideas of the origin both of cancer and of tubercle. Gradually losing ground before the pressure of opposing facts, the doctrine of crasis at length gave way to a local pathology almost as extreme. The theory which superseded it was the celebrated cellular pathology of Virchow; that theory which looked only to the individual elements, which traced all to growth of cells, and which virtually rejected the idea of exudation in the old sense of the word. It was admitted, indeed, that nutritive celluless fluid emerged in disease from the vessels as in health, but it was caught up and appropriated by the cells met with outside the vessels, and especially by the connective-tissue corpuscles. At one time it seemed as if the time-honoured term "exudation" would be banished from pathology, and the old doctrine of inflammation seemed altogether undermined. But this cellular pathology was like the creed it superseded, pushed too far. True to a large extent, it was made to embrace conditions beyond it, and the inevitable reaction came. In 1867, Cohnheim described the transit of the white blood-cells through the unruptured walls of the capillaries, and the old doctrine of exudation had again an empirical foundation. I say Cohnheim *described*, but I did not say he *discovered*. For the discovery had long been made, and the fact that it had been made and had been disregarded is a striking instance of want of appreciation of a cardinal fact, of which so many cases are recorded in the history of all sciences. It is bare justice to record that in 1839 William Addison, now of Brighton, perfectly described the emigration of the white blood-cells as well as many other phenomena which attend inflammation. The fact did not escape notice, and one writer at least—Charles Williams, in his well-known work on the "Principles of Medicine"—appreciated its importance. But, as a practical matter, the discovery fell dead, and when Cohnheim announced the fact twenty-eight years later the world of pathology was stirred to its depths. It is also but justice to observe that the chief microscopic phenomena of inflammation and the processes of stasis and exudation were nearly as well described twenty-five years ago by W. Addison and Williams as they are now, though certainly the proliferation of tissue-cells outside vessels was not known.

At present the pathology of inflammation seems settling down on a mixed humoral and solid basis. It seems to be admitted that the albumen in the blood which feeds the organs partakes of the quality of the food which supplies it, and is modified also by the condition of the organs, whose action prepares its introduction into the main torrent of the blood. Degrees of nutritive adaptability may, therefore, exist in it, and we may fairly assume that the composition of the blood-albumen must vary, and that it is quite possible it may be sometimes so degraded as to justify the idea which underlaid the Vienna doctrine of crasis. But it seems also clear that the main phenomena of nutrition (normal and abnormal) rest with the cells and with the ultimate molecules, so to speak, which, though without a cell-wall, can be classed with cells. The cellular pathology is, to this extent, an undoubted and valuable generalisation.

If the doctrine of inflammation has thus, as it appears to me, made the full circle of change, the same may be almost said of phthisis pulmonalis. Laennec's genius, so sure and accurate when he was dealing with the interpretation of physical phenomena, failed when he attempted a definition of phthisis. Like many a geographer, he wished to fill up his blank map—to insert a coast-line here and a watershed there,—and to have everything defined, described, and completed. It was an impossible attempt, for the country had not been surveyed.

Laennec's opinions on tubercle were widely influenced by those of Bayle, and doubtless his interest in the subject was heightened by the fact that, like Bayle, he was himself the subject of phthisis. Influenced, probably, also by reflection on the hereditary derivation of phthisis, he at last elevated tubercle into a special and peculiar product and as the only sign and cause of phthisis; he took tubercle out of the category of common inflammatory changes, and made, so to speak, an entity of what may be merely a form. His influence was so great, his hypothesis—for it was no more—so exactly chimed in with many of the facts of phthisis, and gave an explanation so simple and complete, that it met with general acceptance.

But in this country there were not wanting those who, from both clinical and pathological stand-points, never accepted Laennec's theory in its integrity. The masterly descriptions of Thomas Addison, of Guy's, published nearly thirty years ago, show how completely that great and original physician had seen the imperfection in the favourite view of

tuberculosis. But Addison was not alone in this. It is but just to the memory of a man whose extraordinary talents did not save him from mistakes which eventually overshadowed a brilliant career, and left him in old age neglected and stranded on the shallows whither a false light had enticed him—it is but just to John Elliotson to recall the fact that he constantly asserted the production of phthisis pulmonalis from common inflammation, and the identity of many so-called tuberculous and inflammatory processes. So also it is but justice to Charles J. B. Williams, a pupil and follower of Laennec, to say that he also brought into great prominence the intimate connexion between inflammation and tubercle.

But it was not until 1847 that Laennec's theory in its exclusiveness was to receive its death-blow. In that year Reinhardt, himself, like Laennec, soon to be a victim of phthisis, published his exhaustive examination of the microscopical characters of tubercle, and asserted that there was no difference between tubercle and common inflammatory products.

Then, gradually opinions seemed to settle down in three directions. There were some who held to the old theory of Laennec, that there was a specific tuberculous product or deposit; some who followed Reinhardt, that the deposit was of a common inflammatory nature; and some who steered between the two, and considered phthisis pulmonalis to be a generic term covering two, if not more, distinguishable morbid conditions. How we now stand in this matter it would be rash to assert, but it seems to me that the late able discussions in this country and in Germany tend more to the idea that the tubercular character is the consequence merely of an anatomical condition, and that the greater or less amount of lymphoid tissue in the lungs and the fact of its involvement, will account for the peculiarity of form.

Time, indeed, has added two important facts to Reinhardt's masterly description; the one is the implication of the lymphoid tissue in the most typical form of tubercle, and the other is the demonstration of the infective character of phthisical inflammation, for which we have much to thank Villemin, Simon, Andrew Clark, Sanderson, Wilson Fox, and others.

There was a moment, indeed, when Villemin first announced the production of tubercle by inoculation, when it seemed as if the specific nature of tubercle might after all be true; but the researches in this country soon proved that the inoculation of many kinds of noxious matter might give rise to tubercle, and that there need not be anything special about the introduced starting-point. And so tubercle has, perhaps, come to this: that it is merely a form of those common changes which are most conveniently grouped as inflammatory, with this addition—that the presence of a special structure impresses on it a special form. The tendency of inquiry seems to me to indicate that we must look to the anatomical condition of the bodily tissues, and especially to the abundance or special condition of the lymphatics in the lungs or throughout the body, to explain the hereditary nature of tubercle in certain cases, and also to account for those instances of general tuberculosis which formed the basis on which Bayle built up his hypothesis of phthisis.

But how in this whirl of controversy, in this endless assignment of names, and discussion of what these names mean, how has the practical physician who had to treat phthisis found his practice changed!—in some ways favourably, in others, as I conceive, unfavourably. The principal change in the treatment of phthisis has been the introduction of the supporting plan, based on the idea of tubercle being the indication of a weak and morbid nutritive condition. Cod-liver oil, practically unknown in my student days, reintroduced in this country (after long years of forgetfulness) by Hughes Bennett, and tested by Charles Williams, has become an article of commerce on an enormous scale; good feeding in other respects, and exercise and pure air to improve the pulmonary circulation, are the main grounds on which many practitioners treat phthisis. So far, the effect of the view of phthisis to which I have referred has been most useful. But, in another aspect, I doubt whether we have not somewhat lost in the little attention paid until lately to the inflammatory conditions. Formerly there was a vast amount of local counter-irritation, and even local bloodletting, which certainly seemed to be very useful, and of measures used with the idea of removing exuded inflammatory products, such as the preparations of iodine, and even mercury. There are many cases of phthisis which appear to be largely benefited by measures of this kind, or by a union of the two plans, and, in so far as the common notion of the peculiar specific nature of tubercle discouraged the use of anti-inflammatory measures in some cases, so far I conceive harm was done.

In two points late researches have, I think, influenced our view of looking at phthisis. In the first place it has been shown how many cases of phthisis are caused by removable conditions; breathing of impure air, constrained positions, syphilis, etc., are now known to produce many cases of wasting lung diseases; and, as it is possible to prevent these, and thus to lessen the prevalence of phthisis, we have now a greater element of hope than formerly. On the contrary, the evidence of the so-called infective nature of phthisis—that is, the way in which it can originate in the lungs from distant infected parts, the way in which it extends to adjoining parts, or, perhaps, to distant parts of the lung by absorption from a diseased lung centre, and thus returns and returns until fatal inroads are made on the organ or the system at large; the constant production, in fact, of fresh centres of spread—is a discouraging aspect: On the whole, the last thirty years have done much for the treatment of phthisis, but it is not all unmixed gain, and the amount of future progress is uncertain.

But I must pass from this subject of tubercle, which might occupy the whole address, to glance at a clinical advance which has done much to extend and to define our views on the great class of the specific febrile diseases. Forty years ago many of the peculiar diseases which, under the term epidemic, or endemic, or in late years zymotic, cause a large mortality among all nations, were well-known, but a large class still remained misunderstood. I can confidently appeal to those of my contemporaries who studied in fever hospitals before the year 1840 to bear me out when I say that few points in practical medicine were more unsatisfactory than the diagnosis and treatment of continued fevers. We seldom had knowledge of what existed, and none of what was coming, and no prevision of what to-morrow might bring forth. The most unexpected turns occurred in different cases—sudden recoveries, sudden relapses, sudden gushes of blood in one case; sudden sinking, or coma, or convulsions in another. No practitioner ever gave more than an uncertain prognosis, for he did not know what changes a day would cause; and the want of knowledge of morbid lesions sometimes led to the employment of improper remedies, such as the use of strong purgatives in advanced typhoid fever.

How wonderful is the change now! We can make in most cases of so-called continued fever a diagnosis as certain as in small-pox or measles; we know what to expect, and can indicate the limits within which the morbific cause acts. When I contrast this certainty with the vague, hesitating, conjectural diagnosis of former times, when I think also of the result of this accurate diagnosis—viz., a recognition of the mode and conditions of spread, a recognition which leads at once to preventive measures—I begin to doubt whether, after all, this is not our greatest advance in practical medicine. Certainly in extent of consequences it stands behind few others. We all know how many men of many countries—France, America, and Germany—have contributed to this great result; but I shall not be accused of national pride if I claim a large share of the honour for our own countrymen. A most active member of this Association, Dr. A. Stewart, was a very early pioneer in this matter, and to one of the greatest physicians of our time, to William Jenner, must be ascribed the immortal honour of the demonstration which converted dubious conjecture into certainty. The great work of Murchison has become the guide of everyone, not only in this country but abroad, for it has been largely translated, and has greatly influenced public opinion in Germany and in France. The researches of Mr. Simon and his able band of investigators have probed the causes of the fevers of England at every point, and if allowed to guide the action of the State, it is not too much to say that the diseases which caused so great a mortality in times past, and which even now kill so many persons, will become things gone by, and as little known in England as leprosy or plague.

Enough has been done in the case of all those diseases to show us how we must act in preventing or in healing them; but I cannot avoid a reference to the inquiries now going on respecting the causes of the so-called specific diseases.

It is now more than thirty years ago that a physician of singularly penetrating and philosophic mind—one of those men who influence less their contemporaries than their successors—wrote a work of remarkable power. Gathering up from all sides the numerous observations whose significance became

apparent only when they were brought together, Robert Williams, of St. Thomas's, first gave, in his work on "Morbid Poisons," a clear demonstration that the several epidemic and contagious diseases must own separate and specific causes. How gradually this belief has gained ground until it is held by most persons I need not say, nor how it bears at once on preventive measures. In all these epidemic diseases we now —or, at least, most persons now—recognise that there is a material cause; that conditions of meteorology, such as heat, moisture, and the like, or conditions of season or locality, or states of the human body itself, are merely additions which influence by aiding or retarding transmission or growth. In this belief, logically born of facts, which is no dream or invention, but a plain deduction, we have a solid ground for action. If material, those causes must enter the body through some channel and by the agency of some other substance—by the aid, that is, of air, of water, or of food, or by broken surfaces of the body. By this conception of the "morbid poisons," to use his own term, Robert Williams marked off a great class of febrile diseases from those which might be produced by alterations in meteorological conditions, by excessive radiant heat, or intense electrical conditions, or parched and burning air, all of which may cause febrile symptoms. He thus simplified and defined, and cleared the ground for future inquiry. But it must be confessed progress has since been slow. It was seen that, if the causes of the epidemic diseases be material, they must come within the scope of modern instrumental inquiry. Either by chemistry, or by microscopical research, it was hoped that they would be seized and recognised and made to give up the secret of their birth, parentage, and power. But it was not known how far behind the delicacy of the problem were the instruments of the day. The recognition of these agents is evidently a task more difficult than to seize and decompose the light of the planets or the dim luminosity of the nebulæ. At present inquiry has carried us to the very threshold. How long will it be until someone opens the door and bids us enter? In the face of so subtle a point, and of so many differences of opinion among the best microscopists, I fear to prophesy; and when Beale takes one side, and Ferdinand Cohn another, he would be a bold man who would decide between them. But I think we may safely say that the sap has been carried up to the very wall of the fortress, though how long it will be till the final assault is delivered it would be rash to say. One may conclude, perhaps, that the problem in question is not a simple one, like trichinosis, for example, where it is simply the entrance into the body of an animal with extraordinary powers of multiplication and penetration; but that in the case of specific diseases we must not only have determinate breeding-places in the body, but also possibly special conditions of nutrition, without which the agent cannot increase and cannot recur.

Closely connected, again, with this question of the nature of the agents which produce small-pox, scarlet fever, measles, typhus, and enteric fever, or other infectious diseases, is that of the causes of septicæmia. I cannot tell in what light the observations of Coze and Feltz, of Klebs, or von Recklinghausen, or Burdon-Sanderson and Klein, and others, or the singular success of Lister and his antiseptic treatment based on the germ-theory, may appear to others. To me they seem in the highest degree important. To refuse them credence, or to pass them by as immaterial, seems to me about as philosophical as it was to discredit Jenner because the protective powers of vaccination seemed at the time so improbable. The rapid multiplication of bacteroid bodies, their colonisation and emigration, the effects they produce by pressure, blockage, and embolism, the changes they cause in the white blood-cells and perhaps in the albumen and fibrine, the disintegration of the white blood-cells, and the fibrillary deposits in the vessels, are all phenomena which can be shown. Can these things be without importance when they not only are real but agree so curiously both with the symptoms of septicæmia and with the most successful treatment of surgical injuries. It does not follow that we have got to the bottom of the question, but surely we have made a step, and that no trifling one, in learning one aspect of "blood-poisoning"—a term true, yet so vague; so useful, indeed, indispensable, but yet not satisfactory, because for the most part it represents only a haze, and not an outline.

But I must pass on to notice the changes in one other branch of pathology. About forty years ago the diseases of the nervous system were very little known. The great discoveries of Bell, and the physiological and microscopical observations of Germany were gradually clearing the subject. At the commencement of the period Marshall Hall was completing his observations on reflex action, and launching into that bitter sea of controversy which poisoned his own happiness, and overshadowed the fame which was justly due to him. That he owed much to his predecessors, and that he was not careful enough to acknowledge it, must be admitted; but the work which he did was yet real and true work, and his name can never be deposed from its honourable niche in this part of pathology. Then followed in quick succession the discovery of the governing power of nerves over contraction of vessels, and over the work of the glands and the secretions of membranes. Then microscopes and experiments together paved the way for a proper understanding of the parts of the chord, and the effect of section or injuries. The recognition of nervous centres; of the comparative independence, so to speak, of ganglia; of the effect produced on these centres by reflex irritation and by direct irritation by the circulation of poisoned blood,—all these and other similar discoveries have occurred in thirty years. Consequently, with much that is still vague, nervous diseases are no longer the hopeless medley of my student days. The recognition of locomotor ataxy and of other paralyses is a step of immense magnitude; but far more than the mere diagnosis of any pathological state, is the fact that the physician has now the condition of the nerves ever in sight, and can to a certain extent explain that heterogeneous group of symptoms which, under the name of sympathies or sometimes metastases, were so great a puzzle to our fathers, and can also see to some extent the cause of those convulsive affections which are attended after death by no physical change we can at present appreciate.

In many other directions practical medicine has also made progress: diseases of the larynx are now seen and not guessed at; internal conditions of distant organs like the kidneys may be disclosed by an examination of the eye; the microscope in many ways gives us information about blood, sputa, urine, which one wonders how our forefathers could do without. Instruments to extend or perfect the senses, to aid touch like the thermometer, or sight like the microscope or laryngoscope, or to show movements like the sphygmograph, are now in constant use, and the senses are multiplied a hundred or thousand fold by their aid. Precision and mechanical accuracy are the aims of everyone, and exactness and thoroughness are becoming more and more the rule from year to year.

Here, then, I must bring this part of my long, but yet too brief, review to a close; it chronicles, I cannot but think, an immense forward movement in practical medicine, but if time had permitted me to go into details, or into a fuller examination of certain parts, I should have been able, perhaps, to bring out the matter more clearly and more completely. But I have said enough to show that we have not stood still, that few subjects can boast more original investigations, and that, in spite of great difficulties, and oftentimes of great differences of opinion, the general knowledge of practical medicine has advanced continuously and has advanced greatly.

But now will occur to all, the question which is the touchstone of all progress: Have we gained in useful power by this knowledge?—do we cure, do we prevent disease more easily and more perfectly than our fathers, or is this knowledge barren, a false light—like that pictured by Milton—making darkness visible, and showing us only that we are helpless?

We must all, I think, acknowledge that therapeutics form the most difficult part of our work, and that it is only slowly that the discoveries of pathology become worked into our daily practice of healing. At first, indeed, pathological discoveries may even perplex therapeutics; and many of us can remember what scepticism (scepticism which was untrue and hurtful) seized many people when the profound alterations of tissue produced by disease were first clearly seen. The reparative powers of nature, the wonderful agencies of drugs, were alike thought to be useless in the face of such profound disorganisations, and at one time it seemed as if the physician's art was to be reduced to a useless diagnosis—useless because sterile of results. But this was a phase merely, and no period has witnessed so many new and useful drugs added to our pharmacopœia, and so much more knowledge of their use, as the last twenty-five years. The essential distinction, however, between the old and the new practice arises, I conceive, from a difference of method. Forty years ago it was only in a comparatively small number of cases that a practitioner could make an accurate diagnosis. What was to be done when the exact nature of the disease remained uncertain? For the most part he took note of the prominent

symptoms and treated them, and looked especially to the general condition. The first thought of many men was whether the patient was plethoric or the reverse; whether he was to be reduced or sustained. I knew intimately a physician who was most successful in his treatment, and who always, when he could not determine the disease, put this question to himself: "Which of these two courses must I take?" and, if he thought the patient required reducing, he bled and gave aperients and diuretics, and restricted the diet. If he thought the patient anæmic and in bad nutrition, he gave good food, bitter tonics, and iron. It was astonishing how many of those ailments, which we all know are difficult to bring under a determined category, were cured by this simple plan when judiciously carried out, and how much benefit was done even when no diagnosis had been made out.

Other men, when a diagnosis was difficult, invariably followed the eliminating plan, giving aperients, and acting on the skin and kidneys, and then after a time changed the plan, and gave tonics and iron; dropsies were treated by digitalis or purgatives or diuretics, without reference to their cardiac or renal cause; cardiac palpitation was treated by rest, blisters, and opium, no matter whether it owned neurotic or organic cause; dyspeptic symptoms, however arising, were treated by prussic acid (then lately introduced by Granville, and made popular by Elliotson); vague, uncertain symptoms which could not be referred to their source were often combated by a succession of remedies termed "alterative," the main drugs being purgatives and then mercury, iodine and antimony, and neutral salts. On looking back as well as I can to what I can remember of the practice of my early student days, it seems to me that a vast amount of good was done by men whose diagnosis we should now look upon as very incomplete. That much was left undone we must allow; but even now there are many cases in which we have to fall back on such a general plan as I have referred to, and often find our cases benefited.

There is of course no doubt that among the measures resorted to in those days depletion was far more commonly practised than it now is. It was of daily occurrence to bleed, and often to bleed largely, and there can be little doubt that the plan was pushed to excess, especially in the period from 1820 to 1840. But I think it would be a mistake to suppose that all practitioners used depletion so largely as is commonly supposed. Some men, like Broussais in Paris—partly from a theory, partly from opposition to others—were bleeders on a scale of magnitude we now shudder at; and even in this country there were men who were followers or rivals of this great Sangrado. But the generality of practitioners practised small bleedings, and seldom carried them to excess—in fact, at one time bleeding was so little used that the head of the Naval Medical Department issued instructions to his surgeons to make more use of the lancet. A great change has now taken place, and the lancet is seldom used, and the time-honoured practice of cupping is almost a thing of the past; and this, in my view, has not arisen from any change of type, of which I can see no proof, but to an improvement in diagnosis and a more direct mode of treating the disease. But I am disposed to agree with some of our best practitioners, who believe that we have too much abandoned an agency which, when well used, is often powerful for good, and that it is not unlikely the pendulum may soon commence to swing the other way, though not, we may hope, ever to reach the extreme point which some of us can remember.

In the present day our practice is, I conceive, differently conducted. Our first thought when we investigate disease is to know precisely the parts affected, to estimate the amount of local injury, and to determine the effect produced on the constitution at large by the abnormal condition. We aim at a diagnosis as accurate and large as possible, and, though this is not always practicable, I think all will allow that there is a considerable degree of certainty. Then, being better acquainted with the course and tendencies of the special condition, we are able to form a better judgment of what is likely to take place, and how it is to be combated. Of course, a vast deal of our treatment is still empirical, and no doubt will be so for many years to come, and oftentimes we must fall back on general rules and treat a constitutional condition without recognising its cause. But, on the whole, we diagnose, I conceive, fairly, and have a tolerable knowledge of how the state we discover can be best dealt with.

If, as I believe, the art of cure has really advanced greatly in the last forty years, the art of prevention has also made great progress, and this has directly arisen from the improvement in diagnosis. The recognition of a disease and its reference to a particular category inevitably lead the mind to probe its causes. This seems an instinct of our nature, probably divinely implanted to impel us in the path of knowledge and improvement. We cannot rest satisfied with seeing the thing; we must know its origin. Hence, during the last forty years has arisen the School of Sanitarians, whose creed is that every disease, as we see it, has its antecedent, and that the problem they have to solve is to reach this antecedent, and to prevent the seed from bearing its fruit.

Either in the action of external nature, or in social habits, or in nutritive conditions, or in conditions proper to the individual, and arising from his mind or mode of thought, the seeds of the diseases are sought, and by degrees the conviction is gaining ground among all classes that we have ourselves to thank for a large number of those maladies which destroy health, embitter life, and rob us of the blessings which we feel ought really to be ours. I need not say to what proportions this belief has grown, and how it is beginning to affect every class in the community; but it is only right to point how directly it springs from the progress of medical science. Let us hope that, as preventive medicine is really the child of curative medicine, and is indissolubly linked to it, those who are conducting the vast plans which the Legislature has devised for improving the national health may remember that the profession which has so far searched out the causes of individual and national ill-health must be entrusted both with the execution of the plans and with the continued search into a subject which is yet almost in its infancy.

And now, gentlemen, I have passed in review, far too briefly, the points which appear to me most interesting when the eye glances back over the varied, smooth and rugged, light and dark, fertile and sterile regions which a man passes over as time carries him, but too quickly, from youth to age. To me the retrospect is cheering; it has given me fresh hope for the continued advance of our knowledge and for the progressive usefulness of our profession. I feel, as I have lightly passed over the records of the profession's work and gains in the last forty years, that we have played no unworthy part in the great drama, and that among the restless activity of modern times and the growth of newly-born sciences, an old art has not stood still, but with ever increasing power is still, as it has always been, a very present help in time of need.

We cannot at the present follow the work of the various sections which after Professor Parkes's address commenced their work. In the Section of Medicine, the President of the Section, Dr. Sibson, F.R.S., delivered an admirable address of a thoroughly practical tone, in which we were glad to notice that he insisted upon the benefit the Association might confer on medicine and mankind by assisting and employing competent observers to investigate various unsolved problems in disease and its treatment. The discussion on cholera in the Health Section we have commented on elsewhere. It was one of the principal events of the day. The day was well closed by the *conversazione* at the Royal College of Surgeons.

This entertainment, given by the President, Vice-Presidents, and Council of the College, was a great and well deserved success. Mr. Curling as the President, Mr. Le Gros Clark and Sir James Paget as Vice-Presidents, were early in attendance to receive the 2000 or nearer 3000 metropolitan and provincial members of the profession who attended. On entering, the halls were seen filled with choice plants from the gardens of Messrs. Veitch, of Chelsea; in the inner hall were more, with Defries' fountains amongst them playing chlorozone all the evening, rendering the air fresh and pleasant. On entering the library, where the President received his guests, was another fine display of rare exotics and medicinal plants, which many members saw growing for the first time—*e.g.*, the cinchona plant, those of the croton oil, coffee, patchouli, vanilla, etc.,—also from the hothouses of the same horticulturists; here, also, were Rimmel's perfume fountains and vaporisers dispensing sweet odours of summer flowers throughout the rooms. The walls were covered with some charming oil and water colour paintings, kindly contributed by Sir Henry Thompson, Messrs. Curling, Prescott Hewett, Hilton, Stone, Vokins, Professors Flower, Erasmus Wilson, etc. Mr. Frank Buckland sent a remarkably fine collection of the *Salmonidæ*, alive and represented by casts splendidly coloured after nature by Mr. Ralfe. Amongst the living specimens were salmon from eggs kept in ice 112 days, and opened the same day as the *Oberon* arrived in New Zealand with her consignment of eggs from England; American

brook trout, great lake trout from Neufchâtel, trout from Norway, hybrids between salmon and trout—the father being a salmon and the mother a trout. In addition to these Mr. Buckland sent a large general collection from his museum. The Rev. Mr. Mayhew contributed some superb specimens of Venetian glass, bronzes, etc., from his fine collection.

In the Council-room was displayed the College plate, consisting of the fine mace, just regilt for the occasion by Messrs. Elkington; John Hunter's flagon; the loving-cup presented by Ranby; autographs of Hunter; and many curious relics, including two of his drawing-room chairs, made of an unknown wood, brought home by the celebrated circumnavigator, Captain Cook, F.R.S., and presented to Hunter (exhibited by Mr. T. M. Stone). Microscopic science was well represented: amongst other interesting specimens was some of Mr. Buckland's oyster spat. Messrs. Baker and Pillischer's photography was illustrated by charming specimens of Vernon Heath, Barraud, Fradelle, the Stereoscopic Company, etc. Messrs. Atkins's admirable filters, well supplied with iced-water, were in great requisition. The refreshments, which were excellent, were supplied by Messrs. Gunter.

We must conclude our notice of the meeting this week with the excellent Address in Surgery delivered by Professor John Wood, of King's College, on Thursday.

ADDRESS IN SURGERY.

By John Wood, F.R.C.S., F.R.S.,

Professor of Surgery in King's College, and Surgeon to King's College Hospital.

Mr. President and Gentlemen,—The responsible duty of delivering to so important an audience an address upon a subject well worthy of more able powers, has come upon me at short notice as the *proximè accessit* to one whose reputation as an author and teacher of surgery had entitled him to the first place in your consideration. The indisposition which led to this, I fear, somewhat unsatisfactory alteration in the programme of our proceedings, has been, I am happy to say, but temporary in its nature. I trust that it will entail upon him no consequences more painful than your disappointment and his own, and upon me nothing more disadvantageous than those comparisons which you may not be able to repress, and which the short notice I have had has not enabled me to diminish, except by an appeal to that liberality which is rarely wanting in our profession. A stimulus to increased mental effort (of which your professional experience will well enable you to estimate the value in critical cases) was supplied to me by the knowledge of the place in which we were to assemble, and the feeling which I entertained of the great worthiness of the occasion. Within these walls and under these auspices I could not refuse to tax my powers, and even to risk that suspicion of temerity which may be attached by some to the undertaking.

The present state of surgical knowledge indicates quite as much as that of any department of human progress, that thorough movement in the dry bones of systems, which, we may hope, is the prelude to more perfect constructions, to an advance in directions more likely to lead to the attainment of that satisfaction which comes from clear knowledge of what we can and ought to do. As our notions are at present, we require the exercise of a shrewd judgment acting upon an extended acquaintance with facts, and in many cases a very delicate balance of opinion indeed, to determine what is the right thing to do, even in the commonest cases. The prime wisdom is now, even more than in Milton's days—

> "Not to know at large of things remote
> From use, obscure and subtle, but to know
> That which before us lies in daily life."

The multitude of counsellors and the diversity of counsel are so great that a surgeon can find authority for almost every variety of opinion and practice. And I believe that no opinions which are honestly advanced, and with due regard to the elements of truth and probability, will remain long without supporters even in the living generation.

In medical science, gentlemen, we have no Pope and no Syllabus. Our councils are liberal assemblages, such as that we form to-day, and our appeal lies to an educated jury,—the public opinion of the profession,—and this jury, moreover, is fortunately by no means compelled to be unanimous in its decisions. And if, by reason of great originality, or of that sort of miscarriage which is not uncommon in the production of men of genius—viz., that of being born before their time—a man's views and deeds are not rightly estimated by his contemporaries, there still remains that ultimate appeal to the judgment of posterity which the possession of a free press and the facility of publication place within the reach of everyone.

It is no wonder that those who have lived to see the rise and fall of many theories and many systems are tempted to become converts to the doctrine of finality, and to consider it very probable *à priori* that whatever is new is therefore not true; and, if by any chance it should happen to be true, it would certainly prove not to be new. When this frame of mind grows upon us, it is well to consider that our past was once a future, and had a more undeveloped past before it, and that the old ways have been led up to by ways still older and, no doubt, worse to travel over.

The study of pathology and the natural history of disease has been leading to a simplification of medical treatment which has in some quarters advanced to the extreme phase of the "expectant" system, which prescribes little beyond the primary necessaries of food and drink, with a regimen which allows the patient ample scope to be comforted by faith and supported by resignation. In the present condition of public intelligence, deplorably wanting in the knowledge of the laws of health and disease, there is required an amount of natural gifts which is not conferred upon every man to inspire in the patient such a robust quality of the former blessing as to enable him to nourish the latter upon so simple a thing as orange-flower water. While we are looking for the coming rain-cloud which brings relief to, or release from, suffering by the operation of laws of which we know more or less perfectly the course and certainty, but which our patient cannot see, it is but natural that he should speculate from our conduct upon the perfection of our eyesight. The talented author of "Middlemarch" has fairly recognised the ideas which prevail in what truth compels us to call the greater portion of our population in Mrs. Mawmsey's remark upon the new medical light who had appeared in her native town, and who, as she was told, went about saying that physic was of no use. "Does he suppose that people will pay him only to come and sit with them and then go away again?" Such are the intelligences that a doctor has even far more frequently to deal with than those of the calibre of Mr. Trumbull, who characterised himself as "one who was not altogether ignorant of the *vis medicatrix*," who "went without shrinking through his abstinence from drugs, much sustained by the application of the thermometer, which implied the importance of his temperature, by the sense that he furnished objects for the microscope, and by learning many new words which seemed suited to the dignity of his secretions."

In the practice of surgery we meet happily with fewer difficulties of this kind than in the sister art of medicine; but occasionally, in obtaining the advantages which result, especially in cases of joint diseases, from the intelligent application of the principle of "rest" so conclusively set forth by our distinguished President of Section, Mr. Hilton, we have to contend with the impatience of the patient or his friends, and perhaps may even fall into the error of giving too much of a good thing, and thus may reach, not the "be thankful" stage, but that of fibrous anchylosis. Here we may have the ill-luck, too, to leave our patient open to the temptations of the quack bone-setter, lately subjected to the serviceable exposure of Dr. Wharton Hood. That last infirmity of long-suffering patients applies his material force upon the hit or miss principle, and, hey presto! the bone which had been "put out" is set with an audible snap, which proves the evident correctness of the remarks upon the numerous fallacies of the faculty, with which the operator improves the occasion, and piles up the agony of his *éclat*.

In face of the latest developments of surgery, it becomes more and more difficult to endorse the opinion of the eccentric veteran surgeon Vincent, "that it was doubtful whether the human race would be worse off than it is if there were no doctors, no accoucheurs, no physic, and no instruments at all." The utter extinction of the weak and sickly might indeed improve the race physically, if not numerically, as is said to be the case among savages; but, as in them, it would in the meanwhile press very hard indeed upon individuals, and ultimately improve the whole tribe off the face of the earth. To a civilised community, hard-heartedness and cruelty are so abhorrent, and the instinct to heal and to relieve pain is so deeply inrooted, that a reaction against such a law of neglect

would infallibly reproduce that kind of superstitious remedy which has already caused in the world's history more suffering than it has relieved. In this respect this innate feeling resembles that instinct of religion with which it was so closely interwoven by the greatest Exemplar of both. We could no more prevent the growth of doctors than of preachers and moralists.

The noblest function of the wisest among us is to enlighten and guide this innate impulse, to keep it under the control of the calm, reflective intellect and of the tender conscience, to prevent the crystallisation of ideas into fixed dogmatic formulæ, which hinder development in science and art as well as in language and literature, and to maintain the honour and true interests of the healing art. There is no better way of doing this than by the promotion of friendly intercourse among the members of the profession; and this I take to be the aim of the great Association under whose auspices we now meet.

On the occasion of the visit of so many leading provincial surgeons to our great metropolitan centre it would seem to be incumbent upon me to allude especially to subjects which chiefly occupy attention at the present time and upon which the foremost minds throughout our own country and the civilised world are now employed, and I do not hesitate to say, as successfully employed in the provinces as in London, and in our own country as in any part of the world. Time will not permit me to give more than a glance at some of these topics, several of which are dealt with, in papers read in the Surgical Section, much more in detail than I can hope to do. In their selection, I am naturally disposed to take those to which my attention has been most practically directed during the past year. I shall thus speak, and I trust that my audience may listen with that interest which attaches itself to subjects of actual experience.

Pyæmia, septicæmia, and erysipelas are undoubtedly the greatest troubles of modern surgery. Without their baneful influence the success of our improved methods would be enormously increased. By their occurrence the best-laid plans go wrong, and may result in the death instead of the restoration of the patient; and this is more deplorable when, as often happens, the operation is one which is not absolutely necessary to save life, but to remove a disability which might be an ill "better to bear than fly to others that we know not of." When, therefore, a system of dressing wounds is brought before us, sanctioned by worthy names, and supported by the results of cases, offering a means of escaping these terrible enemies, it is our bounden duty to give it a fair and full trial.

Such is the antiseptic system of dressing wounds originally developed by Le Maire, in 1860 and 1865, in the use of coal-tar, and its derivative carbolic acid, as an application to wounds. As long ago as 1815, French chemists had proved the antiseptic qualities of oil of tar. As long ago as 1834, Runge discovered carbolic acid and its properties. So slow is the growth of improvement. Coal tar itself, made into an emulsion with saponine by Le Bœuf, and combined with plaster-of-Paris by MM. Corne and Demaux, in 1858, has continued to be used by French surgeons, and has lately been employed in combination with charcoal by Beau, of Toulon ("Du Traitement des Plaies," Baillière and Fils, Paris, 1873). A great impulse was given in this country to the use of carbolic acid by Professor Lister, in February, 1867, well known to the Association from the exposition of his method by that talented surgeon to the meeting at Plymouth. Since that time I have given his system, I believe, a fair trial at King's College Hospital. At the same time, and under the same conditions as far as could be obtained, I have employed the solutions of carbolic acid in oil and water, and those of metallic salts, as well as substances such as chlorozone, etc., but without the elaborate attempts to exclude the unpurified atmospheric air which Lister deems essential.

I shall not attempt, gentlemen, to discuss the question of atmospheric germs, or of indwelling bacteria-like bodies, and their influence upon disease. This question is one of a far wider nature than can be conveniently discussed here, and it involves other departments besides that of surgery. In common with, and in relation to, the question of suppuration in general, and its connexion with tubercle, it can only be solved by the prosecution of those lines of research in pathology and medicine which have been followed so skilfully by Drs. Burdon-Sanderson and Wilson Fox, and which may prove to be lines converging towards an important discovery. As an experimental and scientific mode of research, which may turn out to be also a converging line in surgery, I have the highest possible respect for Professor Lister's system of treating wounds.

Upon his theory of germs, it is consistent and simple enough: but it is as a practical method of treating open wounds, available under ordinary circumstances in hospitals and private practice, in emergencies, and on the battle-field, that it must be estimated and will ultimately take its place; and it is with that view that I have put it, as far as possible, to the test. I began it at a time when the hospital was in a good hygienic condition, and the cases for that time did admirably. I had some cases quite equal to any described by Professor Lister himself. I, at the same time, tried the application of dry lint, without any moisture whatever, to the wound, and in many cases, especially in breast cases, the results were also perfect. In one breast case union by adhesion occurred throughout the wound. I also tried the application of the chloride of zinc solution in the manner originated by Mr. De Morgan, and very good results ensued—viz., healing with the formation of little or no pus. After about six months there came into the hospital a very unfavourable change, and, from inquiries made at the time, I concluded that a similar condition prevailed in most or all of the London hospitals. Erysipelas and its concomitant pyæmia began to show themselves, the former not springing up in the hospital itself, but imported with patients. The wounds now began to suppurate more, primary healing was less common, and the erysipelatous blush appeared with blameworthy impartiality in cases treated in all kinds of ways, and almost as impartially on my own antiseptic side of the hospital as on my colleague Sir William Fergusson's non-antiseptic side. But this I feel bound to say, that there was little or no putrefaction, as evidenced by the odour, in any of my cases, which my eminent colleague shrewdly attributed to the carbolic smell overpowering all others. Upon this point, however, I must say I did not agree with him. I had one case of amputation of the thigh for a tumour of the lower end of the femur, in a man about sixty. I treated it by Lister's method, carefully carried out, and, from beginning to end, there was very little discharge and no putrid or offensive smell whatever; but the wound did not heal, the end of the bone remained unadherent and devoid of granulations, and the man lingered for two months in a declining and emaciated state, and finally succumbed to chronic pyæmia with secondary abscesses in various parts. The occurrence of many other cases similar in character to this has convinced me that the agencies, whatever they are, in pyæmia operate in the general system, or, if through the atmosphere, in other channels besides the wounded part, as in cases of pyæmic poisoning from deep internal glandular pus deposits and in other acute and chronic tubercular affections.

Some time afterwards I had a case of compound fracture of the tibia and fibula, with a limited aperture in the skin, in a man nearly seventy years of age. I put it up carefully in Lister's method, carbolic spray, prepared gauze, and jacquinette complete. On dressing it several days afterwards, suppuration was found to have occurred, and the pus had accumulated considerably in the dressings. The treatment was continued, and kept the wound free from all unpleasantness, but still the amount of suppuration was very considerable. There was burrowing of pus along the muscles and bones, and a total want of union. In this case I was ultimately obliged to amputate below the knee. The amputation wound was also treated antiseptically, but still the amount of pus was considerable, and although from the man's age and reduced condition the progress of healing by granulation was slow, the case did ultimately exceedingly well, and made an excellent stump.

In some cases of psoas abscess treated by Lister's method we had marked success so long as the hospital was healthy. When erysipelas and pyæmia appeared, however, we had others in which the pus in the abscess became putrid and offensive after the first evacuation under the spray and with all the precautions, and I was obliged to make free openings and introduce drainage-tubes through which the abscess could be washed out thoroughly with antiseptic lotion. Such cases show me that we could not without danger depart, in the generality of wounds, from the old rule of providing a free exit for all purulent and offensive discharges, and for the want of this the exclusion of air is not a sufficient compensation. I cannot, consequently, approve of the plans originated by Baron Larrey and followed by Gosselin,(a) and more lately by J. Guérin and Maisonneuve, of

(a) "Des Pansements Rare," 1851.

"occlusion pneumatique" (*Gazette Médicale*, 1866, p. 7), the amount of resemblance to which, in Lister's method, constitutes, it seems to me, some part of its deficiencies. To a great extent, this objection also exists to the plan followed during the second siege of Paris by Alphonse Guérin, of using thick investments of compressed cotton-wool after washing the wound with alcohol, and then leaving it, without disturbance or removal of the deeper layers, for periods varying from a fortnight to two months, or even more. This plan for keeping from the wound injurious atmospheric influences seems to have been deduced from Professor Tyndall's experiments upon the purifying results of the cotton filter of Pasteur. It was shown by Hervey (*Archives Générales de Médecine*, December, 1871) that, as used by Guérin, it neither prevented putrefaction and fetor in the wound, nor the formation of abundance of microzoa therein. Here, again, we have instances of the propriety of that regular and systematic inspection of wounds which the practice of hermetically sealing them up prevents us from obtaining.

With respect to the employment of cotton-wool, combined with due drainage, I look forward with interest to the paper promised for this section by Mr. Callender, who has (he informs me) obtained much success from its use combined with his own form of drainage-tube. Cotton-wool has one great advantage as a dressing in cases of emergency. It is usually easily to be obtained in the necessary quantities after battles and railway accidents, when it is necessary to remove patients directly after injuries or operation; it provides better than most other methods for the protection of the wound or stumps from injury. Tarred oakum possesses all these advantages to an equal degree, and has the superior quality of being also cooler and more antiseptic. Mr. C. Heath, of University College Hospital, tells me that he prefers it to any other dressing, and in the cases in which I have used it it has answered admirably. In the free use of cotton-wool as a dressing during hot weather, I have found patients to complain of the heat of the wound or stump. At these seasons I believe oakum to possess a greater advantage. In cold weather cotton-wool is comfortable enough, and affords an admirable elastic support and due compression to the wound; but in my opinion it has, if used without antiseptics, one great disadvantage which is shared by charpie and other absorbent applications, and which is increased tenfold when used, as in the French hospitals, for stuffing the interior of wounds and stumps to prevent union by adhesion and to absorb discharges. While kept in the wards in readiness for the dresser, these substances, as proved by the experiments of Chalvet and Reveil, as well as those of Eiselt and Kallman, absorb the infective and putrefactive particles which float about in times of epidemic influences, or as exuviæ in a crowded aggregation of wounded patients, and so may become direct vehicles of communication of local infection. The same may also be said of the water and lint used in the wards for the simple water-dressing. Warmth and moisture without antiseptics are very favourable to the diffusion of contagion. And the risk is increased by the carelessness or thoughtlessness which you cannot entirely eliminate from nurses and dressers in passing from one patient to another.

Professor Humphry has informed me that he is quite satisfied with the plan of leaving wounds and stumps uncovered by dressing and entirely undisturbed, having only the discharges wiped or washed away. I am informed by Dr. Werl, late assistant to Billroth, that this plan is uniformly followed in the large hospital at Vienna. Here atmospheric influences have full local play, aided by the accidental contaminations of water, sponges, or tow; and yet, in the spacious and well-ventilated wards and pure air of Addenbrooke's Hospital at Cambridge, the results are far from being unsatisfactory. In a time of bad hygienic influences, epidemic erysipelas, pyæmia, or of an accumulation of wounded patients in a London hospital, it is probable that this would not be the case. After frequent trials, I have come to consider that the free use of Chassaignac's drainage-tubes issuing from the surface of the wound, or from its interior if deep and sinous, and with their outer extremities embedded in cotton-wool or oakum, well permeated with MacDougall's or Calvert's powder, as a disinfectant and absorbent of discharges, the surface of the wound washed over after bleeding has ceased with a mixture of solutions of chloride of zinc and carbolic acid or sulpho-carbolate of zinc, the same solution to saturate the lint dressing, applied in the same way as in water dressing, enveloped in thin guttapercha tissue, and supported by strapping and a light bandage, affords the most readily applied, the lightest, coolest, and the most generally useful application of the antiseptic method; an outer envelope of cotton-wool or oakum, and dressing every day after the first opening of the primary dressing, complete the plan, from which I have obtained as good results as from any other that I have tried, and, what is perhaps important, I have found it less difficult to insure its being properly carried out.

From this you will gather that I agree with Mr. Lund's view, as expressed in his able paper of "Observations" (printed in the *Manchester Medical and Surgical Reports*, 1870), as to the general efficacy of antiseptics, and in his position with respect to the germ theory explanations, although I do not consider the great elaboration of the carbolic or other dressings to be so necessary as he appears to do. I hope to learn somewhat more from his forthcoming paper on the same subject.

In clean incised wounds, where formation of pus is not likely to occur, as in some plastic operations, the hermetically sealing plan will no doubt maintain its position in general use in its most useful form of collodion. But when suppuration ensues it must be got rid of. Its absorption by dry earth, as advocated by Dr. A. Hewson, of Penusylvania ("Earth as a Topical Application in Surgery," Philadelphia, 1872), has the disadvantage of being dirty and offensive to the patients, and of obscuring by its colour the natural appearance of the wound when in contact with it; but as a substitute when better absorbents cannot be obtained, it seems to be of some value. Much the same may be said of charcoal. When this substance is combined with coal-tar, however, as in the way advocated by Dr. Beau, of Toulon, in the work already referred to, it would seem that a great part of the antiseptic vapour would be absorbed by the charcoal, and the two remedies to some extent thus neutralise each other.

Erysipelas does not seem to be much influenced by antiseptic measures. Such cases as are recorded by M. Chédevergue (*Bulletin Général de Thérapeutique*, 1864) as an instance of the detergent power of alcohol as a topical application—viz., of erysipelas appearing upon the body of a patient, but not at all invading the wound itself—have several times occurred to me, and I daresay to most surgeons; and it proves no more than that erysipelas is a constitutional disease; and that though usually, like scarlatina, when happening to wounded patients, showing itself first at the wounded part, it does not invariably do so. But when

> "The life of all the blood
> Is touched corruptibly,"

and pyæmic symptoms force upon us the momentous question, "What should we do to save the patient? and can we do anything?" the answer which was made to me by a surgeon of experience in a case in which the patient got well, "You can do nothing, it is useless trying," would, I suspect, be given by many. In at least four cases of which I have notes, of undoubted pyæmic infection, as evidenced by exacerbations of temperature, secondary abscesses, lobular pneumonia, rigors, the treatment to which I subjected my patients, with little better hopes at first than those which drift into the law of neglect I have just illustrated, was attended with success. They were far from being slight cases, and I had not the advantage of being able to send them away to the benefits of purer air and beyond the reach of hospital influences, as so powerfully inculcated by the teaching of Sir James Paget.

Besides persevering in the antiseptic local treatment, and giving free access of fresh air, I surrounded my patient with a highly antiseptic atmosphere, by placing muslin bags of McDougall's powder around and within the bed, and in abundance about the wound, so that he should both breathe the carbolic and sulphurous vapour, and imbibe it as far as possible through the skin. If the stomach were not feeble or irritable, and able to take abundant nourishment (the primary element of restoration), I also gave three to six grain doses of the sulpho-carbolate of iron, with a view of testing the practice so ably and exhaustively advocated by my friend Dr. Sansom. I took care, as far as possible, not to give the drug soon after nourishment was taken, so as not to interfere with the first stage of digestion, and I discontinued it at once if the appetite fell off, or if there was pain after taking it. Three of the cases showed, in from a week to ten days' time, that peculiar slate-coloured or olive-green coloration of the urine, the cause of which was attributed in a description given by me of one of these cases (in 1868), after a chemical examination by the late Professor Miller, to a modification of the yellow indigo-like colouring matter of the urine by the

action of the carbolic acid upon it. This curious and well-known change has been noticed by Mr. Berkeley Hill, Drs. Fuller, Stevenson, and Wallace. These cases are completely recovered; but I am bound to say that in some other cases, not apparently more serious, but perhaps more insidious, the patients died out quite as comfortably as under any other plan, whether officious or let-alone in character.

I believe that cases of recovery frequently occur under other methods, or no methods, and that at least as much depends upon the age and reparative power of the patient, the amount of blood-poison formed or absorbed, and the general conditions of the atmosphere as upon any system of treatment whatever.

I attach much importance, as I have said, to free drainage in dressing wounds, and when made by the surgeon a good deal more may be done to favour this by a judicious choice of the direction of the incision in resections, etc., and the position of the flaps, etc., in amputations. The plan of making a puncture in the popliteal space, proposed and practised by Mr. Jonathan Hutchinson in excision of the knee-joint, is one which illustrates my meaning. The wound would, if possible, be made to slope towards that part which is most dependent when the patient is laid in bed. In amputations of the thigh, I think for this reason that the circular operation is most objectionable, on account of its forming a hollow, funnel-shaped wound, which, in the necessarily raised position of the stump upon a pillow, holds the discharge like a bucket only slightly tilted. Very good drainage is accomplished in the late Mr. Teale's excellent plan of a single square anterior flap. I have practised Mr. Teale's method with the best results in the leg and forearm, but for other reasons I prefer in the thigh an oblique double flap, with the outer end of the incision placed lower than the inner, and the front flap placed somewhat outside the limb and longer than the hinder. After many trials, I am quite convinced that this gives the most complete drainage, prevents the bone from protruding, and makes a very shapely and serviceable stump, with the cicatrix placed well behind the point of pressure. Another important point bearing on this matter in favouring the escape of discharges from the interior of a wound lies in the manner of securing the arteries. When an artery is twisted in, as in the ancient Roman system, revived by Amussat and Velpeau, and lately tried by Mr. Cooper Forster (*Trans. Clinical Society*, 1870) and Mr. Bryant ("On the Torsion of Arteries," *Medico-Chirurgical Transactions*, ii., p. 199), or when it is secured by a pin or wire, as advocated by the late Sir James Simpson, and practised at Aberdeen and elsewhere; or when it is secured by an antiseptic catgut ligature, cut off short on the vessel, as revived by Professor Lister, and tested and practised by Mr. T. Holmes, the theory is, that the wound should heal in the deeper parts as well as in the more superficial by the direct adhesive process. But this, in the amputation of an extremity or a large resection, is not the rule, and, moreover, in large cities is not usual.

Now, the parts that are most disposed so to heal are the smoothly cut, self-adapting, and vascular tegumentary structures, and these sometimes close up by adhesion, leaving interior cavities, especially about the bone and between the muscles, containing decomposing blood or pus, which afterwards accumulate, burrow, give trouble, and delay the cure, or cause by pyæmia the death of the patient. To prevent this subsequent inconvenience after experience of it seems to be the only rational explanation of the Continental method still employed, of stuffing the whole wound with charpie, so as to insure healing from the bottom, which seems so strange to our notions. If we could be quite sure that by torsion, metallic or antiseptic ligatures, we could secure complete adhesion throughout, the case would be made very much stronger in their favour. But this is certainly the exception, and not the rule. There are other elements at work influencing this, even more powerful than the local treatment. Now, I believe with my esteemed colleague, Sir W. Fergusson, that so long as we have this want of entire union, ligature-threads may have the advantage of keeping open channels for the escape of discharges from the close neighbourhood of the tied arteries, the accompanying veins of which are frequently the sources of effusions of blood after the wound is dressed, which afterwards clot, and may putrefy. These ligature-threads I usually have well steeped in carbolised oil, and saturated so as to be unable to absorb discharges, but utilised to spread around an antiseptic influence. Sometimes, in deep narrow wounds, I place them within or alongside of a drainage-tube. They can thus be made into channels for the introduction of antiseptic agents to the deeper parts, and this consideration may add to the much greater sense of security given to the patient as well as to the surgeon's mind on leaving him, by the use of a safe knot and a string to remove it by when it has performed its work. There is one point in the section of flaps which may, I think, have influence sometimes upon the introduction of pus or septic matter into the cut veins. When these are cut obliquely with the face of the flap, they are opened in a large conic section, and left in an attitude in the shape of a pea, especially when placed on the underlying flap, well adapted for receiving and conducting into their interior matters which gravitate from the surrounding hollow and often funnel-shaped sides. To obviate this, I invariably, in a flap amputation, cut off short the larger veins transversely.

The next subject I shall touch upon belongs to one to which I have directed attention for some years—viz., the radical cure of rupture. I have long thought that we might, in favourable cases, safely do more than we now attempt, to prevent a return of the protrusion after the operation for the relief of strangulation. After performing operations for the radical cure more than two hundred times, I had grounds for the belief (which other operations on the peritoneum also favoured) that, in a healthy subject, the peritoneum might be dealt with as freely and as safely as any other tissue; and also, that the chances of bad results from peritonitis would depend upon the injury sustained by the bowel in strangulation, rather than upon any way of dealing with the peritoneal sac and parietes after the strangulation had been relieved, provided that good drainage be secured. In cases where the bowel and omentum are congested only, and most likely to recover when placed into their natural cavity, in young and healthy lads, with strangulated inguinal hernia, I concluded that the attempt would be justified, and would probably be successful. If so, the advantage of preventing a lifelong trouble and danger from rupture by the operation which relieves strangulation is obvious. The kind of cases I selected for such an attempt, and the nature and results of the proceeding, will be best conveyed to your minds by a short *résumé* of the three cases where I have had the opportunity of carrying it into practice.

On June 29, 1868, was admitted into King's College Hospital a young man, Alfred Fuller, aged 21, 61, Warden-road, St. Pancras, with a strangulated right oblique scrotal hernia. The tumour had occurred suddenly from lifting. It was of the size of the fist, and had been strangulated twenty-four hours. He had constipation, violent retching and vomiting, not fæcal, quick pulse, and anxious face, pain in the epigastrium, and much pain and tenderness in the tumour, upon which several ineffectual attempts at taxis had been made. I put him well under chloroform, and made a fair and full attempt at reduction by the taxis, but in vain. I then made an oblique incision over the tumour, dividing the layers in the usual way, and laying open the sac to the extent of three inches. The sac contained a moderate amount of omentum, covering a knuckle of bowel, all congested, and the bowel slightly ecchymosed, and there was about an ounce and a half of bloody serum in the sac. The point of strangulation was at the deep inguinal ring, and it was divided by an upward cut. The bowel was then drawn down slightly, and carefully examined. It presented the usual indentation, but was smooth and shining. It was then returned, and after it the omentum, the latter being carefully spread over the deep opening. The sides of the sac were then brought together, so as closely to embrace the cord over the whole length of the canal. The handled curved hernia needle used in my operation for the radical cure, armed with silvered wire, was then employed to bring together the sides of the sac, together with the aponeurotic structures along the whole length of the canal, in the way I have described in my work "On Rupture." A good view of the conjoined tendon was obtained, and the wire fixed in it in two places. The loop and ends of the doubled wire were then brought out at the upper and lower ends respectively of the incision. Four interrupted wire sutures were then placed in the skin between these points. The wound was dressed with carbolic lotion, and covered with gutta-percha skin, and cotton-wool powdered with McDougall's powder to absorb the discharges. The interrupted sutures were removed on the fourth day, primary union having been by that time obtained throughout, except where the thick wires passed through the extremities of the wound, and effectively kept up the drainage. These were kept in for ten days. There was not the slightest sign throughout the case

of the peritoneum being inflamed, and the abdominal tenderness which was present at the time of the operation passed away entirely. The sickness ceased directly after the operation, and the bowels were opened naturally two days afterwards. Erysipelas being present at this time in the ward, the patient was attacked by it on the sixth day. A partial reopening of the wound was the consequence, together with suppuration in the fundus of the sac of the hernia. The pus passed freely along the wires, and there was no burrowing.

The suppuration in the sac caused obliteration and shrinking of that structure, and the testis was drawn by the subsequent contraction into the upper part of the scrotum. Some delay in the convalescence was thus produced, but finally the patient was discharged, wearing a light truss, on August 15, 1868.

During the first year after the operation I saw him twice or three times. There was no cough impulse whatever when last seen, all the parts being very firmly traced up in the groin and around the cord. As he was repeatedly enjoined to show himself at once if any pain or weakness showed itself, and seemed fully impressed with the danger from strangulation which he had escaped, I have, I think, some right to conclude that there has been no return. The difficulty of following cases for a number of years in the nomadic habits of that part of our population which furnishes the most numerously favourable cases for the radical cure, is one which I experienced in this case.

The next case was in a patient who had wished much to be operated on for the radical cure before the rupture became strangulated, in consequence of the impossibility of keeping it up with a truss, and the consequent disability from following his employment. I had refused to do so because of his age and the direct nature and great size of the openings.

Martin Webster, aged 52, had suffered from a large right direct inguinal rupture for twenty-six years, which, though at first entirely reducible by rest and the recumbent posture, could not for many years past, on account of the large size of the opening, be entirely pushed back or kept up by any of the great number of trusses which he had tried. He was admitted on April 14, 1872, had been vomiting for eight hours, and was very weak and low. The tumour filled the scrotum, was of the size of the two fists, and was tense, tender, and painful, with the skin of the scrotum red and inflamed from handling. A somewhat prolonged trial of the taxis being made under chloroform, after the application of ice for three hours, and by inversion of the patient without success, the operation of herniotomy was proceeded with by a single oblique incision four inches long. On opening the sac a very large mass of omentum was found adherent at the neck, but not elsewhere, and covered by it was a large fold of small intestine, dark and congested, but still smooth and glistening. After division of the strangulating band at the deep opening, the bowel being found not much damaged at the strictured part was easily reduced. The omentum was congested, but not gangrenous, and, on account of its size and the adhesions somewhat recent at the neck, could not be fairly reduced or retained in the abdomen. The mass of fat, about three-quarters of a pound weight, was then cut off close to the adhesions at the neck of the sac. Such vessels as bled were tied separately, and, the stump being enclosed between the sides of the serous sac, four interrupted sutures of carbolised hemp were applied through the sac and tendinous parietes, and tied up so as to embrace the cord pretty closely. The two uppermost sutures were passed through the stump of omentum itself. These and the ligatures upon the arteries were then tied up in one knot, and left hanging out of the lower angle of the wound to act as a drain for the discharges from the face of the omental stump. Lateral pads of lint and a spica bandage were applied, and the patient placed with his knees drawn up and shoulders raised, and five grains of pilula saponis cum opio given every four hours. The vomiting and distress at once ceased; there was no tympanites and but little tenderness, and the bowels were freely acted on the third day. An abscess subsequently formed in the lower part of the enormous sac, and a small slough formed in the scrotum over the testis. Through the aperture left by this the gland showed some tendency to protrude, but was easily kept in place by strapping and pads. By the use of a drainage-tube through the lower part of the primary incision and out at the aperture left by the slough the matter flowed away freely, and there was no tendency to burrow. The ligatures and sutures had all come away by April 29, and on June 22 he left the hospital with the parts much thickened, firmly braced up, and wearing a truss with a large ring pad. I have seen this patient several times since then, once in this present year. There was then a bulge felt in the groin when he coughed (and he has always a bad winter cough), but there was no sign of any descent into the scrotum, and a light truss kept him very comfortable and able to do a good day's work without inconvenience. He also promised to come to me at once if he had any more trouble with it.

The third case was that of Edward Brown, a waiter, of 14, Surry-street, Strand, aged 21, in whom the rupture, a right oblique scrotal one, had not been observed till the day before his admission, when, after lifting a heavy box, he felt pain and sickness, and felt a lump in his scrotum. A doctor to whom he applied gave him an aperient, after which he began to vomit, and pain was worse, and the tumour increased in size and filled the scrotum. This rapid appearance and increase of the rupture were afterwards explained by its proving to be a congenital hernia with the sac formed by the tunica vaginalis, of which these peculiarities are very characteristic. On March 28, twenty-four hours after the occurrence of the rupture, the symptoms were very intense, and the taxis, with inversion and chloroform, having been fairly tried after two hours' application of ice-bags, I performed herniotomy exactly as in the first case I have described. The omentum and bowel were found in the tunica vaginalis, both congested and slightly ecchymosed, with some effusion of bloody serum. The knuckle of bowel was strangulated, not only by the deep ring, but also by a band of the omentum, necessitating the drawing down of both until the constricted part could be seen and released. It was a case in which the bowel might easily have been passed into the abdomen with the stricture undivided. After the operation the patient was at once relieved; the bowels were opened normally on the third day; no tympanites or tenderness became apparent. The central part of the incision healed by adhesion; a little discharge passed along the wires, which were withdrawn on the fourteenth day after the operation. He was sent out of the hospital April 26, 1873, with a firm adherent cicatrix, and no bulge whatever. On May 12 he showed himself, wearing a light horse-shoe pad truss; not the slightest sign of a return was evident. This patient is here to-day awaiting your inspection.

It has been said, with respect to this operation, that evidence is wanting as to the permanency of the cure, and I am free to confess that it is exceedingly difficult to watch a couple of hundred cases for the space of ten or eleven years. The constitution of human nature is such that you cannot hope for the generality of patients to show themselves occasionally for this length of time, or even to write if they are not further troubled with the ailment of which he has cured them. It requires that powerful spring to gratitude which was said by the cynical French philosopher to consist in "a lively sense of favours to come," which is wanting in a case where there is no more for the doctor to do. I have found that the unsuccessful cases are more likely by the law of gratitude just enunciated to return upon your hands than the successful ones are, as a bad shilling expects to be replaced by a good one. I think, therefore, we have the better right to the position of reckoning in the same proportion of failures and cures cases which have not been seen twelve months after the operation, as those which have been examined after that time.

Now, out of 188 (most of them unselected) cases of inguinal hernia out of the 200 and upwards I have operated on to the present time, of which I have notes—including 7 females and 4 cases of double rupture, both operated on—in 107 cases the results are more or less perfectly known. I find that 51 of these were more or less unsuccessful; of which 42 returned in the first year after operation—that is, the great majority of these were such as would do without wearing a truss after the first year. By far the greater number were so much improved that they were made comfortable by a truss, which was not the case in most instances before the operation. Some, but not many in number, were as bad as before the operation. Mr. Kingdon, of the London Truss Society, kindly forwarded to me in 1863 the names of three of those who had applied to that institution, since the operation, for the supply of a truss.

Out of the 107 cases, 56 continued to be successful subsequently a year after the operation, as ascertained either by direct examination by myself or other surgeons, or satisfactory to the patient himself, and either wearing no truss at all, or only occasionally, as a precaution, after the first year from the operation. Of these—7 were noted from thirteen to twenty-one months after the operation; 7 from two years; 7 from three years; 7 from four to six years; 7 from six to eight

years; 4 from nine to eleven years. Reckoning operations on both sides and repetitions of the operations, I have done the operation more than two hundred times. Out of these, I have had three deaths; one from pyæmia, one from erysipelas, and one from peritonitis. These have been made public to the profession on more than one occasion, because I judged it right and fair that in an operation of this kind the facts should be made known as far as possible. In the last case, as shown by the post-mortem examination (published in the *Medical Times and Gazette* in 1866), the peritonitis was found not to have originated in the parts operated on, but in a knuckle of bowel which had been lodged in the hernia before the operation, while the patient was wearing a strong truss. The cases in which any signs of peritonitis were observed were not more than about twenty in the whole number. One and a half per cent. is not a high average of deaths from purely accidental surgical incidents, and there are very few operations of like kind—as, for example, for the removal of deformity, the cure of prolapsus of viscera, or of hæmorrhoids—which could show more favourably either in this respect or in respect to the somewhat severe test of the length of time in which they have been known to be without a relapse after the operation. And since 42 out of the 51 known unsuccessful cases proved to be so within the first year after operation, and most of the cases were examined once or more at various intervals of time after the operation, I think that in respect to this point we have a right to claim the probability of more, and the certainty of at least as many, good results for the 81 of which I have not been able to get notes after the first twelve months as for the 107 in which I have done so. Under the age of twenty-one years the results in known cases are much more satisfactory, and amount to 75 per cent. of successful cases. But of dry statistics you will think that I have given you, perhaps, more than enough.

The determination of the question as to whether the operation for the radical cure is an appropriate alternative to a lifelong wearing of a truss, and a valuable supplement to the slow and very uncertain cure by truss pressure, will continue to depend upon the age, habits, circumstances, mode of life, and, to some extent, the cruel experience of trusses and wish of the patient after having the matter fairly put before him, and perhaps nearly as much upon the anatomical knowledge, skill, energy, and experience of the surgeon, or his disposition to the finality frame of mind I have alluded to. In any case, whether universally or only occasionally resorted to, it forms, I think, a valuable addition to the resources of surgery.

Cases of ectopia vesicæ and epispadias possess an interest for surgeons who have a tendency to plastic efforts which results, partly from the well-known futility of all operations to relieve them until recent years, and partly from the piteous appeals for relief from the very miserable condition to which the unfortunate patient labouring under this deformity is reduced. During the last ten years that my attention has been directed to this deformity, I have met with between forty and fifty cases, and many more have been recorded by my fellow-labourer in this direction, Professor T. Holmes, who first practised in this country in March, 1863,(b) the plan followed successfully by Pancoast and Ayres in America in 1858. It had been suggested, apparently, by M. Richard's unsuccessful application, in 1853, of Nélaton's principle of laying a flap upon the parts to be covered, with the skin surface downwards, and covering it up with another. Cases have been operated on by Messrs. Simon, Lloyd, Sydney Jones, and Thomas Smith, with, I believe, but little success. I have operated, up to the present time, for the relief of sixteen cases. All except three were males. Of the three females, one, aged 9, died from uræmic poisoning, the kidneys being found extensively affected with cystic degeneration, one being entirely converted into a membranous sac. The other two unsuccessful cases were operated on at too young an age for the extent of the deformity which was present, the constant efforts of crying after the operation acting upon the very protruding bladder and causing entire separation of the flaps after they had partially united.

My first case was operated on by lateral flaps only, not reversed, in October, 1863, and was, after two supplemental operations, entirely successful. The boy died afterwards from erysipelas of the head and face; and I had an opportunity of preserving the parts operated on, which may be seen in the adjoining museum of preparations collected for the purposes of the present Association. It is interesting, as showing the formation of a smooth mucous surface, the deep surface of the superimposed flaps.

All my other cases were more or less successful. Two were shown in the course of last year at the Pathological and the Medical and Chirurgical Societies, in one of which especially the artificial covering was so complete and perfect that for a short time the boy could be made to hold his water by the application of an indiarubber ring around the penis and artificial preputial covering of the urethra. All the thirteen successful cases could be kept dry and comfortable by the application of a guard and indiarubber tube and bag, as in a railway urinal. Eight cases (seven male and one female) were published in the *Medico-Chirurgical Transactions* of 1868, vol. lii. Eight more (six male and two female) have been operated on since that date.

Time will not allow me to give further details of the various methods I have employed to obtain these results. Some of these had been previously employed by Nélaton and his pupils, MM. Richard and Follin, and followed by Pancoast, Ayres, and Holmes. A full description of my methods has been published in the *Medico-Chirurgical Transactions* just alluded to.

I am able, I am glad to say, to give the members of the Association an opportunity of seeing here, or in the neighbouring wards of King's College Hospital, three cases, one of which has been operated on unsuccessfully, one in which the first stage of operation has been reached, and one in which the two operations have been done. From these, they can judge for themselves of the value and utility of the work done.

For the analogous but less disabling condition of *epispadias*, I have operated twice by Nélaton's method with favourable results. For *hypospadias*, in which the urethra was deficient below as far as the scrotum, I have operated three times, upon a plan somewhat similar—viz., a reversed flap from the side of the opening, with another from the scrotum superimposed upon it. In one case—a boy of $1\frac{1}{2}$ years—which had been interfered with considerably by a former unsuccessful operation, the result was an entire failure. In another, a boy of 6 years, the result was so far successful after one operation, that another slighter one will complete it. In a third case, that of an adult male aged 24, the result after two operations was an entire success, enabling him to pass his water comfortably over his trousers, and aiding to some extent the power of sexual connexion.

A similar plan, combined with internal section and dilatation of the strictured urethra, I have found to succeed admirably and completely in two cases of penile urinary fistula communicating with the urethra in front of and close to the scrotum, accompanied with a hard cartilaginous stricture of the urethra. One was a bad traumatic case, which had before been operated on unsuccessfully by another surgeon. Cases of this kind have been long considered to resist all the efforts of plastic surgery; and, before adopting this plan, I had frequently been baffled in attempts to close the fistula.

In connexion with the subject of the treatment of stricture of the urethra, I may mention that among surgical novelties is the plan of M. Demarquay, of passing a long flexible hollow bougie through a perineal urinary fistula previously enlarged by the bistoury, and then one end forwards through the stricture and out at the meatus, and the other end backwards into the bladder.

The ingenious plan of Mr. Furneaux Jordan, of Birmingham, of treating obstinate impassable strictures by attacking them in the rear through an opening from the rectum into the dilated urethra behind the stricture, is a valuable contribution of the year to surgical resources in troublesome cases (see *British Medical Journal*, November 9, 1872, No. 619). Mr. Jordan informs me that he has operated in three cases of the kind with complete success.

In other kinds of plastic surgery much has been done of late years. Since my own successful case of transplantation of skin from the abdomen to the arm for the relief of a frightful deformity of the wrist (published in the *Medico-Chirurgical Transactions* for 1863, vol. xlvi.), I have had two more successful cases. A similar operation has been also successfully performed by Mr. Thomas Smith in the wards of St. Bartholomew's Hospital; and my colleague, Mr. Henry Smith, has quite lately had a very good case of operation upon the same plan, for the relief of an extreme contraction of the elbow after a burn in the left arm of an adult female. In rhinoplasty, in which so much good work has been done by Hamilton and Lichtenburg, I have had some good cases of restoration of the nose from the cheeks and upper lip. Some of those are found

(b) See "Lancet" for June 27, 1863, and his work on "Surgical Treatment of Diseases of Children."

among the photographs laid before the meeting. The last case I have undertaken is about the most difficult one I have ever had to deal with, in the width of the chasm and the extensive loss of substance. The nasal bones, the vomer, ascending portion and a considerable part of the alveolus of the superior maxillary, the whole of the ethmoid except the cribriform plate, have necrosed away, as the result of scrofulous lupus. The great prominence of the frontal sinus also constitutes an element of difficulty. To afford a basis for the new nose turned down from the forehead, I have resorted to the plan frequently followed successfully by Sir William Fergusson, of dissecting off and bringing towards the median line of the whole of both cheeks. To secure the union of these, and to afford a prominence to the point of the nose, I followed a plan that I have employed in three bad cases with very satisfactory results, two of which are shown in the photographs which lie upon the table. At the same operation I turned up the middle third of the upper lip, and split it up from its lower edge, turning over the borders, so as to afford a bridge of support and an extended raw surface for union with the apposed cheeks. This was rendered necessary, to enable the cheeks to meet in the median line, as well as to insure their union to each other. When this was entirely healed, by a second operation I dissected up the mucous membrane from the bridge made of lip-tissue, and reflected it over the gap still left between the eyes, so as to form another bridge of support for the root of the new nose, preventing it from sinking into the gap so as to become too much depressed. I then turned down the new nose from the forehead after the Indian method, fitting it on to the raw surface, which gave it admirable support; and kept up the point of the new nose in a manner which one does not commonly see after this operation. This patient I have in attendance for the inspection of the members, and is still under treatment in the wards of King's College Hospital.

The very original and ingenious method of M. Reverdin I have practised with advantage in many of these rhinoplastic cases, to eke out any deficiencies of skin in corners where it was desirable to prevent puckering, if possible, from contraction, or to substitute skin-tissue for mucous membrane exposed by reversal of the upper-lip structure, which for some time is rather apt to show its parentage too plainly, unless subjected to more friction than is agreeable or possible upon a newly formed nose. In applying this method to large sores of the leg, or those resulting from burns, where the contraction of cicatrisation is impossible or injurious, a certain amount of success has been obtained. Perhaps the healing is somewhat expedited, but it is certainly more accomplished by the cicatrisation and contraction of the original edges of the ulcer than by the increase of the transplanted patches. We have also found a tendency in the resulting cicatrix to ulcerate again readily. I do not think that this method will supersede the necessity for larger transplantations of skin in those severe cases which call most urgently for surgical interference.

Among the recent innovations in operative surgery, I have barely time to notice one which "*l'audace*" of the French school is applying in a manner which those who have reached the rest-and-be-thankful stage of development may well call daring, if not rash. I refer to the use of the *aspirateur* of M. Dieulafoy to relieve distension by puncture of the bladder in cases of retention of urine, and of the intestine in cases of abdominal obstruction, and in joints affected with hydrops articuli, and even to evacuate the fluid contents in strangulated hernia. In the first named of these conditions, it is no doubt valuable as an adjunct to other remedies. In intestinal obstruction Demarquay has not found it of much practical use, because of the rapid re-formation of flatus, which quite corresponds with my own experience of puncture in desperate cases without the aspirator. In the puncture of joints and in the cure of hydatids I have used it, but not frequently enough to pronounce upon its capabilities. I have not yet arrived at the measure of audacity to use it in strangulated hernia. It scarcely agrees with my own impression as to the importance of avoiding any additional injury to the bowel in dealing with strangulated or other herniæ. The propriety and the limits of the use of this instrument are only entering upon the *sub judice* stage, and we must wait for more of those bad consequences following its employment than those which have already occurred, before we can pronounce fairly upon its legitimate use.

In the use of anæsthetics, we find now rising a revival of the rivalry between chloroform and ether, which the fame and support of the late Sir James Y. Simpson had decided in this country in favour of the former. We follow but tardily, in this old country, in that combination of pleasure with utility, which has led lately the inventive genius of our Transatlantic brethren, "ever charming, ever new," to the association of æsthetics with anæsthetics in the performance of operations under these agents to an obbligato accompaniment upon the organ, and an appropriate address by a popular preacher, improving the occasion on behalf of morals. The comparative safety of these agents is unquestionably a most important point, and one that must ultimately decide the matter in favour of that anæsthetic the use of which involves the fewest casualties. The chief difficulty in determining this important point is the natural disinclination to make public such cases. It is less objectionable, however, to do so when a certain lapse of time has occurred after the accident; and it is to be hoped that, in the not very far future, we may arrive generally at that philosophic frame of mind which will consider it as much a duty to publish unsuccessful cases as it is a gratification to achieve the glory of a brilliant result.

In the domain of surgery, gentlemen, are so many regions now undergoing exploration and re-examination, that I may fairly claim an excuse for having led you chiefly over ground which I have myself travelled, and for omitting many equally important territories perhaps more effectively mapped out, and to some of you more interesting. In exploring this domain many pioneers are required, and many very qualified ones are busily at work. Those who have skill and pluck enough to find a new road of investigation, even if it be only to prove that it leads nowhither, deserve commendation for this proof, which is itself good work none. They demand our sympathy perhaps more than those who are lucky enough to lead up to the most auriferous diggings. The age we live in is too much given to the worship of success to afford much of this sympathy; and it accords, usually, too little merit to such as have contributed to prepare a way for the honour which another has reached, profiting, it may be, by their mistaken vestiges in travelling upon the same errand. As we advance, our horizon itself extends; the very multitude of objects brought into view perplexes the perception of them; and even our instruments for detecting and examining them become so numerous as to be themselves *impedimenta* to our progress. The difficulty of deciding upon any given point becomes greater as differences become more minute, and proof more complex and further from our stand-point. The use of the imagination in science has already been powerfully justified; and the time may yet come when a complete and logical proof will be as little possible in scientific knowledge as in dogmatic theology. The theory of probabilities will doubtless be more employed to compensate for the imperfection of the record, and may be turned to advantage in Bastian's archebiosis and Pouchet's germ-theory, as much as in the Darwinian hypothesis. It will thus become easier for the critic to fall into the error of asking for more evidence than the nature of the subject admits of —a sure sign of the limited area of his habitual observations. But even this tendency is productive of good. It is merely the redundant energy of a single-minded instinct in this natural enemy of inventors and innovators—sent, doubtless, as hawks to keep down sparrows, to insure proper limits and decent order among the more imitative minds who follow, prove, and sometimes improve, upon originators, and form schools and fashions. They thus accumulate a chastened experience. When weighted by the synthetical faculty, this instinct constructs eclectic systems, more than ever needed in the present chaos of crude ideas and undigested opinions, to which these swift-winged writers are fearsome scourges. By their keen research they discover when and how things are re-invented and re-discovered, show the limits of their application, give warnings of danger and excess, which, if often falsified, at least inspire a useful caution, or lead to a more insured confirmation. Still more useful are they in deciding when discoverers disagree about priority. Whether right or wrong, they ultimately have the effect of consolidating and rendering more certain a well-grounded reputation. Misled by the Chasles forgeries, they found out that Newton had been preceded in his discovery of gravitation by a French *savant*, and thus elicited an elaborate and conclusive proof of its great originality. They have lately asserted that Harvey had been forestalled in his discovery of the circulation of the blood by Walter Warner, and have thus given us the benefit of the profoundly learned vindication by the Linacre Professor of Anatomy and Physiology at Oxford.

A still greater influence and responsibility than heretofore

will rest upon these labourers in science. The fruition of really great discoveries has been, and will no doubt continue to be, postponed by the blind opposition of these who form the scientific opinions of the age, and, though they usually check one another, so as to act, on the whole, with advantage, yet their neglect or prejudices may undoubtedly prevail, so as to inflict injustice upon individuals, and do injury to science and to mankind, the more lasting in proportion to their position, ability, and conscientiousness.

The following are a few of our distinguished *confrères* who are attending the present meeting from the sister kingdoms and the provinces:—Mr. Porter, Dr. Denham, Mr. Joliffe Tufuell, and Professor Mapother, of Dublin; Dr. Gairdner, Dr. Buchanan, and Dr. Macleod, of Glasgow; Grainger Stewart and Batty Tuke, of Edinburgh; Drs. Ogston, Fraser, and Struthers, from Aberdeen; Chadwick, of Leeds; Southam and Roberts, of Manchester; Husband, of York; Baker and Bartleet, of Birmingham; Swain and Square, of Plymouth; Elliot and Barnes, of Carlisle; Cadge, Cross, and Copeman, of Norwich; Rumsey, of Cheltenham; Desmond and Steele, of Liverpool; Baker, of Derby; Philipson, of Newcastle; Eyton Jones and Griffith, of Wrexham; Ceely, of Aylesbury; Dyke, of Merthyr Tydfil; Ransom, of Nottingham; Waters, of Chester; Hall, of Brighton, etc.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

No. XXIX.

By J. F. CLARKE, M.R.C.S.

For nearly forty years on the Editorial Staff of the "Lancet."

LONDON UNIVERSITY.

(*Continued from page* 49.)

Quarrels of the Medical Officers, and their Influence upon the Success of the North London Hospital.

At the time when University College and Hospital were in the full zenith of their fame and usefulness, the medical officers of the Hospital were constantly quarrelling. On more than one occasion disagreements rose to such a height that they threatened seriously to injure both College and Hospital. So long as the combat was carried on in the board-room of the Hospital the students were unacquainted with the grave differences which existed amongst their teachers. But unfortunately the operating-theatre and the wards of the Hospital became the arena for displays, which, whilst they afforded a fund of amusement to the students, were painful to those who could not fail to perceive the danger to which they exposed the institution. The two foremost men in the Hospital were Elliotson and Liston. Whatever might have been the cause of the quarrel between these two eminent persons, I can affirm that for three or four years they were constantly at daggers drawn. I think there can be no doubt that jealousy was the mainspring of this unfortunate condition of things. Elliotson and Liston were both supreme favourites with the pupils, and neither could bear "a brother near the throne." Elliotson was in the majority on all questions on which a vote was taken. Elliotson's party consisted of Samuel Cooper and Richard Quain; Liston and Anthony Todd Thompson formed the minority. The scenes that took place at the Board were of the most exciting character, and occasionally threatened personal violence. At this time I was in the daily habit of accompanying Liston on his rounds after his visits to the Hospital. He complained to me constantly of the indignities to which he was subjected. "Cantab," he would say, "has attacked me again. It's too much for my temper; I cannot long endure it."(a)

I ventured, on returning home, after reflecting on the false position in which Liston had placed himself, to address a note on one occasion to him, begging of him in the future to restrain his temper, whatever the provocation to which he was subjected might be. I asked him not to feel offended at my freedom in thus tendering him advice. He replied that he never could be offended at anything I could do respecting himself, as he was well assured I had but one object in my interference, which was for his benefit. I have his note now before me in reply to my remonstance, in which he says "for the future I will act on your advice." To some extent he kept his promise, but his impetuous nature led him into many further difficulties, and "the schism" prevailed until Elliotson was forced to resign his appointment, in consequence of his introduction of animal magnetism as a curative process in the treatment of patients submitted to his charge as a physician to the Hospital. In some of my former articles I have discussed this subject; I shall enter more fully into it in future contributions.

(*To be continued.*)

(a) At one of these meetings Liston so far forgot himself as to threaten personal chastisement on his opponent, "Elliotson Cantab,"—which, it should be explained, was Elliotson's cognomen.

REVIEWS.

A Treatise on the Continued Fevers of Great Britain. By Charles Murchison, M.D., LL.D., F.R.S. Second edition. Longmans. Pp. 729.

This new edition of Dr. Murchison's treatise on Continued Fevers appears at an opportune time. Eleven years have elapsed since the publication of the first edition, and during that period a large number of observations on continued fevers have been made and recorded in all parts of the world. In England the labours of the medical staff employed by the Local Government Board have given us carefully investigated records of a number of local epidemics, and have added something at least to our knowledge of the manner in which epidemics of typhoid fever frequently—we do not say always—arise. The same period also has seen London visited with great epidemics of typhus and relapsing fever, and the records of the Fever Hospital during that period are of very great value. Fortunately, the Hospital has possessed in Dr. Murchison and the other members of its staff a set of competent and industrious observers, who have not allowed the pathological harvest which the late epidemic seasons have given to their hands to be lost. The Fever Hospital is now superseded by the new Fever Asylums, but during the period of its usefulness it has been made to contribute a full quota to the advancement of our knowledge of the class of diseases for the treatment of which it was erected.

The present volume is not a mere reprint of the former. Much of the work has been entirely rewritten, and the statistics on which the conclusions in the first edition were based have been largely extended. In his preface Dr. Murchison tells us that "the statistical tables in the first edition were based on 6703 cases of continued fever admitted into the London Fever Hospital during ten years (1848-57), while those in the present edition are based on 28,863 cases admitted during twenty-three years (1848-70)." This latter period comprises the entire modern medical history of the Fever Hospital, for it was not until 1848 the continued fevers were distinguished, and the transfer of the pauper patients to the new Fever Asylums in 1871 cut off the chief source of supply to the Hospital.

The questions which at the present time are mainly attracting the attention of the medical world are those of etiology. The old mists of doubt and dispute as to whether it were possible to cut short fevers, and whether fevers were best treated by heroic bloodletting or by drugs supposed to possess a specific action, have vanished completely from the medical horizon, and their place is taken by the great inquiries, the solution of which is alone capable of raising preventive medicine into an exact science. Such questions are—What is the essence of these diseases? what is contagion? what is a specific morbid poision? what zymotic diseases do in the present day originate *de novo*, and what proportion does the mode of fresh origination bear to the mode of origination by the introduction of specific poison-germs? what part, if any, do microzymes play in the production of zymotic diseases? what are the varieties of typhoid and typhus fevers? and what, on the one hand, is their relation, and what is the relation borne by typhoid fever to miasmatic diseases, on the other? The nearer we can approximate to the true answers to these and the like inquiries, the more certainly shall we arrive at the best means of freeing civilised man from these dire historic scourges.

Very recent experience in our own metropolis unfortunately proves afresh that the poison of enteric fever is sufficiently rife amongst us, and that, however it may get there, it finds its way into quarters where its congeners typhus and relapsing fever rarely, if ever, penetrate. The reader will turn with interest to the pages which contain Dr. Murchison's conclusions

on the much debated subject of the etiology of typhoid. He thus sums them up:—"1. Enteric fever is either an endemic disease, or its epidemics are circumscribed. 2. It is most prevalent in autumn after hot weather. 3. It is independent of overcrowding, and attacks the rich and the poor indiscriminately. 4. It may be generated independently of a previous case, by fermentation of fæcal and perhaps other forms of organic matter. 5. It may be communicated by the sick to persons in health, but even then the poison is not, like that of small-pox, given off from the body in a virulent form, but is developed by the decomposition of the excreta after their discharge. 6. Consequently, an outbreak of enteric fever implies poisoning of air, drinking-water, or other ingesta with decomposing excrement." Of these conclusions—which, if our memory serves us, differ but little from those advanced in the first edition—the fourth, fifth, and sixth are those which are likely to raise controversy.

Dr. Murchison has now for the last fifteen years persistently advanced the possibility of enteric fever having an independent origin from fæcal decomposition and miasma, and his view is supported by a number of authorities, amongst whom he quotes Griesinger, Niemeyer, Liebermeister, Hudson, and Stewart. A large number of observations of local outbreaks are quoted in the work before us in which the poison could not be traced to importation or to any cause more specific than fæcal contamination of water or air. On the other hand, we know that the thesis maintained by Dr. Budd, of Bristol, in this country—that the contagious nature of enteric fever (using the term contagious to signify the production of the fever from a pre-existing germ derived from the sick) is the "master truth" in its history—has certainly gained adherents of late years. It is supported by the history of several of the outbreaks recently observed by Dr. Ballard, and we may fairly say that, supposing truth be divided between the maintainers of these opposite opinions, it seems probable that as much of the precious commodity is possessed by those who assert that at least enteric fever is most frequently disseminated by contagium derived from the sick and conveyed to the healthy through the medium of ingesta, as by those who assert its more frequent independent origination. Dr. Murchison's fifth proposition, although it conveys a general truth, seems to us too sweeping. He himself (p. 460) records several cases in which the attendants on the sick have contracted typhoid fever, and in none of them has there been evidence to prove that the poison which entered into their system was "developed by the decomposition of the excreta after their discharge." It is undoubtedly true that attendants very rarely take typhoid, but, in the rare instances in which it has been communicated, it is an open question whether the poison emanates from the bodies of the sick or is derived from the decomposing alvine excretions. This, in fact, Dr. Murchison himself acknowledges.

We need hardly say that we commend Dr. Murchison's work as the best and most exhaustive treatise on the subject of Continued Fevers in our language. It is a perfect mine of carefully observed and recorded facts. The present edition is illustrated by numerous charts of temperature, and the excellent coloured plates of the cutaneous eruptions of the continued fevers which appeared in the first edition have been reproduced in this. We know of few more valuable treatises on a limited group of diseases in the whole range of practical medical literature.

GENERAL CORRESPONDENCE.

ON THE TREATMENT OF HYDATID CYSTS IN THE VISCERA.

"Palmam qui meruit ferat."

LETTER FROM DR. S. D. BIRD.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your report of the proceedings of the Clinical Society of London on November 8 of last year, there appears an interesting paper by my old friend and fellow-student Dr. Duffin, on seven cases of hydatid of the liver treated by tapping with the fine trocar and canula; and in the discussion which followed, Dr. Greenhow is stated to have said that "Dr. Murchison first brought this plan forward." This is a very great mistake, as it is easy enough to show. When I first arrived in this colony, in February, 1861, I found that diseases of this kind (which are almost as common here as they are in Iceland) were habitually treated in this manner, and with great success. On inquiring amongst the older practitioners, it appeared that tapping had been their usual remedy in almost all cases. The risk of the operation is almost *nil*, and I have many times tapped cysts both in the lung and liver in my consulting-room, in patients who returned to their homes in the country the same day. As much of the fluid as possible is evacuated; and we are in the habit of tapping such cases as soon as the presence of a cyst is detected, or indeed sometimes when it is only suspected. Both liver and lung may safely be explored with the fine trocar, with certain precautions.

I enclose the *Australian Medical Journal* for March, 1871, in which is the report of a paper read by myself before the Medical Society of Victoria, on the diagnosis and treatment of hydatid in the lung. Since this was published I have met with many curious cases of such disease, and as they may be to a certain extent novelties to many of your readers, I will with your permission give short notes of a few of them.

J. W., servant girl, aged 19, was admitted into the Alfred Hospital with a well-defined cyst in the upper lobe of the left lung; I tapped it under the clavicle, but before six ounces of the fluid had escaped by the canula, the cyst gave way into a bronchus (which had probably been perforated by the trocar), and the remainder of its contents were coughed up. The cure of this case occupied an unusual time, as she continued to cough up matter and portions of cyst for several months, but was eventually discharged quite well. I examined her yesterday, and could detect no remains of the disease.

E. G., aged 9 years, a highly nervous little girl, daughter of a country gentleman, was brought to me twelve months ago suffering from a large cyst in the liver, which a homœopathic practitioner had been treating for some months with similars and the external use of vinegar and water. I tapped the cyst at once, and gave bromide of potassium and kamela in full doses. The child never had another symptom connected with the liver, but six months afterwards reappeared with a large cyst in the top of the right lung. This was tapped by Mr. Fitzgerald, the aspirator being used. The same internal remedies were given. I have recently examined the patient, and can find no traces of either cyst, the general health also being perfect.

Some months ago I was consulted by an elderly gentleman for a large hydatid of the liver which had been several times tapped but always refilled. He now declined any further operation. I gave him large doses of bromide and kamela, and in six weeks the tumour had quite subsided and has not since reappeared.

In May, 1871, a man aged 40 was admitted to the Alfred Hospital under my care, suffering from a large cyst, which I diagnosed as occupying the convex surface of the liver rather far back. I tapped him under the ribs, keeping the point of the trochar well up. More than four pints of fluid escaped. A similar operation was required in a few weeks, and subsequently the opening was enlarged, and an elastic catheter introduced. Shortly after each operation the patient had urgent heart symptoms, irregular and intermittent pulse, and lividity, and died suddenly. The liver was found to be small and healthy; the hydatid was above the diaphragm, and had in fact occupied the cavity of the pleura. The liver had not been wounded by the trocar. The following is Professor Halford's account of the heart:—"Hydatid cysts occupy the whole of the outer surface of the heart, extending from the upper surface of the auricles surrounding the large vessels, where some of them are of the size of small oranges. They seem to me to have arisen in the visceral layer of the pericardium, not encroaching much into the muscular substance. The cavities of the heart are untouched by the parasites. The visceral layer of the pericardium is much thickened, and studded with little cysts. It may be said that the echinococci occupied the cavity of the pericardium."

Mr. Fitzgerald, Surgeon to the Melbourne Hospital, recently cut into an old cyst in the lung between the ribs, and emptied it with the finger and scoop. The patient made a rapid recovery.

I have from the experience of a large number of cases quite convinced myself that the bromide of potassium and kamela have a decided influence over the vitality of the parasite when given continuously in large doses. I am, &c.,

S. D. BIRD, M.D., L.R.C.P.,
Lecturer on Materia Medica and Therapeutics in the University of Melbourne.

"SLEEPING SICKNESS."

Letter from Mr. George Gaskoin.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have just seen in your number of July 19 a notice of the "sleeping sickness," or rather the disease of lethargy as found on the African coast, quoted by Dr. John W. Ogle from a letter by Dr. MacCarthy, whose observations appear to have been made in 1869. In the following year, a Lisbon journal, the *Correio Medico*, published some few cases of this extraordinary complaint as occurring in the islands San Tomé and Principe on that coast, from observations by Portuguese physicians made much about the same period of time. There are also a few scanty records, of earlier date, by English physicians. So far the existence and nature of the disease are established and confirmed. The cases described by the Portuguese doctors are of a far more prolonged and serious nature than would be judged from the accounts furnished by Mr. MacCarthy: in none of them is any reference made to extirpation of cervical glands or pressure on the great vessels. I merely mention this fact, having no feeling but that of curiosity on the subject and thankfulness for his contribution. Since my attention was directed to the perusal of these cases, I have felt persuaded that the Arabian physicians, with all their minute divisions of lethargy and head oppression, must have been acquainted with the disease. In some of our own medical dictionaries, even of the present century, *Carus* is described at length. An anæmic condition habitual in the negro first suggests itself, or some poisoned condition of the blood seems, in the absence of further data, a ready way of accounting for it. The alarming coma that occasionally precedes the eruption of small-pox, the excessive head oppression in some cases of malarial fever, would afford an analogy for this. Boerhaave speaks of *Carus* as an apoplexy, which brings it very near to sunstroke. If it were merely a falling to sleep, as Mr. MacCarthy describes it, one need not go out of London to find most singular instances of sleeping sickness, as idiosyncrasy, not as disease; and I have known a sort of imbecile whom nothing could arouse from his slumbers till nature broke the chain. In the course of military operations now in full activity on the West African coast, it would be interesting to learn more of this disease.

I am, &c., George Gaskoin.

OBITUARY.

SURGEON-MAJOR RAMSEY,

Of the 75th Regiment, died at Maritzburg on June 16. A short time before his death he had a severe fall from his horse, and it was at first thought that had caused his death, but a post-mortem examination has proved that this was not altogether correct, though the accident may have hastened the sad event. His funeral was attended with full military honours.

MEDICAL NEWS.

University Intelligence.—University of London.—The following are lists of the candidates who have passed the recent examinations:—

First (B.Sc.) Examination.

First Division.—Peter Phillips Bedson, Owens College; Edward Boyce Cumberland, private study; Thomas Frederick Harris, private study; Samuel Alexander Hill, Royal School of Mines; William Hudson, private study; John Viriamu Jones, University College; Oliver Joseph Lodge, private study; James Gordon MacGregor, Edinburgh University; William Rushton Parker, Caius College, Cambridge; Thomas Slater Tait, Owens College; Claude Metford Thompson, University College; Arthur Thomas Wilkinson, B.A., Wesleyan College, Taunton.

Second Division.—William Brown, Birkbeck Institution; George Christopher, University College; George Simmonds Dunn, B.A., private study; John Gilliott Garhutt, M.A., St. Mary's Hospital; Charles Hopkinson, Owens College; Peter Horrocks, Owens College; John Neville Keynes, B.A., Pembroke, Cambridge, and University Colleges; William Henry Munns, B.A., University College; Frank Prior Purvis, private study; Prasanna Kumár Ráy, University College; Charles Robinson, Owens College; Herbert Rohson, University College; Alexander Simpson, B.A., F. C. Divinity Hall, Aberdeen; Arthur Hewett Spokes, B.A., University College; Charles Alfred Weber, B.A., University College.

Preliminary Scientific (M.B.) Examination.

First Division.—John Wallwork Ashworth, Owens College; William Banks, private study; Arthur Barclay, University of Edinburgh; Peter Phillips Bedson, Owens College; Charles Edward Beevor, University College; Frederick Lucas Benham, University College; Henry Robert Heather Bigg, University College; Samuel Ferguson Bigger, Liverpool School of Medicine; Samuel Herbert Burton, University College; John Joseph Byrne, Owens College and Manchester School of Medicine; Charles Henry Cuming, University College; Henry Davy, Guy's Hospital; Percy Herbert Edmund Freund, St. Thomas's Hospital; John Gilliott Garbutt, M.A., St. Mary's Hospital; William Gristock, University College; Thomas Ernest Hayward, St. Bartholomew's Hospital; Samuel Alexander Hill, Royal School of Mines; Peter Horrocks, Owens College; Boyd Burnett Joll, University College; David Rhys Jones, University College; Oliver Joseph Lodge, private study; John William Mees, Owens College; Richard Shalders Miller, University College; John Francis Nicholson, St. Thomas's Hospital; William Rumney Nicholson, University College; John Priestley, Manchester Royal School of Medicine and Owens College; Walter Pye, St. Bartholomew's Hospital; Charles Ernest Richmond, Owens College; Charles Robinson, Owens College; Herbert Robson, University College; James Ryley, University College; Harrington Sainsbury, University College; Charles Edward Sheppard, St. Thomas's Hospital and Royal School of Mines; Arthur Quarry Silcock, University College; Leader Henry Stevenson, Guy's Hospital; Charters James Symonds, Guy's Hospital; Harold Gilbertson Taylor, King's College; John Todd, University College; Charles John Watson, private study and tuition; Charles Alfred Weber, B.A., University College; Frederick Willcocks, King's College.

Second Division.—James Stanley Newton Boyd, University College; William Brown, Birkbeck Institution and private study; Daniel Catlin Burlingham, University of Edinburgh; Henry Laurence Champneys, Guy's Hospital; Frank Aspland Cooper, University College; Alfred Daniel, University of Edinburgh; Thomas George Davy, St. Bartholomew's Hospital; James Hudson, private study; Edwin Hughes, University College; John Samuel Joule, Anderson's Medical School, Glasgow; David Lloyd, University College; William Pope Mears, London Hospital; John Mortimer, University College; Richard Rundell William Oram, Guy's Hospital; Edmund Howard Paddison, Guy's Hospital; William Rushton Parker, Caius College, Cambridge; Reginald Paul, Middlesex Hospital; Prasanna Kumár Ráy, University College; John Reynolds Salter, University College; William Frederick Shain, Liverpool School of Medicine; William Joseph Spratling, private study and Royal College of Chemistry; William Robert Stewart, London Hospital; John Raglan Thomas, Epsom College and St. Bartholomew's Hospital; John Hinks Vinrace, private study; William Henry Weddell, St. Mary's Hospital; Hubert Foveaux Weiss, St. Bartholomew's Hospital.

Royal College of Physicians of London.—The following is a list of College officers elected on July 31:—*Censors:* William Richard Basham, M.D., George Fincham, M.D., John William Ogle, M.D., and Samuel Osborne Habershon, M.D. *Treasurer:* Frederic John Farre, M.D. *Registrar:* Henry Alfred Pitman, M.D. *Harveian Librarian:* William Munk, M.D. *Examiners:* Anatomy and Physiology—John Burdon Sanderson, M.D., and George Harley, M.D.; Chemistry, Materia Medica, and Practical Pharmacy—William Howship Dickinson, M.D., and Thomas Stevenson, M.D.; Medical Anatomy and the Principles and Practice of Medicine—George Johnson, M.D., and Andrew Whyte Barclay, M.D.; Midwifery and the Diseases peculiar to Women—John Clarke, M.D., and William Smoult Playfair, M.D.; Surgical Anatomy and the Principles and Practice of Surgery—George William Callender, F.R.C.S., and Jonathan Hutchinson, F.R.C.S. *Curators of the Museum:* Frederic John Farre, M.D., Thomas Bevill Peacock, M.D., William Wegg, M.D., and Francis Sibson, M.D.

The following gentleman, having passed the required examinations, will be proposed for admission as a Member:—John Curnow, M.D. Lond., 12, Mitre-court Chambers, E.C.

The following gentlemen were admitted Licentiates:—

Barnard, Charles Edward, 5, Tamworth-road, Croydon.
Bedford, Robert, 85, Hereford-road, W.
Bomford, Gerald, King's College Hospital, W.C.
Curtis, Arthur, Alton, Hampshire.
Davis, Harry, Callington, Cornwall.
Deakin, Charles Washington Shirley, Kingston Grange, Hereford.
Dodd, Alexander Russell, 8, Westbourne-terrace-road, W.
Drake, Arthur John, Stratford, E.
Dyer, John Edward, 21, Guildford-street, W.C.
Eskell, Maurice Clifford, 8, Grosvenor-street, W.
Fowler, Breame Weston, 46, Castle-street East, W.
Gillingham, Alfred, Guy's Hospital, S.E.
Godrich, Alfred, 140, Fulham-road, S.W.
Goodchild, John Arthur, Heathfield House, Ealing, W.
Gray, Frederick Archibald, 5, Charrington-street, N.W.
Green, James, Landport, Portsmouth.
Haig, Percy de Haga, 10, Gilstone-road, S.W.
Harvey, Charles William, University Hospital, W.C.
Hartridge, Gustavus, Shrewsbury.
Keetley, Charles Robert Bell, St. Bartholomew's Hospital, E.C.
Kitchen, Charles Frederick Hewick, 38, Ogilvie-street, Manchester.
Lawrence, George Edgar, 31, Claverton-street, Bath.
Lindsay, William Baltimore, 44, Camden-road, N.W.
Millar, William, 23, Cathcart-road, S.W.
Morris, Sydney, Hayes, Kent.
Murphy, John Francis, Ardravinia, St. John's-hill, Wandsworth, S.W.
Osler, William, 155, Stanhope-street, N.W.
Reid, Alexander, Towlaw, Darlington.
Risdon, George Owen, 24, Charlwood-street, S.W.
Sobey, Arthur Lyne, West London Hospital, W.
Symons, John, 4, Manor-villas, Hackney, E.

Apothecaries' Hall.—The following gentlemen

passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, July 31:

Carter, Albert, Belvedere, Kent.
Carter, Francis Richard, Potter Newton, Leeds.
Corbin, Edward Kinnersley, Guernsey.
Davies, James Harries, Llandyssal, South Wales.
Griffiths, David, Aberayron, South Wales.
Hawton, James Wm. Humbly, Devonport.
Jones, Thomas Evan, Buarthyfoil, Anglesea.
Welch, Wm. John Joseph, Stourbridge.

The following gentlemen also on the same day passed their primary professional examination :—

Bate, George, St. Thomas's Hospital.
Duke, Edgar, Guy's Hospital.
Fox, Richard Hingston, London Hospital.
Jepson, Edward, St. Bartholomew's Hospital.
Spark, John, St. Bartholomew's Hospital.
Spooner, Fredk. Henry, St. Bartholomew's Hospital.
Watts, Fred, St. Bartholomew's Hospital.
Thomson, Samuel John, St. Mary's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Bruce, J. Mitchell, M.D. Lond., M.R.C.P. Lond., M.A.—Assistant-Physician at Charing-cross Hospital, W.C.

Finzi, L. M., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.—Surgeon to the Westminster General Dispensary, *vice* Alfred Ashby, M.B. Lond., F.R.C.S. Eng., resigned.

Paradin, D., M.R.C.S. and L.S.A.—House-Surgeon to the Stamford and Rutland General Infirmary, *vice* A. T. Gibbings, M.B. Lond., M.R.C.S., resigned on account of ill-health.

BIRTHS.

Clover.—On July 31, at 3, Cavendish-place, W., the wife of J. T. Clover F.R.C.S., of a son.

Denton.—On July 29, at Leicester, the wife of Mr. E. R. Denton, surgeon, of a daughter.

Gairdner.—On July 31, at Ardrossan, Ayrshire, the wife of Professor Gairdner, M.D. Glasgow University, of a son.

Simpson.—On August 3, at 52, Queen-street, Edinburgh, the wife of Professor Simpson, of a son.

Watson.—On the 3rd inst., at Tottenham, the wife of Tyndale Watsou, M.D., of a son.

MARRIAGES.

Churchill—Butler.—On July 30, at All Saints', Knightsbridge, Frederick Churchill, M.B., F.R.C.S. Eng., third son of John Churchill, Esq., of Pembridge-square, Bayswater, to Frances, fourth daughter of the late Charles Salisbury Butler, Esq., M.P., of Cazenoves, Upper Clapton, and 48, Prince's-gate, W.

Coates—Beckett.—On July 31, at St. John's Church, Moulsham, Chelmsford, Frederick Thomas Coates, M.R.C.S.E., of Euston-road, London, to Anna Maria, the only daughter of Mr. William Beckett, of Mildmay-road, Chelmsford, late of Walpole, Suffolk.

Croly—Pennington.—On July 31, at Ivy-bridge, South Devon, Richard Croly, M.D., third son of Henry Croly, M.D., F.R.C.S.I., Greenfield, Rathfarnham, Dublin, to Annie, third daughter of Albert Pennington, Esq., of Ivy-bridge.

Field—White.—On July 31, at St. James's, Paddington, George Purdey Field, M.R.C.S., eldest son of Octavius A. Field, Esq., of 43, Sussex-gardens, W., to Pauline Anne Caroline, second daughter of Robert Faulder White, Esq., 35, Sussex-gardens, Hyde-park, W.

Gray—D'Arcy.—On August 2, at Ballymaeward Church, county Galway, George Gray, M.D., Castlewellan, county Down, to Jane Adelaide, daughter of the late Thomas Richardson, J.P., of Fyaquin, county Galway, and widow of Chas. Vesey D'Arcy, J.P., of Bryansford, county Down, and Lieut. H.M.'s late Indian Navy.

McLeod—Dinwiddie.—On July 29, at Teviot Lodge, Hawick, N.B., Donald McLeod, L.R.C.S. Edin., to Jessie, eldest daughter of the late James Dinwiddie, Esq., J.P., Dumfries.

Venning—Pearson.—On August 2, at St. Paul's Church, Brighton, Edgcombe Venning, Surgeon 1st Life Guards, second son of James M. Venning, Esq., of Surry House, Norwich, to Frances Edith, only daughter of Captain Pearson, of 13, Adelaide-crescent, Brighton.

DEATHS.

Alford, Mary Andrews, wife of Henry Alford, surgeon, at The Mount, Taunton, on July 29.

Anderson, William Henry, L.R.C.P. Edin., L.R.C.S. Edin., L.S.A., third son of Wm. Anderson, Esq., of Theddlethorpe, suddenly while bathing in the Thames at Marlow, on July 26.

Fuller, Hugh Pitter, M.R.C.S., for many years Honorary Surgeon to the Royal Asylum of St. Anne's Society, at his residence, Bramerton House, Abbey-road, N.W., on July 29, aged 61.

Glanville, Henry Bateson, infant son of Dr. Glanville, of Spring-grove, Isleworth, at Brighton, on July 31, aged 2 months.

Reade, Henry Cooper, retired Deputy Inspector-General of Military Hospitals, at Clifton, on August 1, aged 56.

Rodwell, George, M R.C.S.E., L.S.A., formerly of the *Edinborough*, E.I.C. Service, at Loddon, Norfolk, on August 5, aged 54 years.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

Bournemouth Dispensary.—Resident Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

Brighton Hospital for Sick Children.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

Essex and Colchester Hospital.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Committee, on or before August 21.

Evelina Hospital for Sick Children, Southwark-bridge-road, S.E.—Registrar. Particulars may be obtained from the Hospital.

Herefordshire Rural Sanitary Authorities.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to T. Llanwarne, St. John-street, Hereford, on or before August 19.

Liverpool Royal Infirmary School of Medicine.—Demonstrator of Anatomy. Applications, with testimonials, to R. Harrison, Registrar (of whom particulars may be obtained), before August 13.

Newton Abbot.—Medical Officer of Health. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to John Alsop, East-street, Newton Abbot, Devon, on or before August 16.

Royal South Hants Infirmary, Southampton.—House-Surgeon. Candidates must be M.R.C.S. and L.S.A. Applications, with testimonials, to the Assistant-Secretary, on or before August 16.

Wolverhampton and Staffordshire General Hospital.—Physician's Assistant. Candidates must be graduates in Medicine of a British University, or be possessed of such medical qualifications as are satisfactory to the Medical Committee. Applications, with testimonials, to the Chairman of the Medical Committee, on or before August 9.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Aston Union.—Mr. Orford has resigned the Deritend District; area 280 population 26,860; salary £60 per annum.

Tendring Union.—Mr. Robert Latten has resigned the Seventh District; area 13,951; population 2918; salary £50 per annum.

Wantage Union.—Mr. A. M. Robinson has resigned the Ilsley District; area 18,950; population 3718; salary £55 per annum.

APPOINTMENTS.

Aberystwyth Union.—Jacob Roberts, M.R.C.S.E., L.S.A., to the Llanfihangel District; Morris Jones, L.R.C.P., M.R.C.S.E., L.S.A., to the Aberystwyth District.

Basford Union.—Wm. Terry, M.R.C.S., L.S.A., to the Kirkby District.

Bath Union.—Thomas McClure, L.R.C.P. Edin., L.R.C.S. Ire., to the Sixth District; Wm. Edward Stainton Stanley, L.R.C.P. Edin., L.R.C.S. Edin., to the Seventh District.

Cardigan Union.—James Mathias Phillips, M D., M.R.C.S.E., L.S.A., to the Second District.

Hinckley Union.—Thomas Sutton Ludlow, M.R.C.S.E., L.S.A., to the Burbage District.

Liskeard Union.—George Kerswill, L.R.C.P., M.R.C.S E., to the Second District.

Liverpool Parish.—Alexander M. S. Hamilton, M.D., M.R.C.S.E., Assistant Medical Officer of the Brownlow-hill Workhouse.

Manchester Township.—Thomas Price, M.R.C.S.E., L.K.Q.C.P. Ire., to the Cathedral District.

Mile-end Old Town Hamlet.—Thomas Loane, M.R.C.S., L.S.A., to the Northern District, the Workhouse, and the Schools.

Norwich Union.—David Simpson Penrice, M.R.C.S.E., L.S.A., to the Third District.

St. Marylebone Parish.—Frederick Wm. Spurgin, M.R.C.S.E., L.S.A., L.R.C.P. Edin., to the All Souls and Cavendish District.

Stockton Union.—Wm. Hodgson Oliver, L.R.C.P. Edin., L.S.A., to the Norton Union.

Woolwich Union.—Robert H. Lloyd, M.R.C.S.E., L.S.A., to the Workhouse and Infirmary.

Royal Medical and Chirurgical Society.—The Library will be closed for one month from August 11 to September 10 (both days inclusive).

A memorial window has recently been put up in Ruabon Church to the memory of the late Mr. William Jones, a surgeon, of Plas Newydd, Ruabon.

Dr. John Lee, of Ashborne, on retiring from practice, has been presented with a chest of silver plate and a fern-engraved silver salver. The following inscription is on the salver:—"Presented to John Lee, Esq., M.D., with a small chest of plate, by his old friends and patients, as a testimonial of the high esteem in which they have held his unvarying kindness during a practice of many years.—July, 1873." The testimonial was accompanied by a book having an illuminated title-page, and the names of the subscribers.

Cholera in Vienna.—"And how about cholera? you will naturally ask," writes the *Times* Vienna correspondent last week. "Well, owing to the energetic measures taken on the part of the authorities in this respect, too, things have greatly mended. All through the latter half of last week the number of attacks ranged from nine to twelve a day, with from one to ten deaths a day, the greatest part of the deaths being earlier cases where patients died of exhaustion. Monday's returns showed, as usual,

the influence of Sunday, and the number of cases went up to twenty-five, and that of deaths to twelve. They were almost all in the poorest districts, and among the poorest classes, five of the nine districts into which Vienna is divided being quite free, and in three there being only one case in each; the hospitals and one district—the second—dividing the rest between them."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Infra Dig.—The circumstances related quite justify the course proposed to be adopted.

Dangers of Obstetric Practice.—The name of the defendant in the action referred to was Rumboll. We believe the patient was attended by an assistant.

G. J. M.—"Digest of the English Census of 1861," compiled from the official returns, and edited by James Lewis, of the Registrar-General's Department (London: Edward Stanford, 1873). This volume is more complete than any previous analysis of a census.

A Six Years' Reader.—The forty-sixth annual gathering of German naturalists and medical practitioners will be held this year at Wiesbaden, from September 18 to 24.

Lex, Spalding.—(B) We have no doubt that an M.B. of Aberdeen, if registered, can recover for medicines prescribed for his patients and supplied by himself. (A) We will endeavour to furnish the required information in our next issue.

DR. C. B. TAYLOR'S INSTRUMENT FOR THE EXTRACTION OF CATARACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I find in your list of surgical instruments exhibited at Vienna a description of my wire spoon for the extraction of cataract. The writer of the notice in question remarks that this instrument is used for the removal of soft cataract. As this is an error, allow me to remark that I use it only to assist the exit of hard cataracts, and that its chief advantage is that it enables us to do this without perceptibly adding to the bulk of the lens. I am, &c., CHARLES BELL TAYLOR, M.D., F.R.C.S.,

Surgeon to the Midland and Nottingham Eye Infirmary.

9, Park-row, Nottingham, August 3.

APPOINTMENTS FOR THE WEEK.

August 9. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

11. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

12. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m., Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

13. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

14. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

15. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, August 2, 1873.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·87 in. The highest was 30·03 in. at the end of the week, and the lowest 29·73 in. on Tuesday evening.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture VI.—Valvular Diseases.

In my last lecture I completed what I had to say in reference to the inflammatory affections of the heart, and I now proceed to speak of valvular diseases, which in so many cases are the effects of previous inflammation. With a view to illustrate the circumstances under which these diseases generally arise, and their relative frequency, I have compiled the following table of cases which I have treated during life, and have had the opportunity of examining after death. The table includes particulars of 107 such cases:—

Table of Cases of Valvular Disease of Heart.

Form of Disease.	Cases.	Ratio per cent.	Males.	Ratio per cent	Females.	Ratio per cent	Mean age.	Range of age.	Mean age.
Aortic Valvular	39	36·44	31	79·4	8	20·5	43·06	21 to 62	Males, 43·07; Females, 44·2.
Originating in malformation ...	12(a)	30·7	10	..	2	...	38·4	18 to 76	
„ injury	2	5·1	2	...	...	...	34·5	33 and 36	
„ rheumatism ...	8	20·5	6	...	2	...	43·5	32 to 56	
„ other causes ...	17	43·5	13	...	4	...	46·7	21 to 64	
Mitral Valvular	36	33·64	18	50·0	18	50·0	26·7	9 to 68	Males, 29·05; Females, 23·4.
Originating in malformation ...	1(b)	2·7	...	...	1	...	...	16	
„ rheumatism ...	23(c)	63·8	10	...	13	...	21·4	9 to 56	
„ other causes ...	12(d)	33·3	8	...	4	...	37·6	9 to 68	
Aortic and Mitral	23	21·64	13	56·5	10	43·4	27·1	11 to 52	Males, 30·4; Females, 22·9.
Originating in malformation ...	3	13·	2	...	1	...	32·3	25 to 37	
„ rheumatism ...	9	39·1	6	...	3	...	17·2	11 to 40	
„ other causes ...	11(e)	47·8	5	...	6	...	33·9	12 to 52	
Mitral and Tricuspid	1	...	...	...	1		...	37	
Aortic, Mitral, and Tricuspid ...	2 } 4	3·7 } 9	...	...	2 } 4	44·4	...	18 and 32	
Pulmonic	1	... } 8·4	1 } 5	55·5	...		...	23	
Do., with obvious malformation...	5(f)	4·6	4	...	1		...	2 and 5 months, 15, 17, 19, 20	
	107	...	67	62·61	40	37·37	32·3	2 and 5 months, and 9 to 76	Males, 34·8; fem. 28·1

The first circumstance which may be observed in the table is that valvular diseases are chiefly confined to the left side of the heart. Thus, of the 107 cases, in nine only, or 8·4 per cent., was the disease situated on the right side, and in three of these the left side also was affected; while in five there were other defects in the heart, obviously of congenital origin. Indeed, I regard all these nine cases as instances of congenital defect. If this be correct, the conclusion follows that serious valvular disease (and these remarks apply only to cases of serious disease—for some slight affection of the valves on the right side is often met with when there is aggravated disease of the left valves) is entirely confined to the left side. For this fact various reasons have been assigned, but probably the true explanation is that the arterial blood being more stimulating, and containing a larger proportion of fibrine, is more apt to excite inflammation and cause fibrinous deposits; certainly the lining membrane of the left auricle, for no other reason that I know, is very constantly found thickened and opaque. It is not however, so clear why the valves of the right side of the heart—those of the pulmonary artery more especially—should so frequently be affected during intra-uterine life, and the only explanation of several which have been given which seems satisfactory, is that the pulmonary artery, being in direct connexion with the umbilical arteries, is specially influenced by exposure to variations of pressure, by which the process of development may be deranged.

The next observation which may be made on the table is the relative frequency of the different forms of valvular disease. Thus it will be seen that of the 107 cases 39, or 36·44 per cent., were cases of aortic valvular disease; 36, or 33·64 per cent., were cases of mitral disease; and 23, or 21·64 per cent., cases of combined disease of the aortic and mitral valves; and the relative frequency of the several forms of disease may, I think, be traced to the different causes which are influential in their production.

The causes which are chiefly conducive to valvular disease may be classed, as in the table, under the following heads:—First, irregularities in the mode of development of the valves, not necessarily at once impairing their efficiency, but predisposing them to become the seat of disease in after life; secondly, injury of the valves during violent muscular exertion; thirdly, inflammatory affections of the heart, originating during the progress of rheumatic fever; and fourthly, various other causes combined, such as changes in the valves (often inflammatory), connected with gout, chorea, renal disease, injuries of the chest, etc.; slow interstitial changes, such as fatty degeneration; alterations in the capacity of the cavities and state of the valves from long-continued overstrain in persons following laborious occupations, etc.;—the effect of these various conditions being often aggravated by habits of intemperance.

It will also be seen on referring to the table that these several causes operate to different degrees in different forms of disease. Thus, of the cases of aortic valvular disease, 12, or 30·7 per cent., are ascribed to irregularities in the development of the valves, though in two of them there is some doubt how far this is correct; 2, or 5·1 per cent., were the result of direct injury to the valves during violent muscular exertion; 8, or 20·5 per cent., are ascribed to rheumatism; and 17, or 43·5 per cent., to the other causes named, of which the effects of hard work and hard living were probably the most influential. Of the cases of mitral valvular disease, one only is stated in the table as due to malformation, and of this there can be no doubt, the intra-uterine origin of the valvular disease being shown by the foramen ovale having been incapable of closing after birth. It is, however, quite possible that other forms of mitral contraction may have thus originated, though the constriction may not have been at the time of birth sufficient to prevent the closure of the fœtal passages. 23 cases, or 63·8 per cent., were ascribed to rheumatism, and 12, or 33·3 per cent., to the various other causes. Aortic and mitral valvular disease combined occupies a somewhat intermediate position between the two other forms of affection. Of the 23 cases of this kind, 3, or 13 per cent., are ascribed to defective conformation of the valves; 9, or 39·1 per cent., to rheumatism; and 11, or 47·8 per cent., to the other combined causes.

The table also illustrates the relative liability to the different forms of disease in the sexes, and so throws further light upon the causes which conduce to them. Of the whole of the 107 cases, 67 occurred in males and 40 in females, or in the proportion of 62·61 and 37·37 per cent. respectively, indicating the much greater tendency to these diseases in men than in women, doubtless partly owing to their greater exposure to various forms of disease connected with constitutional causes, and especially to the influence of over-exertion. Men, it will be observed, are especially liable to suffer from aortic valvular disease, which is obviously the form which would be the most apt to be induced by overwork. Thus it will be seen that of the 39 cases, 31, or 79·4 per cent., occurred in males; and while the proportion of cases originating in malformation and in rheumatism is about equal, there is a great excess in men in the cases traceable to injury and to the various other causes named.

The cases of mitral valvular disease were equal in number in

(a) The origin of two cases in malformation is not quite clear. Two men and one woman had also had rheumatism.
(b) With open foramen ovale.
(c) Two cases in men and two in women are returned as *probably* rheumatic.
(d) One case in female, chorea.
(e) One case in female, chorea.
(f) With contracted pulmonary orifice and an aperture in septum ventriculum, three; with ditto, and also contraction at commencement of infundibular portion of right ventricle, one; with contraction of pulmonary orifice and open foramen ovale, one.

the two sexes, though those traceable to rheumatism were in larger proportion in females, and those arising from the other causes in males.

Combined aortic and mitral valvular disease occupies in this, as in other respects, an intermediate position between the two simple forms of disease—disease of both sets of valves being more common in men than in women, though the difference in the relative frequency in the sexes is much less marked than in aortic valvular disease. The proportion of cases originating in malformation and rheumatism is about equal in the two sexes, but there is a slight excess in the number of cases traceable to the other causes in females.

The influence of age on the prevalence of valvular diseases, and on the tendency to the several forms, is also shown in the table. The general result is that all forms of valvular disease are more common in middle age than at any other period, though they occur throughout the whole of life. Of the different forms of disease, aortic is more common at a somewhat late period of middle age, mitral disease and combined aortic and mitral in early manhood and womanhood, with, however, a wide range of age in each case.

The frequency of rheumatism as a cause of simple and combined mitral disease is very marked; indeed, disease of the two sets of valves, when it occurs in young persons, is very generally traceable to rheumatism.

(To be continued.)

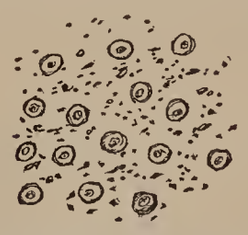
ORIGINAL COMMUNICATIONS.

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, &c., &c.

(*Continued from page* 91.)

I SHALL take as the type of the poison of Australian snakes that of hoplocephalus curtus. This is a faintly yellowish fluid, varying in consistence from thin syrup to thick gum-water. Whether thick or thin, it is always pellucid. Under the microscope, with a power of 420, it appears to contain no cellular or molecular elements, but upon the addition of magenta numberless free nuclei or minute cells at once come into view, their diameter being about 1-4000th of an inch; between these very fine granular matter is seen. The clear fluid, as it is expelled from the fang, contains these microscopic elements, whilst that which is pressed from the gland itself possesses them in much greater numbers. Upon exposure the fluid rapidly thickens, and finally becomes like hard gum, and its colour deepened to a light gamboge. In this state it may be transmitted to any part, and, upon being moistened as we do gum to make gum-water, is found to possess its powers unaltered. For this knowledge of it retaining its powers, which I have since verified in the case of the poison of our snakes, I was originally indebted to Dr. Weir Mitchell, of Philadelphia, U.S. He sent me a pill-box full of dried rattlesnake poison, with which I was enabled to experiment and to ascertain that, excepting the local mischief, the effects upon an animal and the changes occurring in the blood are similar to those caused by the venom of our own snakes. Moreover, I was enabled to prove that they were alike in their remarkable resistance to destruction and in the effects of reagents upon them.



Poison expressed from the bottom of the gland of a recently killed powerful hoplocephalus curtus. It was somewhat turbid. Acid reaction. On applying magenta, millions of the nuclei or poison-cells came into view, which before were invisible. Average diameter 1-4000th inch.

The following observations on this point are from Dr. Weir Mitchell's "Researches on the Venom of the Rattlesnake" ("Smithsonian Contributions to Knowledge," vol. xii.), and although relating to crotalus venom, are strictly true of hoplocephalus poison:—

"When a drop of venom was thrown into cold distilled water it fell rapidly and presented a white appearance, which became marked as it dispersed through the fluid. It finally dissolved in the water without residue. Nitric acid threw down from crotalus venom a dense precipitate. Added in excess, it redissolved the larger part of the precipitate and formed a thin yellowish fluid, in which floated undissolved minute yellow flocculi. Liquor ammoniæ added in excess did not reprecipitate the dissolved material. Chlorohydric acid threw down a dense white precipitate, and, added in excess, completely redissolved it, forming a solution colourless or of a pale yellow, from which ammonia in excess reprecipitated the dissolved substance in opaque white masses. Sulphuric acid threw down from the venom a white precipitate, which, if the acid were hastily added, or if heated, became yellow or brown. Acetic acid caused no precipitate from the venom, whether added to it in large or small amount. Tannic acid produced a dense white precipitate, which proved to be insoluble in water and in an excess of the acid, but was redissolved on the addition of a small amount of ammonia. Ammonia was without visible action upon the venom, as was also lime-water. Alcohol invariably produced in the venom a heavy flocculent precipitate, which, when carefully dried, turned of a pale yellow, and was still more or less soluble in water."

I was enabled to make a few experiments with the venom of the cobra, and when we find, chemically and physically, that that from an Australian snake differs not from that of a snake further removed from it than is the cobra, we should expect there would be an equal similarity, if not a greater, between the latter and hoplocephalus curtus. With either of these poisons it is not necessary in order to produce death that it should be actually injected. Just as I have seen some surgeons vaccinate by simply debrading the cuticle and smearing on the moistened lymph, so have I repeatedly inoculated dogs by a similar process. The result is nearly as certain as, though less speedy than, direct injection. It is remarkable what a small quantity will kill an animal the size of a dog; but, of course, the greater the quantity thrown in, the greater the danger. The poison-glands of snakes that have been years in spirit, as in the museums the world over, will still yield by decoction venom sufficiently powerful to kill.

We now come to consider the effects of the venom upon animal life. They are usually not long in showing themselves. The venom must mix with the blood, the life of man, in order to destroy that life. Indeed, post-mortem examinations reveal that, primarily at least, nothing else but the blood is affected.

In the majority of cases of death from the bite of hoplocephalus curtus the blood is found fluid, sometimes with a trace only of coagulating power; but most frequently that power is destroyed. In man, I think, it is nearly the rule; in dogs, with few exceptions, the same; in birds less fluid; in pregnant animals also less fluid. The fluidity of the blood is attended with another change that has always struck me, more especially in the blood of man. Its colour is altered, and a sort of pale tint possesses it. Shaken with atmospheric air it rapidly absorbs oxygen and regains its arterial character. Beneath the micro-spectroscope it yields the spectra of ordinary blood, as it is oxidised or deoxidised. The fluidity of the blood is owing to the disappearance of its fibrine. In pregnant mammals the amount of this blood element is increased. In birds its quantity is greater than in mammals. In this we see a sufficient cause in these animals for the greater coagulating power of the blood retained after snake-poisoning as compared with mammalian blood.

The fluidity of the blood has always attracted attention. On this subject Dr. Weir Mitchell states, referring to rattlesnake-poisoning, as follows:—

1. That in animals which survive the poisoning for a time the blood is so altered as to render the fibrine incoagulable.

2. Experiments in and out of the body have given proof that this change is gradual, and that the absence of coagulation is not due to checked formation of fibrine, but to alterations produced by the action of the venom in that fibrine which already exists in the circulating blood.

4. The altered blood retains its power to absorb gases, and thus to change its own colour.

From this it would seem, as I have before stated, that cases may occur in which, owing to the presence of a large quantity of fibrine, the power of coagulation may still be retained after death.

But this subject has lately been handled by Dr. Fayrer, of Calcutta, who says—"The blood of animals poisoned to death by the colubrine snakes coagulates after death; that of animals poisoned by the viperidæ remains permanently fluid." This appears to me too sweeping an assertion, for it is contradicted by facts. Dr. Weir Mitchell gives a table of eight

dogs killed by rattlesnakes (viperidæ), in which it is stated that in Case 1 the blood "coagulated pretty well," in Case 4 "coagulated well," in Case 7 "perfectly well"; whilst I have myself seen frequently after death from our snakes (colubrine) perfectly uncoagulable blood; and in a case of cobra-poisoning (another colubrine snake) in a man the blood was everywhere fluid, and remained so in my possession for days. The fact is, there are all degrees of coagulability of the blood after death from either viperine or colubrine snakes; but, in order to arrive at more accurate results, animals of the same species should be experimented upon for one result; of another, for another—man with man, dog with dog, cat with cat, bird with bird, and so on; for it is not possible to obtain the same results with fluids so different as the blood of men and birds.

This fluidity of the blood shows itself occasionally during life by blood-spitting, coughing it up from the lungs, and occasionally passing it in large quantities by the bowels. After death ecchymoses are found along the intestinal track and air-passages. A case is recorded in the Indian journals of a Sepoy having been bitten by a cobra. Three hours after the bite blood-spitting came on. He was then cupped, and the eight ounces of blood taken from him remained perfectly fluid. He subsequently recovered. Dr. Weir Mitchell also mentions the recovery of a dog after hæmorrhage from the bowels and gums; that which was drawn from him at the time of the bleedings remained fluid, but as the dog recovered his blood regained its power of coagulation.

From other records we should regard hæmorrhage as a serious symptom occurring soon after the accident of snake-bite, as showing that a great change had come about in the physics and chemistry of the blood. Dr. Weir Mitchell says:—"A dog was accidentally dropped into my snake-box. He was bitten in a dozen places by as many snakes, and perished in about eighteen minutes. His blood was entirely fluid, and so remained. This was the most rapid case of alteration of the blood with which I have met."

It is not uncommon also to find after rattlesnake-bites, extending upwards from the place of the bite, great discoloration of the skin, depending upon bloody extravasations in the connective tissue surrounding the veins beneath. This is a symptom I have never seen after the bite of an Australian snake, and have only read of once; but it was present to a great degree in the case of the man who was accidentally bitten by a cobra di capella in Melbourne a few years since. I have seen it follow to a very considerable extent the bite of the little English adder.

Pain does not usually accompany the bite of Australian snakes, but is frequently severe after the inoculation of rattlesnake poison. But the changes in the blood, according to my own observations, are similar after the bites of cobra, crotalus, and Australian venomous snakes. When we microscopically examine the poisoned blood shortly after the death of dogs or cats we see the red corpuscles apparently unaltered; they may at times be paler, and crystals of hæmatine may form in greater number than usual. The discs also may assume a more globular character. None of these changes are, however, constant. A still more important alteration or addition soon takes place. A very fine granular matter is seen lying in the spaces between the red corpuscles, and these granules by cohesion form little separate masses, which gradually become converted into cells of 1-1700th inch diameter. Each cell contains a nucleus 1-2800th inch broad, and upon applying magenta the nucleus becomes coloured; at the same time somewhere in the circumference of the cell-wall a brightly-tinted macula appears.

Whatever may be the meaning or importance of this cell-growth, of one thing there is not the least doubt—viz., that it replaces the original nebulous granular matter first seen in the blood; and that first the nucleus becomes visible, then the cell-wall. Now, as I have witnessed these changes occur in the blood after death from cobra and rattlesnake poisoning, and always after death from our Australian snakes, and as it appears they have never been seen upon careful examination by either Dr. Weir Mitchell or Dr. Fayrer, it will be as well for me to insert some original notes out of very many which I possess. I do it only as a matter of microscopic fact, and probably of more histological interest than we at present suppose.

The cells are very liable to be overlooked until once seen; and what is more, the cell-wall is so extremely delicate, appearing before magenta dye is added as a mere film, that the unpractised eye only detects the nucleus, which looks like the ordinary pale opaque white or lymph corpuscle. Of this I will give an illustration. Two of the most scientific men in Melbourne—viz., the Government astronomer and the assayer to the Mint—at the time I was experimenting wished to make observations themselves on the changes occurring in the blood of snake-bitten animals. Accordingly, one morning I had a dog bitten by a tiger snake; within one hour it was dead, and sent untouched by me to these gentlemen. I called on them the same evening about five o'clock. They told me they had been examining the blood from all parts of the dog's body, but could see nothing of the appearances I had so often described. They had just left the laboratory as I entered. I asked them if they had a slide of the blood they had been examining. There was one still on the stage of the microscope. I begged them to return. They did so; and upon my examining the slide I at once saw hundreds of the cells as well formed as could be. After directing their attention to a particular part of the field they presently detected one—the nucleus only first, the cell-wall with more difficulty; and then, one having been mastered, they saw just as many as I could see myself. These observers reported to me the prodigious increase in the number of the cells by the following morning. Now, I have had many instances of a like difficulty in recognising the delicate forms among the red corpuscles.

Copy of Original Notes.

February 10, 1868.—10 a.m.: Dog bitten by a tiger snake (hoplocephalus curtus). Fell in five minutes; became convulsed, but in half an hour got up again. 10.20: Drew some blood—red, coagulable; nothing abnormal beneath the microscope. 11: Dog *in articulo mortis;* drew more blood—colour dark. Under the microscope much nebulous or granular matter, and a few white corpuseles in the intervals of the red corpuscles; other white corpuscles about the field. On applying magenta the nebulous matter takes it readily. 1.15 p.m.: A little blood from brachial vein. The nebulous matter between the red corpuscles aggregated into little masses; nuclei fast appearing; cell-wall becoming visible in some. White corpuscles about the field, pearly and granular. 2.15 p.m.: Blood from femoral vein. Very great quantity of nebulous matter about the field; nuclei becoming very abundant. With one-eighth inch objective and B eye-piece, saw distinctly the cell-wall appearing in a few. 3.15: Still more nuclei seen and cell-wall with same power. 4.15: Cell-wall plainly seen with quarter-inch objective. 5: Abundance of cells appearing. (N.B.—Nothing can exceed the delicacy of the cell-wall. It is certain the cell-wall is the last to appear. The whole business is progressive.) 7.15: Nuclei and cells in immense quantities; the cell-walls so indistinct that only a good observer could see them. On applying magenta the maculæ became evident and the nuclei coloured.

It must be explained that at each of the above times a little fresh blood from the dead animal was taken, not the same drop of blood examined over and over again. It would be useless to tire the reader with more than this one sample of the manner in which my observations have been made. I should not exaggerate by stating that I have given more than one hundred hours of microscopic work to this one point—viz., the origin of these cells. If they be merely the white corpuscles of the blood, at first obscured and then becoming apparent, it is difficult to understand what becomes of the granular matter, which as certainly disappears as these cells appear—unless we adopt the view that white corpuscles may arise out of nebulous matter after the death of an animal. Are we to look upon this nebulous matter in fluid blood as taking the place of fibrine in coagulated blood? If so, it would show a certain relation between the fibrine and white corpuscles, which by many physiologists is believed to exist. After poisoning by prussic acid, Mr. Ralph, of Kew, near Melbourne, saw similar cells in the blood of dogs, and I have myself seen like cells in other blood of dogs and cats which had been kept fluid. So that their presence is not, as I first imagined, peculiar to snake poisoning. The great interest that attaches to them now is their origin and apparent increase after death from nebulous matter. In fact, the process is like that originally detailed by Schwann, of the growth of cells in blastema.

A NEW convalescent hospital at Woolton, Liverpool, was opened by the Mayor of Liverpool on Saturday last.

GLEANINGS IN WAR SANITATION

FROM N. PIROGOFF'S "BESICHTIGUNG DER MILITAIR-SANITÄTS-ANSTALTEN IN DEUTSCHLAND, LOTHRINGEN, UND ELSASS."

By NATHANIEL ALCOCK, L.K.Q.C.P.I., A.M.D.

INITIATED in war sanitation during the expedition to the Caucasus, and matured in the Crimean campaign, this distinguished Russian surgeon brings to the disinterested study of the Franco-Prussian war a mind educated by the most valuable experience, and therefore commands for his writings universal attention. It is on this account that the effort is here made to translate and epitomise the results of his extensive observations.

Surmounting the various difficulties by road and rail, Dr. Pirogoff reached the vicinity of Metz, and there met with Professors Frerichs and Niemeyer, both intent on the investigation of typhus. In all the villages around Metz cattle-plague, typhus, and dysentery prevailed. In some of the hospitals typhus was treated with good results by cold douche, and in many small doses of calomel and castor oil were given for dysentery with (Dr. Pirogoff says) success; but he adds—"nevertheless the mortality from this disease was considerable." It is evident, therefore, that the German surgeons are either unacquainted with, or sceptical of, the curative effects of large doses of ipecacuanha which have been so completely verified by the experience of English surgeons in India, who, since the adoption of ʒj. doses of ipecacuanha, preceded by ʒj. tinct. opii, and repeated even twice within twenty-four hours if necessary, seldom meet with the destructive and uncontrollable forms of dysentery described by the older writers as occurring in spite of the most active mercurial treatment.

Dr. Pirogoff from the first lays the greatest stress upon the necessity of "isolating" and "distributing" the sick and wounded, and expresses a feeling of personal satisfaction that efforts are now being made, as far as the possibility of accommodation and the propinquity of towns to battle-fields render it practicable, to carry out this measure which he so strongly recommended as long since as 1863.

The working of the private and international help is said to be a "real progress of our time"; but this has reference more to what it may be made capable of in the future, than to what it has already accomplished.

The inspection of seventy military hospitals and the sanitary arrangements connected therewith suggests to the author the five following questions:—1. In how far were the principles of the international philanthropy, which found expression in the societies for the help of sick and wounded soldiers, realised in fact? 2. In what relation stood, during the past war, the private and international help to the military administration, and what influence did the "private aid" exercise on the condition of the sick and wounded in the course of the war? 3. In how far has the condition of the wounded in, and immediately after, the battle been improved by the present mode of carrying on war? 4. What success attended, during the past war, the so-called conservative and expectant treatment in general, and especially of those wounds which, according to former belief, demanded an immediate removal of the injured limb? 5. What useful application can our Russian military medical department and our private help draw from the war of 1870 for the benefit of sick and wounded soldiers?

With reference to the question of how far the principles of international help were realised, notice is at once taken of the all-important fact that from force of circumstances arising out of the results of the early battles, and the consequent conversion of the armies into besiegers and besieged, by far the largest proportion of neutral help fell to the lot of the Germans, and this may be of necessity repeated in any future war.

For the correction of this such proposals as those offered at the Berlin Congress—viz., that "before the beginning of the war the foreign aid should be equally divided between the intended belligerents," "that the foreign aid should be used exclusively on behalf of the wounded of the retiring army," or "that it should operate only in the rear of each contending force," are shown to be impracticable. In the first place, a determination to go to war would never be admitted before its declaration; in the second, the action of the society would be still one-sided; and lastly, in these days of rapid manœuvring, the rear of to-day may be anywhere to-morrow.

It is evident, therefore, that the first precept of international help—even-handed neutrality—has not yet been attained, and that the more efficacious the working of the society becomes, and the greater the number returned by its assistance in health to the ranks, the more certainly will the Power which derives least advantage from its benefits insist on the suspension of an influence which daily adds numerical and moral strength to its opponents.

So long, then, as the enclosure of one army by another, the refusal of all communication to the besieged, and the enforced accumulation of sick and wounded within an iron ring as a means of exhausting provisions and of demoralising the uninjured, form the leading features in war, the equal distribution of international help cannot be effected.

Dr. Pirogoff concludes that except by "mutual agreement before the beginning of the war" the difficulty cannot be obviated, and that the "object of the Geneva Convention will be fulfilled only when the surgeons of both contending parties are completely neutral, and the possibility is given them of interchanging their scientific experiences for the welfare of the sick entrusted to their care."

Undeniable as this is, still the reflection arises that when two nations are found who would permit the presence of so large a body of neutrals in the midst of their military operations, by diverting the exercise of so much trust into political channels, war might be altogether averted.

It practically remains that the very success of international philanthropy endangers its existence, unless means be devised for the equal division of its advantages.

As to the second question—viz., the relation in which the private help stood to the military administration, and its influence on the condition of the sick and wounded,—Dr. Pirogoff, in tracing the history of the private help societies, claims the priority of their introduction for Russia, in that she anticipated England in the formation of a sisterhood of nurses early in the Crimean war, but he concedes to America the honour of having first organised private help into an important power, and attributes its success in that country to the fact that the government was not in a position to obstruct, but was compelled to go hand-in-hand with, the society.

In the Franco-Prussian war the opinions regarding the utility of private help varied in accordance with the sources from which they came.

The military surgeons in Prussia were conscious of the inconveniences which spread from the undisciplined ambulances as from so many centres of irregularity, and felt also that the members of some societies, presuming on their high social position, had acted both towards them and towards the more humble societies in a supercilious and dictatorial manner. Yet the very society which was in this respect most culpable acquired, by its aristocratic connexions, an immunity from official restriction that enabled it to render "enormous services." It alone could have broken through the objection of the administration to independent lay interference, which it was feared must, by its irregular constitution, of necessity endanger order and discipline.

Contrary as the system of private help was to the idea of military subordination, nevertheless its greatest value arose from this freedom, inasmuch as while the administration supplied nothing except under the observance of strict control formalities, for complying with which there was no possibility, the societies furnished the means of help without difficulty.

Dr. Pirogoff pays the highest compliments to the work done in the hospitals by the ladies' societies, but at the same time does not conceal the fact that "the majority of German military surgeons unwillingly assent to their independence," and that this feeling, which was "perceptible in the Holstein war, is now more audibly outspoken."

Doubtless, most valuable assistance can be rendered in time of war to the over-taxed medical department of any country by volunteers lay and professional; but it is not too much to expect that if the feelings which prompt their offers are purely humane, patriotic, and unselfish, they may enable them to endure without a sense of lessened dignity the supremacy of those who have adopted as a profession the speciality of military sanitation in all its branches. If, however, any should seek the seat of war with the object of condensing into a few weeks opportunities of practice unattainable in civil life in many years, it is unreasonable that they should expect, by parading the sacrifices at which they have surrendered their services, to supersede those who are unostentatiously discharging their legitimate duties.

Although conscious that the government arrangements succumbed here and there to the press of difficulties, yet Dr.

Pirogoff makes no reproach against the wonderfully arranged Prussian military organisation, but, on the contrary, admits that these failures only show how hard it is in the present condition of the military medical system for any government in time of war to come through blameless; and, sensible of the delicate position of the public departments towards the private societies, he trusts that the teachings of the past will help to define their most suitable relations to each other in the future,—concluding, however, with the opinion that until experience points a way of amalgamating one with the other they ought to work in entire independence, since excessive restraint will choke private efforts in the bud.

It is therefore apparent from all this, that to the mind of an impartial observer two very serious obstacles present themselves against the acceptance of international help as an already fixed institution of civilised communities—firstly, the unsolved difficulty of its equal distribution; and secondly, the inevitable collisions of irregular volunteer societies with the established government services. Under these circumstances it will be improvident for any country to allow, for economical or other reasons, its medical service to languish in the hope that when an emergency arises the deficiency can be more cheaply supplemented by accepting offers of unpaid work. When contemplating the influence which private help exercised "on the condition of the wounded," Dr. Pirogoff enumerates the various temporary hospitals furnished by the societies with all the newest hygienic improvements, the material comforts provided, and the moral influence exerted, and adds that it was all accomplished because they were "sufficiently independent and could act, not in conformity with the will of the Government, but against it."

By the results of the late war the imposing palace-like buildings have been unconditionally condemned, and everything points to the desirability of adopting the detached barrack hospital system in their stead.

The barrack hospital consists of a series of one-storeyed huts standing on supports several feet in height and having openings in the floor for the admission of air. In winter the supports were converted by the addition of boards into complete walls, and a small cellar or ventilation compartment was thereby formed. This communicated by windows with the outer air, and thus the current of air to the floor-ventilators could be regulated. Besides this, above the ceiling of the inhabited room a little attic was enclosed, which also communicated at its sides with the external air, and thus a thorough draught through floor and roof could be at will established.

Dr. Pirogoff believes in the existence of various hospital miasms, some of which are not volatile, and draws a distinction between the air-impurity resulting from simple overcrowding, which sufficient ventilation can disperse, and the "contagious infection," the source of pyæmia and wound diphtheritis, originated by the aggregation of suppurating surfaces, by the admission of fæcal effluvia into sick wards, and by delay in removing soiled dressings, and against which no amount of cubic space can be relied on as a preservative.

Impressed with these ideas, Dr. Pirogoff lays the greatest stress on the necessity of, as much as possible, distributing the sick and so preventing the most potent cause of the development of this poison. He agrees with the American surgeons that a hospital after ten years' use becomes unserviceable, and cannot be freed from infectious germs, and points out the consequent advantage of temporary over permanent hospitals, inasmuch as the former can be periodically broken up, sold, and replaced.

Taking into consideration the fact that this miasm, despite all ventilation, can saturate the walls of occupied apartments, and that its effects are apparent even on those in health, it is not improbable but that the advantages of the detached system may receive serious attention from the civil as well as the military medical authorities.

In addition to the outfitting of hospitals, the private help provided also railway transport waggons for the wounded. Some of these contained but straw for bedding, while others were more elaborately fitted up with screws or strong elastic bands for the suspension of the stretchers on which the patients came. In fine, the good effects of private help were enormous, and its success in the treatment of the sick was mainly attributable to the good food which it could add to the usual hospital diet, to the introduction of hygienic improvements hitherto unknown to female nursing and supervision, and to its having the command of a sufficient number of surgeons. "Neither hospital typhus, nor gangrene, nor hospital infection, found conditions for their spread where private help could act without restraint."

Dr. Pirogoff devotes the third chapter of his book to the question—"In how far has the condition of the wounded on the battle-field immediately after the action been improved by the present mode of warfare?" and concludes with the opinion that "their condition is, under these circumstances, nothing better than in former wars."

In the first and most important particular—the removal of the wounded from the field—all efforts at improvement have been more than counterbalanced by the precision, range, and rapidity of the latest firearms; so that, in the race between the means of saving and the modes of destroying life, the former have been completely outstripped. At the beginning of the war the Prussian Government enrolled 2700 surgeons and provided hospital effects for 40,000 beds, and yet after the first battle medical aid was wanting. The "sanitary detachments" belonging to the corps engaged had not arrived, and, even were they present, would not have been sufficient.

At Saarbruck the natives for two whole days drew the wounded from the fields in country carts, and brought them to their own homes. After the battle of Weissenburg some of the wounded lay for two days where they fell, and in Remilly a street was pointed out in which 1000 wounded were laid down, having been travelling thither for two days and two nights from the field of Gravelotte. From the scene of action at Metz 3000 wounded were sent to Gorze, where Professor Langenbeck with but four assistants was; and such was the pressure that they could receive only the most temporary dressing prior to being passed on to places of greater accommodation.

The self-evident cause of the delay in removing the wounded from the field was of course a deficiency of carrying power. For each severely wounded man four stretcher-bearers are required; and as the ambulances for affording the first and most temporary assistance cannot, owing to the extended range of present weapons, be placed nearer to the battle than three-fourths of a mile, it consequently follows that each set of bearers would be unable to accomplish the distance to and fro more than ten times in one day: this, too, is supposing that they can proceed in each case directly without being turned aside by unevenness of the ground or the approach of heavy firing, and assumes also that they are not impeded by the caution needed in carrying such burdens.

At the lowest calculation, then, 400 bearers will be required to bring in 1000 wounded. This being the case, and as only 400 bearers were allowed to each Prussian army corps, it is easy to understand why the wounded lay whole days and nights upon the field of battle.

However, even in the most civilised country devoting the greatest attention to the development of its military resources, the government will be naturally unwilling to surrender so large a proportion of fighting men to a non-combatant duty. Still the fact is no less established, that unless stretcher-bearers be provided to the extent of 400 to every 1000 helpless men, the wounded must suffer unduly prolonged exposure after every important action. There is therefore but one approximate solution of the difficulty possible—viz., a preconcerted arrangement between the resources of the medical administration and those of private help; and this is a necessity so pressing that one cannot comprehend how it continues to be deferred when so many wounded are seen to die from being left too long to their fate on the battle-field. In the last war the authorities admitted with reluctance the motley detachments of stretcher-bearers collected in haste by private help, and it is quite intelligible that these undisciplined crowds may have spread disorder or hindered the movements of the troops; but these crowds would not have been undisciplined had the authorities, confessing the relatively insignificant number of their sanitary detachments, applied in time to the private societies for co-operation and assistance.

By suitable training under experienced officers "carrying companies" might have been formed, all confusion and obstruction thereby avoided, and very many wounded retrieved from death. Such an organisation would not only bring timely aid to the stricken, but would vastly increase the confidence of those who were still unhurt.

Dr. Pirogoff sees a second very important reason why the rendering of first help in the late war was so defective in the rule that a Prussian surgeon is before all things a soldier, whose duty is to be performed under fire. Consequently, up to September, 1870, forty, and later on eighty, medical officers

had fallen in battle. "Wherefore" (he continues) "allot to one a double duty?" The origin of this superfluous medical heroism dates from the Napoleonic wars, when Larrey introduced the "flying ambulance," whose mission was to plunge into the thickest fight and there to tend the wounded amid a rain of bullets. But we cannot regard primary operations in the same light as our predecessors, nor consider them necessary, successful, or even blameless. We cannot now maintain that an amputation runs less risk in transport than a patient with a broken limb. No one would now leave a surgeon and a wounded man under fire for bullet extraction or for dressing. There is therefore but one occasion for help in action—hæmorrhage from the larger vessels—that occurs but seldom, and its control by pressure every soldier can be taught. Hence are trained stretcher-bearers above all things needful. And not only is the custom of sending surgeons under fire useless, but it is disadvantageous, since they—especially the younger—will avoid the bandaging depôts and moveable hospitals and seek in action opportunities for winning the Iron Cross and other decorations. So long as this regulation stands it will be easily intelligible how Corny and Gorze (where Langenbeck laboured) and Remilly (where the wounded amounted to several thousands) were without surgeons. Again, the surgical work done in the heat of battle is but a waste of power, and scarcely less useless than the feverish practice of the bandage places. Dr. Pirogoff, discrediting the value of operations done under such circumstances, adds, as a further reason why they should not be attempted, that the rapid firing of recent weapons produces such a simultaneous crowd of wounded that the ambulances are immediately thronged, and reliable diagnosis between the cases suitable for operation and for conservative surgery rendered impossible. He therefore assigns to the surgeons at the bandage places the duty of using means to avert impending danger—of transmitting the wounded ticketed with diagnosis cards to prevent all further painful and unnecessary examination, and of dividing the wounded into "those hopelessly injured," "those requiring prompt attention," "those fit for transport," and "the slightly hurt."

Above all things is necessary the quick transition of the wounded through the temporary dressing depôts to a place of permanent rest, for even those most demanding surgical interference will bear immediate transport better than after a capital operation.

From this it appears that the experience of Dr. Pirogoff convinces him of the futility of primary operations, which, he says, were only undertaken to any extent in Strasburg on account of the proximity of the permanent hospitals and the nature of the big gun injuries, and these only proved successful while the hospitals were uncrowded at the commencement of the siege.

The conveyances in use for removing the wounded are far from perfect. In this respect Europe is behind America; and at the same time the effects of the means of carriage for good or ill upon the sufferers is incalculable.

Finally, only on their arrival at the private hospitals or trains does the influence of private help come into play, and "up to this point the condition of the wounded is in no way better than in former wars."

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—This body, which held its first session last year at Bordeaux, is to meet under the Presidency of Professor Quatrefages, at Lyons, during the present month—viz., from August 21 to 28 inclusive. The Medical Section is expected to be very strongly supported by both the Lyons practitioners and those from other parts of France. All who feel interested in the matter may obtain information from Professor Gariel, Secretary of the Council of the Association, 76, Rue de Rennes, Paris.

A STRIKE OF DOCTORS.—The medical practitioners of the Canton Aargau, in Switzerland, have just declared a strike because the remuneration given them for visiting the poor is so wretchedly meagre. It seems that the tariff has not been changed since 1804, and according to it a practitioner, for a visit paid to a pauper at a distance of three-quarters of a league, receives the incredible sum of seventy centimes, or 7d.! For the same distance a *commissionaire* receives a franc.—*Gazette Hebdomadaire*, August 1.

SATURDAY, AUGUST 16, 1873.

THE PROPAGATION OF ZYMOTIC DISEASE BY MILK.

THE present outbreak of enteric fever in Marylebone has had the effect of directing professional attention, in the absence of other assignable causes, to the milk supplied to the infected houses as a probable source of the mischief. We believe that there can be now no reasonable doubt as to the well-grounded character of the suspicion. The proof is being collected and sifted by Mr. Netten Radcliffe, who has been sent into Oxfordshire to inspect the dairies and farms whence is obtained the milk of the company which supplied, it is said, nine-tenths of the smitten houses. We may be certain that no pains to arrive at the truth will be spared by Mr. Radcliffe and by Dr. Whitmore (the Health Officer of Marylebone), and the public and profession will confidently accept their verdict.

The occurrence, however, and the suspicion to which it has given rise, are not likely to be soon forgotten. Coming on the outbreaks of enteric fever at Islington and at Armley, Leeds, which were distinctly traced by Dr. Ballard to contaminated milk; an earlier outbreak of the same fever at Penrith, observed by Dr. W. M. Taylor; and the local epidemic at Parkhead, near Glasgow, observed by Dr. Russell—to all of which the same cause was clearly assigned—the public are not likely soon to lapse into their usual state of indifferent security as to the source and character of their milk-supply. We say "source," for we shall directly prove that there is some evidence that milk may be contaminated with the contagium of zymotic disease, although it may be apparently of fair quality and present the chemical characters of a normal unadulterated fluid.

The subject has been treated with considerable acumen by Dr. John Dougall, the medical officer for the Burgh of Kinning-park, Glasgow, in a paper read before the Sanitary Section of the Philosophical Society of Glasgow, in April last, and which, after being published in the *Glasgow Medical Journal*, has since appeared in a separate form. One of the principal positions maintained by the author is that milk is "a congenial soil for the propagation of zymotic disease." This he

argues first from its constitution: it contains a fermentable or putrescible body, casein, capable of acting as a ferment on sugar of milk, and when putrefying capable of inducing similar changes in other organic substances. Milk contains all the elements necessary to keep up the nutrition of the body, but it is dead organic matter, and is therefore incapable, like the animal body itself, of withstanding the attacks of toxic germs. "It is a more favourable *nidus* for the nurture of contagia than even a sickly organism." Practical dairy-keepers know that it rapidly imbibes effluvia. Milk allowed to stand near putrescible fish will taste and smell of it. The same is true of other putrefying organic matter, and strong-smelling substances, such as turpentine, onions, tobacco, paraffin, lime, etc., will rapidly impart their odour to milk standing near them. Milk, moreover, in virtue of the amount of water it contains, is a soil admirably adapted for zymotic poison. Dr. Dougall also argues that colostrum or "beasting milk" and diseased milk—both of which would contain more or less albumen, and the latter probably epithelium, casts of the lacteal tubes, pus corpuscles, or granular *débris*—would be especially favourable to zymotic vitality.

Accepting the fact that enteric fever can be conveyed through milk, two questions present themselves. First, Is enteric fever the only disease that can be conveyed through this channel? The second is, In what way or ways is the contagium of disease introduced into milk?

The first question must be answered in the negative. Enteric fever is not the only disease that can be propagated through milk. Professor O. Bell, of St. Andrew's, and more recently Dr. Robinson, of Leeds, have called attention to the transmission of scarlatina by this agent. In the St. Andrew's outbreak twenty-six children took scarlatina from swallowing milk mixed with cuticle from the hands of a person who had milked the cows, and was herself desquamating after scarlatina; she had also nursed others with the disease. Dr. Robinson has recorded that twenty-one children were attacked with scarlatina after swallowing milk obtained from a house where several children were ill of the same disease. Dr. Grimshaw, of Dublin, announced in a lecture delivered in March last his belief that the propagation of small-pox and cholera by milk had been observed by himself, and has since communicated to Dr. Dougall the facts on which he grounded his belief. These seem not more than sufficient to warrant a suspicion.

With regard to the second question, In what way or ways may contagion be introduced into milk? it seems possible that the answer must be, In two ways—through water and through air. The most obvious channel of mischief is undoubtedly water—used either for purposes of adulteration or it may be accidentally introduced in processes of cleaning, etc. Knowing as we do how infinitesimally small is the bulk of solid contagium capable of conveying vaccinia or variola, it is impossible to deny that the most trifling accidental addition of infected water may be sufficient to contaminate a considerable quantity of milk. A speck of contagious matter from a typhoid patient left in a can by the water with which it was washed may do all the mischief. But it would seem that even admixture of water is not necessary. It would be dangerous to assert this absolutely, but it is the conclusion to which the observations made in the outbreak of enteric fever at Parkhead, in a second outbreak at Leeds, and in the outbreak at Penrith in 1857, seem to point. In the case of the second Leeds outbreak, reported on by Dr. Robinson, the inmates of the dairy farm whence the milk came were the victims of typhoid fever; the water-supply of the farm was remarkably pure, being obtained from a source at a higher level than the house; but the sick were in a room communicating with the dairy, those who nursed them attended to the milk, the sanitary arrangements were as bad as possible, and the house, cowhouse, and dairy seem to have been in an atmosphere of emanations from the sick. In the case of the Penrith outbreak, three children were down with typhoid fever; their mother nursed them; she milked the cows, which were kept in a byre adjoining the house; the milk was brought into the room where the children were lying sick, and there it remained until distributed to the customers, many of whom took the disease.

Still, we must acknowledge that these facts have not the precision which would warrant us in asserting that pure milk exposed to an atmosphere of contagium is certain to become a vehicle for its propagation. It probably is so, but absolute proof is yet wanting. The evidence in favour of the contamination of milk by water containing febrile poison is stronger, and it is supported by the known facts of the propagation of enteric fever by water-supply. That milk will convey zymotic disease we hold to be absolutely proved, and it is a question whether it is not one of the most certain and dangerous modes by which it may be disseminated. Itself an organic fermentable fluid, it may be that it is suited for the conveyance and spread of zymotic poison in a higher degree than either water or air.

THE ADDRESSES AT THE BRITISH MEDICAL ASSOCIATION.

One of the most interesting, and to our minds most instructive, parts of Professor Wood's address is that devoted to the consideration of the value of the antiseptic system of dressing wounds, especially as regards its power of preventing the occurrence of those terrible foes of the surgeon—erysipelas and pyæmia. Professor Wood gave the system, *à la* Lister, "a fair trial"—and no one who knows him will doubt the fulness and fairness of the trial—at King's College Hospital; and "at the same time, side by side, and under the same conditions, as far as could be obtained, he employed," he says, "the solutions of carbolic acid in oil and water, and those of other antiseptic substances, such as chlorozone, metallic salts, etc., as a dressing, but without the elaborate attempts to exclude the unpurified atmospheric air which Lister deems essential." For a time all went well. Professor Wood began the trial "at a time when the Hospital was in a good hygienic condition, and the cases for that time did admirably." He had "some cases quite equal to any described by Professor Lister himself; but at the same time other cases treated in a different way did equally well." Some he treated "by the application of dry lint, without any moisture whatever, to the wound, and in many cases, especially in breast cases, the results were also perfect"; and in other cases he "tried the application of the chloride of zinc solution in the manner originated by Mr. Campbell De Morgan, and very good results ensued—viz., healing with the formation of little or no pus." The Professor tells us also how Humphry, of Cambridge, has informed him "that he is quite satisfied with his plan of leaving wounds and stumps entirely undisturbed and uncovered by dressings, having only the discharges wiped or washed away"; that Mr. Heath, of University College Hospital, "prefers tarred oakum to any other dressing," and that in the cases in which he has himself used it, it has answered admirably; and that Mr. Callender, of St. Bartholomew's, "has obtained much success from the use of cotton-wool, combined with his own form of drainage-tube." So far we see great success following the Lister method of treatment, but equally happy results obtained under other, very different and much more simple, systems of treatment. Then came a change. "After about six months there came into the hospital," and into all or most of the London hospitals, "a very unfavourable change." Erysipelas was imported into the hospital from without, and pyæmia began also to show itself. Wounds began to suppurate more, healing by "primary intention grew less common, and the blush of erysipelas appeared with a terrible

impartiality in cases treated in all kinds of ways," and "almost as impartially on the Professor's antiseptic side of the hospital as on his colleague Sir W. Fergusson's non-antiseptic side," and cases treated most fully and carefully by Lister's method suffered from pyæmia and from copious suppuration, as well as cases treated in other ways. The only gain—and it is not a small one—from the Lister method seems to have been a freedom from "putrefaction, as evidenced by the odour"; though in some cases of psoas abscess treated by that method even this advantage was not observed, for the Professor says—"When erysipelas and pyæmia appeared, we had cases in which the pus in the abscess became putrid and offensive after the first evacuation under the spray and with all the precautions." All these cases and observations appear to tell strongly against the truth of the germ theory, on which Professor Lister's system of treatment is based. That they do not stand alone, and that in character they are not new to the profession, we need not say; but they are of high value, in character and completeness, and it may surely be admitted that they give strong support to the belief "that the agencies, whatever they are, in pyæmia, operate in the general system, or, if through the atmosphere, in other channels besides the wounded parts." Professor Wood describes how he has successfully treated some cases of pyæmia by "surrounding the patients with a highly antiseptic atmosphere," administering the sulpho-carbolate of iron, and giving plenty of nourishment; but he adds—"I believe that cases of recovery frequently occur under other methods, or no methods, and that at least as much depends upon the age and reparative power of the patient, the amount of blood-poison formed or absorbed, and the general condition of the atmosphere, as upon any system of treatment whatever."

We have neither time nor space to remark on the rest of Professor Wood's address; nor is it needful that we should do so, for his own reputation, the character of his address, and the subjects on which he has dwelt cannot fail to secure for him careful perusal and consideration.

The last of the addresses-in-chief, and certainly not the least important, was the Address in Physiology, by Professor Burdon-Sanderson. This was highly appreciated by the large audience fortunate enough to hear it, and will, we are sure, be eagerly and most attentively perused by the profession at large. We can here do little more than show some reason for our admiration of the address, for it is an argument on the value and importance of Physiology to the art and science of Medicine, and must be read and studied as a whole to perceive its weight and force; it cannot be fully analysed, or reviewed in detail, in the small space at our command. Noting that the opinion "most commonly held" about physiology is, "that though it may be a very good thing in its place, conclusions derived from physiological reasoning ought always to give way to the dictates of practical experience, and that science can never be a guide to practice," and alluding to some of the instances in which it is affirmed that the influence of physiological theory has been injurious, Dr. Sanderson points out how this opinion arises from the misapplication of the word "*physiological*," and how important and desirable it is to draw a distinct line of demarcation between the science of physiology and the science of medicine. The one is empirical, the other experimental. In the first, that of medicine, "experiment has no place, its fundamental facts being gathered, not from experiment, but from case-books and the records of post-mortem examinations: its method consists in systematising and combining the experience of great numbers of trustworthy persons in such a way as to make them applicable to diagnosis and treatment, and admits of being carried out with quite as much exactitude as those methods which are employed in the so-called exact sciences." While in the second, the science of physiology, experiment is everything—"it is built up of experimental results; its mode of working is that which is now understood by the term research." But "between the two regions of experience and research there lies an intermediate territory of speculation, which is a constant source of temptation to even the most practical mind," and this tendency it is neither possible nor desirable to check. But it must be used, not abused; it is for the practical mind to suggest and theorise, while the physiologist doubts, experiments, and tries to answer; thus "both the speculative and the sceptical faculties of the mind are brought into useful exercise—the functions of the one being to set questions on the behalf of clinical medicine, of the other to answer them by experiment. So long as this reciprocal relation is maintained there is no danger in speculation. The danger to science begins when the practical man not only asks his question, but gives his own answer in the name of science. The danger to practice is when he allows such answers, falsely given, to lead him astray from the safe guidance of experience." And then Dr. Sanderson proceeds to "illustrate this reciprocal influence of empirical speculation on the one hand, and experimental scepticism on the other, by a single example"—that of the Physiology of the Febrile State. He sketches those theories of fever "which propose to explain its phenomena by attributing them either to vascular disturbance on the one hand, or to paralysis of a supposed regulating centre on the other," and then proceeds "to try to show what is the true method of investigation in pathological questions." How is the subject he has taken as an example to be attacked? By taking one by one the questions that present themselves concerning it. And the question that comes forward most prominently is, How is the pyrexia produced? "We have but two certainties to start from—First, that in the animal body heat is produced exclusively by chemical change; secondly, that in the particular case to be investigated the rate at which the body is warmed is greater than can be accounted for by any mere accumulation." And the conclusion from these two propositions is, "that such an increase of temperature as occurs in fever must depend on increased oxidation." But "where does such increased oxidation occur?" It may be that it occurs everywhere—"that is, that just as heat is produced normally in every tissue, it must be so produced in fever,"—but this has not yet been proved; and "of the three or four tissues of which the mass of the animal body is composed—the nervous, the glandular, the connective, and the muscular—there is only one which has been sufficiently investigated in its relation to ordinary heat-production—viz., the muscular." With respect to this, it can be shown that "the variations of intensity of which muscular oxidation is capable would be sufficient, quantitatively, to account for the variations of bodily temperature which occur in fever." From this it may be concluded that "any process by which vital activity can be increased in a relatively large mass of living tissue is capable of producing a pyrexia which is in every respect, excepting its cause, a counterpart of that of fever." And thus, Dr. Sanderson observes, "we come back to a very old definition of fever—that fever is the reaction of the living organism against a stimulus. This definition is of value merely as a finger-post—as an indication of the direction in which we must work. I understand it to mean that, if I am to seek successfully for the proximate cause of fever, I must look for it among agents which act either directly or indirectly as excitors or irritants of living tissue."

Dr. Sanderson concludes his most able address with an eloquent and earnest appeal to the Association to help forward pathological research, "as a thing distinct from, though highly serviceable to, practical medicine and surgery." He hopes that much good may arise from the labours of the Royal Scientific Commission, and notes that a scientific inquiry is now in progress "on a large scale at the public expense, which has

for a principal object the investigation of a physiological question—viz., that of the physical conditions which govern the distribution of living beings at the bottom of the deep sea." "We do not doubt for a moment," he remarks, "that the care and thought which have been spent in the case of the *Challenger* expedition—in the selection of competent persons as observers, in organising them under a man of science and acknowledged ability, in dividing the work of research among different individuals, in providing them with proper places to work in and proper instruments to work with—have been wisely spent. Let us, if we desire to promote efficient research in our own province, follow the same principle." And he says finally—"I venture to think that it is an object in every respect worthy of this great Association to further and promote the organisation of physiological and pathological research, by fixing on the questions to be investigated; by appointing persons of acknowledged scientific ability to take the direction of the inquiries; by encouraging young men of the highest ability to devote the earlier years of professional life to research; and by providing the necessary funds."

Dr. Sibson, in his Address in the Section of Medicine, presses the same object on the attention of the Association. There are, he remarks, innumerable important practical questions that call for careful, patient, and unbiased investigation, and there are many young physicians with time at their command and an earnest desire and skilled power to investigate them. "If our Association places at their command the instruments and means of research, their vigorous powers of investigation will bring to light many of those important questions as to the nature and treatment of disease that are as yet comparatively obscure; and thus the science of medicine will be enlarged and elevated by labours inspired by this Association." We ourselves ventured to touch on this subject the week before the Association met, observing that—"a society possessing a revenue of five or six thousands a year might, in the course of four or five years, find the means for clearing up a large number of medical and surgical problems of the highest importance, not merely to the medical profession, but to the world at large"; and we can hardly believe that the Association, if it means to rank at all as a scientific body, will long be content to employ its extensive funds solely or chiefly in providing its members with a weekly journal, nor even in establishing also, as has been suggested, "a large benevolent fund." The Association may be heartily congratulated on its growing strength and importance, and on its improved financial condition; though it may be permitted to us to remark that we cannot wonder that some surprise has been expressed at the appearance of such a sum as £540 under the head of "petty cash," even in a balance-sheet dealing with the expenditure of nearly £9000; and we think that it must be to many a matter of regret that the British Medical Association has not, with such an income, felt able and willing to add a higher lustre and dignity to its late successful meeting in the metropolis, by the commencement of a series of usefully large grants in aid of scientific research.

THE BRITISH MEDICAL ASSOCIATION MEETING.

Now that the meeting of the British Medical Association is fairly over, and our guests have departed, we are in a position to look back and quietly estimate its success. If size is any criterion, its success is undoubted, for we question if such a number of medical men were ever before brought together in one place; but in such a case as this number is but one of the elements to be taken into consideration: social amenities, as they are called—business and pleasure,—have to be duly estimated. Now, as regards arrangement, there can be no doubt but that in the early days of the meeting much more was to be desired: confusion was paramount, and the reason was plain. Twelve hundred men were expected from various parts of the country—even with such a number the meeting would have been numerically a great success,—but instead the officials had double that number upon their shoulders. Under such circumstances previous arrangements, however good—and we have every reason to believe that the arrangements made were excellent,—must fail. But, on the other hand, it cannot be denied that the power of organisation shown was exceedingly great, for out of chaos soon came order, and the gentlemen who worked so hard to make things go right are to be congratulated on the success which crowned their efforts, for by the last days of the meetings the wheels of the great machine were working as smoothly as if they had been in action for months. This, we hold, is most creditable to all concerned.

As we have already pointed out, some of these meetings have been more distinguished by junketting than by work; such, however, cannot be said of the present meeting, in which the work done was of a most interesting character and of the best description. Of the admirable addresses we shall not here speak, but refer rather to the working of the sections, which was unusually good. It may be that the presence of so many distinguished foreigners urged us on to display our working powers, but certain it is that the sections were better attended and the work done was better than they have ever been before. In the Section of Medicine the business had been so arranged that a discussion on some subject of the day should take precedence of all else. On the first day this arrangement fell through, as a paper which had been promised, and to which we believe much pains had been given, on the subject of Alcohol in Pyrexia, had to be withdrawn, owing to the absence of its author, Dr. Anstie, from unavoidable causes. Nevertheless, the early papers in that section—by Dr. Noel Gueneau de Mussy on Enlargement of the Bronchial Glands, and by Dr. Oscar Liebreich on Croton Chloral—were quite brilliant. So it was in the other sections. The discussion on Cholera in the section of Public Health we have already referred to. The chief paper in the Section of Medicine on the second day was by Dr. Grainger Stewart on Chronic Bright's Disease, and that, together with the discussion which followed, in which Dr. Sutton, Dr. Dickinson, Dr. W. Roberts, Dr. M. Fothergill, Dr. G. Johnson, and Dr. Crisp took part, was really the best we have heard on the subject; the views expressed were moderate, and the clinical aspects of the malady, as well as its pathological characteristics, were duly examined. The papers by Dr. Gairdner on a case of Tricuspid Obstruction and by Dr. Dieulafoy on Aspiration were also exceedingly valuable. The discussion on Anæsthetics on the third day was very good.

Surgery is always attractive, and the Surgical Section was both well worked and well attended.

The Section of Obstetrics is generally a favourite one, and this year it was the more likely to be so from the presence of some foreign celebrities. Physiology and Psychology, though comparatively new, held their own manfully, and contributed to the general success. The Public Health Section was, however, that which seemed to draw the largest audience. For the accommodation of such meetings, sectional and general, it would have been difficult to find a place better adapted than King's College, with its numerous large class-rooms and theatres.

The public luncheon has been an important feature in this meeting; and on the first day, when no proper arrangements had been made, the scramble was appalling, but by next day discipline prevailed, and everybody was able to get, if not what he wanted, yet, at all events, a good luncheon. Of the private hospitalities this is not the place to speak, though they have been numerous and sumptuous. Of the more public receptions at the Mansion House and Royal College of Surgeons we have

already spoken, whilst the *conversazione* at University College is elsewhere described. The excursions which took place were partly of the nature of hospitality, for at Windsor the members were invited to a free luncheon, and at Brighton something still more sumptuous was offered for their acceptance; those who visited Hampton Court were even more magnificently entertained by Dr. Langdon Down. Of these excursions little need be said. The first of all essentials on such an occasion —fine weather—was forthcoming, and, after a week of application such as fell to the lot of some in no ordinary measure a holiday under any circumstance would be delightful. Suffice it to say they were all abundantly successful, and constituted a gratifying termination to a most successful meeting.

Two exceedingly interesting excursions were made on Friday—one to Woolwich Arsenal, where some of the most interesting processes were seen in operation; and another to the northern sewage outfall on the river near Barking, and Mr. Hope's sewage farm. This last excursion was selected by many most distinguished visitors, including Professor Virchow, who is just now greatly interested in matters relating to public health. Mr. Spencer Wells's garden party, too, on Friday afternoon was a great success. Many other visits were made. Stafford House, Dorchester House, Grosvenor House, Apsley House, and many other spots of interest attracted much attention.

Of the public dinner we need not speak. Tickets were anxiously sought after, but the number was limited, and much disappointment ensued. Here, once for all, we must say that any disappointment which did so arise depended entirely upon members themselves: again and again they were asked to signify their intention of being present, and had it been known that so many intended to be present it would have been quite as easy to arrange for 2000 as for 1000.

Finally, we must not forget to say a word about the museum and its catalogue. Many unique specimens were there displayed if one had had more time to examine them; but for those who had not, the catalogue will still remain as a memorial of the meeting and a work deserving of much study. One department of it was unique, for never before had so many kinds of electric apparatus adapted for medical use been brought together. Some of the foreign batteries were especially ingenious, those used by Duchenne notably so. A battery by Gaiffe was also conspicuous for its power and small compass; but, turning to those made in this country, we find that in many respects they are rapidly equalling, if not surpassing in every way, the best foreign models. Chief among these we would mention Foveaux's (Weiss's) constant current, and Mayer and Meltzer's compound batteries.

Although our views may in some respects differ from those of the British Medical Association, still we cannot but feel the great value of such meetings—bringing together old friends and affording the means of making new ones. Medical men are too apt to quarrel over little points of etiquette, and often have no means of knowing how good fellows on the whole their neighbours are. Any means of consolidating the profession, and of welding it into a compact body, ought to be welcome to all, and than such we have seen nothing better than the past meeting of the British Medical Association.

THE UTERUS IN PREGNANCY.

The anatomy of the gravid uterus and the fœtal envelopes has been recently investigated afresh by Dr. Kundrat, of Vienna. The account furnished by the author in his paper (*Medizinische Jahrbücher*, 1873, No. 2) is partly confirmatory of the accepted description of these structures, and partly the opposite: in either case it deserves careful attention. The following points, which are the most generally interesting, refer to the human uterus and embryo:—

The mucous membrane of the newly impregnated uterus is known as the decidua, and is familiarly divided into the decidua vera, reflexa, and serotina. In structure it at first somewhat resembles the uterine mucosa in or before menstruation; it is thickened, the glands are dilated, elongated, and tortuous, and there is a great increase of intertubular cells. In all respects the structure of the three portions of the decidua is very similar. Inferiorly the vera suddenly ceases at a short distance from the cervix in an overhanging border, and the cervix takes no part in the formation of the fœtal cavity. Both the Fallopian tubes and their inferior openings are patent during the whole period of pregnancy. When the impregnated ovum reaches the inferior tubal opening its progress, according to Kundrat, is not obstructed by an adhesive growth of the opposite mucous surfaces to each other, as some observers believe, for no such adhesion exists. For the same reason the ovum does not push before it and invaginate a portion of the mucosa, which becomes the decidua reflexa. The latter is clearly an outgrown and infolded portion of the decidua vera; for it possesses glands on its deep or ovular, as well as on its free surface. The ovum is retained at the fundus of the uterus by the swollen decidua. If the swelling is not so great, the ovum may travel down towards the cervix; and it is for this reason that placenta prævia is more common in multiparæ. Kundrat does not believe that the ovum enters the mouth of a gland, but that it developes on the irregular surface of the serotina. As pregnancy advances the uterus enlarges, and the connexion between it and the ovum becomes more intimate and complex. The enlargement of the uterus is at first out of proportion to the growth of the embryo, and a free cavity exists between the vera and the reflexa, which is filled with a somewhat opaque mucoid fluid. It is not till the fourth month that the embryo fills the uterine cavity, and the walls, which were previously disproportionately thick, become disproportionately thin, while the envelopes become transparent. In the fifth month the process has advanced yet another step, by the adhesion—partial at least—of the opposite walls of the uterine cavity: that is, of the decidua vera and the decidua reflexa.

In regard to the connexion between the chorion and the decidua, it has often been represented that the processes or villi of the former pass into the glands of the latter. Kundrat maintains that this arrangement was "but seldom" to be discovered. On the contrary, the chorion-villi were found to be fixed in the grooves of the serotina and on the sides of its elevations by a connective mass composed of mucus and degenerated epithelium. Other villi had buried themselves in the tissue of the serotina, and formed a connexion so intimate that any attempt at separation ended in rupture. It is here that the placenta is afterwards developed. As gestation proceeds the changes on the decidua are very considerable, and in the last months peculiarly interesting. The decidua reflexa becomes attenuated by pressure until reduced to a simple layer of the transparent envelopes of the embryo, of which it forms the most external portion. The decidua vera and decidua serotina, on the other hand, remain as comparatively thick layers of tissue, compact on the surface and cellular, but spongy in their deep portion, from the presence of the numerous ends of the dilated glands, which represent sinuses lined by epithelium. As the termination of pregnancy approaches there occurs, as we have said, a remarkable change on the lining membranes of the uterus. These and also the reflexa become whitish, dull, and of a pale yellowish or even a yellowish-grey tint, opacity replaces transparency, and the process, which is discovered by the microscope to be one of fatty degeneration, passes into the deeper layers. This description of course reminds us of the simultaneous fatty degeneration of the placenta. When parturition occurs a portion of the membranes is expelled with the fœtus,

and it is interesting to inquire what part, if any, of the envelopes is retained. Careful examination certainly reveals that the superficial portion of the decidua vera is, as a rule, included in the fœtal membranes, while the deeper portion is retained, although this is not always the case. During the first week post-partum the discoloured lining membrane of the uterus may be found microscopically to present the characters of the decidua vera, but the sinuses are full of blood, the superficial cellular layer gone, the fatty degeneration extends to the deepest layers, and the tissue generally is infiltrated with round cells and blood. The lochial discharge consists of such cells and of products of disintegration. In the second week post-partum the process has still further advanced, and the epithelium of the exposed sinuses is found to be proliferating. Restitution now begins and advances, and soon there is found on the surface of the muscular coat a fine layer of connective tissue, covered by epithelium and furnished with young glands, to represent the mucosa of the uterus, which is again at rest.

THE WEEK.

TOPICS OF THE DAY.

The outbreak of typhoid fever in Marylebone has been traced to its source. A letter from Professor Corfield, of University College, which appeared in the *Times* of Thursday, acknowledged that the circumstances connected with one out of eight farms from which the company vending the suspected milk obtains its supply "were open to grave suspicion of accidental contamination of the milk." Professor Corfield, with Mr. J. Chalmers Morton, have been appointed by the company to investigate the matter on their behalf, and it is satisfactory to learn from the Professor's letter that the supply from the suspected source is now entirely stopped. It is reported on good authority that not only does enteric fever exist in the part of Oxfordshire where the farm is situated, but that the disease has appeared on the farm itself. It is said that one person (the farmer) died at the farm in June last from an attack which is believed to have been typhoid fever, and that another person is now undoubtedly ill on the farm from that disease. The houses in Marylebone and the adjoining parishes—between forty and fifty in number—in which the fever has appeared have all, with three exceptions, been supplied by the same milk company. Of the three exceptions one may, however, with certainty be referred to the same source—for the only case in it has been that of a child who had been recently on a visit to a family to whom the contaminated milk had been supplied, and the children of which have since suffered from the disease. There is also a statement abroad that in one house in which the same milk had been used, but had been scalded previous to use, no case of fever has appeared. We have further to state that although the dairy company on first receiving a joint letter from Sir William Jenner and Dr. Murchison, on the subject of the prevalence of typhoid fever in families whom they supplied, did not immediately seem to appreciate the possibility of milk-contamination, they have since shown the greatest willingness to have the matter sifted, and have given every facility to Mr. Netten Radcliffe for carrying out his investigation. Dr. Murchison, we believe, was the first to suspect the real source of the mischief. A busy professional contemporary has thought fit to publish the names of a number of medical men in whose families cases of typhoid fever have occurred. We certainly cannot compliment our contemporary upon the good taste or sense which have been displayed in giving these personal and family misfortunes publicity. At present we have heard of four deaths having occurred from the disease.

Cholera is on the increase slowly in Hamburg and the Prussian towns on the Baltic. In the week ending August 2 there were one hundred cases at Hamburg. The disease is rife in Hungary. There is no official account of any cases in England.

Dr. John Mitchell Bruce has been elected Assistant-Physician to Charing-cross Hospital, and Mr. William MacCormack Surgeon to St. Thomas's Hospital.

The rumour that the female medical students were likely to effect an easy entrance to the University of St. Andrews has been contradicted.

HEALTH OF M. NÉLATON.

M. Nélaton, who had gone to Villers, near Trouville, for the benefit of his health, had very much improved, but since his return to Paris a few days ago he is again laid up, and his present condition causes the greatest anxiety among his medical attendants as well as among his numerous friends and clients.

THE ASHANTEE WAR.

By the last intelligence received from Cape Coast Castle, the *Himalaya* would appear to have arrived there with the head-quarters of the 2nd West India Regiment on board. Fortunately for the small garrison of our countrymen holding the Ashantee hordes in check, heavy rains had come on prior to her reaching the station, thus rendering all offensive operations impossible. As we previously reminded our readers, there will be but little opportunity for punishing the invaders until the cessation of the rains in October; meanwhile, although the ranks will once more be filled, and all the suffering resulting from a water-famine will thus be removed, it is to be feared that the troops will suffer considerably from the long period of inaction in such an unhealthy spot. Dysentery of a malignant type is still prevalent, and small-pox has not at all decreased; whilst, to add to the misery of the unfortunate natives who have taken refuge under the protection of the Castle, the heavy rainfall destroyed some of the temporary hospitals, leaving the sick without shelter of any kind. If the 360 men conveyed by the *Himalaya* are a sufficient reinforcement to establish our supremacy when the moment for action arrives, the Government does well to expose no larger contingent to the malarious influences of the Coast; but, even with the potent assistance of Snider rifles and rocket batteries, it does seem rather a hazardous undertaking—when the enemy is authoritatively allowed to number 30,000 fighting men—to attempt the subjection of such a host with so mere a handful. The work to be done upon the present occasion must be thoroughly done, and it should always be borne in mind that the saving of life under the present policy will be very dearly purchased if, from the paucity of the troops we bring into the field, we suffer any check, however inconsiderable, or should we even engage in two or three encounters without obtaining the most decisive results.

LAMBETH PALACE LIBRARY.

The Archbishop of Canterbury having kindly permitted this rare library, with other parts of the Palace, to be visited by members of the British Medical Association during their congress in London, some eighty in all of the members availed themselves of this privilege. After having examined the library known as Juxon's Hall, with its noble Gothic roof, and containing nearly 30,000 volumes, the librarian, S. W. Kershaw, M.A., explained the choice illuminated MSS. which in reality are the "art treasures" of the collection. The librarian then conducted the members over the guard-room, where the portraits of the Archbishops (including the famous Laud, by Vandyke, and Warham, by Holbein) were much appreciated. So interesting a series of distinguished prelates,

each telling his own historical story in bygone events, elicits a peculiar interest to be equalled in few art collections. The private apartments overlooking the spacious grounds—from which are visible the historic towers of Westminster and the modern structure of St. Thomas's Hospital—were next visited. The chapel, a beautiful example of early English architecture, deteriorated only by the ill-placed Renaissance screen erected by Archbishop Laud, was very much admired. Lastly, the visitors ascended the Lollards' Tower, where the prison in which these unhappy victims were confined was shown. This dungeon is as famous in religious history as many other more noted places, and is among the most remarkable group of buildings in the historical pile of Lambeth Palace. We wish to add that the library is open to all students and literary inquirers every Monday, Wednesday, and Friday, and that, by the liberality of the Primate, permission to copy from illuminated MSS. and make extracts is freely accorded.

A DEFECT WHICH SHOULD BE REMEDIED.

In a case of cholera at Limehouse, which the medical officer reported to the Limehouse District Board last week, it was stated that the clothing, etc., of the patient had been destroyed, and the Committee recommended that the friends be reimbursed the value of the goods. It appeared, however, that the Board had the power to disinfect premises, but had not the power to grant remuneration for clothing or other property destroyed to prevent the spread of disease. It was resolved to leave the matter in the hands of the medical officer. A discretionary power to meet such cases as this should be given to all our local boards. The destruction of property under the peremptory order of the medical or sanitary officer, without the power to reimburse the value of the articles destroyed, is a hardship, especially upon persons in indigent circumstances. We trust, therefore, that the recommendation of the Committee will induce the Board to apply to the Local Government Board for authority to compensate persons for articles so destroyed. Such an authority would relieve the medical and sanitary officers from the unpleasant and invidious position in which the conscientious discharge of their duties places them.

HEALTH AND MORTALITY IN CHINA.

"In the recently published medical reports," says the China correspondent of the *Standard*, writing at Shanghai on May 31, "forwarded by the various surgeons of the Imperial Maritime Customs, many very interesting facts are brought to light. The majority of the writers endeavour to prove that China is not an unhealthy place for Europeans to live in, and that when early death occurs it is generally traceable either to a person's own fault or to some organic deficiency of such a nature that death would have occurred from the same cause, at that identical period, in any other part of the world. However this may be, it is a patent fact that deaths in China are unusually sudden. One writer has been bold enough to assert —and there is considerable truth in his statement—that 'good living' and little exercise have something to do with it; and says further that 'it is doubtful whether the ancient Romans in their most luxurious days maintained anything like such a degree of extravagance in living as seems to be the recognised and indispensable fashion in the foreign houses in China.' Everybody knows that 'heart disease' is getting quite fashionable, and there can be no doubt that over-stimulating the system is a common cause of death among persons who fancy themselves healthy because they are robust and plethoric. It is only due to Mr. Hart, the able and indefatigable Inspector-General of Customs in China, to state that the reports to which we have referred owe their origin and comprehension to his industry and capacity. We may state further that Mr. Hart has instituted a system of meteorological observations along the sea-coast of China, which if carried out in the manner which he has indicated cannot fail eventually to be of the greatest importance to the welfare of the inhabitants of China. It has, however, a more important feature with reference to the nations of the West, inasmuch as these observations will afford data which they have never before possessed for comparing the results of meteorological observations from a country hitherto 'a closed book' in regard to this important subject. It is unnecessary for us to state that the influence which the inquiries of Mr. Hart has originated must be of the greatest service to medical science."

PROFESSOR TURNER ON THE PUBLIC HEALTH ACT.

In his address to the graduates of the Edinburgh University at the conclusion of the ceremony for conferring degrees, Professor Turner alluded to the ever-increasing attention paid of late years to the circumstances affecting the health of the people:—

"This led to the passage through Parliament last year of the Public Health Act, which has virtually opened up a new and most important branch of public service to the members of our profession. Although the need which suddenly arose under the provisions of the Act for the appointment within a limited period of a large number of medical officers of health throughout England and Wales, necessarily led to the selection from the general body of the profession of the present officials, there can be little doubt that in course of time this department of the profession will require to be organised on a distinct footing, and that those who aspire to practise it will have to undergo, in addition to the usual medical education, a special preparation and training. When the State imposed duties of so onerous a nature on the members of our profession, it might have been expected that it would at the same time have undertaken to provide those who might be selected to act as medical officers of health with the means of enabling them to obtain that special education which is necessary for the efficient discharge of these duties. From a Government which has shown no particular desire to further the advancement of science, and which has thrown frequent discouragement on efforts to obtain grants of public money for the promotion of the higher and more specialised kinds of education, the establishment of a distinct training school for the public health service, like the Netley School for the army and navy medical service, could scarcely have been looked for. But something ought to have been done to promote and encourage the expansion and utilisation of the resources of the existing educational bodies which are willing to undertake to provide the necessary instruction. In our own University, for example, the sheer want of class-room and laboratory accommodation stands in the way of organising such a system of instruction as would prove a credit to the University and fill a growing public want. A grant of money from the Treasury would enable the University to supply this want, and to send out each year graduates trained to perform the duties required of the public health medical officers."

VACCINATION AT WAKEFIELD.

Notwithstanding the active opposition of Mr. Ward, one of the guardians of the Wakefield Board of Guardians, to the carrying out of the Vaccination Act in that district, the vaccination officer's return, laid before the Board last week, showed that from July 1 to December 31, 1872, the total number of births had been 1425; of these 1041 had been successfully vaccinated, 161 died unvaccinated, 10 were postponed by medical certificate 15, were removed to places unknown, and 98 were unaccounted for.

A NEW MEDICAL WARRANT.

Mr. Cardwell has intimated (says the *Army and Navy Gazette* of last week) that the errors in the recent Medical Warrant are shortly to be rectified, and that a future Warrant ere long to be promulgated will heal all sores. We trust this may be so, and that the promised and looked-for document may not be long in making its appearance. "Hope deferred maketh

the heart sick," we are told. The hearts of the medical officers must be sick indeed.

FEVER IN THE METROPOLIS.

THERE were seventy-six fever patients in the Homerton Hospital last Saturday, being the largest number in that establishment since 1872.

FROM ABROAD.

THE FRENCH MILITARY SURGEONS AND PHARMACIENS—PUBLIC HEALTH OF PARIS IN 1873—PERAMBULATORS.

THE question of the relative positions of the doctors and pharmaciens in the French army, the opinion of the Academy on which was requested by the Minister of War (*Medical Times and Gazette*, July 19, p. 70), has given rise to a warm discussion which has only just terminated. As we have already noticed, the Committee appointed by the Academy, consisting of medical and pharmaceutical members, reported unanimously, after the withdrawal of the latter, in favour not of the abolition or fusion of the pharmaciens, but of their subordination to the medical officers of the army. This resolution, which seems from the medical point of view a rational conclusion enough (and especially so from the French medical point of view, inasmuch as the military pharmaciens are said to be not infrequently in adverse coalition with the Intendance against the medical officers), not unnaturally has caused a considerable amount of irritation on the part of the pharmaciens, both military and civil. It is to be remembered that the pharmacien in France has attained a much higher professional and scientific rank than he enjoys either in this country or in Germany. For example, his education is as elaborate of its kind, and as adequately tested, as that of a doctor; and distinguished members of the body to which he belongs are elected into the Academy of Medicine, where they are on a perfectly equal footing with the other members; and in this debate they have shown that they know how to defend their position. Any attempt, therefore, to bring them into a distinctly subordinate position had something invidious about it, and, as will be seen, had to be at least nominally waived. M. Bussy, a distinguished pharmacien, called the attention of the Academy to the fact that the duties of the military pharmaciens are not confined to the preparation, distribution, selection, and preservation of medicinal agents, but that they are also called upon to enlighten the Administration on various points of importance in military hygiene. A long list of those who had done valuable scientific work might be drawn up. He warned the Academy against recommending the abolition of an institution which had worked well for eighty years for the purpose of satisfying the prevailing mania for imitating the arrangements of the Germans during the late campaign.

But the principal champion of the pharmaciens was M. Poggiale, himself a Military Inspector of Pharmaciens. In considering the questions propounded by the Minister, he observed that fusion of the two bodies at present was quite out of the question, seeing the imperfect education of medical men in chemistry, pharmacy, materia medica, physics, and natural science. As it is now, errors—and even fatal ones—would often arise did not the pharmacien examine and control the prescriptions of military doctors as regards doses. Formerly, when assistant medical officers were admitted to perform the duties of pharmaciens, it was only the cast-off members who presented themselves, and who were found so incompetent that their admission had to be countermanded. The fusion of medicine and surgery has proved mischievous enough in the army, without adding that of pharmacy. The same line of argument exhibits the impropriety of subordinating the pharmaciens to the doctors; for multitudes of questions arise which the latter are incompetent to treat. M. Poggiale cites instances in which the intervention of pharmaciens has proved of the greatest utility in military hygiene, and he refers to many whose names have become famous.

Baron Larrey explained that no one wished to deny the merits and services and the necessity of military pharmaciens; but after all, as regards their functions and the interests of the army, they were only auxiliaries of the medical officers, and should be subordinate to those whose orders they have to carry out.

M. Poggiale, in continuation, observed that the medical body wished to exert the same power over the pharmaciens which they complained as suffering themselves from on the part of the Intendance. One of the useful functions, he observed, of the pharmaciens, who were thus sought to be ridden over, is the control they exercise over the prescriptions of their would-be masters; and without such control the most lamentable accidents would frequently occur. He could lay before the Academy eight prescriptions which would have caused death had they been made up as directed.

M. Boudet, another pharmacien member, followed with much the same line of argument.

The debate was vigorously maintained on the other side by MM. Legouest, Fauvel, Sédillot, and others; while M. Dumas, the celebrated chemist, communicated to the Academy an eloquent pleading in behalf of the pharmaciens. We have not space for farther notice of so prolonged a discussion, interesting as this is in many parts, although, as usual, prolix to a degree and bristling with repetitions. The last discussion was almost as turbulent as if it had taken place in the National Assembly. The first resolution—"That the fusion of military medicine and pharmacy should be rejected as prejudicial to the interests of the army"—was passed unanimously, the pharmaciens agreeing with the other academicians that the results of such a fusion could only be deplorable. The second resolution gave rise to a stormy debate and numerous amendments. It finally stood as follows:—"The present organisation of the military medical service does not correspond to the interests of the army. It is desirable that this service should be placed under a director taken from amidst its own body, and invested with all the attributes which concern the military medical service." The hottest subject of contest was to come. In its third resolution the Committee stated "That the autonomy of the medical military service necessarily implies the subordination of pharmacy to medicine in the army." This the pharmaciens determined if possible to prevent being passed, and completely succeeded, for after a stormy debate it was rejected by 30 to 19 votes. From the tenor of the debate, during which all argument and illustration seemed in favour of the resolution, this result caused much surprise. But it was thought by many academicians that, since the second resolution substantially carried the point in favour of the doctors, it was needless to insist upon the "subordination" so annoying to the pharmaciens. Still, it was remarked that rejecting the resolution was literally to leave unanswered the very question concerning which this laborious and tumultuous debate has so long occupied the attention of the Academy. However this may be literally, the Minister will not remain uninformed of the real opinion of the Academy, that military medicine should obtain emancipation from the trammels of the Intendance, and exercise control over its auxiliaries, the pharmaciens.

M. Besnier, in his report (*Union Méd.*, Nos. 89 and 92) on the health of Paris for the second quarter of 1873, states that the medical constitution of the capital during that period presented nothing special or exceptional—no epidemic having played a preponderant part. He takes the opportunity of comparing the mortality of the first six months of the

year with that of the first six months of five previous years. The general mortality of the civil hospitals and hospices for these six months amounted to 6427 in 1867, 6973 in 1868, 7089 in 1869, 8110 in 1870, 5519 in 1872, and 5944 in 1873. These comparative statistics confirm a statement made by M. Besnier last year, that the gravity of affections of the respiratory organs is on the increase. This is remarkably shown with regard to *pleurisy*, for which thoracentesis is so fashionable a mode of treatment in Paris just now. In 1867 the mortality was 7·03 per cent., and in 1873 it mounted up to 14·66 per cent., being an increase on that of 1872, which was 11·93 per cent. With regard to *croup* we may extract M. Besnier's observations:—

"In former reports I have, by the aid of numerous documents, stated with exactness various particulars which have been little studied, or misunderstood, regarding the history of diphtheritic epidemics. I have shown that in Paris the diphtheritic endemo-epidemic undergoes every year a regular and normal exacerbation, commencing in general, more or less suddenly, about November, and attaining its maximum about April. I have also established that for some years past the progression of the number of deaths caused by croup has been increasing to such a point that the number of deaths from it, which was only 97 in the medical winter (November to April) 1867-68, increased to 181 for the winter of 1871-72, and to 189 for the winter of 1872-73; the six months of these winters exceeding the total figure of the twelve months of the mean year, which, calculated for 1866-69, presents an annual mortality from croup of 179. If I pursue with perseverance this laborious grouping of figures, it is not in order to satisfy merely a statistical curiosity, but to show how wrongfully this class of studies has been neglected. The mortality from croup (as I have several times established) varies not only according to the regions in which it is observed or the seasons of the same year, but also according to annual epidemics. Consequent on this, any statistics, whether partial or general, brought forward in favour of any given mode of treatment, should be controlled by the examination of the general mortality of croup in the locality where the observation is made, and by the study of its mean mortality at the epoch at which the experiment is instituted. The variations may reach 20 per cent. between one year and another, as is shown by the returns of mortality from croup during the first six months of the last six years. In 1868, 162 cases, with 99 deaths (61·11 per cent.); 1869, 146 cases, and 118 deaths (80·82); 1870, 179 cases, with 130 deaths (72·62); 1872, 255 cases, with 176 deaths (69·01); 1873, 248 cases, with 188 deaths (75·80)."

Great as is this mortality from croup, it does not represent the whole truth, for several patients are taken away by their parents just before the fatal moment or when only imperfectly cured.

With respect to *secondary endocarditis*, M. Besnier makes an observation which is of interest. This, whether observed in relation to diphtheritis, erysipelas, purulent infection, eruptive fevers, or, as recently described by M. Lancereaux, intermittent fevers, should not be regarded as dependent on some peculiar conditions of the primary disease. We have, in fact, to do with a whole series of affections of which a changed condition of the blood is a characteristic in common; and under the direct influence of this the endocardium undergoes the changes which pathological anatomists are now investigating with so much success.

The returns of *puerperal mortality* for the six months confirm the conclusion already arrived at in former reports of the immense advantages which have attended domiciliary deliveries as compared with hospital deliveries. Still, Dr. Besnier observes, this must not be exaggerated, since "a considerable number of women still become the subjects of puerperal accidents beyond the sphere of all nosocomial influences, while there is a category of abandoned women, subjected to the most deleterious moral and physical influences, and utterly improvident to the last hour, whom it will always be impossible to provide for otherwise than in hospitals." The mortality from puerperal disease for the first five months is as follows:—Deliveries effected in Paris Hospitals 2774, with 112 deaths; deliveries at the houses of *sages-femmes* 903, with 12 deaths; deliveries effected *à domicile* by official *sages-femmes* 4771, with 19 deaths.

In one of his recent *feuilletons*, M. Latour calls attention to the mischief which may arise from the now almost universal employment of perambulators for the transport of children. He chiefly dwells upon what happens to young infants, who, in place of resting on the nurse's arm and gradually bringing the muscular system which supports the trunk erect into use by exercise, and accustoming their senses to the perception of surrounding objects, now lie recumbent and somnolent in a state of dangerous quiescence. Woman, he believes, is thus abdicating yet another of her functions, which, in all eyes but her own, render her attractive; and although she may relieve herself of some fatigue, it is at the risk of the welfare of her child. "Certain I am that an *enfant à équipage* is a retarded infant: it will walk later, talk later, and smile later." He calls for facts and observations on what he believes to be an important matter in infantile hygiene.

Of its importance scarcely anyone can doubt, when he sees infant after infant propelled along, somnolent and unconscious. But the perambulator mania is probably far more mischievous to children of older growth, as impeding, by the indolent habits it engenders, the general development of the muscular system, and placing the child in a state of mischievous isolation. The careless way in which the perambulator is driven must also not unfrequently be a source of mischief, and some of the severer jerks or greater violence which this gives rise to may not unfrequently be the unsuspected source of cerebro-spinal mischief hereafter to be developed. At all events, the subject is worthy of professional attention, the practice having grown so universal as to render it very desirable to know whether it is so innocuous as this ought to imply.

PARLIAMENTARY.—PUBLIC HEALTH—CONTAGIOUS DISEASES (ANIMALS)—FACTORY ACTS.

In the House of Lords, on Saturday, August 2,

The Public Health Act Amendment Bill passed through Committee.

In the House of Commons, on Monday, August 4,

Mr. Forster made the important announcement that two suggestions of the Committee on the Contagious Diseases (Animals) Act would be immediately carried out—viz., that animals affected with pleuro-pneumonia should be slaughtered, and that the owners should be compensated.

Mr. Mundella withdrew his Factory Acts Amendment Bill in consequence of want of time to proceed with it.

Royal Botanic Society.—At the thirty-fourth anniversary meeting of this Society, on Monday last, a very interesting report was read, from which it appeared that the Council had not lost sight of one of the principal objects of the institution—the study of botany in its relation to medicine, as free orders of admission to the gardens for study for periods of from one to six months had been issued to 210 medical and other students, and to twenty-five artists, and nearly 30,000 cut specimens of plants distributed to the medical schools of the principal metropolitan hospitals, schools of art, and other educational institutions.

Treatment of Diphtheria.—Dr. Lolli, of Trieste, states that while diphtheritis is very fatal in that city, he has lost less than 2 per cent. of his cases in consequence of the efficacy of the treatment he employs. He does not resort to cauterisation, bleeding, purgatives, or emetics, save in very exceptional cases. He maintains the skin in a state of great activity from the very first by keeping the patient in bed, and, if necessary, applying warm applications or mustard. These measures are continued until all local and general symptoms have disappeared. As the sole medicinal agent, he employs the following mixture in different concentration:—Liq. calcis ʒiv. ad lb. j., liq. ferri sesquichl. ♈ j. ad ʒ ij., phenic acid gr. j. ad ♈ j., mel. rosæ ʒ j. With this he paints the fauces every two hours, and gives two spoonfuls of the same in water every two hours.—*Wiener Med. Zeit.*, July 8.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

London, 1873.

[Second Notice.]

King's College, London, is admirably suited and situated to be the head-quarters of a great medical or scientific gathering such as that of last week. It is in the very centre of town, close to three great arteries of the metropolitan microcosm—the Strand, the Thames Embankment, and the Thames itself; and it contains plenty of lecture-rooms, theatres, halls, corridors, and staircases, for the purposes of meeting, discussing, lounging, and chatting. The whole of last week it presented a most animated scene. Carriages of all sorts, from the street-cab to the imposing turn-out of the West-end physician, were constantly passing and repassing under the portico, which informs the outer world that everything inside is done *sancte et sapienter*. The hall was a rendezvous, where might be seen at various times nearly every distinguished member of the English profession and many a renowned foreigner; and the theatres, section-rooms, museum, and last but not least the luncheon-room, seemed never to lose their attractions. The greatest credit is due to the Reception Committee. If during the first day or so of the congress some difficulties were experienced, and discontent was heard of, the members of the Association themselves and no others are to be blamed. Intending visitors were invited by the official organ of the Association for several weeks before the meeting to send in their names to the Reception Committee, in order that they might be properly entertained and cared for. About 700 or 800, we believe, did so, but more than 2000 came. Of course so large and unexpected an accession of visitors tested the powers of the entertainers to the utmost; and if at the first there was some want of smoothness in the working of the machinery, it was very soon removed, and everything went pleasantly. As we have said, great credit is due to the Reception Committee; the various members of it contributed munificently to the hospitality, and every effort was made by them to receive and entertain their guests with generous and considerate attention. The arrangements at King's College were chiefly made by Mr. Cunningham and Mr. Fielder; those at University College, by Professor Marshall; at the Mansion House, by Mr. Durham and Mr. Cross for the Lord Mayor; at the College of Surgeons, by Mr. Stone; and the general management was carried out under the direction of Drs. Quain, Wilks, Stewart, Alexander, Henry, John Murray, and Kelly, and Messrs. Callender, E. Hart, W. Tay, and the secretary, Mr. F. Fowke.

Our notice of the proceedings in the last number of this journal terminated with the report of the Address in Surgery delivered by Mr. John Wood. In the afternoon on Thursday the chief event was the delivery of an address at a Conference of Medical Officers of Health by Mr. Ernest Hart, in which he unsparingly criticised the conduct of Mr. Stansfeld, the President of the Local Government Board, in the matter of the appointment of inspectors for carrying out the provisions of the Public Health Act. Instead of consulting the medical officers attached to the Government department over which he presides, and appointing properly trained and instructed medical inspectors, he employed the old lay inspectors of the Poor-law Board, who have acted on no defined policy, and the result has been that we have had official representatives of the Local Government Board giving instructions and advocating a totally different policy in different districts. At the time the appointments were made we drew attention to the great mistake committed by Mr. Stansfeld in not at once employing a staff of medical inspectors to insure the carrying out the provisions of the Act, and we are glad that Mr. Hart has called public attention to the evils which have resulted from the course pursued by the Government authorities.

We must not linger over the description of the dinner in Lincoln's-inn Hall, graced as it was by the presence of Mr. Gladstone, but must hasten on to Friday, when Professor Burdon-Sanderson, F.R.S., delivered the Address in Physiology.

ADDRESS IN PHYSIOLOGY.

By John Burdon-Sanderson, M.D., F.R.S.,
Professor of Practical Physiology in University College.

The subject on which I have to address you to-day is Physiology, but we are met for the purpose of promoting the progress of medicine. We are, I venture to say, rather a practical than a scientific body, having ends and aims which concern our own good, and that of the community, rather than the promotion of science. Yet, notwithstanding, we all feel that we take a great interest in science—not only in those branches of it which have to do with our everyday work, but in those which have little or no connexion with our art.

There exists, I doubt not, in the minds of all of us, a conviction that science possesses a certain intrinsic value not dependent on its immediate applicability to useful ends. Every day we, like other men, are becoming more and more convinced that it is a desirable thing to search after truth by the observation of nature—that those who occupy themselves in this pursuit are substantial benefactors of their country and of the human race—that the scientific labours of a few men, who do not set forth philanthropy as their motive, who do not profess to sacrifice themselves for the good of mankind, who live quiet unobtrusive lives, and are known for the most part only by their work, may accomplish more for the material welfare of the community than the efforts of armies of philanthropists. If I were to attempt to illustrate this, I should have to turn to other subjects than those which we have before us, for physiology has as yet done little for our art, and consequently little for humanity. I should have to seek for examples among the professors of those sciences which are sufficiently advanced to be brought into practical application. When I think of a life like Faraday's, every year of which brought a new accession of knowledge, and in the end enriched this country to such a degree as ought to secure him the posthumous adoration of all Mammon-worshippers, however little they thought of him when alive; and when we compare the results of his life with the life itself, with the contracted laboratory in which he laboured, with the mean salary on which he lived, with his quiet devotion to science, with the constancy of his religious faith, and finally with the end of that life—mind and body exhausted in work—how great in such a man does that insatiable spirit of inquiry seem, which finds its constant and all-sufficient pleasure in the discovery of new truth—in wresting from Nature her secrets by strenuous intellectual effort!

In an address, which I had the honour of giving at the opening of the Physiological Section of the British Association, I endeavoured to combat the now prevailing view, entertained by many men of science, that it is desirable, in the interests of physiology, that it should be as completely as possible separated from medicine, on the ground that, being founded on experimental research, and using the same methods of investigation as are used in the sciences of physics and chemistry, it ought, for all purposes of teaching and study, to be regarded as part of them. I was then addressing an audience of zoologists and botanists, scarcely any, or at all events few, of whom were medical men. I was, therefore, not surprised that the views then expressed, as to the necessary connexion which exists between medicine and physiology, were strongly objected to, and that my belief in the association of practical medicine with any subject deserving the name of a science was attributed to my own professional bias.

I founded my argument on the natural relation which must always exist between every art and the sciences on which it is founded; maintaining that to try to separate medicine from physiology would be as unreasonable as to separate telegraphy from electricity, engineering from mechanics, or navigation from astronomy.

When I was called upon to deliver the Address on Physiology before this Association, I at once determined to follow out the same line of thought—not going over the same ground, but pursuing it in a direction which was before precluded, and which would have neither fitted the occasion nor the composition of the audience at Brighton. Then it was necessary to look at the question from the side of physical science; now I propose to look at it from the side of medicine.

The subject is, I think, one of considerable importance both to medicine and to physiology, but also of considerable difficulty. Conscious of this, I should not have made bold to take it up,

had I not felt that I could entirely depend on your sympathy and indulgence.

I have no doubt that we are all agreed in entertaining a high opinion of the value of physiology, and that we are all anxious to promote its progress. Beyond this, I should not be surprised to find very great differences of opinion. There are probably some who think that every physician ought to be a physiologist—that in the selection of remedies and the diagnosis of disease he ought to call in the aid of physiological considerations, and be guided, not merely by experience (or by empiricism, as we call it when we want to slight its value), but also by science. Freely admitting that physiology is scarcely as yet sufficiently advanced in the work of investigation to advise safely on practical subjects, they would look forward to a time when it will be otherwise; believing that, as the science approaches maturity, it will assume an authority in the decision of practical questions to which now it has no just pretensions. I am convinced, however, that this is not the view usually entertained by the profession at large. The opinion certainly most common is that, although physiology may be a very good thing in its place, conclusions derived from physiological reasoning ought always to give way to the dictates of practical experience, and that science never can be a guide to practice. Those who employ this mode of expression refer, as to a convincing argument in support of it, to the numerous instances in the history of medicine in which the influence of what they are pleased to term *physiological* theory has been injurious.

They refer, *e.g.*, to the overfeeding and overstimulating treatment of disease during the last twenty years; to the unreasonable disuse of venesection; to the neglect of antimony and other so-called antiphlogistics; to the undervaluing of mercurial remedies; to the purgative treatment of cholera; and to other instances in which they say that practical medicine has been injured by allowing *physiological* theory to dominate over experience.

With the exception of the misapplication of a single word I have not very much to object to in the view so expressed. But that word, in relation to the subject of my present discourse, is somewhat important. It is the word "physiological"! The cases on which the whole argument is founded are undoubtedly good examples of the injury done to medicine by allowing theory to dominate over practice; but in no single instance can the theory referred to be termed, with any regard to exactitude of expression, physiological. Take the example of mercurial remedies as the most familiar, and as having relation to a therapeutical investigation set on foot some years ago by this Association. What is the state of the case?

Physiological experiment has proved that mercury exercises no influence in increasing the secretion of the liver. Experience has proved ten thousand times that, in certain sufficiently well-defined disturbances of the digestive organs, the traditional blue-pill and black-draught at once relieve the symptoms, and restore the disordered functions to the normal, and the patient from misery to comfort. These are the two facts, the one physiological, the other practical or empirical. Out of these spring two theories; one that mercurial remedies are useless, the other that mercury acts beneficially by exciting the secretion of bile. Both are demonstrably false. The former, certain writers on the subject are pleased to call physiological. All I can do on the part of physiology is to repudiate it altogether. It is an inference which practical men, and not physiologists, have with sufficient consideration drawn from physiological facts. It is an example, in short, not of the injury which physiology does to medicine, but of the undeserved discredit which practical men throw upon science, by attempting to apply its facts without any sufficient knowledge of their bearing.

I have entered upon these considerations for the purpose of showing that, in the present position of physiology and medicine, it is highly desirable for the welfare of both to draw a distinct line of demarcation between them. On the one side of this line we have what may be properly called the science of medicine—a science in which experiment has no place, its fundamental facts being gathered, not from experiment, but from case-books and the records of post-mortem examinations. Its method consists in systematising and combining the experience of great numbers of trustworthy persons in such a way as to make them applicable to diagnosis and treatment, and admits of being carried out with quite as much exactitude as those methods which are employed in the so-called exact sciences.

In physiology, experiment is everything. Just as the science of medicine proper may be described as based on the observation of cases, and in the orderly classification of the recorded clinical facts, so physiological science is built up of experimental results. Its mode of working is that which is now understood by the term research, the nature of which is best expressed by the well-known words of Harvey, in founding the Harveian Oration, in which he declares his purpose to be that the orator should stir up his hearers to search out the secrets of nature by way of experiment.

The distinction between medicine as an empirical, and physiology as an experimental science, though easy to state, is difficult to maintain practically. For between the two regions of experience and research there lies an intermediate territory of speculation, which is a constant source of temptation even to the most practical mind. Whether he will it or not, he is constantly led by the subjects which occupy his thoughts in practice to speculations on the nature and origin of disease. For every intelligent man—every man who is possessed of that insatiable desire to understand all that he observes, which is the basis of all intellectual effort—has constantly presented to him, in the practice of our profession, facts which furnish the very stimulus required to call the speculative tendency into action. Already practised in the faculty of accurate observation, he is constantly being tempted to undertake the work of investigation; in other words, not to content himself with the appreciation of the facts which bear upon diagnosis and treatment, but to engage in inquiries relating to the intimate nature, the origin and essence, of the diseased processes he has before him.

Is it either possible or desirable to check this tendency to speculation? Certainly not. So long as practical medicine lasts, and the minds of men are constituted as they are, speculation will continue. Practical men will still make excursions into this border-land of imagination; will still make advances, so to speak, towards physiology. Our efforts, therefore, ought to be, not to prevent speculation, not to reject these advances, but, on the contrary, to advance on our side to meet them. For the process by which we get new knowledge is a reciprocal one—theory and experiment, question and answer. The practical mind suggests and theorises; the physiologist doubts, experiments, and tries to answer. Or, putting it in terms more directly applicable to our subject, the clinical observer analyses the facts of disease, separating them from each other, and ascertaining, by the application to the case of the numerical method (the great instrument of his science), which are the most important—*i.e.*, the most constant characteristics of the disease,—and in this way sets questions. The experimental man begins his investigations where the other terminates his analysis; and sets to work, not on the whole disease as it presents itself in its complication of phenomena, but on the simpler processes, such, *e.g.*, as fever, inflammation, catarrh, into which the clinicist has resolved it. With these he proceeds by the same methods as are used in all the other experimental sciences. Having a phenomenon, he seeks for its cause, directing his efforts to the discovery, among the perhaps numerous conditions to which it may be attributed, of the one on which it is actually dependent, and by means of which it can always be reproduced.

In this way both the speculative and the sceptical faculties of the mind are brought into useful exercise—the function of the one being to set questions on the behalf of clinical medicine, of the other to answer them by experiment. So long as this reciprocal relation is maintained, there is no danger in speculation. This danger to science begins when the practical man not only asks his question, but gives his own answer in the name of science. The danger to practice is when he allows such answers, falsely given, to lead him astray from the safe guidance of experience.

I desire to illustrate this reciprocal influence of empirical speculation on the one hand, and experimental scepticism on the other, by a single example—endeavouring to show how, as I have said, both work together for the progress of pathology.

Before proceeding, however, I would guard myself against a misunderstanding. When I place the two functions of suggestive and experimental work, so to speak, in opposition, I do not mean that the two should not be exercised by the same person. For, although there may be conditions in the recent progress of science which render it necessary now, more than in former times, that there should be division of labour, we have abundant proof in the history of our science that the advances have been made by men who have looked at questions from both sides, in whose intellects imagination and

doubt, question and answer, speculation and experiment, have had equal scope.

I now return to my examples. The one that I shall take is that of the Physiology of the Febrile State—a subject which, at the present moment, occupies the attention of a larger number of workers than any other question in pathology. And in pursuance of my plan, I will endeavour, first, to trace the development of the chief scientific theories which prevail on the subject—in other words, the questions which have been asked by clinical medicine, and the responses of experimental science, and then to show in what direction permanent progress can alone be made.

I would state to you at the outset that I shall not have to bring before you any brilliant scientific achievements. On the contrary, you will see that the more sceptically we test the answers already given, the less considerable will they appear in proportion to the numerous questions which still remain unsettled.

At the present moment the theory of fever which exercises the widest influence and is most generally accepted is that of Virchow, the main characteristic of which is that it places the *fons et origo* of the febrile state in the nervous centres. To deal with it I must carry you back to the year 1851, which may be considered as an era in the history of this subject, if not in the development of the science of pathology in general, inasmuch as it is from this year that the use of the thermometer as an instrument of clinical observation may be said to date. For it was in 1851 that Traube, physiologist and physician in one, published the earliest systematised thermometrical observations of febrile diseases.

As regards the doctrine of fever, the effect of the introduction of this method was to bring us back to the notion which is expressed in the old Hippocratic word "pyrexia"—a word which implied the recognition of increase of temperature as the essence of the febrile state. For among the earliest results of the observations of Traube and his immediate followers was the demonstration of the fact—which no one had suspected before—that in fever the elevation of bodily temperature is characteristic of the whole process; and that in those fevers in particular in which the cold and the hot stage are most distinct from each other, the condition of the patient is as truly pyrexic in the former as in the latter, however little it may seem to be so to himself or to others; in short, that amid all the varieties in the subjective state of the patient, in the state of the skin and of the circulation, the objective fact of increased temperature remains.

The immediate expression of the impulse thus given to the pathological thought in reference to fever was the development of the theory of Virchow just referred to. Founded directly on clinical observations, it seeks, like other theories of similar origin, to harmonise these observations with each other by regarding them as parts of the same physiological process. The first step in its construction was to bring the two chief components or constituents of fever—viz., pyrexia and increased discharge of oxidation products—into causal (*i.e.*, physiological) relation with each other.

Virchow's is essentially a neurotic theory. It points to the functional disorder of a hypothetical nervous centre, the so-called regulation or moderation centre, the exact position of which he does not pretend to determine, assigning to it, however, a place somewhere in the intracranial part of the spinal cord. The normal function of this centre is to preside over the bodily temperature; for it is owing to its agency that the oxidation processes, which may be said to constitute the life of out tissues in health, are so controlled that the bodily temperature, even in the most internal parts, never rises above 100° Fahr.

In disease, *i.e.*, in fever, the wholesome influence of this centre is paralysed, and the normal oxidation processes gain the upper hand, as shown by the increased discharge of oxidised products by the lungs and kidneys, and the general wasting of the body, while the temperature rises.

Here I must ask leave to make a digression. While all this was going on in Germany, our own countryman Parkes was observing without theorising in England. So early as 1853 he had made both thermometrical observations and urine analyses in fever, which so far confirmed those of German observers. The results of his observations were published in his Gulstonian lectures on pyrexia. In these lectures, while concurring with Virchow in regarding fever as primarily a neurotic process—a process having its primary seat in the nervous centres—and supporting this view by a variety of convincing arguments derived from clinical observations, he, with characteristic and wise caution, neither followed him into his physiological explanation nor substituted any other theory for it. It is now twenty years since the lectures were published; and although they are full of facts and observations which at the time were new, I do not think they contain any expressions or statements which the author, if he were to republish them, would find it advisable to retract. The reason is that Dr. Parkes approached his subject in a truly sceptical mind, and refused to give way to the besetting temptation to physiologise. He contented himself with setting questions; not that he failed to see with perfect clearness the theoretical bearing of the facts, but because he knew that physiology was not at that time in a position to answer his questions with any approach to certainty. Would that other equally earnest inquirers were endowed with the same wise cautiousness!

To return to Virchow. As I said before, he made no pretension to assign any definite position to the supposed regulation centre, either anatomically or by physiological experiment. The first serious attempt to do so was made by Naunyn and Quincke many years afterwards. The evidence was sought by the method usually followed in physiology. When the physiologist desires to find out what is the value of a particular organ in relation to a particular function, he observes the modifications which that function undergoes when the activity of the organ in question is either disturbed or annulled. In the case of functions of intracranial organs in general, this is a matter of great difficulty; still more is it a difficulty when the organ, like the hypothetical heat-centre, has its seat in the most vital part of the nervous system; for it is not possible to eliminate its activity without interfering with other important activities of neighbouring parts.

These experiments consisted simply in observing the effects of dividing the spinal cord on temperature, under different circumstances, at different heights—viz., at different distances from the medulla. Now ordinarily, when the spinal cord is divided in the cervical portion, the effect on temperature is very marked. The result of the operation is not only (I need scarcely say) to paralyse the voluntary muscles, but to paralyse the vascular nerves.

The consequence of this vaso-motor paralysis is (as has been ascertained by repeated measurement) to retard the circulation, diminish the work done by the heart, and diminish the temperature. The temperature sinks because heat is given off at the surface more rapidly than it is evolved in the tissues—a fact which is proved by the observation that if the animal be wrapped in cotton-wool its cooling is delayed, though it cannot be wholly prevented; while, on the other hand, if its body is immersed in a conducting medium, such as water at the ordinary temperature, so as to favour the loss of heat at the surface, the depression of internal heat is correspondingly accelerated.

The experiment of Naunyn and Quincke may be regarded as an imitation or reproduction of the well-known case of dislocation of the lower cervical veterbræ recorded by the late Sir Benjamin Bredie, in which he observed a very rapid increase of temperature with acceleration of pulse before death. Having destroyed the continuity of the spinal cord by crushing at the level of the sixth or seventh cervical vertebræ, Naunyn and Quincke observed that, if the animal were placed in a chamber at a temperature varying from 82° to 86° Fahr., there was always an elevation of temperature amounting to three or four degrees, which, as in Sir Benjamin Brodie's case, was continued until death. This they attributed to the severance of those channels by which, according to the theory of Virchow, the intracranial part of the spinal cord controls those chemical processes by which heat is produced.

Having repeated the experiments of Naunyn and Quincke on one or two occasions, and failed to obtain any warming effect which could not be accounted for otherwise, I was not surprised, and was indeed somewhat gratified, to find that Professor Rosenthal, in an extensive series of experiments, had come to the same negative result—that is to say, had found that in all cases of division of the cord in the cervical region the effect of the operation is to depress the bodily temperature below the normal standard. The error of Naunyn and Quincke was evidently due to their having neglected to compare carefully the phenomena produced under the influence of the agent to be investigated with those which present themselves under otherwise similar conditions. For it is an invariable rule in experimental investigation, that no result can be accepted as proving the parentage of any given phenomenon until it has been

shown by counter-experiments that the effect is not produced under circumstances which, in every other respect excepting the presence of the supposed cause, are identical with those of the original experiment.

With these recent observations of Rosenthal, the history of the regulation centre theory may for the moment be said to terminate. It has not been definitely proved that the encephalon contains no such centre, but its existence has been rendered extremely improbable. For, although a great number of experiments have been planned for the express purpose of eliciting evidence of its action, all have failed. In few words, the history of the theory is this:—Framed to account for clinical facts, it was for years accepted by clinical pathologists as a good physiological explanation, until at last its importance claimed for it the attention of experimental physiologists, when it was found not to stand the test of investigation.

I now proceed to other theories having this in common, that while they place the origin of the febrile state in disturbance of the nervous system, they explain the influence of that disturbance in the production of pyrexia by supposing it to be exercised through the organs of circulation. There are two such theories which are of sufficient importance to merit attention — one of them is endorsed by Traube, to whose clinical researches at the beginning of the present era in pathology I have already made reference; the other has attached to it the name of the distinguished French physiologist with whose presence we are now honoured. Thrown out by him in a lecture, probably rather as a suggestion than as a mature theory, it has received from medical theorists an extent of application which one may venture to suppose that its reputed author did not contemplate.

Both theories take their start from the ordinary physiological doctrine of the distribution of heat in the bodies of warm-blooded animals. As set forth with admirable clearness by Huxley in his little "School Physiology," it may be stated as follows:—The heat which is communicated to the blood in every living part of the body by the chemical changes which constitute its life, is distributed therefrom to every other part by the blood-stream; but between the external parts—*i.e.*, those which are in contact with relatively cool external media—and the internal parts there is this important difference, that whereas in the interior all is production, at the exterior the production is far more than balanced by the loss—*i.e.*, by the giving off of heat by evaporation and radiation: consequently, if it were not that, by means of the circulation, fresh supplies of heat are constantly being brought to the surface from the warmer parts at the centre, the surface would rapidly cool, as, indeed, it actually does when the circulation is much weakened. Hence, in respect of its function in the distribution of heat, the circulation is rightly compared by physiological teachers to a hot-water apparatus; and they use this similitude, be it observed, not as a representation of the facts, but merely as a diagram or schema. Even for this purpose the ordinary hot-water apparatus requires considerable modification in its plan, in order to serve as an illustration. In the first place, we must suppose that the movement of the water is determined, not, as in the ordinary case, by the variations of density due to heat, but by the action of a pump representing the heart; and that the heat is communicated to the water, not at one focus, the stove, but in all parts of the system (as *e.g.*, still following our friend Huxley, by a number of little gas-jets arranged at short intervals underneath the pipes); and secondly, we must have our pump placed at the centre of the system, and our water-pipes, some in protected positions close to each other and carefully covered with hay-ropes and other appliances for preventing loss of heat, others exposed to the air, divided by repeated branching and kept constantly moist, to represent the conditions of the circulation in the exposed and external parts of the body. So arranged, the apparatus would give us a very true diagram of the circulation in relation to the distribution of heat, and it is not difficult to see what the results would be, both as regards the maintenance of temperature in the whole system and its distribution in different parts. The temperature of the internal protected tubes would be always greater, that of the external exposed tubes always less, than the mean temperature of the whole apparatus; but, provided that the dryness and temperature of the external media and the relative quantities of water passing to the external and internal parts, and the heat communicated by the gas-jets remained unchanged, the mean temperature of the whole system would be constant, just as it is in the animal body. Any alteration of any of these factors would declare itself either in general warming or cooling, which, however, would only go on until a new balance of loss and gain was established. If, *e.g.*, the relative quantity of water flowing through the external parts were increased, either by facilitating the flow in the protected tubes or by hindering it in the exposed ones, this would at once tell in an increase of the general temperature in the whole system, which effect would continue until, by increased evaporation and more rapid radiation at the exposed surfaces, equilibrium was again established. The former condition representing health, this might be regarded as fever.

Out of considerations of this sort sprang the two theories of fever to which we now desire to direct our attention. According to Marcy, fever consists in a general relaxation of the vascular system of the external parts of the body; referring to our schema we find that the effect of this must be to let blood of a higher temperature from the central pump flow more freely into them and warm them up. Hence the hot skin of fever. According to Traube, on the contrary, the surface vessels are contracted; consequently, the flow of blood through the exposed parts is hindered, while that through the internal organs remains unimpeded. Hence, again referring to the schema, the general temperature of the body rises, and you have fever. Is it not strange that on the same physiological scaffolding such opposite structures should be erected?

The vaso-motor theory of fever in either of its forms is not only defective as leaving the collateral constituents of the febrile state (viz., those which relate to nutrition and secretion) unaccounted for, but fails to explain even the very phenomena (those of circulation and bodily temperature) on which it is constructed. It is perfectly true that in the animal body as in the schema, if we alter the relative quantity of blood flowing in external and internal parts, or vary the velocity of the blood-stream, we produce corresponding variations both in the distribution of temperature and in the mean temperature of the body. But experiment shows—1, that the maximum effect thus produced is not comparable in quantity to the elevation of temperature actually observed in fever; and 2, that the direction in which the effect manifests itself varies, being determined by complicated combinations of circumstances of which neither theory takes any account. These are, among others, the external temperature at the time, and the vigour with which the heart responds to the increased resistance. Considering that we can produce much more decided vaso-motor effects experimentally than any which can be supposed to exist in fever, and can graduate those effects at will, we may consider it as proved, at all events as regards vascular contraction, that this condition is quite inadequate to account even for the temperature result attributed to it.

The notion that the heat of skin in fever is dependent upon what may be called a determination of blood to the surface, is in like manner negatived by the fact previously referred to, in relation to the regulation theory that under all varieties of condition the invariable effects of vascular relaxation is the contrary to that which the theory supposes—viz., to depress the bodily temperature,—and that this cooling takes place even when the animal is protected as much as possible from the influence of external media by packing it in cotton-wool and so forth. A more striking, though not to the physiologist a more conclusive, proof of the inadequacy of any conceivable change in the distribution of the blood to produce pyrexia is to be found in an experiment of Liebermeister's, of which I will now endeavour to give an account. It is an experiment not made on dog, cat, or rabbit, but on a willing human subject. It can, however, be substantially repeated on the lower animals with a similar result.

If you take two ordinary warm baths at the temperature of the body, and, after careful agitation of the water, put a healthy person in the one, leaving the other unoccupied; the mass of water in each being the same, and then after a time remove the subject of experiment, and again measure the temperature of the water after agitation, it is found—1, that, whereas in the unoccupied bath the temperature of the water has sunk, the occupied bath has either remained at the same temperature, or at all events has lost less than the other; and 2, that the subject's body has become warmer, because, being surrounded entirely with a conducting medium neither cooler nor warmer than itself, no heat whatever has been lost at the surface; so that all the internal heat produced during the period of immersion has accumulated—that is to say, has gone to the good of the bodily temperature.

This is the experiment. Its value lies in the information it gives us as to the maximum result which can possibly be attained by complete suppression of the surface discharge by mere accumulation of the heat normally produced. The thermometrical results of the experiment as compared with temperature measurements—*e.g.*, intermittent fever during the period of fervescence—show that the rate at which the temperature rises in the accession of ague is at least four times as great as the maximum effect of accumulation.

I need scarcely say that I have not exhausted all the theories of fever in the sketch I have attempted to give of those which propose to explain its phenomena by attributing them either to vascular disturbance on the one hand, or to paralysis of a supposed regulating centre on the other. I now proceed to the second use that I wish to make of my example, to try to show what is the true method of investigation in pathological questions.

How must this question of fever be attacked? It seems to be too strong a position to be carried by assault, and must be got at by a combination of well-directed approaches. The questions must be taken as they present themselves, one by one. This done, the combining of the results into a theory will require as little genius as the taking of a fortress requires military skill from the moment that all the commanding positions are already in the hands of the besiegers.

The first step is to select among the constituent phenomena of fever those which are the most important—in other words, to classify the characteristics of the febrile state according to the greater or less degree in which they are essential. This can of course be done on one principle only, that according to which those phenomena are regarded as most important which are most constantly present. On this principle we have no difficulty in placing pyrexia first; next comes, probably, loss of weight; next, frequency of pulse; and after these other concomitant phenomena more or less dependent on them.

Taking pyrexia as a phenomenon by itself, we want to know how it can be produced. We have but two certainties to start from—first, that in the animal body heat is produced exclusively by chemical change; secondly, that in the particular case to be investigated the rate at which the body is warmed is greater than can be accounted for by any mere accumulation. The first of these propositions is axiomatic, being an almost immediate consequence of the law of conservation of force; the second arises from experiments like that of Liebermeister on the human subject, as well as from others more exact on animals. By the combination of these two propositions we come to the conclusion that such an increase of temperature as occurs in fever must depend on increased oxidation.

The next question relates to the seat of the process—where does such increased oxidation occur? Here we have no sufficient information. Admitting that the most probable answer is—everywhere, that is, that just as heat is produced normally in every tissue it must be so produced in fever, it would be most unjustifiable to assume that it is so.

Of the three or four tissues of which the mass of the animal body is composed—the nervous, the glandular, the connective, and the muscular—there is one only which has as yet been sufficiently investigated in its relation to ordinary heat-production—viz., the muscular. With respect to this tissue, it cannot be shown that it is the special seat of the increased chemical activity which produces fever, but it can be shown that, even if every other source of heat-production were excluded, the variations of intensity of which muscular oxidation is capable would be sufficient quantitatively to account for the variations of bodily temperature which occur in fever. In this respect, therefore, I propose to refer to some of the experimental facts known to physiology as to this heat-producing function of muscle.

I will first mention an experiment which belongs neither to the laboratory nor to the hospital, our two ordinary sources of information. A man works in an extremely hot place, for example the stoke-hole of a tropical steam-vessel, where he is subject to a temperature of perhaps 120° to 130° Fahr. Under such circumstances a dog would soon die, but so efficient is the apparatus for the discharge of heat at the surface in the human body, that not only life but continued muscular work is possible. If now we place the same man under slightly altered circumstances, and set him to work in what is termed a "dead end" in one of the so-called "hot mines" in Cornwall, where not only the air is heated, but the workman is rained upon by the incessant dripping of water at a temperature of say 105° Fahr., so that the air is constantly saturated with moisture, we find that, although the temperature is nothing like so high as in the stoke-hole, he suffers so much more from the effect of it that continued labour is impossible. After remaining by a great effort of the will for ten minutes at the most, he can endure the distress no longer, but rushes out to cool himself, and after a few minutes' rest in a well-ventilated gallery is himself again.

To understand the difference between the two cases, all we have to do is to compare the man's bodily temperature as he escapes exhausted from the hot working with that which he possesses while labouring in the stoke-hole. In both instances there is excessive production of heat, and, as we know from other experiments, excessive discharge from the body of carbonic acid; but in the one the over-production is balanced by the surface cooling, in the other such cooling is impossible, the man's body itself receiving the overplus, which goes on accumulating until, if I may use the expression, he is warmed up into fever—a fever which, although transitory, yet so long as it lasts shows all the characteristics of the febrile state—the quick pulse, the muscular and nervous prostration, the increased temperature, and increased discharge of oxidised products.

The experiment I have been relating is a ready-made one and may be called a rough one; it exemplifies the physiological fact that the excessive heat-production which is determined by muscular exertion, if not compensated for by increased discharge, raises the bodily temperature and thus produces functional disorders which closely correspond to those of fever.

The same thing may be demonstrated with greater exactitude by experiments on animals. Nothing, *e.g.*, could be more striking by way of illustration of the heat-producing function of muscle than the comparison of the effect of the two well-know poisons curare and strychnia on bodily temperature—curare by paralysing the muscles, cooling the body so effectually that, as every experimenter knows, it is impossible with the utmost precautions to prevent the temperature from sinking; while under the influence of strychnia the heat produced is so much increased that the temperature rapidly rises to that of fever.

I trust that, after what has been said, it is scarcely necessary to observe that I am not drifting towards a new theory of pyrexia. My object is not to show that fever has its seat in muscle, but that any process by which vital activity can be increased in a relatively large mass of living tissue is capable of producing a pyrexia which is, in every respect excepting its cause, a counterpart of that of fever. Of the bearing of this conclusion we can judge better if we put it in another form; for in other words it amounts to this, that pyrexia may be produced by any agent, whether originating in the nervous system, as in the case of the man working in the hot mine, or in the blood, as in the case of the animal poisoned by strychnia, which stimulates a great mass of living tissue to increased action. In this way we come back to a very old definition of fever—that fever is the reaction of the living organism against a stimulus. This definition is of value merely as a finger-post, as an indicator of the direction in which we must work. I understand it to mean that, if I am to seek successfully for the proximate cause of fever, I must look for it among agents which act, either directly or indirectly, as excitors or irritants of living tissue. Examples of indirect action I have already given. I now proceed to submit to your consideration a third example, which I conceive to be one of direct action.

It has now come to be an extremely well-known fact in pathology that if the exudation liquids of certain acute inflammations are mixed, even in extremely small quantity, with the blood-stream, the inevitable result is the production of a pyrexia, which in its development, progress, and concomitant phenomena, so far as they have yet been studied, exhibits all the characters of the febrile state. I have no intention of entering at all into the consideration of this remarkable process, and refer to it here merely by way of illustration. I am altogether unable to state on what tissue mass the poison in question exercises its influence; all I want to do is to point out that, whatever answer is eventually given by experiment to this question, the only possible conception that can be formed of its mode of action is that which regards it as a direct tissue-stimulant.

I have not time to enter upon the other constituents of fever, each of which requires as careful and separate investigation as that of pyrexia—the phenomenon of shivering and the changes which accompany it in the circulation, affecting the arterial pressure and the distribution of the blood to different parts; the changes which occur in the hygrometric condition

of the skin and mucous membrane, and in the glandular apparatus connected with the latter; the changes which occur in the tissues in fever, so well investigated by Dr. Beale in the fever of cattle-plague; and last, but not least, the chemical changes which occur in the blood. Each of these requires to form the subject of a separate and detailed investigation, and until this is carried out it is premature to go any further in theorising than is necessary for the purpose of obtaining what I have already indicated as finger-posts.

I have now come to the end of my time if not of your patience, and I must attempt what I feel myself singularly incompetent for—I must appeal to you to use all your influence to promote the prosecution of pathological research in this country.

Having this in view, I chose the subject of fever, partly because I am myself deeply interested in it, and partly because fever and inflammation have always in the history of medicine been the pivots on which pathological teaching has turned. If, therefore, pathology is of any value at all, if it is of use to know not only the external characteristics on which we base our diagnosis of disease, but the internal and hidden processes which constitute its essence, the question of fever cannot fail to interest us. But it is not in support of this or that line of inquiry in particular that I would appeal to you. What I would urge is that this Association ought to help forward pathological research as a thing distinct from, though highly serviceable to, practical medicine and surgery; that we should support it, not merely on the ground of its immediate utility or of the direct applicability of the results to be obtained, but on the broad principle of its scientific value.

As regards the eventual utility of scientific research in general it is not needful for me to address you. You have heard the subject argued, and probably read the numerous publications which have recently appeared in connexion with the work of the Royal Scientific Commission, the result of whose labours I earnestly hope may be to obtain from our legislature a permanent recognition of the national importance of research. As regards physical science in general, indeed, there can I think be no doubt that eventually, and it is to be hoped at no very distant period, this country, which owes its boundless wealth no less to its scientific men than to its statesmen, will tardily but freely and fully acknowledge its obligation.

It is quite possible that our science will not at first participate in the advantages of this change. The question whether it does so or not will, I think, much depend upon the medical profession, of which this Association is the representative body.

By the earnest and energetic pleading of men belonging to our profession, the public ear has been successfully gained for the claims of other branches of physical science not immediately connected with medicine. At the present moment we have a scientific inquiry in progress on a large scale at the public expense which has for a principal object the investigation of a physiological question—viz., that of the physical conditions which govern the distribution of living beings at the bottom of the deep sea. Many of us, I do not doubt, take a deep interest in the success of this undertaking, for the carrying out of which the best instrumental appliances have been provided, and the most skilful and carefully trained observers selected.

I do not refer to this expedition because I think that the magnificent preparations which have been made are at all out of proportion to the importance of the objects. I refer to it for the purpose of making a comparison between these inquiries and those in which we as pathologists are interested. The able staff of naturalists on board the *Challenger* concern themselves with the animals which inhabit the depths of the ocean, and with the conditions which affect their life; we occupy ourselves with human beings and the physical agents which affect their life. These agents are altogether similar in their nature to the others, and require the same methods for their investigation.

We do not for a moment doubt that the care and thought which have been spent in the case of the *Challenger* expedition —in the selection of competent persons as observers, in organising them under a man of science of acknowledged ability, in dividing the work of research among different individuals, in providing them with proper places to work in and proper instruments to work with—have been wisely spent.

Let us, if we desire to promote efficient research in our own province, follow the same principle. Let us not suppose that because in the past history of medicine the employment of an hour here and an hour there, of weary leisure stolen, as it were, from the practical duties of a laborious profession, has accomplished great things, that this is the most efficient way of proceeding now. It must be admitted that circumstances have changed, and that as we possess resources which before did not exist we ought to use them. In the first place we have young men trained in the methods of chemical and physical work, who no doubt would show themselves as zealous and devoted to experimental researches in physiology and pathology as the young men now on board the *Challenger* in their several lines of inquiry. We have long had hospitals as fields of investigation, and now we have laboratories for the proper carrying on of our work. What we chiefly require is organisation, a clear definition of the purposes to be attained, and a combination of the various agencies at our disposal towards their attainment.

I venture to think that it is an object in every respect worthy of this great Association to further and promote the organisation of physiological and pathological research, by fixing on the questions to be investigated, by appointing persons of acknowledged scientific ability to take the direction of the inquiries, by encouraging young men of the highest ability to devote the earlier years of professional life to research, and by providing the necessary funds.

After the reading of Dr. Sanderson's address, Professor Virchow, who was most enthusiastically received, rose and said:—

Gentlemen,—I have accepted the agreeable duty to propose the thanks of this meeting to Dr. Burdon-Sanderson, for his able address. Indeed, he has touched the most important questions concerning the relations between physiology and pathology, or, in other words, between theory and practice. Is it correct, is it a thing of public necessity to advance in the path of experiment and of research, and to induce the profession to bring in strong connexion their practical theories with the theoretical views of modern science? In my country this question is answered in the affirmative sense. I myself commenced the struggle when, twenty-five years ago, I began my *Arehives* of pathological anatomy and physiology, and of clinical medicine, and when I proved the postulate that clinical medicine should be in accord with practical physiology. The victory of this tendency was confirmed when, in 1856, the Prussian Government took the decision to found the first pathological institute. Since that time each year has brought new proofs of the correctness of this mode. In all civilised countries our science has followed the same course, and if now the English Government and the English profession agree to found large pathological institutes, what they do is nothing else but to accomplish that national tendency originated by the two most illustrious members of the College of Physicians and of the College of Surgeons—William Harvey and John Hunter. Each pathological institute in the world is a monument erected to the memory of those two heroes of science; and, gentlemen, I believe, if no other reason existed, it should be a debt of gratitude to establish that sort of institute where *their* method could be pursued and transmitted to the coming generation. But I am somewhat surprised that such a question should be discussed, and the answer be doubtful, in the country which for many centuries has given to the whole world the highest representatives of the successful combination of medical or surgical practice and theoretical speculation. May I be allowed to recall at this time, and in this place, the memory of a man who, after my opinion, is for ever the best example of what a correct method and an intrepid philosophical sense can attain—I mean the memory of Glisson. He, with his colleagues of London, has shown what calm and diligent observation produces in the investigations of the most dark points of practical medicine, when based upon good anatomical knowledge. But the same Glisson, who seemed to be a mere empiric, has employed the most earnest efforts for finding a general formula for the phenomena of life; and it was by following in his footsteps that Haller came to the doctrine of irritability, the fundamental thesis of modern biology. We also, in prosecuting the so-called physiological theory, are in the way of Glisson—the way of good practice. The scientific man, whether he be a practical man or not, analyses, diagnoses, divides the phenomena of life. In this way he arrives very soon at an apparently distinctive result. The unity of life, the unity of disease, however, is destroyed. So in the theory of fever we find no resemblance between

the modern, and generally accepted, view of fever dependent on various local and general influences, and the former doctrine of essential fever, placed in each system of older medicine at the head of the special diseases. What is inflammatory fever now, and what was it forty years ago? Now we know that pneumonia is a local affection, developing itself in a regular series of stages. But these stages do not correspond to the stages of fever concomitant and excited by that local affection. Nay, the fever can cease, the disease, considered as unity, can be finished by a regular crisis, but the local affection is not always finished, it can make further progress, and it can persist by a series of dangerous metamorphoses. The old unitarian doctrine could not give any explanation of these particulars. We observe that pneumonia is a local affection, proceeding ordinarily from lobule to lobule; and, if we look upon the inflamed lung of a man who has died in the stage of acme, we see in the same way, placed side by side, all the different stages of local development—the most advanced hepatisation immediately at the side of red hepatisation, and that at the side of the first signs of the malady. Thus the fever makes its way, and the local affection makes its way; and sometimes we find the local affection without fever, or with only a very insignificant fever. But the local affection is not a single one. Each affected lobule, each affected lung-cell, presents its particular and independent affection. Should the practical man not recognise these compound things? Should he continue to contemplate the disease as a unity, only because the patient is an individual? No, gentleman, disease is a unity only in an elementary organism—in a cell. It is always a compound phenomenon in a higher, in a compound organism; and nobody will have a clear knowledge of disease if he is not enabled to divide the disease into its elementary components. This is shown by that branch of medical science which has now reached the highest degree of scientific surety—ophthalmology—whose methods make it possible to fix real elementary textural alterations, and their continuation to compound diseases. So, gentlemen, will the physiologist divide so-called fever into a series of elementary processes. But I hope the future will show that it was not completely erroneous to believe that all these elementary processes could be reduced to a primary central affection, and that either the vaso-motor nerves or the trophic nerves should derive their roots from the optical centre. But never can we return to the so-called practical view of essential fever; never to the opinion that not only the fever, but also all those local affections combined with it, could form a real unity.

In the evening of Friday, perhaps the most delightful of the *conversaziones* was given by the Professors of University College. Nothing could be more charming than the arrangements and decorations. University College is especially well suited for the purpose of a *conversazione*. The library, the Flaxman gallery, the long corridors, and the portico and grounds, lit up with the electric light, and traversed by numerous groups of well-dressed guests of both sexes, the excellent glee singing under the direction of Dr. F. Roberts, and the music of the Guard's band in front of the portico, left a recollection of pleasurable sensations that will be as lasting as any of the reminiscences of this memorable meeting.

REVIEWS.

Old Age in Bath. By Dr. H. J. Hunter. Bath: W. Lewis. Pp. 75.

We have to thank Dr. Henry Julian Hunter for the very pleasant employment of a before-dinner hour. His little book—recollections of two well-nigh forgotten physicians—Dr. John Sherwen and Dr. Thomas Cogan, both of whom were Bath celebrities—with the addition of some unpublished remains of the poet Wordsworth, and of the late antiquary and genealogist Joseph Hunter, make together as charming a little volume of "ana" as any we have met with for a long time. The literary workmanship is exceedingly good—there is much of taste, much of humour, and here and there a touch of nature which enlists the reader's sympathy, and the anecdotal character of the whole fixes his attention. Dr. Sherwen had been an Indian surgeon. He was educated at Aberdeen, though a Cumberland man. Dr. Hunter gives us a curious tradition of the means taken formerly to recruit the Indian Medical Service, which we hope our Aberdeen friends will forgive us for reproducing:—"It used to be the practice with the Hon. East India Company, when a supply of surgeons was required for the eastern colonies, to send a ship to lie off the city of Aberdeen. A boat was then sent ashore, and aboard the boat was a coal fire and a great stew-pot full of fat English pork and peasc. The lean city was speedily aware of the presence. Pleased with the grateful scent, the granite fronts of the colleges relaxed into a smile, order was loosened, and one by one the hungry young leeches slipped down to the boat. The mess of pottage soon made easy terms, and about a score of medical officers were on their way to the land of pagoda trees." Sherwen in the East studied Shakespeare and philology. Returning to England he practised as a general practitioner at Enfield, and then, after obtaining a medical degree and the recognition of the College of Physicians, he commenced practice at Bath, where he distinguished himself as a writer in the Rowley controversy—maintaining that Chatterton did not forge the Rowley poems—and as a commentator on Shakespeare. It was when travelling in France with Sherwen that Tom Paine, Quaker and *bon vivant*, made the celebrated epigram on Count Zenobio's nose:—

> "Going along the other day
> Upon a certain plan,
> I met a nose upon the way;
> Behind *it* was a man.
> I called upon the nose to stop,
> And, when it had done so,
> The man behind it he came up;
> *They* made Zenobio."

Dr. Cogan was bred as a dissenting minister, but, as he was neither a Calvinist nor did he believe in the everlasting punishment of a great mass of mankind, he quitted the pulpit, married a rich young Dutch lady, studied at Leyden, took a medical degree, and became one of the leading accoucheurs of London. After having made a fortune he first retired to Holland, whence he was driven by the French revolutionary armies, and finally settled at Bath. He is perhaps best known as the founder of the Royal Humane Society, and as a writer on metaphysical subjects. To those of our readers who love scraps of biographical information pleasantly given we can confidently recommend Dr. Hunter's modest little *brochure*. His account of the visit of the late Joseph Hunter to Wordsworth is full of interest—it reminds us of De Quincey's recollections.

The Philosophy of Evolution (An Actonian Prize Essay). By B. Thompson Lowne, M.R.C.S., F.L.S., etc. London: Van Voorst. 1873. Pp. 159.

Mr. Lowne has produced a very readable and well-composed essay on the subject of evolution. We do not find that he has added much, if anything, to the arguments for or against the evolutionary theory; and those who are not convinced of the truth of that theory by the writings of Mr. Darwin and his immediate followers will certainly not be convinced by Mr. Lowne's essay. Nevertheless, Mr. Lowne certainly puts the case for the evolutionists in a sufficiently favourable light; he writes clearly and distinctly, and although his argument, we believe, is by no means sufficient to account in any convincing degree for the facts of the life history of this planet as far as they are known to us, it is a well-drawn account of a speculation which probably shadows forth a partial truth. If we have a fault to find with Mr. Lowne's essay it is with its dogmatic tone. For instance, he tells us the hypothesis of evolution is supported by facts, analogy, and reason, but he forgets to tell us that there are numberless facts it is utterly powerless to explain; he gives but little weight to the fact that there is no evidence whatever of the observed evolution of a new species from a pre-existing form, and that the modifications which are observed under exciting influences never rise to the value or import of specific differences, and are for the most part transitory—altering with the influences which appear to give rise to them. The oft-quoted ascent from the Palæotherium through Hipparion to the Horse is made to do duty in support of the evolutionary hypothesis—although it has always seemed to us that any argument founded on the osseous structures alone of a series of animals must be inconclusive. But, allowing it its full weight, we are not justified in drawing from it an inference stronger than that drawn (in the preface to the "Anatomy of Vertebrates") from it and analogous facts by Professor Owen, whose labours and sagacity have furnished materials for the speculations of many who are not prepared to adopt his cautious reserve.

"The most intelligible idea of homologous parts in such series is that they are due to inheritance. How inherited, or what may be the manner of operance of the secondary cause in the production of species, remains in the hypothetical state exemplified by the guess-endeavours of Lamarck, Darwin, Wallace, and others."

Pharmacopœia of the University College Hospital. Published by Authority of the Medical Committee. Edited by W. Martindale. Printed by Taylor and Francis. 1873.

This is a carefully edited collection of the formulæ in use in the wards of University College Hospital. Many of the combinations seem to us very good ones, and the little book, we think, is worthy of a wider circulation than that for which it has been specially compiled. Besides the hospital pharmacopœia it contains an appendix giving the general heads under which cases should be reported and accounts of autopsies drawn up—an addition useful to the clinical clerk or dresser.

MEDICAL NEWS.

University of London.—The following are lists of the candidates who have passed the recent examinations:—

First M.B. Examination.

First Division.—Harry Beecham Briggs, King's College; Lewis John Hobson, University College; Arthur Henry Jones, Guy's Hospital; Cyril Lloyd Jones, Guy's Hospital; Charles Arthur Mercier, London Hospital; Augustus Joseph Pepper, University College; Thomas King Rogers, University College; Ernest William White, King's College.

Second Division.—Paul Morgan Chapman, University College; Thomas Robert Hood Clunn, Guy's Hospital; Eugène Crétin, St. Bartholomew's Hospital; Edward Joshua Edwardes, St. Mary's Hospital; John Gatchell Hancock, King's College; Leander Starr Jameson, University College; William Henry Lamb, Guy's Hospital; Rhinallt Navalw ap Joan Pughe, Liverpool Royal Infirmary School of Medicine; Bernard Matthias Simon Roth, University College; William Joseph Seward, University College; George Henry Voelcker, University College; George Edward Williamson, London Hospital.

Excluding Physiology.

First Division.—John Christian Ferrier, Guy's Hospital.

Second Division.—Richard Legg Batterbury, King's College; Edward Marriott Cooke, King's College; Herbert Duke, Guy's Hospital; Charles Walter Evans, University College; John Benjamin Hellier, Leeds School of Medicine; Arthur Jermyn Landon, St. Bartholomew's Hospital; John Geoffrey Langley, University College; Wm. Whitchurch Taunton, B.Sc., University College; Benjamin Arthur Whitelegge, University College.

Physiology only.

Second Division.—Richard Hickman, St. Mary's Hospital; George William Homan, King's College; George Hawson Keyworth, Guy's Hospital; James Arthur Rigby, Guy's Hospital.

University of Aberdeen.—During the past year the following candidates, after the usual examinations, received Degrees in Medicine and Surgery:—

The Degree of M.D.

Geo. Roper, M.R.C.S. Eng., L.S.A., Aylsham, Norfolk. At the same time, William Thomas Benham, M.B., C.M., Bristol; Francis Henry Bodman, M.B., Devizes; Alexander Brebner, M.B., C.M., Army Medical Department; Archibald Carmichael, M.B., C.M., Barrow-in-Furness; William Henry Edwards, M.B., C.M., Antigua, W. Indies; James Frederic Goodhart, M.B., C.M., London; Samuel Thomas Knaggs, M.B., C.M., Newcastle, New South Wales; Nathaniel Lawrence, M.B., C.M., Longside; Patrick Mitchell, M.B., C.M., Old Rain; Thomas Raitt, M.B., C.M., Accrington; James Shepherd, M.B., C.M., Aberdeen; Henry Waldo, M.B., C.M., London; Alfred Walker, M.B., London; Charles John Wharry, M.B., C.M., Hong-Kong; and William Whitelaw, M.B., C.M., Cupar-Fife, received promotion to the Degree of M.D.

The Degree of M.B.

James Adams, Kingsbridge, Devon; John Findlay Arthur, Banchory-Devenick; Alfred Baldock, M.R.C.S. Eng., L.S.A., London; Percy Hugh Benson, Whitby; Alexander George Burness, Woburn, Bedfordshire; Anthony Butler, Forres; James Cantlie, M.A., Dufftown, Banffshire; Eber Chambers, M.R.C.S. Eng., Isle of Wight; Louis Richard Connor, Doncaster; Meldon Joseph Dempsey, M.R.C.S. Eng., L.S.A. Lond.; William Donald, King Edward, Banff; Arthur Henry Downes, Munslow, Salop; John Edward Ferguson, Cove, Kincardineshire; Albert Frederick Field, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond., Canterbury; Charles Henry Fowler, M.R.C.S. Eng. and L.S.A., St. Helena; Alexander Davidson Fraser, Aberdeen; John Edward Garner, Woodside, Aberdeen; John Roubel Gray, Aberdeen; William Gregory, L.R.C.P.&S. Edin., India; Charles Cormack Greig, Fyvie; John George Hall, Aberdeen; Henry Arthur Hallett, Poonah, India; Pemberton Abel Hoole, Graham's Town, Cape of Good Hope; Francis Ed. Jackson, M.R.C.S. Eng., L.S.A., Chertsey, Surrey; Walter Gawen King, Poole, Dorset; William Lawson, Tullynessle, Alford; Henry Martin Lechler, London; Ralph Winnington Leftwich, London; William Frederick Lill, M.R.C.S. Eng., L.S.A. Lond., Nottingham; Edward James Lloyd, North Wales; Stephen Mackenzie, M.R.C.S. Eng., London; William Mearns, M.A., Fintray; Forbes Fraser Maitland Moir, Kildrummy; Clement Frederick Fenn Murrell, M.R.C.S. Eng., L.S.A. Lond., Great Yarmouth; Charles Frederic Newcombe, Nottingham; Henry Alfred Alford Nicholls, London; Charles Oakes, L.S.A. Lond., L.M., Dublin; Francis Ogston, Aberdeen; David Aikman Patterson, Dover; William Peacey, M.R.C.S. Eng., London; Henry John Robbins, Wellingborough; William Roberts, M.R.C.S. Eng., L.S.A., London; James Russell, Croydon, Surrey; John Scott, M.A., Aberdeen; William Japp Sinclair, M.A., Laurencekirk; Charles Gordon Lennox Skinner, Ballindalloch; Francis Henry Spencer, M.R.C.S. Eng., L.S.A., Chippenham, Wilts; John Bellhouse Bowden Triggs, L.S.A. Lond., Falmouth, Cornwall; Alex. Reid Urquhart, Elgin; Albert John Venn, Shepton-Mallett; James Walker, Aberdeen; Lionel Alexander Weatherley, Portishead, Somersetshire; William Edward Webb, Winborne, Dorset; Henry Wilcox, St. Neots, Hunts; John Frederick Wilkin, M.R.C.P. Edin. and M.R.C.S. Eng., Folkestone; Alexander John Willcocks, M.R.C.S. Eng., Deyrah Dooa, India; and Robert Mortimer Yule, Aberdeen.

The Degree of C.M.

John Findlay Arthur, Alfred Baldock, Percy Hugh Benson, Alex. George Burness, Anthony Butler, James Cantlie, Eber Chambers, Louis Richard Connor, John Cran, William Douald, Arthur Henry Downes, John Edward Ferguson, Albert Frederick Field, Alex. Davidson Fraser, John Edward Garner, John Roubel Gray, Charles Cormack Greig, John George Hall, Henry Arthur Hallett, Pemberton Abel Hoole, Walter Gawen King, Wm. Lawson, Henry Martin Lechler, Ralph Winnington Leftwich, Edward James Lloyd, Stephen Mackenzie, William Mearns, Forbes Fraser Maitland Moir, Clement Fred. F. Murrell, Charles Frederic Newcombe, Henry Alfred Alford Nicholls, Charles Oakes, Francis Ogston, David Aikman Patterson, William Peacey, Henry John Robbins, William Roberts, James Russell, John Scott, Wm. Japp Sinclair, Charles Gordon Lennox Skinner, Francis Henry Spencer, John B. Bowden Triggs, Alex. Reid Urquhart, Albert John Venn, James Walker, Lionel Alex. Weatherley, William Edward Webb, John Frederick Wilkin, and Robert Mortimer Yule. Of the above-mentioned candidates, Eber Chambers, Arthur Henry Downes, Albert Frederick Field, Stephen Mackenzie, Forbes Fraser Maitland Moir, William Japp Sinclair, and James Walker received their Degrees in Medicine and Surgery, with Highest Academical Honours; Percy Hugh Benson, Ralph Winuington Leftwich, and Henry Wilcox their Degrees in Medicine, with Academical Honours; James Cantlie, Charles Frederic Newcombe, and Alexander Reid Urquhart their Degrees in Surgery, with Academical Honours. The Thesis of Stephen Mackenzie, on "Tumours of the Middle Lobe of the Cerebellum," was considered deserving of high commendation.

At the same time, James M'Call Fehrsen, Henry George Travers Strickland, and William Herbert Williamson were certified as having passed all the Examiuations, but did not graduate.

At the late Graduation Term the following were declared to have passed part of their Examinations:—

Samuel H. Bailey, William Bannerman, Robert S. F. Barnes, Adam Blackhall, Frederick J. Brennand, James H. Cartwright, Walter C. G. Collins, Charles James Connon, William R. Cossham, George Cran, James Cran, Kharshedji A. Dalal, Sorabshah H. Dantra, Rashel T. Davison, William F. Edgelow, Thomas Fiddes, William Geddie, John Harris, Francis Hay, Herbert J. Ilott, John F. Innes, Arthur C. James, John H. Jenkins, T. Siddall Jones, Charles Lamond, Robert Laws, George Le Mottée, John F. Floyd, James P. Lumsden, Alex. M. M'Aldowie, Robt. J. Morice, William Morrish, Alfred K. Newman, John C. Pearson, Alfred E. Prockter, Frederick Robertson, Frederick H. Saunders, Robert G. Smith, Alfred F. Stevens, Alexander F. Trail, Frank W. Trevor, Edward A. White, Henry Cox Wilkin, and Julius J. E. Willmott.

Royal College of Physicians of London.—The following gentleman was elected Fellow of the College on August 6:—James Muter Turnbull, M.D. Edin., 86, Rodney-street, Liverpool.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Aug. 7:

Clift, Martin Luther, Central-street, E.C.
Godrich, Alfred, Fulham-road, S.W.
Risdon, George Owen, Charlwood-street, Pimlico.

The following gentleman also on the same day passed his primary professional examination:—

Little, Henry Selby, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Cox, William Ashley, M.B. Edin., L.R.C.P. Lond., M.R.C.S. Eng.—House-Surgeon to the North Staffordshire Infirmary, Hartshill, Stoke-upon-Trent, *vice* Mr. Alfred Cotterill, resigned.

Dodson, Andrew, M.R.C.S. Eng.—Resident Medical Officer at the Birmingham and Midland Hospital for Sick Children.

Fosbroke, G. H., M.R.C.S.E., L.S.A. Lond.—Medical Officer of Health for Stratford-on-Avon.

Jordan, F. W., M.R.C.S.E., L.R.C.P. Lond.—Assistant House-Surgeon to the Sheffield General Infirmary.

Strange, W., M.D.—Medical Officer of Health for the City of Worcester.

BIRTHS.

Airey.—On August 2, at 27, Dacre-park, Lee, the wife of Hubert Airey, M.D., of a daughter.

Butt.—On August 3, at 12, Kilburn Priory, N.W., the wife of William F. Butt, L.R.C.P. Lond., of 12, South-street, Park-lane, of a daughter.

Collins.—On June 27, at Dorchester House, Montreal, Canada, the wife of W. Collins, M.D., Surgeon Scots Fusilier Guards, of a daughter.

De Lisle.—On August 9, at Panorama House, Guernsey, the wife of Frederick Irving de Lisle, L.R.C.P., of a son.

Ellis.—On August 10, at Shipley, Yorkshire, the wife of W. H. Ellis M.R.C.S.E., of a son.

Leake.—On August 8, at Gertrude Villa, Crescent-road, Ramsgate, the wife of Dr. Jonas R. Leake, H.P. Army Medical Staff, late H.M.'s 80th Regiment, of a son.

MOORE.—On August 9, at Cambridge-heath, London, the wife of Dr. Edward Moore, of a daughter.

WALKER.—On August 7, at 48, Stanley-road, Bootle, the wife of George Charles Walker, M.D., of a son.

MARRIAGES.

BAYLY—DE KRAUCHY.—On July 19, by special licence, at the Church of the Sacred Heart, Camberwell, Alfred Bernard, eldest son of the late Alfred Henry Bayly, M.R.C.S., of Sloane-street, to Bertha, eldest daughter of Count John de Krauchy, Irun, Spain.

BOWER - GUTHRIE.—On August 6, at the parish church, Metheringham, Sleaford, W. Bower, L.R.C.P., L.R.C.S. Edin., son of W. Bower, surgeon, of Metheringham, to Frances Guthrie, second daughter of the late Geo. Guthrie, Esq., of Merevale, Warwickshire.

BRADLEY—GREENWOOD.—On August 6, at Churchkirk, George Alfred, youngest son of the late Christopher Bradley, surgeon, of Church, to Alice, second daughter of the late John Greenwood, Esq., of Fulledge House, Burnley.

COOKSON—SOFFE.—On August 6, at Edisham, near Bungay, Suffolk, Albert Nestfield Cookson, surgeon, Nuneaton, Warwickshire, third son of the late Rev. Frederic Cookson, vicar of Stow Upland, Suffolk, to Frances Jane, only daughter of the late William Soffe, Esq., Romsey, Hampshire.

HARRIS—BUCKLAND.—On August 11, at St. Stephen's, Shepherd's Bush, William Harris, L.R.C.P., etc., Melton, Suffolk, to Annie Buckland, R.A.M., daughter of James Warwick Buckland, Esq., late of H.M. Customs, London.

HONISON—BRAYBROOKE.—On August 6, at St. John's Church, Manchester, Andrew Honison, B.A., M.B., C.M., of Paramatta, New South Wales, to Sarah, second daughter of S. H. Braybrooke, Esq., Northwood House, Manchester.

MCCALMAN—HOGGAN.—On August 7, at St. Jude's, Southsea, Robert, Gilmour McCalman, M.B., C.M., eldest son of the Rev. Hugh McCalman, of Latheron, to Jeannette Marie, eldest daughter of William Hoggan, M.R.C.P. Lond., Staff Surgeon R.N.

MARRIOTT—MAYCOCK.—On August 9, at St. Mary's, Newington, Surrey, William Kenaz, the youngest son of John Marriott, M.D., of Colston Bassett, Bingham, Notts, to Maria, second surviving daughter of Mr. William Maycock, of 59, Lorrimore-road, Kennington.

MEADOWS - BRETT.—On July 2, at St. Paul's Cathedral, Calcutta, Charles J. W. Meadows, Surgeon H.M. Bengal Army, to Clara, younger daughter of Alfred Brett, Esq., The Limes, Peckham, Surrey.

SPURGIN—SALE.—On August 6, at Clifton, Rugby, Herbert Branwhite Spurgin, Surgeon 48th Northampton and Rutland Militia, of Northampton, to Jane Anna, younger daughter of the late Edward Sale, Esq.

DEATHS.

BROWNE, DOROTHY, relict of Robert Caue Browne, M.D., of Arkley Lodge, Herefordshire, on August 10, in her 73rd year.

CLARKE, MARGARET, widow of James Clarke, M.D., at The Knoll, Clevedon, on August 7, aged 85.

DILLON, FANNY PLURA, daughter of the late Garrett Dillon, M.D., late of Spanish-place, Manchester-square.

RAWLINS, ARMSTRONG PLAXTON, only surviving child of Martha and Frederic W. Armstrong Rawlins, M.D., at Stroud-green-road, Finsbury-park, on August 11, aged 3½ years.

REED, RAYNES, Surgeon 2nd Battalion H.M.'s 12th Foot, and eldest son of the late Baynes Roach Reed, M.D., at Ferozepore, Central India, on July 5, aged 37.

WHITE, STEPHEN, L.S.A., at Bayswater, after a few hours' illness, on August 8, in his 81st year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BOURNEMOUTH DISPENSARY.—Resident Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

ESSEX AND COLCHESTER HOSPITAL.—House-Surgeon and Apothecary. Candidates must be duly qualified. Applications, with testimonials, to the Committee, on or before August 21.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Registrar. Particulars may be obtained from the Hospital.

HEREFORDSHIRE RURAL SANITARY AUTHORITIES.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to T. Llanwarne, St. John-street, Hereford, on or before August 19.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Demonstrator of Anatomy. Applications, with testimonials, to R. Harrison, Registrar (of whom particulars may be obtained), before August 13.

NEWTON ABBOT.—Medical Officer of Health. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to John Alsop, East-street, Newton Abbot, Devon, on or before August 16.

ROYAL SOUTH HANTS INFIRMARY, SOUTHAMPTON.—House-Surgeon. Candidates must be M.R.C.S. and L.S.A. Applications, with testimonials, to the Assistant-Secretary, on or before August 16.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Belper Union.—Mr. Cantrell has resigned the Wirksworth District; area 10,865; population 5645; salary £33 per annum.

Droitwich Union.—Mr. Alfred J. G. Waters has resigned the Ombersley District; area 7475; population 2506; salary £62 10s. per annum.

Lodlow and Clavering Union.—The Second District is vacant; area 15,522; population 3834; salary £55 6s. 4d. per annum. The Workhouse is vacant; salary £40 per annum.

Tenterden Union.—Dr. Joyce has resigned the Rolvenden District; area 6650; population 1620; salary £45 per annum.

APPOINTMENTS.

Ampthill Union.—Henry Fredk. Holland, M.D., M.R.C.S.E., L.S.A., to the Workhouse.

Bridgwater Union.—Ephraim F. H. Burroughs, L.R.C.S.I., L.A.H., to the Middlezoy District.

Cirencester Union.—John Douglas Watson, M.B. Edin. and C.M., to the Parish of Sapperton.

Newbury Union.—Richard Hickman, M.R.C.S.E., L.S.A., to the First District.

Woburn Union.—George A. D. Mahon, M.R.C.S., L.S.A., to the Aspley Guise District.

ROYAL COLLEGE OF SURGEONS.—It may save our readers some trouble to remind them that the Library and Museum of the College will be closed as usual during the month of September for the necessary cleaning, dusting, repairs, etc.

MR. GEORGE HAYNES FOSBROKE, son of Mr. Fosbroke, surgeon, of Bidford, has been appointed Medical Officer of Health for the district comprising the unions of Stratford, Evesham, and Alcester, and the towns of Stratford and Evesham, at a salary of £600 per annum. There were sixty-three candidates.

THE first Bishop of British Kaffraria, the Rev. Dr. Callaway, a missionary of the Church of England, at Spring Vale, Natal, just nominated, was some years ago a surgeon in Southwark, and, we believe, the son of the late Mr. Callaway, Surgeon of Guy's Hospital.

THE new infirmary at Lanark, containing thirty beds, has just been opened. The medical officers are Alexander M. Adams, L.R.C.P. Edin., James Ewin, M.D. St. And., and Alexander H. Gray, M.D. Glasg.

THE British Medical Benevolent Fund has received the sum of £30 from Miss Caroline Brown, completing a donation for the present year of £100 from this lady. The pressure on the charity is very great, and half the applications for aid at the last meeting of the Committee were unavoidably postponed or passed over from want of means.

THE Officer of Health of St. George's, Hanover-square, summoned several coffee-dealers last week for selling adulterated coffee. The defence was that pure coffee could not be sold at the price they charged (1s. 4d. and 1s. 5d. per lb.), and that its being a mixture was stated on the packet. The magistrates inflicted fines, and stated that as pure coffee was asked for it should have been supplied; the intimation of its being a mixture was no legal excuse.

THE report of the Committee of Management of the Hospital for Consumption and Diseases of the Chest, Brompton, presented at the quarterly court of the corporation held last week, stated that increased accommodation for seventeen patients had been provided in the "South Branch" in the past quarter. Three more houses opposite had been purchased to carry out their scheme of extension. The Court of Chancery had paid a portion of the late Miss Read's bequest, amounting to £61,938 0s. 1d., new 3 per cent. stock. The number of patients admitted since May 29 was 198; discharged, many greatly benefited, 207; died, 11; new out-patient cases, 2195.

ROBUR.—It is a well-known fact that a new brand of champagne, if it takes with the public, becomes a fortune to the happy proprietor thereof, and that something of the same kind may happen with regard to spirits—our English gin is a standing example. When Dutch William came over, out of compliment to him hollands became the fashionable drink, and the endeavour to imitate it on the part of our distillers resulted in the well-known article which now bears the name of gin. Such being the case, there is no reason why a new flavoured spirit, especially if wholesome, should not make its way. At all events, the proprietors of Robur are endeavouring to try the experiment. This spirit, besides the pure alcohol, contains a flavouring matter derived from tea, and is devoid, they assure us, of any unwholesome constituent. We have taken the trouble to procure a bottle on our own account, and find the liquor of a dark-red colour—somewhat oily-looking—having a taste pleasantly aromatic at first, afterwards slightly bitter, and producing a feeling of warmth at the epigastrium. We take it that it might be exceedingly useful as a kind of liqueur intermediate between dry curaçoa and absinthe, being both aromatic and stimulant.

INDIAN MEDICAL SERVICE.—The following candidates were successful at the competitive examinations for H.M.'s Indian Medical Service, held at London in February, and at Netley in August, 1873, after having passed through a course at the Army Medical School at Netley:—

	Names.	Studied at	Number of Marks.
1.	Wilkie, D.	Glasgow and Berlin	(a)6142
2.	Battersby, W. E.	Dublin	5745
3.	Wall, A. J.	London	5613
4.	Moodie, R.	Edinburgh and Vienna	5511
5.	Goldsmith, S. J.	London	4144
6.	Thomas, A. A.	London	4651
7.	Tuohy, F. S.	Cork	4616
8.	Moynan, W. E. B.	Dublin and Galway	4586
9.	MacDonald, D. P.	Dublin, Cork, and London	4413
10.	Browne, W. R.	Dublin and Belfast	4360
11.	Baker, O.	London	4343
12.	Mallins, H.	Dublin	3915
13.	Wright, F. W.	Edinburgh	3904
14.	Robinson, M.	London	3865
15.	Leapingwell, A.	London	3460
16.	Dill, J. S.	Belfast and Dublin	3200

(a) Has obtained the Herbert Prize.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Dr. Campbell, Christchurch.—Your letter, with enclosure, received.

Sceptic.—A national conference of spiritualists, lasting three days, was held in Liverpool last week. Mr. T. Everitt, of London, presided.

A New Subscriber.—Dr. John Leake was the founder of the Westminster Lying-in Hospital.

Rusticus.—The Ettles Prize of £40 for the best graduate of the year in the University of Edinburgh was awarded on the 1st inst. to Mr. John Wilson Alston, Australia.

THE DILATATION OF STRICTURES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It appears to me, in reading Dr. Tibbit's two fatal cases after Holt's operation in your last week's issue, that the lesson to be learned is—not to hastily attempt too much. Both strictures were split with the largest sized dilator at once. Had the smallest sized dilator been used first and the other sizes in rotation till, at the second or third repetition of the operation, the largest had been attained, the results would in all probability have been different.

I am, &c.,

August 7. A COUNTRY SURGEON.

A Tutor, a Successful Candidate, etc.—We will endeavour to publish the result of the recent Arts examination shortly.

J. B., St. George's.—There will not be any examination at the College until November. The registration will take place, as usual, during the first ten days in October.

B. C. P.—Staff Surgeon S. S. D. Wells, of the *Lord Warden*, has been appointed to the medical charge of Haulbowline Hospital, Malta.

G. O. F.—Francesco Bonafide was an Italian physician and professor of botany at Padua in 1533. He was famous for suggesting the botanical garden established there in 1540, which really began a new era in the knowledge of plants.

THE NOMENCLATURE OF PHTHISICAL DISEASE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have carefully read the great "tubercle" controversy, but I am in doubt whether it is still correct to use the word "tubercular" to express that large class of cases of pulmonary phthisis in which the disease is hereditary and occurs in connexion with large chests, long bones, fine features, and superior intelligence. The word "tubercular," as used in this sense, may have been founded on a fanciful or erroneous pathology; but it should continue to be used to express the same clinical fact till a more appropriate word can be found. I think Dr. Wilks uses the word in this way, and not in connexion with its former pathological meaning.

Shrewsbury, August 9. I am, &c., W. J. MARSH.

Globule.—A committee of homœopathic physicians in Prussia have addressed a formal petition to Prince Bismarck, requesting that professional chairs for homœopathy may be added to the universities, and that medical inspectors may be appointed, to insure proper supervision of the homœopathic practice.

M. W., Wörth.—Claus Wormius, an able Danish physician, was made canon of a Cathedral by Christian IV. as a reward for his medical services, and died in 1654.

THE TESTIMONIAL TO SIR WILLIAM FERGUSSON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It appears that the Edinburgh College of Surgeons are anxious to have a replica of the portrait of Sir William Fergusson which is proposed to be subscribed for to be presented to the London College. As probably the subscriptions will mostly come from Sir William's old pupils at King's College, I would suggest that there be another replica to be presented to King's College Hospital, the scene of Sir William's brilliant success as an operator and a surgeon.

I am, &c.,

Clapham-road, August. AN ASSOCIATE OF KING'S COLLEGE.

A QUERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Is it proper or etiquette for one medical man to refuse a consultation with another when specially asked to do so by the patient or relatives? The cases referred to were as follows:—I was asked by the parent of one patient and the husband of another if I would go to give my advice. I was told at the same time that a professional brother was in attendance. I refused to go until they informed their doctor (who was the same in both cases) that they wished me to visit. I was then asked if I would meet in consultation, to which request I agreed. The parent of the one and husband of the other went to their doctor and requested him to fix a time, but were told that there was no necessity, etc. One of them at the same time asked him to meet another medical man (if he had any objection to me), but this also he refused. I know he would not meet this medical man on any occasion, so I take it that he did not act with courtesy to me. If he was friendly inclined to me, ought he not to have given way to the friends' wishes?

Also I will feel obliged by being informed on the following circumstances:—When a message is left in my consulting-room for me to see a patient who was a stranger to me, and not knowing who was the former medical attendant (if he had any), am I compelled to ask if the family had a regular attendant, or is it the patient's duty to tell me that he wishes me to attend for myself? Supposing that after a few days' attendance I accidentally become aware that such and such a doctor was the former attendant, must I make my bow and leave, although invited to continue? I always make it my business to ask, if sent for to attend a confinement, if I had not been engaged, etc., but I want to know if it is not a sign of wishing to employ me when I am deliberately sent for and no other doctor's name mentioned as having been the family doctor. Is there no such thing as changing the doctor, even though there is no fault found? I am told here that, under all circumstances, I must ask questions of this kind before even prescribing for my patient, and that I must refuse to do so if he had a medical attendant on any former occasion.

An explanation through your valuable columns will, therefore, oblige

M.B., N.Z.

*** 1. It is always a mistake to decline a consultation with a qualified medical practitioner unless some strong personal or moral reason intervenes. 2. We think that it would be better to inquire who has been in attendance. If the patient says that he has dismissed or does not wish to see his former medical attendant, the course is clear. He has a perfect right to employ anyone he pleases.

EXAMINATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—"Dead men tell no tales" runs a proverb denied by the skilled pathologist who accurately traces the course and progress of morbid lesions, finding out where the strain has been most severe, what benefit or injury has been induced by treatment, why and how the beautiful complex machinery of life stands still never to work again. The human body at various ages may be compared to the tiny fragile yacht, the disabled bark, or the battered old hulk cast in sore distress, for which the hidden rocks, the dangerous channels, and the treacherous winds are pointed out to be avoided by the experienced pilot, and the crippled craft steered into the harbours of safety. The honest physician is that pilot. Equally in the detection of crime, in the protection of society, morbid pathology, dogging the footsteps of clinical medicine, brings to light foul play, often brings to the scaffold the most subtle poisoner. At Netley there is of its kind a magnificent pathological museum, illustrating not merely the results of warfare, but also the lesions induced by tropical service, by syphilis, vice, or intemperance, the section including pericarditis, endocarditis, valvular diseases, aneurisms, atheromatous deposits, cardiac abscesses, ulcers, polypi and concretions, all specially valuable. For a number of reasons it is impossible to write an account of the collection just now, but the man who has the time and leisure carefully to examine and epitomise the best specimens, might publish a book of extreme professional interest. A few notes were taken, somehow mislaid, and, unwilling to trust to a treacherous memory, I will not inflict on your readers erroneous statements. There are some wonderful livers enormously enlarged or extremely contracted, else containing gigantic multilocular cysts; one containing a needle; the fatty, waxy, amyloid, cirrhosed, tuberculated, nodulated, gummatised, melanosed, duct dilated, duct obliterated, honeycombed, riddled by hydatids, or containing calcareous deposits,—in short, livers of all denominations, some ruptured by mechanical injury, others peculiar in the number of lobes, others showing the various ways by which abscesses empty themselves. The spleen down to a quarter of an ounce or up to fifty pounds. The kidneys most peculiar in shape, joined together like cocked hats; the capsules enormously dilated. It makes one shudder, to look at a kidney consisting of a shell enclosing a cavity you might put your fist into, to think of the amount of suffering undergone. Abscesses in the brain, disorganisation, foreign bodies embedded, how wonderful that the victims should have survived so long! There are specimens of the "soldier spot," but as this condition is found in civil life and even in young children, this misnomer is now more happily applied to the bald heads of aged assistant-surgeons. Someone has decamped with the money extracted from the thigh of a Hanoverian soldier (shot at Waterloo) who had no pockets, much less cash. In the same manner part of the cranium has been found embedded in the thigh, a tooth in the temporal muscle, and the olecranon of one man in the elbow of another. There is a cabinet of calculi in addition to many instances of calculi in the kidney, and in one man's bladder there are six which occasioned but little pain. The lesions of typhoid fever and dysentery are singularly instructive, especially in pointing out the danger of purgatives. It may not be out of place to give the questions of a recent examination which ought to have been undergone years ago. In middle age to go to school to toil at Gray's "Anatomy," Holmes's "Surgery," Russell Reynolds, Aitken, Parkes's "Hygiene," Green's "Pathology" (a capital book), Blue-books, and tropical medicine, is very hard work, to rake up subjects studied twenty years ago. For a long time specially employed, surgery and morbid anatomy uncommonly rusty, not coming within my province. This examination in one sense is a test, in another it is none, but rejection is simply professional ruin. When a man has been in busy practice for fourteen long years, and the lives of husbands, wives, and children have been

ORIGINAL LECTURES.

LECTURES ON THE DIAGNOSIS OF TUMOURS OF THE BRAIN.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,
Physician to the London Hospital, and to the Hospital for the Epileptic and Paralysed.

Lecture II.

Before I speak of the several classes of symptoms in cases of intra-cranial tumours and other kinds of adventitious products, I have to make a statement which may surprise some of you. It is that occasionally *there are no symptoms* in these cases. And frequently when symptoms are present they are insignificant in comparison with the size of the tumour found post-mortem, or, more correctly speaking, in comparison with what we might theoretically infer from the size of the tumour. But I say "post-mortem"? Well, it is a fact that a patient will *die* without cerebral symptoms—die of non-cerebral disease—and yet an adventitious product be found within his cranium; or he may die suddenly in the midst of apparent good health, and we find an adventitious product of some standing.

It is an abrupt change of subject to speak of *absence* of symptoms after putting them in groups. It was, however, absolutely necessary to group them first, because, although all symptoms *may be* absent, those absent most frequently are the *specially* nervous—those of Class 2 (see page 139). This is just the contrary of what one would expect at first glance.

Now you will understand how it is that I have used such expressions as "may be" with regard to symptoms producible by cerebral tumours. In the cases without symptoms the tumour is nearly always of the cerebrum or cerebellum—not affecting the motor tract. Yet there may be a tumour in the motor tract itself without paralysis. This is rare.

Let me quote authorities as to what I may call the "latency" of intracranial tumours and other adventitious products. Gull says of cerebral abscess—"It is generally seated in the substance of the hemispheres, where it is known that extensive disorgauisation may go on without any indication, provided the corpora striata, thalami optici, and other central parts be not involved, the cerebrum and cerebellum appearing to have, like other organs, a surplusage not required on ordinary occasions."(a) Again Gull says—"In many instances even at last it is not the abscess itself which occasions the symptoms, but the reactive inflammations around it." I will also quote more recent statements on this point. Callender says—"Extensive disease of the brain may thus destroy the upper, back, and middle parts of the hemispheres, without giving rise to symptoms, if we except the occurrence of headache."(b) Dr. T. H. Andrew has collected seventy-two cases of injuries to the brain, "the majority of them being where the ball or shot remained in the interior of the cranium, producing little or no constitutional disturbance, in some few the patient dying many years after from disease entirely foreign to the injury."(c)

However, as the part of the encephalon directly destroyed by the adventitious product, or indirectly incapacitated by squeezing, must have had *some* function, it is safer to say, and quite enough for our present purpose, which is clinical, that frequently there may be no *obvious* or striking symptoms from adventitious products in the cerebrum or cerebellum. Yet when there is no striking defect there may be a dulling of mind (slowness, hebetude, incapacity for *continued* mental exertion); still, there are no *symptoms* which make the patient seek a doctor until perhaps shortly before death. The patient's mind may be so generally reduced to a lower level that neither he nor his friends notice any failure; or they may notice "alterations" of disposition, which they put down to wrong causes—to the influence of external circumstances, for example. There is, doubtless, from every degree of lesion to the cerebral hemisphere, loss of some special or "delicate" intellectual processes, and correspondingly of some of the finer emotions; for every intellectual act is accompanied by emotion. To adapt an expression from ophthalmology, there is no doubt a "limitation of the mental field," a limitation of the area of consciousness. The finer intellectual processes and emotions are not absolutely necessary for ordinary routine life. Hence, slight deteriorations of intellect and feeling are overlooked or are misinterpreted. Slight failure of mental power is only apparent when something occurs demanding more than mere routine application, especially if that something be of a new *kind*. As you know, I believe that when intellect fails the patient is necessarily reduced also to a lower level of feeling (disposition). There is a twofold effect: loss of the finer emotions, and increased excitability of the coarser ones. In slight degrees of mental imperfection there is only a slight exaggeration of the natural disposition: the bad-tempered man takes offence *more* readily, the naturally sensual man indulges with *less* regard to decency, and so on.

Such mental symptoms, when discovered, do not by themselves point to *tumour*. They are, indeed, not symptoms of any *one* sort of pathological process, but symptoms of loss of the most special sensori-motor processes by *any* kind of *slow* pathological change. They point of necessity to the cerebral hemisphere as the part affected by the tumour. But, as we shall see, that part may, as in cases of tumour of the cerebellum, be affected in a very indirect way. There is in tumour of the middle lobe of the cerebellum obstruction to return of blood by the veins of Galen: as a consequence of this there is effusion into the ventricles, and hence squeezing of the cerebral hemispheres.

So far I have spoken of cases in which adventitious products have produced no marked symptoms; neither those of Class 1 nor those of Class 2. But more often there are symptoms of Class 1, but none of Class 2. Very often indeed in the early stage of a case of cerebral tumour there are present only the symptoms mentioned in Class 1; or, to speak in detail, it is common to find in the early stages of cases of intracranial tumour (and other adventitious products) that although there are severe headache, vomiting, and double optic neuritis, there is no palsy, no convulsion, no affection of speech, and no obvious mental failure. Now, as I have told you innumerable times, there may be no defect of sight with optic neuritis, and, therefore, the only symptoms actually presented in the early stages of cerebral tumour may be headache and vomiting. As there are then no nervous symptoms proper, the result is that cases of cerebral tumour are rarely diagnosed in their earliest stages. The symptoms are put down to disorder of the digestive organs, especially of the liver, and to other wrong causes. The "bilious" vomiting especially misleads.

I do not say that tumours of *particular parts* of the cerebrum do not produce special nervous symptoms. When the adventitious product is in the neighbourhood of the left corpus striatum, there may be some defect of speech. I believe, too, that disease in the right cerebral hemisphere—especially in the posterior lobe of that hemisphere—is more likely to cause mental defect than disease in the left hemisphere is: I mean mental defect other than affection of speech. But I now speak very generally, and I repeat, that a large adventitious product may be found in the cerebrum or cerebellum of a patient who has had no obvious symptoms related thereto, either mental or physical, except perhaps shortly before his death, or, at any rate, none severe enough to send him to a doctor. And I repeat that very often the symptoms the patient has are often those not specially nervous—not those of Class 2.

This is of so great importance in many ways that I will relate several cases in illustration. I choose cases which have value for other reasons than because they bear on the matter at present under remark. In particular the cases show that from cerebral abscess and from some cerebral tumours you may have *sudden* symptoms, quite contrary to what theoretically you might expect. The abscess bursts, or vessels of the tumour bleed.

A clinical illustration of latency of an adventitious product is occasionally given by cerebral abscess. (See above quotation from Gull.) In the last volume of our Reports(d) I mentioned the case of a man forty-seven years of age, whom I attended some years ago with Dr. Daniel H. Tuke (then of York); that patient became suddenly comatose and hemiplegic from rupture of an abscess in one cerebral hemisphere into the lateral ventricle. This abscess had no doubt existed for some time. Dr. Talfourd Jones has related in this journal a remarkable case of cerebral abscess of the same bearing. I have made an autopsy on a patient who died

(a) *Guy's Hospital Reports*, vol. iii., 3rd series.
(b) *St. Bartholomew's Hospital Reports*, vol. ii., p. 440: "The Anatomy of Brain Shocks."
(c) *Pennsylvania Hospital Reports*, vol. i.
(d) *London Hospital Reports*, vol. iv., 1868, p. 384.

with hepatic abscess, but who had had cerebral symptoms (convulsions) on the day before his death only, and yet we found three cerebral abscesses. But you may find cerebral abscess in a patient who has died with no noticeable cerebral symptoms. Thus the late Dr. Rooke, of the *Dreadnought*, showed me a brain taken from a patient who died of phthisis, and who had had no cerebral symptoms. I shall shortly speak of abscess of the cerebellum.

The cases for further illustration deserve your careful attention. Death by hæmorrhage from cerebral tumour is an important clinical department of our subject.

In cases of cerebral tumour there is occasionally absence of symptoms until hæmorrhage occurs from the tumour, and then you may have suddenly symptoms of apoplexy; there is cerebral hæmorrhage, although the bleeding is from the vessels of a tumour and not from the legitimate vessels of the brain. This hæmorrhage if large and sudden causes apoplexy. I will give you an illustration (recorded in *Lancet*, November 23, 1869). A man, 56 years of age, was discharged on July 1 from the *Dreadnought* for a simple infraction of the hospital regulations. Dr. Harry Leach, under whose observation the patient had been in that hospital, told me that the only symptom was pain in the head. I must not say, then, that the man had *no* symptoms from the tumour, but that they were not what I have called specially nervous—not those of Class 2. On July 10 he was brought to the London Hospital comatose, and he died there that night. The day before he had been *found in the street* in a condition which led the police to suppose he was drunk; they took him home. As he did not get up next morning he was looked after at mid-day. At the autopsy we found a vascular tumour in the posterior lobe of the left cerebral hemisphere close upon the middle cornu and descending cornu. In the lateral ventricle were several ounces of blood, which had presumably come from the tumour, as no part of the brain was broken up except the wall of the middle cornu near the tumour. Obviously, the diagnosis of cerebral tumour in this case was impossible. As we knew nothing whatever of the patient's previous headache until after the autopsy, we had *no evidence* bearing on the existence of tumour, and if we had heard of the headache it would not have been decisive. Later on I shall mention a case in which, when a patient had got apparently rid of symptoms of tumour, death occurred by apoplexy consequent on hæmorrhage from that tumour— a glioma.

We occasionally obtain illustrations of latency of adventitious products from the cases in which there is secondary cancer of the brain. In some of these cases, while I am as yet unable to say that there are "no obvious cerebral symptoms," we may say that the symptoms are slight in comparison with the extent of the cerebral lesion we find; or, to speak quite strictly, in comparison with what we should from superficial theoretical reasoning infer from the extent of the lesion. A patient died of cancer of the root of the lung. We found post-mortem that the greater part of the right anterior cerebral lobe was cancerous, the grey matter seeming to be replaced by cancer. Besides, there was a mass the size of a walnut just under the surface in the parietal lobe of each cerebral hemisphere. In this case there had been no affection of speech and no paralysis—no *local* paralysis at all events. And as to mind, the only things noticed were that sometimes, not always, the man gave very strange replies, and that he was very odd in his manner—more than odd, for he would get up and make water on the floor. These mental peculiarities of course showed that there was something wrong with the brain; but from them alone not even a guess could have been made either as to the extent of the cerebral disease or as to its nature. It might have been inferred from the fact, or rather from the diagnosis of there being cancer *somewhere* in the patient's body, that even symptoms so trivial or so general were owing to secondary cancer of the brain. But I repeat, *from the cerebral symptoms themselves* we could have arrived at no such grave diagnosis. Of course I do not say that secondary cancer of the brain does not often, nor even usually, produce very marked special nervous symptoms. A little while later Dr. Stephen Mackenzie drew my attention to the case of a patient, afterwards under my care, who had cancer of the root of the lung, and in whom the first observed symptoms were cerebral. It was plain that the brain was seriously damaged, and Dr. Mackenzie's inference that the damage was cancerous was at once accepted by myself, and the autopsy showed that we were right. Whether there shall be special symptoms or not depends on the exact part in which the cancer "happens" to grow.

Absence of symptoms—*i.e.*, of obvious symptoms—is observed in some cases of tumour of the cerebellum. I give you an illustration of the absence of special nervous symptoms from disease of *both* lobes of the cerebellum (case recorded in *Medical Mirror*, September 1, 1869). In 1869 I had under my care a man, 39 years of age, who had paralysis of the right arm, following a convulsive seizure limited to that limb. This symptom, the autopsy showed, was owing to a tumour of the hinder part of the first (uppermost) frontal convolution of the opposite cerebral hemisphere. So here you see a tumour of the cerebrum *did* produce symptoms; but do not omit to notice that the paralysis followed a convulsive seizure; the paralysis of the arm was not produced by the *destroying* action of the tumour. Moreover, the patient had had severe headache, and there were slight changes in his optic discs. But there was also a tumour in each lobe of his cerebellum, although there were no symptoms—no motor symptoms at all events—referable to his cerebellum, for there were no "leg symptoms" of any kind. Twelve days before his death the man walked absolutely well. I say this very confidently. When I first saw the patient I felt certain that we should find at least a little paralysis of the leg, because it is rare to find paralysis of the arm without some weakness of the leg. But I know now, from other cases, that there may be *absolute* palsy limited to a part of the body (face or arm) following a convulsion which has been limited or nearly limited to that part. I have recorded such a case (*St. Andrews Transactions*, vol. iii.).

I told my then clinical clerk, Mr. Clouting, that we should be sure to find at least *some* palsy of the right leg if we got the patient up to walk. But, as I say, the patient walked absolutely well. He walked with naked legs on bare boards. I looked critically, because I only expected to find a *slight* defect in the right leg. During his life I felt certain the patient had disease of the left cerebral hemisphere, but it never occurred to me to suppose that there was disease of the cerebellum. It could not have occurred to me, as there were no symptoms referable to it.

So you see that symptoms from adventitious products in the encephalon are occasionally none at all, and very frequently only those of the first class. In the case of Grimwood (case recorded in this journal, Nov. 16, 1872) there were for a long time the symptoms of the first class only, and even to the last there were no symptoms which we could attribute to the cerebellum, in which we found the tumour. The palsies of the sixth nerves which occurred late in the case were evidently owing to indirect pressure, and not to *destruction* of part of the cerebellum. We have recently had two cases of abscess of one lobe of the cerebellum—one under Mr. Maunder's care and one under my care.(f) In each of these cases, whilst there were some of the symptoms of Class 1, there were no symptoms of Class 2.

The generalisation is that *destruction* of a considerable part of either the cerebrum or cerebellum (especially if that destruction be effected slowly) can occur without the production of striking symptoms of any sort—"mental" or "physical." Now, remark that I say *destruction;* I do not use the vague expression "disease." If even a *small* tumour of the surface of the cerebrum leads to *instability* of neighbouring grey matter, then you may have very marked motor symptoms. You may then have motor symptoms of two opposite sorts. There is first convulsion—the direct result of the discharge of the unstable grey matter,—and second there may be, as an indirect result of the discharge, paralysis of the parts "overworked" in that convulsion.

Let us take an illustration. In the case of tumour of the first left frontal convolution instanced above, the paralysis of the right arm did not occur because that tumour had destroyed so much of the brain—the arm was paralysed after it had been convulsed; it was paralysed as an indirect result of a discharge of grey matter which was not destroyed but very unstable. Here, then, the tumour "caused" paralysis, not as a clot does when it breaks up the motor tract, but in the very indirect way I have described.

Next, observe that a patient may *have had* severe symptoms attributable to an adventitious product in the cranium; he may recover, or at all events get for a while into a state of health so far good as may lead persons who have not made many post-mortem examinations to think the diagnosis of an adventitious product in such a case "unpractical." Thus I saw under the care of Dr. Ramskill, in this hospital, a man, 23

(f) These cases are reported in the Mirror of the *Lancet*, March 29, 1873.

years of age, who had had convulsive seizures, and who had double optic neuritis and intense headache. After a while he was so far well as to go about the ward and to *read the newspaper:* he took his food well. In such cases you may hear it said that there "could be no tumour," because the patient had got rid of his symptoms. There certainly are no strong theoretical reasons why he should not have got rid of symptoms owing to an adventitious product when we know that an adventitious product need not produce any obvious symptoms. The patient died one night in two or three hours by hæmorrhage from a gliomatous tumour of the right anterior lobe. (Autopsy by Dr. Sutton.) I published a brief note of this case (*Lancet*, October 23, 1869).

In that case sight was apparently good; oftener perhaps there is defect or loss of sight to limit the expression "recovery." It is not at all uncommon for a patient to get rid of all symptoms of tumour except that he remains blind or defective in sight. It would be a great mistake to suppose that this sort of recovery negatived tumour.

I have spoken at length on this matter because it is very erroneous to suppose that the absence of paralysis or convulsions, loss or defect of speech, or, in short, the absence of any *specially* nervous symptom—of any symptom in Class 2,—nay, of any symptom whatever,—negatives the existence of an adventitious product within the cranium. If the patient has only the three great symptoms of Class 1, the diagnosis of an adventitious product is almost certain; and this notwithstanding that his general health is good, and notwithstanding that he improves and for a time becomes apparently well. I do not now hesitate to say that in the earliest stage of some of these cases the ophthalmoscope alone will enable you to make a correct diagnosis. If any healthy-looking patient has "bilious" vomiting, severe headache, and optic neuritis (even if his sight be absolutely perfect), it is next to an absolute certainty that that patient has some "coarse" intracranial disease—an adventitious product of some kind, and most probably a tumour.

Another thing to be mentioned is that a patient may live some years with intracranial tumour. A young woman(g) who was under Mr. Hulke's care in 1865 for optic neuritis and other nervous symptoms, and later under mine for a further development of the latter, died in 1872 under the care of Dr. Claye Shaw, in the Leavesden Asylum. A tumour growing from the floor of the right sphenoidal fossa of the skull was found post-mortem.

COMMENTARIES ON DISEASES IN CHILDREN.

By EUSTACE SMITH, M.D. Lond.,

Physician to His Majesty the King of the Belgians,
Physician to the East London Hospital for Children,
Assistant-Physician to the Victoria-park Hospital for Diseases of the Chest.

IV.—Pleurisy.

(*Continued from page* 117.)

Pleurisy in the child frequently passes unrecognised, and in hospital practice it is common enough to meet with cases of the disease the nature of which seems to have been previously misapprehended. "Low fever" or "debility" are names constantly applied to cases of pleuritic effusion; but here, in all probability, the chest had never been examined at all. In other instances, where an examination of the chest had been made, but no doubt very hurriedly and superficially, the disease is spoken of as "liver complaint" or "phthisis." An error in diagnosis is only excusable after we have exhausted all the methods at our command to arrive at a conclusion. In no case of disease in the child should an examination of the chest be omitted, and if there be any obscurity in the symptoms, such an examination is imperatively called for. Even when the examination is made with all care, an error may still be fallen into, and the disease be confounded with pneumonia. This mistake is hardly to be wondered at when we remember the resemblance between the physical signs of the two diseases—a resemblance which is by no means so generally recognised as its importance requires. If, however, we consider the whole aspect of the case, noting the manner of invasion of the disease, and comparing the physical signs with the general symptoms, this, with accurate observation of the character of the signs, will in most cases enable us to avoid an error.

The initial symptoms—pain in the side or belly, followed by cough, with usually fever, but only slight reduction of the strength—should at once suggest pleurisy, and these symptoms are tolerably constant. There is little disturbance of the natural relation between the pulse and the respiration; and the face, unless the pain be severe, seldom shows evidence of distress. In pneumonia the pain in the side, if present at all, is slight, and occurs subsequently to the cough, the pulse-respiration ratio is greatly perverted, the prostration is as a rule extreme, and the child has the aspect of one seriously ill.

When effusion has taken place, the dead, flat percussion-note with greatly increased resistance, the bronchial or weak breathing, and the increased resonance of the voice or cry—these signs discovered at the base, and *found at the front of the chest as well as at the back*, are very characteristic. In basic pneumonia they would be limited, at any rate at first, to the back or the front, and would not be found in both situations; and besides, the puff of fine crepitation caught at the end of a deep breath is seldom absent in pneumonia, and is very different from the larger superficial crackling sound produced in an inflamed pleura. On account of the feebleness of vocal vibration of the chest-wall in children, no information is to be derived from the absence of fremitus unless this is to be felt over other parts of the parietes; nor, on the other hand, does a strong fremitus exclude the presence of fluid, for vibration of the chest-wall may persist even where the effusion is copious. In a boy, aged 10 years, lately a patient in the East London Children's Hospital, and from whose chest ten ounces of fluid were removed by paracentesis, vocal vibration before the operation was well marked, and was little, if at all, weaker over the diseased side than over the healthy part of the chest. Alterations in the voice or cry present in themselves nothing characteristic unless the quality is markedly ægophonic, in which case only may the sign be considered presumptive of the presence of fluid in the chest.

When the effusion reaches high up in the chest the heart is displaced and the intercostal spaces are obliterated, and these are very valuable diagnostic signs. In such a case, too, the complete absence of rhonchus over a dull area of large extent is much more common in pleurisy than in other forms of chest disease, and if present in a case of acute consolidation of the lung would not persist for many days in succession. Again, the alteration in the shape of the affected side, which becomes somewhat square in outline, as evidenced by the cyrtometer, is a very characteristic feature of an extensive pleuritic effusion, and one which is not found in cases of consolidation.

In the diagnosis of pleurisy in the young child, morbid growths in the lung, which in the adult often occasion great perplexity, may be left out of consideration. One case, indeed, occurring in a boy of fourteen, has been placed upon record by Dr. Clifford Allbutt; but such cases are, fortunately, very rare, and I do not know of any instance in which a young child has been found so affected.

A combination of pleurisy with pneumonia is often met with. In these cases the general symptoms are more severe, and the pulse-respiration ratio is perverted; but, if attention be paid to the character and distribution of the physical signs, the presence of fluid can scarcely be overlooked. Often, however, in these cases the pleurisy is of the fibrinous variety in which scarcely any fluid is present. Here, if friction be absent, as so frequently happens in young children, the diagnosis is extremely difficult, and the complication constantly remains undetected. It is common in the post-mortem examination of such cases to meet with recent signs of fibrinous pleurisy, the existence of which had been unsuspected during life.

When pleurisy occupies the right side and the effused fluid is small in amount, its existence sometimes passes unrecognised, especially as friction is often absent, and the very limited dulness is attributed to the liver, which in young children rises higher in the chest than is the case with adults. If, however, proper care be taken, the mistake should not be made. The dulness produced by a small collection of fluid, such as would be present in the case supposed, presents all the characters which have already been sufficiently dilated upon. It is a perfectly dead dulness, and is accompanied by a marked sense of resistance. Besides, the upper limit is very clearly defined; and this is a very important distinguishing mark. In the case

(g) I published the early part of the life-history of her case (*Royal Ophthalmic Hospital Reports*, vol. v., p. 4).

of ordinary liver dulness at the right base, the dulness passes somewhat gradually into clearness, for the thin border of the lung overlies the upper margin of the liver, and so modifies the percussion-note at that point; while in the case of a small liquid effusion the transition from extreme dulness to clearness is usually abrupt. Again, in cases where an enlarged liver rises up into the chest, the dulness reaches to a higher level in the front than at the back, while in the case of fluid the level of dulness, if higher at one point than another, would be highest posteriorly. In all cases of uncertainty percussion should be made while the patient is in different positions, so as to test the effect of gravity upon the dulness. If the note become clear on a change of position, the presence of fluid is placed beyond the possibility of doubt. A good instance of the condition here described is seen in the case of Maurice R., as noted on February 4. If the child had been seen for the first time on that date, the presence of pleurisy might on a careless examination have passed undetected. In cases of basic lung disease, such as that of Martha B., the diagnosis is more difficult. The distinguishing points in that case have already been insisted upon. If any doubt exist, an exploratory puncture with a fine trocar—a proceeding which is absolutely harmless to the patient—should if possible be had recourse to.

The diagnosis between pleurisy and hydrothorax presents some difficulty, for the physical signs are identical—being due in each case to a collection of fluid in the chest cavity. Hydrothorax, however, is usually double, and there is no accession of fever when the effusion occurs, as is almost always the case at the onset of a secondary pleurisy. Besides, in a passive exudation resulting from some impediment to the circulation, evidence is usually to be obtained of similar effusions taking place in other parts of the body.

Between pleurisy and collapse of the lung the distinguishing points have already been discussed in a previous paper. (See *Medical Times and Gazette*, May 31, p. 568.)

Simple primary pleurisy generally ends in recovery, and even when the disease has reached the stage of empyema the prognosis is not as a rule unfavourable. The great danger in such cases is the occurrence of acute tuberculosis as a result of the purulent collection. In estimating the chances of recovery in a case of empyema, the thermometer is a very trustworthy guide. If the temperature remains high we should always regard the symptom with anxiety, although such cases do not necessarily end badly; but if, after remaining high for a considerable time, the evening temperature suddenly falls to a point below the natural level of health, an unfavourable termination to the disease may be regarded as imminent.

The age of the child has not appeared to me to influence the prognosis of primary pleurisy. Infants, if strong, have seemed to do as well as older children; but pleurisy, attacking an infant worn and wasted by a long course of bad feeding, is necessarily a very fatal disease.

In secondary pleurisy the danger is in proportion to the degree of weakness of the patient at the time the complication occurs. On account of the serious reduction of the strength which takes place in pneumonia, pleurisy coming on secondarily in such a case renders the chance of the patient's recovery very doubtful indeed.

The treatment of pleurisy at first is simple, and consists in perfect quiet, warmth to the chest, a carefully ordered diet, and the administration of a simple saline. The severe measures which used to be at once resorted to in the treatment of every case of pleuritic effusion, are now set aside for simpler remedies. Bleeding need only be mentioned to be condemned. The only form in which it would be for a moment admissible is that of the application of a leech to the side to relieve pain; but this is now unnecessary, as we have in the hypodermic injecting syringe an instrument which enables us to effect the same object rapidly, and without the withdrawal of blood. In pleurisy a child wants all his strength, and to lower it is to do him harm. Mercury, again, which used to be the indispensable remedy at a time when its influence in promoting the absorption of all serous exudations was held in universal belief, is now practically abandoned in the treatment of pleurisy. In children the drug should never be given unless the indications for its employment are very decided, on account of the anæmia and depression which it is so apt to induce; and the best authorities now concur in believing its value as an absorbent in cases of pleuritic effusions to be more than doubtful.

The child should be kept perfectly quiet in bed. Hot linseed-meal poultices, frequently renewed, should be applied to his chest; or the upper part of the body may be swathed, not too tightly, in a broad flannel bandage wound round and round the chest and crossed over the shoulders. His diet should be carefully suited to his powers of digestion, and should consist principally of milk and light broth. For medicine he may take a citrate of potash mixture or a draught containing a solution of acetate of ammonia with sweet spirits of nitre. If the pain in the side be severe, the hypodermic injection of morphia, in the proportion of one-thirtieth of a grain for a child of twelve months old, will give very rapid relief.

In children who are old enough to describe their sensations, very severe pain referred to the epigastrium and accompanied by marked oppression of breathing is usually indicative of inflammation affecting the pleura overlying the diaphragm; and in such cases the action of this muscle during respiration may cause great suffering. When this occurs the application of a bandage to the belly, so as considerably to restrict the action of the diaphragm, will often give immediate ease.

If the cough be distressing, small doses of opium should be given by the mouth. It is important to keep the bowels properly relieved, for any distension of the stomach would increase the uneasiness of the patient. For the same reason a careful watch should be kept over the digestive functions, and any signs of dyspeptic fermentation of food should at once cause us to reconsider the dietary, and restrict the quantity of farinaceous or other fermentable matter which is being taken. Violent purgation is to be avoided, for, as in all acute chest disorders, irritation of the bowels seems to be attended with anything but benefit to the patient.

When effusion into the pleura has ceased, measures must be at once adopted to hasten absorption of the fluid. Counter-irritation of the chest-wall has long been extensively employed to effect this object, and although the value of the practice has lately been called in question, yet in this disease it has always seemed to me to yield very satisfactory results. I have certainly met with many cases where fluid, which under treatment previously adopted had not perceptibly diminished in quantity, has begun at once to be absorbed immediately that counter-irritation was made use of, and this although the other treatment remained in all respects the same. I prefer the tincture of iodine to any other form of counter-irritant. A spot about the size of the palm of the hand should be well painted over with the tincture twice a day until the skin begins to crack and peel. Another spot of the same size should then be selected, and the process be repeated in exactly the same manner.

At this time the child should be put upon as dry a diet as possible, for by diminishing the quantity of fluid taken into the body the blood is stinted of necessary liquid, and a stimulus is thus given to absorption. For medicines the iodide of potassium is very useful, and generally increases very much the secretion from the kidneys. Iron, in the form of the tincture of the perchloride, is also of great service, and should be given in tolerably large doses—five to twenty drops, according to the age.

If the above measures are not found to produce the desired result it will be necessary at once to consider the advisability of paracentesis. This can now be done so completely without risk by the pneumatic aspirator that there should be no hesitation about performing the operation the moment it is thought advisable to do so. On account of the early period at which the fluid becomes purulent in children, and the danger of such purulent collection giving rise to tuberculosis—a result of the disease which ought especially to be guarded against,—an effusion should never be allowed to remain longer than three weeks if no signs of absorption have been discovered. Even before that period it is sometimes necessary to evacuate the pleural contents. Thus, if, without causing actual attacks of dyspnœa, the accumulation of fluid be so great as to press upon the opposite lung and hamper the breathing, or if there have been several fits of dyspnœa when the collection of fluid is large—in either case the operation should be performed without unnecessary delay.

A fine canula should be chosen, and the puncture should be made, as recommended by Bowditch, in a line drawn downwards from the angle of the scapula. Bowditch recommends the operator to ascertain by percussion the inferior limits of the sound lung, and to introduce the canula two inches above this level on the affected side. If, on account of the thickness of false membranes, no fluid is found at the spot first selected, a second puncture can be made a little higher up, nearer the axillary line. The whole of the fluid need not be withdrawn,

for the operation usually gives a sufficient impetus to absorption to enable the rest of the fluid to be removed by the natural processes of nature. If, however, this should not be the case, and purulent fluid should reform and become offensive, the fluid should be withdrawn as completely as possible, and the pleura should then be washed out with warm water, or with a weak solution of carbolic acid. If this plan do not succeed, one of Chassaignac's fenestrated drainage-tubes may be passed through the original opening and be brought out at another part of the intercostal space. The ends of the tube can then be tied loosely together. By this means accumulation of matter is prevented, the fluid slowly draining away.

A better plan, however, of treating these cases, and one which prevents the admission of air, is that perfected by Dr. Playfair, and advocated by him in his paper read before the Medico-Chirurgical Society, and published in vol. xiv. of the *Transactions*. The chest is perforated by a canula just large enough to allow the passage of a piece of ordinary fine drainage-tubing. This is passed through the canula directly the flow of pus is found to be free, and the canula is withdrawn. The free end of the drainage-pipe is then attached to a short glass tube, to the other end of which is fitted several feet of ordinary caoutchouc tubing. This last dips into a bottle half full of water. The apparatus, when applied, is left in position for as many days as pus continues to flow, being kept in place by a fine wire twisted round the drainage-pipe as it issues from the chest, and fixed by strapping to the chest-wall. If properly adapted, the integuments close round the tube at its point of exit, and prevent the entrance of air.

If the case be seen for the first time when the empyema is pointing, the swelling should be immediately lanced, so as to allow of the escape of the fluid. The diet at this time should be as nutritious as possible. Meat, eggs, and milk should be given as freely as the child's powers of digestion will allow, but the stomach should not be overloaded with too large a quantity of food at one time. Especial care, indeed, should be taken not to *overfeed* the patient in our anxiety to supply material necessary to enable him to withstand the exhausting drain upon his system caused by the purulent discharge. Cod-liver oil is very useful in such cases, and I have found Dr. de Jongh's light-brown oil to be more completely digested by weakly children than the oils in common use in hospitals. M. Dubouć recommends the administration of tannin after evacuation of the fluid in empyema. He states that this drug acts as a tonic astringent, improving digestion and diminishing secretion. It may be given in doses of from three to five grains several times in the day. Small quantities of wine or brandy are also required in these cases.

The above method of treatment is also applicable to cases of secondary pleurisy accompanied by effusion of fluid. In dry pleurisies, such as are common in cases of phthisis, the pain is best relieved by mustard poultices, or by small blisters if the child be old enough.

ORIGINAL COMMUNICATIONS.

ON CONSTIPATION SIMULATING DIARRHŒA.(a)

By DAVID NELSON, M.D. Edin.,

Formerly Physician to the Queen's Hospital, and Professor of Clinical Medicine; afterwards Professor of the Principles and Practice of Medicine in the Queen's College.

The present paper is brought before you, not from there being anything very recondite in the matter, but from the number and great frequency of the cases in which I have observed an overlooking of the true causes at work in the production of what is viewed as a common-place complaint, and the serious consequences which have accrued from such inattention. Indeed, these so-called simple and ordinary ailments are of far greater material and vital interest to mankind at large than those others that are certainly very fatal, but comparatively uncommon, yet which, on that very account, are full of a curious and attractive interest, denied to those others which really ought to claim a close attention from their great mortality in the aggregate; just as it has happened again and again that more persons have died, in certain seasons, of an epidemic influenza than of typhus.

(a) Read before the Midland Medical Society, Birmingham.

It is from this tendency in the general mass of human beings that we see medical students often deserting the routine of cases in the wards of a hospital, and rushing afar off to witness one of catalepsy or hydrophobia; and the surgical pupils perhaps habitually neglecting that on which they will be mostly employed in their after practice, and yet crowding the operating theatre to see the performance of lithotomy or excision of the tongue—exploits which they have no more intention of ever attempting to imitate than of flying to the moon. Not that these latter spectacles should be neglected,—very far from it; but that a student should, at the same time, pay due attention to those matters which shall form the chief business of his after-life, as well as indulge this natural curiosity upon others which he shall never in all probability be called upon to treat.

> "Rightly to know
> That which before us lies in daily life
> Is the prime wisdom."

This subject which I now handle is one of those matters of daily concern, not simple, but involving the whole complicated question of nutrition and evacuation, though it be only in connexion with the latter function that I now propose to consider it. In the natural and healthy state of the intestines, much latitude is to be allowed in consistency with general soundness of condition, under that law of compensation which rules throughout all nature, but more especially within living organisms, where, in the oscillation of action and reaction, we daily find fit balances ultimately maintained, notwithstanding innumerable variations of circumstances leading to extremely opposite conditions of functional activity and functional repose. In the function now under consideration—namely, that of periodical evacuation—the latitude under varying conditions is, as I have said, considerable, for it will be modified either by repletion or starvation,—the first augmenting and the second diminishing the body of excrement; or by active exercise or sedentary habits,—the one exalting and the other depressing the nervous and muscular energies for purposes of expulsion. Besides these usual and natural variations, there have been, of course, abundant curious instances in both extremes, such as those two cases in Heberden's practice, the one patient having an intestinal motion only once in a month, and the other being moved twelve times a day through a period of thirty years. Some have been known to aver that this irregularity of the function, even to a great degree, does not materially affect health, and have practically acted upon that belief, while others have looked upon even a moderate amount of stiffness or firmness as a serious consideration, and to be rectified forthwith by purgatives. Thus it is, as the public saying goes, "Doctors do *indeed differ*." How such differences tend to shake confidence in the faculty at large, was instanced to me by one who had been a resident medical officer in a hospital where one of the physicians (of the evacuative school), examining one of his patients, laid great stress upon the function being in abeyance even for a brief time. It so happened that the occupant of the next bed, not having had a motion for three days or so, took alarm, and drew the attention of *his* physician (of an opposite school) to that fact, when he received the more confounding than consolatory reply, that it did not matter if it were a week or even more.

But, putting aside occasional alternations of inaction followed by a compensatory and safe reaction, and admitting that actual disease may not always accrue from protracted constipation; yet, seeing that, from the undue retention of such offensive and effete matters, there must be reabsorption and the determination of disagreeable molecules and odours to the skin, lungs, and elsewhere, and taking also into account the natural habits of the cat and dog tribes, whose food and other modes of living are so similar, so far as they go, to those of man, we are led from such facts and analogies to concur with the view of so acute and profound an observer as Cullen—viz., that every deviation from one diurnal motion is an approach to an unnatural state; that is to say, an approach, however slight, towards actual disease, repeated approaches bringing the patient nearer and nearer to it.

Accepting this, as I do, it follows that, whenever such deviation occurs, there should be an endeavour to restore or induce natural action; not, certainly, by any powerful appeals, such as are made by calomel, or jalap, or the popular salts and senna, but it may be merely by some judicious alteration in diet, or a resort to more active exercise; or, if these fail, to the very mildest forms of aperient, rather calculated to arouse peristaltic action than to stimulate the mucous and other follicles. We know that patients, especially of the lower class,

are very apt to neglect this function, and that workpeople of very sedentary habits, such as shoemakers, tailors, dressmakers, etc., suffer more especially from such neglect; though there be another set who, through hints from newspaper advertisements, etc., do, on the contrary, always have an array of pills and a stock of Epsom salts and senna on hand, with which they proceed to do execution, but in such wise that the shaking received by the general system from so violent an excitement, followed by depression, deters them from resorting to the remedy again until matters have once more gone ahead; and thus they subject their bodies to alternations of such extreme constipation and extreme purgation as gradually leads up to the onset of some formidable chronic symptoms, which the physician, however, is expected to rectify at once by a few strokes of his pen.

Amongst these is this false diarrhœa, or the simulation thereof by actual constipation, in which frequent and teasing, but ineffectual, evacuations occur many times in the day, with abdominal pains and nausea, the whole of such evacuations put together not nearly equalling one natural motion. Yet most patients, whether of a higher or lower class, only excepting the comparatively few who have been taught to regard with proper and prudent respect the mystery of physic and of nature as its domain, and to know

"What dire results from small beginnings flow,"—

most of them, I say, are apt to think that such symptoms as either constipation or looseness obviously speak for themselves, and utter, as it were, their own diagnosis from within their own bodies, and do not require any regular medical investigation. Hence it is that self or home treatment, with an appeal to the druggist as to what he thinks is most effectual in either case, is too often the rule; and hence there shall and does accrue, in too many instances, a steady augmentation of the fundamental real malady, with an apparent but delusive relief of the leading sensational and visible phenomena from time to time, such as pain or this seeming diarrhœa. Nor only in self or home treatment alone or under druggists may these results occur, but also amongst parochial and club patients when the practitioner is too often either overburdened by others or self-burdened with excess of work, which he must accomplish within a given time or else expose himself to unjust but ruinous complaints. And the same observation applies to the out-patient system of hospitals and dispensaries and to all of us in common under similar circumstances, when, under the pressure of business disproportionate to time, we ask the patient what he complains of, and prescribe in accordance with his statement of affairs, although a few brief questions and a few taps on the abdomen might perhaps settle the point.

Of course there are sundry remoter as well as direct causes of this obstipative condition of the intestines, such as tumours, be they cancerous, scirrhous, or otherwise; thickening and ordinary hardening of the coats of the gut; enlargement and adhesion or fixity of the womb, or pregnancy, or swelled prostate gland, and old hæmorrhoids; besides torpidity of the liver, with pale fæces; or too little or too mild a diet; or primary loss of muscular tone and of nervous sensibility from brain or spine disease; or secondary paralytic inertness from long-continued pressure and overstretching of the muscular fibres, leading to a loss of sensibility and of contractile power; or a like state induced by a habit of resisting the calls of nature from mere laziness, and disinclination to leave a warm bed or a warm room in cold or rough weather.

If the constipation exists simply by itself, it is clearly recognised, and remedies, appropriate or inappropriate, just as the case may be—but, at all events, so as to be efficient for the expulsion of fæces,—are employed; but if it assume the character above indicated, of frequent, troublesome, and petty efforts, and small discharges, with colicky pains, then the very opposite treatment is often adopted, and chalk and catechu mixture, with opiates, resorted to, with decided arrest of the annoying evacuations and a riddance from tormenting pains: but with a steady increase of the source of the evil, and a propagation of the disease upwards, till an habitual dyspepsia, that has all along troubled the patient with a sense of heaviness, and constant eructations of gas, and perhaps mouthfuls of sour fluid, culminates in a thorough prostration of the natural powers of the stomach and liver, with regurgitation of vitiated sour bile or choleic acid, and a rejection of all food, even though it should be but a little milk or small quantities of tea, or even spoonfuls of water, putting out of the question meat, or bread, or vegetables, or wine, or beer.

In so-called diarrhœa of this kind, it will be found, as already observed, that all the numerous motions in a day will not, united, equal one proper clearance. It will also be found that amidst the liquid dejections there shall be generally, or from time to time, discovered—it may be very minute, but yet very hard, fragments of indurated fæces, like small grit, but still indicating the source from which it has come; as well as, in some instances, agglomerated particles of chalk, along with a peculiar odour belonging to long-retained fæcal excrement—"an ancient and fish-like smell," as Shakespeare has it,—combined with that of foul brass or oxidised copper. There will likewise be discovered, under percussion, a deeply marked dulness of sound, either over the greater part of the abdomen, or at least in some part or parts, more or less, over the course of the colon; and perhaps even large hard masses may be felt, resembling cancer or scirrhus, or other such solid tumour, though a tolerably sure distinction may generally be at once drawn by the experienced examiner, from the physiognomical aspect and complexion of the patient, coupled with the previous history of the case and the general condition of the body.

And now for our procedure as to treatment. For that, I think, we must be guided by numerous collateral considerations of age, sex, and general strength and condition, though one invariable rule must govern in every case—namely, that no very potent or active remedies should be used in the first instance, lest from the induction of a very powerful action from above or below—though chiefly from above,—and before the obstructing matters are ready to yield easily and safely, we may bring about such a struggle and commotion midway as shall not only inflict violent pain, but it may be usher in death itself, from inflammatory processes or from intussusception. The milder aperients, therefore, will be first called into play, not, however, excluding from that category small doses of blue pill, such as three or four grains, in union with a like amount of socotrine aloes, or some of the watery extracts, coupled with ipecacuanha and capsicum or ginger. But, along with these, it is generally desirable to make use of mild injections—say, merely gruel and olive oil, but frequently repeated, and in considerable quantity; while, for subduction of the acid or oily vomitings, draughts of bicarbonate of soda or potassa, with calumba and hydrocyanic acid, such draughts being administered in teaspoonfuls at a time and at intervals of two or three minutes, being also diluted with iced water, which iced water, by itself, may be taken as the patient desires.

If we be called upon to act at this comparatively early stage—though it be, indeed, a late one, so far as the lower intestines are concerned—then I think we may reasonably hope for success by the employment of such safe and mild aperients, aided by such kind of injections and such stomachic draughts, along with abstinence from all food, except perhaps of the most mild liquid kind, and even then in the smallest quantities at a time, and cooled with ice, as above said. Under a treatment of this sort the sickness and vomiting are likely to be subdued, and the natural peristaltic action restored, the flatus ceasing to be projected from the gullet, and rather making its way in a downward course, as felt and heard by the patient himself. The pains may fluctuate, becoming more or less severe as the hard masses or imprisoned gases may be forced through the twistings of the gut; but if all go right there will finally be a thorough clearance, with complete relief from all the symptoms, and a permanently improved state of health by judicious counsel as to future diet and general regimen.

But we may encounter cases of a more complicated and obstinate order, in which more potent and special agents have to be resorted to by the mouth; while the injections have to be raised to a more stimulating efficacy by the addition of strong salines, or oil of turpentine, or asafœtida. Of such agents it may here be as well to take a review in their relation to the age, strength, and general condition of the sufferer, as well as to each of their own peculiar modes of action. And first, as regards the most extensively operating and efficient amongst them—namely, calomel,—it may be observed that this medicament, as stimulating the liver, the pancreas, and the whole system of minuter glands along the digestive tract, is especially available after the failure of simpler remedies, having some other purgative conjoined with it, as aloes or colocynth, and such a carminative as ginger or capsicum,—not excluding opium if the pain be severe, which does not, when in moderate quantity, materially retard the purgative action, but only modifies it. Besides the socotrine aloes and extract of colocynth above spoken of, others, according to their

ordinary usage, might use the scammony or gamboge; but I should always feel disposed to have most of such matters in the form of watery extract, because I believe their more vehement and protracted griping qualities are due to the particles of their insoluble resins clinging to the mucous surface, and thereby keeping up a violent and useless commotion, very undesirable in the cases under consideration, nay, dangerous in the extreme under certain circumstances. Even the calomel, which acts with so slow, heavy, and effectual, but exhausting or depressing force, I should confine for use upon the young and vigorous only, unless other agents failed. The podophyllin acts much after the manner of calomel, but with more protracted squeezing of the liver, if one may so speak; for while the first usually dislodges the masses along with a clay-like semi-fluid in which such harder masses seem embedded, the podophyllin in corresponding doses will continue to gripe and gripe with numerous straining motions, like those of dysentery, and amounting at last to mere spirtings of a yellow bilious mucus, though that perhaps might be obviated by the employment of a like watery extract thereof,—even as the griping of senna is prevented by the infusion being made from cold instead of hot water. As to croton oil, I should seldom be inclined to use it, except in cases of stupor; and though some gentlemen present may possibly consider it a mere prejudice on my part, I am no friend of elaterium under any circumstances at all—except, perhaps, in certain cases of ascites or hydrothorax. In anasarcous dropsies the work of this elaterium may be as effectually performed, and much more safely, by a combination of the supertartrate of potassa with a moderate admixture of jalap, joined with ginger. Jalap, of course, requires the same caution in its use as the others; but the supertartrate of potassa in small doses has a most satisfactory effect in inviting an additional flow of mucus, and thus melting or softening down the hardened fæces in a quiet manner, without that exhausting and drastic action which characterises its exhibition in full doses. This, therefore, as well as the other saline aperients, such as the acidified sulphates of soda or magnesia, or Seidlitz powders, combined with compound tincture of senna or otherwise, according to circumstances, are useful as adjuncts. The oil of turpentine I should never think of employing in such cases through the mouth; though, as already observed, it may prove a very valuable remedy indeed, especially when joined with asafœtida, in sluggishness of the colon, by acting directly thereon as a powerful and warming stimulant.

(*To be continued.*)

PRACTICE OF MEDICINE IN SMYRNA: POISONING.

By JAMES M'CRAITH, M.D., F.R.C.S.,
Surgeon to the British Seamen's Hospital, Smyrna.

Poisoning is an art pretty well known in the East, but until lately very few cases were brought to light. Lately the Turkish tribunals pursue and punish the perpetrators, and in doubtful circumstances investigate the case. In three instances I have been mixed up in the investigation. In two of these cases I have been able to prove the presence of arsenic; in the third case I believe no poisoning took place. This was the case of a captain in the army, whose wife could with difficulty be persuaded that her husband had not been poisoned. An autopsy was made, and the contents of the stomach were examined, but no poison detected. The man died very suddenly—too suddenly for the effects of most poisons known here. The second case was that of a wife poisoned by her husband. He was her second husband; and a son by the first husband, suspecting that his mother was poisoned by the stepfather, took his mother's body on his back, and brought it from their village, some miles, down to the sea, embarked it in a boat, and brought it to Smyrna, where he made his accusation, and an autopsy was ordered. This took place at the Ottoman Civil Hospital—an establishment lately put in order, and at present managed in a manner very creditable to the directors. Dr. Borg, the Physician to the Hospital, not wishing to take the entire responsibility on himself, and not practised in such investigations, requested my aid. Contrary to old Turkish prejudices, an autopsy was allowed, and the stomach presented all the symptoms or signs of arsenical poisoning—highly inflammatory appearances, and ulcerations in many places (chiefly at cardiac end), to some of which were adherent particles of a yellow, "mortar-like" matter: this was the yellow sulphuret of arsenic. The contents of the stomach were also shown to contain arsenic. Besides the symptoms of her illness and the pathological appearance of the mucous membrane, which clearly indicated arsenical poisoning, the following proofs were adduced:—The possession of arsenic by the accused; about a drachm of white arsenic, in a copper cup, was produced as having been found in his possession. A small particle of the yellow matter found in the stomach, when thrown on a piece of clear-burning charcoal, diffused, in a close room, a most unmistakable odour of garlic. The few grains of yellow matter (sealed up), the contents of the stomach, viscus included (sealed up), the coffee-cup and contents—white powder (sealed up), were all sent to my cabinet, when the following chemical experiments were performed:—Upon examining somes boxes of chemical apparatus which I possess I found that the copper-test (Reinsch's) was the only one I could apply; and for this I was obliged to extemporise my apparatus as follows: I found a small coil of fine copper wire in one of my boxes; this I beat out into a ribbon shape, making of it a thin foil an eighth of an inch broad, which I cut up into pieces of a quarter of an inch long: this gave me the bright copper-foil I required. I boiled some eight or ten of these pieces of copper-foil in distilled water, with an eighth of dilute muriatic acid, in a test-tube. After boiling for some ten minutes the copper remained as bright as ever; this I took as proof of the freedom from arsenic of my materials—viz., the copper and muriatic acid. Upon adding about a quarter of a grain of the yellow matter, and again boiling, I found the pieces of copper-foil changed to a steel-grey colour; these I washed and dried on bibulous paper and put them by, marking them No. 1. I repeated this experiment, but instead of the yellow matter from the stomach I added an eighth of a grain of arsenic got from the chemist. The result was precisely the same, pieces of bright copper-foil being turned, by deposit of arsenic, to a steel-grey colour. These, washed and dried, I marked No. 2. Both of these pieces of stained copper foil, well dried on a small disc of porcelain (my box contained a number of these, like the dishes of a child's doll-house), and deposited—separately, of course—at the bottom of a small tube (such as are used for the detection of arsenic), well dried previously, gave, on the application of the flame of a spirit-lamp, a well-marked ring of arsenical stain, similar in both. The question was to prove this ring or stain in both to be arsenic. I repeated the experiment, but in place of exposing the pieces of stained copper-foil to heat in a tube, I exposed them to heat on the porcelain disc, and when well dried I covered them with a heated slip of glass. The result was a well-marked stain, exactly the same in both (that from the yellow matter, and from the known arsenic), and which, when examined under the microscope ($\frac{1}{8}$ lens), showed a number of crystals of "arsenious acid," clearly proving the yellow matter found adhering to the ulcerated spots on the mucous membrane of the stomach to be a form of arsenic—the yellow sulphuret. It was swallowed as white or metallic arsenic, and became "sulphuret of arsenic" in the decomposing stomach. Inadvertently I first placed the glass with the stained surface uppermost, and was much disappointed at not finding the crystals I was expecting; but, quickly rectifying this mistake, I was much pleased at being able to recognise the crystals as "arsenious acid" but they were very small, and scattered over a large surface, so I repeated the experiment, modifying it as follows:—I filed off a glass tube of about a quarter of an inch in diameter a small piece—say a quarter of an inch in length—and into this I packed a number of the pieces of copper-foil, stained by the process I have described, well washed and dried. I applied heat to this, placed on end on the porcelain disc, and got the stain on the glass placed over it. The result was a stain much better marked on the glass, of the diameter of the piece of glass tube. This circular stain, when examined under the microscope, gave a dense mass of larger and more defined octahedral crystals, in their usual variety; some seen as perfect octahedra, others as dark squares, others as triangular and octahedral, variously truncated. This experiment for the detection of arsenic in all manner of organic mixtures is so simple that it can be performed by almost anyone, and the result is most satisfactory. You see the crystals of arsenious acid, which do not resemble any other that may be possibly produced from any other known volatile substance, enabling you to give positive evidence of the existence of arsenic in the matter under examination. The materials you employ are few and simple—distilled water, copper-foil, and

dilute muriatic acid; and yon prove their purity, or freedom from arsenic, in a most easy and satisfactory manner. The Turks poison with arsenic in the following ingenions manner: They throw a quantity of arsenic on burning charcoal, and they hold a coffee-cup over the fumes: the arsenic is deposited in the cnp. These cups are generally deposited, with the bottom reversed, one over the other. The cup with the adherent arsenic is taken up, and the coffee is poured into it from the pot in which it is prepared. The same coffee is poured out for several persons, bnt of course no one is poisoned except the person to whom the particular cup is served, though all are served from the same coffee-pot—thus avoiding all acts which may lead to suspicion.

The third case—the last I have been engaged in—is that of a Jew attempting to poison another Jew. There is a colony of Jews here in Smyrna, descendants of those expelled from Spain some centuries since. They nnmber perhaps 10,000 or 12,000 persons. I have never known for the last twenty years an instance of any serious crime amongst them—the present being a solitary instance. Murder is quite unknown amongst them. This year is, it appears, an exceptional one amongst them, as two instances have occurred of suicide by arsenic amongst them; on both occasions a quarrel with the wife being the cause. Of these cases the Turkish tribunals take no notice. The case of attempted poisoning is the following:—A Jew had a thriving trade in the red caps, or "fezzes," nniversally worn in this country. A competitor set up a shop opposite, and, it appears, interfered with the first. This latter prepared some sweetmeat (called here "Haratlicoom," a Turkish word meaning "easily swallowed"), and he employed a boy to sell this sweetmeat to the "new-comer," telling him to sell it at half-price, or for whatever he could get. The new-comer refnsed to bny at any price; bnt a neighbour in the next shop, seeing this sweetmeat offered at snch a cheap rate, bought it, and ate a small piece, putting the rest by, "per la senora et la creature"—for the wife and little ones. His conjugal and parental affection saved his life. The little he had eaten, however, nearly killled him, and, snspicion being awakened, the Turkish doctor who attended him, recognising the symptoms of arsenical poisoning, the sweetmeat and some of the vomit were sent, sealed up, to me for examination. The vomit had a very disagreeable smell; it remained in my "cabinet" or study for a few days till I was at leisnre to make the analysis; and when mixed with the acid it effervesced, and gave off a very resinous smell. The patient had suppression of urine, and probably the vomit contained "urea," which had changed to carbonate of ammonia by decomposition. This, on being boiled with the pieces of copper-foil, gave no indication of arsenic; but on adding some two or three grains of the white sugary matter contained in the sweetmeat the foil became coloured like steel, and a quantity of arsenions acid crystals were, by heat, deposited on the glass, unequivocally proving the presence of arsenic in the sweetmeat. Great numbers of perfect octahedra, with the other nsual forms, visible under the microscope. In this instance only two foreign substances were used—the acid and the copper-foil,—and the first boiling in the vomit proved these free from the presence of arsenic, eqnally with the vomit. The accused was convicted. There is nothing new, nothing not well known previously in all I have described; but the process is so simple, the apparatns necessary for the experiment I have almost extemporised, the result so satisfactory, that it onght to snpersede all other processes. The resulting deposit is seen as arsenious acid on the glass, and will remain fixed and unchanged for years, easily recognisable by anyone, not depending on evanescent colours or on the purity of a nnmber of tests; in fine, can be pnt in practice by any tolerably well-informed medical man, and not at all requiring a professed chemist or expert for its performance. Were it not for the light I was enabled to throw on these cases, it is most probable that the delinqnents would have escaped. By this process also the quantitative analysis may be made. You have only to boil the entire qnantity of vomit proved to contain arsenic, in repeated quantities of copper-foil of known weight as long as they become coloured—nntil, in fact, the whole of the arsenic contained in the matter under examination be deposited on the copper-foil. The difference in weight gained by the foil will of course represent the qnantity of the arsenic contained in the vomit or other matter under examination.

Snch is a sketch of the manners of the people here in Turkey, and the experience of a medical man in its criminal jurisprndence. I may, on a future occasion, give you a chapter of my experience in another criminal subject—that of abortion, a not nnfrequent crime amongst the various races (Turks, Christians, and Jews) of this country. I must qualify the assertion, and say, to their credit, a rare one amongst the latter commnnity.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

CASES UNDER THE CARE OF MR. WAGSTAFFE.

Case 1.—*Large Tumour of Parotid—Removal.*

Thomas B., aged 56, a shopkeeper, was admitted on July 17. Fully fifteen years ago he noticed a tnmour in left parotid region, about the size of a bean; it was movable and never painful. It at first showed itself in the region of the socia parotidis. He never found the affected side of throat or month dry. It has rapidly increased during the last six or eight months, with slight pain beneath the ear. It burst in January last spontaneously, and some clear oily flnid escaped. His brother had a tumour taken out of his arm twelve months ago by Mr. Pearse. There is no history of a blow, but he received a cnt across the cheek, by falling, thirty years ago. Health excellent; no implication of nerves of month, facial nerve, or parotid duct; submaxillary glands on the affected side slightly enlarged; pain as of steady pressure below ear; temporal artery felt distinctly pulsating above; no venous enlargement.

July 23.—3.30 p.m.: Operation commenced. After the administration of chloroform, a transverse incision was made, avoiding the chief projections. The npper flap was not easily separated, as the tumour was adherent to fascia at the zygoma; anteriorly and below the tumour was readily separated, and behind it did not dip deeply. The transverse facial branch of nerve was involved in the upper part of the tnmour, and had to be divided; Stenon's dnct was not exposed; several small vessels reqnired to be twisted. There was a good deal of bleeding at the time. The wonnd was closed with silver sntures. The masseter mnscle was quite denuded of fascia. A carbolic oil pad, and light mannal pressure was kept up for an honr. 5 p.m.: Temperature 98·4°. 9 p.m: Patient comfortable, bnt the lower half of the orbicularis palpebrarum was powerless. Temperature 100·1°.

24th.—9 a.m.: Temperature 101·2°. There is bagging below extensively. The plng removed, and a connter opening was made in the most dependent point of bagging; under chloroform.

25th.—Has done admirably; no bagging. Every alternate suture was removed to-day. Nausea from chloroform continned for two days.

26th.—Upper part of orbicularis palpebrarum paralysed. Patient up to-day.

30th.—We have had the opportunity of seeing this case to-day, and were pleased to find the patient so far convalescent as to be able to take out-of-doors exercise. The wound was to a very great extent united; there was, however, a moderate amonnt of paralysis of the side of the face.

Case 2.—*Smashed Foot—Subastragalar Amputation.*

David F., aged 18, boiler maker, was admitted on May 21, at 7.45 a.m. Foot crushed by fall of metal. Tarso-metatarsal articulations laid open. The foot was pulped in front of this. Subastragalar ampntation was performed immediately by making an incision corresponding for the upper part with the margins of the wound from over neck of astragalus along inner side to front of heel, then backwards in median line to behind heel, then ronnd below the external malleolns to point first started from. Forcible inversion; dissection at first from above and outside, then from behind. The anterior tibial artery was twisted; the posterior was tied with catgnt ligatnre after torsion had failed. Oozing from tendo Achillis. 2 p.m.: There was free hæmorrhage. The wonnd had to be opened entirely, when the bleeding was found to proceed from a vessel behind the tendo Achillis; this was ligatured.

May 22.—Restless night. Temperature 102°, 10 a.m.; Pulse 120, temperature 101·8°, 10 p.m.

25th.—Improved. Suppuration has occurred along the tendons of the leg, so a counter-opening was made on inner side about one inch above the ankle. The arrangement of the flap was altered in order that a projecting angle in front might be done away with.

June 8.—A counter-opening made higher up on the inner side of the leg where the skin was red, and where a probe passed to; another incision was then made at outer side opposite to the highest part of suppuration. This extended through the interosseous membranes.

July 12.—Amputation wound closed a few days after above operation, except the surface-wound. All discharge has ceased.

About a week later the higher wounds ceased discharging and closed. For the last fortnight there has been only a granulating surface-wound; this was grafted ten days ago. He has borne his weight on the stump for the last fortnight.

26th.—Wound healed.

Case 3.—Compound Fracture of Leg—Supra-condyloid Amputation.

Henry W., aged 16, smith. A heavy millwheel fell on his leg, completely smashing it to within a short distance below the knee. There was much bruising of skin. On admission, on June 20, at 2 p.m., venous oozing occurred after portions of trousers were pulled out of the wound. About half a pint was lost after admission. At 3 p.m. was operated on by Mr. Wagstaffe, assisted by Mr. MacCormac. Skin much separated in front and behind to a point opposite the knee-joint, so that it was necessary to form flaps by operating above the knee. Gritti's supra-condyloid amputation of femur was performed, and about an inch and a half of femur was removed. The patella was sliced, and placed upon the under surface of the femur. The extensor muscles were stretched a good deal as soon as the patella passed the edge of the femur. There was a good deal of oozing from the small vessels of the flaps. The limb was bandaged from hip downwards. After the operation the patient was restless towards evening. A microscopic examination of some blood from his finger showed the existence in it of numerous bacteria.

June 21. — Bandage removed, being soaked and rather offensive. Finger put in wound to insure position of patella, of which Mr. Wagstaffe was doubtful. The bandage was then reapplied. During the afternoon and evening he was delirious—out of bed and on floor.

July 22.—The wound has done well. Extension has been kept up by a shield on front and back of stump, and a solution of sulphate of zinc (gr. iv. ad ℥j.) has been used.

July 30.—Is now quite convalescent.

BRISTOL GENERAL HOSPITAL.

EMPYEMA — PNEUMOTHORAX.

(Under the care of Dr. BURDER.)

[Reported by Mr. F. Howell Thomas.]

J. R. was admitted July 22. About fourteen days ago he says he strained himself whilst at work, but had not felt any pain until this morning, when, whilst running to catch a train, he was seized with shivering and severe pain in his left side, especially when he breathed. Breath very short; temperature 104°. Lungs: Percussion—anteriorly, fairly resonant (respiration harsh); posteriorly, somewhat dull at left base, resonant at right base (respiration tubular). Vocal fremitus slightly increased at left base. No pleuritic crackle. Heart sounds very rapid; dulness normal. Temperature, evening, 103°.

July 13.—Lungs: Anteriorly, fairly resonant; posteriorly, dull at left base, resonant at right base. Respirations: Anteriorly, harsh tubular; posteriorly, left base inaudible. Total absence of vocal fremitus at left base; right base harsh, tubular. Temperature: Morning, 101°; evening, 102·6°. Less pain in left side.

14th.—Percussion: Anteriorly, dull left side, resonant right side; posteriorly, dull at left base and wall of chest, resonant at right. Respiration as yesterday, excepting that it is inaudible on left side anteriorly. The heart is displaced to right of sternum; complains of great pain in left side. Temperature: Morning, 101·4°; evening, 102·4°.

15th.—Pain continues in left side. Expectorates bloody sputa.

16th.—Pain not so severe. The effusion was thought to be pus, because of the severe constitutional disturbance. Temperature: Morning, 100°; evening, 101°.

17th.—Percussion: Anteriorly, hyper-resonant on left side, resonant on right side; posteriorly, left base dull, but directly below the inferior angle of the scapula there is a circumscribed area where the percussion-note is tympanitic; right base somewhat dull. Respirations: Anteriorly, harsh tubular on right side, inaudible on left; posteriorly, harsh tubular at right base, inaudible at left. Temperature: Morning, 101°; evening, 101·4°.

18th.—Temperature: Morning, 100·2°; evening, 100·8°.

19th.—Temperature: Morning, 98·4°; evening, 100·4°.

20th.—Physical signs remain the same. The difficulty of breathing more marked. Tapping was not performed on account of the evidence of air. The respirations have varied from 33 to 38 per minute, never exceeding 38. Temperature: Morning, 99·4°; evening, 102·6°. Pulse feeble.

21st.—Temperature: Morning, 99·4°; evening, 102°.

22nd.—Temperature: Morning, 101·4°; evening, 101·6°.

23rd.—Complains of great pain in his right side, where there is a loud pleuritic crackle. Temperature: Morning, 99°; respirations 38; pulse very feeble.

Died at 4 p.m.

24th.—*Autopsy* (twenty-four hours after death).—Decomposition commenced; abdomen and chest much distended. On opening the chest a quantity of air escaped from the left side of an offensive character. The left side was full of pus, containing several quarts. The pleura was thickened, very soft, and suppurative; it appeared to be one immense slough. There were adhesions to the chest-wall and diaphragm. The left lung weighed eleven ounces; it was entirely collapsed, and sank at once in water, there being no air in it. On the posterior surface of the lower lobe there was a distinct erosion about the size of two pins' heads, through which the air had escaped. The right lung weighed twenty ounces and three-quarters; œdematous. There was hardly any blood in it. The pleura was covered with recent lymph. Heart, liver, kidneys, and spleen normal. Intestines full of gas; otherwise normal.

EMPYEMA—PARACENTESIS THORACIS.

(Under the care of Dr. FRIPP.)

W. H., aged 18, admitted June 2. Patient had rheumatic fever eight years ago; with the exception of this has been healthy all his life. Had an attack similar to the present one just after last Christmas. For the last month has not been feeling well, but did his work up to three days ago, when he gave up. He says he felt no pain, only he was too weak to go on with it. He shivered, and his breath became very short. He felt a great deal of pain in his left side yesterday, but not before. Coughs, and expectorates a little phlegm. Lungs.—Anterior: Percussion dull on left side, resonant on right side. Posterior: Percussion dull at left base and along left wall of chest, resonant at right base. Respirations.—Anterior: Harsh, tubular. Posterior: Inaudible at left base; right base harsh; absence of vocal fremitus at left base. Heart is displaced to the right of the sternum. Morning: Pulse 126; respirations 34; temperature 101·4°. Evening: Pulse 126; respirations 36; temperature 101·6°. June 8.—Morning: Has continued about the same; complains of more difficulty in breathing; physical signs remain the same. Pus was thought to be effused on account of the temperature being so high and the severe constitutional disturbance. Pulse 126; respiration 38; temperature 100·6°. Evening: Pulse 138; respiration 48; temperature 101·6°. The shortness of breath being severe, the House-Surgeon, Dr. Elliott, tapped with the pneumatic aspirator, and removed forty-two ounces of fetid pus.

9th.—Expresses himself easier. Pulse 124; respiration 32; temperature 101°. Evening: Pulse 128; respiration 33; temperature 102·4°.

10th.—Pulse 120; respiration 32; temperature 100°. A drainage-tube was now passed; the pus discharged was fetid. Surgical emphysema came on at the left side of the anterior surface of the chest. Evening: Pulse 122; respiration 32; temperature 100·4°.

11th.—Emphysema has disappeared. Physical signs remain the same. A great discharge of pus on the poultice. Breathing easier. Morning: Pulse 120; respiration 34; temperature 99·6°. Evening: Pulse 128; respiration 32; temperature 101·6°.

16th.—The discharge having got very much less in quantity, the drainage-tube was withdrawn. Feels better. Coughs a little. Physical signs remain the same, except that a faint

respiratory murmur can be heard at the left base. Morning: Pulse 118; respiration 28; temperature 99·4°. Evening: Pulse 126; respiration 34; temperature 102·4°.

19th.—Diarrhœa. Discharge still continues on the poultice.

26th.—Diarrhœa ceased. No cough. Discharge continues. Pulse weaker. Say he feels very weak. Physical signs remain the same.

July 3.—Physical signs remain the same. Discharge still continues. Pulse is getting weaker. Evening temperature is generally two or three degrees higher than the morning; breathing is easy, and he does not complain of pain. He continued in the same state until death, July 19, apparently dying from exhaustion.

Autopsy (July 21).—Body emaciated. On opening chest, the left cavity was half full of pus. The pleura was thick, soft, and suppurated; it appeared to be nothing but a slough. The chest-wall on the upper part was ulcerated; in the lower part smooth. There were adhesions to the chest-wall and diaphragm. The left lung weighed 21 ozs.; it was in a state of atrophy; it floated in water; there was not any collapse. The bronchial glands were enlarged; some calcareous bodies were found in the lung substance. Right lung weighed 21 ozs.; the substance was pale and œdematous. Heart weighed 11 ozs.; normal. Liver weighed 4 lbs.; substance lardaceous. Spleen weighed 3½ ozs.; soft. Kidneys: Weight of both 13½ ozs.; pale. Intestines: There were some patches of congestion in the ileum, but otherwise the intestines were normal.

SATURDAY, AUGUST 23, 1873.

SEWAGE AND DISEASE.

The discovery of the cause of the outbreak of enteric fever in Marylebone has naturally led to much public discussion as to the mode in which the poisonous material has been conveyed into the milk. In our article on the propagation of zymotic disease by milk, last week, we discussed two methods—one a tolerably certain one, the other a probably possible one—in which the contagium of disease may be conveyed into milk. The certain mode is by polluted water, the more doubtful by polluted air. But the outbreak has led to the publication of speculations as to the mode of infection of milk, to which the actual facts of the case give not the slightest confirmation, but which nevertheless, in the very imperfect state of our knowledge of the precise methods in which diseases are propagated, may be allowed to demand examination.

On Saturday last a well-known member of our profession—Mr. Alfred Smee, F.R.S.—published a letter in the *Times* newspaper, in the first sentence of which he announced that he is "in a position to explain the occurrence of typhoid fever from the use of milk." The subsequent part of his communication, however, fails to corroborate the opening sentence; for the only fact which Mr. Smee adduces as capable of throwing light upon the occurrence is that some cows of his own, fed on two occasions with sewage grass, produced a milk which, after keeping for twenty-four hours, had a slightly rancid odour, and a butter of an offensive character, which turned rancid a day or two after it was made. Mr. Smee, however, does not add that anyone who partook of this milk or this butter was made ill in the slightest degree by it. Now, in the first place, we are informed on the best authority that the pastures of the farm from which the infected milk was exported were not irrigated by sewage, nor in any other mode was sewage manure specially employed. We cannot, therefore, but think it a great pity, so far as this particular outbreak of fever is concerned, that a theory should have been started which might have had the effect of diverting the attention of the scientific public from the real source of the mischief. The account which Professor Corfield, the expert employed by the milk company, has published in a medical contemporary, proves that there were ample means and opportunity for contamination of the water used in the dairy operations at the farm from the privy in which the excreta from one, if not two, patients suffering from enteric fever were received; but Dr. Corfield does not say one word as to sewage irrigation or the employment of putrid manure in the pastures. On one occasion a quantity of blood and putrid matter, discharged from the bowels of the farmer who died in June, was buried by order of the doctor in a field immediately outside the farm premises. But burying in one isolated spot is quite a different thing from manuring by sewage, and there is no evidence that the cows were fed in the field in question. On the other hand, there is a direct communication by soakage from the privy to the well, and the water of this well, which supplied the pump used in the dairy, is so bad that it has long been condemned by medical men as unfit for drinking purposes, and was not so used by the residents on the farm. Besides the soakage from the privy, the well is so situated as to drain the whole premises, including soakage from a ditch which received fluids from the pigsties, the dairy, and a manure heap on which the house slops were thrown. Anything worse than the arrangements, from a sanitary point of view, could scarcely be conceived. The epidemic itself is an instance of widespread typhoid poisoning, in which the poison was collected in a well in Oxfordshire, and thence carefully conveyed, and distributed in London. The middle ages believed that epidemics were produced by poisoning wells; it has been reserved for the nineteenth century to prove the fact.

We are justified, therefore, in saying that as there is nothing in the facts alleged by Mr. Smee which would support the hypothesis that milk produced on land manured by sewage is capable of giving specific enteric fever, so neither does the Marylebone outbreak lend a shadow of confirmation to that hypothesis. But, separating the hypothesis from this special outbreak, it is of vital importance that the inquiry be made whether there is any evidence that sewage used as manure is capable of so affecting the produce of the land—either animal or vegetable—as to render it unfit for human food, and the means either of propagating the germs of specific disease derived from the sewage or of producing other toxic effects. *In limine*, it must be acknowledged that disease has from time to time appeared to arise in the neighbourhood of land irrigated with sewage as a consequence of the

pollution of the air or water. In the *Medical Times and Gazette* of April 17, 1869, is a notice of an outbreak of dysentery in the Cumberland and Westmoreland Lunatic Asylum, which seems to have been due to emanations from some sewage-irrigated land in close proximity to the Asylum. In the number for May 24 of the present year we noticed an outbreak of enteric fever at Ecton, near Northampton, which was investigated by Dr. Buchanan, and which appeared to have originated amongst some labourers who were at work on a farm irrigated by the sewage of Northampton, and who drank some water from a brook which received the water that had drained through the soil of the farm, as well as any of the sewage that had been discharged from the farm without passing through the soil. These occurrences, and others of a similar bearing, may be held to prove that sewage itself can produce toxic effects, and that sewage irrigation, unless proper care be taken, not only in its application, filtering, and deodorisation, but also in apportioning precisely the quantity used to the area over which it is spread, is not a proceeding entirely devoid of danger. But it does not help us to an answer whether the toxic qualities of sewage are capable of reappearing and producing their effects in animal and vegetable produce.

With regard to vegetable produce, we have, on the one hand, Mr. Smee's assertion that putrid matters can affect vegetables, but whether by communicating to them toxic qualities he does not say. On the other hand, there is an enormous mass of evidence that the vegetable produce of much sewage-irrigated land is eaten both by man and animal without any ill effects accruing. In the *Times* of Tuesday, for instance, is a letter from Dr. Williams, of the Sussex Lunatic Asylum at Hayward's Heath, who states that thirty cows and twelve horses are fed with the ryegrass grown on land irrigated with the sewage of the Asylum, and that the inmates of the Asylum get their dairy produce from the cows, and that no bad effects have ever resulted. But besides ryegrass, beet-root, oats, and other vegetables have been raised on sewage farms and made the food of man and animals with impunity. We have no evidence that the poison of enteric fever can produce that fever either in carnivorous or herbivorous animals, and all proof is wanting that any poisonous effect other than enteric fever has been produced in animals by sewage vegetable produce. With regard to man, evidence is also lacking. Of course if sewage has been used in a proportion too great for the soil to absorb and decompose, it may remain on the surface and adhere to the vegetables grown. It is conceivable that a danger might arise were such vegetable matter made human food. But we believe there is no evidence of mischief having arisen from such contamination.

The other question of possible contamination through animal produce, and especially through milk, is that of greatest interest at the present juncture. Positive evidence of the toxic contamination of milk and other animal produce by sewage we believe to be entirely wanting. It was supposed that sewage pastures would spread far and wide entozoa amongst our population. But, although theoretically this would appear probable, we know of no evidence that diseases of this kind have increased since cattle have been fed on sewage grass. With regard to dairy produce, one outbreak of typhoid in the neighbourhood of Croydon was attributed to milk from a sewage farm, but tadpoles were found in the milk, which settled the question as to the real source of contamination. On the other hand, the observations of Dr. Alfred Carpenter of Croydon, Professor Corfield, and a number of other scientific witnesses are unanimous as to the excellent character both of milk and butter produced from sewage grass, and we may confidently assert that the greatly preponderating weight of evidence is against the occurrence of any contamination. But it may be dangerous to dogmatise as to its possibility. No secretion of the body is more delicately sensitive to diet than the mammary. To say nothing of the epidemics of obscure disease which in the United States are referred to milk, it is well known that milk may be rendered poisonous by cows or goats being allowed to feed upon poisonous umbelliferous and other toxic plants. It is also certain that some organic poisons may be passed through the systems of several animals without losing toxic power. Thus the blood of an animal killed with the poison of the cobra is itself poisonous, and will rapidly kill if it be injected into the veins of another. But beyond such scattered facts, which may be supposed to be analogous, there is no evidence that the germs of a specific disease, such as typhoid, can be taken into the cow's system through the channel of sewage grass, be thence excreted by the mammary glands, and, producing no toxic effect on the cow, can spread enteric fever amongst the children who drink her milk. Such a sequence of events is most likely impossible; but if possible, there has been no outbreak of fever or other disease in this country which would warrant us in believing that it has taken place.

THE RELATIONS BETWEEN PRESCRIBERS AND DISPENSERS.

An inquest involving some points of interest to the profession was held at Ramsgate last week, before Mr. Martin, the coroner. The questions arising out of the case seem to us of so much importance that we shall offer no apology for reproducing the following somewhat lengthy abstract of the evidence. The deceased was an ironmonger in King-street, Ramsgate, and was 34 years of age. It appeared that he was occasionally in the habit of drinking to excess, and had had more than one attack of delirium tremens. On the previous day (Wednesday) he was observed to be in a highly excited state, but not very violent. His ordinary medical attendant, Mr. Cresswell, being from home, Mr. J. R. Leake (on the Retired List of her Majesty's army), L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., was called in at ten o'clock in the morning to see the deceased. He found him sitting on the sofa, suffering from the usual symptoms of delirium tremens. He ordered him to bed, and gave him one grain of opium. He saw him again in the afternoon; he was still in a high state of excitement, but he had had sleep. Other medicine was ordered, which had the effect of producing more quietude. At eight o'clock at night, the effect of the medicine having passed off, and the excitement having returned, Mr. Leake ordered the following draught:—Tincture of digitalis half an ounce in half an ounce of distilled water. This prescription Mr. Fisher, a druggist in the town, refused to dispense, observing that anyone who took it would be a dead man, or words to that effect. On visiting the patient again at 10.30 p.m. Mr. Leake found that the draught he had ordered had not been taken, and that the medicine could not be procured. Mr. Leake said:—

"I gave the deceased something out of my own medicine-chest—a dose of morphia; but it was too mild, and had no effect. I had no other medicine in the house. I then left the deceased, and did not see him again. I forgot to state that on account of this message from Mr. Fisher, the mother of the deceased told me that from what she had heard she had lost all confidence in me, and that she did not know what to do. I was summoned again at one o'clock, but I sent back word that as they had lost all confidence in me, and my medicine had not been made up, I could not take any further care of the case. I should also state that at half-past eleven, seeing that the draught I had given had not produced sleep, I gave them a pill containing two grains of opium, which would have produced some sleep, but I afterwards found he had not even taken that."

In answer to questions, Mr. Leake said that he had known persons who had taken a similar dose of digitalis with the best results. He had read a paper on the subject before the British Medical Association at Leeds, and he had known cases

in which larger doses were given for palpitation of the heart and delirium. He thought Mr. Fisher was not justified in refusing to make up the medicine, and that upon him (Mr. Leake) the whole responsibility respecting the matter rested. Mr. Fisher explained that, seeing the dose of digitalis ordered was so much beyond the usual one—being, in fact, about eight times more than that recognised by Squire and the British Pharmacopœia,—he declined the responsibility of making up such a dose, and said that any medical practitioner wishing to give such a dose as that ought to come and explain the case requiring it. Mr. Cresswell, having entered the room at this time, was examined as a witness. He was the ordinary medical attendant of the deceased, and saw him for the last time on Tuesday evening, and prescribed for him. He was then suffering from a slight attack of delirium tremens, which threatened to be very severe if not attended to. Deceased was of intemperate habits, and he had attended him for two or three attacks of the disease before. The dose of digitalis ordered by Mr. Leake was not an ordinary one. Under such conditions as prevailed in this case he (Mr. Cresswell) should have had no objection to give it. An ordinary dose in such a case as this would be like "throwing feathers upon him." He had given doses of morphia in such cases which might astonish many there. In his opinion, then, the draught ordered by Mr. Leake should have been dispensed and administered at the time, as everything depended in these cases on the promptitude with which they were applied. Mr. Fisher desired to call some medical witnesses, and asked the coroner to allow two chemists who were with him to give evidence that they would not have dispensed the prescription. There was no law which bound him to dispense such a dose. A juryman having asked Mr. Fisher that, as the medical gentleman who ordered the medicine was a stranger to him, ought he not to have gone for an explanation? Mr. Fisher replied—"No; we are not bound to run after medical men." In his summing-up the coroner observed that all the jury had to do was to determine the cause of death. He said:—

"You can have little difficulty in arriving at a conclusion as to this point, because the medical evidence showed that the deceased died from exhaustion and natural causes, and from nothing which was given him. If you think proper to add a rider to your verdict, you are at perfect liberty to do so; but this question as to whether the chemist was bound to make up the prescription is a delicate one, and not one that I think you ought to go into. I have referred to Squire's 'Pharmacopœia,' and the dose is put there as from ten to thirty minims; the dose here is half an ounce, which is equal to 240—certainly a startling difference, and it is entirely for you to say whether you will consider it. You must remember that the evidence will be put before the public by means of the press, and if Mr. Fisher, as the chemist, has done wrong, there are the means of coming to a proper conclusion as to that point through a proper tribunal. You see that the deceased had been so before, and that last Tuesday, in opposition to the advice of his medical attendant, he continued drinking, and so brought on the further attack which resulted in his death."

The room was then cleared, and the jury left to themselves for consultation. After some time, the coroner having returned, the foreman said the verdict was that death had resulted from natural causes, accelerated by excessive drinking, and the jury thought the chemist ought to have dispensed the prescription of the physician.

Since the inquest several communications have been made to the *Kent Coast Times*, one of them, numerously signed by medical practitioners and chemists, justifying the conduct of Mr. Fisher. This case is one of very considerable importance to the profession—first, in reference to the dose of digitalis ordered; and secondly, in regard to the conduct of the druggist in refusing to dispense the prescription. As to the first, it is quite true that the ordinary dose of the tincture of digitalis is that stated by the coroner; but if, in addition to Squire and the Pharmacopœia, the Court had had the opportunity of referring to Waring's "Manual of Practical Therapeutics"—a very useful book,—it would have been seen that the dose of digitalis ordered by Mr. Leake had been frequently administered with most beneficial results by Dr. Jones, of Jersey, in cases of delirium tremens. Dr. Peacock and Dr. M. Mackenzie and others have administered this remedy in what might be considered very large doses. Dr. Peacock draws the following conclusions:—(1) That digitalis, when exhibited in full doses, does not by any means produce the amount of depression which our previous experience of its action in small doses would lead us to expect; and (2) that the remedy, in conjunction with other means, may probably be very usefully employed in certain cases of the disease, and especially when it occurs in young and robust persons, whose strength has not been broken down by prolonged habits of intemperance. It should be stated, however, that Dr. Laycock, on the other hand, regards the evidence in favour of the calming effect of digitalis in this disease as of the vaguest kind, and states that there is no indication of the class of cases in which it may be safely prescribed. Dr. Sharkey has related several cases in which he administered from two to four drachms of the tincture of digitalis in a single dose for epilepsy, in the majority of which it was productive of decided benefit. Dr. Waring himself states—"There appears to be a peculiar tolerance of digitalis in these affections, but its use in the above-named doses can hardly be regarded as safe or admissible in a majority of cases." So much for the first question involved in the inquiry. With regard to the second, we think it was Mr. Fisher's bounden duty to have sought an immediate interview with Mr. Leake: the case was imminent, and life was at stake; and we cannot endorse his flippant remark that, under certain circumstances, he was not "bound to run after medical men." In cases in which there may be a reasonable doubt that some mistake has been made by the practitioner prescribing, we contend that the dispensing chemist would not be justified in failing to consult the prescriber. In the present case there might have been a suspicion in the mind of Mr. Fisher that half an ounce had been inadvertently prescribed for half a drachm. Beyond this we cannot go, and we think the jury had no other alternative than to censure the conduct of Mr. Fisher, bound as they were to find their verdict in consonance with the evidence which was produced before them.

YARKAND AS SEEN BY A PHYSICIAN.

The interest which recent events have excited with regard to Central Asia is one which has long existed in the minds of some, and has fed itself on the scanty details available for giving a faint acquaintance with countries which have been closed since the days of the Ser Marco Polo even to our own time. The latest information we have as to Eastern Turkestan is mainly from the pen of a physician.(a)

The interest of such an expedition was great, and Dr. Henderson entered on his duties with corresponding hopes. Unfortunately, the orders given to Mr. Forsyth were very explicit, necessitating a quick march and speedy return, and hence but comparatively few opportunities were afforded for seeing the domestic arrangements of the country. The third of the three Europeans, however, who constituted the expedition was Mr. Shaw, who had already made his adventurous way into the heart of the country, and to his book the reader might refer for details not to be found in Dr. Henderson's, whilst the latter very far exceeds the former in accurate scientific information. Most unfortunately for science, Schlagentweit, a German traveller,

(a) "Lahore to Yarkand: Incidents of the Route and Natural History of the Countries traversed by the Expedition of 1870, under T. D. Forsyth, Esq., C.B." By George Henderson, M.D., F.L.S., Medical Officer to the Expedition, Officiating Superintendent of the Botanic Gardens, Calcutta; and Allan O. Hume, Esq., C.B., F.L.S., Secretary to the Government of India for the Department of Agriculture, Revenue, and Commerce. London: L. Reeve and Co. Pp. 370.

who had collected much information as regards this country, was murdered by Wali Khan—a ruffian who preceded the present Atalik Ghazi in the rule of this country. The visit of Mr. Forsyth was a purely friendly one, hence his instructions to keep out of all political disputes or questions. First the way led through Kashmir, which, being now a favourite excursion-ground of the British officer on leave from the plains, is tolerably well known in all parts, even far into what we are accustomed to call Thibet. Dr. Henderson has, however, contrived to enhance our interest in the country by photographs taken on the march, and here published in heliotype. At Srinagur the travellers met Mr. Hayward, who had also visited Yarkand, and was now on his way to explore the Pamir Steppe; a few weeks after he, too, was barbarously murdered. In truth, it requires no slight devotion to the work of geographical exploration to attempt it, even, in such bigoted countries, where scientific instruments are looked upon either as instruments of devilry or the first step in the onward route of conquest the inhabitants fear on the part of England. From Kashmir the travellers crossed by a pass 16,000 feet high into Ladak, but that was not by any means the greatest elevation attained. This pass is, however, stopped, or nearly so, by snow in winter. Beyond this pass the people begin to assume the Tartar type, are mostly Buddhists in religion, and are generally addicted to the sport, recently naturalised amongst us, called "polo," which is the national game in all parts of Central Asia where horses abound. Among the Buddhists of Thibet, as elsewhere, the monastic system is in full force, the monasteries being usually perched high up on a rock. Their worship is mainly conducted by machinery. They make use of cylinders of wood or copper, containing a roll of parchment on which prayers have been written. Each turn of the cylinder is held to be equal to a single repetition of the prayers, and so the "lamas," as they are called, are, if not otherwise occupied, generally engaged in turning one of these machines. Sometimes they are turned by water-power.

At Lé the travellers had to provide for one of the most trying journeys it is possible to contemplate. The country beyond to the borders of Yarkand is a stony desert, devoid even of grass for cattle save here and there near streams. The distance is nearly a month's journey—twenty-seven marches,—and this had to be performed at an elevation of about 15,000 feet—*i.e.*, nearly the height of Mont Blanc. A few days out from Lé, however, they had to cross a pass—the Chang-la—18,000 feet high. In so doing almost everyone suffered from the rarity of the atmosphere—in Mr. Forsyth's case the pulse went up to 100, the respirations to 22 per minute. Some complained of a feeling of suffocation, and could not sleep; but a few deep inspirations relieved this feeling. Intense headache was complained of, with great prostration of mind and body, the temper became irritable, and there was most distressing nausea. In some the lips became blue; and in Mr. Shaw's case the temperature, as indicated by the thermometer, sank one or two degrees. Such is the exceedingly interesting account given of the effects of great rarification of the atmosphere by Dr. Henderson. We may mention that here the barometer stood at 15·73°, the thermometer at 61° Fahr., and water boiled at 181° Fahr. Such unpleasant effects do not last long: they pass away as soon as travellers have become habituated to the elevation, for 500 feet below the top of the pass they came to a well-cultivated valley, and all nausea and other symptoms passed off. On descending from the pass on the northern side, however, the traveller reaches only the high table-land already spoken of, which in some places—especially away to the west, on the upper waters of the Oxus—reaches a tremendous elevation, constituting what the natives are wont to call the Dome of the World. In these regions rain hardly ever falls, even snow falls lightly, and the whole water seems rapidly draining off. Wherever water can be obtained, however, cultivation goes on. Up to a height of 15,000 feet above the sea grain crops grow and ripen. Higher up still willows grow, and their leaves serve as fodder for the cattle.

In crossing the desert beyond Lé, Dr. Henderson remarked with surprise that the native Thibetans or Bots always slept in the open air, with a bank of stones raised behind them to keep off the cold wind; but this sleeping in the open air is common enough in temperatures very much lower on the northern steppes. Here it was only 23° Fahr., but in Siberia up towards Anadyrsk the traveller will have to sleep out with the temperature at 40° below Zero. (See, *passim*, Kennan's "Tent Life in Siberia," and Brook's "Reindeers, Dogs, and Snow-shoes.") The clothing of the natives of these parts consists to a considerable extent of sheepskins with the wool turned inwards, and they are excessively dirty. The highest point where the travellers rested for the night was 18,850 feet above the level of the sea. Yet here Dr. Henderson remarks that though the servants found it impossible to cook pulse, from the low boiling-point (180° Fahr.), ravens and butterflies flew with as much vigour as they did lower down. In these regions a cold wind of great intensity sometimes blows, and is very dangerous—especially as men and horses are exhausted from the extreme rarity of the air. In such a position it is hardly pleasant to find provisions failing, yet that was the predicament in which our travellers found themselves—deceived as usual by native officials; but by a few forced marches they reached Shahidulla and the Atalik Ghazi's territories. In this part of the journey they passed over a deposit of pure sulphate of magnesia not less than twenty feet in thickness. On reaching the borders of Yarkand, our travellers were introduced to Yarkandi fashions by the presentation of a *dastarkhan*—literally a tablecloth, but meaning a feast of sweatmeats, fruit, etc., with which it is the custom of the country to begin the repast, just as we end with them. In this district the Kirghiz and Wákis were the travellers' carriers, but they complained greatly of the turbulence and insolence of the latter. The reason of this is not very apparent, but even in their native Wakán the Wákis do not seem to be over-obliging.

In Yarkand proper the country seems not unlike England; fruit of all kinds abounds, game is plentiful, and the mutton of the country delicious. So our travellers feasted. Even the cooking was unobjectionable. The beverage of the country is tea—probably, though this is not mentioned, of the kind called brick-tea, which is mainly used in these regions. Under the reign of the present monarch the laws seem strictly enforced—and bloody laws they are. One prominent feature of the country seems carelessness of human life; for the most trivial offence the native is liable to have his throat cut—the national mode of execution. Not many details are given us as to the diseases of the country, save that goître is unusually prevalent. Cataract, too, is common, and Dr. Henderson saw one case of leprosy and one of elephantiasis, both in boys.

Canals are common; the cotton and Indian corn cultivated are excellent; in short, the country is a most fruitful one. But we must take leave of our travellers, commending Dr. Henderson's book to our readers, especially for the admirable description and figures of birds and plants contained in its latter portion, to which we are unable further to allude. Their stay at Yarkand was brief, for they had strict orders to return before winter, and they left without seeing the Atalik Ghazi.

THE WEEK.

TOPICS OF THE DAY.

The epidemic of enteric fever in the West-end of London may now, we hope, be said to be at an end. No fresh cases have been heard of, and although it is estimated that about

500 persons have suffered, the mortality has not been great. Of course, a number of people are still ill, and some are even dangerously so, but as a rule the type of the fever does not seem to have been severe. Amongst its victims we are sorry to count the Rev. Mr. Butler, curate of All Saints', Norfolk-square, and secretary to the Dudley Stuart Refuge. The cause of the fever is now so clear—the contamination with typhoid excreta at the farm in Oxfordshire of a well from which water used in dairy purposes was drawn is so clearly established, and the limitation of the fever to persons who partook of the milk so contaminated has been so carefully made out—that further proof is almost superfluous. It is furnished, however, by the fact that the spread of the fever has abruptly ceased with the discontinuance of the infected milk-supply. There may, however, even yet be a danger of its extending if the utmost care be not taken in every case to destroy by processes of disinfection the contagium which is contained in the excreta of each patient.

England continues free from cholera—a fact on which we may greatly congratulate ourselves, considering its prevalence in Hamburg and the Baltic ports. The last advices contain the official announcement of its presence at Stettin. It is also at Munich; and if the accounts of the numbers who have succumbed to the disease in Hungary are rightly reported, it is clear that the cholera of 1873 has lost none of the virulence of former years.

The Executive Committee of the General Medical Council met on August 7. A letter was read from the examining bodies in Ireland co-operating for the formation of a Conjoint Board of Examinations, which stated "that the licensing bodies co-operating in this scheme have unanimously resolved to adhere to the Preliminary Examinations defined in Clause V. of the Scheme (June 28, 1872), and to add to the number of examiners two additional Examiners in Practical Pharmacy, to be nominated by Apothecaries' Hall." They also request that the Committee will convene a meeting of the General Medical Council to consider the Scheme as so amended. Subsequent correspondence shows that the number of examiners to be appointed by the Apothecaries' Hall in pharmacy has been raised to three with the consent of the King and Queen's College of Physicians and the other co-operating bodies. The whole of the correspondence was ordered to be entered on the minutes, but the Executive Committee (very wisely, we think) resolved "That it is inexpedient to call at present a meeting of the General Medical Council." It would therefore seem that the Conjoint Scheme in Ireland is accepted by all the medical authorities except the Queen's University. But if the General Medical Council is to be called together each time a medical examining body sends in its adhesion to one of these schemes, the accounts of the Council would soon show a far less flourishing state of finances than at present. If it be true, as is rumoured, that the Government will early next session give the Apothecaries' Society of England the same aid in passing an enabling Bill through Parliament that was given to the University of London, we may see a Conjoint Board in England started with the adhesion of all the English examining bodies in 1874. But Scotland still breathes defiance, and we shall have an exodus of English students to Scotland, drawn thither by the attractions of examinations cheaper in money and requirements.

The gloomy apprehensions which we thought it right to make public with regard to the Ashantee war are only too likely to be realised. The *Times* correspondent's letter tells of small-pox, enteric and remittent fevers, and dysentery of unusually severe type. The sanitary arrangements seem until quite recently to have been as bad as possible, and there was no proper sanitary inspection or staff of sanitary officers. Deputy Surgeon-General Home, V.C., C.B., is now doing all he can, with the help of a sanitary commission, to improve the state of things; but he himself has been very ill with dysentery, although he courageously refused to leave his post and to return to England. The *Times* correspondent writes—"The unhealthy condition of Cape Coast continues, and is daily and hourly increasing. We may add that the Ashantees are not yet conquered."

We learn from a statement in the *Bristol Times* that the resignation of the honorary medical and surgical staff of the Bristol Hospital for Women and Children arose, not from the fact that a lady doctor had been appointed house-surgeon, but simply because she refused to carry out the orders of the honorary staff. The same paper announces that the hospital is now under the care of an efficient honorary medical staff. We do not know who may compose the new staff, but we hope that no professional men of any standing and respectability would take office in an institution from which the medical officers have been compelled under such circumstances to retire.

There has been a report circulated in some of the daily papers that Dr. Braxton Hicks, of Guy's Hospital, had died from a poisoned wound. We are most glad to say that this is unfounded. Dr. Braxton Hicks, we believe, did injure his right hand, but he is now, we are happy to say, quite convalescent.

We are glad also to observe that Mr. Erichsen is now recovered sufficiently to appear in professional circles again, and will be prepared to commence work in October at University College.

Nélaton, the eminent French surgeon, still lies in a very precarious state.

INDIAN MEDICAL SERVICE.

The new Royal Warrant for the Indian Medical Service (says the *Army and Navy Gazette*) has at length been published. Its prominent feature is the abolition of Assistant-Surgeon—Henceforth the Surgeon takes the lowest step in the scale, rising, after twelve years' service and due passing of tests, to the rank of Surgeon-Major. His subsequent rise to a Deputy Surgeon-General and a full Surgeon-General will be determined by "selection for ability and merit." At fifty-five years of age the Surgeon-Major, if unpromoted, must retire, and the same lot will await all Surgeons of the two highest grades after sixty-five years. This rule, however, is partially relaxed in favour of Surgeons who entered the service before January 13, 1860. Room is also left for "special cases" when the continuance of an officer in active employment may "appear to be for the good of our service." This Warrant is more liberal than might have been anticipated, but it still, in some respects, shows a spirit unfriendly to our brethren. It is to be hoped that the "relaxation" of the rules mentioned will be carried out to its utmost extent in favour of those whom it concerns.

INFLAMMATION OF THE CORNEA IN AFFECTIONS OF THE TRIGEMINUS.

Professor Eberth, of Zürich, proposes a new explanation of the occurrence of keratitis after section, injury, or disease of the fifth cranial nerve. This pathologist, whose observations and opinions are worthy of the greatest respect, has for some time maintained that the severity of the process in traumatic keratitis depends upon the conveyance of bacteria into the cornea by the foreign body, and not upon the trauma directly. He now describes (*Centralblatt*, July 19, 1873, No. 32) the occurrence of a similar keratitis without any external wound whatever—by the settlement of the organisms in the cornea after section of the trigeminus. The exophthalmos, loss of sensibility, diminished nictitation, and the desiccation of the exposed corneal surface lead on to inflammation, with the production of bacteric masses indistinguishable by the microscope

from the condition in diphtheritic keratitis. The most superficial puncture of the affected spot causes a rapid extension of the disease. The second element, therefore, which has not been previously recognised in the etiology of keratitis after injury of the fifth nerve—but which, according to Eberth, is essential—is the presence of bacteria in the atmosphere. Both the condition of the globe after the section or disease of the nerve, and the condition of the atmosphere, will of course vary in different cases. The occurrence of the keratitis will therefore be influenced by the degree and extent of the desiccation, the amount of protrusion, and the size of the ocular aperture. And, on the other hand, the quantity of bacteria in the air and the presence of epithelial abrasions will determine the severity, rapidity, and extent of the inflammatory destruction.

DEATHS FROM STARVATION.

In the central division of Middlesex, according to a Parliamentary return issued last week, no fewer than eighty-three persons died from starvation last year, or from disease accelerated by want of food. Only four of these persons were receiving outdoor relief. Thirteen deaths so caused occurred in the Eastern Division of Middlesex, and one only in the City and Liberty of Westminster. No death from privation occurred in the City of London and Southwark.

VACCINATION IN SHOREDITCH.

According to the last periodical return, presented to the Shoreditch Guardians last week, there had been 2627 births in the half-year ending at the commencement of June last, and of these 2039, or 85 per cent., had been successfully vaccinated.

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

The thirty-fourth annual report of the Registrar-General has just been issued for the year 1871. It is most valuable and interesting for its comprehensive details, and statistics of the health, disease, and mortality of England. It exhibits great skill in its design and arrangement, is clear, intelligible, and masterly, and affords information and suggestions of the highest importance to the national health.

"The number of deaths registered in 1871 was 514,879, or 450 less than were returned in 1870 out of a population which is estimated to have increased by 281,496 in the following year. The excess of births over deaths registered in 1871 was 282,549; with the exception of the years 1867 and 1868, the greatest balance on the side of growth ever recorded in any year since registration was instituted in this country. To every 1000 of the population there were 22·6 deaths in the year, the mortality having been slightly below the rate for 1870, while it was also a little above the average annual rates in thirty-four years. Such average, represented by the mean of thirty-four annual rates, was 22·4 per 1000; in sixteen years of lowest mortality since 1840 the average annual rate was 21·5, in fourteen years of highest mortality 23·4: the year 1871 approached more nearly to the high than to the low average. In the most unhealthy year (1849) of the series there was one death to every forty persons living, in the healthiest year (1856) one in forty-nine. The healthy and unhealthy years do not alternate singly, but mostly in groups of three or four years; a reason for this appears in the fact that the death-rate is to a great extent governed by the mortality from zymotic diseases, and that an epidemic of either of these commonly takes two or more years to run its course.

"*Sex and Age.*—The 514,879 deaths registered in 1871 comprised 265,563, or 51·6 per cent. of males, and 249,316, or 48·4 per cent. of females. Males constitute 49 per cent., females 51 per cent. of the living population, and the ratio of males dying to males living in 1871 was 23·9 per 1000, of females dying to females living 21·3. So taking the deaths alone the proportion of males to females dying was as 107 to 100, but having regard to the larger number of females in the population out of which the deaths occurred, the proportion of male to female deaths out of equal numbers of both sexes living was as 112 to 100. The rate of mortality at all ages among males has somewhat increased of late years, while the female rate has diminished. The ages of the population at the Census of 1871 having now been ascertained, the rate of mortality of the two sexes at different ages in 1871 was, of males at the rate of 23·9 per 1000 living; of females 21·3. In the first five years of life the male rate was 71·7, the female 62·4; at ages 5 and under 10 years 8·3 and 7·5; at 10-15 the rates are at their lowest, 4·4 for males, 4·5 for females; at 15-25 both sexes experienced a nearly equal mortality, 7·7 and 7·4; thenceforward both male and female rates increase to the end of life, the male being invariably highest, as at 25-35 male 11·1, female 9·7; at 35-45 male 14·4, female 12·3, and so on. Comparison of the mortality in 1871 with the average annual rate in 1861-70 shows for males a diminution of nearly 2 per 1000 in the rate of deaths at ages 0-5, an increase of about 1 per 1000 at ages 25-65, and a decrease at the more advanced ages; the female rate in 1871 at ages 0-5 was 1·4 per 1000 below the ten years' average, at ages 5-55 there was no difference worthy of note, at 55-65 there was an increase, and at 75-95 a decrease. The rates at the extreme ages of 95 years and upwards fluctuate greatly in consequence of the relatively small number of cases coming under observation."

The causes of death in 1871 were—

"1. *Zymotic Diseases.*—The 123,030 deaths by this class of causes, marshalled under four orders, exceeded the average numbers; and the excess was entirely due to small-pox. In the previous year the excess was due to the epidemic of scarlet fever. Since the year 1865 diarrhœa has been unusually fatal. The cholera epidemic of 1866 was preceded and followed by epidemics of diarrhœa. In the miasmatic order, scarlet fever, which was at its maximum in 1870, was still a leading disease; but fever was declining. Enteric fever was by far the most fatal of the three forms of continued fever. Among the enthetic diseases, syphilis is the most fatal, for to it 1742 deaths were referred. The rate of mortality by this disease is lower than it was in the three previous years. Hydrophobia prevailed quite epidemically in this year. Never before did so many die of this distressing disease. The deaths by it in the four years 1868-71 were 7, 18, 32, and 56. To alcoholism in one form or other 740 deaths were referred; 370 having been registered as delirium tremens and 370 as intemperance. This class of deaths attained the highest pitch in 1865, when 612 deaths by delirium tremens, and 437 by intemperance were recorded; since that date the deaths have declined. No doubt many other diseases are indirectly the result of drinking to excess, so that the deaths by alcoholism are understated; but as the relative accuracy of the returns is probably increasing, the fall of the deaths from 1049 in 1865 to 740 in 1871 is evidence of decrease in the bad habit of drunkenness. The parasitic diseases, including thrush as well as worms, were not more fatal than usual.

"2. *Constitutional Diseases.*—One of the diathetic diseases, gout, is more fatal than delirium tremens, and in its various forms is sometimes entered under disguised names. Scrofula, tabes, hydrocephalus, and phthisis were all below the average rate of their fatality.

"3. *Local Diseases.*—The most fatal order embraces the diseases of the respiratory organs; and it is growing yearly more fatal. The death-rate by bronchitis rose from 1188 per 1,000,000 in the years 1850-59 to 1749 in the ten years following, to 2097 in 1870, and to 2112 in 1871; bronchitis under its name is apparently absorbing cases formerly accounted as pneumonia or asthma and perhaps as phthisis. The deaths by affections of the brain, nerves, and senses vary little from the average; and there is no evident increase. To convulsion fewer deaths were referred than in previous years; yet their number was 25,309. Apoplexy and paralysis and insanity were somewhat more fatal in the year than previously. Heart disease is occurring more frequently in the returns than it did, and its causes require fuller investigation. It is now fatal to 1 annually in every 1000 living, and the deaths in the last year were 26,219. Diseases of the digestive organs were not fatal to so many; yet of them 21,621 died, including 8711 by the various affections of the liver. The diseases of the urinary organs were fatal to 7628 people; those of the organs of generation, locomotion, and the integumentary system together were fatal to only 4616 lives.

"4. *Developmental Diseases.*—9650 deaths are ascribed to premature birth, 1418 to malformations, including 570 by cyanosis, 390 by spina bifida, 458 by other malformations, and

4108 by teething. The mothers who died in childbirth were 3935, including 1464 by puerperal fever (*métria*), which during the last two years has been more prevalent than it had been since 1864 and 1865, when the disease was epidemic. The excess in the number of 2471 deaths from what have been called the accidents of childbearing tells strongly in favour of the efforts that are being made for the education of the midwives by whom so many of the women of England are attended. The deaths of children under one year of age amounted to 125,868. No less than 9650 of these were born prematurely. The causes of the deaths of 22,463 are returned as atrophy and debility; these are cases of defective nutrition. Nearly the same number, or 20,089, are classed as deaths by convulsions. Then 15,662 of the deaths were by diarrhœa. Thus, adding these numbers together, we have 58,214 deaths of infants from causes by no means clear; by ill-defined diseases; or by diseases which are symptoms either of other diseases or the consequences of improper nutriment. The deaths of 1224 infants are directly ascribed to the want of breast-milk, and no doubt this is only a small proportion of the numbers who die or are irreparably injured for want of nature's food. A large number of the deaths of infants were from small-pox, measles, scarlet fever, and hooping cough; scrofula, tabes, phthisis, water on the brain. Bronchitis and pneumonia are two of the other great causes of infant death; to those diseases 18,245 deaths are due. 1723 infants died violent deaths, of which 1568 were returned as accidental, including 1098 infants suffocated, generally by overlaying. 147 cases of infanticide out of the 125,868 dying were returned by the coroners.

"5. *Violent Deaths.*—The number of violent deaths in England is exceedingly great, and it is increasing. The numbers so returned were 11,727 in 1838, 14,040 in 1854, and 16,993 in 1871. A part of the increase is due to increase of population; but correcting for this, the general result is, that in the year 1854 the violent deaths to 1,000,000 living were 759, on which there was no considerable increase until the years 1863-4-5, when the rate of violent deaths rose to 772, 826, and 835; that year 1865, was the maximum, for through the next five years the rate declined to 745 in 1870, but was 752 in 1871. By suicide the deaths to the million living were remarkably uniform; 66 in 1858, and 66 in 1871. By homicide, including infanticide, in the same years the rate was 18 and 17, there having been a slight swell up to 23 in the cholera year 1866. Executions declined. The greatest reduction is in the violent deaths by burns and scalds, which fell from 162, 153, and 161, in the years 1858-59-60, to 116 in each of the last two years 1870-71. The deaths by drowning registered at home have also declined. The numbers drowned at sea were registered by the Registrar-General of merchant seamen; they amounted to 2476, of which 1500 happened by wreck, 976 by other accidents or negligences."

FROM ABROAD.—TREATMENT OF RECOVERING LUNATICS—DEATH-RATES IN AMERICA AND EUROPE — SUPPRESSION OF AN ANATOMICAL MUSEUM IN BOSTON.

THE *Philadelphia Medical Times* (June 28) publishes an interesting letter from a recovered lunatic, some portions of which we reproduce, under the conviction that they advert to points that are not sufficiently taken into consideration. After stating that he had been an inmate of three asylums, and that he had inhabited one of these long after being sufficiently well to observe and form a judgment of what was going on, and adding that in all these asylums he had received great kindness, he proceeds to say—

"I have talked with many insane people, and found that many of them have pains and physical annoyances which are not much looked after in asylums. I was surprised to find lately that examination of the urine is necessary, and know that no one in any of these places did look at mine. Asylum doctors cannot be much blamed, because where I have been there was always too few doctors, and the youngest ones were always going and coming. Even if a doctor lives among crazy people constantly he must tire of their complaints, of which so many are false, and therefore must be heedless of real ones. My remedy would be to get one or two doctors outside to come once a week and see such cases, and perhaps they would be fresher to see into bodily ailments.

"I saw in asylums many persons who were harmless, and who I guess would be more happy at home, and sometimes were really incurable. I suppose that if the cause of a man's madness was in what surrounded him at home he ought to be away from it; but if this is not so, why must he be in an asylum unless he be so handled by his disease as to be dangerous? It may seem a little thing, but I used to have at home a great variety of eating, and in one asylum, though food was in plenty, it was coarser than people well off at home are accustomed to, and it was not various. Perhaps if the visiting doctors could come in at meals now and then, it would be a good thing. As to managers, they come on set days, and know very little of all that goes on. The worst complaint I can make is what kept back my recovery a long while. I saw in asylums many people who were just so far well that the monotony of their lives was dreadful. You cannot amuse a man all the time; and if a man has been a hard worker, as he gets better he ought, as I think, to be put to work. I would say—Do so much labour of one kind or another, and if you do it you will have certain privileges—better diet, a moderate use of tobacco if wanted, or a ride outside. I was a long while just so that if I had had a reason to work I would gladly have done it, in a garden or a field. Cannot this be carried out as a system in some asylum? No one but a nearly sane man knows what it is to have to walk about with more crazy people all around, and to have just games and the like to fill up his day. My own feelings would make me think that good hard labour would help some people as they got better."

Dr. Russell read a paper at the New York Academy of Medicine on the "Mortality in the various States of the Union," of which the following abstract is given in the *New York Medical Record*, July 1. Both the American and foreign data have been obtained from official sources:—

"The highest death-rate in the United States was given by Memphis—viz., 46·6 per 1000 inhabitants; in Savannah it was 39·2; in Vicksburg, 36·5; in Troy, 34; in Hoboken, 32·9; in New York, 32·6; in Newark, 31·6; in New Orleans, 30·6; in Boston, 30·5; in Philadelphia, 26·1; in Brooklyn, 28·1; in St. Louis, 20·1; in Chicago, 27·6; in Baltimore, 25·1; in Cincinnati, 20·5; and in San Francisco, 17·2.

"Of the larger British cities, Dublin yielded the greatest death-rate—viz., 29·9, that of Manchester being 28·6, of Glasgow 28·4, of Leeds 27·9, and of Liverpool 27·1. The death-rate of London was as low as 21·4—less than that of any other important city. On the Continent the highest death-rate was the enormous one at Prague of 48·9 per 1000. It was also excessive in Cadiz—44·7. In Munich it was 41·8; in Rome, 36·7; in Naples, 35·7; in Florence, 31·1; in Athens, 33; in Berlin, having a little less population than New York, the mortality is nearly the same—viz., 32·3 per 1000. In Bologna it was 32·2, and in Vienna, Genoa, Stockholm, and Nice 31·8—the deaths of invalid strangers greatly augmenting the mortality of this last city. High death-rates also prevailed in Havre, Rotterdam, Leghorn, Venice, and Milan, ranging between 31 and 30. In Paris it was stated at 21·1; but all deaths of strangers and travellers are there excluded. The lowest mortality was given by the Swiss cities in Zurich, Geneva, and Basle—viz., 13·9, 19·4, and 20·9, and in Christiania 20·7. Algiers furnished the rate of 33·6. Those of Bombay and Calcutta were by no means high—viz., 29·2 and 25. In Madras the rate rose to 35, in Montreal to 37·3, and in Havana to 35·1. The highest known rate prevailed at Valparaiso (the only South American city returned), where it was 66·9 per 1000."

We believe that some of the figures here given need verification.

From an account which appears in the *Boston Medical and Surgical Journal* of July 24 we learn that that city has been as well as our own, defiled by one of the so-called "Anatomical Museums." However, prompt and decisive action has been taken for its suppression. It seems that no such exhibition can there be opened without the licence of the Corporation, and a successful application has been made for the withdrawal of this.

"It will be remembered that the destructive fire of May 30 swept away one of the disgraces of the city, 'Dr. Jourdain's Gallery of Anatomy.' The exhibition was a type of its class. It was a collection of anatomical models and dissections, with

representations of skin and venereal diseases, most improper for public exhibition, and calculated to excite the morbid curiosity of the young, together with its peculiar forms of hypochondria. Vile pamphlets were at hand to induce those having or fearing disease to consult the proprietor. The harm which this single establishment must have done cannot be calculated. Directly after the fire a sensational notice appeared in the papers to the effect that orders for new specimens had been sent by telegraph to some of the capitals of Europe, and that the place would reopen."

This, however, was prevented by the prompt application of the "Boston Society of Medical Observation" to the Mayor and Council, calling upon them in the name of morality and public decency to refuse their licence, and offering to produce evidence as to the indecent and immoral character of the exhibition in question. The Society received the gratifying reply that not only would the licence be withheld, but that a similar licence which had been applied for on account of a similar exhibition had been refused. The Society calls upon the profession in other parts of the country to imitate this line of action; for even when such prompt co-operation on the part of the civic authorities may not be forthcoming, at least the public will be made aware that a protest against so mischievous a nuisance has been entered, and in that way its opinion eventually influenced.

PROFESSOR HOLMES'S LECTURES AT THE COLLEGE OF SURGEONS.

Abstract of Lecture VI.

Continuing the subject of the treatment of axillary aneurism, Professor Holmes remarked that although he had dwelt on the possibility of the cure of this disease by compression, and had urged its trial in the place of the ligature of the subclavian, he would not have it supposed that the treatment is one to be lightly undertaken or easy to carry out. Experience has proved that there are cases in which intermitting or rapid pressure may be successfully employed; but can we distinguish such cases? or ought the surgeon always to commence treatment by a trial of pressure? The latter would be an improvement on the indiscriminate resort to the ligature, but Mr. Holmes is not certain that indications may not be found for selecting those cases in which pressure gives most promise of success, or in which it is most desirable to reject that treatment. In the first place, there are some cases usually classed as axillary aneurism, but which may be more accurately described as rupture of the axillary artery, on which, as far as present experience goes, pressure has but little chance of succeeding. In these the essential features of aneurism—viz., a sac capable of contracting on the coagulating blood—is wanting, and without the assistance of this contraction not even the ligature of the artery above can be trusted to succeed, still less the certainly feeble influence of indirect compression. The Professor thinks that in cases where there is good reason to believe that an artery has been ruptured and no complete sac has formed, the old operation, if practicable, should always be preferred; and he referred to a very interesting paper by Dr. Liddell in the *American Journal*, January, 1864, in which the author describes a case of traumatic aneurism from gunshot, and concludes (without having at that time seen Mr. Syme's writings) that in many such cases the old operation is to be preferred.

Again, there are cases of axillary aneurism in which the tumour—or, as Professor Spence thinks, the action of the nerves irritated by the tumour—has raised the clavicle so much that compression of the subclavian is rendered doubly difficult. In such instances the ligature of that artery is also an operation of much difficulty and danger, and the surgeon, before attempting it, should maturely weigh the other plans which have been proposed for the treatment of such aneurisms—viz., electro-puncture, coagulating injection, manipulation, and the old operation as practised by Mr. Syme. They may be taken, perhaps, in that order. Electro-puncture is, Professor Holmes thinks, on the whole the least dangerous. The injection of perchloride of iron will usually be prohibited by the impossibility under these circumstances of suspending the circulation, though, if the elevation of the clavicle is not extreme, it may be possible to compress the artery for the short time requisite for this purpose, and it then holds out a more definite prospect of cure than galvano-puncture. Manipulation can only be expected to succeed when the sac is of rather small size and contains some clot already. But then a tumour of this kind can only under exceptional circumstances so elevate the clavicle as to preclude the more ordinary methods of treatment.

The use of electricity in the treatment of aneurism has up to the present time been reserved almost exclusively for the treatment of internal aneurisms; and very properly—since, whatever may be the future prospects of electrolysis, we do not as yet know enough of its effects on the blood of an aneurism to enable us to predict what will be its results in any given case with any approach to certainty, and for external aneurisms we possess means far more uniform in their action, and far more successful.

That manipulation might be successfully practised in axillary aneurism Professor Holmes does not doubt, though it seems to him that the effects of this method of treatment are too uncertain to render it likely ever to come much into use in a form of aneurism like the axillary, where the artery leading to the tumour is usually fairly accessible. Yet, if pressure has been tried in a case and failed, if the condition of the patient or of the artery renders the surgeon unwilling to risk the operation of ligature, and if there is evidence of the presence of a good deal of clot in the sac, in such a case there would be a fair opportunity for attempting to dislodge a portion of this clot and push it into the distal opening of the sac.

The surgeon's object in manipulation is to produce the same effect designedly as occurred accidentally in two cases referred to by the lecturer—viz., one by Beck, of spontaneous cure of axillary aneurism by the impaction of clot; and the other a similar case related by Poland, in which spontaneous cure by impaction occurred under the use of a compressing bandage. But much more experience of the manipulation-treatment is necessary before we can say what the chance of success may be.

Finally there is the bold proposal of Mr. Syme of reviving the old operation. If the tumour extends so high that pressure cannot be used, and whilst its size prevents the use of manipulation and galvanism, or coagulating injections are either contraindicated or have been tried in vain, the choice of the surgeon must be between the ligature of the subclavian and the old operation. The former is very fatal under these circumstances; the latter is as yet untried except in cases of ruptured artery such as those operated on by Paget, Syme, Callender, and others. The form of the sac and its exact relations to the vein and nerves become now matters of the most vital importance. Besides the great dangers which beset the old operation in every part of the body—viz., disease of the arterial coats where the ligature is applied, and of discovering the lower end of the vessel—there are two dangers special to the operation in this particular situation, one resulting from the close connexion between the brachial plexus and the sac, and the other from the very large relative size of the branches of the axillary artery. The many risks of this operation should therefore lead to its use being restricted to some exceptional cases such as have been specified; and any surgeon who chooses to resort to it must have made up his mind to an operation involving difficulties which he has no means of foreseeing. He cannot tell where the opening of the artery will be found, nor what part may be in contact with the tumour he is going to lay open, nor what branches he may have to tie besides the trunk. He must make all necessary preparations for amputation in case it should prove necessary; and a preliminary incision above the clavicle, through which the subclavian can be immediately secured in this latter event, is a precaution which should never be neglected.

The facts brought forward in reference to axillary aneurism, Professor Holmes thinks, are sufficient to establish the following propositions:—

1. That there are a great number of these aneurisms, both traumatic and spontaneous, which are amenable to gradual intermitting pressure, when carefully applied to the artery above the tumour.

2. That in cases where this is not possible, from the pain which the patient experiences on pressure, the application of rapid total compression under anæsthesia may effect a cure.

3. That the ligature of the subclavian artery is so dangerous

an operation, both from its own risks and from the proximity of the sac, that it ought to be restricted to cases where pressure has failed, and to those in which, from the size and rapid growth of the axillary tumour, the surgeon thinks pressure unadvisable.

4. That the old operation is to be preferred to the ligature of the subclavian in cases of ruptured artery, and that it may be practised in cases where, from the elevation of the shoulder, or from the extent of the tumour, the surgeon would find it difficult to tie the subclavian, or fears in doing so to injure the sac; but that the anatomical relations of axillary aneurism render this a peculiarly hazardous proceeding, and the surgeon should always be prepared to amputate if necessary.

5. That in very large axillary aneurisms, if any treatment be adopted, the arm should be amputated at the joint after ligature of the subclavian.

Aneurisms occurring below the axilla may be divided into arterial ancurisms of the brachial artery, arterio-venous aneurisms at the bend of the elbow, and aneurisms, of the arteries of the forearm and hand.

Arterial aneurisms of the brachial artery are almost always the result of wounds. Yet cases of spontaneous aneurism of this artery are on record. Mr. Birkett gives one such case in the Guy's Hospital Reports for 1862. Another and a very interesting case recorded by Kade was referred to by the lecturer; and references are given by Fischer to three other cases of spontaneous brachial aneurism; and if the three cases by Pelletan, Liston, and Spanton, another reported in the *Gazette des Hôpitaux*, 1860, p. 770, and a second case by Mr. Birkett since the publication of his first case, are added to these, we have all the cases of spontaneous aneurism of the brachial artery of which the Professor had been able to obtain any knowledge. Spontaneous aneurism of the brachial artery is therefore a very rare disease, and when it occurs it is generally significant of disease of the heart, aud is the effect probably of the lodgment of an embolic clot in a weakened artery. Much care should be bestowed on the examination of such a case, and its treatment should obviously not be too active. If cardiac disease or extensive arterial degeneration exists, the patient's life cannot be prolonged, and he is a very bad subject for the ligature; nor is the disease usually in itself so formidable as to justify the risk. So that persevering attempts at pressure should be made (digital by preference), and the artery is so accessible that they will in all probability succeed.

Traumatic brachial aneurism is still more under the influence of compressiou. Fischer's table contains references to fifteen cases which seem to have been merely arterial—*i.e.*, in which there is no mention of any injury to a vein. Digital compression was successfully used in twelve of these cases; in a thirteenth direct pressure effected a cure; in the fourteenth case the brachial artery was tied, but the patient died from erysipelas; in the remaining case digital pressure failed, but no further treatment is recorded. In these aneurisms if compression fails it may be a question whether the old operation is not better than the Hunterian ligature, for the sac is often imperfect, and coagulation consequently either very slow or altogether deficient.

The arterio-venous aneurisms at the bend of the elbow, the result of unskilful bleeding, are now very rare in this country.

The treatment, when any was adopted, before the introduction of digital pressure, consisted usually in the incision of the sac and the ligature of the arterial orifices. Instrumental pressure did occasionally succeed, but not very often, on account of the venous congestion which it caused, and the Hunterian ligature was justly discredited. Such cases as that of Sir C. Bell, of which the preparation was produced, where he tied the artery above the tumour, and the patient died of gangrene, show both the inefficacy and the dangers of tying the artery at a distance from the sac, while the old operation is not very dangerous, and is indubitably curative.

Digital pressure, however, even applied only to the artery above, has frequently effected a cure. Fischer's tables give twelve cases, nine of which were successfully treated by digital compression. In some of these nine cases the pressure was applied to the artery only, but in at least four of them digital compression was applied both directly to the venous orifice of the aneurism and indirectly to the artery leading to it.

The lecturer here referred to a diagram representing the method employed by Vanzetti. The artery and vein are seen communicating on either side with a sac, and Vanzetti had noticed that slight pressure on the apex of the sac stopped the continuous venous murmur. A finger is represeuted in the diagram at this point obstructing the entrance of the venous current into the sac, thus placing the tumour for the time under the same conditions as a common ancurism. Pressure is then made by another finger on some convenient part of the artery above.

Knowing as we now do the efficacy of direct pressure thus applied in conjunction with indirect compression of the artery for the cure of varicose aneurism, it may be worth while to treat cases of aneurismal varix by the prolonged application of that slight amount of pressure which would probably suffice in many of them to close the venous orifice. Allowing that in many of these cases the symptoms are not urgent, still the disease is worth curing if it can be done without danger.

Lastly, we have aneurisms below the bend of the elbow. These are usually traumatic, and therefore, as a rule, affect the most superficial parts of the vessels and those most exposed to injury—the radial and ulnar near the wrist or the palmar arch. But spontaneous aneurism of the arteries of the forearm is by no means so rare as used to be thought. It usually depends either on diseased heart, or is a symptom of extensive disease of the arteries. In either case the patient's general condition is of far more importance than the local mischief. On the subject of spontaneous aneurisms occurring below the axilla, an interesting paper will be found in the *Medical Times and Gazette* for 1865, vol i., p. 567, by Mr. D. Spanton. He discovered records of four cases of spontaneous aneurism of the arteries of the forearm, and, upon inquiries at forty-one of the principal metropolitan and provincial hospitals, he was able to learn of only three other cases. Out of eleven cases of aneurism of the forearm, disease of the heart was proved to exist in five, and was suspected in a sixth. Compression was tried in three of these eleven cases, but with no benefit. Apart from the concomitant disease of the heart or great vessels, these aneurisms are easily curable. Even in the presence of such disease they are very frequently treated with success. Traumatic aneurisms, as well as spontaneous aneurisms, of the forearm and hand are also very often curable by compression, although this treatment also often fails. This depends mainly on the formation of the sac. If the sac is completely formed of stout resilient tissues, compression is likely to succeed. If, on the other hand, there is a weak, flaccid tumour which collapses a little but does not disappear when the pulsation is stopped, leaving an ill-defined bag of fluid blood, the probability is that pressure will fail. If the patient were nervous and irritable, likely to be depressed by failure, and sensitive to the pains of pressure, it would be better to perform the radical operation at once. There is this advantage in the application of pressure to aneurism of the upper extremity which the method does not possess in its application to the lower limb—namely, that it does not necessitate confinement to bed, but the patient can all the while enjoy the benefit of fresh air and exercise. The list of 337 cases of aneurism tabulated by Professor Holmes contains thirteen below the bend of the elbow: seven of these are said to have been traumatic, and an eighth (an aneurism of the palmar arch) probably was so; it was cured by direct pressure.

Indirect pressure was tried in three of the seven cases, and in two with success. In the case where pressure failed, and in three others, the clots were turned out of the tumour and both ends of the artery tied, and in all instances with success. In the remaining case—one of ulnar traumatic aneurism—it is merely noted that the ulnar artery was successfully tied. There was a ninth case, in which an aneurism of the palmar arch had been cut into before the patient's admission into hospital, and where the hæmorrhage proved fatal.

There remain four cases of spontaneous aneurism, one of the radial and three of the ulnar artery. Digital compression was used successfully in one case, the brachial was tied successfully in two; and in the remaining case compression of the brachial failed, but, as the man was near his death from aneurism of the aorta, nothing further was done, and he died a month afterwards.

In Fischer's tables are references to thirteen cases in which digital compressiou has been employed—none of them being comprised in Professor Holmes's list. One of these was a spontaneous aneurism of the ulnar in a patient with diseased heart, and one a spontaneous aneurism of the radial with no note as to any concomitant disease. In the former compression failed, and nothing further was done; in the latter it succeeded.

Of six cases of traumatic aneurism of the radial and five of the palmar arch, all but two were cured by compression. In one of these two cases the injection of perchloride of iron, and in the other the ligature, effected a cure.

It will be seen from this account that in traumatic aneurism of the arteries of the forearm there is good prospect of cure by digital pressure. When this has failed, Professor Holmes would always be in favour of the ligature of both ends of the vessel, not being aware of any case in which it has failed. They have, it is true, been treated with success in various other ways—by the injection of perchloride of iron, by the action of chloride of zinc, and by galvano-puncture. It is even possible that cures may have been effected by the Hunterian operation. But all these methods are, to say the least, quite as dangerous as the simple incision of the sac, and far more uncertain; so that there seems no reason for submitting the patient to any such experimental surgery. In those cases of spontaneous aneurisms in which, after the failure of compression, the surgeon wishes to proceed further, the brachial artery, the Professor considers, should be tied. But it must be remembered that many of these tumours seem to be of embolic origin, and it is the opinion of many good pathologists that such aneurisms are slow to rupture. It is only, then, in case of rapid growth of the aneurism, or some exceptional condition, such as pain from the neighbourhood of a nerve, that any such operation should be contemplated.

NOTES ON MADRAS AS A WINTER RESIDENCE.

No. IV.

A Few Words on Snakes—Visit to Dr. Shortt—Experiments on different Snake Poisons and different Animals—Properties of Potass as an Antidote.

Coming as I did to India fresh from the perusal of Fayrer's magnificent "Thanatophidia of India," and puzzled, as one cannot help being, by the controversy connected with Professor Halford's discovery of the use of ammonia in snake-bite, I hoped eagerly to be permitted to see some of the experiments of the great Madras ophiologist Dr. John Shortt; and I was not disappointed, for Dr. Shortt not only devoted a morning to the demonstration of his most interesting and dangerous collection of live snakes, but invited all the leading members of the medical profession to be present, and gave a sumptuous breakfast afterwards, to which the ladies of their families were invited. Nothing in the shape of hospitality could be more perfect, and nothing could offer a stronger or more exquisite contrast to the horrors and dangers of the snake experiments.

At 7 a.m. on a certain January morning the party assembled at Dr. Shortt's house near Madras. There we were invited to walk into an adjoining yard, where our curiosity was first gratified by the sight of Dr. Shortt's snakemen—a wiry set of naked savages from the hills, whose dexterity and courage in handling the snakes we had plenty of opportunity of admiring. When they put a stick neatly on the back of a snake's neck, and their great toe on the end of the creature's tail, it was quite at their mercy.

Then we inspected the snakes themselves, which were kept in cages in an outhouse, and learned incidentally how they would eat frogs when refusing every other aliment. There was the cobra, the bungarus, and the daboia—the last a sluggish, virulent brute with a shawl-pattern.

Then began some experiments—first, to show us the effects of the poison generally. Our host's snakemen had collected a set of most mangy, miserable dogs—creatures with wolf-like jaws—whom it was necessary to handle as cleverly as they did the snakes, and who little dreamed of the euthanasia in store for them. One of these was bitten by a cobra on the upper and inner part of the thigh. He cried out when the bite was inflicted, but, being let go, soon walked under a bench, where he sat down and began licking the wound, apparently in no pain. It was soon noticed that he dragged the leg a little after him, then that he became drowsy and torpid; after this, salivation, some diarrhœa, and a convulsive fit; but, speaking broadly, I should say that the death was an easy one—the creature seemed to sleep its life away, as if it had been poisoned with some intense narcotic poison. To show us the difference in the action of the poison on different animals, a fowl was bitten, which slept itself to death likewise, but much more speedily. It was curious to see how the poor creature tried to keep itself awake and upright, and how it supported its head by resting its beak on the ground.

In these experiments the dexterity and fearlessness which Dr. Shortt exhibited in fixing the snake—first by putting a stick on the back of its neck, then seizing it by encircling its throat close to the head with the finger and thumb, the thumb being applied to the back of the head and the index finger to the lower jaw, so that the snake could not open its mouth without leave, meanwhile he allowing the creature to coil itself round his arm; the evident spiteful delight which the snake took in biting, for it was no mere nibble, but a good firm grasp that he gave, taking as much as he could between his jaws; the look of malignant satisfaction in his dull eyes; and the evident danger of the experiments to the operator and possibly to the bystanders,—all these things, I confess, made me feel horribly nervous, as I was not very well that day, whilst some gallant officers present, though brave as lions, were compelled to ask for a *peg* and quit the scene of operations.

Attempts were made to get snakes to bite each other, and after some trials a cobra bit one rat snake (not poisonous), and a daboia another; but no ill-consequence followed. We then were shown the different effects of the poison of different snakes. For instance, a dog which died from a cobra-bite was cut open, and all the blood from its heart and great vessels taken in a glass vessel. It coagulated firmly, and had the appearance of healthy blood.

We next saw the process by which snake poison is collected and preserved for experimental purposes. The bowl of a spoon covered with silver paper is presented to the snake, and he bites at it. His fangs go through the paper and press against the inside of the bowl of the spoon, where a few drops exude, which can be collected and dried for future use. It was curious to see how unwilling the snake was to let go the spoon, and how Dr. Shortt performed the perilous feat of opening its mouth.

Well, a little of the poison of a daboia so collected was mixed in a spoon with some blood from a living dog. The effect was remarkable. The blood did not coagulate, as did that from the heart of the dog bitten by the cobra, but degenerated into a shiny liquid of arterial colour; and whilst the blood from the cobra-bitten dog displayed its red globules in a natural condition, that mixed with the daboia poison presented them all in a state of dissolution—the globules were shrunk up, collapsed, and empty. This was remarkable considering how little difference there was in the symptoms of the two poisons in the living animals. Nothing like an increased growth of cells of any kind was observed.

We next witnessed a set of experiments to show the effects of liquor potassæ on the snake poison and on animals poisoned with it. For this purpose a solution was made of four grains of dried cobra poison in half an ounce of distilled water. The dried poison had not lost an atom of its virulence (as we afterwards saw) although it was taken in August, 1870. The solution was slightly opalescent. On adding liquor potassæ to a still further diluted quantity, some striking chemical change evidently took place, for it speedily became of a bluish-black colour—at first slight; afterwards intense, like newly prepared ink.

Having satisfied us of the reaction between the potass and the poison, experiments were made on animals. Two dogs injected with the solution of cobra poison into the cellular tissue of the parietes of the chest died in one hour and thirty-five minutes and in two hours and forty-seven minutes respectively; whilst one dog that was injected first with cobra poison, and with diluted liquor potassæ afterwards, survived for four hours and fifty-seven minutes; and a rabbit that was injected with the dark mixture of cobra poison and liquor potassæ was quite unaffected by the operation.

This is a short summary of a most interesting series of experiments which lasted for three hours, and of which I only pretend to give the general results, for I was very unwell at the time, and my memoranda scanty. The reader will see at once that in the effects of the liquor potassæ Dr. Shortt seems to point if not to an antidote yet to something like one. I subjoin an extract from the *Madras Monthly Journal of Medical Science*, containing a case in which Dr. Shortt's diagnosis and treatment were both exemplified. The hæmorrhagic symptoms

from stomach, mouth, and kidneys and the broken-up corpuscles in the urine pointed to the *viper* rather than to the cobra, whilst the use of the potass by mouth, by enema, and by bath, and the recovery, show that there is a thread here in Dr. Shortt's hands which is well worth following out.

Snakes are by no meaus rare in Madras. I heard Dr. Shortt say that there was no "compound"—*i.e.*, garden—without its cobra. One of the largest of his live stock came from the garden of one of the most eminent medical dignitaries. People who walk out at night always carry lanterns, and some carry a piece of chain, which they rattle against the ground to frighten snakes away. It is said that the bangles and metallic anklets of the women are of use in this way. During four months that I spent in a country house near Madras, there was no week in which a snake was not killed near the house—and they came in sometimes. By one of those odd coincidences which puzzle us, whilst I am writing this letter, on the morning of May 23, up rushes a servant, saying, "Please, sar, snake in muster's bed-room." So down I go, and sure enough there is a little olive-green snake, which was discovered under the edge of the matting close to my dressing-table. How did it come there? Why, the matting was rolled up yesterday and taken out into the "compound" to be dusted, and before it was brought in probably one of the snakes which live in the palmyra trees hid himself in it. In fact, where any living creature can hide, a snake can. The fortunate thing is that they seem more inclined to run away than to fight.

It is in vain that you ask for cases of snake-bite at the General Hospital. The people who are bitten die before they can be brought in; but there is one class of exceptions. Dr. Paul tells me that occasionally, but very rarely, a juggler, who had been meddling with his snakes when tipsy, is brought in. But the number of deaths ascribed to snakes in the mortuary register is great, though vague.

Population and Deaths from Snake-bite in the Madras Presidency (*total population* 30,839,275).

Year.	Snake-bite.	Killed by wild beasts.	Snake-bite and killed by wild beasts.
1866	1890	313	—
1867	1810	334	—
1868	2344	288	—
1869	2317	242	—
1870	—	—	2729
1871	—	—	3387
1872	—	—	3116

(In England and Wales, with a population of 22,712,266 in 1871, there were 1126 violent deaths on railways and 1229 deaths from horse conveyance. In London, with a population of 3,254,260, there were in the same year 228 deaths from street accidents.)

The snake deaths and wild beast deaths were *lumped* by command of the Government of India for 1870, 1871, and 1872. They will be separated next year. [The sums paid for destruction of snakes shall be dealt with in my next.] Snake-bites, as I said, are rare in hospitals; but I saw one on June 29 in the Gencral Hospital, Madras. The patient in the preceding night had been bitten by a small bungarus. The snake was killed and identified. The patient was brought to the hospital, where the little toe of the left foot presented two minute punctures. He complained of pain, and was in a desperate fright. The punctures were each converted into a free incision; the foot was put into warm water, with a ligature round the ankle to encourage bleeding; some brandy was given; and next morning the only remaining vestige of injury were the two small parallel cuts. The man was bitten, without doubt, but *certes* there was not a symptom of poisoning.

I subjoin reports of two cases of snake-bite by Drs. Shortt and Paul from the *Madras Monthly Journal of Medical Science*:

Case of Snake-bite—Recovery.(a)

(Under the care of J. L. Paul, A.M., M.D., Surgeon to the General Hospital.)

Y.C., carpenter, aged 40 years, was brought to hospital by the police at 4 a.m. on May 16, 1871. Patient stated that he was bitten by a snake, the character of which he could not recognise, on the dorsum of his left foot at 7 p.m. last night, while on his way to Washermanpettah. He returned in a cart, but did nothing for the relief of his symptoms beyond lying on the pyal of a friend's house in Cholay, where he was found by the police vomiting and purging.

On admission, patient presented symptoms of great depression; he had a stupid, drunken look; eyes dull, listless, with drooping lids and inactive pupils; answered questions rationally but listlessly and in monosyllables; skin cold; pulse very rapid and feeble. The lips were swollen, and some bloody fluid was flowing from the mouth. It seemed at first to issue from the gums only, which were ecchymotic, with the corresponding teeth loosened as if the patient had fallen on his face. But the blood issuing from the mouth was soon found to come from the stomach as well. The urine that he passed was also bloody, and in a few hours he passed a bloody stool. On examining the left foot it was found to be slightly swollen, hot and painful to the touch. On its dorsum a small puncture could be seen from which fluid blood issued on pressure. A plasma of ipecacuan was applied over the wound, and ammonia ℥xxx. and brandy ʒj. every half-hour were prescribed by Mr. Brockman, who saw the case on admission. Dr. Shortt kindly saw the patient at noon, and recognised the symptoms as those arising from the bite of the viper tribe. He recommended the substitution of potash for ammonia, as in his own experiments he had found that snake poison previously mixed with potash was innocuous on injection into animals, and therefore he believed it a better antidote than ammonia in cases of poisoning. Liquor potassæ ℥xx. with brandy ʒj. and water ʒss. was ordered to be given every twenty minutes, and an enema with brandy ʒss. and liq. potassæ ʒj. every hour. The wound was scarified and allowed to bleed, and the patient put into an alkaline bath and retained for half an hour. To have beef-tea and what nourishment he can take. Urine acid, sp. gr. 1020. On boiling a precipitate of albumen fell, tinged with the colouring matter of the blood. Before boiling the urine emitted a bloody or fleshy smell, but after boiling it was distinctly urinous. Under the microscope tesselated epithelium from the bladder, and broken up blood corpuscles were seen.

May 16, 5 p.m.—Bloody discharge from the mouth continues; passed urine, still bloody in character, three times since noon, and has had three or four motions, which are very dark like those passed in melæna, and contain several clotted masses. Drowsy, eyelids drooping; twitching of the muscular fibrillæ in both upper and lower extremities noticed. Temperature rising; as taken by the thermometer 102·8°. Pulse has ranged about 140 since noon. Urine still acid to litmus paper.

17th.—Patient has continued in the same drowsy and listless state, but having little or no sound sleep. He complained of pain in the foot and also in the abdomen several times. Pulse varied, from 130 to 150, small and irregular; temperature 102·3° at 2 a.m. Vomited twelve times during the night, the vomited matter consisting of bloody fluid with clots of blood, which ceased after vomiting a large quantity at about one o'clock; passed eight motions, all more or less bloody, and urine five times. That passed in the earlier part of the night was very dark in colour and acid in reaction; that passed as the morning advanced was lighter in colour. He complained of thirst and took all the nourishment that was given him, with the exception of beef-tea, which he refused on one occasion. Continue the potash and brandy every half-hour and the enemata every third hour. Evening: Patient feels stronger; vomited once during the day some curdled milk, but no blood. Passed four bilious stools with very little blood, and twice urine of lighter colour. Pulse 128; skin warm; says he feels sick from his medicine. Continue medicine and enemata.

18th.—Is still drowsy-looking, with drooping lids. Conjunctivæ yellow, with some jaundice of face. Vomited four times in the night, and had five stools; the vomited matters contain no blood, and the stools are large, dark, and watery, and contain little or no blood. Urine still stained with blood, sp. gr. 1012, of acid reaction. Temperature 100°; pulse 120. Omit all medicine and brandy. Evening: Had three stools during the day, fæculent, frothy and offensive; complains of giddiness and confusion; vomited twice, no blood. Temperature 100·3°; pulse 104. Slept during the day for three hours.

19th.—Patient is still drowsy; sight hazy; conjunctivæ yellow; no motion last night; vomited once; urine contains no blood, sp. gr. 1010, not acid; temperature 99·6°; pulse 98. Poultice to foot.

20th.—He is not so drowsy this morning; eyelids slightly drooping; can discern objects at some distance; conjunctivæ and face still jaundiced. Bowels were moved twice yesterday, the stools are natural; he has passed urine five times, the urine is

(a) Reprinted from the *Madras Monthly Journal of Medical Science: Madras Hospital Reports.*

of a light straw colour, neutral to test paper, sp. gr. 1010; skin warm and moist; temperature 99·4°; pulse 78; the wound is painful and is discharging a thin fluid. Continue poultice.

21st.—Patient looks lively this morning; eyelids still slightly drooping; conjunctivæ yellow; eyes are dim; bowels moved twice, stools are natural. Passed urine five times the same as yesterday; skin warm and moist; temperature 99·4°; pulse 78.

22nd.—Patient states this morning that he feels quite well, expresses a desire to have his food increased; had no stool; temperature 99·2°; pulse 70. There is a little pain complained of in the foot. Continue poultice.

23rd.—Patient is much the same. Continue poultice.

24th.—Patient is improving. Continue poultice.

25th.—Patient is gaining strength, and is improving in health. Continue poultice.

26th.—Patient is doing well; the scarified part is nearly well. To have it strapped with adhesive plaster.

27th.—Quite well. Discharged.

Cases of Snake-bite.(b)

(By John Shortt, M.D., Surgeon Superintendent-General of Vaccination, Madras Presidency.)

To the kindness of Dr. Balfour, Inspector-General Indian Medical Department, I am indebted for a copy of the following letter from Dr. Robertson, of the 1st Regiment N.I., Kamptee:—

"With reference to Circular Memorandum No. 2408, dated May 19, 1871, from the Secretary to the Inspector-General, Indian Medical Department, Madras, I have the honour to report that on the 4th and 5th instant two fatal cases of snake-bite occurred in this cantonment. It appears that on the afternoon of the 4th a woman was collecting some leaves in a garden about a mile beyond the cavalry lines when she suddenly found herself bitten by a snake. She hurried home to her friends in the bazaar, and is reported to have died in about an hour from receipt of the injury. It is believed no treatment of any kind was adopted. Her body was subsequently brought to the dispensary. Immediately above right heel two small punctures were observed, from which a little blood had trickled; there was no œdema or congestion of the limb. About noon on the 5th a man was brought to the dispensary by the police on account of a supposed snake-bite. It was reported that he had slept during the previous night in the verandah of a house distant about two miles from the cantonment; that about 3 a.m. he felt bitten in the back by some insect, but at the time took no further notice of it and went to sleep again. In the morning he felt very unwell, and the neighbours, becoming alarmed, reported the circumstances to the police. On admission he appeared drowsy, but answered questions satisfactorily, and confirmed the above statement. At the part pointed out by him there was no apparent mark of injury, but subsequently two very small punctures were discovered, about two inches to the left of the first lumbar vertebræ. He complained of pain generally all over the body, had slight spasms, and suffered from a choking sensation in the throat, with difficulty of swallowing; pulse small and feeble. After admission he rapidly became quite unconscious; pupils were dilated, and spasms increased in severity and frequency till about 6 p.m., when he died. Immediately on admission half a drachm of liquor potassæ dissolved in two ounces of brandy was given. Unfortunately, the patient was able to swallow only one dose, but an enema containing one ounce of brandy and a half-drachm of liquor potassæ was given every half-hour for the first three hours, and subsequently an enema containing one ounce of brandy and two drachms of spirit. ammon. aromat. The part supposed to have been bitten was rubbed with liquor potassæ. As no punctures were then visible, cupping was not applied. Sinapisms were also applied to the nape of the neck, chest, and epigastrium, and turpentine frictions to the lower extremities. Once or twice after the enema the pulse rose for a short time, otherwise the treatment employed did not appear to produce any effect."

This case is of considerable interest, and it is to be regretted that the other means—such as the potash bath, etc.—were not tried, more especially as the patient was unable to swallow; and it is a pity that in testing the potash treatment any other remedy should have been used.

It will be observed that in Dr. Paul's case of snake-bite—republished above—the patient was not taken to the hospital till nine hours after he was bitten, and on admission he was treated with brandy and ammonia by the Resident Assistant-Surgeon (Mr. Brockman), and as he became worse and passed large quantities of blood by the stomach, urethra, and bowels, and as blood was also oozing freely from the gums, a few doses of perchloride of iron were administered as a styptic to arrest bleeding from the mucous surfaces, but without effect. Mr. Brockman now kindly invited me over, and when I arrived at the hospital it was 12 noon, or eighteen hours after the patient had been bitten. The man was quite drowsy and listless; pulse thready and fluttering; skin dry; mouth, lips, moustache, and hands were stained with blood, which was also oozing freely from the gums. The patient was easily aroused, and replied correctly but listlessly to questions, and soon relapsed into the same drowsy, listless state, with the eyes dull, half-closed, and turned upwards with evident ptosis and inability to look upwards or raise the upper lids. He complained much of pain and numbness in both the lower extremities from the pelvis downwards, the muscles of which were acting spasmodically with constant twitching of the fibrillæ. The left foot was swollen, and the instep had a sodden feel; the visible fang-point was laid open to the extent of two inches; the part was infiltrated with dark blood, and a little oozed out. In my presence both bladder and bowels were voided, and contained much venous or dark-coloured blood. As the man was evidently sinking, and on ascertaining from Mr. Brockman that the patient was getting much worse, I suggested a trial of the potash treatment, to which he kindly assented. The treatment was commenced at 12.30 noon, when the liquor potassæ and brandy, as noted in the case, were administered. The patient was then made to sit in a hot hip-bath, to which was added four ounces of the liquor potassæ, the warm water was thrown over his body, from the shoulders downwards, the incision on the left instep was opened out by the finger, and well washed in the bath with the potash water. The effect of the bath was to relieve the spasms of the lower extremities immediately. The patient was made to wash out his mouth frequently with the water from the bath, in which he was kept for half an hour; and as the wound bled freely in the bath, a pledget of lint was placed over it, a bandage applied to the foot, and on his removal his foot was kept immersed in the bath for some time longer. The patient was seen by Dr. Paul in the evening, who kindly permitted the potash treatment to be continued. On boiling, the urine contained (half-and-half) equal parts of (blood) albumen and urine. The snake that bit him is called rutha vyrien, the bungarus arcuatus, which is readily recognised by the natives, and stands next to the cobra in the deadliness of its wound, except that death does not take place quite so rapidly as in that of the cobra; but it seems characteristic of this species of snake poison to render the blood so fluid that the vessels can no longer retain their contents, which consequently ooze out from most of the mucous openings, and on this account this snake has in Tamil been characteristically termed the blood viper or rutha vyrien. From my own experiments, also, the viperine poison generally has a tendency to cause a fluidity of the blood, and in this quality the bungarus stands at the head of the list. Many people, however, disbelieve this fluidity and oozing of the blood from mucous surfaces by snake-bite, and attribute such reports as fabulous, originating in "travellers' tales." The patient was seen by Drs. Paul, Chipperfield, and Brockman, the Surgeon, Physician, and Resident Assistant-Surgeon of the General Hospital, and also by Dr. Rickard, Assistant-Surgeon doing duty at the General Hospital, Madras. This is the third case of snake-bite cured by the potash treatment: the first two were occasioned by cobras and the present one by a bungarus; the first case was published in the *Lancet*, vol. i., 1870, page 540, the second case in the *Madras Monthly Journal of Medical Science*, vol. i., January to June, 1870, page 450, and the present is the third case. In the first, suction and ligature were called into play; in the second ligature only, in addition to potash treatment; but in this last neither suction nor ligature was made use of, but the potash treatment alone was relied on. The treatment is rational, and not ostensibly miraculous, as reported in the Australian newspapers, where patients from snake-bite are said to be moribund, and on the injection of a few drops of ammonia into a vein immediately start up on their legs perfectly well. Long before I had the opportunity of testing the action of the liquor potassæ on the human subject, I ascertained the property it possessed of neutralising snake poison, and the difficulty I experienced was to introduce some means to expedite its action in the living blood. After repeated trials and experiments, I found that

(b) Reprinted from the *Madras Monthly Journal of Medical Science*.

brandy as a diffusible stimulant roused the nervous system, excited the circulation, and thus carried the potash into it as rapidly as possible, and enabled it to overtake and neutralise the poison in the blood. The secret of success, then, consists in bringing the patient's system rapidly under the influence of the brandy—or in other words to make the patient *drunk* as speedily as possible, and maintain this effect for some time after. During the first forty-five hours of the patient's stay in hospital he took seventy-two ounces of brandy and four ounces and a half of the liquor potassæ by the mouth, fourteen ounces of brandy and three ounces and a half of the liquor potassæ by means of enemata through the rectum, and four ounces of the liquor potassæ was used in the bath he had. In all eighty-six ounces of brandy, and eleven ounces of the liquor potassæ were used in this case!

TREATMENT OF SNAKE-BITE BY INTRAVENOUS INJECTION OF AMMONIA A CENTURY AGO.

Extract from a Letter from F. Fontana *to* M. Gibelin, *Aix-en-Provence.* ("*Opuscoli Scientifici di Felice Fontana*," *page* 125). *Dated Florence, July* 10, 1782. (*Translated from the Italian.*)

"It is very true that our Italian journals report several cures by *ammonia injected into the veins of persons bitten by the viper:* and it is also true that these cases partake of the marvellous and almost of the miraculous. It appears, moreover, that certain individuals have had great pleasure in assuring the public that a true specific against that poison has been discovered,—that which I had sought in vain for many years, and which with philosophical candour I had declared the inutility of searching for. I must confess that it did not occur to me that I should find a remedy in 'Medicinâ Infusoria.' . . . I have experimented with lambs and rabbits. The lambs have been bitten two or three times, but the rabbits twice only, in the thigh, and the ammonia has been injected into the jugular vein immediately after the bites were inflicted. The doses used were of twenty to forty drops—not sufficient, as I had ascertained by experiment, to destroy the animals, for larger quantities might have been hurtful. Three lambs were thus treated, and they all died—two in less than two hours; one in a few minutes. Of several rabbits that were bitten, only two lived for ten hours, the rest died in less than an hour. Twelve experiments, I know, may not be sufficient to prove the absolute inutility of the ammonia in the treatment of viper-bite; but they are sufficient to prove that that fluid is not a specific as it is reputed. And they show moreover that one should not place any confidence in the few favourable cases that are quoted by the supporters of that remedy.

"So long as physicians do not perform experiments, the useful art of healing will not make much progress, and this is the reason why the medical art has remained stationary from the days of Hippocrates until now, whilst all other sciences have been making gigantic strides. The physician regards as a remedy for the disorder that medicament which has been followed by recovery, when in sound logic no other deduction can be drawn than that the vaunted remedy has not killed the patient; and we see that the physician quietly reasons and believes that the sick person would have certainly died had he not been treated by him, and with this supposes that which he does not know, and which is most likely altogether untrue. And it is not sufficient that the patient has recovered, but he is further convinced that without the remedy he must have died."

With reference to the use of ammonia as an external application or administered by the stomach, he says (p. 111, Fontana on Poisons)—"It is, then, a fact proved that ammonia is entirely useless, whether applied simply to the bitten part or whether taken internally, and there is even reason to suspect that it was hurtful."

Royal College of Surgeons.—At a meeting of the Council on Thursday, the 14th inst., Mr. Thomas Rivington Wheeler, of Tunbridge, Sevenoaks, was elected a Fellow; his diploma of Membership dated May 10, 1843. The Council will not meet again until October.

Académie de Médecine.—At the meeting of Aug. 12 the Academy elected into the section of Medical Pathology Professor Hirtz, formerly of Strasburg, and now of Nancy.

FRANCE.

Paris, August 18.

Condition of the Maternity Wards, and Causes of Mortality in the Paris Hospitals—Value of New Remedies and Dressings—Cotton-Wool Dressings—Jardin d'Acclimatization—Fattening Chickens—Training Zebras.

In continuation of my note on hospitalism in Paris, I may here observe that the remarks I made as to the insanitary condition of the hospitals in the French capital apply with redoubled force to the maternity and lying-in wards. Here, as in the surgical wards, septo-pyæmia—known under the name of "puerperal fever"—commits great havoc, which may also be attributed to overcrowding; for in one room, where there should not be more than six or eight patients, you will find at least twelve, with only a metre between the beds, and if to this be added the new-born infants, the number is nearly doubled. The cradles of the infants are placed between the patients' beds, which must necessarily reduce the cubic space to a considerable extent; and although this is rather more than that allowed in the other wards, it is still far from sufficient for the well-being of any human subjects, whether healthy or otherwise. Many attempts have been made to remedy this deplorable state of things, but the apathy of the French in these matters is incomprehensible, and the red-tapeism by which the hospital physicians and surgeons are hampered places it out of their power to propose any reform. In confirmation of this, I have heard a celebrated hospital accoucheur say that he had, some twenty years ago, applied for certain measures for the amelioration of the lying-in women and their offspring, and it is only lately that one of those measures has been conceded. This consists in the employment of wet nurses to replace the mothers prematurely confined, or otherwise unable to suckle their children, at least during their stay in hospital.

In conversation with a well-known surgeon on the subject of the great mortality in the Paris hospitals, he said that the true cause was not to be sought either on the walls, in the atmosphere, or in germs, but in the different operative procedures, and the low vitality of the subjects operated on; and in order to prevent septicæmia or pyæmia, the surgeon should have recourse to such methods of operation as would reduce these accidents to a minimum, supporting at the same time the strength of the patient by wine and good diet. The former he would answer for, and his plan consisted in crushing or tearing, not cutting, the tissues, which latter leaves the vessels gaping, and thus facilitates the absorption of putrid or putrescent matter; and if the diet and other comforts were properly attended to, he should never have had a single death in his wards, as he never had one in his private practice. In the hospitals, he continued, the patients had the best medical and surgical advice, but the want of proper nursing and good food nullified all other advantages, and the patients either succumbed from starvation or indirectly from its effects.

Whenever anything new is introduced in medicine or surgery it is generally adopted with more or less of enthusiasm, and before a proper trial is given the operation or cure is often held up as infallible; but, like all things human, its fame is but transitory, or it lasts only till eclipsed by another nine days' wonder, and so on. Thus, it was thought that in the eucalyptus globulus a good substitute was found for quinine in intermittent fever, and balsam of copaiba in gonorrhœa—in both of which these new remedies have signally failed. The propylamine, so much vaunted in rheumatism, is a complete failure; and chloral hydrate as a hypnotic is not in much favour in the Paris hospitals, but it is considered a good antiseptic, and has been lately employed as a detersive in foul ulcers. You are aware that carbolic acid has also been proposed as a substitute for quinine as a febrifuge; but as its use as such has been attended with uncertain results, it has almost been abandoned, and recourse is had to the time-honoured antiperiodics. It is now recommended as a nervine, but whether it will be entitled to take its place as such remains to be seen. M. Bert, a young physiologist, after some

experiments with carbolic acid on animals, which he injected pure into the stomach in doses of three to four grammes for a dog, and one gramme for a rabbit, has come to the following conclusion:—"That carbolic acid in large doses acts principally on the excitability of the spinal marrow, whence result convulsions of a clonic and irregular character which affect in succession different parts of the same muscle. These convulsions leave intact muscular contractility and nervous excitability properly so-called, and are arrested by chloroform, chloral hydrate, ether, curare, etc. In other words, carbolic acid in poisonous doses is a convulsivant, which fact would point to its utility in certain forms of paralysis, or as an antidote to certain poisons. This action of carbolic acid on the nervous system is altogether independent of its effects of another order which it exercises on the organic corpuscles, and of the sort of imputrescible combination which it forms with the divers agents of fermentation and putrefaction which exist in the air." But even as an antiseptic or disinfectant, carbolic acid has considerably fallen, and the essence of the eucalyptus globulus is now extensively employed in its stead. The eucalyptus globulus has certainly a more agreeable odour, but whether it possesses antiseptic properties is another question, which time and clinical experience alone can solve.

The accidents that have lately occurred with the aspiratory instrument have shaken the faith of many physicians and surgeons, and the old plans of treatment in the cases in which the instrument has been employed are being resumed. The "pansement à l'ouate," or cotton-wool dressing, is already on the wane. It is considered by some as being unscientific, and not free from danger; but, setting aside the prejudice entertained against the cotton itself, this mode of dressing large wounds and amputated limbs has somewhat disappointed the expectations of most surgeons here. Not wishing to condemn it without giving it a fair trial, some who had adopted it told me that it was certainly most useful in amputations: the patients felt comfortable with it, but they do not approve of its being kept on so long undisturbed (thirty days on an average) as recommended and practised by Alphonse Guérin, as fatal cases of secondary hæmorrhage have occurred which might have been prevented with the other modes of dressing; whereas, with the cotton-wool employed according to the rules laid down by M. Guérin, it is impossible to see what may be going on under it. Besides this, when suppuration takes place—which it does not always prevent—the pus is retained, putrefaction of the latter takes place, and becomes a source of danger, not only to the patient himself, but to those around him. Taking all these disadvantages into consideration, some surgeons, looking upon the germ theory as a myth, at least so far as regards wounds and ulcers, have made a sort of compromise between the cotton-wool and the ordinary modes of dressing. For instance, Professor Dolbeau, of the Beaujon Hospital, applies the former, and keeps it on for about fifteen days, and then replaces this by other dressings according to the circumstances of the case. He had recourse to this plan, as, in a case of amputation of the leg he had treated in this way, mortification set in, of which he only became aware by the stench which emanated from the limb, which, to save the man's life, he was obliged to remove from above the knee. From his own experience M. Dolbeau also found that in wounds dressed with cotton-wool the process of cicatrisation was undoubtedly slow, and in cases of fracture the formation of the callus was very much retarded. Some surgeons will not have the cotton-wool dressing in their wards on any account—at least, not to the extent employed by M. Guérin. Besides the disadvantages mentioned above, cotton-wool is a dirty dressing, for whilst preparing the wool for use the surgeon and his assistants are covered with particles which become detached and float about in the air, much to the annoyance of the patients in the ward. M. Tillaux, I must say, has been more successful with the cotton-wool dressing, and he employs it in a variety of cases. At the Hôpital Lariboisière, to which he is now surgeon, he lately removed an enormous tumour from the right breast of a woman aged 57. He then covered the wound with cotton-wool and sent the patient home, where she was watched and followed, and recovered in six weeks after the operation, the dressing having been only once changed during all that time. The tumour, which was elastic, irregular, and fluctuating where the skin was red and somewhat thinned, weighed 6½ kilos. (about 13 lbs.) It was not adherent to the pectoral muscles, and began at the nipple. There were no diseased glands in the axilla. The circumference of the tumour at its base was thirty inches and a quarter; vertical diameter, six inches and three-quarters; transverse ditto, eight inches and three-quarters; circumference in the middle, thirty-one inches and a half; and the wound left by its removal measured, when stitched, fifteen inches and a quarter in length. The development of the tumour took place rapidly, and it attained its present size in the space of two years. M. Tillaux diagnosed it to be an adeno-sarcomatous tumour.

Among the promenades in summer, the "Jardin d'Acclimatization" forms one of the greatest attractions. It is situated in the "Bois de Boulogne," just outside Paris, and was founded about thirteen years ago by a private company. The Jardin d'Acclimatization, as it names implies, is intended for the acclimatisation of every species of exotic animals or vegetables, useful or agreeable, domestic or wild; but besides these are also to be found the best specimens of indigenous animals and plants. These gardens suffered a good deal during the Prussian siege and the Commune, and many of the animals disappeared to serve as food for the starving Parisians. They are, however, being restored, and under the able superintendence of M. A. Geoffroy Saint-Hilaire, son of the great naturalist, the Jardin d'Acclimatization is fast recovering its former splendour. I shall not here attempt to give your readers a description of the grounds and all to be seen in the place, but I may mention, *en passant*, that having visited the splendid aquarium, aviary, hothouse, menagerie, etc., I was attracted to a cottage with the words "Engraissement Mécanique des Volailles" written over the door. This is a new establishment, and intended to show how poultry may be fattened for the table at the least possible expense and delay. The process is a cruel one, but, when one considers that these creatures are destined for the food of man, it matters little whether they are killed outright or be prepared for ultimate slaughter. The birds, which consist of common fowls, ducks, and turkeys, are confined in small open stalls, which are just large enough to receive them, and in which they are so fastened that they can hardly move. Here they are fed with an emulsion composed of milk and oatmeal, which is pumped into their gizzards at stated hours. This is all the food they get, and, with the exception of the ducks, which are allowed a little water, they have no other drink. This, I was told by the director, who is also the inventor of the machine, is sufficient to fatten them in from twelve to eighteen days. They are taken in from three to six months old, and the cost of feeding is trifling compared with the other modes. A little further on is to be seen a young filly just foaled, which is looked upon as a curiosity, as it is the offspring of a marc-mule with an Arab horse, and the first specimen of the kind known in France. With the exception of the colour of its coat, which, like that of its dam, is of an iron grey, the filly takes more after its sire. The zebras are the finest specimens I have seen, and M. Geoffroy Saint-Hilaire, the present director, has been trying to train a pair for draught, but he has had to give it up, owing to the indomitable nature of these animals. A cross between a zebra and a horse was produced about six years ago in these gardens, but the colt, which was like its dam, did not survive more than six weeks. The zebras here have never been known to breed among themselves.

PROVINCIAL CORRESPONDENCE.

BIRMINGHAM.

August 6.

GUARDIANS AND THEIR MEDICAL OFFICERS—SURGEONCY OF THE GAOL—SURGICAL INSTRUMENTS—HEALTH OF THE TOWN.

THE medical officers of the Birmingham parish have just had administered to them a most unmerited snubbing by the guardians. It appears that they had the temerity to apply for an increase of salary to the extent of £50 a year, basing their application on length of servitude—most of them having been in office over eleven years,—increased cost of living, both for men and beast, and a decrease of parochial income, in consequence of the loss of the vaccination appointments which they formerly held, and from which they derived considerable emolument. Instead of their application being received in a proper and courteous manner, it was pronounced to be "extraordinary," and unceremoniously shelved for other business of a totally opposite character. In one instance, however, the guardians relaxed in their rigid parsimony in favour of one

of the staff, whose salary they increased by £25 a year, owing to the large number of midwifery cases which occurred in his district.

For the surgeoncy to the gaol, the stipend of which has been reduced to the paltry sum of £100 a year, there are only four candidates, and these all strangers to the town. This shows the slight estimation in which the appointment is held by resident surgeons, who consider the pay for the labour and responsibility involved totally inadequate. The work at the gaol is heavy, and we predict that the authorities in whose hands the office rests will, in the long run, find to their cost that it is not the wisest policy to have work done cheaply.

Our town is becoming quite famous for the designing and manufacturing of surgical instruments. *Apropos* of this subject, we may mention that our attention has been directed to the assortment of Mr. Salt, of this place, who is an F.R.S.L., and who has for many years occupied a foremost place in the list of provincial surgical instrument makers. He is not only a manufacturer, but an author of several important surgical works as well. His new "insufflator," made on the suggestion of Mr. Clay for the treatment of uterine diseases, is a very useful and ingenious instrument. It has been used in chronic, inflammatory, and malignant affections, and the results have been most satisfactory; it is now well known in the profession. This instrument of Mr. Clay's has been modified by Mr. Wilders, of the Queen's Hospital, and made subservient to the treatment of diseases of the urinary passage, more especially in gleet and gonorrhœa, with marked success.

Mr. Salt's clinical thermometer is one of the best of its kind, although two others, similar in appearance and construction, have lately appeared in the market. This thermometer is fixed in an "aluminium" case, and is propelled and retracted in a manner somewhat similar to the American pencil—viz., by rotating the small end to the right and left respectively. In addition to being portable when sheathed and long when protruded, it is the only instrument in which case and thermometer are inseparable. The shape of the case (fluted) prevents it from rolling off the table, and as, when retracted, the thermometer is wholly within the case, it is protected from being broken whilst the index is being replaced. The instrument is neat in appearance, and convenient for the waistcoat-pocket or the ordinary dressing-case.

Mr. Salt has also made a new vaccinator, quite unique of its kind. It is called the "mitrailleuse," and contains within itself a good supply of capillary tubes and two lancets—one fixed and the other movable. It is a capital invention, and will doubtless become a favourite with all public vaccinators.

With the decline of small-pox diarrhœa has sprung up and is assuming epidemic proportions. Coming on with incessant sickness and purging, it is succeeded by cramps and exhaustion. The mortality from it to the present time has not been great. We are inclined to think that one of the principal causes of this complaint here in adults arises from the large quantities of bad beer, in a state of fermentation, which is drunk by the working classes—that which is brewed and concocted on the premises, and which is very far from being pure and unadulterated.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Aug. 14:

Boodle, Robert Maxwell, Park-terrace, Highbury.
Emmerson, Wm. Lindsay, Seaton Colliery, Durham.
Satchell, Walter Alfred, Argyll-road, Kensington.

The following gentlemen also on the same day passed their primary professional examination:—

Bartlett, Henry, Guy's Hospital.
Kellard, James T. W. S., Guy's Hospital.
Collenette, Frank de Beaucamp, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CONOLLY, FULLOM, M.R.C.S. Eng., L.S.A., L.R.C.P. Edin.—Assistant Medical Officer of the Derbyshire Lunatic Asylum, Mickleover, *vice* Mr. Courtenay, appointed Resident Medical Superintendent of the Limerick District Lunatic Asylum.

DAVIES, JOHN, M.R.C.S.E.—House-Physician to the Westminster Hospital for twelve months.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—Jacob Edward Dyas, to be Staff Surgeon in her Majesty's Fleet, with seniority of July 12, 1873.

WAR OFFICE.—MEDICAL DEPARTMENT.—Staff Assistant-Surgeon Alexander Neill, from half-pay, to be Surgeon, *vice* Francis Alfred Turton, promoted.

BIRTHS.

BINGHAM.—On August 6, at Church-street, Alfreton, the wife of John J. Bingham, L.R.C.P., M.R.C.S., of a son.

DURHAM.—On August 15, at West House Aldwick, near Bognor, the wife of Arthur E. Durham, M.B., F.R.C.S. Eng., of 82, Brook-street, Grosvenor-square, of a daughter.

EDGELOW.—On August 17, at 18, Hertford-street, Mayfair, W., the wife of George Edgelow, M.D., of a son.

ELLIOTT.—On August 18, at Manor-road, Forest-hill, the wife of John W. Elliott, M.R.C.S. Eng., of a son.

HAYES.—On August 14, at Basingstoke, the wife of Hawkesley Roche Hayes, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

PARSONS.—On August 6, at St. James's-street, Dover, the wife of Charles Parsons, M.D., of a son.

PROVIS.—On August 15, at The Chantry, Mere, Wilts, the wife of W. Provis, L.R.C.P. Edin., M.R.C.S. Eng., of a son.

SAXBY.—On August 2, at Inveray, the wife of Henry L. Saxby, M.D., of a son.

SHILLITOE.—On August 13, at Birch Mount, Sydenham-hill, the wife of Buxton Shillitoe, F.R.C.S., of a daughter.

SMITH.—On August 16, at Vine Cottage, Babbicombe, Torquay, the wife of Clement M. Smith, M.D., of a daughter.

MARRIAGES.

BROWNING—NETTLEFOLD.—On August 16, at St. Stephen's, North Bow, Henry S. Browning, Esq., of 24, Paternoster-square, to Amelia Elizabeth, only child of the late Edward Nettlefold, M.D.

CAVAFY—RALLI.—On August 16, at the Greek Church, London-wall, John Cavafy, M.D., son of G. Cavafy, Esq., of 26, Pembridge-gardens, W., to Marigo, daughter of Antonio Ralli, Esq., of Clapham-park.

CLARKE—MACGREGOR.—On August 6, at 43, East Claremont-street, Edinburgh, Alexander Carson Clarke, M.D., M.R.C.S.E., Manchester, to Jane, only daughter of the late John MacGregor, Esq., Edinburgh.

FORREST—RODGER.—On August 14, at St. Luke's Church, Cheltenham, John, son of the late Dr. John Forrest, C.B., Inspector-General of Hospitals, Honorary Physician to the Queen, to Eveline, younger daughter of John Graham Rodger, Esq., of 1, College-lawn, Cheltenham.

HARRIS—BUCKLAND.—On August 11, at St. Stephen's, Shepherd's-bush, William Harris, L.R.C.P., etc., Melton, Suffolk, eldest surviving son of Henry Harris, M.D., F.R.C.S., etc., Redruth, to Annie Buckland, R.A.M., daughter of James Warwick Buckland, Esq., late of her Majesty's Customs, London.

JELLARD—GEDDES.—On August 13, at Wrabness, Essex, Frederick Pering, only son of the late P. Jellard, Esq., of Kingsbridge, Devon, to Mary Margaret, elder daughter of the late David Geddes, M.D., R.N.

KOUGH—MILLAR.—On August 12, at Monkstown Church, county Dublin, Edward Kough, M.B., of Windlesham, Surrey, to Mary Elizabeth, daughter of Adam Millar, Esq., of Queen's-park, Monkstown, county Dublin.

MAIR—MORGAN.—On August 13, at Llansamlet, Glamorganshire, A. Hunter Mair, M.A., M.B., C.M., of Morriston, Swansea, to Annie Margaretta, second daughter of the Rev. M. L. Morgan, B.D., vicar of Llansamlet.

LANG—SMITH.—On August 13, at St. Patrick's Church, Waterford, Thomas B. Lang, M.D., of Groombridge, Sussex, to Emily, second daughter of Thomas D. Smith, Esq., of Waterford.

SLATER—BEAN.—On July 14, at St. Paul's Cathedral, Calcutta, John S. Slater, Esq., C.E., Public Works Department, Bengal Presidency, third son of the Rev. S. Slater, Simla, to Jessie Frances, daughter of John Bean, Surgeon-Major Bombay Medical Service, retired.

SLIMON—CRONDACE.—On August 12, at St. Mary's, Putney, George C. Slimon, M.D., to Ellen Elizabeth, eldest daughter of the late George Crondace, M.R.C.S., Durham.

WEBB—LOVELL.—On August 12, at St. Michael's, Compton Martin, Somerset, Anthony Edward Webb, of the city of Bath, solicitor, to Ellen Mary, eldest daughter of William Frederick Lovell, of Compton Martin, Somerset.

WILSON—ANDREWS.—On August 12, at Broadwater Church, Taylor Dalrymple Wilson, Lieutenant 21st (R.N.B.) Fusileers, third son of Dr. T. W. Wilson, of Worcester-park, Surrey, late Presidency Surgeon of Calcutta, to Fanny Amelia May, eldest daughter of C. G. Andrews, late Surgeon-Major H.M. Indian Army.

DEATHS.

AUSTIN, EDWARD V., M.R.C.S. Eng., L.S.A., at Reigate, Surrey, suddenly, of heart disease, on August 9, aged 63.

DIXON, HALLAM MOORE, M.D., Medical Superintendent on board H.M.S. *Hamadryad* Hospital Ship, Cardiff, on August 6, aged 43.

EDWARDES, ROBERT, M.R.C.S. Eng., Staff Surgeon R.N., on August 15, aged 38.

SAXBY, HENRY L., M.D., at Inveray, on August 4, aged 37.

TRAVIS, NATHANIEL, F.R.C.P. Lond., M.D. Edin., F.R.C.P. Edin., of Nice, eldest surviving son of William Travis, M.D., formerly of Scarborough, at Brussels, on August 14, aged 71.

WADD, MABEL AGNES, daughter of Frederick J. Wadd, M.B., M.R.C.S. Eng., at Beaconsfield, Bucks, on August 15, aged 2 years.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ARDWICK AND ANCOATS NEW DISPENSARY AND HOSPITAL, MANCHESTER.—Senior House-Surgeon. Applications, with testimonials, to the Rev.

W. Hutton, Honorary Secretary, 57, Higher Ardwick, Manchester, on or before August 30.

Bournemouth Dispensary.—Resident Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the President of the Bournemouth Dispensary, care of J. G. Douglas, M.B., on or before August 28.

Brighton Hospital for Sick Children.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

Brighton and Hove Lying-in Institution.—House-Surgeon. Candidates must be M.R.C.S. of Great Britain or Ireland, and L.R.C.P. or L.S.A. Lond. Applications, with testimonials, to the Chairman of the Committee of Management, 76, West-street, Brighton, on or before September 3.

Burton Infirmary and Dispensary.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Honorary Secretary, J. C. Grinling, Esq., Burton-on-Trent, on or before September 1.

Clayton Hospital and Wakefield General Dispensary.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to John Binks, Esq., Honorary Secretary, Wakefield.

East Suffolk Hospital, Ipswich.—House-Surgeon and Secretary. Candidates must be unmarried, and M.R.C.S.E. and L.S.A., or L.R.C.P. Applications, with testimonials, to the Secretary, on or before September 2.

Evelina Hospital for Sick Children, Southwark-bridge-road, S.E.—Registrar. Particulars may be obtained from the Hospital.

General Hospital, Birmingham.—Resident Registrar and Pathologist. Candidates must be duly qualified. Applications, with testimonials, to the House-Governor and Secretary, on or before September 6.

Inverary (Parish of).—Medical Officer. Applications, with testimonials, to A. Henderson, Esq., Town Clerk, Town Clerk's Office, Inverary, on or before August 30.

Manchester Royal Infirmary, Dispensary, and Lunatic Hospital.—Honorary Assistant-Physician. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Board, on or before August 30.

Newcastle-upon-Tyne Borough Lunatic Asylum.—Assistant Medical Officer. Candidates must be registered. Applications, with testimonials, to John Atkinson, Clerk to the Committee of Visitors, on or before August 30.

St. Thomas's Hospital.—Resident Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Applications, with testimonials, to the Treasurer.

Skipton and Settle Union, Yorkshire.—Medical Officer of Health. Candidates must be legally qualified medical practitioners, and registered. Applications, with testimonials (three copies of each), to Thomas Brown, Esq., solicitor, Skipton, on or before September 5.

Ripon Dispensary and House of Recovery.—Resident House-Surgeon and Dispenser. Candidates must be unmarried, and duly qualified Applications, with testimonials, to the Honorary Secretaries, on or before August 30.

Wantage Union.—Medical Officer. Candidates must be duly qualified, Applications, with testimonials, to Edward Ormond, Clerk of the Union. Wantage, on or before September 8.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Alresford Union.—Mr. George Hayles has resigned the Second District; area 22,094; population 3510: salary £100 per annum.

East Ashford Union.—Mr. W. F. Brook has resigned the First District; area 15,752; population 2901; salary £60 per annum. Also the Workhouse; salary £55 per annum.

Loddon and Clavering Union.—The Second District is vacant; area 15,522; population 3834; salary £55 6s. 4d. per annum. Also the Workhouse; salary £40 per annum.

Romney Marsh Union.—Mr. F. H. Wood has resigned the Brookland District; area 7686; population 966; salary £50 per annum.

Tendring Union.—Mr. Allen Freshfield has resigned the First District; area 3306; population 5070; salary £56 per annum.

APPOINTMENTS.

Banbury Union.—John Colegrave, M.R.C.S. Eng., L.S.A., to the Bloxham District.

Bridgwater Union.—Ephraim F. H. Burroughs, L.R.C.S. Ire., L.A.H. Dub., to the Middlezoy District.

Cirencester Union.—John D. Watson, M.D. and C.M. Univ. Edin., to the Western District.

Wigan Borough.—Mr. Ralph Betley as Analyst.

Woburn Union.—George A. D. Mahon, M.R.C.S. Eng., L.S.A., to the Aspley Guise District.

SUPERANNUATION ALLOWANCES.

Longtown Union.—Dr. Wm. Graham has been granted an annual allowance of £30 per annum, after having served as Medical Officer for the Low District and the Workhouse for a period of over thirty years.

Rochdale Union.—Mr. A. Coventry, late Medical Officer for the Spotland District and the Workhouse, has received an annual allowance of £50 after twenty-eight years' service.

Dr. J. R. Shields has been appointed Medical Officer of Health for Llanidloes.

The following medical officers of the volunteer service have lately passed the necessary examination at the Army Medical Board in order to obtain the increased capitation grant for their corps, viz.:—Dr. Baines, Surgeon, and Mr. William Keen, Assistant-Surgeon, 1st Middlesex Engineer Volunteers.

Professor Rokitansky.—This distinguished ornament of the Vienna Medical School has announced to the Professoren-Collegium that next year he will have attained his seventieth year. According to the regulations he should then retire from his professorship, and be placed on the pension-list. It seems, however, that, seeing the great loss his retirement would inflict on the Vienna School—the founder of which he may be almost considered,—an effort will be made to have his case regarded as an exceptional one as long as his present good health and teaching-power continue.

The Anderson School of Natural History.—This establishment, on Pennikese Island, was formally opened on July 8 by an address of Professor Agassiz, the director. The number of students has been limited to fifty-six, being but a small portion of the applicants. There is scarcely a State in the Union that is not represented, most of the pupils being professors and teachers in normal and high schools and colleges. The building which is being erected will contain on its upper storeys the dormitories, while the floor will be arranged as laboratories. Each of the two wings (united by a spacious lecture and dining hall) will contain twenty-eight aquaria and working tables—one for each student, who is responsible for their condition. Want of attention in this matter will forfeit the right of remaining at the School. The island is about sixteen miles south of New Bedford, and is about three-quarters of a mile long by half a mile round, and comprises about one hundred acres. Mr. Galloupe has followed up Mr. Anderson's magnificent present of the island by giving the school a yacht of eighty tons. Professor Agassiz will be assisted by numerous "scientists," among whom are Drs. Wilder and Packard, Count Pourtales, Professors Waterhouse Hawkins, Mitchell, Brown-Séquard, Guyot, etc. In the circular which Professor Agassiz has addressed to applicants he says that Pennikese Island is to be regarded, not as a place for recreation, but real hard work and original observation, little or no recourse to books being encouraged during the summer session. "I want to prepare those who attend to observe for themselves, that they may hereafter be able to make the most of their opportunities for study of nature." It will be obligatory on the part of the students to make special collections to carry home and use as a basis for teaching others.—*New York Medical Record*, July 15.

Cod-liver Oil Loaves.—MM. Carre and Lemoine state that of all means of disguising the taste of cod-liver oil its introduction into bread during panification is the best. Every pound of bread should contain seventy-five grammes of oil (five spoonfuls) and about ninety grammes of milk. Small loaves may be made weighing 150 grammes, and containing only two spoonfuls of oil. They are very white and pleasant to look at, and have so little taste of the oil that both children and adults eat them with ease. Thirty-four of these rolls are delivered every day at the Enfants Malades for the use of M. Bouchut's little patients, and the children look out for them with pleasure. They are easily digested, and create no repugnance whatever. In private practice adults make use of them as their ordinary diet.—*Bulletin de Thérap.*

Removing Bitter Taste of Medicines.—Sugared substances in concentrated solution much diminish bitter tastes. Thus, while the infusion of gentian is excessively disagreeable, its syrup can be very well taken if it be not diluted with water, and weakening the action of the sugar. But the body that seems to enjoy this property in the highest degree is glycerhizin, or the sweet principle of liquorice. By its aid we can almost immediately dispel the bitter taste of quinine, colocynth, aloes, quassia, etc.—merely chewing a morsel of liquorice-root. Aloes may thus be powdered and sifted without inconvenience. The liquorice must be kept in the mouth for a longer time in proportion as the bitterness of the substance to be overcome is intense or its solution more concentrated.—*Rev. Méd.*, July 5.

Electricity in Toothache.—In an interesting paper in the *Bulletin de Thérapeutique* (July 15), M. Bouchaud relates several cases in which this has been successful, and thus sums up his opinion upon the subject:—"If in odontalgia we employ a continuous or constant electric current, derived from a mean of ten elements, applying the positive pole to the cheek on a level with the painful tooth, and the negative pole to the anterior-lateral region of the neck, we are enabled almost always in the course of a few minutes to procure nearly absolute relief, which in the majority of cases persists indefinitely."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Berryman, St. John's, New Brunswick.—Letter with enclosure received.

Lady Students.—The Universities of Göttingen and Heidelberg have resolved not to admit any lady students.

Quis.—Dr. George Bate died at his house in Hatton-garden, April 19, 1668. He was buried at Kingston-on-Thames.

C. and P.—Mr. Graham, Registrar, Somerset House, states that between 1860 and 1869 no less than 26,185 persons were drowned accidentally in England and Wales, giving an average of 2680 per year.

We are requested to state that the Aylesbury Dairy Company is not the company which has been mentioned as having supplied the infected milk in Marylebone and its neighbourhood.

B. E. V.—Mr. Anderson is the House-Surgeon of the Jamsetjee Jeejeebhoy Hospital, Bombay.

Ambrose.—On September 23, 1518, the College of Physicians was incorporated by letters patent granted to Thomas Linacre and others, who were constituted a perpetual "Commonalty or Fellowship of the Faculty of Physic." To Linacre is due the merit of establishing the College.

Secundus.—Peter Templeman was a physician, and practised in London, but in 1753 he obtained a situation in the British Museum as keeper of the Reading Room, and from that time diverted his attention from the profession, and devoted his whole time to literature. He wrote several medical works; was born at Dorchester in 1711.

F. F.—A small edition of "Fruits and Farinacea, the Proper Food of Man," by the late Mr. Smith, of Malton, has been edited for the Vegetarian Society by Professor Francis W. Newman. It is published by Mr. F. Pitman, London.

COMMUNICATIONS have been received from—

Dr. W. Arding; Dr. J. M. Lindsay; Mr. Stocker; Dr. Britton; Mr. J. Ashton; Dr. Braxton Hicks; Dr. H. Harris; Dr. Strange; An Army Medical Officer; Mr. J. Chatto; Dr. Peacock; Mr. F. Howell Thomas; Dr. J. Hughlings-Jackson.

PERIODICALS AND NEWSPAPERS RECEIVED—

New York Medical Journal—Le Progrès Médical—Gazette Médicale—The Halifax Guardian—Guy's Hospital Gazette—Tribune Médicale—France Médical—Lancet—British Medical Journal—Gazette Hebdomadaire—London Medical Record—American Journal of Insanity, July—Berliner Klinische Wochenschrift Centralblatt für die Medizinischen Wissenschaften.

BOOKS RECEIVED—

Moore on Meteorology in its bearing on Health and Disease—Balfour's Statistics of Cholera—Economical Cookery, by Lady Style—Hogg on Skin Diseases—Galabin on the Connexion of Bright's Disease with Changes in the Vascular System—West Riding Lunatic Asylum Medical Reports, vol. iii.—Report on the Hospital for the Insane, Gladesville, New South Wales—Report of the State Lunatic Asylum, Utica, N.Y.—The Harveian Oration for 1873, by Professor Rolleston—Carter on the Microscopic Structure of Urinary Calculi.

APPOINTMENTS FOR THE WEEK.

August 23. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

25. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

26. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

27. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

28. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

29. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, August 16, 1873.

BIRTHS.

Births of Boys, 1109; Girls, 1127; Total, 2236.
Average of 10 corresponding years 1863-72, 2040 1.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	867	741	1608
Average of the ten years 1863-72	760·0	709·0	1469·0
Average corrected to increased population	...	...	1616
Deaths of people aged 80 and upwards	...	...	9

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Population, 1871.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping-cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhœa.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·855 in.
Mean temperature	63·5°
Highest point of thermometer	85·6°
Lowest point of thermometer	48·0°
Mean dew-point temperature	55·0°
General direction of wind	S.W. & W.S.W.
Whole amount of rain in the week	0·55 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, August 16, 1873, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1873.*	Persons to an Acre. (1873.)	Births Registered during the week ending Aug. 16.	Deaths Registered during the week ending Aug. 16.	Temperature of Air (Fahr.) Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values.	Temp. of Air (Cent.) Weekly Mean of Mean Daily Values.	Rain Fall. In Inches.	In Centimetres.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·86 in. The highest was 29·96 in. on Thursday evening, and the lowest 29·69 in. on Saturday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

Senior Physician to St. Thomas's Hospital.

Lecture VI.—Valvular Diseases.

(*Continued from page* 170.)

Aortic Valvular Disease.

1. When the aortic valves are malformed, the segments may either be increased in number or deficient, and in either case it is probable that the valvular apparatus is less efficient, and more liable to become the seat of disease in after life. The most common condition is that there are only two segments, one of them being much larger than the other, and displaying on its upper or arterial side the appearance of a rudimentary separation. Less frequently all the curtains are more or less completely united, and there are the indications of imperfect division in the form of three frœna, or, as they were termed by Mr. Hunter, *cross bars*, on the upper side. When there are only two curtains, the larger one is imperfectly supported towards the centre, and is apt to be stretched and fall below the other, and often its edge becomes everted, in either case admitting of regurgitation. The larger fold also is apt, at the point which indicates the imperfect division, not to expand adequately with the progress of growth and in correspondence with the increasing calibre of the aortic orifice, and so when the valves fall back an aperture may be left by which the blood may regurgitate into the ventricle. This condition is, therefore, more especially liable to lead to incompetency; but the valves are also apt to be the seat of acute or chronic inflammation, and so, being thickened and indurated, to become also a source of obstruction.
